Impact Study of the Coding as Another Language Curriculum:

Study B

June 2023

Authors: Zhanxia Yang, Patricia Moore Shaffer, Courtney Hagan,
Parastu Dubash, Marina Bers

Abstract
The aim of this study was to explore how the Coding as Another Language using ScratchJr (CAL-ScratchJr) curriculum, developed by Boston College’s DevTech Research Group utilizing the ScratchJr app, impacted second grade students’ computational thinking, coding skills, and reading comprehension. To accomplish this, the research team randomly assigned 20 schools in a school district located in a northeastern state of the United States to teach the Coding as Another Language curriculum or to a “business as usual” control condition. As a result, ten schools were assigned to the treatment group and the remaining ten schools were assigned to the control group. Participants in this study, referred to as Impact Study B, initially included 13 teachers and 247 students from 17 classrooms in the treatment group, and 10 teachers and 103 students from 12 classrooms in the control group. Hierarchical linear modeling was used to assess the impact of the CAL-ScratchJr curriculum on these second grade students’ computational thinking, coding skills, and reading comprehension. Results showed that the CAL-ScratchJr curriculum intervention had a significantly positive impact on students’ coding performance while no notable difference was found on students’ computational thinking as both groups showed significantly higher increases of computational thinking from the baseline. Additionally, an examination of students’ standardized literacy achievement across the two conditions found no notable difference findings, suggesting that even though the treatment group students allocated regular class time for the CAL-ScratchJr curriculum, the students in the treatment group showed comparable growth with the students in the control group on standardized literacy achievement assessments.

This research reported here was supported by the Institute of Education Sciences, U.S. Department of Education, through grant #U411C220202 to DevTech Research Group at Boston College.

Background

In the automated economy, computer programming is essential across diverse disciplines. Occupations that value programming skills provide as much as 20% of “career-track” job openings (Burning Glass Technologies, 2016), and the number of jobs in information technology will grow 12.5% from 2014 to 2024 (Fayer, Lacey, & Watson, 2017). To meet this growing need, there has been an increase in new educational policies and frameworks at the federal and state level to prepare K-12 students for computer science (CS) related professions.

While most of the CS education implementation is taking place at the late elementary, middle school, high school, and college levels (Guzdial, 2008; Wilson, Sudol, Stephenson & Stehlik, 2010), educational frameworks, standards, and best practices position CS instruction to start in kindergarten (Barron et al., 2011; International Society for Technology in Education, 2007; NAEYC and Fred Rogers Center for Early Learning and Children’s Media, 2012; U.S. Department of Education, 2010; White House, 2016; U.S. Department of Education & U.S. Department of Health and Human Services, 2016; Paciga & Donohue, 2017).

There are both economic and developmental reasons to start CS education early. Research shows that educational interventions that begin in early childhood are associated with lower costs and more durable effects than interventions that begin later in a child’s education (e.g., Cunha & Heckman, 2007; Heckman & Masterov, 2007). Two National Research Council reports—Eager to Learn (2001) and From Neurons to Neighborhoods (2002)—detail the importance of early experiences for later school achievement. Furthermore, research shows how children who are exposed to STEM curriculum at an early age demonstrate fewer gender-based stereotypes regarding STEM careers, increased interest in engineering and computer science (Sullivan & Bers, 2018; Metz, 2007; Steele, 1997), and fewer obstacles entering these fields later in life (Madill et al., 2007; Markert, 1996).

If CS education is to start in the early years, when children are just starting to develop literacy and numeracy skills as well as learn “schooling,” there is a need for pedagogical approaches, curriculum, and programming languages that are developmentally appropriate for young children (Bers, 2018; Bers et al, 2022). Since the need to support the STEM pipeline is a weak rationale for the introduction of CS in early childhood education, CS must be integrated with foundational content areas such as math and literacy. If we are going to start computer science education in kindergarten, the rationale shouldn’t be the creation of the future workforce, but the future citizenry (Bers, 2022).

The work conducted in this study is grounded on Bers’ previous work that understands “Coding as a Another Language (CAL)” (Bers, 2018, 2019). Within this framework, those who learn how to code from a young age will not only be able to participate in the automated economy but will also have a civic voice. As children learn how to code, they also develop their creativity to grow a society of innovators (Resnick, 2018). A literate person knows that reading and writing are tools for meaning making and, ultimately, tools of power because they support new ways of thinking (Papert, 1980). The same is true for computer programming and computational thinking.
Researchers have coined the term “computational thinking” to refer to an analytical process rooted in the discipline of computer science. It involves thinking recursively, applying abstraction, breaking up a complex problem in smaller tasks, and using heuristic reasoning to discover a solution (Wing, 2006; 2011). There is debate whether computational thinking can be classified as a unique category of thought (Gadanidis, 2017; Pei, Weintrop, & Wilensky, 2018). However, the term has grown popular at a time when schools are incorporating CS in massive ways and developing frameworks (K–12 Computer Science Framework Steering Committee, 2016). While computational thinking is not the same as coding, the act of coding can facilitate the spread of computational thinking (Bers, 2021; Relkin et al, 2021).

CAL-ScratchJr addresses the teaching of computational thinking through both unplugged activities and on-screen coding with ScratchJr, when integrated with other content areas, in particular math and literacy, in the K-2 segment.

ScratchJr is the first programming language explicitly designed for young children, 5 to 7 years, to meet their developmental needs. ScratchJr is the result of a long-lasting collaboration between the DevTech Research Group, now at Boston College, and the MIT Lifelong Kindergarten Group funded by the National Science Foundation and the Scratch Foundation (Bers & Resnick, 2015). ScratchJr enables children to create interactive stories and games by snapping together graphical programming blocks to make characters move, jump, dance, and sing. Through ScratchJr young children learn how to code and how to engage in computational thinking while creating personally meaningful projects. Since its launch in 2014, there have been 40 million users with an average of 2.4 million users per month over the past 6 months and has actively been used in every country in the world (except North Korea). The app can be freely downloaded to iPads, Android tablets, iPhones and Android phones, Amazon Kindle tablets, and Chromebook devices, and it has been translated to Spanish as well as a dozen other languages.

The ScratchJr team began collecting analytics data in 2016. Since then, as of February 2023, over 167 million projects have been created, and existing projects have been edited over 275 million times, indicating that users are improving and debugging their projects over time. The DevTech Research Group has developed curricula and teaching materials to integrate ScratchJr with other content areas in early childhood in both formal and informal learning settings. Three twenty-hour curriculum units have been developed to accompany the ScratchJr app: Animated Genres, Playground Games, and Reinforcing Common Core. In addition, several activities were developed in the form of coding cards (Bers & Sullivan, 2018) as well as the Coding as Another Language curriculum to support literacy integration. The CAL-ScratchJr curriculum builds on previous work by also incorporating math, low-tech materials, and unplugged games to address powerful computational ideas, skills, and habits of mind that promote computational thinking.

Pilot studies found that children in K-2 can master ScratchJr, which in turn supports learning of problem solving, foundational programming, and discipline-specific content in math and literacy (Flannery et al., 2013). Combined pilot work representing a total sample of N = 333 children (aged 5-7 years) revealed that children used ScratchJr to make creative projects, which supported literacy practices of exploring and utilizing narrative structures, decoding symbols, and reading and writing digital media. (Flannery et al., 2013; Portelance & Bers, 2015). Further, pilot work demonstrated that ScratchJr can support learning outcomes when educators use diverse teaching approaches, although positive learning outcomes are more pronounced when the learning is child-directed and open-ended (Strawhacker, Lee, & Bers, 2017).
Despite programming becoming popular and ScratchJr and its resources being widely utilized, there is a lack of well-researched, evidence-based integrated early childhood CS curriculum and professional development strategies. Technology and pedagogy are not the same thing. As new programming languages that are developmentally appropriate emerge and are widely used, such as ScratchJr, there is a need to conceptualize pedagogical approaches for teaching CS in the early years. These approaches must be consistent with developmentally appropriate practice (Bredekamp, S, 1987) and must embrace the maturational stages of children by inviting play and discovery, socialization, and creativity (Bers, 2018a).

In response to the pedagogical needs, DevTech Research Group developed the CAL-ScratchJr curriculum through design-based research, iterating curriculum development, field testing, and curriculum revision (Bers et al., 2023). In this process, many considerations were included such as expert review of materials for content and selection of books and songs to reflect diversity. Additionally teachers’ feedback was considered such as the need for socio emotional learning on top of integrating the teaching of coding with literacy. This curriculum is organized around powerful ideas that are fundamental to computational thinking and, at the same time, are developmentally appropriate for young children. The curriculum introduces coding and computational thinking in a playful, developmentally appropriate way by integrating powerful ideas of computer science with literacy skills. In this study, we examine the CAL-ScratchJr curriculum’s impacts on students' coding skills, computational thinking, and literacy performance.

**Study Description**

**Research Questions for the study**

Research Question 1: What is the impact of three months of CAL-ScratchJr curriculum on second grade students’ computational thinking compared to the business-as-usual condition?

Research Question 2: What is the impact of three months of CAL-ScratchJr curriculum on second grade students’ coding skills compared to the business-as-usual condition?

Research Question 3: What is the impact of three months of CAL-ScratchJr curriculum on second grade students’ standardized literacy performance compared to the business-as-usual condition?

**Intervention Condition**

The schools that were assigned to the treatment group implemented the CAL-ScratchJr curriculum to their students during School Year (SY) 2021-2022. Students were intended to receive a total of 24 lessons of 45 minutes each. The impact of the intervention is measured by comparing student outcomes in the treatment and the control group. Student outcomes are measured before and after the implementation of the curriculum/business-as-usual.

Although the current study focuses on the impact examination during SY 2021-2022, which used cluster randomized control trials that included both treatment and control groups, the CAL-ScratchJr curriculum was implemented using a delayed treatment design. That is, schools in the control group will implement the CAL-ScratchJr curriculum in SY 2022-2023.
Teachers in the treatment schools were trained in February 2022 in the delivery of the CAL-ScratchJr curriculum and provided resources and support to implement the curriculum during a 12-week period (Spring 2022). Teachers in the control schools delivered business-as-usual during SY 2021-2022 and delayed implementation of the intervention until SY 2022-2023. Teachers in control schools did not have access to training or the curriculum during SY 2021-2022. For Impact Study B held during SY 2021-2022, the DevTech Research Group trained the teachers delivering the curriculum in CAL-ScratchJr intervention schools.

The CAL-ScratchJr curriculum builds on DevTech’s previously developed pilot units (Bers, 2018) and is aligned with the K-12 Computer Science Framework (K-12 Computer Science Framework Steering Committee, 2016) and the Standards for Technological Literacy (International Technology and Engineering Education Association, 2007), as well as the Common Core Frameworks for Math and Literacy (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010).

**Program Intervention**

Before implementation of the CAL-ScratchJr curriculum, 13 second-grade teachers in 10 CAL schools received professional development (PD) training on the implementation of the ScratchJr app in the classroom and the CAL-ScratchJr curriculum. This included attending two 2-hour PD workshops (total of 4 hours), completing their own ScratchJr project, and exploring lessons in CAL-ScratchJr curriculum.

Students were intended to receive a total of 24 CAL-ScratchJr curriculum lessons of 45 minutes each. Teachers implemented the CAL-ScratchJr curriculum lessons during regular school hours in between regular curricula. For Impact Study B, classroom teachers or supporting enrichment teachers, implemented the curriculum to the whole class in a classroom setting.

In Impact Study B, 13 second-grade teachers (84.6% female; average number of years teaching = 13.3 years) delivered the CAL-ScratchJr curriculum to 323 students; among these students, 247 consented to participate in the study. These students were enrolled in the treatment schools as of March 2022 when the implementation started. The average number of CAL-ScratchJr lessons completed by the end of implementation was 12.9. The total number of CAL-ScratchJr lessons to complete was 24 lessons. Teachers were able to begin implementing the lessons in their classroom after pre-testing and continued until the end of the school year.

Fidelity of the intervention’s implementation was assessed for the intervention’s three key components (CAL-ScratchJr curriculum, DevTech Research Group teacher training, and coaching). Seven indicators of implementation were measured to assess the extent to which the three key components were implemented (curriculum dissemination, group training participation, group training content, embedded onsite coaching–availability, embedded onsite coaching–satisfaction, virtual coaching–availability, and virtual coaching–satisfaction) (see table 10).
Setting
This multi-site study took place at 20 different schools within one school district in a northeastern state in the United States. The school district is public, high-poverty, and in an urban environment. The CAL-ScratchJr curriculum was deployed to child participants within the classroom context by teachers (who had been trained to implement the CAL-ScratchJr curriculum) at variable rates across the length of the intervention. Methods for randomization were standardized.

Control Condition
The schools that were assigned to the control group received no intervention of the CAL-ScratchJr curriculum during SY 2021-2022. Instead, these control schools did business-as-usual (e.g., taught literacy in the literacy block) and the teachers from the control group did not have access to training or the curriculum during SY 2021-2022. The control group schools delayed implementation of the CAL-ScratchJr implementation until SY 2022-2023, which is beyond the scope of the study.

Study Participants
Central office staff of the school district invited kindergarten, first, and second grade teachers to submit their interest to participate during the period from June 2021 to January 2022. Principals from the schools where these participating teachers worked were then invited to approve the participation. After receiving both the teachers’ consents and the school principals’ approval, 30 schools were identified. Due to limited resources and challenges during COVID, research effort was focused on the second grade. For this study, we excluded 10 schools that did not have 2nd grade participation. Among the remaining 20 schools with 2nd grade participation, two strata were created: a) four schools with participation from three grade levels, including kindergarten, 1st, and 2nd grade; b) 16 schools with participation from at least one 2nd grade classroom but not all the three grade levels. At the beginning of February 2022 prior to outcome testing, random assignments were done within each stratum. As a result, 10 schools were assigned to the treatment group and 10 to the control group from the two strata. Students who enrolled in the schools after random assignment are not included in the impact analysis. Figure 1.1 to 1.3 show the CONSORT flow of participants from the 20 schools by each outcome.

After agreement of participation from teachers and school principals, students’ parental consent forms were sent to be collected and coordinated by a site coordinator. Parents from the treatment and control groups were required to sign and return a form if they consented for their child to participate in the study. Parental consents were received after the random assignment and before outcome measures were collected. The CAL-ScratchJr curriculum intervention was for the treatment group and the control group did business-as-usual. In the treatment schools, all students in the teacher’s class would receive the curriculum, but only those who had parent consent would participate in data collection as part of the research study.

Sample Alignment with Those Served by the Program

The evaluation sample for the creative coding proficiency as measured by Coding Stages Assessment (CSA) and computational thinking as measured by TechCheck includes all consented second grade students who were offered the intervention over the duration of the evaluation and for whom each outcome measure was not missing.

The evaluation sample for the post-implementation literacy, as measured by MAP Reading Fluency in the Spring, only included students who took the assessment on or after May 23, 2022, which was an estimated date of post-implementation and was a starting date for post-CSA and post-TechCheck data collection in Study B.

Design and Measures

Independence of the Impact Evaluation

The evaluation was conducted by Shaffer Evaluation Group (SEG). Shaffer Evaluation Group worked closely with the Research and Evaluation team of the DevTech Research Group, which worked independently from the intervention development and implementation team. A firewall was implemented between the DevTech Research and Evaluation team and the intervention development and implementation team. All decisions regarding assignment, data collection, data analysis, and final reporting were made by the Shaffer Evaluation Group.
In order to ensure independence, a dedicated Assessment Team consisting of research assistants was employed to evaluate the two outcomes (CSA and TechCheck). These research assistants were recruited separately and independently from the DevTech Research Group. Assessment Team members were not aware of the experimental design or any other aspects of the research, including knowledge of which schools, teachers or students had been assigned to control or treatment conditions. The hiring process was overseen by the Shaffer Evaluation Group, in collaboration with school coordinators, to guarantee an unbiased selection. By employing this approach, we aimed to establish a robust and impartial assessment process.

While impact analyses were conducted by the DevTech Research and Evaluation team, the Shaffer Evaluation Group conducted verification of the impact models for each research question of the study. During this verification process, SEG ensured that all data at the student level that was collected was included in the analysis. If student-level data was dropped from analysis, SEG verified that the reason for dropping the case was objective in nature. In addition to verifying the data cleaning process, SEG also verified the analysis. During this verification process, SEG verified that the code DevTech used included all appropriate variables in each unconditional and conditional model, verified the correct number of observations and schools in each unconditional and conditional model, verified each beta was in bounds, and finally ran RMarkdown to spot-check that the same results were found.

**Pre-Registration of the Study Design**

This study was originally registered in the Registry of Efficacy and Effectiveness Studies (REES) on August 22, 2022. The original registry ID number is 13200.1v1. The original study design was restricted to the second grade. The original research questions as well as findings that address the pre-specified research analyses are identified in this report by a ‘+’ symbol. The Study B focuses on the second grade although the study design registration was updated on Friday February 24, 2023 to expand the study to include kindergarten and first grade in Study A.

**Design**

During Impact Study B, the DevTech Research Group trained the teachers who delivered the curriculum in the schools. The impact of the intervention was measured by comparing student outcomes in the treatment group (CAL-ScratchJr group) and the control group. Student outcomes were measured before and after the implementation of the curriculum/business-as-usual. CAL-ScratchJr group students were compared using two-level hierarchical linear modeling (HLM), controlling for covariates at the student and school levels, to test for differences in the outcomes of computational thinking, coding skills, and literacy comprehension skills.

**Measures**

To address each of the research questions, this study used multiple instruments to assess the various outcomes (Table 1). Each instrument is described in more detail below.

**TechCheck**

*TechCheck* assesses students’ computational thinking (Relkin et al., 2020). This measure was developed by the intervention developer and validated with 769 five-to-nine-year-old students. In the current study, reliability was $\alpha = 0.60$ in the baseline and $\alpha = 0.62$ in the post assessment. TechCheck was correlated with TACTIC-KIBO ($r = .53$). This measure consists of 15 questions that are in a multiple-choice format, resulting in a *TechCheck* score that ranges from 0 to 15. Data for the current study was collected March 2022 - June 2022. Example items include: “What comes next” after showing a series of shapes. Please see more details about this instrument on the DevTech Research Group [website](#). To ensure the early readers can understand the question, narrators read the questions to the student synchronously via Zoom by sharing a window with the TechCheck questions.
**Coding Stages Assessment (CSA)**

CSA assesses students' coding knowledge and programming language. This measure was developed by the intervention developer and validated with 118 five-to-eight-year-olds (de Ruiter & Bers, 2021). This assessment has 30 items presented in five stages. According to de Ruiter and Bers (2021), the total CSA score, which ranged from 0 to 39, was calculated as a weighted score of the five stages, with higher weights assigned to more advanced stages. Data for the current study was collected March 2022 - June 2022. Example items include: “Can you show me where you tap on the screen to make the program go?.” Please see more details about this instrument on the DevTech Research Group website. In the current study, the internal consistency was $\lambda \_6 = .77$ for the baseline coding assessment and $\lambda \_6 = .68$ for the post coding assessment.

Trained research assistants administered the assessment via Zoom synchronously by sharing a window with visual prompts for each question in the assessment and narrating each question to the participating students. Participating students then coded in the ScratchJr app on their own device and presented their ScratchJr coding via Zoom with verbal explanations (when applicable). The research assistants rated students’ responses to each question either as “Satisfactory” or “Unsatisfactory.” Because the students have support using ScratchJr, all students in both treatment and control groups were able to start the ScratchJr app and continue the coding assessment.

All research assistants completed a systematic CSA training; after passing the CSA training test at the end of the training, qualified research assistants then took reliability checks for CSA. The research assistants demonstrated a great inter-rater reliability; specifically, a minimum Cohen’s Kappa of 0.82 with an experienced rater was set as the standard to proceed for administering the CSA to the research participants in the study.

**Literacy**

The MAP Reading Fluency measures students’ oral reading fluency, foundational skills, and literal comprehension using an adaptive benchmark. The participating school district has been using this assessment to measure their students’ literacy achievement. For this study, the Adaptive Oral Reading subtest of MAP Reading Fluency was used since it is a common assessment type assigned to the majority of students. Students can be assessed in the Fall, Winter, and Spring. The Winter and Spring data were utilized as the pre and post curriculum implementation data for the current study.

**Sample Sizes and Attrition**

Study B sample size information is reported in Table 2, both for clusters and individuals, by condition and for each outcome. Outcome for coding skill is labeled as post-CSA, computational thinking as post-TechCheck, and standardized MAP Reading Fluency literacy performance as post-LA. The number randomized is the number of students and schools at enrollment, respectively. The number of schools and students in the analytic sample are the number of non-missing data at both the pre and the post stage for each outcome.
Reasons for school attrition are summarized below. For the CSA and TechCheck in the treatment condition, there were three cases of school attrition: one resulted from informed withdrawal from a teacher who was the only teacher in the school before collecting parental consents and two were due to incomplete data collection at the post stage. In the control condition, for the CSA and TechCheck outcomes, there were four cases of school attrition: two resulted from informed withdrawal prior to collecting parental consents, one was due to a non-responsive teacher participant who was the only teacher in the school, and one was due to incomplete data collection at pre- and/or post-stages. For the literacy outcome, in the treatment group, there were three cases of school attrition and, in the control group, there were five cases of school attrition. Except for the three informed withdrawals mentioned above, most of the school attrition for the literacy outcome was due to the non-mandatory nature of the assessment.

Table 3 summarizes the observed overall attrition and differential attrition and assigns an attrition level by outcome level according to WWC boundaries for defining high versus low attrition for randomized control trials (What Works Clearinghouse, 2022). Attrition may be defined as high at the cluster level and the student level. The attrition was due primarily to the parent consent rate (76.3%), not being able to collect data because of challenges during the COVID-19 pandemic and limited resources, and the district’s policy that the literacy assessment was not mandatory.

Data Analysis and Findings

Baseline Equivalence

The baseline mean difference between the treatment and control groups was calculated using a multi-level model that adjusts for clustering by having students at level 1 and schools at level 2 and included the baseline measures as the outcome variable. The analytic sample for each outcome differs slightly due to differences in response rates across outcomes.

Table 4 presents descriptive statistics by condition for each analytic sample in the study: baseline measures of coding skills as measured by CSA, computational thinking as measured by TechCheck, and literacy as measured by passing or fail in the Adaptive Oral Reading subtest of MAP Reading Fluency in Impact Study B. The standardized difference (Hedges’ g) between control and treatment groups on TechCheck is lower than 0.05 and therefore satisfies the WWC standard for baseline equivalence (What Works Clearinghouse, 2022). The standardized difference (Hedges’ g) between control and treatment groups on CSA is 0.07, which requires statistical adjustment to satisfy the baseline equivalence standard. The standardized difference (Cox index) between control and treatment groups on the literacy assessment is 0.20, which requires statistical adjustment to satisfy the baseline equivalence standard. Nevertheless, all three outcomes included baseline measures respectively in examining the treatment effect on the outcomes.

Background characteristics beyond those required for assessing baseline equivalence are also presented in Table 5 by each condition, including gender (Female or Male), Individualized Education Plan status (Yes or No), Limited English Language Proficiency status (Yes or No), and disadvantaged social-economic status (Yes or No).
Program Effects

Approach to estimating program effects:
The method used to estimate the impacts of CAL-ScratchJr curriculum implementation is multilevel modeling at two levels. See the statistical models below:

- **Level-1: Student Level**
  \[ Y_{ij} = \beta_{0j} + \beta_{1j} Y_{ij}^* + \sum_{m=1}^{M} \beta_{2mj} X_{mij} + \varepsilon_{ij} \]

- **Level-2: Cluster (School) Level**
  \[ \beta_{0j} = \gamma_{00} + \gamma_{01} T_j + \sum_{q=1}^{Q} \gamma_{02,q} W_{qj} + \mu_{0j} \]
  \[ \beta_{1j} = \gamma_{10} \]
  \[ \beta_{2mj} = \gamma_{2,m0} \]

Where,
- \( Y_{ij} \) = the outcome score for the \( i \)th student in the \( j \)th school.
- \( \beta_{0j} \) = the intercept for school \( j \).
- \( \beta_{1j} \) = the effect of pretest in school \( j \).
- \( Y_{ij}^* \) = a pre-test measure for the \( i \)th student in the \( j \)th school.
- \( \beta_{2mj} \) = the effects of student covariates in school \( j \).
- \( X_{mij} \) = the \( m \)th of \( M \) additional covariates for student \( i \) in school \( j \).
- \( \varepsilon_{ij} \) = a residual error term for student \( i \) in school \( j \).
- \( \gamma_{00} \) = the mean intercept
- \( \gamma_{01} \) = estimated treatment impact
- \( T_j \) = 1 if school \( j \) is assigned to treatment (CAL), and = 0 if school \( j \) is assigned to control.
- \( \gamma_{02,q} \) = the effect of school-level covariate (percent of students receiving free/reduced-price lunch);
- \( W_{qj} \) = the \( q \)th of \( Q \) covariates for school \( j \).
- \( \mu_{0j} \) = random intercept term – deviation of cluster \( j \)'s mean from the grand mean, conditional on covariates; assumed to be normally distributed with mean 0 and variance \( \tau_{00}^2 \).
- \( \gamma_{10} \) = mean effect of pretest
- \( \gamma_{2,m0} \) = mean effect of student covariate \( m \).
All outcome measures were collected at the student level and the treatment indicator was at the school level. Clustering was addressed by allowing random intercept among schools.

All covariates in the model were included. One exception is the gender variable and the school-level averaged baseline CSA score when predicting the CSA outcome. Due to the limited variability and the small sample size, these two variables were not included as covariates in the impact model that predicts the CSA outcome.

The impact model for the dichotomous literacy outcome used a linear probability model with the adjustment of all the above-mentioned student level and school level covariates.

No participants or units were excluded from the analysis except for the ones that are missing data (see Alignment of the Sample section).

**Approach to handling missing data:**
Only students with data present at both the pre-test and the post-test were included in the analytical sample. Baseline equivalence from all outcome measures was established based on the analytical sample, which list-wise deleted those students who had missing data at either the pre or the post time points.

Table 6 presents the extent of missing data by outcome and condition. One should note that the numbers used in this table include all possible roster students. The number of consented students for research is smaller than the number of students from the roster, thus, the actual missing rate from the consented students is smaller than the ones in the table.

**Findings**
Regarding research question 1, which inquired about the impact of three months of the CAL-ScratchJr curriculum on second-grade student participants’ computational thinking, the treatment group showed no notable difference compared to the business-as-usual control group (Hedge’s g = -0.09). Table 7 presents descriptive statistics (means, standard deviations) and sample sizes by condition for each outcome measure at each time point (pre and post assessments).

Regarding research question 2, which inquired about the impact of three months of CAL-ScratchJr curriculum on second-grade student participants’ coding skills, the treatment group showed significantly higher coding skills compared to the business-as-usual control group (Hedge’s g = 0.39). The Hedge’s g effect size of 0.39 indicated a medium effect size of the impact of the curriculum. The CAL-ScratchJr curriculum was successful in terms of improving students’ coding performance.

Regarding research question 3, which inquired about the impact of three months of CAL-ScratchJr curriculum on second-grade student participants’ literacy performance compared to the business-as-usual condition, the treatment group showed no notable difference compared to the business-as-usual control group (Cox index = -0.19). Table 8 presents sample sizes, means, and the beta coefficients for the grouping variable (treatment or control) by condition for the dichotomous literacy outcome. Consistent with the WWC standards (2022), Cox index was computed as the effect size measure for this dichotomous outcome. Table 8 presents the mean (average probability of passing) in the control group...
with the adjustment of school cluster effect and the mean of the treatment group by adding the regression coefficient in the full model with adjustment of covariates and cluster effect from school.

Table 9.1 to Table 9.3 report the sample sizes, means, and standard deviations in both conditions for samples with and without missing data.

**Discussion**

The CAL-ScratchJr curriculum showed a positive impact on students’ coding performance in the CAL group compared to the control group. Unlike the coding performance, the treatment group did not show a notable difference in students’ computational thinking when compared to the control group although both groups showed significantly higher computational thinking scores compared to baseline. Few research studies have examined the effect of early childhood computer science curriculum interventions on students’ computational thinking. Among the few we found, research reported mixed findings regarding the impact of a computer science intervention on students’ computational thinking. For example, Grillo-Hill, Mahoney, Chow, and Li (2019) examined the effect of codeSpark Academy on one domain of computational thinking and found no significant effect. Oluk and Cakir (2021) examined the effect of code.org on sixth grade students and reported a significant increase on students’ algorithm development and computational thinking skills in the intervention group. However, the grade level and limited details regarding the number of schools or the number of classrooms investigated left little generalizability of Oluk’s study to other studies. Additionally, code.org activities include the overly aligned and abstract unplugged computational thinking practices, which made the curricula not comparable with other curricula that do not explicitly teach computational thinking such as codeSpark Academy or the CAL-ScratchJr curricula. Our research team, Relkin et al. (2021) also conducted a quasi-experimental study and found a significant effect of the CAL-KIBO curriculum on first graders’ computational thinking but not on second graders. However, the significant effect among the first graders was associated with a significantly higher baseline in the intervention group, which made it difficult to attribute the effect to the intervention.

No significant difference was found regarding literacy performance when the CAL group was compared to the control group. One should note that because literacy was not a mandatory assessment, the sample size is small, especially in the control group. While there are uncertainties associated with findings from a small sample size, the results did not show a negative impact on student’s literacy associated with CAL-ScratchJr curriculum implementation.

In summary, the CAL-ScratchJr showed a positive impact on students’ coding performance. While no significant impact was found on students’ computational thinking compared to the control group, recent research does not offer valid evidence that similar computer science curricula affect computational thinking either. The results also provided empirical evidence that the CAL-ScratchJr curriculum can be implemented in authentic classroom settings without negatively impacting students’ performance on standardized literacy assessments even though some class time was allocated to the CAL-ScratchJr curriculum.
The study was conducted during the COVID-19 pandemic when many schools, teachers, and students were challenged with absences and quarantines. As a result, the CAL-ScratchJr curriculum was implemented at various levels of fidelity. Teachers do report that time was one of their main challenges during the pandemic. Nevertheless, teachers shared how excited their students were to engage with the CAL-ScratchJr curriculum.

The DevTech Research Group plans to expand the program to more schools, including engaging additional schools in CAL-ScratchJr professional development training and providing support for implementation of the CAL-ScratchJr curriculum. Planning is underway to make automated interactive assessments to reduce cost and improve efficiency in research, since the current assessment of coding skills and computational thinking were administered one-on-one by trained research assistants, which is labor-intensive.

**Fidelity of Implementation Study**

**Fidelity Measurement**

The fidelity of CAL-ScratchJr curriculum implementation was assessed by examining three key components: (1) revised CAL-ScratchJr curriculum, (2) DevTech Research Group teacher training, and (3) teacher coaching. In Impact Study B, the revised CAL-ScratchJr curriculum component encompassed one indicator: curriculum dissemination (measured by completing lesson log entry). The DevTech training component encompassed two indicators: group training participation (measured by an attendance sheet) and group training content (measured by a topic list checklist). The coaching component encompassed four indicators: onsite coaching availability, onsite coaching satisfaction, virtual coaching availability, and virtual coaching satisfaction (all measured by teacher self-report survey). The scoring model for assessing fidelity of implementation is presented in Table 10.

**Fidelity Findings**

Overall, Impact Study B achieved fidelity for some of the three components. In key component one, curriculum dissemination, 10 teachers (out of 13 total) accessed the curriculum, or completed a lesson log entry, and therefore earned a score of ‘1’ at the teacher-level. At the school-level, five schools had 90% or more teachers earn a score of ‘1’, while there was one school that had 51-75% of teachers earn a score of ‘1’ and one school had 26-50% of teachers earn a score of ‘1’. This resulted in an overall sample-level score of ‘2’, with 71.4% of schools earning a score of ‘1’ or inadequate implementation. However, there may have been stronger implementation of curriculum dissemination, as all teachers received copies of the curriculum multiple times. There were low rates of responses for lesson log entries by teachers, potentially impacting the fidelity score.

In key component two, DevTech Research Group teacher training, 12 teachers (out of 13 total) participated in the provided group training. This included attending training in synchronous or asynchronous format. The non-participating teacher was due to withdrawal from the study right after the random assignment. Further, eleven out of twelve indicators were observed during the first part of the group training and seven out of seven indicators were observed during part 2. Overall, across indicators in component two, there was a score of ‘6’ at the program level indicating adequate implementation.
For coaching, the third key component, five teachers out of the 13 requested either an onsite or virtual coach. Of the two teachers who requested a virtual coach, two received a response to the request. There was an average satisfaction of 2.5 (on a rating scale of 1 = needs a lot of improvement - 5 = couldn’t be better) with virtual coaching. Of the three teachers who requested an onsite coach, all three received a response to their request. There was an average satisfaction of 4.0 with onsite coaching. Overall, this component earned a sum score of ‘7’ indicating adequate implementation.

Overall, two out of three components were implemented with fidelity. Details of fidelity of implementation scores are provided in Table 11.
