Exploring the Link Between Cognitively Relevant Actions and Geometric Reasoning: A Pilot Study

Doy Kim, Mitchell J. Nathan
doy.kim@wisc.edu, mnathan@wisc.edu
University of Wisconsin-Madison

Abstract: The potential of grounded cognition and action-based learning is garnering increasing attention. This pilot study investigates the effect of performing cognitively relevant actions and the role of simulated action through gesturing on geometric reasoning. The results suggested that directing students to perform cognitively relevant actions led to a lower likelihood of correct intuition and insight formulation but a higher likelihood of correct proof formulation. Meanwhile, prompting students to use gestures was associated with a higher likelihood of correct intuition, insight, and proof formulation. However, the effects were not statistically distinguishable from zero. Nevertheless, the results hinted at a promising direction for further research into the moderating effect of simulated action. This investigation offers insight into embodied learning design and contributes to the discussion of the pedagogical potential of body movements to improve students' geometric reasoning.

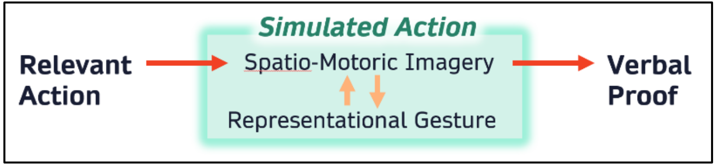
Theoretical framework and literature review

The theories of embodied cognition see human cognition not as an abstract mental activity but as caused or constituted by our body's perception and action (Shapiro, 2011). Among the varying perspectives under the banner of embodied cognition, *grounded cognition* places simulation's role in cognition at the center. The core tenet of grounded cognition is that cognition is a result of "simulation, bodily states, and situated action" (Barsalou, 2008, p. 617). The simulation that underlies cognition comprises mental and body-based action representations, which are in a reciprocal relationship. For example, when spatio-motoric imagery activates relevant neural areas for motor control and visual perception beyond a certain threshold, it gives rise to *representational gesture*s, spontaneously produced co-speech gestures that depict the semantic content of speech (Alibali et al., 2001; Hostetter & Alibali, 2008). At the same time, representational gestures ground complex ideas by introducing spatio-motoric action information to the speaker's mental representations and helping the speaker manage spatio-motoric information (Kita et al., 2017). We call these reciprocal processes between spatio-motoric imagery and representational gestures *simulated action*.

In recent years, action-based embodied learning has gained attention, where students' sensorimotor experience becomes a perceptual ground for referencing through various modalities, including gesture and speech (Abrahamson & Sánchez-García, 2016). In mathematics, actions that ground abstract concepts were proposed to influence students' geometric reasoning (Williams-Pierce et al., 2017). Performing *cognitively relevant actions* – actions designed to provide concept-specific body-based representations (hereafter, *relevant actions*) – was theorized to help produce correct verbal proof by feeding relevant spatio-motoric information to students' simulated action (i.e., activating spatio-motoric imagery and producing representational gestures) (Nathan & Walkington, 2017; Walkington et al., 2022). In other words, simulated action is believed to mediate the effect of performing relevant actions on verbal proof production (Figure 1).

Figure 1

Performing Relevant Action, Simulated Action, and Verbal Proof Production



Three circumstances motivate our study. First, the research on the effect of relevant action on geometric reasoning is nascent, and there are only a few relevant studies. Second, the few empirical findings have been ambivalent: Some found statistically distinguishable non-zero effects, while others did not. Third, to our best knowledge, no empirical study has examined the role of simulated action despite its critical importance as an intermediary between performing relevant action and geometric reasoning. This study aims to estimate the effect of relevant action on geometric reasoning and gather experimental evidence to understand the role of simulated action. Two research questions guided this study: ‘Does performing relevant actions promote geometric reasoning? If so, by how much?’ (*RQ1*) and ‘Does simulated action mediate relevant action’s effect on geometric reasoning?’ (*RQ2*). In addition, we asked an exploratory research question ‘Does simulated action moderate relevant action’s effect on geometric reasoning?’(RQ3) Here, we report the results from a pilot study.

Method

Sample

The sample consists of 32 adult undergraduate students recruited from a large university in the Midwestern United States. All 32 participants were English-speaking students, but 10 spoke different languages at home (31.25%). There were 11 males (65.62%) and 21 females (34.38%), and no other gender self-identification was provided. Regarding mathematics course experience, 13 students (40.63%) had only taken mathematics courses below the level of college calculus, and 19 students (59.37%) had taken courses equivalent to or more advanced than college calculus.

Design features and protocols

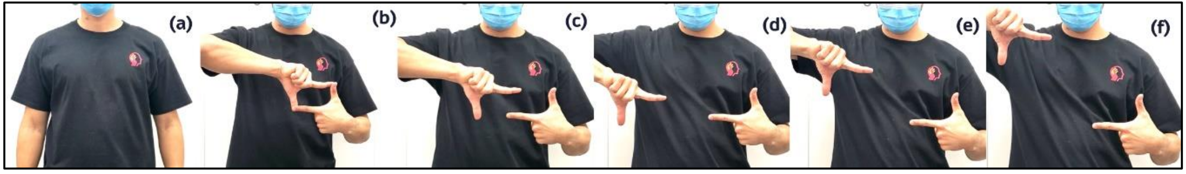
We designed a repeated-measure, 2-by-2 factorial, group-randomized experiment in which we directed students to perform relevant actions or prompted them to use representative gestures (Table 1). The main task was to prove or disprove a given geometric conjecture. Each student completed five conjectures. We selected conjectures from secondary mathematics textbooks that explore the general properties of geometric shapes. The verbiage was modified so that all the conjectures are either always true or false (e.g., “If you triple each side of any quadrilateral, then the area is always 9 times greater” (The *quadrilateral conjecture*)). The order of conjecture presentation was counterbalanced by using a Latin square to create four conjecture orders.

Table 1
Protocol Variation by Experiment Condition for Each Conjecture

	Directed		Not Directed	
	Prompted	Not Prompted	Prompted	Not Prompted
1	Directed to perform relevant actions	Directed to perform relevant actions	N/A	N/A
2	Read a conjecture	Read a conjecture	Read a conjecture	Read a conjecture
3	Prompted to use gestures with verbal proof	N/A	Prompted to use gestures with verbal proof	N/A
4	Proved the conjecture	Proved the conjecture	Proved the conjecture	Proved the conjecture

In the *Directed* conditions, we asked students to perform relevant actions by watching video clips of an actor and following the movements. Each relevant action was designed to help visualize the key geometric objects and their transformation relevant to the veracity of a given conjecture. For example, the relevant actions for the quadrilateral conjecture enact the idea of expanding a quadrilateral so that its sides are three times longer (Figure 2). In the *Prompted* conditions, we asked them to use hand gestures to support their verbal proofs and help the listener’s understanding. Such a request was to boost their simulated action process more than usual by making them more conscious about their spatio-motoric imagery and representational gestures.

Figure 2
Relevant Actions for the Quadrilateral Conjecture (In Six Frames, from (a) to (f))



Students were paired and randomized into different conditions as a group. The paired students came into an isolated lab space simultaneously and performed verbal proof tasks. We chose to pair students to elicit more representational gestures even in the absence of prompting. Since the outcome was measured at the conjecture level within a student, we introduced a few constraints to prevent spillover between students. First, the two students took turns in proving conjectures. Second, they proved different sets of five conjectures that mirror each other in topic and wording but differ in shapes or properties. Third, when a student was asked to watch video clips, the other student turned around, not to see the video. The video did not have audio. Fourth, when a student was actively proving, the other student was asked not to react in any fashion.

Analysis and predictions

160 video clips of individual proofs were generated from the video and audio recordings of participants' engagement in the task (16 groups x 2 participants x 5 conjectures). Each proof was the unit of analysis. We excluded one case of non-compliance, where the participant was prompted to use gestures but did not, leaving the total observations 159. As outcome measures of geometric reasoning, one of the authors transcribed and coded for *intuition* (The immediate assessment of the conjecture's truth value is correct), *insight* (The explanation is only composed of the key mathematical ideas that are relevant to prove the conjecture correctly) and *proof* (The explanation is general, logical, and operational (Harel & Sowder, 2007)) as binary variables. The three codes captured different levels of rigor in proof. Producing *representational gestures* was also coded as a binary variable among the students in the Not Prompted conditions. We used two-level hierarchical linear models (HLM) to estimate the treatment effect and account for the nested nature of the data (proof outcomes nested within students). We did not consider the random effect of group membership since the between-group variation was negligible.

Regarding RQ1, we predicted we would find a positive effect of directing relevant actions on intuition, insight, and proof (*H1*). For RQ2, we expected a positive effect of gesture prompting on intuition, insight, and proof (*H2a*), a positive effect of directing relevant action on representational gesture production (*H2b*), a positive association of representational gesture production with intuition, insight, and proof among the students who were in the Not Prompted conditions (*H2c*). For the exploratory question RQ3, we tested the interaction effect between directing relevant action and gesture prompting on geometric reasoning measures without an a priori hypothesis.

Results

The relevant statistics are in Table 2. For H1, the results were mixed. Compared to the Not Directed conditions, the odds ratios in the Directed conditions were 6.15% lower for intuition (d_{cox}=-.04), 1.50% lower for insight (d_{cox}=-.01), and 9.01% higher for proof (d_{cox}=.05). Consistent with H2a, the odds ratios in the Prompted conditions were 5.65% higher for intuition (d_{cox}=.03), 13.78% higher for insight (d_{cox}=.03), 4.39% higher for proof (d_{cox}=.03). However, directing to perform relevant actions was associated with a 5.69% lower odds ratio of producing representational gestures (d_{cox}=-.04), which was inconsistent with H2b. In contrast, Consistent with H2c, using representational gestures was associated with an 8.37% higher odds ratio for intuition (d_{cox}=.05), 16.38% higher for insight (d_{cox}=.09), 9.42% higher for proof (d_{cox}=.06). As for the exploratory question, the directions of the interaction effects between directing relevant actions and gesture prompting were mixed, while the magnitudes were relatively large. The effect of directing relevant actions in the Prompted condition as odds ratios was 82.42% lower for intuition (d_{cox}=-1.05), 73.18% lower for insight (d_{cox}=-.80), while 66.87% higher for proof (d_{cox}=.31) than the Not Prompted conditions. All the differences were not statistically significant at a 95% confidence level.

Discussion and conclusion

We reported the results from a pilot study where we examined the effect of cognitively relevant actions on geometric reasoning by comparing the students who were directed to perform relevant actions against those who did not. Also, we examined the role of simulated action by prompting half the students to use gestures while formulating proofs and comparing them to those who were asked to use gestures. Our estimation showed that performing relevant actions led to lower likelihoods of correct intuition and insight formulation but a higher likelihood of correct proof formulation; gesture prompting led to higher likelihoods of correct intuition, insight, and proof formulation; performing relevant actions led to a lower likelihood of representational gesture production; and using representational gestures was linked to a higher likelihood of correct intuition, insight, and proof formulation.

The results lent little support to the positive effect of performing relevant actions (RQ1) or the mediating role of simulated action (RQ2). Only the hypotheses about the positive effect of gesture prompting (H2a) and the positive association between representational gesture and geometric reasoning (H2) were consistent with the results. Furthermore, the effect size estimates were minimal and not statistically distinguishable from zero at a 95 % confidence level. As a result, we could not make meaningful inferences about either the effect of performing relevant actions or the mediating role of simulated action from the present pilot study.

However, some noteworthy findings hinted at a promising direction for future research. The exploratory analysis of the interaction between performing relevant actions and being prompted to gesture (RQ3) showed a relatively large interaction effect on geometric reasoning compared to other effects of interest. For example, prompting to gesture was linked to an 82.42% lower effect of performing relevant action on intuition and a 73.18% lower effect on insight. In addition, notwithstanding the p-values over the .05 threshold, the corresponding p-values are among the lowest (.14 and .10, respectively). Considering the small sample we collected for the pilot study, we take the large effect sizes and the relatively low p-values as encouraging signs for a further, larger-scale investigation into the moderating effect of simulated action.

Besides the small sample size, the pilot study presented above has a few additional limitations for interpreting the results: Coding was done only by one author; the conjectures were not standardized; and the cognitive relevant actions used for the intervention were not validated.

Nevertheless, this investigation contributes to a broader discussion of the pedagogical potential of body movements in the mathematics classroom. Especially the findings of a larger-scale study will inform the development of action-based embodied learning design in geometry and other areas of mathematics. Experimental evidence for the effectiveness of performing cognitively relevant actions will help mathematics teachers and curriculum developers consider including cognitively relevant actions to improve students' geometric reasoning. On the other hand, the potential moderating role of simulated action between cognitively relevant action and geometric reasoning hints at the value of attending to students' simulated action by guiding their gestures per the directed relevant actions.

Supporting Near-Peer Women Mentors in Out-of-School Time STEM Programming

Bo Ju, DePaul University, bju1@depaul.edu

Nichole Pinkard, Northwestern University, nichole.pinkard@northwestern.edu

Abstract: This study examined the experiences of near-peer women mentors in an out-of-school time (OST) STEM program for middle school girls of color. 11 mentors reported and reflected upon their overall experiences in interviews. Key findings include that, for example, training is an essential part of mentors' work; they wish to have more training on pedagogy and more opportunities to bond with other mentors. This study extends the literature on STEM mentoring in OST environments, deepens the understanding of mentors' experience in STEM programming, and provides important implications for mentor training and OST STEM program design, such as providing opportunities for reflective practices to understand mentor needs, supporting mentors' non-STEM skill development, involving mentors in working towards the program goal, and fostering community building among women mentors.

Introduction

Studies indicate that women mentoring girls' learning and career development is a promising means of promoting girls in science, technology, engineering, and mathematics (STEM) (e.g., Stoeger et al., 2016). Intentionally recruiting women as mentors and role models creates an inviting out-of-school time (OST) environment for girls to participate, build confidence, and develop interest in STEM. This study shines the spotlight on supporting women mentors in near-peer women-girls mentorship in OST STEM space. Near-peer women mentors, who are normally college or high school students, are also traditionally underrepresented in STEM. Getting a better understanding of how near-peer women mentors perceive their mentoring experience informs the design of an effective mentoring program that benefits both women mentors and girls. Here, we seek answers to these questions, "How do near-peer women mentors perceive their experiences in an OST STEM program for girls?", and "How might we support them?"

Literature review

Peer or near-peer mentorship

The definition of mentoring has grown since the 1980s, and there is no one widely accepted definition because of its complexity. Mentors perform three primary functions: (1) providing vocational or skill support that directly enhances their career; (2) offering psychosocial support via counseling, friendship, confirmation, and encouragement; and (3) functioning as role models by demonstrating appropriate behaviors (Kram, 1985).

Peer or near-peer mentors have been perceived as more relatable than mentors with hierarchical status (e.g., Vandal et al., 2018). In education, such mentorship has been linked to student success in many aspects, such as socialization (Allen et al., 1999), and engagement in STEM (Wilson et al., 2012). The engagement of peer or near-peer mentors has also been frequently reported as a potential structural solution (e.g., Zaniewski & Reinholz, 2016) to solve the issue of mentor scarcity and mentee retention, which is critical for women in STEM.

Near-peer women-girls mentorship in STEM

Identity is particularly important for those who are traditionally underrepresented in STEM. Women, for example, experience significant discouragement or isolation in a climate with few role models and mentors, a dearth of female peers, and perceived bias against women in STEM (Seymour & Hewitt, 1994). Strengthening girls' STEM identities, near-peer women-girls mentorship helps them develop a sense of belonging (Inzlicht & Good, 2006) by connecting with same-gendered role models who are close in age, knowledge, and experience (Stout et al., 2013). Women mentors help girls alleviate negative stereotypes and build confidence in STEM because women appreciate those who understand their experiences and unique challenges (Bernstein, et al., 2010) and are able to see that others "like them" can be successful in their field.

Impact of mentoring on mentors and contribution to the literature

As is shown in the increasing but still lacking literature (e.g., Petersen et al., 2020), near-peer mentoring in STEM has been proven to be beneficial for mentors, through such means as solidifying mentors' prior STEM knowledge and skills (e.g., Garcia et al, 2021), enhancing leadership skills (Gunn, Lee, & Steed, 2017), and developing professional networking (Lim et al., 2017). Additionally, heavy reliance on survey-based data collection methods also raises validity concerns (Allen et al., 2007). In this study, we mainly conducted 1-1 interviews to obtain a deep understanding of mentors' experiences.

Methods

Research context and participants

The Digital Youth Divas (DYD) is an on-going project for middle school girls of color in a mid-sized racially and socioeconomically diverse community. Since its inception in 2013, the DYD has been implemented in various configurations, including weekly workshops, summer camps, and showcases. It has trained around 40 near-peer women mentors who have taught approximately 500 girls. Each session involves hands-on learning experiences designed to make connections between STEM and girls' own interests, such as art, fashion, or music.

In this study context, 13 mentors facilitated 16-week workshops for a total of 47 10-12-year-old girls. The girls were racially diverse: approximately 30% identified as African American, 26.42% Latino or Hispanic, and 11.32% Caribbean Islander. Among 11 mentors who agreed to take part in this study, all identified as women, the average age was 18, 7 were high school students, and four were undergraduate students (see Table 1).

Table 1
Background Information of 11 Mentor Participants

Participant ID	Gender (W=Women; M=men)	Age	Education level
P1	W	22	Undergraduate
P2	W	20	Undergraduate
P3	W	19	Undergraduate
P4	W	21	Undergraduate
P5	W	17	High School
P6	W	17	High School
P7	W	16	High School
P8	W	18	High School
P9	W	17	High School
P10	W	16	High School
P11	W	15	High School

Data collection and analysis

Due to the COVID-19 pandemic, we conducted the interviews via Zoom, and each lasted 60 minutes. We asked questions such as "What are some things that you wanted more of in this position?" "Do you feel you've gained any skills in this position?" Interviews were audio-recorded, and extensive notes were taken. 96-page transcripts in Word were analyzed using a thematic approach. I read through all transcripts and notes and looked for patterns to find overarching themes. A four-question self-assessment was also distributed via Qualtrics asking about their work performance, engagement, work preparation, and acknowledgement received at work. I manually calculated the percentages of the 11 valid responses for each item. In this paper, we present preliminary results that describe how near-peer women mentors perceived their experiences in a same-gendered STEM learning environment and design implications that help create a supportive environment for women mentors.

Preliminary results

We provide preliminary results from this work by briefly describing mentors' responsibilities, experiences they enjoyed, challenges they faced, and personal growth.

Mentors' responsibilities

Mentors mentioned three major aspects of their work; training, facilitating, and making connections with girls. All participants saw training as an essential task for a mentor. Unlike undergraduate mentors who perceived their job as "teaching STEM knowledge or skills" or "helping with projects," high school mentors focused more on making personal connections with the girls.

Enjoyable experiences

Both interview and survey data indicated that mentors actively participated and enjoyed a comfortable and supportive same-gendered working atmosphere. High school mentors often looked up to the undergraduate mentors for guidance and help. P6 said, "I really liked how there was just like a big community of girls and women who wanted to do STEM and liked [that] they can all relate to each other."

Challenges

Mentors brought up two areas as the greatest source of challenges, training and communication. First, despite the fact that all mentors felt that training was beneficial, 73% of the mentors (n=8) pointed out some training logistics for improvement (e.g., "there was not much training after the program started"); and over half of the mentors said that the training content should be deeper and broader, covering pedagogy and communication, for example. P4 would love to learn more about "making conversations with girls and creating an inclusive learning environment".

Second, 55% of the mentors hoped to get more informed about the program overall. P1 brought up, "we weren't clearly communicated about everything that was going on [in the program]." Furthermore, around half of the mentors claimed that they desired more bonding time with other mentors. P7 said that "[having] dinner together really created a group identity", and they felt more motivated at work. High school mentors were interested in more bonding time with undergraduate mentors to seek resources and advice on college and career.

Personal growth

More than half of the mentors (n>5) claimed they experienced personal growth in STEM knowledge, career, communication skills, and confidence. All mentors claimed that they gained STEM knowledge and skills during programming, such as 3D printing, coding, etc. They also explicitly claimed that working as a mentor helped with their professional development (e.g., leadership skills). P9 said it "helped me learn how to navigate a workplace setting". More than half of the mentors (55%) further indicated that their social and communication skills improved. P5 said, "I've always struggled to be more open. I feel like this job made me step up a little bit [by] giving me more responsibilities. This job made me more confident."

Reflections and implications

This study supports and extends the literature with high school and undergraduate women mentors anecdotally expressing their personal development and challenges. Tasks mentors described reflected Kram and Isabella's (1985) description of peer mentor functions, including knowledge and information sharing, emotional support, and friendship. Reflecting on mentors' perceived experiences, we proposed these design principles.

(a) Provide opportunities for reflective practices to understand mentor needs: Reflective practices (e.g., biweekly survey) help program designers develop more effective interventions and help mentors recognize the value of their work and boost their confidence and motivation.

(b) Support development of mentors' non-STEM skills: Effective mentor training that equip mentors with important skills is one of various factors that determine the success of mentoring interventions (Stoeger et al., 2019). Mentors in this study felt that training on pedagogy and communication were important but lacking.

(c) Involve mentors in working towards the program goal: Providing a clear picture of the program, ensures that everyone on the team works closely towards a communal goal in a supportive and motivating work environment. Ambiguity about the program results in a weak connection (Garcia et al., 2021) among everyone in the program, which prevented mentors from fully participating in and growing with the program.

(d) Foster community-building among women mentors: Women mentors in this study enjoyed working with and bonding with other women mentors outside of the work occasion. Interestingly, high school mentors considered undergraduate mentors as "role models" and were willing to seek advice for their future academic and career development. The bond can be created, fostered, and strengthened in a safe and supportive community.

As a limitation of this study, we acknowledge that we present findings from a small data set using mainly one qualitative method, one-on-on interview. With a vivid picture of women mentors' experience even at this small scale, we are inspired and motivated to explore more deeply how girls and parents perceive such mentorship and how women mentors grow in their future STEM learning and career pathways.

How Aligned Curriculum Design of Thinking Moves and Thinking Routines Influences Students’ Movie Analysis and Perception of Learning

Mingfong Jan, Graduate Institute of Learning and Instruction, National Central University,
mingfongjan@gmail.com

Abstract: The Visible Thinking approach (VT) is designed to develop thinking skills. However, the effective implementation of VT in teaching can be hindered by misalignments in coordinating course objectives, thinking routines (TRs), and thinking moves (TMs), leading to a lack of attention to students' thinking performance. To address this issue, this study developed a college-level EFL Movie English course that incorporated four selected TMs, course-specific goals, and matching TRs, along with a designed TMs assessment rubric. We examined the impact of this curriculum on students' movie analysis performance and their perception of thinking and learning, using self-evaluation, analysis writing, and self-reflection from participants. The results indicated improvements in four TMs, with considering different viewpoints and perspectives showing the greatest improvement. Furthermore, students' reflections demonstrated a positive influence on their thinking and learning. The study highlights the importance of course alignments for a VT approach to effectively function as a thinking curriculum.

Importance of teaching thinking

Current education trends emphasize the importance of teaching thinking, but studies suggest that discrete or decontextualized teaching of thinking is ineffective for developing integrated thinking skills (Resnick, 1987; Beyer, 2008). Thinking education, according to Resnick (1987), is believed to be more effective when embedded into a social setting and the success lies in long-term engagement and social interactions in a sociocultural environment where thinking is valued and supported (Resnick, 1987). Teaching of thinking should be guided and embedded in curriculum and situated in a sociocultural environment where thinking is made visible and thinking dispositions can be enculturated through long-term engagement in thinking (Tishman, Jay, & Perkins, 1993).

Visible Thinking Approach

Visible Thinking approach (VT), developed by Visible Thinking Project of Harvard Graduate School of Education, has caught much attention in recent years and was and proved to yield positive influence in deeper learning and cultivation of thinking dispositions (Ritchhart & Church, 2020). VT has three main cores: *thinking routines (TRs), thinking moves (TMs), and thinking dispositions*. *TRs* are a set of procedures that expert teachers of thinking employ as tools for activating students’ thinking, guiding students to take thinking actions (TMs), making students’ thinking visible, creating cultures of thinking, and eventually cultivating students’ *thinking dispositions*. Through repeated use of TRs, teachers can have on-going assessment of students’ thinking and learning to give needed support, and students gradually internalize use of TRs and eventually develop thinking dispositions (Ritchhart, Church & Morrison, 2011; Ritchhart, 2015).

Applications of visible thinking and thinking curriculum misalignments

VT has been applied and researched in diverse subject matters, such as social studies (Lim, 2017), math teaching methodology (Gholam, 2018), critical writing in economics (Lin, Zeng & Lim, 2018), clinical reasoning (Delany & Golding, 2014), and language learning. As to language learning, VT was proved enhance discussion or interaction in ESL or EFL (Balboa & Briesmaster, 2018; Dajani, 2016; Khalid & Yang, 2021) and college-level EFL academic writing (Hooper, 2015). However, despite that VT is an effective approach to teaching of thinking, there is a common set of misalignments present in previous research. We call them thinking curriculum misalignments. Thinking curriculum misalignments means failure to align course objectives, TRs, TMs, and learning assessment. These misalignments have caused some problems. First, misalignments between TRs, TMs and course objectives lead to ambiguity of how TRs assist students’ thinking and learning and help reach course objectives. For example, some research only used TRs to promote language interaction without addressing connection to TMs (Balboa & Briesmaster, 2018), and some claimed to promote said thinking but the failed to aligned its use of TRs (Hooper, 2015). Some falsely called TRs as “visual” thinking routines without addressing course objectives (Gholam, 2018). Another problem is that misalignments between use of TRs and learning assessment makes it hard to explain how assessment reveals students’ change of thinking. For example, some research used periodical exams or standardized tests as assessment but failed to explain influence of use of TRs (Lin, Zeng, & Lim, 2018); some claimed students' improvement of thinking without providing direct evidence (Gholam, 2018); yet another used writing assessment as direct evidence but failed to align its use of TRs and TMs (Hooper, 2015). Thus, there is an urgent need for alignments of course objectives, TRs, TMs, and learning assessment. We wish to solve the above problems by proposing an aligned thinking curriculum design and see how the aligned curriculum affects learners' thinking and learning outcome. We ask: 1) In what way does aligned design of TRs & TMs-incorporated curriculum and teaching intervention affect students' performance of movie analysis? 2) In what way does aligned design of TRs & TMs-incorporated curriculum and teaching intervention affect students' perception of thinking and learning?

Research methods

We employed a case study method (Creswell & Poth, 2013) because case study can respond to the complexity of a real-world context via observation and collection of multiple sources of evidence. Also, in response to the uniqueness of our aligned thinking curriculum and our research focus on how the aligned curriculum affects students' thinking and learning, we adopted purposive selection approach (Creswell & Poth, 2013) and selected a 3-credit EFL elective in a Taiwanese university, titled *English Movies & Social Issues* to enact our curriculum.

Case description: Aligned TRs & TMs-incorporated curriculum and teaching intervention

Our design of the aligned TRs & TMs-incorporated curriculum was enacted in the *English Movies & Social Issues* course for a semester (eighteen weeks), and the VT approach was the underlying principle of all course activities and interaction. This course was an EFL course designed for intermediate level non-English majored students. There were 20 students in this class, all of whom were Taiwanese. One of the researchers was also the instructor in this case. Throughout the semester, four movies were analyzed. We adapted the design principle suggested by Ron Ritchhart (2015) and proposed our aligned curriculum design by 1) selecting four TMs (building explanations and interpretations, making connections, considering different viewpoints and perspectives, and reasoning with evidence) that correspond to course nature and common thinking weakness observed by the researchers; 2) translating TMs into course-specific goals statements; 3) selecting TRs that match the goals statements; and 4) designing assessment rubric that uses four TMs as criteria and divided each into three levels with aligned description of performance. Take TM considering different viewpoints and perspectives for example. It was translated as course objectives and forthcoming rubric as: challenge the perspective of the movie, look at things from the perspectives of different people or things, and step inside the movie character's position and his/her perspective. To reach these objectives, TRs *Circle of viewpoints* and *Step inside* were then used repeatedly in different movies to guide students' thinking and movie analysis. Then TM considering different viewpoints and perspective taking were used to assess students' performance and provide feedback.

Data collection and analysis

We collected the following data to respond to our research questions: a pre- and post-test of thinking self-evaluation, movie analysis writing, and students' self-reflection. First, twenty pre and post-test of thinking self-evaluations were collected in Week 2 (pre-test) & Week 16 (post-test). Students evaluated their degree of agreement to each statement on a 5-point Likert scale. The results were analyzed with descriptive statistics and t-test. Secondly, eighteen movie analysis writing was collected in Week 2 & Week 17 (Writing 1 and Writing 2) and required students to analyze social issues in the movie "Hidden Figures." They were graded with the TM grading rubric, which was piloted in another similar course and showed high reliability (Cronbach's α value is 0.886). The results were analyzed with descriptive statistics and t-test to capture students' change of performance. To further capture the qualitative nature of students' learning process, eighteen students' self-reflections about their learning experience were collected in Week 18 and analyzed by open-coding approach.

Results

How TRs & TMs-incorporated curriculum affects students' movie analysis

As shown in Table 1, analysis results of pre and post-test of thinking self-evaluation showed that p-values have all reached significant statistical difference between pre- and post-tests for all four TMs. And the TM considering different viewpoints and perspectives has the biggest effect size (-0.96), followed by the TM building explanations and interpretations (-0.83).

Table 1
Analysis result of pre and post-test of thinking self-evaluation (n=20)

thinking moves	pretest average	posttest average	average difference	t	df	p	Cohen's d
building explanations and interpretations	3.65	4.213	0.563	-3.71	19	0.001*	-0.83
making connections	3.717	4.067	0.35	-2.101	19	0.049*	-0.47
considering different viewpoints & perspectives	3.633	4.167	0.534	-4.292	19	< .001*	-0.96
reasoning with evidence	3.5083	4.117	0.534	-2.43	19	0.025*	-0.543

Secondly, as shown in Table 2, analysis results of movie analysis showed that p-values have all reached significant statistical difference between average score of Writing 1 and Writing 2 for all four TMs. The TM considering different viewpoints and perspectives has the biggest effect size (-1.062), followed by making connections (-0.709).

Table 2
Analysis Results of movie analysis writing (n=18)

thinking moves	**Writing 1 average**	**Writing 2 average**	**average difference**	**t**	**df**	**p**	**Cohen's d**
building explanations & interpretations	2.556	2.833	0.277	-2.557	17	0.02*	-0.603
making connections	2	2.556	0.556	-3.007	17	0.008*	-0.709
considering different viewpoints & perspectives	1.5	2.278	0.778	-4.507	17	< .001*	-1.062
reasoning with evidence	2.444	2.667	0.223	-2.204	17	0.042*	-0.519

To sum up, the above two analysis results showed that while students' use of TMs have improved consistently, the most obvious improvement was shown in considering different viewpoints and perspectives.

How TRs & TMs-incorporated curriculum affects students' perception of thinking and learning

Students' self-reflection demonstrated two themes: perception of thinking improvement and learning process. The first theme corresponds with the targeted TMs very well that students' reflection about improvement of thinking could easily fall into four topics titled as four TMs. The second theme about learning process was divided into two topics: expression confidence and gain from group discussion. We then calculated the number of students whose reflections fall into each theme and topic and presented the result in Table 3.

Table 3
Coding results of students' self-reflection (n=18)

Theme	**Topics**	**No. of students**
Perception of thinking improvement	building explanations & interpretations	13
	making connections	17
	considering different viewpoints & perspectives	15
	reasoning with evidence	10
Learning process	expression confidence	10
	gain from group collaboration and discussion	12

As shown in Table 3, 15 students (83%) mentioned their improvement in considering different viewpoints and 17 students (94%) felt improvement in making connections. We can see that aside from the positive research results of movie analysis writing, students also perceived overall improvement of their thinking. The second theme helped the researchers capture students' learning process. Ten students (56%) felt more confident and more expressive in group discussions and gained a sense of achievement. Twelve students (67%) reported gain from group collaboration and discussion and reflected that the constant group sharing and collaboration by following thinking routines gave them an open space to listen to different opinions and thus inspired them to trigger more thoughts of their own. Meanwhile, they felt interaction and feedback they give each other genuinely and supportively boosted their confidence of expression and provided them new perspectives.

Discussion and implications

In response to problems brought by thinking curriculum misalignments, we proposed an aligned TRs and TMs-incorporated curriculum and analyze its impact on students thinking and learning. Our positive research results lead to three important implications. First, our alignments make it possible to explain how use of TRs corresponds to course objectives and our TM grading rubric makes students' action of thinking and learning outcome assessable and traceable to course objectives. Second, our alignments provided practitioners an applicable example of how generic principle of teaching of thinking can be transformed into domain-specific design principle. Third, the present design of a thinking curriculum solved the problem of decontextualized teaching of thinking and situated teaching of thinking in a meaningful social context. The alignments send a clear message to students about the importance of deepened thinking and building knowledge in the community of learning. This echoed with previous literature that learning happens when thinking is made visible and situated in a community of practice (Collins, Brown, & Holum, 1991). We acknowledge our limitation of addressing only four TMs. Further research may be conducted to assess other TMs. It'd be also valuable to adopt our thinking curriculum alignment in other courses to generate a more solid design principle.

“As a Woman, I Learned to Be Hard”: Exploring a Network of Dualisms in the Geoscience Education Department

Sarah El Halwany, Maryam Taheri, Jennifer D. Adams
sarah.elhalwany@ucalgary.ca, maryam.taheri2@ucalgary.ca, jennifer.adams1@ucalgary.ca
University of Calgary, Alberta, Canada

Abstract: This paper explores how geoscience education contributes to a ‘linked networked of dualisms’ (Plumwood, 1991) that reinforce binary distinctions between feminine/masculine, nature/culture and emotion/reason. We examine how those demarcations get enacted at the level of the ‘skin’ (Ahmed & Stacy, 2001) and are *felt* as ‘atmospheric practices’ (Bill & Somensen, 2021). The linkage between those dualisms became apparent following interviews with ‘Jessica’ a graduate student in the geoscience department retelling her experiences with sexual harassment and microaggressions in a culture where she had to ‘learn how to be hard’ as part of a ‘work hard, play hard’ culture. We explore the various ramifications of ‘hardness’ in relation to the gendered and material practices that perform Jessica’s ways of being as a student in the geoscience department. One conclusion is that ‘over-representation of the rationalist Man’ (Wynter, 2003) in this setting happens *affectively*, at the level of the skin.

Introduction

This paper is situated within the vast literature that examines issues of under representation, microaggressions and social inequities faced by racially and gender diverse students in science education and STEM majors (e.g., Vakil, & Ayers, 2019). One of the ways that science education maintains those inequities is by reproducing existing hegemonic structures in society (Strong et al., 2016). This paper explores how geoscience education, (broadly a STEM related field) contributes to a ‘linked networked of dualisms’ (Plumwood, 1991) that reinforces binary distinctions between feminine/masculine, nature/culture and emotion/reason. We examine how those demarcations get enacted and are sensed at the level of the ‘skin’ (Ahmed & Stacy, 2001) as ‘atmospheric practices’ (Bill & Somensen, 2021) and are not simply conceptually/discursively rehearsed. The emotional and corporeal aspects that make up students’ lived experiences in STEM are often overlooked and without such understanding, “the struggle against (racial and gendered) inequity will always be incomplete” (Bonilla Silva, 2019, p. 2). This paper explores how practices within geoscience leave their impressions on the ‘skin’ of ‘Jessica’ a graduate student in the geoscience department retelling her experiences with sexual harassment and micro-aggressions in what she describes as a “work hard, play hard culture”.

Ecofeminism and affect

Geoscience education focuses on fostering an understanding of the Earth and its history. In generating such knowledges, the geosciences rely heavily on practices, that involve extraction of non-renewable resources and the displacement of communities to produce goods and luxuries for industrialized countries (Marin Spiotta et al., 2020). Hence, Monarezz et al. (2021) see racism and colonialism to be necessarily intertwined with the history of geoscience (and other related fields, e.g., paleontology). With a recognition of patriarchal edifices within projects of colonialism (Wilson, 2005), St John et al. (2016) discuss pervasiveness of sexual harassment in the geoscience department. In considering this context, ecofeminists offer important insights that highlight “important connections between how one treats women, people of color, and the underclass on one hand and how one treats the nonhuman natural environment on the other” (Warren, 1997, p. xi). Shiva (1993) finds that it’s especially important “to examine the connections between the violence of unjust, non-sustainable economic systems and the growing frequency and brutality of violence against women” (p. xiv). Braidotti et al. (1994) similarly argue: “that we must recognize that women and nature are simultaneously subjugated, and that this subjugation takes historically and culturally specific forms” (p. 75). For instance, Western philosophies have taught us “that our bodies and emotions are untrustworthy sources of knowledge” (Kheel, 2009, p. 2). As such, emotions have often been feminized as subjugated ways of knowing, setting them squarely against reason and judgment (see Boler, 2004). The invisibility of bodies and knowledges is not only tied to a dismissal of emotions but to their hierarchies (what emotions are deemed acceptable and not in Western societies) and how such hierarchies have served to further de-legitimize historically marginalized peoples, with implications for contemporary schooling practices (Zembylas, 2022).

Our paper draws on ecofeminist scholars and feminist-affect scholars in suggesting that “rationalism is the key to the connected oppressions of women and nature in the West” (Plumwood, 1991, p. 3) and to highlight how those connected dualities are themselves enacted affectively and corporeally. Ahmed and Stacy (2001) propose a 'thinking through the skin' as a thinking not on "the body as the lost object of thought but on the modes of being-with and being-for, where one touches and is touched by others" (p. 1). To consider the interface between bodies and their worlds is to analyze how 'bodies' *surface* in social relationships "without necessarily fetishizing the body" (p. 3). Hence, emotion/reason duality is not simply relegated to a conceptual separation that is reproduced discursively, but such a demarcation is sensed/produced at the interface of the skin. Cultural geographers have attended to the spatiality and affects of the lived body in social settings by turning to "atmospheric practices and atmospheres as practiced" (Bill & Somensen, 2021, p. 305). An atmospheric practice is the *attunement* to people, objects and places through the affects of the lived body; it's the feeling you get when you enter a room. The notion of affective atmosphere insists that our intimate feelings do not belong to us but are an effect of how bodies encounter other bodies. Yet, Ahmed reminds us, how we become attuned and attune others to our bodies come from 'past encounters'. In that sense, "the work of equality is a deeply corporeal work" (Ahmed, 2014, p. 101) accounting for the effects and affects of a skin that does not simply contain us but that exposes us to others (Ahmed, 2004).

Åhäll (2018) seeks to reclaim affect as a feminist knowledge, offering a critique to the separation between affect and emotion which tends to reinforce "a binary, gendered logic between a mobile, impersonal and masculinized affect and a contained, feminized, personal emotion" (p. 40). For her, "there is no feminism without affect" (p. 38). This means that how we feel about the world, already tells us how the world works, which helps to generate feminist questions (where feminism is understood beyond just 'women's stuff'). Such feminist questions can support more nuanced insights about how humans encounter each other in educational spaces.

Sensing geoscience education is an attunement to how bodies touch and are touched (materially, emotionally/affectively). Vea (2020) argues that "practicing affect" is a way of knowing and feeling in situated learning practices. Similarly, in our analysis we focus on how *practices* are in themselves 'felt' phenomena that intertwine bodies with their social and material environments (Bill & Somensen, 2021). We outline those practices through the experiences of 'Jessica' a graduate student in the geoscience department re-telling her experiences with sexual harassment in her undergraduate degree and how she had to learn to develop a 'hard (skin)' in this environment. As such, we advance that geoscience education is implicated in "the social and cultural production of the skin" (p. 4) (and relatedly categorizations of the human, see McKittrick, 2015; Adams & Weinstein, 2020), affecting how women (and possibly other gendered and racialized groups) might experience their belonging to the field.

Methodology and context

Data for this study comes from a larger project that examines race and gender-based issues in STEM education at the postsecondary level. Data collected for this research include an exploratory survey of students' experiences of gender and race-based discrimination in STEM fields in a major Canadian city and follow up interviews with consenting participants to gain an in-depth understanding of their experiences. The present research takes a case study approach (Stake, 1995) looking at the experiences of 'Jessica', a graduate student in the geoscience department. A case study affords a possibility to study the particularities and complexities surrounding students' experiences (Stake, 1995). At the time of the interview, Jessica identified as a white heterosexual woman. Two interviews were conducted with Jessica. The first interview was for one hour and the second follow up interview was for 45 minutes. In the first interview, Jessica shared personal experiences with sexual harassment and microaggressions, that were mostly pronounced during her undergraduate degree. In the follow up interview, we asked Jessica to further elaborate on previous answers based on emerging themes. The authors also invited Jessica to provide her feedback on data analysis and dissemination and to check specificities of experiences shared in the first interview. For our analysis, we focused on specific practices of how bodies come into contact with other bodies, as a result of attuning to the affective intensity and hardness of recounted moments that were felt on the surfaces of Sarah's skin (first author, cisgender woman) encountering the stories of 'Jessica' in the moment of the interview. Rather than asking what those practices mean, our analysis looks at what those practices 'do' in materializing surfaces and boundaries (Ahmed, 2007), giving the geoscience department its distinct atmospheric 'feel'.

Discussion of findings

Jessica described geoscience education as a 'work hard, play hard' culture, which could be viewed as an "atmospheric practice" (Bill & Simonsen, 2021) surrounding how students are attuned and attune themselves and others to their education in this field. We trace the 'work hard play hard' atmosphere to four material and bodily practices: drinking, forcing, blocking and carrying, as evident in stories shared by Jessica. We intentionally use those verbs to highlight *the affective forces* that work on the skin and are worked by the skin to contour the body as ‘given’ either (emotional) woman/ (rationalist) man, nature/culture, and that serve to re-intensify the entanglements between those dualities (Plumwood, 1991).

Drinking

In elaborating on the ‘hardness’ aspect of the geoscience education culture, Jessica mentioned how it rests on heavy drinking and partying. She recounted an experience where, following field work (where students go to the field to apply learned techniques), an instructor stopped the bus next to a liquor store and bought a case of beer for everyone to celebrate their hard work in the field, asking them not to tell anyone. The pervasive and secretive drinking culture perpetuated by some of the teaching faculty, and where drinking is seen as a way to forge relationships for future employability, draw boundaries for who can (and what it takes to) participate in this culture. Heavy drinking is considered “the mark of man” (Dempster, 2009), reproducing an atmosphere of masculinity, attuning bodies to objects (alcohol), to each other and to their relationship to a practice that defines the field.

Forcing

Jessica shared her experiences with another male student who would call her in the middle of the night, kiss her without her consent, touch her inappropriately, and force a hug after showing up uninvited to her apartment. She discusses the occurrences of those events in relation to various out-of-school networking events that are essential to students’ success in their degree (e.g., forging relationships and bonding in those social events facilitate group work inside the classroom, as Jessica later explained). Relatedly, Jessica discussed the sanitized version of her courses in geoscience that overlooked how geographers trespassed lands and forcefully displaced communities through their extractive practices, portraying them instead as “rugged explorers, working with rocks who made ‘great’ contributions to science”. In its various bodily enactments, practices of forcing and trespassing justify and entangle the instrumental treatments of women and nature.

Blocking

Jessica described instances where a male classmate would repeatedly and intentionally block her when she is talking to her friends, standing in between them, shaking their hands, as if she didn’t exist. In confiding to her female supervisor who supported her during those difficult times, she advised her to “to put an armor on” to be able to deal with those things. As such, Jessica learned to develop a ‘hard skin’, not showing her vulnerabilities nor her emotions, yet still somehow mocked at. Those various instances of being blocked (by her male colleague) and her attempts at blocking her emotions through putting a hard skin, show how the geoscience department simultaneously de-humanizes women while re-entangling the emotional with the feminine.

Carrying

In field school, Jessica, along with 3 other women in the program, felt pressured to work extra hard, so they could prove themselves. She mentioned having to “carry more to keep up with the rest of the guys”. Later in the day, she would hear her peers chatting in the middle of the night about who she had a crush on. She said, in this culture: “it would be safer to be in a relationship, it’s sort of a visible boundary to let people know that [as a woman you are] off limits”. Retelling her emotional state during those times, she mentioned having to “carry a black cloud over her head”. Carrying speaks to the material (physical) and atmospheric aspects of inhabiting a ‘female body’ and further contributes to the exclusionary boundaries of the geoscience department.

Conclusion and significance

The “work hard, play hard” affective atmosphere and its constitutive bodily and material practices in the geoscience department contribute to a ‘rationalist conception of the human’ that operate to justify instrumental treatment of humans and non-humans (White, 2013). One conclusion is that the ‘over-representation of the rationalist Man’ (Wynter, 2003) in this setting happens *affectively*, at the level of the skin. Challenging atmospheric practices of STEM education (in this case a work hard, play hard culture) may be an entry point to “decolonizing the very institutions that have shaped our ontologies of what it means to be human” (Adams & Weinstein, 2020, p. 248). This study further meets previous research that looks at how ‘emotions’ are a target in their own right for processes of identification (Vea, 2020). While the present analysis draws on experiences of one student who identifies as a white woman in a STEM-related field, our analysis acknowledges the need for an intersectional lens that takes into better account the nuanced sensations that delimit how different groups (with both visible and less visible identity traits) might experience their belonging to STEM fields.

Mind the (Is/ought) Gap: A Call for an Applied Ethics of Design-Based Research

Abstract: Design-based research typically aims to mediate certain actions that learning scientists perceive as worthy or good, meaning that it is an inherently ethical activity. However, the ethical considerations that motivate learning scientists are oftentimes left implicit. In this paper we call for an applied ethics of DBR, which would make the ethical reasoning that is fundamental to our work a more systematic part of our scholarship. We begin by explaining why moral responsibility for learners' actions can be viewed as shared between learners and the learning scientists who designed their learning environment. We then posit that coherentism, which combines top-down and bottom-up methods of moral justification, is the most apt approach to an applied ethics of DBR. Finally, we conclude by highlighting one way in which an ethics of DBR might transcend the learning sciences community to advance ethical theory more broadly.

Introduction: The ethics of DBR

What motivates learning scientists to engage in design-based research (DBR), and how can they be sure that their efforts are worthwhile? We posit that ethical considerations are fundamental to DBR, even though they are oftentimes left implicit in learning sciences literature. Sandoval's (2014) notion of conjecture mapping, for instance, details how DBR is intended to mediate a shift from *what is* towards *what ought to be*, meaning that it is an inherently ethical process because it requires researchers hold the view that some actions and outcomes are in some way *better* than others. And yet, there is no rubric in his proposed logic model dedicated to articulating or justifying the moral reasoning undergirding researchers' DBR work (Cf. Cohen, Ben-Zvi & Hod, 2023).

In what follows, we address three issues that are key to developing the ethics of DBR. In the first section we argue that learning scientists bear some moral responsibility for students' actions, even though it is students themselves who are meant to become better people or do better deeds as a result of DBR. In the second section we call for the development of an applied ethics of DBR akin to what can be found in other specialized fields such as medicine, law, business, or war. We also posit in this section that the unique features of DBR lend themselves to a *coherentist* method of moral justification, which combines top-down and bottom-up approaches to moral reasoning. And finally, in the third section we outline a unique type of empirical ethics that we envision for the learning sciences community and explain why we believe that learning scientists are well-positioned to make a meaningful contribution to ethical discourse more broadly. Our overarching goal is to encourage learning scientists to be more explicit about their ethical commitments, and to provide some rudimentary conceptual tools that might ultimately pave the path towards a systematic and rigorous ethical literature to complement and extend the rich DBR discourse that has already taken hold in our community.

From an ethics of design to an ethics of DBR

Underlying any ethical discourse is the assumption that people strive (or ought to strive) to do good deeds and avoid doing bad ones. Once this has been established, ethical reasoning touches on questions such as what makes one deed better than another, how might an agent distinguish between good and bad deeds, or what course of action an agent ought to choose when two deeds (or more) are available. Ethical discourse also assumes a measure of agency comprising freedom and intentionality because for agents' actions to be good or bad, they must be aware of what they are doing and be capable of doing something else instead. Assisting those in need is typically viewed as good, and stealing as bad, only if they reflect choices made by an agent. Simply digesting one's food after eating it is an action that usually involves neither free will nor intentions, and hence is ethically neutral.

One corollary to all of this is that ethical discourse typically focuses on the relationship between agents and *their own* actions, meaning that bringing it to bear on DBR might be challenging. DBR does not form a direct link between scholars' agency and their own actions, but rather is oriented towards the actions of others: it is centered on a process whereby researchers design and investigate a learning environment in which they hope that learners – *not* researchers themselves – will act in certain ways. To put things differently, we might argue that DBR either affords students enough agency or it doesn't. If it does, and students still have enough intentionality and free will for their actions to be considered good or bad, then we might argue that designing the learning environment is morally neutral. On the other hand, if the learning environment denies agency by forcing learners to act in certain ways, then students' actions would be rendered neutral because they had no choice in the matter. This analysis would lead us to articulate the ethics of DBR in zero-sum terms: either scholars' actions are ethically charged and learners' actions are neutral, or vice versa, but not both.

An alternative view that accounts for a complementary contribution of learners and researchers to learners' action builds on the notion of mediation, which has always been central to the learning sciences. Verbeek (2009) identified perception and action as two primary forms of mediation. Some tools, such as glasses or thermometers, amplify and reduce certain aspects of reality in ways that shape how we perceive it, while other tools, such as speedbumps or disposable cups, are imbued with scripts (a term he borrowed from Latour, 1992) that "suggest specific actions and discourage others" (Verbeek, 2009, p. 230; see also Norman, 2013). Given the ubiquity of technology and the fact that almost all human activity is mediated by one technology or another, Verbeek argues that it would be futile to discuss ethics in isolation from technology. His conclusion is that agency must be viewed as distributed between individuals and the technologies that mediate their perception of reality, their potential actions on it, and by extension also their sense of self and others. For instance, all ethical questions surrounding pregnancy and unborn fetuses are shaped by the technologies that allow us to see inside people's bodies and act upon them, such as ultrasound and other sophisticated tests, procedures, and medications. These technologies cannot determine *on their own* whether, or under what circumstances, abortions are ethical; but neither can any ethical discussion of abortion disregard the technologies that are available. Verbeek therefore concludes that "design is inherently a moral activity. By designing artifacts that will inevitably play a mediating role in people's actions and experience, thus helping to shape (moral) decisions and practices, designers 'materialize morality'; they are 'doing ethics by other means'" (p. 235).

In a similar vein, we maintain that learners' actions are inevitably mediated by their learning environment, which can include curricular materials, task structures, participant structures, and more (Sandoval, 2014). All these elements are designed to amplify and reduce how learners perceive certain elements of the curriculum and of reality and are imbued with scripts that call on learners to engage in some actions and avoid others. Adopting Verbeek's approach therefore suggests that the morality of learners' actions is distributed between learners, their learning environments, and their designers. By extension, we would argue that by engaging in DBR, learning scientists must assume some of the moral responsibility for students' actions (but not all of it!), and must explain – to themselves and others – why they view some educational actions and outcomes as better than others. But where do scholars' views of good, bad, right, and wrong come from, and how can they justify them? We address this question in the next section.

The case for coherentism in DBR

By calling for a more robust discourse surrounding the ethical dimensions of DBR we are expressing the hope that learning scientists will eventually develop a body of *applied ethics* akin to those found in medicine, business, war, law, and other fields. In contrast to general moral theories about what is good and right (and how to justify claims about what is good and right), applied ethics are concerned with more practical questions that arise in specific settings – often professional ones. They are intended to guide professionals and practitioners in their work by addressing the unique circumstances that they regularly encounter (Beauchamp, 2005).

We have already suggested that when scholars answer questions about the knowledge and skills students *ought* to acquire or how their identities or communities *should* develop amid learning, they should systematically justify the claim that these are *good* outcomes. Especially given that learning scientists design learning environments with the explicit aim of altering the current state of affairs, they must be equipped to convince themselves and others that they are doing the right thing. But how are they to know what is right? Beauchamp (2005) distinguished between *top-down* and *bottom-up* methods of justification in applied ethics. *Top-down* models are those that seek to bring general convictions about what is good to bear on a specific field such as DBR. For instance, learning scientists who are morally committed to safeguarding the future of the planet by minimizing human reliance of fossil fuels may design a learning environment with the goal of strengthening learners' understanding of global warming (Herman, 2015). They would view such a learning environment as *good* because it is aligned with their broader ethical convictions, namely their belief that they are morally responsible to do more to mitigate global warming. In contrast, bottom-up models extrapolate general ethical imperatives from individual cases that are viewed as authoritative. A good example in the learning sciences is the centrality of expertise, which learning scientists often viewed as an ideal type worth emulating. The *Reading Like a Historian* project is a case in point; it constitutes a DBR effort to teach students to adopt some cognitive tools used by expert historians, whose expertise is the primary justification for their tools' *goodness* (Reisman, 2012).

On its own, each of these methods of justification is fundamentally flawed (Beauchamp, 2005). The bottom-up method is a classic case of the is/ought problem, originally articulated by Hume (1739), who warned against moral reasoning that infers from the empirical (*what is*) to the ethical (*what ought to be*) without providing ample evidence. In other words, the fact that expert historians ask certain questions when they read historical texts does not in itself justify the claim that this is what they – or anyone else – *ought* to do. In a similar vein, the top-down method is always insufficient on its own because translating general moral principles into real-world contexts requires specification, meaning that it must account for "feasibility, efficiency, cultural pluralism, political procedures, uncertainty about risk, non-compliance by disaffected parties, moral dilemmas, and the like" (Beauchamp, 2005, pp. 12-13). For example, climate change is a politically charged topic that may arouse resistance or be unsettling (Herman, 2015; Walsh & Tsurusaki, 2017). Therefore, learning scientists ought to take learners' expected responses and emotions into account alongside their commitment to mitigating climate change because simply teaching about climate change will not necessarily result in the desired outcome. Hence, the commitment to the future of the planet cannot on its own justify the design of a specific learning environment intended to teach about climate science.

Coherentism is an approach that integrates the top-down and bottom-up models by applying moral theory and principles to increasingly more specific cases, and simultaneously developing the said theory based on the experience and insight gained by applying it. Gutierrez and Jurow's (2016) approach to Social Design Experiments demonstrates how a coherentist approach can be implemented by learning scientists who are engaged with the ethical dimensions of DBR. In their own words, Gutierrez and Jurow's (2016, p. 565) approach is intended to advance "[1] the social agenda of ameliorating and redressing historical injustices, *and* [2] the development of theories focused on the organization of equitable learning opportunities." The first goal embodies a top-down approach and the second embodies a bottom-up one, whereas the combination between the two embodies coherentism. Due to the iterative nature of DBR, a coherentist approach is especially apt for our research community. Within coherentism, broad moral theories (e.g., "ameliorating and redressing historical injustices") and specific examples of how they are applied (e.g., how to design for "equitable learning opportunities") are *always* taken to be dynamic and subject to change in light of one another. Indeed, according to Beauchamp (2005, p. 11), when adopting the coherentist approach

> we have no reason in applied ethics to anticipate that the process of achieving moral coherence will either come to an end or be perfected. A moral framework adequate for applied ethics is more a process than a finished product; and moral problems […] should be considered projects in need of continual adjustment by reflective equilibrium.

A vision of empirical ethics in DBR

In this final section we outline how we think an applied ethics of DBR can transcend the confines of the learning sciences community and have a broader impact on ethical theory. To accomplish this, we briefly shift our gaze to bioethics, a field that has witnessed the emergence of a new genre of research known as *empirical bioethics*. This sub-field "seeks to ask and answer questions of bioethical interest in a way that draws on the strengths of both philosophical and empirical analysis" (Davies, Ives, & Dunn, 2015, p. 1). Dating to the beginning of the century, the empirical turn in bioethics emerged as an alternative to traditional forms of applied ethics dominated by theologians and philosophers, which many physicians considered "too abstract, too general, too speculative, and too dogmatic" to inform their day-to-day work (Borry, Schotsmans, & Dietrickx, 2005, p. 64). According to McMillan (2017, p. 31), "good empirical ethics[...] should fuse robust ethical argument with the groundedness and sensitivity to context that result from a well-constructed empirical investigation."

We maintain that due to the unique nature of DBR, learning scientists are well-poised to contribute to efforts to advance a more empirically grounded applied ethics that can transcend the is/ought gap by adopting a coherentist approach that employs innovative empirical methods. For example, one promising innovation in DBR along these lines is Participatory Design Research, an approach that has called on learning scientists to develop an ethical discourse that is dually grounded in ideology and rigorous empirical research. In their discussion of Participatory Design Research, Bang and Vossoughi (2016, p. 174) argued that current research paradigms often "maintain, either explicitly or implicitly, normative hierarchically powered decision-making structures." These hierarchies notably include implicit ethical judgements and moral reasoning about what is right and good, which means that they foreground scholars' views in ways that can suppress the views of students, teachers, and other partners in DBR projects. As an alternative, Bang and Vossoughi (2016) propose a participatory approach to DBR that would require learning scientists to undermine these power structures by widening their views of what constitutes empirical research to include "historical, relational, and axiological perspectives and the ways these are embodied and experienced." (p. 174) In line with this emerging research paradigm, it has become increasingly more common for learning scientists engaged in DBR to be forthcoming about their own lived histories in order to empirically frame their research partnerships in terms of subject-subject relations. Foregrounding our positionalities as researchers in a systematic way and analyzing their consequentiality as a key element of our methodology offers a compelling example of the unique contribution that our community stands to make to a broader ethical discourse because it holds promise as a way of theorizing how we draw on empirical research to make the leap from *what is* to what we believe *ought to be*, and how our scholarship can help get us there.

Conclusion

We are convinced that all learning scientists who design and integrate innovative learning environments do so because they want to make a valuable contribution to learners and to society. But up until now, our community's engagement with the ethical considerations driving their work has been somewhat sparse and anecdotal. The purpose of this paper was to lay some foundations for a more robust and systematic ethical discourse that might become a core element of DBR. We started out by showing how the ethics of design employ the notion of mediation to support the claim that agency and moral responsibility for learners' actions is distributed between learners and researchers. We then went on to outline a crucial correlation between the iterative design of DBR and the coherentist approach to moral justification in applied ethics, which combines top-down and bottom-up methods of moral reasoning. Finally, we identified participatory design research as one methodological innovation that an empirical ethics of DBR stands to contribute to other fields. By foregrounding researchers' positionalities, the participatory approach to DBR can help elucidate the theoretical leap from what is to what ought to be, a puzzle that has eluded ethicists for centuries.

The Relationship Between Appropriation and Guided Participation During Teacher Professional Learning

Jen Munson, Northwestern University, jmunson@northwestern.edu
Erin E. Baldinger, University of Minnesota, eebaldinger@umn.edu
Amber Armstrong, armst417@umn.edu

Abstract: In a community of practice, such as those designed to support teachers' professional development, learning is fostered through participation in the joint enterprise of the community as teachers appropriate practice and engage in guided participation of practice. Because sociocultural activity is not sequential or isolated, this study explores the interaction between guided participation and appropriation in one environment designed to support teacher learning: side-by-side coaching. In side-by-side coaching, a teacher and coach partner to co-enact a focal pedagogical practice with the teacher's students during instruction. In our analysis, we explore the relationship between appropriation and guided participation during side-by-side coaching, finding two kinds of teacher learning opportunities at their intersection. Both theoretically and analytically, our findings indicate that appropriation is inherent to the process of teacher learning, rather than an outcome or end point.

Introduction

In a community of practice, such as those designed to support teachers' professional development, learning is fostered through participation in the joint enterprise of the community (Wenger, 1998). Participation is construed broadly in this theoretical approach, from working alongside a more knowledgeable other to interacting with the community's tools and artifacts. Rogoff (1995) further developed this theory of learning into an analytic lens, proposing that participation in communities occurs – and can be analyzed – in three interdependent planes: the apprenticeship plane, the guided participation plane, and the participatory appropriation plane. In the apprenticeship plane, participation in activity is shaped by sociohistorical, cultural, and institutional contexts. In the guided participation plane, individuals participate in shared activity, communicating and coordinating efforts, refining and participating in activity. While in the appropriation plane, individuals take up, transform, and enact practices, making them part of their repertoire. Rogoff argues that in any system of sociocultural activity all planes are relevant and mutually constituted.

These approaches to learning in sociocultural activity have been widely taken up in research on teacher professional learning, across teaching disciplines, school levels, and learning designs (e.g., Grossman et al., 2001; Horn, 2005; Loucks-Horsely et al., 2009). Much attention has foregrounded the guided participation plane, focusing on interactions between and among teachers and teacher educators, how such interactions are designed, sequenced, and co-constructed (e.g., Gibbons et al., 2021; Horn, 2010). Other forms of research focus on the effects of professional development (PD) and examine appropriation as it occurs after PD, when teachers return to their classrooms to implement what they have learned (c.f., Longhurst et al., 2022). This work foregrounds one plane over others to examine its mechanisms and implications, an approach Rogoff (1995) argued was appropriate provided all planes were acknowledged.

Ultimately, sociocultural activity is not sequential or isolated, (Rogoff, 1995). Instead, learning involves moving between multiple planes. In this study, we investigated how guided participation and appropriation co-occur and support one another during teacher professional learning (e.g., Ghousseini et al., 2015). Broadly, we seek to understand the learning opportunities emerging at the juncture of appropriation and guided participation.

This study explores guided participation and appropriation in one environment designed to support teacher learning: side-by-side coaching. In side-by-side coaching, a teacher and coach co-enact a focal pedagogical practice with the teacher's students during instruction. Either adult might lead interactions with students, and the pair engage in professional discourse about the enacted practice as it occurs, making decisions or addressing emergent problems of practice. In our analysis, rather than foregrounding one plane, we explore the relationship between two by asking: What is the relationship between appropriation and guided participation during side-by-side coaching? How did these structures interact to support teacher learning opportunities?

Methods

Study design, participants, and data

This study was embedded in a teacher-initiated research-practice partnership between teachers at a public, urban elementary school in California and the mathematics teacher educators at a local university, including the first author who served as the coach. The three participating teachers spanned different grade levels (Grades 1, 2, and 4) and stages of their careers (2-17 years teaching experience). All three shared the goal of learning to support students to learn collaboratively through problem solving and discourse. The coaching period of this study lasted four weeks for each teacher. Each week, the teacher and coach engaged in side-by-side coaching during two mathematics lessons, for a total of 7-8 lessons of side-by-side coaching per teacher and 21 side-by-side coaching lessons across the three teachers. Within these lessons, we focused on conferring interactions, where the teacher and coach interacted with small groups of collaborating students (Munson, 2019); it was these conferring interactions that teachers were learning to facilitate and was, therefore, the initial unit of analysis.

Analysis

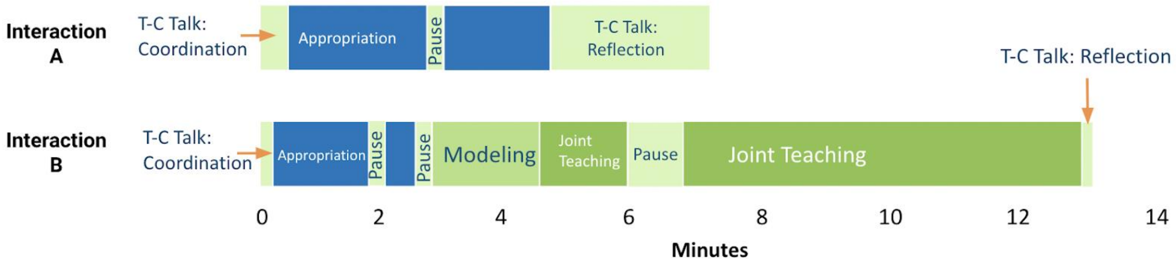
In the first phase of analysis, we coded each conferring interaction (n=50) for the type of participation drawing on Rogoff's conceptions of guided participation and appropriation. We operationalized guided participation and appropriation by who was leading instruction (teacher, coach, or both), the instructional activity, and whether students were part of the interaction. *Appropriation* of conferring was conceptualized as occurring during a conferring interaction when coaching was taking place and the teacher was leading the instruction. We operationalized *guided participation* around the central principle that guided participation involved both the teacher and coach participating in conferring (the focal pedagogical practice) or professional sensemaking through coaching. We isolated instances of appropriation and guided participation across all 50 conferring interactions and identified five types of guided participation that occurred within conferring interactions: (1) joint teaching, (2) modeling, (3) coordination, (4) pauses, and (5) reflection. In the second phase of analysis, we looked for patterns in how instances of appropriation were sequenced with and related to instances of guided participation within conferring interactions. We created maps of each conferring interaction to show the sequence and duration of participation in each form of activity. We then looked for patterns in how these instances were sequenced across all 50 conferring interactions.

Findings

We found that in side-by-side coaching, teachers moved between appropriation of practice and five forms of guided participation. Appropriation was common during coaching, occurring in 23 of 50 conferring interactions. Across these 23 conferring interactions, there were 35 instances of appropriation, indicating that appropriation and guided participation were sometimes interspersed. The mean duration of each instance of appropriation was approximately 2.5 minutes, with conferring interactions lasting approximately 11 minutes on average.

Appropriation interacted with guided participation in two primary ways. First, appropriation was often interspersed with pauses, a form of guided participation in which the coach and teacher stepped back from interacting with students to discuss student thinking and make instructional decisions about what to do next (c.f., Interaction A in Figure 1). These brief interactions allowed the teacher to resume appropriation with new ideas or directions. Second, appropriation often occurred at the beginning of conferring interactions, then gave way to other forms of guided participation, most frequently joint teaching with the coach or the coach modeling instruction (c.f., Interaction B in Figure 1). In these instances, appropriation allowed the teacher to identify areas where guided participation could further support their learning.

Figure 1
Examples of Two Structures of Conferring Interactions Including Appropriation and Guided Participation



First, conferring interactions in which appropriation was interwoven with pauses (n=5) allowed the teacher to take full responsibility for enacting the focal practice while occasionally accessing the coach for support making decisions and interpreting student thinking (c.f., Interaction A in Figure 1). In those interactions, guided participation occurred through coordination prior to engaging with students, where the teacher and coach discussed how the interaction might proceed; reflection following the interaction; and pauses during the conferring interaction, where the teacher and coach stepped back from the conversation with students to engage in discussion before re-engaging with students.

For example, Interaction A shown in Figure 1 illustrates a conferring interaction that began with coordinating the roles of the teacher and coach, followed by several minutes of appropriation by the teacher. During this conferring interaction, the students were playing a game about telling time on analog clocks, and the teacher, Hope, wanted to check that students were using the correct hands on the clock to tell time. After sharing this plan with the coach during coordination, Hope listened in as a group of students began working. As the students got going, Hope asked them to explain how they were able to determine the time, and how they knew which hand was the hour hand. The students offered that the "long hand is the hour hand" while the other hand "kept moving around." Hope seemed to notice some confusion the students had in distinguishing the hour, minute, and second hands. The coach paused the interaction at that point, saying to Hope, "Maybe tell them you want them to focus on this clock," referring to the clock on the activity sheet, rather than the clock on the classroom wall. Hope immediately took up this suggestion, resuming her appropriation of the conferring practice. Through this engagement with the clock drawn on the activity sheet, the students were able to work with Hope to differentiate the hour and minute hands, and correctly determine the time being represented. After the interaction with students ended, the coach and teacher reflected on the interaction for several minutes before moving on to the next phase of the lesson. As part of the reflection, they discussed the challenge of the clock on the wall, which had a moving second hand, as compared to the clocks students were using, which just had hour and minute hands. They wondered together about multiple representations of clocks that students might see, and the mathematics involved in telling time. In this interaction and others like it, the pause created the opportunity for the teacher to access a targeted pedagogical move that she could immediately implement to further the interaction with students while continuing to appropriate the practice with students.

Second, in conferring interactions where appropriation was followed by joint teaching or modeling (c.f., Interaction B in Figure 1), the teacher was able to locate the frontier of their comfort with independent enactment and shift into guided participation though joint teaching with or modeling by the coach (n=16). In joint teaching, the coach and teacher actively co-led instruction, while in modeling, the teacher actively observed the coach leading the conferring interaction with students. All of these conferring interactions also included moments in which the coach and teacher paused instruction to make sense of student thinking and make decisions about instructional next steps. Appropriation, in interactions with this structure, served as an entry point to guided participation in the enactment of the focal practice.

For example, Interaction B in Figure 1 shows a conferring interaction that began with coordination, where the teacher, Hope, told the coach she wanted to check in with a student and her partner who had been struggling. Hope began by eliciting the pair's thinking about whether 9 = 10 - 1 was true or false, and one of the students said she was starting with the nine. The coach interrupted for a brief pause, asking Hope what she noticed about the child's thinking. Hope posited that the child was thinking about the problem left to right, and then resumed the interaction with the students. The pair then claimed that the equation was false because 9 + 9 = 18. Both students appeared to have introduced addition to the equation. The coach turned to Hope for another pause at this point, saying "It seems like the equation is really tripping us up. The symbols, right?" The coach asked to step in with the students, and at that point the interaction shifted into modeling as a form of guided participation. The coach asked the students a series of questions about the meaning of the equal sign. Once the coach had re-established an understanding of what the equal sign represented, Hope rejoined the conversation, shifting from modeling to joint teaching as both the teacher and coach continued to press on the students' interpretation of the equation. Using an equation mat to model the equation, eventually the students were able to make sense of the equal sign and distinguish the meaning of 9 = 10 - 1 from 9 + 9 = 18. As Hope and the coach left this group, Hope reflected on the interaction and wondered if other groups might need the same support with the equation mat. In this interaction, Hope led the interaction with students, appropriating conferring, until it became unclear how to fully uncover what the pair were confused about. Following a pause, the coach stepped in and modeled a set of probing questions, creating the opportunity for Hope to rejoin the conversation and engage in joint teaching. This final, extended engagement in guided participation with students through joint teaching helped the students distinguish comparing from joining and also gave Hope insight into the potential needs in the rest of the class.

Discussion

Drawing on a community of practice approach to teacher learning, practice-based and practice-embedded teacher learning designs have primarily focused on developing a repertoire of pedagogical tools to support guided participation in the practices under investigation. However, Rogoff's (1995) framework argues for considering the interdependence between guided participation and appropriation in joint activity. Applying this analytic lens to side-by-side coaching, we find that, indeed, appropriation interacted with guided participation to support opportunities for teachers to learn to enact practice. At the juncture of appropriation and guided participation, teachers had the agency to draw on a more knowledgeable other to fuel appropriation or explore emergent problems of practice in joint activity. That is, appropriation and guided participation were mutually supportive. Appropriation supported identifying the emergent problems of practice that could be grappled with during pauses, joint teaching, and modeling. Guided participation in the form of pauses supported further appropriation by addressing teachers' emergent questions such that they could re-enter teaching leading the interaction. Both theoretically and analytically, our findings indicate that appropriation is inherent to the process of teacher learning, rather than an outcome or end point.

While this study examined side-by-side coaching, we believe that there are additional settings in which appropriation and guided participation might co-occur, including student teaching (e.g., Valencia et al., 2009), lesson study (e.g., Fernandez & Yoshida, 2012), and other forms of practice-embedded professional learning (Gibbons et al., 2021). This raises the question of whether other designs which include movement between appropriation and guided participation may create the two kinds of learning opportunities identified here: opportunities to seek sensemaking or decision-making support and opportunities to identify an emergent problem of practices and seek joint participation on enactment. We call on the field to consider both how teacher professional learning may be designed to create such opportunities to learn and to further investigate whether other learning opportunities emerge at the nexus of appropriation and guided participation in varied learning contexts.

Activating Resources for Incorporating Culturally Relevant Teaching in STEM Curricula

Jooeun Shim, University of Pennsylvania, jshim@upenn.edu
Susan A. Yoon, University of Pennsylvania, yoonsa@upenn.edu

Abstract: Studies reveal that significant instructional challenges persist when teachers integrate culturally relevant teaching (CRT) in science classrooms, often due to insufficient structural support and available resources. Additionally, teaching of STEM requires teachers to have access beyond material resources, such as lesson plans that they acquire in professional development. We present a case study of one experienced science teacher implementing an innovative STEM curriculum that integrates bioinformatics, data literacy, and mobile learning. We use a resource activation framework to examine constraints occurring when implementing the curriculum that was specifically designed for CRT. We analyzed the teacher's daily reflection posts, classroom observation notes, and a post-implementation interview. We found that symbolic resources (i.e., perceived institutional social values that are ascribed to different forms of instruction) impacted the teacher’s instructional choices. Our findings suggest that successful implementation of STEM curricula is dependent on teacher’s activation of different forms of resources often simultaneously.

Introduction

Studies on equitable science teaching in urban schools stress the need to design inquiry-based curricula that involve culturally relevant teaching (CRT) (Brown, 2017). Traditionally underrepresented groups, such as people of color, enter and are retained in STEM fields at lesser degrees (NSF, 2018). CRT can lessen the educational debt experienced by students who have been historically underrepresented in STEM disciplines (Ladson-Billings, 2006). CRT is a pedagogy of empowerment (Ladson-Billings, 1995), linking learning and culture in ways that aim to improve academic success, foster critical consciousness, and support cultural competence in the classroom, which give students opportunities to relate themselves to science in and out of school. Common barriers for enacting CRT in STEM include lack of structure and resources for preparing teachers, such as professional development (PD) training opportunities, model teachers who can positively demonstrate CRT instruction, and curricula of CRT that align with the standards (Barron et al., 2021). These limitations are amplified when teaching with innovative STEM curricula which focused on emerging disciplines, such as bioinformatics, computational thinking, machine learning, and data science**.** This is because in-depth conversations of CRT have not quite yet emerged (Brown, 2017).

Literature on implementing STEM curricula indicates that their successful implementation in classrooms depends on external resources beyond individual experiences and resources that teachers can acquire in PD (Brand, 2020). These resources, among others, can take the form of cultural resources, such as teachers’ pedagogical skills, or symbolic resources, such as the importance that STEM ideas have in the standard curriculum (Rivera Maulucci, 2010). Yet how teachers understand and activate essential resources to successfully implement innovative STEM curricula is still not well understood (Wang et al., 2020). Moreover, research on STEM education typically focuses on two forms of resources that are material, such as teaching supplies or curricula, and cultural resources, such as students’ prior knowledge (Brand, 2020). The demands of teaching dictate that teachers should utilize multiple resources simultaneously, and supporting teachers requires a more robust understanding of the complex nature of the resources that teachers draw upon (Rich, 2021). Rivera Maulucci (2010) proposed a resource activation framework that aims to systematically explore the ways that teachers utilize diverse resources concurrently. For STEM curricula to be incorporated with CRT, we used a resource activation lens to analyze an in-service teacher’s experience in adapting and teaching a bioinformatics problem-based learning unit in which students collect, analyze, and visualize air quality data collected through mobile apps and sensors. This study is guided by the following questions: (1) What resources did the expert science teacher activate to implement the bioinformatics curriculum? and (2) how did the interrelationships between the resources impact the activation?

Theoretical framework

This work is guided by the resource activation framework (Rivera Maulucci, 2010). According to Rivera Maulucci (2010), “activation” refers to an intentional use and adaptation of knowledge and commitments to improve pedagogical strategies and support teaching practices. In her resource activation framework, resources for teaching science can be categorized as material, cultural, social, and symbolic resources. Available *material resources* include learning supplies, such as textbooks, data collection devices, computers, and consumable equipment. Material resources can result from the context in which teachers work. Activating material resources could look like a teacher finding a short news clip that reports inaccurate data representation which could easily mislead the audience, and using it to facilitate students' discussion about the application and ethical use of data in the real world. *Cultural resources* are "knowledge, skills, education, and experiences within particular contexts" (Maulucci, 2010, p. 824). In an educational setting, cultural resources include the understanding of students and the teaching context; teachers' knowledge and conceptual understanding of data literacy (e.g., context, variability, aggregate, visualization, and inference); teachers' pedagogical and instructional strategies to foster critical data literacy and/or school's preferred instructional approach (e.g., problem-based learning, inquiry-driven learning, mobile learning, culturally relevant pedagogy); students' knowledge, experience, language, and academic abilities; and the culture of the school. *Symbolic resources* refer to value or prestige a community ascribes to an activity or goal. In an educational setting, symbolic resources refer to the perceived status or importance of teaching and learning. Symbolic resources highlight the institutional social value that is ascribed to different forms of instruction. For example, in our study, whether and how data literacy in STEM domains is prioritized, and recognition of teachers' efforts to integrate data literacy into their existing curricula. A teacher's symbolic resources might be activated when a principal recognizes the teacher for their efforts to bring cutting-edge knowledge into her science classroom or when the teacher is afforded some autonomy to design lessons using new pedagogy.

Methodology

Context

This study is part of a larger NSF-funded project that aims at constructing an innovative STEM curriculum in the context of bioinformatics that integrates culturally relevant pedagogy into the high school science classroom (Yoon et al., 2022). The curriculum is grounded in real-world problem solving that engages students with the community issue of asthma and air quality to explore data literacy as it pertains to biology. This issue was chosen because it is a problem that is highly relevant in the city, especially among students of color (Bryant-Stephens et al., 2012). A three-week summer PD workshop was designed to help teachers teach this curriculum. We ran the PD for 75 hours in July 2019. During the PD, six teachers learned the bioinformatics content and were introduced to pedagogical concepts such as student-centered, community-centered, and culturally relevant approaches. Teachers were asked to reflect on their learning after morning and afternoon sessions in a Google Classroom site that was created for sharing and storing of PD resources.

Participants

We used a case study method which requires researchers to purposefully select information-rich cases, as they will allow researchers an in-depth understanding of relevant and critical issues under investigation (Yin, 2017). To gain such insight, we chose to investigate Tracy, one of the teachers who participated in the PD, who implemented the curriculum in her environmental science class at a public high school in the Northeast U.S. She had been nominated as an expert teacher by the director of science in the school district. She identified herself as African American and was in her 5th year of teaching, with previous experience teaching biology, environmental science, and AP environmental science, all at the high school level. On the pre-PD survey, she indicated her passion toward teaching science. She responded, "I love Biology, I love to get students just as excited as I am in the subject(s)," and "I hope that I complete the PD with more knowledge, with something I can take back to my student in the classroom. Something that is real life, relatable to my students, and hands-on." These comments highlight her strong interest in providing authentic and meaningful learning experiences to her class.

Data source and analysis

We collected three data sources: daily reflection posts, classroom observation notes, and a post-implementation interview. The daily reflection posts were gathered to learn about how her perception of CRT changed as a result of PD participation. These posts were based on prompts given by the PD instructors, were submitted to Google Classroom throughout the PD. The prompts included, "1) What do you think about this content in terms of how you already teach? 2) What issues or challenges do you foresee in teaching this content to your students?" A total of 15 reflections were collected. The observation notes included descriptions of the classroom conditions, the teacher's instructional practices, and the activities and interactions among students taking place. Tracy's class was observed 9 times out of the 14 classes devoted to this project, which totaled 16 hours of instruction. Observation ranged in length from 33 minutes to 55 minutes with an average length of 46 minutes. The semi-structured post-implementation interview, which lasted 67 minutes, was conducted to probe the teacher's specific practices, beliefs, and understanding of implementing the new curricula, as well as the teacher's experience of preparing the class and participating in the project. Authors deductively coded data to identify instances that demonstrated the teacher activating resources in four categories of material, cultural, social, and symbolic resources. For example, the teacher's interview response, "[The principal] is very supportive over new [curriculum ideas] and if it supports the students' learning, then he will try his best to support it," was coded as symbolic because the teacher had symbolic support from the principal to pursue a more innovative approach to science teaching. Any discrepancies that occurred were negotiated until consensus on the codes was reached.

Findings

Shift in symbolic resources to navigate cultural and material resources

During the PD, Tracy did not appear to have enough symbolic resources for her to navigate cultural resources and turn them into material resources. In the PD, the teacher was asked to post a reflection after each morning and afternoon session. One of her posts captured how she initially felt about CRT in her instructional practices.

> It is a topic that I don't cover unless students bring it up. I stick strictly to the curriculum. However, I think I'm sensitive to the student racial/social needs just because I'm an African American woman who also grew up in [City] ... but I shouldn't use that as an excuse. I will try to educate myself on implementing social and environmental awareness into my curriculum; especially in AP [Environmental Science]. The only issue I foresee is educating myself and trying not to impose my personal feelings on the issues discussed.

In this post, Tracy explained that CRT was not part of her core instructional approach prior to the PD, but expressed an interest in incorporating it more. She also mentioned in her post-implementation interview, "we have to [be] making sure that what we're teaching, it's aligned to the standards, and that we just don't have the standard and [are] teaching whatever we want." She pointed out the lack of recognition from the school district for bringing CRT to science class while taking standards into account. These examples illustrate that there were not enough symbolic resources for her to navigate culturally relevant approaches (cultural resource) and incorporate them into activities in science class (material resource).

To overcome symbolic resource constraints, through the PD, Tracy was able to connect her shared identity to teaching goals which extended access to symbolic resources. For example, in the second half of her reflection post above, Tracy expressed an affirming attitude toward incorporating CRT in her science class. Her perceived importance of CRT indicates that her view of science teaching has shifted (symbolic resource) and that she admitted to using her positional identity as a source of strength in pursuing her interest in incorporating CRT in her implementation. In other words, symbolically, her positionality and PD experiences amplified her perceived value of CRT in science, as well as its perceived importance by others at the school.

Activating symbolic resources to make space for racial and cultural connections

During the school-year implementation, activating symbolic resources were salient in Tracy's class implementation and it drove the energies and focus to engage in choosing authentic and real-world examples. In other words, Tracy adapted the curricula acquired from PD in ways that reflected her students' interests and context. Tracy used symbolic resources in several ways to activate cultural and material resources simultaneously.

She actively sought to incorporate personally relevant and real-world examples to students, such as lead levels in children's blood in the city. For example, in the observation note on the lesson introducing data visualization, the researcher detailed that Tracy used a picture of [City] that included information about the incidence of children with high blood lead levels. Then, the class discussed what could be the cause of high lead levels in children's blood and looked at the correlation between environmental variables and health. In her interview, she explained the reason for this adjustment and said, "I felt like that was really good for the kids because they're from [City]. They can see the area that they live in. They can analyze that." Tracy clearly intended to bring CRT for science into the classroom to help students engage with and learn science. In another example, she discussed an oil refinery fire and explosion incident in [City] which happened six months prior to the lesson. As she used this example, many of the students actually remembered the incident and started to talk about it. Tracy extended the conversation by asking, "What do you think that did to the air quality for people who lived in that area? How did that affect them? And what type of people live in that area?" In her interview, she articulated a clear goal for students to be able to personally connect with the community issues and solve them in science as she tried to "bring in that real-world information and trying to take something that doesn't seem realistic and making it realistic because they already know that it happened. Maybe so many kids even actually live near [near the incident].” These examples reveal that Tracy connected science to issues that concerned students’ communities (cultural resource) and used examples that students were familiar with (material resource) as she considered them valuable to science instruction (symbolic resource).

Discussion

This study advances the current literature on STEM implementation by providing empirical evidence of how a teacher activated different types of resources in order to successfully implement new curricula. These findings indicate that the teacher relied on diverse resources in addition to the material resources that she acquired in the PD (Maulucci, 2010). While other studies have shown that CRT is not limited to curricular practices perceived as important for teacher enactment (Barron et al., 2021), this study’s outcome extends this conversation in terms of how symbolic resources are activated by teachers to implement CRT. In this paper, the teacher’s view of social and community issues and the decision chosen to navigate her belief motivated her to identify and activate multiple resources for CRT. Still, a focus on symbolic resources may begin to excavate some of the initial structural barriers that might derail implementation of STEM education. We argue that developing teachers’ resource activation is an important instructional practice for teaching STEM curricula that incorporate CRT. Finally, it is important to note that teacher PD should provide more opportunities for teachers to identify available resources and ways to activate different types of resources in various situations.

Get Loud on TikTok: Climate Action & Critical Data Practices

Ha Nguyen, Prasina Parameswaran
ha.nguyen@usu.edu, prasina.parameswaran@usu.edu
Utah State University

Abstract: Climate education that focuses on scientific facts at a global scale is often distant from youth's everyday experiences. To better frame climate education, in this work, we analyze youth-created, short-form videos on the social media site TikTok to understand how youth experience and discuss climate change and climate action. Data analysis reveals multiple discussion themes, namely advocacy, sustainability practices, knowledge sharing, and reaction. Youth demonstrate a variety of practices with data, including using personal data, combining data sources, situating data in personal and local contexts, and positioning their experiences as valid data points. We discuss implications for framing climate education and data practices to incorporate how youth interact with data in everyday contexts.

Introduction

Climate change-induced impacts threaten the livelihoods of communities around the world. Against this backdrop, learning standards have emphasized the role of education in promoting climate action (NGSS, 2013). Such learning stems from understanding of everyday decision-making and takes place beyond the classrooms. To inform the framing of climate education, researchers have analyzed youth-created written and multimedia artifacts in learning contexts (Littrell et al., 2020; Zummo et al., 2021). Social media presents another source to study how youth learn through creating and interacting with content (Greenhow & Lewin, 2016; Literat & Kligler-Vilenchik, 2019). In this study, we analyze youth-created, short-form videos on the social media site TikTok to examine how youth frame understanding of climate change and climate action. TikTok presents a generative research site, with 2 billion monthly active users globally and a significant number of users aged 13 to 24 years old (Iqbal, 2023).

In developing understanding of climate change, youth navigate multiple data sources, such as news, scientific research, and policy reports; experiences with local climate patterns; and personal sustainability practices. Social media platforms amplify the exposure to these different data streams. As content creators on social media platforms, youth have the opportunity to combine various data sources through multimedia channels such as image, audio, and video footage (Askari et al., 2018). These affordances can invite youth to engage in *critical data practices*—ways in which youth "access, engage with, and are positioned by and position data in relation to their lives and communities" (Calabrese Barton et al., 2021; p. 1). In this work, we explore how social media afford opportunities for youth to discuss content and engage in critical data practices. We ask:

- RQ1: What discussion themes emerge on TikTok in relation to climate change and climate action?
- RQ2: What data practices do youth engage in when discussing these themes?

Social media for self-expression and learning

Social media platforms provide sites for self-expression and learning (Mills et al., 2018). Self-expression invites youth to draw from personal funds of knowledge, defined as practices and experiences with family, community, peer, and popular culture (Moje et al., 2004). Greenhow and Lewin (2016) reported on how young people aged 16 to 25 used Facebook to discuss environmental science issues. They found that youth employed article links, photos, and text to illustrate multiple topics of personal interests. Through the process, youth might learn to draw from everyday lives to articulate scientific understanding (Mills et al., 2018). Beyond sharing knowledge, youth use social media to express emotions (Wielk & Standlee, 2021). In climate education contexts, social media can be key sites to display strong emotions, such as fear, anger, and frustration, to appeal to broad audiences (Wielk & Standlee, 2021). Youth may also emphasize hopefulness to build agency for climate movements (Soler-i-Martí et al., 2022). Emotional expressions can be conducive for learning, particularly within social action contexts (Vea, 2020) such as climate change and climate action discussion.

Data practices

In addition to self-expression, exploring content on social media sites like TikTok allows us to examine the data practices that youth engage in. Education researchers have highlighted the importance of accounting for both "big" data (e.g., large-scale, aggregated statistics from institutional datasets) and "small" data (e.g., personal experiences), as one way of interpreting, critiquing, and participating in data literacy (Calabrese Barton et al., 2021; Irgens et al., 2020; Lee et al., 2022). Such views of data as consisting of both "big" and "small" data are grounded in frameworks of racial data literacy (Philip et al., 2016) and data feminism (D'Ignazio & Klein, 2020). Both frameworks highlight the importance of personal experiences within social, political, and historical contexts, as one way to examine and redefine power behind data sampling, analysis, and communication.

Scholars have proposed ways to combine "big" and "small" data in youth's lived experiences (Irgens et al., 2020). For example, Calabrese Barton et al. (2021) examined the critical data practices in which youth remixed, repositioned, and recontextualized data to make sense of the COVID-19 pandemic. Remixing entails combining data sources to present a more rounded view of one's experiences. Recontextualizing refers to critiquing data within personal and community practices. Finally, repositioning occurs when youth view themselves as agents and not just parts of the aggregate statistics. Youth use small, personal narratives to counter the perspectives from large-scale data as part of youth activism. These practices are meaningful in climate education. First, they help to situate data in grounded contexts and allow youth to critique broader socioecological impacts of human actions (Littrell et al., 2020; McGowan & Bell, 2022). Second, they position youth to notice who is missing in data patterns. Such critiques build towards reimagining data work (D'Ignazio & Klein, 2020).

Methodology

Data sources

The data sample consisted of 410 videos in English from TikTok, a social media site for creating and sharing short-form videos. To sample videos related to climate change and climate action, we first searched for videos tagged with "#climateaction" on the site and identified additional, thematically related tags that frequently appeared with this tag, including #climatechange, #sustainability, #ecotok, and #environmentalactivism. We added the first 100 results under each of those hashtags to our data sample (i.e., top 100 videos when searching for "#sustainability"). The results were curated by TikTok to show videos that used the hashtags and had large counts of views, shares, and comments. After removing duplicates (11 videos) and videos unrelated to climate change or climate action (79 videos), the final sample consisted of 410 videos from 248 creators. The videos were published between June 2020 and August 2022. On average, the videos were 35.8 seconds in length ($SD = 31.3$ seconds). Before data collection, we obtained confirmation from the university's Institutional Review Board that the research did not involve human subjects because the videos were public. We did not store locally any personally identifiable data such as profile pictures, video, and audio.

Analytical approaches

The coding scheme consisted of two dimensions: (1) discussion themes, and (2) data practices. We developed the discussion themes codes inductively by watching a sample of 20% of the videos and noting the key topics. Advocacy-themed videos invited others to take action or acknowledged the work of climate activists, many of whom are from BIPOC (Black, Indigenous, and People of Colors) communities. Sustainability videos demonstrated eco-friendly and sustainability practices. Knowledge sharing videos disseminated news and institutional reports. Finally, Reaction videos expressed emotions in response to climate policies and practices.

For data practices, we turned to critical data practices for remixing, recontextualizing, and repositioning (Calabrese Barton et al., 2021). Remixing combined data sources and data types. Meanwhile, recontextualizing situated data within personal and local contexts (e.g., city, state, country), and repositioning used personal and community perspectives to critique and counter other data sources and data narratives. Additionally, to understand whether youth drew from personal experiences in their videos, we added a code for "personal data".

We analyzed the videos for presence (coded as 1) or non-presence (0) of codes. The authors first coded 20% of the data separately, discussed coding discrepancies, and coded another 20% of the corpus separately to reach substantial inter-rater agreement (Cohen's κ values: .93, .97, .92, .91 for the discussion themes, and .73 for remixing, .71 for recontextualizing, .61 for repositioning). We resolved disagreements through three rounds of discussions. The first author coded the remaining data. We explored the discussion themes, and ran Chi-squared tests to examine how young people leveraged different data practices to discuss different themes.

Figure 1

Screenshots Showing Advocacy (panel A), Sustainability (B), News (C), and Reaction (D)

A. Advocacy

B. Sustainability

C. News/ Knowledge

D. Reaction

Findings

Youth discussed a variety of themes in their videos, including advocacy (31%), eco-friendly and sustainability practices (31%), sharing knowledge (21%), and reaction (17%). Panel A (Figure 1) shows a screenshot from an advocacy-themed video that acknowledges environmental activists from Latin America. As an example of sustainability practices, Panel B (Figure 1) shows footage of a newly planted garden of native milkweeds. For knowledge sharing, youth employed multiple approaches, such as dancing or lip-synching while displaying climate-related information on screen (panel C). Finally, reaction videos displayed a range of emotions—worries at the lack of action (panel D), hope, determination to act, and reminder for self-care to combat climate anxiety.

Data practices

The videos also showcased data practices—drawing from personal experiences (34% of videos), remixing data from various sources (29%), recontextualizing in personal and local contexts (44%), and repositioning "small", personal narratives as data points to supplement or counter institutional data (5%). Personal data came from experiences with climate-induced hazards at local levels and first-hand accounts of how such hazards disproportionately affected different groups (e.g., people with disability, lower income groups, island nations). In painting a comprehensive picture for their audiences, youth remixed data sources, such as news, scientific reports, and sustainability practices. For example, in discussing the latest climate report that predicts an increase in the average global temperature by more than 1.5 degrees in the next five years, a creator combined screenshots of the report with popular culture (a screen from the cartoon The Simpsons) and sustainability practices (e.g., renewable energy, efficiency standards). In these cases, youth demonstrate critical data practices. They determine which information might be more relevant to their audience and visualize different data types in relatable lights.

In curating from diverse data sources, youth recontextualized data and climate science discourse in their lives and communities. For example, in supporting divestment from fossil fuels, a video creator discussed ways for her viewers to examine their universities' investments. The creator pointed out that "At first glance, you might not see any fossil fuel investments explicitly" because investments could be bundled in mutual funds. She then provided a data tool she used (Fossil Free Funds) to look up the portfolio of different funds. Here, the creator critiqued the completeness of a data source and illustrated a data tool within a personally relevant context.

Furthermore, youth demonstrated instances of repositioning data—using the experiences of themselves and their communities as counter data points and not just parts of large-scale, anonymized statistics. In one video, a creator sat in front of the camera and used his experience to challenge the accessibility of outdoors recreations to different communities: "Saying just "get out into nature" can be very disconnected […] Nature's been commodified and something that is rarer and rarer and people only with wealth and whiteness can access." This example illustrates a case of positioning one's experiences in community to counter a dominant narrative.

Youth used data practices to support different discussion themes. Chi-squared tests suggested significant relation between themes and remixing, $\chi^2(3, N = 410) = 12.63$, $p = .01$, recontextualizing, $\chi^2(3, N = 410) = 33.55$, $p < .001$, and utilizing personal data, $\chi^2(3, N = 410) = 99.26$, $p < .001$. There was no significant association between themes and repositioning, $\chi^2(3, N = 410) = 4.03$, $p = .26$. Post hoc analyses with Bonferroni corrections suggested pairwise differences between themes, meaning that videos of different themes employed data practices differently. For example, videos that featured sustainable practices relied more on personal data and recontextualizing than other themes (personal data: 68%, other themes: 12%-16%; pairwise p range <.001 - .02; recontextualizing: 64%, compared to 25%-41% in others; pairwise p range <.001 - .03). An explanation of this finding is that youth demonstrated sustainable practices in familiar contexts (e.g., home, garden, transportation), transforming the abstract idea of individual responsibility into concrete experiences.

Discussion & conclusion

Our work explores how youth participate in discussion surrounding climate change on social media. A limitation is that the analysis was conducted with videos in English, and we invite future work to consider videos in other languages to examine the broader, global discourse. While we did not find cases of misinformation in our data corpus, extending the analyses to capture such instances in the comments on the videos can be a future direction.

Our work adds to understanding of how social media can reveal insights into youth's self-expression of important civic topics, specifically the multiple data practices that youth engage in. In curating data for an audience on the platform, youth situate data in relatable contexts, remix various data types, and position their experiences as valid data points. These practices may present opportunities to interweave data sources and validate perspectives from small data. Researchers have argued that small data provide the contextual grounding for understanding large-scale data patterns (Calabrese Barton et al., 2021). Attending to youth's social media practices offers a way to better understand such data practices. Importantly, the current research has implications for the design of learning environments to make climate education relatable to youth. We do not argue that all educators should adopt TikTok in instruction, as there are real concerns of jeopardizing students' privacy. Rather, findings illustrate how we may reenact the platform's affordances in learning design, for example, to encourage youth to create data narratives and articulate the links between climate action and personal contexts. Educators can also draw from the discussion themes and various data practices, to scaffold climate education conversations.

Designing Bugs or Doing Another Project: Effects on Secondary Students' Self-Beliefs in Computer Science

Luis Morales-Navarro, University of Pennsylvania, luismn@upenn.edu

Abstract: Debugging—finding and fixing bugs in code—is a heterogeneous process that shapes novice learners' self-beliefs and motivation in computing. Our Debugging by Design intervention (DbD) provocatively puts students in control over bugs by having them collaborate on designing creative buggy projects during an electronic textiles unit in an introductory computing course. We implemented DbD virtually in eight classrooms with two teachers in public schools with historically marginalized populations, using a quasi-experimental design. Data from this study included post-activity results from a validated survey instrument (N=144). For all students, project completion correlated with increased computer science creative expression and e-textiles coding self-efficacy. In the comparison classes, project completion correlated with reduced programming anxiety, problem-solving competency beliefs, and programming self-concept. In DbD classes, project completion is uniquely correlated with increased fascination with design and programming growth mindset. In the discussion, we consider the relative benefits of DbD versus other open-ended projects.

Introduction and background

Debugging—finding and fixing bugs in code—is an essential computational practice, a heterogeneous and open-ended process that shapes how novice learners perceive themselves in relation to computing which impacts their motivation to persist (DeLiema et al., 2022). While debugging is often difficult to learn and to teach (McCauley et al., 2008), encountering bugs can generate fear and anxiety, leading to disengagement and the avoidance of computer science (CS) (Kinnunen & Simon, 2010). Typical debugging teaching practices and curricula emphasize top-down instructionist designs that focus on small, isolated problems and linear strategies for finding well-defined bugs (see McCauley et al., 2008). Contrastingly, in our approach of Debugging by Design (DbD) students create, exchange, and solve buggy open-ended, personally relevant projects. We build on a longstanding tradition of constructionism, emphasizing learner agency by designing applications for others (Harel & Papert, 1990). DbD aims to put students in control over bugs, framing failure as a productive, social experience rather than a negative, discouraging one. Exploratory work on DbD found that students engaged in practices that characterize growth mindsets such as choosing challenges that led to more learning, praising effort, approaching learning as constant improvement, and developing comfort with failure (Morales-Navarro et al., 2021). Weeks after completing DbD, students expressed greater comfort and improved skills in debugging (Fields et al., 2021).

When encountering bugs in computing, students engage with a wide set of values and processes, including self-beliefs that are shaped by experiencing failure and that impact how they react to future failures. Self-beliefs are an array of different self-terms—for instance, self-concept and self-efficacy—that share an emphasis on the beliefs individuals hold about their own abilities and attributes (Valentine et al., 2004), in this case about computing. Measuring student beliefs is important because pernicious belief systems, together with structural inequities, play a role in limiting the participation of historically marginalized groups in computing (Margolis et al., 2017). At the same time, addressing students' beliefs about their own abilities in computing can have an impact in their participation and help shift in their views of CS ability from something that is innate to something that is developed with experience and practice. Since DbD aims to empower students in debugging—by designing creative, multimodal buggy projects for others to solve—we measured student self-beliefs about computing in a quasi-experimental design study within a broader e-textiles unit, asking: Did participation in the DbD/comparison (Music) activity impact students' project completion? Did completing either class project relate to students' CS self-beliefs and was this influenced by whether students were in the DbD or the comparison (Music) activities?

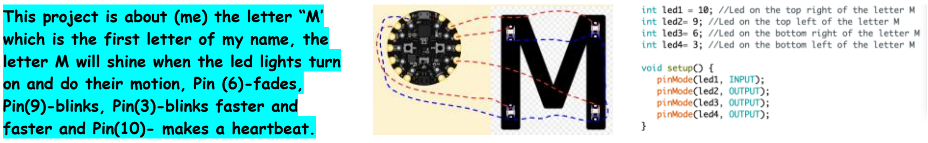
Debugging by Design

DbD took place within the e-textiles unit of *Exploring Computer Science* (ECS), an inquiry-based CS curriculum committed to broadening participation in computing by addressing the structural inequities and beliefs systems that limit participation from historically marginalized groups (Margolis et al., 2017). During the 10-12 weeks e-textiles unit students create four projects. In these open-ended physical computing activities that integrate coding, circuitry, and crafting, facing failure and unanticipated challenges are expected and inherent in the learning process with problems distributed across modalities (Kafai et al., 2019).

In designing DbD, we extended constructionist approaches by shifting the focus from designing functional artifacts (Harel & Papert, 1990) to designing non-functional, or buggy, projects for others (see Fields et al., 2021). The DbD activity was designed to take place during eight 50-minute-long lessons. Due to the Covid-19 pandemic, together with one experienced e-textiles teacher (not in this study), we created a version of the curriculum that could be taught online with students at home. At the beginning of the activity, students discussed with each other different errors and problems they had encountered when creating e-textile projects. Then student groups decided on the bugs they wanted to include in their designs. They were required to have at least 5 bugs in their code but limited to 1 bug in their circuit diagram. After receiving teacher approval on designs, they wrote a project statement, made a circuit and aesthetic diagram of a buggy project and prepared buggy code for the project (see Figure 1). Teachers then helped students exchange project plans with each other; students built and solved each other's buggy designs. In this study we also designed a *comparison activity* where in place of DbD, students created a new project with programmed music. This provided opportunities to go deeper into programming (by coding tones and rhythms, using arrays, for loops, and conditionals) and the inevitable debugging that happens in creating e-textiles projects without the explicit focus on designing bugs for others, unique to DbD. In this study we were curious to find out the potential benefits of the different activities.

Figure 1

A student DbD design: project description, circuitry and aesthetic design, and buggy code excerpt.



This project is about (me) the letter "M' which is the first letter of my name, the letter M will shine when the led lights turn on and do their motion, Pin (6)-fades, Pin(9)-blinks, Pin(3)-blinks faster and faster and Pin(10)- makes a heartbeat.

```
int led1 = 10; //Led on the top right of the letter M
int led2= 9; //Led on the top left of the letter M
int led3= 6; //Led on the bottom right of the letter M
int led4= 3; //Led on the bottom left of the letter M

void setup() {
   pinMode(led1, INPUT);
   pinMode(led2, OUTPUT);
   pinMode(led3, OUTPUT);
   pinMode(led4, OUTPUT);
}
```

Methods

Context and participants

Two experienced teachers at different schools, with high percentages of historically marginalized secondary student populations (58-95% free and reduced lunch; 85-99% non-white), taught eight ECS classes with e-textiles. In Spring 2021 these two schools, in two large West Coast districts, offered online instruction due to the COVID-19 pandemic. Using a quasi-experimental design, five classes participated in the DbD activity (158 students; 90 took the post-survey with 37% identifying as female, 91% speaking a language other than English at home, 58% with no prior CS experience) while three classes (93 students; 54 took the post-survey with 22% identifying as female, 83% speaking a language other than English at home, 46% with no prior CS experience) focused on the comparison (Music) activity. Teachers randomly and pragmatically (e.g., fitting their block schedule) chose classes to implement the activities. Because of the timing of the study at the end of the virtual school year in the second year of the pandemic, there was a high degree of attrition in student participation in the schools. Our IRB allowed for collecting anonymous surveys while identifying the teacher and class period. We did not request information on ethnicity because we believed (and the IRB board agreed) that collecting ethnicity alongside gender by classroom would inevitably make students identifiable. Due to the nature of the implementation of the study, i.e., during a pandemic with virtual schooling, simply comparing DbD against the comparison activity was insufficient as some students started the projects but did not finish them. As such, to investigate the relationship between project completion in both DbD and comparison activities and student CS self-beliefs, we included a survey question about project completion—how far they got in the DbD or music projects— designed to allow us to compare survey responses and how much students participated in the DbD or comparison (Music) activities.

Data collection and analysis

To assess the impact of DbD and comparison activities, 144 students completed a survey at the end of their respective activities. The survey contained a previously validated instrument for nine CS self-beliefs constructs (see Table 1; for details about the instrument see Morales-Navarro, in press) using confirmatory factor analysis (with factor loadings average of .742 and range between .491 to .875; reliabilities between .713 and .889). For the present study, each construct also demonstrated good reliability (all Cronbach's alphas ranged between .729 and .918). For each construct, responses were recorded using a four-point Likert scale to encourage greater reflection and avoid neutral or indifferent responses (1=strongly disagree; 4=strongly agree). To determine project completion in both activities, the survey asked, “Please select the option that best describes how far you got in completing the following project”; responses ranged from “Didn’t do it” (1) to “Finished” (5). Teachers created assignments that required students to complete our online survey in their school’s learning management systems with time to complete the survey during class and as homework within a certain time. To assess the impact of DbD, two sets of analyses were conducted. First, an analysis of variance (ANOVA) was conducted to examine differences between DbD and comparison activities on project completion. Second, within DbD and comparison activities, correlation analysis examined the potential bidirectional relationship project completion had with the nine CS Beliefs (see Table 1).

Findings

Notably, ANOVA results found no significant difference between DbD (M = 1.537, SD 2.56) and comparison (M = 2.56, SD = 1.550) activities in terms of project completion, F (1, 142) = 0.000, p = 1, partial η2 = 0.

For students doing either DbD or comparison activities, correlation results show that the extent to which they completed the project was related to significant increases in CS creative expression and e-textiles coding self-efficacy (see Table 1**)**. This reinforces findings from previous studies (Kafai et al., 2019) that showed gains in creativity and e-textiles coding self-efficacy during the e-textiles unit without DbD or the extra music project activities. That said, it is worth noting that highly engaged students or those with previous CS backgrounds may have been more likely to complete the projects in both activities. Similarly, access to Wi-Fi and other learning resources during virtual pandemic school very likely influenced project completion.

Table 1

Correlation between project completion and constructs across DbD (N = 90) and comparison (N = 54).

Construct	DbD	Comparison	Construct	DbD	Comparison
CS Beliefs			CS Mindset		
Problem solving competency beliefs	.191	.364**	Programming fixed mindset	-.032	-.178
Fascination in design	.257*	.229	Programming growth mindset	.313**	.230+
Value of CS	.201	.266	CS Outcomes		
CS creative expression	.284**	.363**	Programming anxiety	.042	-.330*
E-Textiles coding self-efficacy	.321**	.335*	Programming self-concept	.190	.297*

+p < .10, *p < .05, **p < .01, ***p<.001

Among those doing the DbD activity, the extent to which they completed their projects (designing intentionally buggy artifacts and solving their peers’ buggy projects) correlated with significant increases in fascination in design and programming growth mindsets. This highlights how designing and solving bugs may influence students’ beliefs about design and the potential of creating personally meaningful failure or buggy artifacts in empowering learners to design bugs and engage with their designs in novel ways (Fields et al., 2021). The correlation of project completion with programming growth mindset in the DbD condition supports earlier findings that suggest that agency-driven debugging approaches may be particularly well suited to promote growth mindset (Morales-Navarro et al., 2021). It is also worth considering that while the survey was conducted right after students completed the activity, earlier work found a marked difference in students' perception of DbD immediately after completing it and several weeks after, with most students expressing distress and frustration about bugs right after the activity but comfort and competence with bugs weeks after the activity (Fields et al., 2021). For the comparison activity students, project completion correlated with lower programming anxiety, higher problem-solving competency beliefs, and programming self-concept. This is not surprising as the project pushed students into new programming domains (i.e., music, arrays, etc.), suggesting that this helped students gain confidence in their coding abilities.

Discussion

Our study takes a holistic approach to studying constructionist, CS education interventions by looking at the relationship between secondary students’ computing self-beliefs and completing one of two creative physical computing projects in a quasi-experimental design. One highlight from our results is that students’ perspectives on themselves with computing relate to how far they got in making the projects. This finding, across both DbD and comparison groups, foregrounds that making personally relevant e-textiles projects, whether a normal open-ended project or a specifically buggy project, may be beneficial for students' development of self-beliefs in CS. This suggests that progressing toward completion in projects is important for students to fully benefit from constructionist learning activities. As Harel and Papert (1990) argue, creating projects contributes to the affective side of cognition as learners shape their relationships with the concepts they encounter through personal appropriation of knowledge. Even amid a global pandemic at the end of a year of virtual classes, in public schools with high percentages of marginalized students (by class and ethnicity), significant results demonstrate the potential gains from engaging students in making these creative, challenging projects. With Debugging by Design (DbD), project completion was uniquely correlated with programming growth mindset, demonstrating a potentially distinct benefit of DbD that complements open-ended, constructionist-driven projects more generally. These findings are important because programming growth mindset is particularly important for retention, perseverance, and endurance amongst marginalized populations in CS (Kinnunen & Simon, 2010; Margolis et al., 2017). Therefore, educators and researchers should further consider the role that integrating DbD projects may have in supporting students when making projects.

Our research provides many potential directions for future study. Research should explore the specific roles of different aspects of DbD—both designing bugs for peers and solving bugs by peers—in fostering growth mindsets. Our earlier case study research in one classroom documented that students exhibited growth mindset practices largely while designing bugs (Morales-Navarro et al., 2021), yet this current study demonstrates the importance of doing the entire scope of the DbD project, from designing to solving peers' buggy projects. At the same time, replicating this study in in-person classroom settings and conducting case studies of students' design processes could be beneficial to better understand the differences between DbD and comparison activities in relation to self-beliefs without so many other factors in play (e.g., a pandemic, virtual education). Further, while we attend to self-beliefs in this study, future research should also investigate what contributions DbD or comparison activities make to learners' conceptual understanding, for instance developing breadth of knowledge about types of bugs or strategies for identifying and solving bugs. Finally, we have explored DbD in one specific context—designing e-textiles in an introductory computing course; many other applications are possible.

Building Belonging for Multiply Marginalized Neurodivergent Students in STEM Higher Education

Rachel Bonnette, University at Buffalo, rnbonnet@buffalo.edu

Abstract: Neurodivergent students often struggle with a sense of belonging, given barriers to self-advocacy, mental health, and social skills. This is even more challenging for multiply marginalized students, such women and people of color who are underrepresented in STEM programs. Exacerbating these problems is the dearth of effective professional development for helping STEM instructors better teach neurodivergent students. To prototype inclusive, effective training, we collected survey data from undergraduate STEM students about their experiences as neurodivergent students and what needs and recommendations they had for instructor practice. This short paper presents preliminary survey results and a theoretical curriculum approach for instructor professional development for neurodiversity in STEM.

Introduction

Any class, at any grade level, may include students with typical neurodevelopment (neurotypical), as well as students with attention deficit/hyperactivity disorder, autistic students, and many others whose ways of thinking and processing differ from the expected norm (Neurodivergent) (Kapp, 2020). Many neurodivergent students have abilities and traits that are highly valued in college, including strong interest in subjects like Computer Science or Engineering (Wei et al., 2013), creativity, or systematic thinking (Baron-Cohen et al., 2009). Unfortunately, approximately 30% of neurodivergent students who enter STEM programs drop or transfer out before graduation (Wei et al., 2014). Neurodivergent students can struggle in learning environments designed for their neurotypical peers (Fabiano et al., 2018), and often face mental health and relationship challenges that impact their sense of belonging (White et al., 2011). From a social model of disability, disability is a product of environmental barriers and practices that could—and should—change to better all, like the inclusion of ramps for those with mobility differences (Shakespear, 2006). Teaching practices and learning environments can change to make learning easier for all students, but especially those with neurodivergent traits. Creating ecosystems of belonging calls for preparing instructors to make inclusive classrooms (O'Keefe, 2013; Thurston et al., 2017); thus, the need for neurodiversity professional development.

Professional development for inclusive classrooms

College instructors are not typically trained on neurodivergent needs, but studies show that professional development can be an effective approach to improving instructor interactions with neurodivergent students (Thurston et al., 2017). Likewise, good relationships between instructors and students can make a difference for students' sense of belonging, an important part of long-term motivation to remain in college (Morrow & Ackerman, 2012; Vaccaro et al., 2015). For neurodivergent students, their instructors' behavior and practices have two significant impacts. First, instructors play an important role in students' self-advocacy. Prior experiences with instructors who reject accommodations because they believe them to be unfair or unreasonable can teach students not to trust their instructors with accommodations (Sarrett, 2018). This is a long-term problem, since most instructors require that students disclose their accommodations early in the semester or not at all. Trained instructors, meanwhile, are less likely to discourage students from using their accommodations (Wynants & Dennis, 2017). Second, despite an instructor's best intentions, their teaching practices can be more inclusive only if they are knowledgeable of neurodivergent needs. Instructors without neurodiversity training may believe, for example, that they are helping neurodivergent students by providing a few long-term, extremely flexible deadlines, when this can make anxiety and time management more difficult for students with memory issues (Ericson, 2017). With a critical level of knowledge, however, instructors who are aware of reading anxiety among students with dyslexia or ADHD may use more frequent, smaller deadlines to help students stay on track and lower anxiety. Likewise, instructors may avoid giving students notes or presentations from classes to preserve accountability and make sure students are paying attention during class. But for neurodivergent students (i.e., students with auditory processing differences, distraction from sensory difficulties like flickering lights, or attention disorders) the task of trying to take notes may instead impede learning (Maydosz & Raver, 2010). Providing notes or a simple outline to all students could improve learning for all and prevent students from failing.

Intersectionality in STEM

The intersection between neurodiversity and other types of diversity compounds these challenges for neurodivergent students and their instructors. *Intersectionality* is a theoretical lens for understanding how things like race, gender, disability, and power within a social structure collectively impact individual students (Collins & Bilge, 2020). The experiences of neurodivergent students who are diverse in other ways (i.e., multiply marginalized) are inherently different from those who represent the majority group in their program (Mallipeddi & VanDaalen, 2021). Thus, context is relevant to the effectiveness of training. In this case, we are interested in science, technology, engineering, and mathematics programs (STEM) in the United States, where women, queer, and Black, Latinx, and indigenous students face high rates of discrimination and a low sense of belonging as underrepresented members of their field (Mooney & Becker, 2020). There is a lack of empirical research exploring the ways in which fear of discrimination or other intersectional factors will impact neurodivergent students. Historically, interventions and research conducted without the input of those with disabilities tend to be ineffective and even harmful (Kapp, 2020). To prevent this, professional development design must begin with inclusive research design. In this case, that means including the historically underrepresented knowledge and expertise of multiply marginalized neurodivergent students from STEM programs.

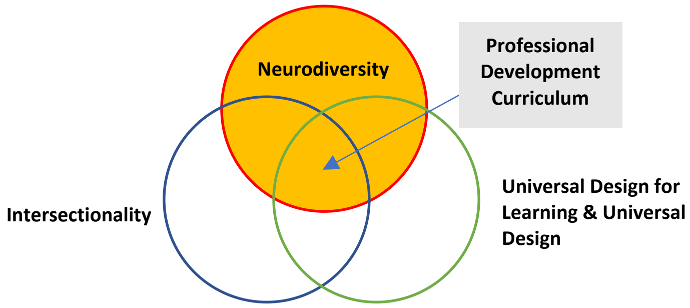
Surveying neurodivergent students

Our process of designing neurodiversity professional development began with an examination of the literature. However, it was not clear from published research findings what needs neurodivergent students of all genders or races require instructors to know about or know how to address. Consequently, in the spring of 2022, we created and distributed a survey among undergraduate and graduate STEM students in an international university in the northeastern United States. Survey prompts asked whether students identified as neurodivergent, regardless of a medical diagnosis, as a lack of diagnosis was likely to bias the sample towards white males (Begeer et al., 2009; Zuckerman et al., 2021). Students were also asked for demographic data, whether they had experienced common neurodivergent challenges, and asked to provide information about how instructors could improve. Students (n=54) were grouped based on whether they had identified as belonging to groups that would be multiply marginalized in STEM (e.g., white, female, and neurodivergent, rather than white, male, and neurodivergent). Preliminary mixed-methods analyses (e.g., chi-squared tests of independence and open coding procedures on qualitative responses) suggest significant differences in responses between multiply or singly marginalized students. In particular, a substantial proportion of multiply marginalized neurodivergent students reported that *peer and instructor lack of awareness about neurodiversity* was a significant problem as compared to their singly marginalized peers. Qualitative responses echoed the problem, for example, “I feel guilt whenever I’ve tried to explain myself to my instructors. I’m always behind deadline and missing assignments.” Comparatively, few singly marginalized students reported this problem (neurodivergent and white or Asian male with no additional disabilities). Qualitative responses further indicated that multiply marginalized students’ perception of instructor awareness impacted other factors, such as *time management* and *class format challenges*. They attributed this to perceptions of instructors’ willingness to provide requested support, such as notes or recordings, extra time to complete assignments, or honoring accommodations. Most of the multiply marginalized students requested that instructors better understand their accommodations requests and have a better general understanding of how their conditions impacted their daily lives. Although students were not explicitly asked about discrimination on a basis of race or gender, multiply marginalized students more frequently indicated that a fear of discrimination limited their willingness to self-advocate, while some majority/singly marginalized students expressed that they had openly discussed their neurodiversity with instructors or found their own solutions to problems. Both groups had suggestions that could be relatively simple to implement, such as structured breaks, more clarity in online lesson formats or assignment guidelines, and the provision of notes or slides to review confusing lessons.

Prototyping professional development for STEM instructors

Based on the nature of the problem, literature related to the stated issues, and preliminary findings, we have determined a need for professional development rooted in neurodiversity literature, Intersectionality, and effective pedagogical approaches to respond to student needs. Each of these topics is significantly larger than what is strictly necessary or practical to incorporate into a professional development course. Instead, prior literature and student responses suggest the potential for focusing on several discrete areas within each, drilling down from knowledge to solutions. First, this approach begins with generally applicable neurodiversity awareness (e.g., how to define it, how different models of disability help us to understand how it impacts students and the barriers they encounter, and common neurodivergent struggles in classrooms), a critical foundation that multiply marginalized students identified as central to their sense of belonging in their program. Not all instructors are aware neurodiversity even exists, let alone the impact it has on seemingly able-bodied students. Second, we can build on this foundation to teach instructors to anticipate overlap with issues of race, gender, discrimination, and other contextual factors that impact multiply marginalized students. This is essential, despite the variety of universities that now offer diversity training of some kind, because other training does not typically address the impacts on self-advocacy of students' perceptions, fears, and experiences with racial or gender discrimination. Third and finally, this foundational knowledge forms the basis for applying pedagogical approaches like Universal Design, Universal Design for Learning, and Universal Design for Instruction. Each of these approaches provide frameworks for examining and transforming learning environments, teaching practices, and instructional tools to make them more inclusive for neurodiverse classrooms. We chose these frameworks because of the demonstrated success in both making classrooms and instructional practices more neurodiversity-inclusive and because they have been used effectively in STEM fields (e.g., Thurston et al., 2017). Additionally, at their core is the goal of improving instruction for all students. This is essential for neurodiversity inclusivity, since all students are different, even if they share some needs. Small changes can make a big difference to students' ability to engage meaningfully with class, like how reducing noise in a classroom and providing better lighting improves all student learning, but can make the difference between frustration and flourishing for neurodivergent students (Kinnealey et al., 2012). Many of the students' recommendations or requests were possible to fulfil with the application of a Universal Design-related framework. As one student explained, "Recorded lectures and/or video lectures help me cope with my zone out periods because they allow me to rewind to a spot where I was still focused and watch again," an option that could be utilized by instructors without official accommodations requests to support students with auditory processing, attention, and mental health problems. Through this three-part approach, all overlapping with a foundation of neurodiversity knowledge and awareness, we can build a curriculum for inclusivity in STEM (see Figure 1).

Figure 1
Key areas of focus for curriculum in neurodiversity professional development



Conclusion

These preliminary findings indicate that instructors must learn more about neurodiversity to positively impact students, but that neurodiversity must be viewed from an Intersectional lens. Additionally, instructors must be armed with effective pedagogical approaches to improve students' learning in neurodiverse classes. We recommend that curriculum for professional development for neurodiversity be founded the overlap between these three factors, building on existing literature as well as diverse student opinions. Once instructors understand these concepts and how they overlap, they can be equipped with effective frameworks and practices for transforming classroom practice to improve learning environments and student-teacher relationships, such as Universal Design for Learning. We recognize that additional topics, or alternative pedagogical approaches, could improve learning for neurodivergent students; this is but one solution. Likewise, we acknowledge that students will, at times, request changes that are not to their benefit (e.g., the complete removal of deadlines). But, we advocate the use of collaborative approaches that can temper student expertise of their experiences with the expertise of existing research on neurodivergent learning and student behavior. What is important is that student voices be included in the first place, to ensure that the foundation of instructor practice rests in genuine understanding of diverse and intersectional student experiences above all else.

The Influence of Open-Ended Exploration in STEM-Focused Minecraft Environments on Post-Intervention Knowledge Assessments

Matthew Gadbury, Kayla Zimmer, H Chad Lane
gadbury2@illinois.edu, kaylamz2@illinois.edu, hclane@illinois.edu
University of Illinois Urbana-Champaign

Abstract: Video games continue to be heavily researched mediums for knowledge acquisition and transfer. However, there is not a lot of research looking at how adolescent learners actively explore open-ended game environments and comprehend the conceptual STEM knowledge embedded in-game. Additionally, using a popular game, Minecraft, has potential to attract the attention and interest of young learners through a means that poses low barriers for engaging STEM content. Existing familiarity with game mechanics in Minecraft allows learners to focus on content without having to learn new controls. This research looks at how interest in STEM and Minecraft is related to the amount learners explore their environment, as well as their performance on knowledge questions posed at the end of a one-week summer camp experience. Findings suggest that existing interest has little effect on exploration habits, but exploration habits do influence the amount of conceptual knowledge learners recall in interviews.

Introduction & background

Novelty of information or situations is considered a key ingredient for inducing information-seeking behavior in learners (Baram-Tsabari, 2015), where the learner feels rewarded by exploring and closing an information gap (Hidi, 2016). Closure of information gaps result in positive affect and can lead to a self-boosting effect where more knowledge gaps are identified, explored, and closed (Murayama, 2022). The relevance of the material to the person also makes a difference, where learners who can relate content to the self are more likely to continue engagement and deepen understanding (Renninger & Hidi, 2021). Research on valuing of content by learners has shown marked increases in interest when utility-value interventions are used in classrooms, such as prompting learners to connect information to their personal experience (Harackiewicz, Smith & Priniski, 2016). Both personal relevance and novelty have been identified as interest triggers, or aspects of the environment that might motivate a learner to actively explore content for meaning (Renninger, Bachrach, Hidi, 2019). Flum and Kaplan (2006), raise the importance of exploration and information-seeking as an educational goal and argue intentional exploration induces information-seeking, leads to reflection, and forces reorganization of one's self-concept, leading to the development of self-sustaining, enduring interest. Open-ended video games, such as Minecraft, possess adaptable features that can be used to extricate how open exploration of an environment contributes to interest development and concept learning.

Minecraft is a popular open-ended sandbox game that provides players a great deal of autonomy to explore, build, and create (Baek et al., 2020). Minecraft has been used to some success in educational settings to improve creativity (Checa-Romero, 2018), increase interest in math (Bos et al., 2014), and understand how pre-existing interest in STEM might influence engagement with scientific measurement tools (Lane et al., 2022). Given the possibilities to utilize Minecraft for education and research, we examine how exploration of rich, customized worlds in Minecraft is influenced by interest in STEM and contributes to conceptual understanding of Earth Science and Astronomy content.

Participants

Participants in the study ($n = 12$) were middle school students participating in a one-week summer camp program organized in partnership with a university in the western United States. Of the participants, 12% were female, 4 identified as White/Caucasian, 2 identified as Hispanic, and 6 preferred not to answer. Participants attended the summer camp for 4 hours each day, for a consecutive 5 days (20 contact hours total).

Materials & procedure

Most of each day was spent playing on our Minecraft server, which hosts 15 customized maps of hypothetical version of Earth (i.e. What if Earth orbited a colder sun) and known exoplanets (i.e. Kepler 182-f). Maps were designed in consultation with an astrophysicist who approved of all astronomy and earth science content built into each map. Each map features non-playable characters (NPCs) the player can interact with and learn more about the environment. There are also quests the players are prompted to undertake that might include taking measurements of radiation, finding a specific item, or uncovering the reason behind a phenomenon occurring. Every participant was provided a laptop, mouse, and access to Minecraft: Java Edition (see Figure 1).

Figure 1
Setup for 1-week camp using Minecraft to introduce hypothetical Astronomy scenarios

Participants completed a STEM & Minecraft interest survey, validated by our lab, before the start of the program. The survey consisted of 25 Likert-type items related to STEM interest, 20 Likert-type items related to STEM-related Minecraft interest and 5 menu-based or open-ended demographic questions. Likert-type items were worded “On a scale from 1 (not at all interested) to 5 (extremely interested), how interested are you in the following activities:”. An example of a STEM interest question is “Learning about how different plastics, resins, and powders change during 3D printing”, and an example of a STEM-related Minecraft question is, “Creating systems to transport resources”. Participants were introduced to our server through exploration of rocket launch facility and lunar base. These worlds prompted players to take science measurements, type in-game observations, and explore the environment. Subsequent worlds were briefly introduced before players were given the freedom to explore and complete quests. Exploration of each world was followed by discussions unpacking the features of the world and causation of visible phenomena. Other activities, such as drawing and demonstrations with inflatables, augmented Minecraft play. On the final day of camp, each participant was interviewed one-on-one by a member of the research team. Interview questions focused on participant interest in STEM (i.e. “Do you ever search the internet for information about outer space or watch YouTube videos about space?”) and included a series of knowledge questions referencing course material. An example of a knowledge question is, “What can you tell me about the moon and how it affects us here on Earth?”, and transfer questions immediately follow, such as “What do you think would happen on Earth if the moon doubled in size?”.

Analysis

Aggregate scores for STEM interest and Minecraft interest were calculated from the pre-survey. If participants completed the survey in less than 4 minutes their survey data was discarded. An exploration metric was calculated for each participant based on how many squares of a 10x10 grid overlaid on each map they visited. Location data was collected every 3 seconds for each participant, and a numeric output representing their exploration was generated. For example, if a participant’s exploration crossed into a total of 25 grid spaces they would have an exploration metric of 25 for that particular world. Average exploration for each participant was calculated for all maps they were present for and explored. In total, 11 maps were included in the average, and the average constitutes a participant’s overall exploration metric.

Interviews were analyzed using a coding scheme based on the work of Renninger, Bachrach, & Hidi (2019) that details possible interest triggers in informal environments. The triggers were adapted to capture participant behaviors related to interest development, such as their tendency to seek out additional information (Renninger & Hidi, 2021), expressions of positive affect regarding STEM learning in Minecraft (Hidi & Renninger, 2006), as well as intent to reengage with content. The adapted scheme was developed from previous data and reliability was assessed (Yi, Gadbury, & Lane, 2021). The coding scheme consists of 7 possible codes (i.e. MCL = interest in learning STEM in Minecraft, IS = information-seeking behavior, AFF = liking or excitement). Two researchers on the project segmented interviews into “interest episodes” and then applied the codes. An interest episode is a response that reflects the triggers mentioned previously, such as stating that Math or Science is their favorite subject in school. Once segmented, each researcher independently coded all interviews and then compared codes. Researchers achieved 99% agreement. Disagreements were resolved in conference.

Knowledge questions from interviews were segmented by one researcher, and a scoring scheme was applied by two researchers to assess correctness of answers. Answers for each question were provided by an expert in Astronomy and broken down into three levels of reasoning. A participant received a “0” if they stated, “I don’t know” or the answer was off-topic, a “1” if their answer was on-topic but incorrect, a “2” if the answer provided evidence and was partially correct, and a “3” if the answer was entirely correct and/or included in-depth reasoning and inference as to why the phenomena occurred. Scoring was done by both researchers for 10 participants and a total of 89 responses. Researchers achieved 82% agreement on scores, and disagreements were resolved through discussion. Average scores were then calculated for each participant.

Because of a small sample size and predominantly non-normally distributed data, non-parametric analysis was used to examine the correlations between the variables.

Results

Spearman correlations revealed a significant relationship between only the exploration metric and the score on the knowledge questions from the interviews (see Table 1). Results showed a low overall mean exploration across all participants, considering that a score of 100 is possible. However, not every square of the overlaid grid contains information or content, and therefore are not relevant to learner goals. Additionally, standard deviation is low for exploration, which indicates similar exploration metrics across participants. All other correlations were non-significant, but moderate correlations were found between interest episodes from interviews and Minecraft interest from survey, STEM interest from survey and knowledge questions scores, as well as STEM and Minecraft survey interest. The negative relationship between MC Int and STEM Int is unusual, as the validation process of the surveys revealed positive correlations between the two constructs. Granted, this does not rule out the possibility that some participants sign up for the camp based solely on the opportunity to play Minecraft. Observations from staff noted that learners with high interest in Minecraft tend to disengage from the STEM content in favor of testing the limits of our customized server and engaging in games, such as hide and seek, within Minecraft.

Table 1

Spearman correlations for summer camp interest an knowledge

	Expl	KnQu	IntEps	STEM Int	MC Int
Expl	1				
KnQu	0.62*	1			
IntEps	0.17	0.17	1		
STEM Int	0.08	0.3	0.02	1	
MC Int	-0.03	-0.53	0.57	-0.3	1
mean	13.05	16.3	12	81.38	80.09
sd	1.66	2.31	2.45	11.65	12.36

Note: Expl = Exploration, KnQu = knowledge question score, IntEps = Interest episodes from interview, STEM Int = STEM interest score from survey, MC Int = Minecraft interest score from survey. * = $p < .05$

Discussion

Relatively higher exploration was associated with higher mean scores on knowledge questions in a 1-on-1 interview near the end of the camp experience. This significant result points towards the possibility that the more of a map a participant explores, the more NPCs they will meet, the more content they will expose themselves to, and in the end the more concepts they will comprehend and recall at test. Greater exploration indicates a propensity for breadth of understanding, whereas limited exploration might indicate a participant became more focused on a point of interest, promoting depth of understanding. Since the questions cover broad concepts across the worlds then it follows that a breadth approach tends to result in higher mean scores on a knowledge assessment.

Exploration had near zero correlations with STEM and Minecraft interest, which might indicate the environment being explored is novel enough to trigger situational interest or excitement for the content, regardless of initial interest in STEM or Minecraft prior to entering the experience. The survey more closely captures the enduring interest a learner has in STEM and their relationship with different STEM domains. Regardless of enduring STEM interest the learner enters the camp with, they will find something in each world worth exploring and pre-existing interest does not play a major role in exploration/exploitation decisions. The relationship between STEM interest episodes from interviews is also low and non-significant, which points towards a similar conclusion. One of the overall goals of the broader project is to attract learners of varying abilities so seeing learners of varying levels of interest explore in similar manners reflects positively on the goals of the project. However, while not significant, STEM interest does bear a positive correlation with performance on knowledge questions, raising the notion that kids with higher STEM interest also possess higher levels of general STEM knowledge, can apply that knowledge broadly, and can perform better than those with lower levels of interest and knowledge. On the other hand, Minecraft interest is negatively correlated with performance on knowledge questions to a moderate degree, which could be a result of learners focusing more on playing Minecraft in personally preferred ways instead of our intended goals. Perhaps, learners with high interest in a popular game tend to have preferred playstyles they easily fall into that often do not align with educational goals.

Limitations and future directions

Additional measures should be taken to determine differences between depth of understanding regarding concepts versus breadth of understanding. Concluding participants who explore less are not comprehending concepts as much as those exploring more the map devalues possible points of interest where they may want to develop a more in-depth knowledge, such as crop growth or animal habits on these worlds. Time spent in map locations where salient signals related to content are present is worth considering in future analyses of exploratory behavior. Also, continued research with larger sample sizes should be conducted to assess the generalizability of the results.

Closer examination of playstyles and engagement with educational content, in relation to Minecraft interest, should be undertaken to see if learners with increased familiarity tend to favor their own preferences over the intended goals of the intervention. This could be a cautionary take on customizing popular games for educational purposes. Additionally, a measure of situational interest would help unpack how much engagement with the Minecraft environment is influencing a learner's immediate interest, and thereby their inclination to explore and acquire knowledge. A lack of triggered situational interest might be related to disengagement with the game environments and task goals laid out at the beginning of the camp.

The Digital Game-Based Language Learning Experience for Vocabulary Learning

Mahjabin Chowdhury, Madeleine Barth, Jonan Phillip Donaldson
mahjabin@tamu.edu, mkbarth12@tamu.edu, jonandonaldson@tamu.edu
Texas A&M University

Abstract: Vocabulary plays a pivotal role in language learning, and it is widely accepted that an increase in vocabulary improves the learning experience of a second language. Literature shows that one of the impressive benefits of digital game-based language learning (DGBLL) is that it helps students' vocabulary development. This study examines learners' vocabulary learning experiences in a DGBLL context grounded in constructionist theory as they built their own games based on their understanding of different non-fiction texts. Network analysis of interviews found that *application, fun*, and *game-making* were the core components of the learners' experiences and that *translating information, enjoying non-fiction texts*, and *enjoyment* were most critical to the learners' involvement.

Introduction and background

The K-12 school population in the United States is witnessing a significant increase in enrollment of English language learners (ELLs), who comprise the fastest-growing sector (Enyinnah, 2014). However, teaching ELLs can pose a challenge due to differences in language and culture (Kelley et al., 2010). One solution to this issue is digital game-based language learning (DGBLL), which involves creating digital games to promote learning (Khalili, 2014). DGBLL has the potential to facilitate language acquisition and provide ELLs with the necessary language skills for success in their academic pursuits.

To explore the effectiveness of DGBLL, this study tasked students with creating their own video games based on non-fiction texts that they had no prior knowledge of. The study aimed to identify the aspects of DGBLL that aided students in learning new vocabulary while designing their games, while also evaluating their attitudes toward language learning and technology.

This study is based on constructivist theory, constructionist theory, motivation theory, and dual coding theory. Constructivist learning theory is grounded in the work of Piaget (1952), Vygotsky (1978), and Bruner (1996), who defined learning as the active construction of knowledge and meaning. Constructivist learning theory is different because it expands the constructivist perspective on learning (Papert, 1993) by placing more emphasis on the art of learning and on the significance of learning through making (Ackermann, 2001). Motivation theory focuses on the factors that engage learners in the learning process and help to explain their learning outcomes, either intrinsically or extrinsically (Deci & Ryan, 2013). Additionally, dual coding theory states that cognition refers to two different subsystems, a verbal system that is directly composed of language, and a nonverbal system that processes nonverbal objects and events. Hence, knowledge consists of the use of verbal and nonverbal systems (Sadoski, 2005).

In particular, the study employed Scratch (https://scratch.mit.edu/), a programming platform developed by the Massachusetts Institute of Technology Media Lab, which offers a development environment and a website where users can share projects, games, and ideas (Moreno-León & Robles, 2015).

Over eight weeks, young learners participated in an online game-based language learning workshop comprising eight 50-minute sessions. Following the program's conclusion, the researcher conducted interviews with the participants. The study sought to answer the following research questions: *(1) What were the leverage points in networks of relationships regarding aspects of learner experiences that can be used to design DGBLL experiences in the future? (2) How were learner experiences related to aspects of learning theory in which the program was grounded, and what does this indicate about how different aspects of constructionist theory are related to different aspects of dual coding theory and/or motivation theory?*

Methods

Thirteen elementary school-age (9-13 years old) learners participated in this study. Participants were second-generation Bangladeshi American ELL students, and all the students spoke Bengali at home. Parents reported that these students had beginner to intermediate-level proficiency in Bengali. The students were also struggling readers in English and had low English vocabulary knowledge. None of the participants had used Scratch before.

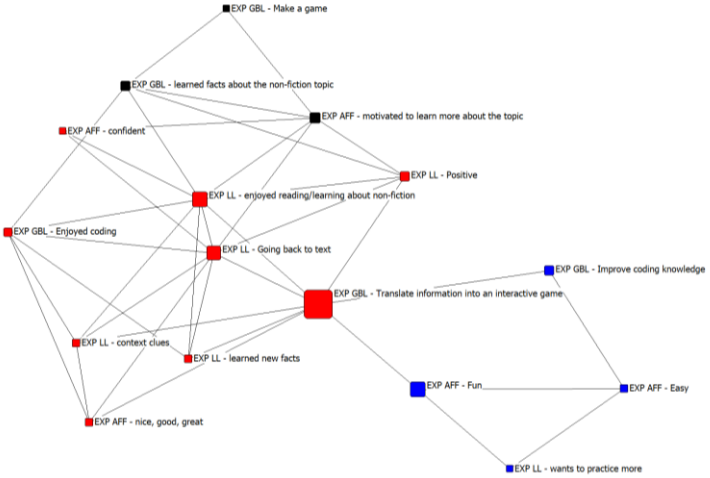
The curriculum for the program was developed by the lead researcher (the first author), and the fifty-minute sessions were conducted through interactive guided learning on Zoom. Each session involved students reading a non-fiction text, developing new vocabulary knowledge, and creating games using Scratch. The instructors facilitated the sessions by reading the non-fiction text aloud, explaining unfamiliar words, and demonstrating how to design a game. Moreover, students collaborated in Zoom breakout rooms and asynchronously used Google documents and Scratch between sessions. Although students worked together to generate ideas, they designed their digital games independently.

This is a convergent mixed methods case study, and measure for this study includes semi-structured interviews. All the interview data were coded in MAXQDA Analytics Pro qualitative analysis software based on the in-vivo coding for emergent codes, axial coding (Corbin & Strauss, 2015), and *a priori* categories based on the theories in which this study is grounded (Thornberg, 2012). To answer the research questions, the researcher conducted semantic network analysis using MAXQDA (Donaldson & Allen-Handy, 2020). For the first research question, clustered semantic network maps of learner experiences in terms of affect, game-based learning, and language learning were used to identify how various aspects of learners' experiences were related. After that, betweenness measures of centrality were used to identify leverage points (Freeman, 1977), which could be used to design more powerful DGBLL experiences in the future. For the second question, clustered semantic network maps of strengths and weaknesses of the design were used to identify the relationships between design strengths and weaknesses. Betweenness centrality measures were calculated, and these measures in the maps were used to identify leverage points in each theory which could provide insights to strengthen other theories.

Findings

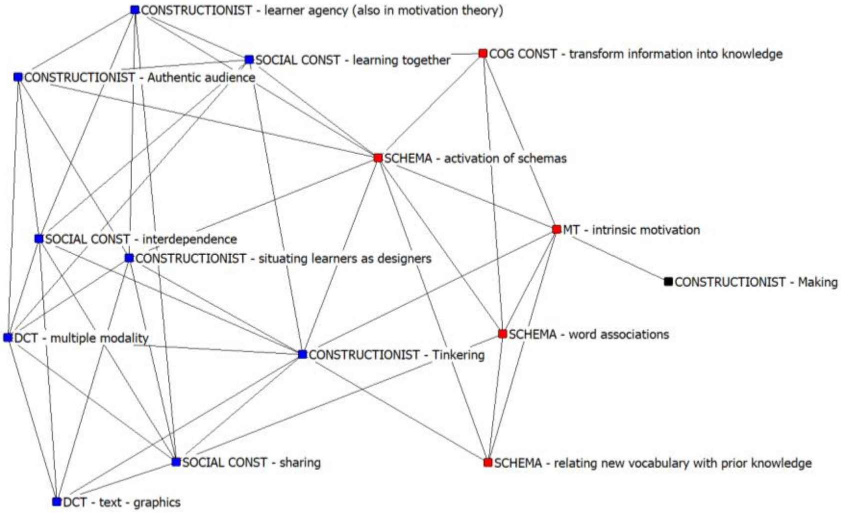
To answer research question one, a three-cluster semantic network map (Q= 0.23) was generated using the categories "game-based learning experience" (GBL), "language learning experience" (LL), and "affective experience" (AFF) using the Girvan-Newman algorithm (Girvan & Newman, 2002) (Figure 1). The network map was created using the correlation matrix at the $p<0.001$ confidence level. It was discovered that the most prominent leverage point was the game-based learning experience code of *translate information into an interactive game.* This leverage point indicates that the DGBLL experience may provide the unique affordance of contextualized language learning where the students use the language in a meaningful, goal-focused way (Reinhardt, 2018). Contextualization is known to be one of the most effective methods of second language vocabulary learning as it helps the learners to remember the vocabulary in semantically related groupings (Nation, 2001). Additionally, this DGBLL design provides students with space for sheltered use of language where they are able to progress through scaffolded steps (Reiser & Tabak, 2014). For example, thinking about all the leverage points closely, it includes the whole cycle of the workshop from start to finish. Therefore, if educators want to design a powerful DGBLL experience, they are well-advised to design their own workshops such that they are generative experiences that construct meaningful representations in the DGBLL context. Additionally, educators should include opportunities for reading, while also leveraging the positive affective experiences *(fun)*.

Figure 1
Learners' Experiences–GBL vs LL vs AFF (Leverage Points)



To answer research question two, a semantic network map was generated in the analysis software using the codes for the categories "constructionist theory," "dual-coding theory," and "motivation theory" (Figure 2). Using the Girvan-Newman algorithm (Girvan & Newman, 2002), the researcher identified a three-cluster semantic map (Q = 0.22) using the correlation matrix at the $p<0.001$ level. The ***construction-together*** cluster shows that several aspects of constructionist theory–including *focused tinkering, authentic audience*, and *situating learners as designers*–are connected to aspects of *interdependence* and *learning together* from social constructivist theory. This emphasizes how DGBLL allows for opportunities of collaboration (Reinhardt, 2018). Furthermore, the ***schema-construction*** cluster shows that the code of *activation of schemas* is connected to the codes of *relating new vocabulary with prior knowledge,* and *word associations.* This aligns with the schema theory of vocabulary learning which contends that connecting new words with prior knowledge and making word associations helps the learners to activate their schema which in turn, results in their vocabulary learning (Rasinski et al., 2017). Moreover, if we take the ***construction-together*** cluster and the ***schema-construction*** cluster, the first cluster includes all the nodes that points to the active, external learning by making artifacts whereas the second cluster includes all the nodes that points to the internal, cognitive process of knowledge construction. This aligns with the feature of constructionist theory where the learners make artifacts (in this case, digital games) and these artifacts mirror the embodied cognition of learners' minds (Papert & Harel, 1991). The **most interesting** finding is that this **externa**l (social constructivist) and **internal** (cognitive constructivist) process **simultaneously** helps the learner with knowledge construction (in this case, vocabulary learning). Even though the code of *making* is not a part of a cluster, it an important node in creating the dyad with the code of *intrinsic motivation.* Without this node, the semantic map becomes weak. This dyad suggests that the DGBLL context may have the potential for promoting intrinsic motivation.

Figure 2
Learning Theories



Implications and conclusion

Findings from this study of DGBLL for second language vocabulary learning show that DGBLL contexts may promote intrinsic motivation for the learners and provide them with the opportunity of contextualized language learning where vocabulary is learned through narrative in the gaming context (Pu & Zhong, 2018; Rahmi, 2018). Our findings provide evidence that DGBLL context has the potential to provide students with a learning experience which is based on the constructionist and social constructivist learning theories where students can be more *generative*, *collaborative* and share ideas with each other while promoting intrinsic motivation among the learners. Additionally, our findings emphasize the way that constructionist theory can be enhanced by the implication of social constructivist theory. While DGBLL has the option to only participate in constructivist theory and the code of *making*, implementing social constructivism and codes such as *tinkering, learner agency (also in motivation theory),* and *learning together* can enhance the positive learning experience in the design. Therefore, we suggest using these multiple learning theories in the learning experience designs may be beneficial for the development of learners' knowledge.

Investigating 'Investigation and Design' in Introductory Science Courses for Transformative Professional Development

Leighanna Hinojosa, Devarati Bhattacharya, Anne Egger
Leighanna.Hinojosa@CWU.edu, Devarati.Bhattacharya@CWU.edu, Anne.Egger@CWU.edu
Central Washington University

Abstract: Teaching with Investigation and Design in Science (TIDeS) envisions that future teachers will learn science as undergraduates the way they are expected to teach science in the K–12 classroom: engaging all students in science investigation and engineering design in a discourse-filled, context-rich, inclusive learning process. The TIDeS project seeks to catalyze transformation of introductory undergraduate science courses by supporting faculty in the development and implementation of high-quality, rigorously tested curricular materials. To fully support faculty in the development and implementation of their new materials, we review analysis of baseline observational and interview data of 15 materials developers to better understand and address the needs of TIDeS instructors.

Introduction

Teaching with Investigation and Design in Science (TIDeS) is a National Science Foundation-funded project that envisions that future teachers will learn science as undergraduates as they are expected to teach science in their future classrooms. The majority of science courses that future teachers enroll in are introductory, general education courses, thus TIDeS focuses on these courses and the faculty who teach them. The project has four guiding principles: (1) Students will engage in scientific investigation and engineering design to deepen their understanding of core ideas; (2) Faculty and the curricular materials they use will cultivate an equitable learning environment where all students have equal access to learning and feel valued and supported in their learning; (3) Students will engage in addressing questions and solving problems that are relevant to their lives; and (4) Students will engage in authentic and meaningful scenarios that make use of real data and models and reflect the actual practice of science and engineering. The first goal of the project is to engage and support undergraduate faculty in developing, testing, and implementing high-quality instructional materials that put investigation and design at the center of introductory science courses. As of fall, 2022, three teams of instructors are in the process of creating new materials that will meet the guiding principles and goals of the project as encoded in a rubric, similar to the process described in Egger and colleagues (2019).

The second goal of the project is to assess the impact of the use of the materials and the development process. We are particularly interested in learning about how instructors' beliefs about teaching and their teaching practices change as they undergo a long-term, rigorous curriculum development and professional learning process structured around the guiding principles. To assess change, we started by collecting baseline data from instructors prior to any professional development or implementation of new materials in their classroom. Here, we present those baseline data and how we used those data to inform our professional development.

Methods

Participants

The materials developers (MDs) are 15 instructors who teach introductory undergraduate biology, Earth science, environmental science, and physics courses. Six teach at community colleges, two at bachelors-only institutions, four at masters-granting institutions, and three at doctoral/research institutions; the institutions are in 11 states across the country.

Data collection

We interviewed MDs using a seven-question, semi-structured interview protocol adapted from the Teacher Beliefs Interview (Luft and Roehrig, 2007). We asked: (1) How do you describe your role as a teacher; (2) How do you see your students; (3) Describe one of your most successful teaching experiences within this class and why you felt it was successful; (4) Describe one of your least successful teaching experiences and why you felt that way; (5) How do you decide how to approach a particular content area or topic in this class; (6) How do you know when learning is occurring or has occurred; and (7) What kind of support or professional development do you feel would benefit you most as a teacher in this class?

Responses to the first six questions were coded using the five categories of teacher beliefs identified in Luft and Reohrig (2007): *traditional*, where the focus is on information, transmission, structure, or sources; *instructive*, where the focus is on providing experiences, and is instructor-centered; *transitional*, where the focus is on instructor-student relationships and/or an affective response; *responsive*, where the focus is on collaboration, feedback, or knowledge and skills development; and *reform-based*, where the focus is on mediating student knowledge. Responses to question 7 were not coded as this related to support needed by the MD rather than a question to elicit teaching beliefs. In addition,, we coded interviews for TIDeS guiding principles to look for alignment prior to their involvement in TIDeS curriculum development.

We also observed 14 of 15 MDs teaching using an observation protocol adapted from the Classroom Observation Protocol for Undergraduate STEM (COPUS) (Smith et al., 2013) and the Science Discourse Instrument (SDI) (Fishman et al., 2017. Thirty-four observations were coded and categorized into COPUS profiles or instructional styles: instructor-centered, interactive-lecturer, or student-centered (Stains et al., 2018); and student and instructor behaviors were plotted over time. In addition, 27 15-minute segments of discourse were identified and transcribed from 12 of 15 MDs and coded using the SDI. All analysis were completed by two researchers. For coder reliability, researchers coded the same subset of observations and interviews separately, compared coding, and refined coding analysis upon consensus before continuing to code all observations and interviews. Both interview and observational protocols were tested for validity in a prior pilot study (Bhattacharya and colleagues, 2022).

Findings

Results from interview coding analysis showed MDs teaching beliefs as primarily *instructive* to *transitional.* COPUS results from the thirty-four observations indicate that the most common instructor practices were presenting (70 ± 26% of the total 2-min intervals of a given class) followed by guiding (55 ± 32%); while the most common student practices were receiving information (74 ± 25%) followed by students talking (41 ± 23%). COPUS analysis indicates that four of the observed MDs were profiled as instructor-centered, and four were interactive lecturers. Three were both instructor-centered and interactive lecturers; two use more student-centered practices. To examine the relationship between beliefs and practices, we compared results from interviews to COPUS profiles (Figure 1).

Table 1

Material developers' beliefs and instructional styles

	Interview

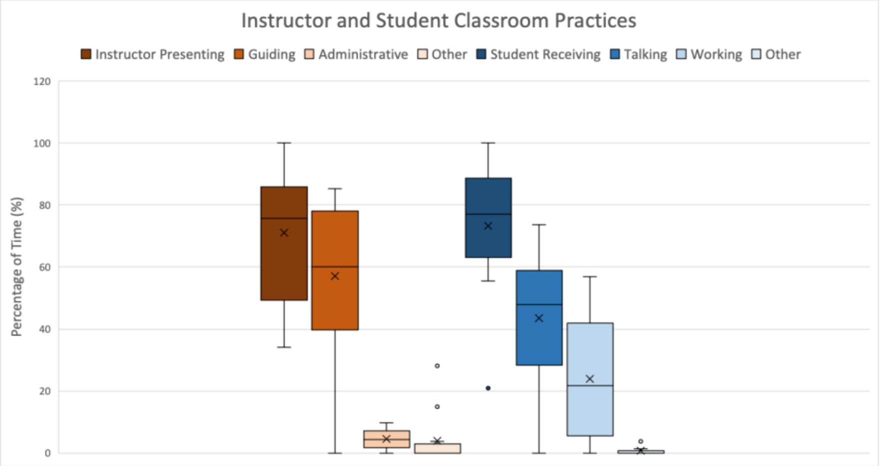
6	*/xx*	*/x*	*/x*	*/*		*Didactic (1); Interactive (1)*
7		x	xxxx	/	/	Didactic (3)
8	*/x*	*//xxx*	*/*			*Interactive (1); Student-centered (1)*
9	*x*	*xxx*	*xx*			*Didactic (2)*
10		*x//*	*xx///*	*/*		*Didactic (1); Interactive (2); Student-centered (1)*
11		*xx*	*xxxx*			*Didactic (2)*
12	*xx*	*/xx*	*/x*			*n/a*
13		xxx	xxx			Interactive (1)
14	x	xxx	xx			Didactic (1); Interactive (2); Student-centered (1)
15		*/x*	*/xxxx*			*Didactic (1)*

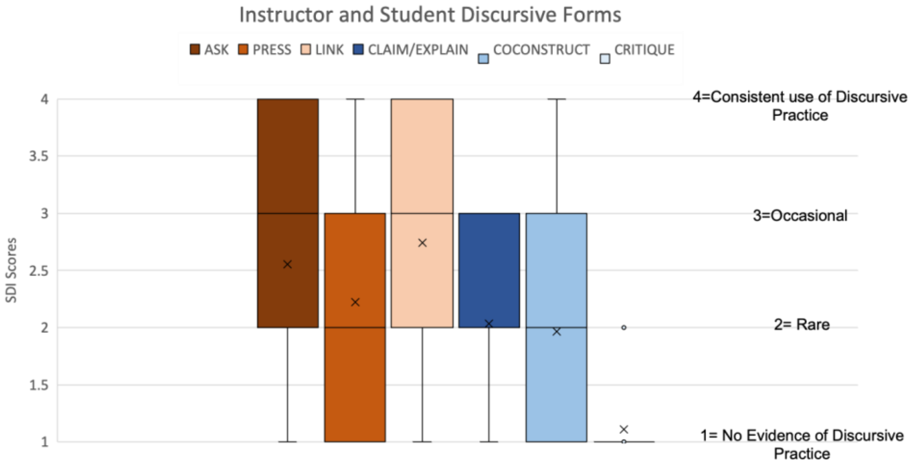
The SDI provides greater detail about the teaching practices of the MDs. Classroom science discourse focused on *building explanations* (across 63% of the 27 segments analyzed), *sharing observations* (41%), and *reviewing/recapping prior lessons* and *sharing background knowledge* (33% each) (Figure 1). There was no captured discourse with the purpose to 'design investigations'—a major component of the TIDeS project. We also noted very little think time was given to students during discourse.

Figure 1
Instructor and Student Practices in Classroom Observations (n=14 MDs)



We used the SDI discursive rubrics to assign scores of 1 to 4 for frequency of: (1) ASK: Do the instructors ask open ended questions intended to elicit diverse student responses; (2) PRESS: Do the instructors press students to support their contributions with evidence and/or reasoning; (3) LINK: Does the instructor connect students' ideas and positions in a way that helps build and develop the discussion; (4) CLAIMS: Do students offer explanations or claims/conjectures supported by evidence; (5) CO-CONSTRUCTION: Do students' contributions link to and build on each other to co-construct understanding; and (6) CRITIQUE: Are students offering critiques of the contributions of other students or the teacher? (Figure 2).

Figure 3
Instructor and Student Discursive Forms and Frequencies (n=12 MDs)



Instructors frequently use ASK and LINK discourse practices, but rarely PRESS students for more information. Students occasionally make CLAIMS, but rarely CO-CONSTRUCT their understanding and do not CRITIQUE their peers or the instructor in whole class discussions.

We did not expect to see alignment of teaching beliefs with the TIDeS guiding principles, and we found few instances. While all instructors are thinking about equity issues, they are not fully actualizing the guiding principle of *equitable learning.* There was no mention of students co-constructing their understanding through communication of ideas nor discussion of how the instructor invites students to express their prior knowledge or experiences in the classroom. Most lacking was the practice of *scientific investigation*, and *asking questions and solving problems* that are relevant to students, however all instructors understand the importance of relevance.

Discussion

Our results indicate that the observed practices of the instructors are not always aligned with their beliefs about teaching and learning science. For example, MDs expressed an awareness of and importance of equity issues in science learning whether or not they used equity-focused strategies in their teaching practices. While their beliefs represent a strong desire for creating equitable learning environments, MDs rarely provided students opportunities to participate in more student-centered activities in class. This misalignment of teaching beliefs and practices is further evidenced when comparing instructional styles to their teaching beliefs. Observational data showed that students are mostly listening or receiving information during class while MDs present this information, which resembles more traditional methods of teaching and learning that we strive to move away from in TIDeS. When examining science discourse in the classrooms, MDs tended to ask open-ended questions and link students' contributions, however, there were fewer instances of pressing students for their reasoning and linking in a way that allowed students to compare/contrast student contributions within the captured discussions. More guidance may be needed to support MDs in eliciting and working with their students' thinking in the moments of classroom activities/discussion. Students also rarely made or did not make claims supported by evidence, nor did they build upon or critique each other's contributions in a way that co-constructed their understanding. Therefore, students will need more scaffolded opportunities to participate fully in the classroom science discourse and activities.

Informed by this research, TIDeS researchers held a series of online webinars meant to provide supporting professional development for MDs. Presently, there have been eight 1-to-3-hour webinars covering a range of topics. All MDs were shown their aggregate data from baseline analysis during four of these professional development webinars. MDs also received a summary analysis of their baseline observational data for individual review and reflection. Other topics of webinars included scientific investigation and engineering design, equity in science learning, and using the language of the Next Generation Science Standards (NGSS). MDs were also given time to share progress and receive feedback within these webinar spaces. *Future directions* include continuing to share aggregate results from the implementation phases to participating MDs. Professional development workshops will continue to focus on classroom activities that engage students in scientific investigation and engineering design that reflect the actual practice of science, on strategies for facilitating productive science discourse, and equity strategies in science learning. The purpose of the webinars is, and will continue to be, to support MDs in enacting more of their beliefs in their teaching practices. Data analysis from implementation is on-going and will continue to inform the professional development of the TIDeS MDs and will be compared to baseline data to analyze change in teaching practices and beliefs across the course of the TIDeS project.

Articulating a Sociocultural Framework for Identifying and Assessing Computational Thinking

Nina Bonderup Dohn, University of Southern Denmark, nina@sdu.dk

Abstract: The aim of this conceptual paper is to develop a socioculturally informed theoretical framework for identifying and assessing Computational Thinking (CT); with the purpose of providing guidance for educational practice as regards developing specific assessment tasks. Currently, understandings of CT diverge, rendering the identification of CT ambiguous and the foci for assessing CT unclear. Most existing empirical forms of CT-assessments draw on a cognitive approach to CT and emphasize programming skills and/or students' knowledge about computer science concepts. These forms do not clearly meet an *engagement condition* for CT-activities: that a CT-activity must require learners to engage with algorithmic processes. The framework developed here draws on James Greeno's sociocultural reconceptualization of cognitive phenomena at four different levels. For each level, it is articulated what engagement with algorithms consists in and what criteria for demonstrating engagement are. In addition, examples of assessment tasks at each level are provided.

Introduction

Following Wing (2006), Computational Thinking (CT) has increasingly gained the attention of policy makers, educators and researchers alike for its prime significance for citizens in the 21st century (e.g., Bocconi et al., 2022; Shute et al., 2017). As pointed out by Shute et al. (2017), there is, however, as yet no common, accepted definition of CT. This renders the identification of CT in practice ambiguous and the foci for assessing CT unclear.

This conceptual short paper aims to contribute to the articulation of a socioculturally informed (Greeno & TMSMTAPG, 1998; Wertsch, 1998) theoretical framework for identifying and assessing CT. The purpose is to provide guidance for educational practice as regards developing specific assessment tasks. The framework should encompass activities promoted by the different understandings of CT, given some reconceptualization of the activities to align them with a sociocultural approach. For this reconceptualization, I draw on Greeno's contrastive delineation of cognitive and sociocultural analyses of "cognitive phenomena" (Greeno, 2011)

Recent conceptualizations of CT-activities across the different understandings

In a recent article, Kafai et al. (2020) point out that, despite variances at the level of detail, the different understandings of CT broadly fall within three overall approaches: a cognitive, a situated, and a critical approach.

The first approach focuses on individual problem-solving understood as a sequential process of cognitive information-processing. Decomposition, pattern abstraction and modeling, design of an algorithmic solution, debugging, iteration and generalization are key CT elements emphasized by this approach (Shute et al., 2017).

The second approach originates in Resnick's (2014) constructionism, focusing on learners' creation of digital artefacts and participation in digital practices in collaboration with others. The approach emphasizes social and situated aspects of CT, but not in the sociocultural sense of negotiation of shared meaning (Wenger, 1998). Rather, the intellectual heritage from Resnick's constructionism is clear: the social and situated aspects are emphasized for their significance for the individual's construction of meaning. Personal expression, sense-making and creativity, and the individual's development of "computational fluency" (Kafai et al., 2020, p. 46) in digital practices are thus highlighted as key to CT within this approach.

The third approach focuses on learners' critical engagement with the political, moral, and ethical challenges connected with the design and use of IT. Central to this approach is the critique of algorithms underlying existing computational systems (e.g., social media, face-recognition software, or crime-prediction software) to reveal implicit biases and resulting inequities. In addition, the approach focuses on learners developing a nuanced and reflective understanding of computational systems in use, to allow construction of computer systems that are ethically, socially, and environmentally sensitive. The goals of reflection, critique and sensitive construction are integrated in an overall goal of "computational empowerment" (Dindler et al., 2020).

Dohn et al. (2022) identify what they term an *engagement condition* as a common trait across the different approaches. The engagement condition states that for a learning activity to be a CT-activity, the activity must require that learners engage with algorithmic processes. The approaches differ in their conceptualizations of "engagement with algorithms". For the cognitive approach, developing an algorithmic solution is key; for the situated approach, participation in digital practices; for the critical approach, critiquing underlying algorithms. Still, as shown below, the engagement condition allows integrating all three approaches within one framework.

Articulating a sociocultural framework for identifying and assessing CT

The engagement condition implies two questions that are central to articulating a framework for identifying and assessing CT: 1) What constitutes "engagement with algorithms"? 2) What counts as "demonstrating engagement"? The former is ontological, asking what "engagement with algorithms" *is*. The latter is epistemological, asking how we can *recognize* "engagement with algorithms" in student activity. Thus, the second question asks what the criteria are according to which an activity demonstrates "engagement with algorithms".

A recent review of existing empirical forms of CT-assessments shows a clear dominancy of the cognitive approach to CT (Tang et al., 2020). Furthermore, the authors point out that most assessments concentrate on programming skills and/or evaluate students' knowledge about computer science concepts such as selection, looping, algorithms, and sorting. They note that this is problematic since it is not explained "why assessing CT skills can be interchangeable with assessing programming or computational concepts." (p. 8). Given the engagement condition, the problem is that students may have knowledge *about* computer science concepts such as algorithms without *engaging* with the algorithms (question 1). Further, even within the cognitive approach to CT, it is not clear why being able to articulate such knowledge should be viewed as a criterion for "demonstrating engagement" (question 2). As regards programming skills, it may seem reasonable to say that programming activity "demonstrates engagement with algorithms" (question 2). However, even within the cognitive approach, it appears too restricted to view programming as the only way of "demonstrating engagement with algorithms" (question 2), let alone take it to constitute "engagement with algorithms" per se (question 1).

In contrast to the somewhat problematic assessment forms highlighted in the review by Tang et al. (2020), the aim of the present short paper is to contribute to a framework for identifying and assessing CT which can encompass all three approaches to CT. Furthermore, as the cognitive approach to CT has been dominant, the majority of assessment frameworks have been articulated based on a cognitivist understanding on learning. In consequence, it is under-explored how to approach assessment of students' shared negotiation of CT-subject-matter (e.g., how to follow and critique CT procedures). Therefore, my further aim is to provide a complementary perspective, based on a sociocultural understanding of learning. To clarify, this does not mean articulating the framework from the point of view of what Kafai et al. (2020) call the situated approach to CT: This so-called situated approach, as indicated, still focuses on the individual's sense-making, rather than on the social negotiation of meaning in a student group or classroom. In contrast, a sociocultural understanding of learning focuses on development of patterns of participation in a student group, development of shared repertoires of informational resources, and negotiation of interactional identities (Greeno & TMSMTAPG, 1998; Sfard, 1998; Wenger, 1998). I draw on Greeno's (2011) sociocultural reconceptualization of "cognitive phenomena" in articulating my alternative to dominant cognitivist assessment frameworks, in order to provide sociocultural answers to the ontological and epistemological questions above.

Greeno (2011) points out that cognitivist and sociocultural approaches agree on four levels of cognitive phenomena, but that they differ in their conceptualizations of these phenomena:

- *Level 1: Routine comprehension, conceptual understanding, problem-solving*. Conceptualized by cognitivist approaches as information-processing operations, schemata, acquiring components of procedures etc. Greeno embeds this in a sociocultural analysis focused on conversational contributions, patterns of reasoning in practice, and shared repertoire of schemata.
- *Level 2: Emergent understanding.* Conceptualized by cognitivist approaches as generative reasoning and flexibility in thinking. Sociocultural analyses at this level focus on negotiating different interpretations for mutual understanding, and positioning in interaction.
- *Level 3: Adopting tasks*. Conceptualized by cognitivist approaches as understanding task instructions and having task-level motivation. Within a sociocultural analysis, this level concerns practices that encourage problematizing and resolving, where students are positioned with competence.
- *Level 4: Conceptual growth, commitment to learning goals, sustained participation in learning practices.* Conceptualized by cognitivist approaches as conceptual change, motivational traits, and ways of knowing. Embedded in sociocultural analyses of changes in discourse practice, and positional, intellective identities regarding learning.

Applying Greeno's general analysis to the framework of CT-activities from Dohn et al. (2022) leads to the following levels of CT-activities, and accompanying answers at each level to the two engagement questions concerning ontological constitution and epistemological criteria:

- *Level 1 CT phenomena: Sequential, step-by-step rule-following.* Engagement with algorithms (ontological constitution) at this level is conceptualized socioculturally as rule-following reasoning in communicating with others, using analogue and/or digital means (question 1). Demonstrating engagement (epistemological criteria) at this level is understood socioculturally as done through i) conversational contributions, in particular use of specific terminology indicating step-by-step reasoning. In addition, engagement can be demonstrated by ii) using existing programs to solve tasks, provided the programs in question are acknowledged by students and teacher to be appropriate (question 2). This level mainly concerns CT phenomena emphasized by the cognitive approach to CT.

- *Level 2 CT phenomena: Creative construction and critical evaluation of algorithmic solutions*. Engagement with algorithms (ontological constitution) at this level is conceptualized socioculturally as a) creative construction together with others of shared algorithmic solutions (analogue and/or digital), involving substantial negotiation of the solutions' significance and b) critiquing the effects of algorithms in use. Demonstrating engagement (epistemological criteria) at this level is understood socioculturally as done through dialogic development of algorithmic solutions, explaining rationales and limitations, and imagining consequences. All three approaches to CT emphasize (different) CT phenomena at this level: Construction of algorithmic solutions by the cognitive approach; creative construction together with others by the situated approach; critiquing effects by the critical approach.

Table 1
Sociocultural framework for identifying and assessing Computational Thinking

Cognitive phenomenon	Sociocultural analysis focuses on	Ontological constitution of CT (engagement with algorithms)	Epistemological criteria for CT (demonstrating engagement)	Example of assessment task, to be performed with others
Level 1: Routine comprehension, conceptual understanding, problem-solving	Conversational contributions, patterns of reasoning in practice, shared repertoire of schemata	Sequential, step-by-step, rule-following reasoning in communicating with others, using analogue and/or digital means	Conversational contributions, use of specific terminology indicating step-by-step reasoning. And/or use of existing programs to solve task	Articulate flowchart/computer simulation of specific step-by-step procedure
Level 2: Emergent understanding	Negotiating interpretations, positioning in interaction	Creative constructing shared algorithmic solutions (analogue and/or digital), negotiating their significance, critiquing effects of algorithms in use	Dialogic development of algorithmic solution, explaining rationales and limitations, imagining consequences	Construct a flowchart (analogue) or program (digital) that models a named procedure. Explain the model and its limitations
Level 3: Adopting tasks	Practices that encourage problematizing, students positioned with competence	Initiating algorithmic task solution, initiating critique of algorithms in use	Agentic positioning regarding algorithmic solutions: Initiating construction. Querying validity and appropriateness	Open task that can be solved in several ways, including algorithmically
Level 4: Conceptual growth, sustained participation	Changes in discourse practice, positional identities	Sustained practice of agentic articulation of algorithmic perspective	Sustained discourse about algorithmic solutions: Repeated unenforced choice of initiating, constructing, and critiquing algorithmic solutions	Larger project with parts where each part can be solved in several ways, including algorithmically, and where the solution of one part constrains the others

- *Level 3 CT phenomena*: *Initiating algorithmic tasks and critical evaluations.* Engagement with algorithms (ontological constitution) at this level is conceptualized socioculturally as consisting in students' initiation, in dialogue with others, of algorithmic task solution and critique of algorithms in use. Demonstrating engagement (epistemological criteria) at this level is understood socioculturally as done through agentic positioning of oneself and others regarding algorithmic solutions. In particular, agentic positioning in the form of initiating shared construction of task solutions and/or of querying the validity and appropriateness of existing task solutions. All three approaches to CT emphasize *student initiation* at this level, albeit with somewhat different foci: Initiation of algorithmic task solutions by the cognitive approach; initiation of shared construction by the situated approach; initiation of queries regarding validity and appropriateness by the critical approach.

- *Level 4 CT phenomena: Sustained participation in algorithmic practices*. Engagement with algorithms (ontological constitution) at this level is conceptualized socioculturally as sustained practice of agentic articulation of algorithmic perspectives. Demonstrating engagement (epistemological criteria) at this level is understood socioculturally as done through sustained discourse about algorithmic solutions, in particular through repeated, unenforced choice of initiating, constructing, and critiquing – together with others – algorithmic solutions. All three approaches to CT emphasize *sustained participation* at this level, focusing on, respectively, sustained practice of initiating and constructing (cognitive and situated approaches) and critiquing (critical approach).

Table 1 summarizes the main points developed here for a sociocultural framework for identifying and assessing CT. The first column articulates Greeno's levels of cognitive phenomena. The second column contains Greeno's formulation of the general sociocultural focus for the level in question. The three remaining columns are specific to CT and constitute the novel contribution of the present short paper. Column 3 articulates what engagement with algorithms consists in for the CT phenomena at the given level (ontological constitution of CT at the given level). Column 4 presents the epistemological criteria for CT at the given level (i.e., what counts as demonstrating engagement with algorithms at the given level). Specific assessment tasks should allow students in negotiation with one another to demonstrate engagement with algorithms (i.e., live up to the epistemological criteria). The last column therefore provides examples of assessment tasks at each level for which this is the case.

A Case Study of Practice-Based Science Enacted in General and Inclusive Elementary Science Classrooms: How do Teachers Provide Verbal Supports for Science and Engineering Practices?

Sarah Lilly, University of Virginia, scl9qp@virginia.edu
Anne M. McAlister, University at Buffalo, annemcal@buffalo.edu
Jennifer L. Chiu, University of Virginia, jlc4dz@virginia.edu

Abstract: Despite the importance of providing practice-based science to students in inclusive settings, little research investigates how teachers differentiate their support. This embedded, single case study examines how two elementary teachers enacted a four-week, practice-based science project in general and inclusive classrooms. Findings show that teachers necessarily customized practice-based science curricular materials to specific learning contexts, and highlight the potential unintended outcomes that may arise as students in different classes received different kinds of verbal support. This study provides insight into the ways that teachers can modify their enactment of activities to support students to engage in practice-based science, and the kinds of professional development experiences that elementary teachers may need to be able to support all students to engage in practice-based science.

Introduction and background

Science frameworks aim to engage students in the practices of scientists (e.g., American Society of Engineering Education (ASEE), 2020; K-12 Computer Science Framework, 2016; NGSS Lead States, 2013). For example, in the United States, the Next Generation Science Standards (NGSS) call for students to engage in science and engineering practices (SEPs), which include using mathematical and computational thinking to develop models and explanations of the natural world. Practice-based science puts forth a vision of students learning specific disciplinary content through the lens of cross cutting concepts (e.g., patterns, energy, scale) with students having agency over the kinds of questions and problems they answer and solve in classrooms. Expectations to facilitate these kinds of practice-based science experiences for students place high demands on teachers. For example, the NGSS promotes that teachers need to understand not only how to support students to engage in computational thinking practices but also how computational thinking practices relate to science content and practices (Weintrop et al., 2016). Elementary teachers, especially those who may not have disciplinary backgrounds in science, engineering, mathematics, or computer science, may need help to engage their students in these kinds of experiences. Moreover, research suggests that teachers hold high expectations in science for students with and without learning disabilities, but they may need support to provide high-quality science opportunities for all students (Taylor et al., 2018). Despite the importance of providing practice-based science to students in inclusive settings (where students with and without learning disabilities are together), and understanding how teachers enact curriculum materials (e.g., Lowell et al., 2021), very little research investigates how teachers provide differentiated support through their enactment of practice-based science in inclusive settings. This study then uses a framework of teachers' classroom enactment (Lilly et al., 2023) to explore how multiple factors, such as curricular materials, teacher characteristics, and classroom context may affect how teachers use verbal supports to (1) make practice-based science activities more accessible for students (Reiser & Tabak, 2014) and (2) to help students engage in SEPs in ways that are authentic to that of scientists and engineers (i.e., National Academy of Engineering and National Research Council 2014). In particular, we ask: *To what extent and how do teachers provide verbal support of SEPs in whole-class discussions in inclusive and general class contexts?*

Methods

This study uses an embedded, single case study methodology (Yin, 2018) to explore the enactment of a four-week, practice-based science project by two teachers, Mr. Skelton and Ms. Banet (pseudonyms), in a public elementary school in the southeastern United States. Both Mr. Skelton and Ms. Banet had over five years of experience teaching science in elementary contexts, undergraduate degrees in science, prior experience implementing a pilot version of the project, and professional development in practice-based science concepts and pedagogical strategies with the project designers. Mr. Skelton was a school-wide STEM coordinator and Ms. Banet was a fifth-grade mathematics and science classroom teacher. In this study, Mr. Skelton and Ms. Banet co-taught the project to two fifth-grade science classes. One class had a higher proportion of students also in advanced mathematics courses (the General Class) and the other class had a higher proportion of students with

Individualized Educational Plans (IEPs; the Inclusive Class). Teachers supported students to engage in hands-on investigations to develop conceptual models of how water runoff relates to different surface materials, generate engineering designs to reduce water runoff on their school grounds, and create computational models to test their engineering designs. This study focuses on the enactment of three lessons over 50 minute class periods. In the science lesson, teachers supported students to *carry out an investigation* to learn how surface material relates to water absorption and *construct an explanation* of their findings (Inclusive Class: three periods; General Class: four periods). In the engineering lesson, teachers supported students to *generate and compare multiple design solutions* to determine which solution best met design criteria and then *communicated information* about their design solutions (each class: three periods). In the computer science lesson, teachers supported students to *develop computational models* to calculate total water absorbed in their different designs and then *interpret and test the model* (Inclusive Class: four periods; General Class: five periods). The teachers had a teacher's guide outlining the focal SEPs (italicized above) and pedagogical strategies. After transcribing lesson recordings, two researchers coded when the teachers spoke in whole-class discussion as teacher talk; coded turns of teacher talk as supporting the curricula or classroom management; and coded supporting the curricula talk as SEP-specific support or as not SEP-specific support. For each coding level, the researchers achieved inter-rater reliability above 80% over 20% of the data and reached consensus on disagreements (Miles et al., 2020). The two researchers worked together to note if instances of verbal support were aligned to a focal SEP as suggested by the Teacher Guide or aligned to an additional SEP. The researchers then considered themes across SEP-specific support for each lesson.

Results

Between classes, verbal support for SEPs was most different in the science lesson, somewhat similar in the engineering lesson, and most similar in the computer science lesson (Table 1). The SEPs that teachers supported sometimes differed from the focal SEPs outlined in the teacher's guide (bold, Table 1). The teachers added more support for SEPs that were not focal SEPs in both classes in the science and engineering lessons, and support in the computer science lesson focused almost entirely on focal SEPs in both classes (Table 1).

Table 1
Science and Engineering Practices Supported in Two Classes Across Three Disciplines

Science and Engineering Practices	Science		Engineering		Computer Science	
	Inclusive (n=177)	**General** (n=168)	**Inclusive** (n=74)	**General** (n=64)	**Inclusive** (n=280)	**General** (n=332)
Defining problems	2%	4%	53%	52%	-	-
Developing and using models	3%	6%	16%	9%	**54%**	**46%**
Planning and carrying out investigations	**15%**	**21%**	-	-	-	-
Analyzing and interpreting data	**20%**	**14%**	-	-	2%	4%
Using math & computational thinking	10%	10%	-	-	**44%**	**50%**
Constructing explanations	**-**	**19%**	-	-	-	-
Designing solutions	-	-	**15%**	**17%**	-	-
Engaging in argument from evidence	**50%**	**26%**	-	-	-	-
Obtaining, evaluating, & communicating information	-	-	**16%**	**22%**	-	-
Percentage on Focal Practices	**85%**	**80%**	**31%**	**39%**	**98%**	**96%**

Science lesson

In the science lesson, the Inclusive Class received nearly twice as much support towards *engaging in argument from evidence* (50%) as the General Class (26%; Table 1). For example, Ms. Banet supported the Inclusive Class to engage in argument from evidence by first supporting their understanding of what can be used as scientific evidence, saying "And when you tested it, how much water did grass absorb? Is that evidence?" This enacted verbal support for *engaging in argument from evidence* aligned with the teacher's guide, where teachers were prompted to support students to find evidence in their data to help them to answer a scientific question. Meanwhile, in the General Class, the teachers gave instructions to students to *engage in argument from evidence* in small groups without giving this support for defining evidence. For example, Ms. Banet said, "With your partners, answer *how do different surfaces affect where water goes*. You're going to make a claim, and then going to give evidence. I'm going to let you guys go for it. Talk with your table." The verbal support offered to the General Class was also in line with the teacher's guide suggestion of "Depending on your students, and their experience with explanations, you could do this in small groups." Thus, the teachers choose to enact different suggested support from the teacher's guide to support the Inclusive Class to understand what scientific evidence is and to support the General Class to engage in the practice themselves. Additionally, for the focal SEP of constructing explanations, the Inclusive Class did not receive verbal support (0%) while the General Class did (19%). These examples illustrate differences in teachers' verbal support of the science lesson's focal SEPs.

Engineering lesson

More than half of the teachers' verbal support in both classes supported students to engage in *defining problems* (Inclusive: 53%; General: 52%) and *developing and using models* (Inclusive: 16%; General: 9%), which were not focal SEPs (Table 1). For example teachers' verbal support focused on helping students to define constraints by understanding specific vocabulary (Table 2). These examples also show that teachers added support for SEPs that were not in the teacher's guide to help students engage in the focal SEPs. Specifically, by supporting students to understand the problem, students could then design solutions and communicate information.

Table 2
Examples of Teacher's Verbal Support for Defining Problems in the Engineering Lesson

Inclusive Class	General Class
Mr. Skelton: What were the four things asked for? Student: Prevent water runoff. Mr. Skelton: Prevent means none at all… Student: Reduce. Mr. Skelton: Preventing is really hard to do. So reduce water runoff. What else? Student: To withstand heavy storms. Mr. Skelton: You used the right word. Withstand, be able to tolerate or handle heavy storms.	Mr. Skelton: Tell me one criteria. Student: Minimize budget. Mr. Skelton: What does minimize mean? Student: Stay in budget. Mr. Skelton: Stay in the budget; the word minimize is important because if one design costs $1.2 million and another one costs $1 million, a lot of times people don't want to spend extra money. So stay in budget, even minimize.

Computer science lesson

In the computer science lesson, teachers focused most of their verbal support on the focal practices of *using mathematics and computational thinking* (Inclusive: 44%, General: 50%) and *developing and using models* (Inclusive: 54%, General: 46%; Table 1). In the Inclusive Class, verbal support for *using mathematics and computational thinking* focused on supporting students to understand that familiar concepts from mathematics were present in the unfamiliar task of building computer models. For example, Ms. Banet said, "So it says equal to, is greater than, plus, minus. What do you think those green boxes represent? Do they look familiar?" After the student responded, "Yeah, I see it in math," Mr. Skelton said, "And what it's expressing here is a relationship between two things, so this plus this, this minus this. You can drag these over if you want to express a relationship between two blocks." This support was in line with the teacher's guide, which suggested asking students "Has anyone seen anything like this before? Can you tell us how it works?" Meanwhile, in the General Class, the teachers' verbal support to engage in *using mathematics and computational thinking* focused on supporting students to understand how and why mathematics concepts are used in computer science. For example, Mr. Skelton asked students to explain a loop in their program. A student responded, "So it has to run to elapsed time every time it runs. Once elapsed time is the same as the rain duration then it stops repeating." And Mr. Skelton said, "So once elapsed time is equal to this, it stops repeating because we're going to be adding to the elapsed time, every cycle. See what happens by changing the elapsed time, adding two hours. Play around with it." This support aligns with the teacher's guide suggestions for how students might describe a loop: "It tells the model to start raining, and then repeat until the elapsed time is equal to the rain duration: add the hourly rainfall to the total rainfall, then change the elapsed time by adding one (adding an hour to the elapsed time)." In the General Class, such verbal support in whole-class discussion often prepared students to work on their own models as well as to discuss their models after their individual or small-group work. In both classes, the teachers also supported students to engage in *developing and using models*. For example, teachers gave the two classes a basic computational model of water run-off and supported them to state observations and understand the model through whole-class discussion. This followed the teacher's guide which suggested that teachers ask students to observe and evaluate different output values, for example to "check the rain gauge" and "see if they match what they expected." The General Class received additional verbal support, in line with the teacher's guide, to understand how to develop code for their models. Thus, both classes were verbally supported to use a specific computational model to represent scientific phenomena, while the General Class was also verbally supported to develop their own computational model.

Discussion and conclusions

This study's exploration of the differences in teachers' verbal supports of SEPs demonstrates that teachers may need support to offer authentic practice-based science opportunities while meeting the needs of all of their students in different classroom contexts. Findings show that teachers necessarily customize practice-based science curricular materials to specific learning contexts, and also highlight the potential unintended outcomes that may arise as different classes received different kinds of verbal support. For example, the two classes were being supported to engage in different SEPs or engage differently with the SEPs than was intended by the teacher's guide. This may have afforded certain students more access to engage in specific practices. For example, although redefining the problem was not a focal SEP, the additional support was in line with authentic engineering design practices in which engineers understand the problem before ideating solutions (Crismond & Adams, 2012). Further, results are in line with prior research that suggests that general education teachers may need additional support to meet students' individual needs without limiting students' opportunities to engage in NGSS practices. Studies that examine how teachers modify their enactment of practice-based science curriculum to address their students' needs are then important to help curriculum designers to leverage teachers' expertise with the goal of creating more inclusive practice-based science curricula, to help each teacher to develop pedagogical strategies across disciplines, and to support teachers to connect classroom activities to authentic disciplinary practices (i.e., National Academy of Engineering and National Research Council 2014). Our findings show that classroom context, specifically whether students had taken advanced mathematics and their individualized needs, affected which SEPs students had opportunities to engage in. Therefore, it is important to understand how teachers modify their enactment of practice-based science projects so that curriculum designers can include supports for teachers to help all students to authentically engage in SEPs.

Abstract: This article extends long standing work in the learning sciences that evidences the interdependence of identity, belonging, and learning. Informed by a grounded theory analysis of 19 interviews conducted within the geographic areas of Central Kentucky and Appalachia, with alumni from five community-based youth arts organizations, this analysis draws on subset of data from a large-scale, multi-sited and international study into the enduring effects of participating in out-of-school arts programming. By analyzing the existence of long-term effects through the narratological accounts of people at least ten years beyond program participation, this study further develops the field's understanding of the way learning, belonging and identity are deeply intertwined.

Introduction

This study builds upon and extends long standing work in the learning sciences that evidences the interdependence of identity, belonging, and learning. While learning sciences has evolved with the times from its early design-based studies in classrooms to its contemporary emphasis on learning in digitally mediated environments, what has remained constant is a persistent acknowledgement of the centrality of the constructs of identity and belonging to the phenomenon of learning. To date, however, most studies within the field that have centered their inquiries on examining learning, belonging, and identity have been *in-context* and *short-term*. Well known examples include, for instance, the development of identity within science journalism and history (e.g., Polman, 2006), the making of productive STEM identities in afterschool spaces (e.g., Tan et al., 2013), and the demonstration of math competence in basketball and track and field settings (e.g., Nasir 2012).

Less is known, however, about the relationship between learning, belonging, and identity from a long-term, longitudinal, or life-course perspective. Of note, too, recent learning sciences scholarship has tended to focus less on studies of learning squarely within the arts genre. Pursuing inquiry within this noted area of wanting is important for a few fundamental reasons. Firstly, because learning is a life-wide, life-deep, and life-long phenomenon (Bell & Banks, 2012), a retrospective/life-course methodological approach is well merited, with potential to yield novel insights into the shape and texture of learning over time. Secondly, the 'arts', broadly conceived, occupies a substantive part of afterschool programming in the United States, and as learning scientists not only do we have a long history and are well trained to study informal/non-formal/not-school settings (e.g., Cole, 1995; Sefton-Green, 2012), but the arts are "central to our understanding of learning and knowing and therefore of crucial importance to the learning sciences" (Halverson & Sawyer, 2022, p. 1). Thirdly, the first-person, narratological analysis made possible by the reflective construction of the experience of learning solicited by life-course interview questions enables opportunities for both past and present identity formation work to become highly visible and therefore able to be examined for themes and patterns. The present study, then, presents an analysis of a subset of data from a large-scale, multi-sited and international study into the enduring effects of participating in out-of-school arts programming for young people, with a particular focus on how people describe identity formation and a sense of belonging within the context of out-of-school arts learning contexts.

Theoretical perspective: Centering identity within the learning sciences

This study's conceptual framework brings together theoretical heuristics that have emerged from qualitative studies into the relationship between identity and learning. Initially pioneered by psychologists like Vygotsky (1934/1978) and Bateson (1972) and ushered into prominence by everyday cognition researchers such as Lave (1993) and Wenger (1998), the notion that a young person's identity is central to their learning experience is well documented within the field of learning and development. All situated within the camp of what is commonly called a sociocultural approach, the definitions of the three constructs brought together to constitute this theoretical perspective are as follows: *learning* as shifting participation in meaningful sociocultural activity (e.g. Rogoff, 2011); *identity* as a construction of self profoundly influenced by the multiple settings that youth negotiate daily and that emerge historically, local, and interactionally (Nasir, 2012; Wortham, 2004); and *belonging* as the sense that youths' social selves are accepted and valued and that there is room for youth to personally contribute to the activity/practice (Nasir, 2011; 2012). Indeed, these neo-Vygotskian scholars have shown, both in and outside of the classroom, how interwoven the processes of social identification and learning are—and the implications this has for how contemporary designers of learning environments should consider how, for example, to ensure the presence of 'necessary social conditions for learning'—including room for repair, the availability of multiple roles, space to personally contribute to the practice, and a sense of social belonging (Nasir, 2012). When these are present, according to this ontological model of learning, the ability for the mutual constitution of social identification and learning to take place through "the intertwining of local cognitive models and models of identity" (Wortham, 2004, p. 53) becomes possible. Put simply, this study proceeds with the guiding assumption that learning flourishes when young people feel as if their identit(ies) and ways of sense-making and being are valued in the context of the learning environments in which they are embedded.

Data and methods

This analysis focuses on 19 interviews conducted within the state of Kentucky (including the geographic areas of Central Kentucky and Appalachia) with alumni from five Kentucky-based community-based arts organizations, all of whom focused their provision of services on low to middle income youth, and whose genres ranged from music and dance to creative writing and theater. These 19 interviews are part of a larger corpus of interview and survey data with similar program participants located across five US urban locations in California, Kentucky and New York, and two large international cities in Australia and the United Kingdom. While the Kentucky participants in this sample were predominantly white, participants from the other locations were predominantly people of color.

The findings presented below emerged from moving fluidly between inductive coding attuned to low-inferential thematic chunking of prose, and theoretically informed deductive coding, focused on the constructs of identity and belonging (Miles & Huberman, 1994). Ultimately, parent level codes included central theoretical constructs like "identity" (with child level codes such as "participant description of self-formation/shift in self" and "participant identification with a genre/type/formal role") and "belonging" (with child level codes such as "participant expression of a sense of feeling accepted for who they are" and "participant expression of a sense of being valued/mattering in the space/place"). While all 19 interviews were coded using the qualitative software Dedoose to surface broader level patterns and frequencies, the following presentation of analysis highlights two cases of alumni that serve as illustrative examples of the broader phenomenon of the interdependence of identity, belonging, and learning that emerged as participants reflected on their participation from at least one decade ago.

The interdependence of identity, belonging and learning: Insights from two case studies

As the following two illustrative cases show, the entanglement of the constructs of identity, belonging, and learning emerged simultaneously and with great frequency from the data. Consider Aster, a 25-year- old biracial policy analyst from Appalachia who participated in a community-based theatre program as a teenager and now teaches circus arts in her non-working time. In the following response, Aster is talking to the first author, about midway through the interview, about her formal schooling experiences:

> "Elementary school was rough…And you know, middle school is where I got involved with [theater program] and made yeah, you know, some stronger friendships through there. So, I do think that the program kind of helped me, not, I don't think stand up for myself is the right word, but **just to be okay with who I am** and try to not worry about what other people were saying or thinking. Yeah. Yeah. Um, and then I kind of kept that mentality going into high school and still, still understanding that like I loved doing that program and **I want to continue finding ways to get that same feeling** or those same friendships. And I ended up, um, **joining the dance team** for my high school career" (**emphasis** mine).

As Aster reflects on her formal schooling experiences, she articulates them as "rough", alongside noting the contrary in the type of environment the OST program provided, in that its conditions enabled her to claim to be "be okay with who [she] is" (coded: *identity formation*) in ways that prompted her to continue to be involved in/and find new spaces that allowed her to experience *belonging* (code applied to final two sentences of above except). In addition to this, the program provided her with a context within which to "be" - to become a learner - to not only be okay with who she is but to become who she wants to be - a narrative device used to communicate the way she becomes more confident and content with herself as both a learner and community member. It helped, as Aster recounts, , her make sense of what it means to learn as part of a collective, which helps her to be okay with who she is but also serves to concretize her identity as both a critical member of a school community and consequently a member of a much larger arts world. Of note, Aster's use of an active verb tense and future-oriented claim about wanting to "continue finding ways" provide evidence of the *in-situ* identity formation work in which she is still actively engaged, and which, we conjecture, were facilitated early on by her participation in a program that made such vulnerability around identity experimentation and formation visible.

Later in the interview, when Aster is asked to reflect on if and how the program influenced her approach to how she lives her life, she recounts the following:

> **"And honestly like all the way from joining, like in my first [program experience] in 2008 to now, like it has really, it's really given me a love for teaching**. Yeah. Cause I would not be the person I am today. If someone wouldn't have said, okay, Aster, this is how you sing a song in a group. Yeah. Or, okay. Aster, when this person goes upstage, then you have to go this way. Yeah. Yeah. Um, it's just, **it's just really fulfilling for me to be able to say I'm a part of the arts**; that I perform and I teach" (**emphasis** mine).

Aster allows herself to be acted on, to become a type of apprentice, all the while developing an ambition to pass on what she has learned to others. She develops a vocation to both teach and perform - to impart knowledge and to shape the learning experiences of others but to also continue her own personal journey as a performing artist in her own right. This suggests an identity duality that is anchored in affect - affecting others through learning and teaching as well as affecting others through performance. In the above excerpt, then, the reflective construction of the experience of learning—while not named as such by Aster in either of these life-story narrative excerpts—evidences her shifting participation within an activity setting through the "intertwining of a local cognitive model and a model of identity" (Wortham, 2004, p. 53) that occurred as she moved from the periphery of the arts community (as a newcomer and novice) toward the center (as someone who "performs" and "teaches" the arts). Furthermore, this excerpt also illustrates the interdependent relationships between identity, learning *and* belonging. Aster articulates the ways in which participating in the program and experiencing a sense of belonging therein has both shaped the development of an identity (e.g., "I'm part of the arts") that is ongoing at the time of the interviews and facilitated a life-long learning that is also ongoing.

The second illustrative case is of Vance, a 65-year-old white retired grocer who was born, raised, and still lives in a rural area of central Kentucky. For three years during his adolescence, Vance participated in a youth orchestra program as a bassoon player. For his career, Vance followed in the footsteps of his family and took over the family business of owning and operating a mom-and-pop style grocery/eatery. At the time of the interview, he had been retired for about seven years. While the arts didn't become his career, his passion for and practice of the arts greatly shaped his experience of the world and his place within it. In fact, after retiring, returned to college to complete his bachelor's degree, switching from what he initially started as a teenager (Business/Management) to attaining a BA in Music. In the following excerpt, Vance responds, with a smile and a chuckle, to the question of how he lives his life and/or sees the world: "Well I have frequently told people that I'm a musician who happens to be in a grocery store." By identifying first as a musician, as making that identification known through recounting it verbally to others as well in the interview process, Vance reveals the primacy of the arts to his life's trajectory as well as his own agency to craft that narrative through a small, albeit strong, discursive identity performance.

Extending upon the influence that participating in the arts had on him, Vance went on to say, later in the interview, that he

> "...**can't imagine a life without music**. Yeah. I just can't. I, I don't know, it's just, I don't know. It's fun. Yeah. It, uh, and the friends, the, the, the **relationships that you can build**….You know, and one of the things that with age and experience is that you, your ear becomes more sophisticated and, and you can really begin to appreciate just how extraordinary, uh, some of the, uh, some, the people that you hear play and, and you can really appreciate it more. Yeah. And it, and inspires you to, you know, to continue to, uh, improve. And, um, I want, **I want to keep going as long as I can play, as long as I can**…" (**emphasis** mine).

Vance's case demonstrates the ways his sustained participation in music is intertwined with his sense of belonging as fostered through relationships, and identity as a musician. In recounting the influence of the arts on his life, Vance reflects on the centrality of the social bonds and friendship that have allowed him not only a vibrant social life as a result of the arts (which he mentioned throughout this interview), but also contribute to a sense of belonging that enriches his own artistic appreciation and inspires him to continue learning and “improve”—thereby shifting his participation in music—for as long as he physically can. As he says, quite directly, he “can’t imagine a life without music,” suggesting again his own understanding and functioning of the interdependence between his identity as a musician, his sense of belonging to the music community, and his own life-long learning pursuits. Vance’s notable articulation of his more experienced ear connotes a profound effect that is only made apparent and consequential to him through retrospective life course analysis. Of interest, he couches a justification of his age in a narrative of appreciation and expertise—two strong elements of his musical identity and his sense of self as a learner.

Discussion and conclusion

Analysis of life-course interview data from people who participated in out-of-school arts programming in their adolescence cement and extend what is already known within the field of the learning sciences about the interdependence of identity, belonging, and learning. The various aspects of what it means to form an identity, to belong and to learn are informed by both context and time. By analyzing the existence of long-term effects through the narratives of people at least ten years beyond program participation, we further develop an understanding of the way learning, belonging and identity are deeply intertwined. People articulate versions of themselves–versions that are informed by their learning experiences and consequential understandings of who they are and who they have become. Retrospective life course analysis is therefore a methodology that may help the learning sciences field further ground such theoretical insights. Whilst the study extends empirical evidence on how learning, belonging and identity are interdependent, it also sheds light on the how people experience learning over the long-term, and how learning and structured arts opportunity shapes people's lives and the stories they tell about themselves.

To be clear, the present line of inquiry is still in progress, as triangulation of these data within the extensive corpus of data from which they are situated is ongoing. What is clear, however, is the need within our design science field to further examine, problematize, and tear down the obstacles that lie in the way of actualizing the design principles for identity development and social belonging that are evidenced to consequentially and meaningfully shape the learning experiences of young people, especially those whose identities are historically and contemporarily marginalized and/or minoritized. It is toward discussion and reflection on this continually pressing problem of theory and practice that this short paper presentation is offered.

Systematic Literature Review of Teachers' Digital Competence in K-12 Education: Defining the Concept

Hulya Avci, Susan J. Pedersen
hulya.avci@tamu.edu, spedersen@exchange.tamu.edu
Texas A&M University, United States

Abstract: The current proposal is part of a larger study that aims to synthesize the existing research on in-service teachers' digital competence over the last ten years in the context of K-12 education. In this presentation, we will focus on the definition of 'digital competence' and its overlap with similar terms. This systematic literature review used three databases, Web of Science, ERIC, and Education Source, to store, identify and critically appraise published studies on teachers' digital competence at different levels of K-12 education. A total of 33 studies were identified as eligible to be included in this review. Results reveal that though many publications defined digital competence through the EU policy framework, the field still uses various multiple terms related to digital competence, and there is still no universally accepted definition.

Introduction

In recent years, there has been an increasing number of studies focusing on the role and use of digital technologies in the knowledge-based society. The advent of digital knowledge-based societies makes digital competencies the key competency essentials for teaching (Castells, 2010). In-service teachers at K-12 schools notably should improve their digital competences to meet the expanded needs of teaching and adjust to the new instructional methods compared to pre-service teachers who are expected to eagerly use technology in the classroom (Huang et al., 2021). The term "digital competence" can be broadly described as "the set of knowledge, skills, and attitudes that are required when using Information and Communication Technology (ICT) and digital media to perform tasks; solve problems; communicate; manage information; collaborate; create and share content, and build knowledge effectively" (Ferrari, 2012, p. 4). The European Union Digital Competence Framework for Educators (DigCompEdu) uses digital competence as 'digital literacy' and acknowledges it as one of the eight key competences for lifelong learning (Ferrari & Punie, 2013). This review considers different terms and definitions of digital competence, such as digital literacy (Buckingham, 2006), media literacy (Pangrazio et al., 2020), computer literacy (Nawaz & Kundi, 2010), ICT competency (NICS, 2010), ICT or digital skills (Tanhua-Piiroinen et al., 2020), information literacy (Bundy, 2004) and technological literacy (Martin, 2008).

Recently, many reviews have focused on digital competence and digital literacy (e.g., Sánchez-Caballé et al., 2020; Spante et al., 2018). Particularly, current studies have concentrated on pre-service teachers' digital competence (e.g., Basilotta-Gómez-Pablos, 2022; Torres-Hernández & Gallego-Arrufat, 2022; Zhao et al., 2021) and different practices (e.g., models, assessment, frameworks) as well as digital competence in higher education (e.g., Fernández-Batanero et al., 2021; Sillat et al., 2021). However, there is a lack of studies to better understand the digital competence of in-service teachers (McGarr & McDonagh, 2019). Although most reviews have provided qualitatively conceptual frameworks, dimensions, and models of digital competence, often in higher education, there have been almost no reviews focusing specifically on the digital competence of K-12 teachers.

In this review, we systematically explored the application of digital competence in K-12 education to give insights into the definition of digital competence. The overarching purpose of this work is to provide a systematic review of the peer-reviewed journal articles published between 2012 and 2022 that examined the digital competence of teachers at K-12 schools (e.g., elementary/primary/secondary/middle/junior high school). The review focused on the following research question: *How has the concept of digital competence been defined in terms of teachers in K-12 education?*

Method

The study was represented as a systematic review of the literature on teachers' digital competence in K-12 education and conducted according to the criteria suggested by the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines (Moher et al., 2015). To ensure the dependability and reliability of the data, the PRISMA checklist was taken into consideration as the selection criteria and synthesis of the selected papers (Hutton et al., 2016). The eligibility of the studies based on the inclusion and exclusion criteria is displayed in Table 1. We used three electronic databases, Web of Science, ERIC, and Education Source. The hand-searching of the topic and reference lists of included articles were conducted to identify any relevant studies missing in the database search. We searched the selected key terms in the title, keywords, subject headings, and abstract of the paper across the three databases. The quoted descriptors were associated with the Boolean Operators 'AND' and 'OR' and a Proximity Operator 'N3' leading the search to the target searched terms. The search strings for the concept "digital competence" were exemplified through ERIC as follows.

> (TI "computer skills" OR "digital skills" OR "computer competenc*" OR "ICT competenc*" OR "digital competenc*" OR "digital literacy" OR "technological literacy" OR (computer OR digital OR technolog*) N3 (skill* OR literacy OR competenc*) OR AB "computer skills" OR "digital skills" OR "computer competenc*" OR "ICT competenc*" OR "digital competenc*" OR "digital literacy" OR "technological literacy" OR (computer OR digital OR technolog*) N3 (skill* OR literacy OR competenc*))

Table 1

Inclusion and Exclusion Criteria

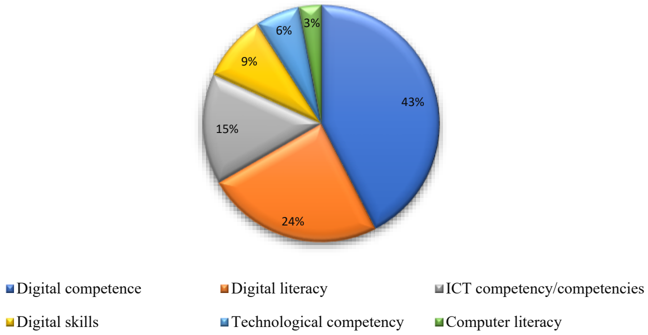
	Included	Excluded
Time frame	Articles published from 2012-2022	Articles not published from 2012-2022
Publication type	Peer-reviewed articles	Grey literature
Focus	Studies focusing on digital competence and other related terms (e.g., digital literacy)	Articles focusing on other aspects (e.g., self-efficacy, technology integration)
Language	English	Other languages
Target Population	Articles on K-12 in-service teachers at elementary/primary/secondary/high schools	Articles focusing on student teachers, pre-service teachers, future teachers

Results

Regarding the analysis of the 33 selected articles, multiple terms have been used to describe the concept of digital competence. The distribution of the concepts is shown in Figure 1. In general, these selected studies described the definition of digital competence with reference to both research and national or international policies (e.g., DigCompEdu, UNESCO) or only to policies or research, and developed their own definitions through the literature. 22 studies described the definition of digital competence by using policy frameworks. Eight articles defined digital competence by referring to the European Framework for the Digital Competence of Educators which includes six areas of digital skills and 22 competencies concerning educators' professional practices.

Figure 1

Distribution of the Concepts Used in the Included Articles (n = 33)



The six areas are divided into educators' professional and pedagogic competences and consist of (a) "professional engagement" – the ability to use digital technologies to communicate and collaborate for professional development, (b) "digital resources" – the ability to search, locate, create and share digital resources, (c) "teaching and learning" – the ability to effectively apply digital technologies into teaching and learning processes, (d) "assessment" – the ability to use digital technologies and methods to improve assessment, (e) "empowering learners" – the ability to use digital technologies to develop inclusive, personalized and engaging learning environments, and (f) "facilitating learners' digital competence" – the ability to support learners to benefit from digital technologies to obtain information, communicate, create content, solve problems (Redecker, 2017, p. 16). Four publications cited the National Institute of Educational Technology and Teacher Training (INTEF, 2017). The framework includes digital competences following other European guidelines; as such, focusing on information and information literacy, problem-solving, digital security, communication and collaboration, and digital content development. Four publications presented the ICT standards suggested by the *International Society* *for Technology in Education* (ISTE) for school teachers, organizing them into a variety of stages (e.g., basic, intermediate, and advanced) so that teachers can achieve a certain degree of technological and pedagogical competences (Romero-Tena et al., 2020). In addition to the policy frameworks set by public and private international institutions (e.g., UNESCO, ISTE), authors of 10 publications adopted definitions used in previously published research. There are three studies that defined digital competence by developing their own definition. Some example studies with their concept definition source were displayed in Table 2.

Table 2

Characterization of Sample of Articles Included in the Review

Author(s)	Year	Country	Sample Size	Grade Level	Definition (based on)
Álvarez & Mercè	2015	Spain	2,656	Secondary	UNESCO, ISTE, INTEF
Sauers & McLeod	2018	USA	922	Secondary	Research
Olofsson et al.	2020	Sweden	25	Upper secondary	Framework by Swedish National Agency for Education
Lucas et al.	2021	Portugal	1,071	Primary, secondary	DigCompEdu
Cattaneo et al.	2022	Switzerland	1,692	Secondary	Research, DigCompEdu

Discussion

The synthesis of the definitions in the included studies revealed that the concept of digital competence has been defined in various ways in the context of K-12 education. This indicates the complexity of the term, digital competence, which has been used in multiple contexts across different countries and thus led to the deficiency of a universally accepted definition. Furthermore, the relative lack of literature focusing on in-service teachers' digital competence in different levels of K-12 schools does not help us conduct a comprehensive examination of literature to better understand teachers' digital competence. It should be noted that teachers' need for using digital technologies might change in terms of subject and grade taught, individual (e.g., age, teaching experience, self-efficacy, motivation), and contextual (e.g., access to digital resources, collegiality, school climate) factors. Thus, there is a need for a benchmark of digital skills that can address teachers' needs and enable sound measurement of teachers' mastery of digital competence in K-12 education.

Abstract: This study examines how a rural-serving school district aimed to provide elementary-level computer science (CS) by offering instruction during students' computer lab time. As part of a research-practice partnership, cross-context mathematics and CS lessons were co-designed to expansively frame and highlight connections across – as opposed to integration within – the two subjects. Findings indicated that most students who engaged with the lessons across the lab and classroom contexts reported finding the lessons interesting, seeing connections to their mathematics classes, and understanding the programming. In contrast, a three-level logistic regression model showed that students who only learned about mathematics connections within the CS lessons (thus not in a cross-context way) reported statistically significant lower levels of interest, connections, and understanding.

Introduction

There is broad consensus among policy makers, educators, and researchers that it is essential for all students to have opportunities to learn foundational ideas of computer science (CS) and explore computational thinking (Vakil, 2018). Yet, many school districts face barriers in providing equitable and high-quality access to elementary-level computer science instruction given constraints in their local educational infrastructures.

In this paper, we describe how one rural-serving school district aimed to address these barriers as key problems of practice in their elementary schools. In particular, the partner school district decided to offer CS instruction in elementary school during students' weekly computer lab time, which is required and thus a part of all students' elementary experiences. To address this problem, a design team, comprised of teachers, paraprofessional CS educators, district administrators, and researchers, collaboratively designed and tested an approach in which CS connections were highlighted and identified *across* subject contexts, as opposed to integrated *within* (National Research Council, 2014; Weintrop et al., 2016). The cross-context design was informed by the theory of expansive framing, in which disparate contexts are reframed into a single, unified frame so that ideas in one context are extended through the entire frame (Engle et al., 2012). Mathematics was chosen as the subject area for making connections by framing mathematics as a context to learn CS concepts.

In particular, we examine the cross-context approach as it applied in practice for upper elementary school students. We address how critical it is for students to make the cross-context connections in both the mathematics and CS lessons or whether it is sufficient for them to only make connections during their computer lab instruction. In this paper, we present the results of implementing these lessons in elementary school contexts. In one school, the cross-context group, students participated in the cross-context lessons during both regular mathematics classroom and computer lab instruction. In two other schools in the school district, the CS-only group, lessons were only taught in the computer lab led by the paraprofessionals. Thus, the CS-only group participated in the CS lessons that integrated mathematics; however, these lessons were only taught in the computer lab setting and not also in the regular classrooms. Our research was guided by the following question: *Did students' perceptions in the cross-context group differ from their peers in the CS-only group?*

Theoretical framework: Expansive framing

Expansive framing is both an instructional approach and a theoretical framework to explain transfer of learning from a situated and sociocultural perspective (Engle et al., 2012). Expansive framing posits that broadly framing curricula across contexts (e.g., time, place, people, role, and topic) can foster expectations that content learned in one setting will be useful in other settings. The theory advocates for the importance of interleaving contextual features to promote transfer between the contexts. Additionally, framing expansively helps promote student creation of and authorship in their own learning by inviting students to draw upon their prior knowledge, holding them accountable for their own learning, and portraying them as independent knowledge generators (Engle et al., 2012). Use of this theory has been growing in instructional settings, including CS education (Grover et al., 2014).

In this study, we drew upon expansive framing to inform the collaborative design of cross-contextual CS-math lessons. Specifically, CS concepts were framed within the mathematics lessons through prompts that linked mathematics and CS ideas. Mathematics was also framed within lessons in the computer lab that reified conceptual understanding of mathematics topics and supported student creation through programming.

Cross-contextual, expansively framed CS-mathematics lessons

For the design of the instructional unit, mathematics was identified as an ideal subject area for making connections with CS concepts as there is a long history investigating such synergies (e.g., Papert, 1980; Weintrop et al., 2020). Further, a recent literature review (Shehzad et al., 2023) of CS-math integration found that connections between math and CS concepts need to be explicitly made through instruction. Thus, the proposed solution involved identifying and highlighting CS connections across subject contexts (as opposed to only integrating CS in math lessons) in mutually supportive and expansively framed ways. Thus, math-integrated CS instruction was added to students' weekly computer lab time; CS instruction also occurred in the mathematics class through mini-lessons that were embedded into existing standards-aligned mathematics routines with an emphasis on highlighting computing concepts. These expansively framed mini-lessons also helped classroom teachers see and articulate mathematical connections to CS ideas, an important goal in efforts to create cross-contextual connections (Fisler et al., 2021).

Lessons were designed to build connections between math routines in class and CS instruction in the computer lab. For example, in one math routine, teachers used if-then-else conditional logic within the following kinds of prompts to help students recall their knowledge of quadrilaterals: "if a quadrilateral is regular, then it has four **<blank>** sides, else it is not regular." The correct answer was congruent or equal. The goal was thus to expansively frame CS and math concepts rather than learning to program in Scratch in isolation (Grover et al., 2014). Table 1 shows key principles of expansive framing and examples of how each principle was instantiated in classroom math routines and lab coding activities. These features of the lessons that connected concepts across contexts and promoted student authorship were intended to foster transfer of content between settings.

Table 1
Examples of Expansive Framing Principles Instantiated in Lessons

Expansive Framing	Instantiation in Mathematics	Instantiation in Coding
Connecting contexts	Use conditional statements (CS) to classify quadrilaterals (math) Script teacher statements with physical and temporal references Use images from coding activities to demonstrate math concept	Embed math content in coding activities Add educative elements to Scratch cards
Promoting authorship	Engaging in think-pair-share math routines hold students accountable for their learning Engaging in shape sorting activity supports multiple correct answers and creative thinking	Students create and code their own quiz

While we co-designed two instructional units, the present study focuses on the geometry unit. The mathematics unit was designed as a menu of six math routines that teachers could choose from as a warm-up to typical mathematics lessons in their geometry unit. The CS lessons were designed as extension activities to existing instruction and contained two math-integrated lessons. Table 2 summarizes topics covered in the geometry unit, specifically the two lessons on quadrilaterals and triangles.

Table 2
Cross-Contextual and Expansive Framing of Mathematics and Computer Science in Geometry Unit

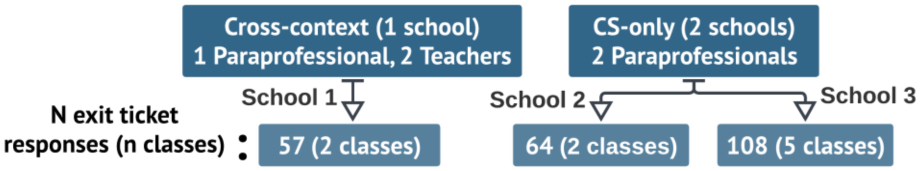
Math Topic	Math Big Ideas	Computing Big Ideas	CS-Math Connections
Quadrilaterals	Reasoning with polygons Classifying shapes	Conditionals, variables, abstraction	Use conditional statements to reason about polygons and attributes
Triangles	Classifying triangle types	Conditionals, variables, loops	Program shapes with exterior angles

Methods

This research took place in a rural-serving district in the western United States. We collected student data in three elementary schools. In School 1, the math lessons were taught during regular math time by two classroom teachers and the CS lessons were taught during computer lab time by the school's paraprofessional (the cross-context group; N=57 students). In the other two schools, only the CS lessons were taught by the two schools' paraprofessionals (CS-only group; N=172 students). Figure 1 shows the number of teachers, paraprofessionals, and responses from students who participated in the study.

Figure 1

Number of classes, teachers, paraprofessionals and exit tickets collected by lesson, implementation, and school



Immediately following each lesson in the computer lab, students completed a short three-question exit ticket survey about their perception of the lesson. Table 3 shows the constructs addressed and questions asked of students in these exit tickets. Students were asked to either respond with "yes" or "no" to each statement.

Table 3

Exit Ticket Items. Students Responded Either Yes or No

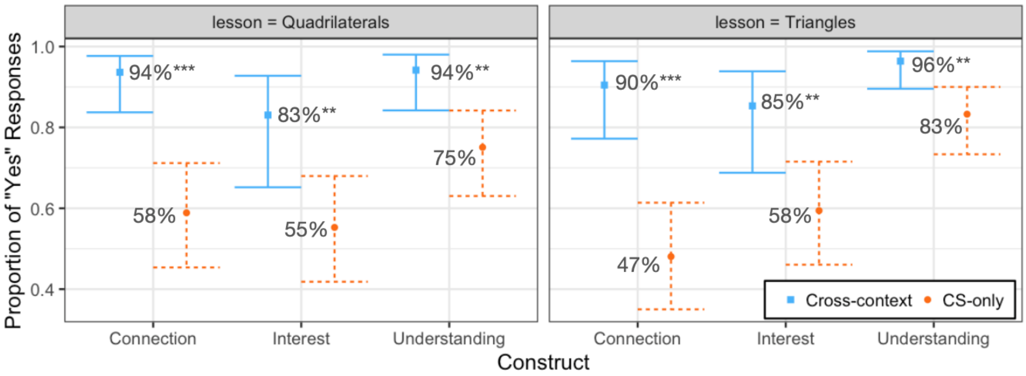
Construct	Exit Ticket Prompt
Interest	I found today's computer lab lesson interesting.
Connection	Today's computer lab was related to what I do in math class.
Understanding	I understood what we did in computer lab today.

As students' responses were binary (yes/no), to address the research question we compared the differences between responses of the cross-context students to the CS-only students using a three-level logistic regression model where survey items were treated as level-1 units, individual students were treated as level-2 units, and individual classes were treated as level-3 units. The CS-only group was treated as the reference group.

The study comes with limitations. First, we were working with unidentified student data; thus, we could not match student data collected across the two lessons, resulting in loss of power and inability to take student-specific differences across lessons into account. Second, the surveys used self-reported measures, which may suffer from bias due to respondents' subjective frames of references. Despite these limitations, exit ticket measures are increasingly being used in implementation research in education (Yeager et al., 2013) due their simplicity and ease of administration.

Figure 2

Estimated marginal means of "Yes" responses modelled using multilevel logistic regression



*** p<.001, ** p<.01, p-values were adjusted using the method of false discovery rate

Findings

To address our research question, we contrasted the perceptions of students in the cross-context group to students in two other schools where the CS-math connections were only taught in the CS lessons during computer lab time. Results from a three-level logistic regression model with random intercepts across exit ticket items (level-1), students (level-2), and classes (level-3) are presented in Figure 2. Across both the quadrilateral and triangle lessons and compared to their peers in the CS-only implementation, more students in the cross-context implementations found the lessons interesting, saw connections to their mathematics classes, and understood the programming, and these differences were significantly higher. For example, on the question related to *perceived connection between the CS lesson and their mathematics* class, the average probabilities of responding "yes" by the cross-context students were 94% and 90% for the quadrilaterals lesson and the triangles lesson respectively and were significantly higher than their peers in the CS-only group. This suggests that encountering CS and mathematics content in both the classroom and the computer lab helped students better see the connections. The average probabilities of responding "yes" were also significantly higher for students in the cross-context group on the questions related to *perceived interest in the lesson* and *perceived understanding of the lesson* (see Figure 2).

Conclusion and implications

This paper describes the co-design of fifth-grade cross-contextual mathematics and CS lessons. The approach involved identifying and highlighting CS connections across mathematics and CS contexts in expansively framed ways. This work thus contributes to a reconsideration of what CS integration can look like in elementary schools.

The paper also reports findings examining students' experiences of these lessons. Most students in the cross-context group reported that they found the lessons interesting, saw connections to their mathematics classes, and understood the programming; moreover, these perceptions were significantly higher than students in the CS-only groups. These findings show the value in building connections into classroom lessons and the importance of making and highlighting the connections, as suggested by the theory of expansive framing, between both the CS and mathematics contexts. While not the focus of the present study, helping students see the connections between mathematics and CS also has the potential to help them more deeply understand the content in both disciplines.

Understanding and Predicting Teachers' Intention to Use Educational Chatbots

Ismail Celik, Hanni Muukkonen
ismail.celik@oulu.fi, hanni.muukkonen@oulu.fi
University of Oulu, Finland

Abstract: Less is known about factors affecting teachers' educational chatbot use. Therefore, the current study attempted to extend Technology Acceptance Model (TAM) constructs (ease of use, perceived usefulness, and attitude) by adding subjective norm and trust; then, investigate how these constructs influenced teachers' intention to use educational chatbots. Results indicated that together ease of use and perceived usefulness contributed to attitude towards using educational chatbots, in turn, a positive attitude led to an increase in the intention to use. Whereas perceived usefulness is found to have positive effect on intention to use, no relation is seen between ease of use and intention to use. Further, subjective norm and teachers' trust in educational chatbots are found to be positive determinants of the intention to use educational chatbots. Our study implies that developers of educational chatbots should consider not only the technical but also the pedagogical features of chatbots.

Introduction

Artificial intelligence (AI) has become widespread in everyday life. In fact, whether we are aware or not, various technologies are operated with the help of AI, and these are described as AI-based tools. The chatbot is regarded as one of the most frequently utilized AI technologies (Wang et al., 2021). Today, many sectors such as business and health benefit from chatbots for several purposes. Recently, educational scientists noticed the pedagogical assets of chatbots in K-12 education (Luckin & Cukurova, 2019). The affordances of chatbots are expected to transform K-12 education into a more learner-centered approach (Celik, 2023). Specifically, chatbots offer personalized learning opportunities (Cox, 2021), and help teachers reveal learner needs (Luckin & Cukurova, 2019). Consequently, chatbots can reduce teachers' workload during the planning, implementation, and assessment stages of teaching (Celik et al., 2022).

Despite its demonstrated advantages, the integration of chatbots in K-12 education is lagging compared to other sectors such as business and health (Miao et al., 2021). This is explicitly related to the role of teachers in the educational integration of AI-based tools, which has been overlooked and neglected until now (Seufert et al., 2021). Indeed, teachers are considered as important end users of AI technologies and stakeholders of AI integration in K-12 education (Luckin & Cukurova, 2019). Therefore, the underlying factors that affect their intention to use chatbots are critical in terms of effective AI integration. However, little is known about such factors regarding teachers' chatbots use. Therefore, the current study aims to investigate factors affecting teachers' intention to use educational chatbots. To achieve this aim, we draw upon Technology Acceptance Model (TAM) since it is a robust framework in explaining user acceptance of emerging technologies (Arpaci, 2016). We created a research model of hypothesized relations using TAM constructs (perceived usefulness, attitude, and ease of use). In addition to these constructs; the research model incorporated two additional constructs namely *trust* and *subjective norm* to better explain the intention to use chatbots. Each hypothesis in the research model is detailed below.

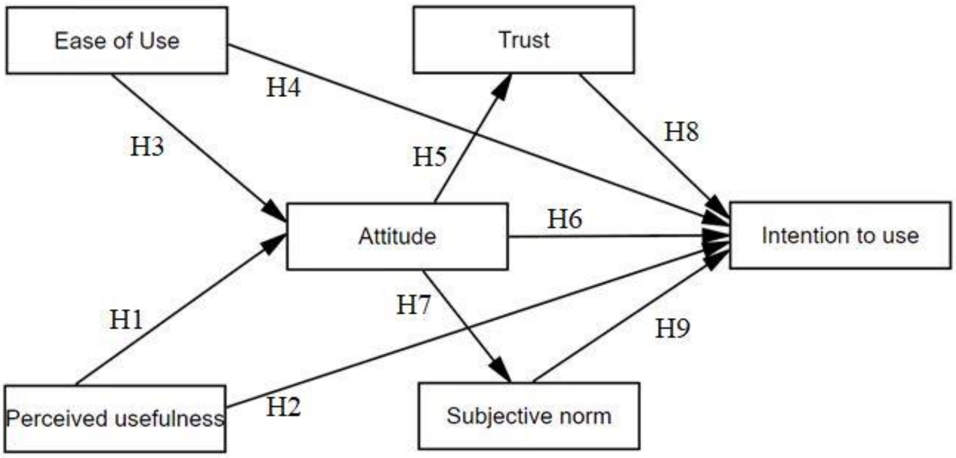
Research model and hypotheses

TAM refers to a theoretical framework that is validated to explain factors that determine the acceptance of information systems (Davis, 1989). Perceived ease of use and perceived usefulness are considered the main constructs that directly or indirectly predict behavioral intention for using technology. In the current study context, perceived usefulness refers to the degree to which a teacher believes that using educational chatbots enhances his or her work performance (Davis, 1989). The more teachers perceive chatbots as a useful tool (such as through searching for educational material on the Internet), the more likely they could have intention to utilize chatbots in their teaching. Meanwhile, ease of use is described as the degree to which a teacher believes the chatbot is effort-free to use (Davis, 1989). In this regard, as teachers perceive educational chatbots as easy to interact with, they might exploit these tools for teaching purposes. TAM posits that both perceived usefulness and ease of use are positively associated with attitude towards using chatbots, which is defined as a teacher's general affective response to the use of educational chatbots. Therefore, in light of TAM, we also hypothesize that attitude towards using a chatbot is a positive and significant determinant of teachers' intention to use such AI-based tools.

In order to contribute to the power of the TAM for explaining the intention to use chatbots, we added two research variables to the research model, subjective norm and trust. The extension of TAM with additional construct is also common in previous research (e.g., Arpaci, 2016). Trust refers to teachers' confidence in the reliability and trustworthiness of the suggestions and decisions offered by educational chatbots. Trust in using chatbots depends on the privacy issues and educational appropriateness of the chatbot suggestions. Subjective norm could be determined as teachers' perception of whether their counterparts who are important to them suggest they ought or ought not to use educational chatbots (Fishbein & Ajzen, 1975). We also argue that both trust and subjective norm are positively related to teachers' intention to use chatbots. In other words, when teachers trust in the chatbot suggestions and recognize their friends use chatbots, it is more possible for them to use chatbots. In this study, we propose the following hypothesis based on TAM and previous research. The hypothesized research model is illustrated in Figure 1.

- **H1.** Perceived usefulness positively influences teachers' attitudes toward using educational chatbots.
- **H2.** Perceived usefulness positively influences teachers' intention to use educational chatbots.
- **H3.** Ease of use positively influences teachers' attitudes toward using educational chatbots.
- **H4.** Ease of use positively influences teachers' intention to use educational chatbots.
- **H5.** Attitude positively influences teachers' trust in educational chatbots.
- **H6.** Attitude positively influences teachers' intention to use educational chatbots.
- **H7.** Attitude positively influence teachers' subjective norm about educational chatbots.
- **H8.** Trust positively influences teachers' teachers' intention to use educational chatbots.
- **H9.** Subjective norm positively influences teachers' intention to use educational chatbots.

Figure 1
Research Model



Methodology

Participants

In Turkey, the Ministry of Education developed an interactive environment for online distance education during the COVID-19 pandemic, namely EBA platform. All teachers working at the K-12 level in Turkey used the platform. In the process of distance education, a chatbot entitled *EBA assistant* started to serve as a conversational agent in the platform (Cbot, 2022). We collected self-reported data from 163 teachers (92 female, 71 male) with experience in using EBA assistants.

Data collection tool

To collect self-reported data, we developed an instrument based on previous research in TAM and chatbot acceptance. An online survey questionnaire was designed using the questionnaire items that had been successfully validated in previous research of perceived usefulness and ease of use (e.g., Davis, 1989), subjective norm, attitude, and intention to use (e.g., Ajzen, 1991), and trust (Arpaci, et al., 2015). Cronbach's alpha coefficients with number of items of the sub-scales: perceived usefulness (4 items, 0.87), ease of use (3 items, 0.78), subjective norm (3 items, 0.82), attitude (4 items, 0.75), and intention to use (4 items, 0.82).

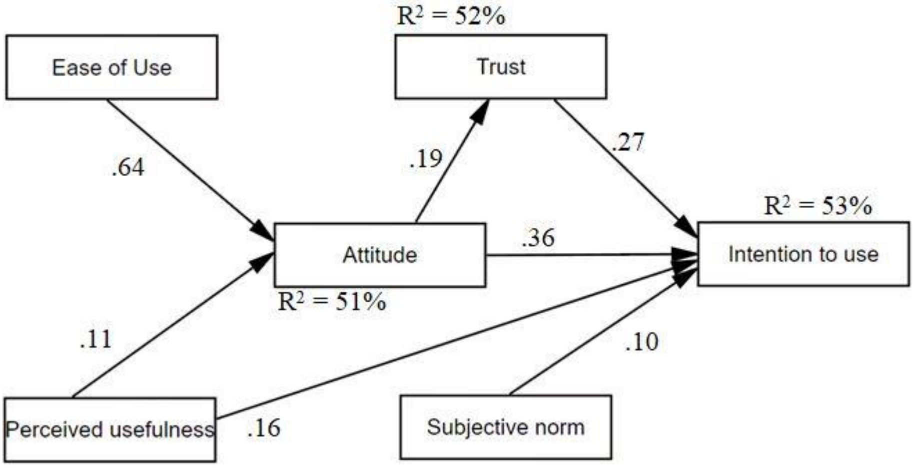
Data analysis

In this study, we performed the structural equation modeling (SEM) approach to test hypothesized relations that exist among the six research constructs. SEM analysis is a statistical approach to reveal the causal relationships among the variables (Bentler, 1990). To test the research model, the path coefficients, namely, the standardized regression values (betas) were determined. SEM analysis was performed through SPSS 22.0 and AMOS 18.0 software.

Results

SEM is performed to assess the relationships among the research variables: perceived usefulness, ease of use, attitude, trust, subjective norm, and intention to use chatbots. After removing the insignificant paths from the hypothesized model, the research model is acceptable with the standardized estimations showing a robust fit: $\chi2 = 2.548$, df = 2, p = 0.459; GFI = 0.998; AGFI = 0.986; CFI = 0.997; TLI = 0.999; NFI = 0.998; RMSEA = 0.012, according to good and acceptable fit indices suggested by Hu and Bentler,1999). As illustrated in Figure 2, perceived usefulness is found to positively influence the attitude ($\beta = 0.11$; H1 accepted) and intention to use chatbots ($\beta = 0.16$; H2 accepted). Ease of use is positively related to the attitude ($\beta = 0.64$; H3 accepted), but is no significantly associated with the intention to use chatbots (H4 rejected; $p>0.05$). Further, SEM analysis indicated that attitude towards using chatbots positively influences intention to use ($\beta = 0.36$; H6 accepted) and trust ($\beta = 0.19$; H5 accepted). However, no relationship is found between attitude and subjective norm (H7 rejected; $p>0.05$). Our analysis also reveals that the intention to use chatbots is significantly and positively related to both trust ($\beta = 0.27$; H8 accepted) and subjective norm ($\beta = 0.10$; H9 accepted). Together attitude and trust explain 53% of intentions to use chatbots. Also, 51% variance of attitude is accounted for ease of use and perceived usefulness. Attitude towards using chatbots explains 52% of trust in chatbots.

Figure 2
Research Model with Standardized Estimates



Discussion and conclusions

The current study attempted to extend TAM constructs (ease of use, perceived usefulness, and attitude) by adding subjective norm and trust; then, how these constructs influenced the intention to use educational chatbots. As we expected, both ease of use and perceived usefulness are positively associated with the intention to use chatbots. Further, whereas perceived usefulness is found to have a positive effect on the intention to use, no relation is seen between ease of use and the intention to use. This means, before using chatbots, teachers first need to recognize the educational benefits of chatbots. Further, whether a chatbot is easy to use or not, teachers should consider chatbots as useful technology; ultimately, they can use them for educational purposes. In line with previous research, in the acceptance of emerging technologies, perceived usefulness is a key determinant of the intention to use (Chocarro et al., 2021).

Together ease of use and perceived usefulness contributed to attitude towards using educational chatbots, in turn, a positive attitude reflected in more increased intention to use. Accordingly, as teachers believe that educational chatbot would foster their productivity and performance, and the chatbot is effort-free to use, their emotional reaction to chatbots is positively promoted. Supporting this finding, Bernard and Arnold (2019) suggested that emotional engagement with the virtual and intelligent agents has led to an increase in behavioral intention for using these agents. Teachers' trust in educational chatbots is found to be a positive determinant of intention to use educational chatbots. Indeed, teachers are reluctant to use chatbots when they think that decisions and suggestions of chatbots are not reasonable and meaningful (Nazaretsky et al., 2022). Further, if teachers have some concerns about data privacy, they can hesitate to utilize chatbots (Nazaretsky et al., 2022). Our study implies that developers of educational chatbots should consider not only the technical but also the pedagogical features of chatbots. SEM analysis also indicated that subjective norm is positively related to intention to use, meaning that if important people according to teachers use and suggest educational chatbots, teachers are also more likely to utilize chatbots for professional purposes. Collaboration and communication among teachers play an important role in the acceptance and integration of educational technologies (Watson & Rockinson-Szapkiw, 2021). In such a process, teachers might be aware of emerging technologies and the educational use of these technologies. As empirically evidenced in this study, the community influence on teachers' choice to use chatbots.

Abstract: As the grounded and embodied cognition (GEC) paradigm continues to inform teaching and learning research, action-cognition transduction (ACT) suggests that performing cognitively relevant movements can enhance students' conceptualizations. For learning mathematics, participants' awareness of the relationship between the cognitively relevant movements and the geometric conjectures they are reasoning about remains underexplored. Research in analogical problem-solving underscores the importance for problem solvers to notice similarities between two analogous domains before adapting the solution from one problem to the other. This pilot study investigates differences in participants' reasoning and gestures before and after receiving a hint drawing their attention to the cognitive relevance of the movements they performed. The data suggest that when correctly reasoning about the geometric conjectures, participants explicitly leveraged spontaneous replays of the cognitively relevant movements in their explanations after receiving the hint.

Introduction

Theories of *grounded and embodied cognition* (GEC) represent an emerging paradigm in cognitive sciences that increasingly inform research on teaching and learning (Nathan & Walkington, 2017) by describing the relationships between cognitive processes to learners' bodies and their environments. In particular, GEC research examines the role of sensorimotor processes, such as movement and gesture, and how they both influence and are influenced by cognitive processes. While several studies provide experimental evidence suggesting that movement can enhance cognitive states, not all movement has been shown to be equally beneficial (Nathan et al., 2014; Walkington et al., 2022). To construct suitable interventions leveraging these insights, it is necessary to understand what makes certain movements more effective than others in supporting learning.

Some GEC theories, such as *action-cognition transduction* (ACT) (Nathan & Walkington, 2017), suggest that body states that appropriately and reciprocally map to a concept improve performance on specific tasks like mathematical proof production (Nathan et al., 2014; Walkington et al., 2022). In this context, *body states* can refer to movements, poses, or preparatory motor programs (i.e., planning) that are activated. Some body states, such as gestures, have been shown to carry representational content useful in learning contexts. For example, Walkington and colleagues (2022) found that gestures can support an individual's ability to reason geometrically by focusing students' "limited cognitive resources on task relevant information gleaned from effective actions, which can facilitate the construction of schemas used in future task performance" (p. 27). Operationalizing these findings prompted the following research question: What factors can scaffold a learner to better "glean" the relevant information from these actions?

Theory

A growing body of research suggests that cognitive states can also be influenced by body states. Abrahamson and colleagues showed how eliciting a child's coordinated proportional movements (e.g., raising one's hands at rates in a ratio of 1 to 2) offers a sensorimotor basis for multiplicative reasoning (Abrahamson & Bakker, 2016). One theoretical model describing this bi-directional relationship between body states and cognitive states is *Action-Cognition Transduction* (ACT) (Nathan & Walkington, 2017). Demonstrating this relationship, Nathan and Martinez (2015) manipulated readers' gesture production while they learned from a scientific text. When participants' gestures were experimentally inhibited, their inference making in a subsequent learning assessment was also impaired

Scholars highlight that gestures can reveal the "leading edge" of what a speaker knows before they can verbalize that knowledge (Church & Goldin-Meadow, 1986). In a qualitative study of gesturing by students solving problems in mathematics classrooms, Garcia and Infante found students made two distinct types of gestures: *static (non-dynamic) gestures* -- gestures illustrating either an imagined mathematical object or a fixed length -- and *dynamic gestures* -- gestures that depict both an imagined mathematical object and perform transformations upon that object (Garcia & Infante, 2012). In support, Nathan and colleagues (2021) found that performing non-dynamic gestures predicted mathematical insight and intuition that was not well articulated verbally, while performing dynamic gestures was strongly predictive of a student's ability to produce valid mathematical proofs.

Learning scientists have investigated how eliciting gestures during educational experiences can foster learning. *Directed actions* are purposeful movements integrated into curricular activities that are given to learners to intentionally ground body movements to novel concepts. In mathematical thinking, researchers have explored the reciprocal effect of body states on cognitive states under the ACT framework by observing the effects that performing directed actions has on participants' cognition, their mathematical thinking, and performance on mathematical tasks (Nathan & Walkington, 2017; Walkington et al., 2019; Zhang et al., 2021). Evidence from these studies suggests that inducing body states through directed actions can, like gestures, impact learners' subsequent performance on cognitive tasks.

There is increasing evidence that directed actions can positively impact learning. Walkington and colleagues (2022) found that *cognitively relevant* directed actions significantly impacted students' proof performances compared to cognitively irrelevant actions (scrambled versions of the relevant action poses), and this effect was *moderated* by gesture. Specifically, participants who performed gestural replays of relevant directed actions as they were reasoning had superior explanations than those performing no gesture. Walkington and colleagues (2022) proposed that performing cognitively relevant directed actions leads participants to generate more accurate embodied simulations of the world around them. Though all learners performed directed actions throughout the experiment, only a subset also performed gestural replays. Identifying which factors encourage learners to replay directed actions remains understudied.

Participants might not replay directed actions because the movements do not activate an embodied simulation of the target concept (i.e., not activating an aligned embodied schema). The embodied schema might not be activating the *salient* features of a representation. Working memory theory (Baddeley, 2012) posits that attentional allocation to audible (verbal) and visuo-spatial (visual) information loads perceptual information into working memory. According to Mayer's (2014) Multimedia Learning, multimodal representations must complement one another while minimizing cognitive load. Since there is no guarantee that directed actions, as a pedagogical tool, will be taken up by the learner and used to scaffold their conceptualization, design features are *conceptually salient* when they convey information relevant to a target concept (Rau, 2020), that is, they must sufficiently activate an embodied action schema that does not anchor learners to non-salient features or disrupt the processes of conceptualization.

Research in analogical problem solving suggests that individuals solving a target problem fail to spontaneously notice the relevance of a semantically remote source analog (Gick & Holyoak, 1980). Research supports the importance of problem solvers noticing similarities between two analogous domains (Thomas & Lleras, 2007). Directed actions that are cognitively relevant to the target domain are designed to be better tools for fostering insights. Thus, we hypothesize that providing a verbal hint connecting movements (i.e., directed actions) to concepts may improve problem solving and proof production. In the current study, we use a new online platform built to invoke embodied geometric reasoning to address the following research question: How do participants' gestures and answers change after being provided a hint regarding the cognitive relevance of the directed actions?

Methods

A convenience sample of 27 university students were recruited for this study. Participants played through an online augmented reality game built for this experiment to capture evidence of learners' connection between movements, mathematical thinking, and verbal reasoning (Fogel et al., 2022). The game, *The Hidden Village-Online* (THV-O), takes players through an eight-chapter story about a two-dimensional world populated by different shapes. Using a webcam, THV-O detects participants' bodies in real time and leverages the positional data to project a real-time animation of the player into the fictional world of shapes with an on-screen avatar that is effectively a mirrored image of the player.

To investigate the influence of movements on cognitive states, players were directed to perform the directed actions before they began reasoning about each geometry conjecture. To avoid ordering effects, tasks were ordered using a Latin-square factorial design. The directed actions for each conjecture were designed to be cognitively relevant (ref. Nathan et al., 2021; Nathan & Walkington, 2017; Walkington et al., 2022) to reasoning about the statement. Participants were to indicate whether a conjecture was true or false, then explain *why* they believed the statement to be true or false. Participants were video recorded as they played THV-O. For the intervention, after the fourth conjecture, players were given a semi-structured interview, at the end of which they were given the following hint (inspired by those provided in analogical problem-solving experiments): "*performing some movements can be helpful while reasoning about abstract concepts, like geometry*", before playing through the remaining 4 conjectures.

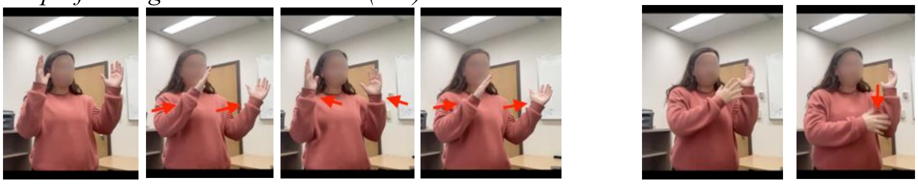
We analyzed the video and transcript data qualitatively using a coding scheme developed through a grounded approach informed by prior analyses (Nathan et al., 2021) on similar data. Specifically, we identified when individuals performed a REPLAY GESTURE, indicating when a participant (unprompted) spontaneously recreated the directed action as part of their explanation; this gesture could be a dynamic or a non-dynamic reproduction of the directed action. Cohen's κ was estimated for the code, with agreement exceeding the conventional κ = 0.65 threshold for inter-rater reliability.

Results

Before receiving the hint, some participants performed a REPLAY GESTURE as they reasoned about the conjecture. However, the verbal rationale accompanying the gesture did not explicitly reference how their movements informed their thinking. After receiving the hint, some used a REPLAY GESTURE, or a precise recreation of the directed actions, as a grounded warrant to support their evaluation of the conjecture. For example (Figure 1), participant Jill (a pseudonym) explicitly referenced the directed actions in her explanation and performed a REPLAY GESTURE raising her hands in front of her face (Figure 1A), then moves arms to the side (Figure 1B), then back (Figure 1C) and forth (Figure 1D) again.

Figure 1

Jill performing a REPLAY GESTURE (A-D)



(A) (B) (C) (D) (E) (F)

[1] The area of a parallelogram is the same as the area of a rectangle with the same base and height. True
[2] So this one with the movement... <performed REPLAY GESTURE, shown in (A)-(D)>
[3] These are the same length. So that's why I would think it's true. You're just moving them...
[4] But the length of my hand isn't changing. <performed a *static* depictive gesture, shown in (E)-(F)> So…

In line [1], Jill restated the conjecture she was reasoning about and correctly evaluated that the statement was true. Having provided correct intuition, Jill referenced the directed actions she had performed just before and performed a REPLAY GESTURE, emphasizing that the length of the two shapes represented by the discrete poses she moved between "are the same length...you're just moving them" (line [2]), suggesting that she had gleaned relevant information from the directed actions in justifying her response.

Discussion

Consistent with findings from prior studies (Walkington et al., 2022), some participants performed REPLAY GESTUREs while providing an explanation before receiving an explicit hint. After receiving a hint, some participants' REPLAY GESTUREs explicitly supported their correct verbal evaluation of the geometric conjectures. Explicitly supporting their evaluation with REPLAY GESTUREs suggests that the hint could help lead people to consciously leverage the cognitive relevance of the movements. Additionally, scaffolding the conceptual salience of the directed actions through scaffolds like hints can help optimize the efficacy of interventions using directed actions. We suggest that directing people to make cognitively relevant body movements can help improve their mathematical reasoning, especially when the salience of movements remains outside of conscious awareness.

Future studies will use sets of related conjectures to attempt to further isolate changes in behavior as a result scaffolding interventions. Admittedly, performing the cognitively relevant movements is not guaranteed to improve performance (ref. Walkington et al., 2022), and students did not perform REPLAY GESTUREs when evaluating every conjecture. Just because a subject matter expert selects a series of movements they deem relevant does not guarantee that the learner perceives what is salient. Moreover, whether hints or other scaffolds are the best type of intervention remains unclear.

Not without limitations, this study, as most pilot work, had a small sample size. Thus, we can only provide qualitative evidence to support these claims. Collecting more data and conducting further qualitative data analysis, including quantitative and quantitative ethnographic techniques, will strengthen our ability to make these claims. Nonetheless, a growing corpus of evidence suggests that when directed actions are cognitively relevant, they can be effective at reinforcing a grounded understanding of abstract concepts like universal geometry theorems and improving mathematical reasoning. Individuals do not have to be aware of the relevance of the directed actions for there to be benefits for problem solving—they can make that deductive leap as they reason about the mathematics. Investigating guidelines and best practices for how to design and deploy effective directed actions could help address this issue. Overall, designing cognitively relevant directed actions seems to hinge on the participant's recognition of such. Refining the design and presentation of cognitively relevant directed actions to improve mathematical reasoning allows us to better integrate them as pedagogical tools in embodied and grounded curricula.

Abstract: Developing models and using mathematics are two key practices in internationally recognized science education standards such as the Next Generation Science Standards (NGSS, 2013). In this paper, we used a virtual performance-based formative assessment to capture students' competencies at both *developing* and *evaluating* mathematical models in science inquiry contexts aligned with the NGSS (2013). Results show that model development and evaluation competencies are correlated, but students who demonstrate proficiency with model development often struggle with evaluation. Nuanced data illustrate how components of modeling competencies differ and how they may be related.

Introduction

Standards such as the Next Generation Science Standards (NGSS, 2013) emphasize that students must become competent at key science practices, including "Developing and Using Models" (Practice 2) and "Using Mathematics and Computational Thinking" (Practice 5). Here, we define *mathematical models* as mathematical representations, such as equations and graphs, that illustrate and predict scientific phenomena (Harrison & Treagust, 2000). The NGSS (2013) expects that students will "develop and/or use [models]…including mathematical models…to generate data that support explanations, predict phenomena, analyze systems, and/or solve problems" and evaluate the limitations of those models because they "contain approximations and assumptions that limit the range of validity and predictive power" (NGSS 2013, Appendix F, p. 6). However, students often struggle in many ways, such as: labeling axes and selecting data for graphical models (Lai et al., 2016), explaining the underlying assumptions and limitations (Nixon, et al., 2016), and ascertaining validity by comparing models to real-world data (Wilensky & Reisman, 2006).

To help students become more proficient at mathematical modeling, we are iteratively designing virtual labs that require students to build mathematical models as part of their investigative process within the Inquiry Intelligent Tutoring System (Inq-ITS; Dickler et al., 2021; Olsen et al., 2022). Inq-ITS labs are designed to be performance-based formative assessments, using educational data-mined and knowledge-engineered algorithms to automatically assess students' competencies (Gobert et al., 2013; Sao Pedro et al., 2013b). In recent work, we developed algorithms to auto-score how students create graphs and build best bit curves through data.

In this study, we explore what kinds of challenges students have when building mathematical models to better understand what kinds of support students may need to be successful. We expect that students with the highest proficiency can: (1) effectively develop mathematical models of scientific phenomena, (2) articulate the assumptions they made when building their model, (3) articulate how the assumptions impose limitations on how well the model can make valid predictions, and (4) richly integrate understanding of the scientific phenomenon (Schwarz et al., 2009; Windschitl et al., 2008). Given the complexity of mathematical modeling, many students may fall in the "messy middle," where they have "some pieces of knowledge and ability to respond to complex science tasks, but not all" (Gotwals & Songer, 2010, p. 277). To better understand students' competencies with mathematical modeling, we address the following research questions: (1) To what extent are students' model development and evaluation competencies correlated, and (2) When students' model development and evaluation competencies differ, what difficulties do students seem to demonstrate?

Method

Forty-one middle and high school students from four different teachers completed an Inq-ITS momentum virtual lab (NGSS DCI PS2.A). Its goal was to have students develop a mathematical model (i.e., graph and corresponding equation) that illustrates how the mass of a moving car affects its momentum before colliding into a stationary car. During the first three stages of the investigation (Collecting Data, Plotting Data, and Building Models), students collect data using a simulation, select the x- and y-axes for their graph, select which data to plot on their graph, determine the type of mathematical function (i.e., linear, inverse, square, inverse square, or horizontal) that best fits the shape of the plotted data, and select a coefficient and constant for that mathematical function that best fits the data on the graph. Students' scores on these stages were calculated using previously developed algorithms (Dickler et al., 2021). The activity then prompts students to write in their own words a reflection on their model development process. Specifically, students are asked the following question:

> "Your mathematical model makes predictions about the momentum of Car #1 before the collision when you change the mass of Car #1. Do other conditions need to be met in order for your mathematical model to make good predictions? For example, do other variables like the mass of Car #2, or the velocity of Car #1 before collision need to be specific values? Can they be different values? Please explain and provide enough detail so that a friend who did not build your mathematical model could reconstruct it and could understand how to use it."

Measures

We refer to students' performance on the first part of activity as their *model development competencies* because the tasks require students to construct a mathematical model (best-fit curve) from data they collect. We measure these competencies as the sum of fine-grained, sub-practice scores, which were automatically assessed as either 0 (incorrect) or 1 (correct) using educational data-mined and knowledge-engineered algorithms that generate scores based on students' interactions within the Inq-ITS environment (Sao Pedro et al., 2013b; Olsen et al., 2022). We note that performance on these tasks may also indicate competency in other practices as well.

We refer to how students evaluate their models through writing as their *model evaluation competencies* because this task requires students to evaluate the limitations of the mathematical model they developed. Automated scoring was not available for this prompt as this activity is still in pilot testing. Thus, two of the paper's authors independently hand-scored all students' responses across two dimensions: correctness (0 for incorrect or non-answer, 1 for partially correct, 2 for fully correct) and relevance (0 for not relevant, 1 for relevant). Authors agreed 100% for the *relevance* dimension and 82.9% (unweighted Cohen's kappa = 0.70) for the *correctness* dimension. Disagreements were discussed, and the agreed-upon scores were used for analyses.

Results

RQ1: Comparing students' model development and evaluation competencies

We first examined the relationship between students' scores on the two types of competencies using a Pearson's correlation. Students' model development and model evaluation competencies were moderately positively correlated, $r(39) = .58, p < .001$, suggesting that students tend to be proficient (or not) at both competencies together. Though a correlation was performed, it is likely that model evaluation is, at least in part, dependent on students' competencies with model development, as suggested by learning progressions (Schwarz et al., 2009).

Table 1

Raw count and percentages of students (N = 41) with each categorical competency level. Note: The "Medium" (7-8) range for model development had no students and is omitted.

		Model Development Competency Level	
		Low (Scores: 0-6)	High (Scores: 9-10)
Model Evaluation Competency Level	Low (Scores: 0-1)	8 (19.5%)	10 (24.4%) *Messy Middle Group 1*
	Medium (Score: 2)	2 (4.9%) *Messy Middle Group 2*	18 (43.4%) *Messy Middle Group 3*
	High (Score: 3)	0 (0.0%)	3 (7.3%)
	Total	10 (24.4%)	31 (75.6%)

We further disaggregated their performance on each competency into "high," "medium," and "low" categories (Table 1) to examine cases where students performed well at one competency and not another. Most students (75.6%) performed "high" on model development, indicating that these students have the inquiry competencies (e.g., collecting unconfounded data) and mathematical/graphical competencies (e.g., determining the best-fit curve) to complete the activity. However, very few students (7.3%) performed "high" on model evaluation, suggesting that students may not fully understand the importance of collecting and plotting controlled data, or they may struggle with describing how to evaluate models. These findings suggest a need for supports, like embedded real-time scaffolding, that can address these difficulties.

RQ2: Differences between model development and evaluation

As shown in Table 1, there were three groups of students in which competencies did not align. For each group, we triangulated the interaction logs of how students built their models with the written text of how they evaluated their models to identify any commonalities for how students struggle.

Group 1: High model development, low model evaluation

Students in Group 1 (24.4%) were proficient at developing models but stated incorrect and/or irrelevant responses when evaluating their model. For example, Student A, who had no errors when developing their model, stated, "no nothing else needs to be added because its [*sic*] very accurate." Another student, Student B, with no errors simply responded, "The line best fits the dots." These responses suggest that although these students can execute the procedures of developing mathematical models, they may lack conceptual understanding about how that process embeds assumptions and limitations about their model. For example, by stating that their models are "very accurate" and "fits the dots," they may believe that their model does not have any limitations. They may not recognize that their model will only predict well when the other variables for which they controlled have the exact same measurements. Such students may require supports that highlight the importance of the variables they controlled and how those controls impact the general applicability of their models.

Group 2: Low model development, medium model evaluation

Only two students (4.9%) demonstrated poor model development competencies. Student C plotted uncontrolled trials, and Student D selected the incorrect variable for x-axis. Both students did not recognize their errors when looking at the graph, which could suggest that they may be struggling with interpretation (Glazer, 2011). Therefore, students in this group may require more targeted support on specific sub-practices (e.g., plotting controlled trials for Student C and choosing the axes for the graph for Student D).

Group 3: High model development, medium model evaluation

Students in Group 3 (43.4%) were proficient at developing models but gave only partially correct answers when evaluating their models. One consistent error made by these students was stating that the "mass of the stationary car" needed to be a certain value for the model to be used to make predictions. However, students should recognize, either through prior scientific content knowledge or the virtual lab investigation, that only the *velocity of the moving car* needs to remain constant since this is the only other simulation variable that would affect the moving car's momentum *before* the collision with the stationary car. This finding aligns with previous research showing the need to support students in defining the boundaries of their models (Eidin et al., 2020), which may help students to develop a deeper understanding of the scientific phenomenon being modeled (Wilensky & Reisman, 2006; Windschitl et al., 2008), as envisioned by the NGSS (2013).

Discussion

Developing and evaluating mathematical models in science inquiry contexts is important for science learning (NGSS, 2013). However, teachers rarely provide students with the opportunity to construct and evaluate their *own* models (Schwarz et al., 2009). Furthermore, assessing these competencies is challenging (Furtak et al., 2017). Here, we presented a novel design for Inq-ITS virtual labs to formatively assess students' competencies on fine-grained components of NGSS-aligned mathematical modeling practices. By unpacking NGSS Practice 2 (Developing and Using Models) and Practice 5 (Using Mathematics and Computational Thinking), assessments can provide important information on students' modeling competencies. We used the virtual labs to investigate how students develop and evaluate mathematical models, and what specific difficulties they encounter when doing so. Consistent with prior work on constructing and critiquing graphs (Vitale et al., 2015), we found that students' model development and evaluation competencies are correlated, but that many students who performed well on model development still struggled with model evaluation. More specifically, students in the "messy middle" who performed well on model development tended to struggle with understanding how the development process affects the limitations of the model (e.g., Group 1) or how the boundaries of the system can also affect the limitations of the model (e.g., Group 3). Our findings also shed light on the importance of *fine-grained* assessments that can specifically target the sub-components of modeling practices. Namely, we found that students in Group 2 had different difficulties with the model development stages, which teachers would need to address differently when providing support. These findings suggest that students' difficulties with facets of modeling are likely varied. As such, it is vital that formative assessments are operationalized at a fine-grained enough level to identify exactly how students are struggling so that optimum support may be provided.

Overall, the design work presented in this paper sheds light on how online formative, performance-based assessments can be used to capture rigorous, rich, and nuanced data on students' competencies. With this data, systems, like Inq-ITS, can be further augmented to provide targeted, real-time support to students on the specific sub-practice for which they are struggling as well as to teachers on how best to support their students. Furthermore, this work contributes to and deepens the existing literature on general scientific modeling (e.g., Schwarz et al., 2009; Windschitl et al., 2008) by drawing a deeper attention to *mathematical* modeling done in the context of science inquiry, important to NGSS (2013) Practices 2 and 5. By developing scalable formative assessments that address students' competencies with both *developing* and *evaluating* mathematical models in science inquiry contexts, we can begin to address inter-dependencies between these aspects of modeling to develop a learning progression that includes components of scientific mathematical modeling competencies. Furthermore, unlike previous work on science graphing (e.g., Vitale et al., 2015), we assess students' competencies with evaluating models they developed themselves, capturing a more authentic, integrated version of the science practice envisioned by the NGSS (2013). Although the virtual lab in this study focused on only one physical science topic (i.e., momentum) and one type of mathematical relationship (i.e., linear), future work will investigate mathematical modeling across a broader range of science topics.

Abstract: Teachers play critical roles in both co-design processes and intervention studies, yet both approaches have distinct theoretical underpinnings that impact how teachers interact and what they contribute. In this paper, we analyze the co-design and implementation of an intervention called *Fraction Ball (FB)*, a game-based curriculum that teaches fractions and decimals to elementary students. We present preliminary analysis of the contributions from teachers who participated in the co-design or intervention study. We argue participating in different aspects of the project will illuminate different factors that might affect the implementation, and lead to different adaptations to address these factors. Teachers identified nine factors as influential in the implementation of *FB* across four levels, including school, teacher, students, and intervention levels. The findings demonstrate that teachers contribute differently based on their role in the project and has implications for how we co-design interventions and frame teachers' roles in the future.

Introduction

Teachers play critical roles in both co-design and intervention studies such as Randomized-Control Trials (RCT). In co-design, teachers and researchers engage in a collaborative process to develop curriculum that fit into the learning context and address their unique needs (Penuel et al., 2007). Such curricula can then be used as classroom intervention materials. In RCTs, teachers are positioned as participants that enact interventions designed by researchers and their collaborators. Co-design and RCT processes have different theoretical assumptions, affecting how they are typically developed and studied and teachers' roles within them. In our paper, we present a study that examined teachers' contributions in the co-design process and intervention study of *Fraction Ball (FB),* a game-based curriculum that teaches fractions and decimals to elementary schoolers (Bustamante, 2022). We co-designed the *FB* intervention with two schools and implemented an RCT with four different schools, all in the same school district. We describe the factors that teachers identified as important for the success of *FB* and discuss what they did or suggested to address them (i.e., adaptations).

Perspectives and theoretical framework

Traditional RCT studies prioritize fidelity, reflecting how researchers want participants to implement their interventions as designed with minimal deviation (Carroll et al., 2007). Yet, there is a growing movement to examine the adaptations that inevitably emerge when interventions are implemented (Durlak & DuPre, 2008). There is a long history of education research that observes that teachers, almost always, make modifications to new interventions in their classroom (Lipsky, 2010). Such adaptations have been shown to improve learning outcomes, as teachers typically make adaptations based on their experiences and knowledge of their students and learning environments (Durlak, 2010). Durlak and DuPre (2008) highlight the factors that often affect interventions including community factors, personnel characteristics, and innovation characteristics. These topics are often the focus of the co-design, wherein researchers begin by understanding the community context, the teachers' needs and the learning context to create innovative learning materials.

Scholars who study interventions argue that community participation in designing innovations can improve outcomes and inform fidelity and adaptations (Durlak & DuPre, 2008). Theoretically, co-design processes argue for the process of mutual adaptation from the beginning. Mutual adaptation is the process of researchers and stakeholders dynamically altering the intervention to improve and strengthen the innovation (Lotan et al., 1986). Co-design foregrounds mutual adaptations by asking teachers to engage in design with researchers while explicitly addressing their unique learning goals and context (Fishman et al., 2013; Penuel et al., 2014), whereas intervention studies prioritize mutual adaptation less often. Whether interacting in the co-design process or intervention studies, teachers have different pedagogical preferences, organizational politics to navigate, along with classroom needs, values, and norms that affect how they design and implement curriculum.

In this paper, we present a preliminary analysis of the different contributions toward the *FB* intervention from teachers who participated in the co-design or the RCT. We argue that implementing an intervention compared to imagining what implementation might be like includes different assumptions and processes, therefore, leads to different factors that affect the implementation, and in turn, different adaptations to address them. We ask the questions, *what factors do teachers identify that might influence the implementation of FB* and *what adaptations do teachers create to address these factors?*

Methods

FB is a learning activity that utilizes a basketball court painted into equal segments to reinforce fraction and decimal learning (see Figure 1). The spatial layout of the court is designed to reinforce fraction magnitude understanding, and students' shots are translated into fraction and decimal points and tallied on a number line. Students work in groups to play a series of games shown to improve students' rational number understanding. This study was completed as part of a multi-year research-practice partnership with a public school district in a low-income, predominantly Latine community in Southern California. We worked with six elementary schools: two schools in the co-design ($N = 20$ teachers) and four different schools in the RCT ($N = 16$ teachers).

Figure 1

Left: FB court. Middle: Students keeping teams' score on the number line. Right: Students working on a collaborative classroom lesson.

We collected video data, observation notes, and artifacts during co-design sessions where the focus was to create classroom lessons for *FB*. We held five 90-minute co-design sessions, repeating the first twice and the second three times. In the first session, we play-tested an existing game and lesson and generated new lesson ideas. The second session consisted of a gallery walk of the lessons that teachers created, with small group work to iterate and develop a cohesive lesson.

We conducted an RCT with four schools and 16 teachers using the co-designed curricula as the intervention. Eight teachers taught *FB* and eight taught their class business-as-usual. Teachers were supplied with an activity guide, lesson scripts, slide decks, worksheets, and materials needed to facilitate the intervention that were developed through our co-design process. After the intervention, we recorded hour-long focus groups with the eight teachers who implemented *FB*. Control teachers were not interviewed.

To analyze the co-design and intervention data, we first conducted affinity diagramming (Hanington & Martin, 2012). We examined all data and pulled ideas and feedback into design ideas and inductively clustered data into themes. We analyzed 305 data points from the co-design sessions and 345 from the implementation. To achieve reliability, two researchers analyzed the co-design data, and three researchers analyzed the implementation data, negotiating themes and reviewing the data until consensus was reached. We then leveraged those themes to identify factors that impacted *FB*. Through an iterative process of clustering, three researchers synthesized findings into nine preliminary factors within four levels.

Findings

We identified nine factors, across four levels including school, teacher, students, and intervention levels (see table 1 for definitions and examples of adaptations that emerged). At the intervention level, teachers highlighted three factors – management and facilitation in the classroom and on the court and the sequence of the lessons. Teachers differentiated the classroom and court because the routines and materials are different working within the boundaries of their classrooms compared to outside on the court. Student level factors included their prior knowledge around the math concepts and basketball, sense of belonging and representation, and inclusion. While much of the focus of the co-design and implementation was on the intervention and how it might support student learning, teachers described factors regarding their needs and the school logistics. At the teacher level, two factors emerged – community and support, and preparedness. Teachers emphasized that a teacher community was critical so they could collaborate and learn from each other and highlighted the need for materials to help them learn the games and implement *FB* with ease. Lastly, teachers called attention to the school factors, or contextual details at the schools that might affect *FB*. These factors varied from school to school but included booking courts, handling noise on the court, and managing schedules. In table 1 we describe examples of how teachers suggested or implemented adaptations to address these design factors. First, we note that not all factors had adaptations. For instance, making *FB* inclusive for all students, especially those with different learning abilities was a high priority for our co-design teachers, compared to our intervention teachers where it was not a focus. Similarly, students' sense of belonging was not a focus of our co-design sessions, however several teachers who implemented the intervention made it a priority in their classrooms.

Table 1
Factors teachers identified that might influence FB, and their adaptations to address them.

Level	*Factor*	**Definition:** Definition of factors	**Adaptations:** What teachers did or suggested to address these factors
Intervention	*Classroom management and facilitation*	The routines and materials needed for teachers to ensure the instruction is delivered in the classroom.	Co-design: Create scripts that are detailed but not overwhelming for classroom lessons. Intervention: Teacher consolidated a worksheet into one page to consolidate activity.
	Court management and facilitation	The routines and materials needed for teachers to ensure the instruction is delivered on the court.	Co-design: Adding a tracking sheet on the court so more students can document shots. Intervention: Teacher created a roles chart, so students know where to go.
	Sequencing	How concepts and aspects of *FB* are ordered.	Co-design: Front loading instructions about the game before moving to the outdoor court. Intervention: Finish intervention with games that are particularly fun.
Student	*Prior knowledge*	How students' background knowledge on math or basketball affects *FB*.	Co-design: Simpler activities for students who have less fraction knowledge. Intervention: Teacher connected past lessons with current lesson to build connections
	Student belonging and representation	Helping students see themselves in the curriculum and game play.	Co-design: N/A Intervention: Teacher built a bulletin board so kids could see themselves playing the game.
	Student inclusion	Sensitivity to students of all physical and learning abilities.	Co-design: Refashioning *FB* into Cornhole increases accessibility. Intervention: N/A
Teacher	*Teacher community & support*	Creating a community for teachers to support each other through *FB* implementation.	Co-design: PE teachers and math teachers need should be in close communication to make sure learning goals are aligned. *Intervention*: Call for conversations between teachers about their experiences with *FB*.
	Teacher preparedness	Training and readiness so that teachers are prepared and ready to deliver instruction	*Co-design*: Wanting digital worksheets so that there is no paper preparation. *Intervention*: Video of students playing FB to teach teachers.

School	*Logistics*	Fixed contextual details at the school level that affect the implementation of *FB*.	*Co-design*: Book courts in advance when space is limited, using megaphones to counter noise. *Intervention*: Rescheduling *FB* when it conflicts with a school-wide event.

Discussion and conclusion

Our study identified factors that affected the *FB* intervention from both co-design and RCT teachers' perspectives, and adaptations they suggested or implemented to address them. The high-level factors that emerged mirror findings from Durlak and DuPre (2008) regarding aspects that affect interventions (e.g., community, personnel, and intervention factors). The factors highlight elements that emerged for teachers, including potential tensions, areas for improvement, and sometimes fixed constraints at different levels. The adaptations that teachers made or suggested illuminate possible solutions to those factors, and ideas that make our intervention more usable and flexible in the classroom (Lortan et al., 1986). However, we also acknowledge that not all factors have adaptations to address them. Due to the theoretically different approaches to co-design and RCT studies (Durlak & DuPre, 2008), some teachers in the intervention felt constrained by the materials and that they could not make adaptations to the materials so as not to alter the research findings. As opposed to the co-design teachers, who were encouraged to make changes from the start. Additionally, because this is an innovative, game-based intervention that was new to teachers, coming up with adaptations can be challenging. Identifying the differences between teachers participating in the co-design or RCT informs how we might co-design interventions in the future, how we might frame teachers' roles differently to support adaptation and highlights the differences in contributions teachers make at different stages in the project. Our future work will apply this code book to the entirety of the dataset to explore the frequency of these factors, all adaptations that emerged to address them, and the differences between teachers' who engaged in the co-design and intervention.

Fostering Youth Identity Development Through Critical Pedagogical Practices and Agentive Action in Sustainability Learning

Isis Howard, Arizona State University, ilhoward@asu.edu
Michelle Jordan, Arizona State University, michelle.e.jordan@asu.edu

Abstract: This DBR study examines how critical pedagogical practices of testimonios and intersectional modeling coupled with agentive techniques engaged youth in holistic identity development. We qualitatively analyzed observations, interviews, and artifacts related to seven youths' participation in an informal program focused on community-centered renewable energy engineering framed by sustainability learning. Findings suggest that coupling of student agency with critical pedagogical practices allowed youth to connect their agentive action in their community and fostered youth holistic identity.

Introduction

Normative cultural education practices rarely address different cultural knowledge as an asset and often limit opportunities for youth from minority communities to have meaningful learning experiences that foster identity development. Innovative instructional practices are needed to engage youth from minority communities in agency and identity development. This study is concerned with these issues in relation to sustainability learning experiences for high school youth from the same Latin@ community. Youth from minority communities in particular often operate in educational spaces that deny their cultural knowledge and experiences and limit their agency in their community and academic spaces, particularly with sustainability issues in which minority communities are disproportionately impacted by environmental issues (Beltrán et al., 2016). *Sustainability* in this context is defined as meeting the environmental, social, and economic needs of the present while supporting the needs of the future (Trott & Weinberg, 2020). Consequently, it is recognized as a larger social issue where youth, especially minority youth have an impact. Although *agency* has been well researched in the field of sustainability education, more attention to critical pedagogical perspectives and its effect on agency is needed. Along with engagement with sustainability, there is a need to design learning experiences from a critical perspective that examines the intersections of youths' identities as a resource for sustainable practices (Maina-Okori et al., 2018). Thus, the purpose of this design-based study was to design and test an approach to fostering youths' holistic identities in an informal learning program, exploring how critical pedagogical practices and agentive practices foster identity development and help youth relate their identity to sustainability.

Literature review

Critical pedagogy is a field of research that aims to analyze power and oppression and their relation to education. Over time, researchers have critiqued this framework and extended its pedagogical practices. For instance, *border pedagogy* engages students in critical thinking around power, meaning, and identity (Cervantes-Soon & Carrillo, 2016) using pedagogical practices such as *testimonios* to challenge dominant education narratives of knowledge and allow learners to use their knowledge to debate power issues using their history, experiences, and identity. Testimonios practice was centered in the current study's designed learning environment because it allows individuals to engage in discourse around their personal experiences and co-create an understanding of cultural and social influences on "our material realities and perspectives of life" (Cervantes-Soon & Carrillo, 2016, p. 292), while reframing dominant knowledge related to sustainability.

In conjunction with critical pedagogical practices, fostering youth agency is an essential commitment that guides the designed learning innovation that is the focus of this study. Individual agency is needed to promote transformational action in communities (Stetsenko & Arievitch, 2004). People's identities are created and shaped by these agentive actions. Agency is an essential aspect of sustainability education because it fosters youths' abilities to change the social norms that challenge youths' involvement in their community. Therefore, to engage youth in identity development, designs must engage participants in consequential learning and position them with rightful presence (Calabrese Barton & Tan, 20191). Moreover, positioning youth as contributors to their local community by engaging in real work with real consequences can facilitate opportunities for identity development and agency (Jordan et al., 2021).

In this study, we frame identity using a holistic identity lens. *Holistic identity* pertains to the co-development of social (e.g., race, ethnicity, gender) and role (e.g., student, engineer, mentor) identities (Stets & Burke, 2000). Examining multiple factors of identity is important as individuals belong to multiple identities at once, and these intersections create unique experiences of privilege and oppression (Crenshaw, 1989). As a result, researchers have developed models to allow individuals to examine their intersecting identities and acknowledge that multiple intersecting identities influence how individuals understand other aspects of their identity and themselves as a whole. Additionally, individuals' identities are simultaneously being shaped and are shaping social interaction in their communities, including interactions related to sustainability efforts.

Method

This study took a design-based research (DBR) approach (Mckenney & Reeves, 2019) to enact multiple iterations of a co-designed innovation coupling critical pedagogical practices with youth agency. We conjectured that the intertwining of critical and agentive practices in the design of sustainability learning environments would allow youth to critically reflect on their identity and how it relates to their community and their idea of sustainability. Further, as youth develop their holistic identity, they will be able to connect their identity to the sustainable agentive actions they undertake within their communities. The research question guiding our qualitative interpretive analysis was as follows: *How does coupling critical pedagogical practice with agentive practices engage youth in holistic identity development related to sustainability practice?*

Participants and context

This study was part of a larger design-based innovation designed to engage high school scholars intentionally recruited from the same local community in energy engineering research. In the instantiation of the program that is the focus of the current analysis, seven youth participants participated in the program, five of whom identified as Latin@, one identified as White, and one as Asian. Six of the youths identified as female and one as male. These youth scholars initially spent six weeks in a summer research experience program, collaborating with university researchers to learn about sustainable energy transitions, develop research questions, build solar energy monitoring systems, and mediate between scientists and middle school partners who would implement the project in their shared community during the subsequent school year. This initial intensive learning experience was followed by monthly meetings across the school year, during which the youth engaged in the focal activities of the current study, described below. Both authors were co-designers of focal activities. The first author is a master's degree student in a learning sciences program who identifies as an Afro-Latina female. The second author is a university professor who identifies as a White female.

The critical pedagogies that comprised the focal activities for this study were enacted across two workshops that occurred over four sessions during the second half of the school year. Workshop 1 began with framing the connection between youths' identity, their community, and sustainability in their work on their collective project. We invited youth to connect sustainability, community, and identity through a photovoice-inspired testimonio project. The first author led the youth in reviewing the UN Sustainable Development Goals (SDGs) and introduced the challenge: Take and post a photo that represents a solution to address one of the UN SDGs in your community; explain why you chose that goal and how your solution contributes (or not) to the social transformation of sustainability. During the subsequent session, the youth reported on their solutions and reflected on how sustainability is related to their community-engineering project and their identity. Youths then reflected on how their actions contributed to social transformation in their community using contradictions and resistance as a frame (McWilliams & Penuel, 2017) to understand the impact of their testimonio-proposed solutions and their collective project.

During Workshop 2, youth completed intersecting identity models (Jones, 2016), which included aspects of their social and role identities (e.g., race, gender, career goals), and compared them to their middle school partners' models. This activity also informed their subsequent feedback as critical friends to the middle schoolers on a similar SDG activity. The feedback session was framed by having the youths connect to the conversations about the contradiction and resistance of sustainability efforts in the first workshop. Youths were tasked with providing feedback on how the middle schoolers could address their holistic and community identities in the activity and how their work could address contradictions in sustainability efforts. This pedagogical practice allowed youth to reflect critically on the relationship between their own and community members' identities. The workshop highlighted why it is essential to understand our identity and our community identity when working on community-centered sustainability projects.

Data collection and analysis

Data sources included audio-video recordings, transcripts, and chat files from Zoom from four workshop sessions. Youths' photovoice slides, intersecting identity models, and critical friend feedback were also collected. Pre-post semi-structured interviews were conducted to elicit youth's reflection on identity and agency.

The first author used interaction analysis to create content logs and conduct initial qualitative analysis of recordings of the workshop sessions (Jordan & Henderson, 1995). Making extensive memos across multiple viewings, she identified representative vignettes in which the group was engaged with critical pedagogical practices coupled with agentive practice, as defined by the frameworks above. Both authors met to interrogate these vignettes, interpreting their influence on holistic identity development (i.e., social and role; Stets & Burke, 2000) for each participant across time and between participants. We also analyzed the photovoice-inspired testimonios to understand how youth were engaging their identity and agentic positioning in relation to their community-centered sustainability efforts. To further interpret holistic identity development, the first author led data-driven coding (Decuir-Gunby et al., 2011) of interview transcripts and recorded workshop sessions to examine what aspects of identity were expressed by each participant (e.g., Gender, Career goals, Engineer, Age) and how they were expressed over time. Examining the relationship between (a) identities expressed by youth, (b) their agentive positioning in their community-centered sustainability project, and (c) the critical pedagogical practices of testimonios and contradiction and resistance (Workshop 1), and intersecting identity modeling and critical friend feedback (Workshop 2), we created tables and compared experiences within and across the youth.

Findings

Connecting identity, community, and sustainability in photovoice-inspired testimonios

Overall, youths developed holistic identity to some extent over the four workshop sessions. Six of seven youths reported that the critical practices coupled with agentive practices of social change allowed them to reflect on their identity and its connection to sustainability and community, and to consider how their identities interact within themselves as well as with others in their community. Holistic identity development was first exhibited in identities beginning to be expressed by youth in their photovoice-inspired testimonios.

As one illustrative example representative of other participants' connection of youths' role identities to their sustainability efforts across the dataset, we offer Christopher's photovoice-inspired testimonio. His contribution featured a photograph he took of his high school and description of his effort to create an essential life skills class to would help other students learn practical and useful skills for the future (e.g., *"how to manage their time and selves, finances…"*), a solution to address UN SDG 4, Quality Education. In his testimonio, Christopher illuminates the personal and cultural experiences of Hispanic students at his school and deconstructs the school's educational culture (e.g., *"they've had bad experiences because of how flawed it is"*). In his explanation, he connects his personal and community identity to sustainability for quality education for all:

> *I believe that good education can make good people, but I also have a friend who hates school… Obviously, I feel included in this [Hispanic] community, and I want to help out to improve the quality of the education that students are receiving here by trying to implement a new class that…would be very helpful to them because it'll teach them real-life practical skills...*

This personal account showcases Christopher's agency not only in creating the life skills class but also in countering the dominant narrative of the current education system, which he saw as under-serving its largely Hispanic student population (80%), with whom Christopher identified. He related his experience of wanting to create this class due to his own experience and his friend's experience at his high school.

According to Stetsenko and Arievitch (2004), the conceptualization of the self as a process allows an individual to express agency and simultaneously contribute to social practices that can change the world. We interpreted Christopher's agentive positioning of his identity in relation to other members of his community, along with his strong stance for change of education quality for his community, as allowing him to engage in individual agency toward social change. His identity was influenced by his community and agentive action toward social change in the low-quality education system at his school. The critical pedagogical practice of testimonio and examining contradictions of the educational system as it serves some communities, coupled with Christopher's resistance to poor quality education and his agentive positioning of himself as a leader in the community sustainability project, indicates these practices started to foster his holistic identity development.

Generally, all the youths identified or positioned themselves in relation to their photovoice-inspired testimonio by connecting their role identities (e.g., student, mentor, engineer, designer) to sustainability projects and critically reflecting on the contradictions and resistance related to these sustainability efforts. However, they struggled to connect their social identity (e.g., race/ethnicity or socioeconomic class) with sustainability.

Intersecting identities modeling for holistic identity development

Completing the identity model allowed the youth to reflect on aspects of their identity that they were unsure about. By the end of Workshop 2, most of the youth connected their social identities, directly or indirectly, to their role identities. Additionally, the intersecting identity modeling helped the youth understand different aspects of their identity and the identities they share with their community. While most youth reported feeling that completing the models was "easy", four youths also expressed difficulty relating to the difference between race and ethnicity (e.g., "*...the only thing I did struggle with the tiny bit was just, like, the race versus ethnicity… because I wasn't* *sure what to put.")*. Although similar struggles with social identity were expressed by four of the five youths, who identified as "Hispanic", each revised their identity model to accommodate this difference following the group discussion. Framing of race and ethnicity thus provided new awareness, thus contributing to the youths' understanding of holistic identity development.

While all the youths were able to identify the importance of thinking about social and role identities, responses varied in the extent to which they were able to connect their own social identity with their role identity. As an example of one of the youths who struggled with this connection, Jessica expressed:

> *I'm not sure how those things, specifically, have affected…my experiences…I'm sure my experiences have been affected by my gender, age, and race [but] I'm not really sure about the connection there.*

It was evident throughout the session that Jessica recognized that social identities can influence the role identity of an engineer. However, she did not explicitly frame this concerning her identity. When asked to clarify this connection, Jessica struggled to connect her social identity to her community sustainability work. Although she struggled with this connection, she did develop some awareness of holistic identity, expressing that her social identity influenced her experiences. Before the intersecting identity modeling activity, when addressing identities, Jessica talked about aspects of her identity as independent factors (e.g. "*things like ethnicity, race, and gender are, I guess, important to always address when we're working with people*") but did not explore these factors in terms of intersectionality. Not until the final reflective interview did she begin to reflect on their interdependencies (e.g., *"My age, race, and gender influence my experience, or class and race and relevant aspects for our community-engineering project"*). Thus, there is evidence of some holistic identity development, but the innovation did not fully support Jessica's connecting these identity intersections.

Significance

Our interpretive analysis suggests that critical pedagogical practices coupled with agentive practices allowed youth to think about how their identities interact with each other and others in their community. Moreover, introducing youth to the idea of contradiction and resistance concerning their sustainability project allowed them to think further about the relationship between themselves and sustainability efforts in their community, furthering their holistic identity development. Nonetheless, youth who struggled to connect their role and social identities also struggled to connect their individual contributions to the larger system of social change. Findings suggest that understanding youths' perspectives on sustainability, community, and their relationship to their identity can help educators and researchers design more productive opportunities for youth.

Drawing Upon Computational Experiences to Navigate Ontologies

Xiaoyu Tang, Matthew Lira
xiaoyu-tang@uiowa.edu, matthew-lira@uiowa.edu
University of Iowa

Abstract: STEM students experience challenges when reasoning about complex systems that combine multiple ontologies. Computational environments, however, support students because these environments distinguish between aggregate patterns and individual interactions. This investigation explores students learning about a complex system that combines two ontologies: chemical and electrical potentials in biological cells. We conducted a training-study that involved pre and posttests and a computational environment (NetLogo) to visualize the system. To gain insight into how students learned from the environment, we assessed students' drawings. We found that computational experiences inspired changes to students' drawing style and prompted them to draw new physical entities. By incorporating these new entities, students demonstrated one step toward their learning to navigate multiple ontologies in STEM education.

Introduction

Multiple ontologies in STEM education

When STEM scholars draw firm or flexible distinctions between how they classify nature, they highlighttheir ontological commitments. *Ontologies* refer to broad categories that exist in nature—e.g., Things or Processes (Chi, 2005). In advanced science, ontologies sometimes demand flexibility. For example, in genetics, students learn to characterize genes as both molecular *matter* and as hereditary *information* (Duncan & Reiser, 2007). When students adopt a molecular lens, they consider a gene as *a segment of a DNA molecule* whereas adopting a classic genetics lens entails reasoning about *hereditary patterns*. To solve the pressing problems of their time, scientists needed to use multiple ontologies to understand natural entities. Today, the normative undergraduate science curriculum demands ontological flexibility from students.

Multiple ontologies in quantitative biology education

We introduce a new ontological challenge that manifests at an intersection between the life and physical sciences. The challenge involves students learning to recognize two ontologies—one *deterministic physical force* and one *probabilistic process*—that influence the movement of *ions,* or charged atoms, across the membrane of a biological cell. This phenomenon is called the Resting Membrane Potential (RMP). *Resting* refers to *dynamic equilibrium* or equal rates of two processes that occur in opposite directions. The *membrane potential* reflects an electrical driving force—measured as a voltage—that exists across cells. This electrical force prevents ions from diffusing until they reach equal concentrations.

The RMP poses an ontological challenge because students must recognize that the same individual ion holds two physical properties that create two ontologically distinct influences upon the ion's motion. Prior investigations demonstrate that when students reason about one entity that belongs to two ontologies, they experience learning challenges (Duncan & Reiser, 2007). Our prior research determined that ontological challenges arose from the fact that students readily recognize the probabilistic influence but neglected the deterministic influence (Lira & Stieff, *accepted with revisions*). This means that students fail to recognize physical forces that exist between individual ions as has been seen in other domains (Cooper et al., 2015).

Computational environments represent individual and aggregate patterns

Computational learning environments afford students insight into how physical interactions between individual entities in a system produce aggregate quantitative patterns (Sengupta & Wilensky, 2009). To illustrate, first consider that science equations typically model aggregate quantities such as the amount of total charge (i.e., current) that flows through a resistor. In contrast, computational environments like NetLogo represent both interactions between individual entities and the aggregated patterns that emerge from these interactions. For example, Sengupta and Wilensky demonstrated that after working with a computational environment modeling electricity, undergraduate physics students shifted from reasoning only about aggregate level quantities (e.g., "*current* cannot flow …") to reasoning about both aggregate and individual levels (e.g., "... no resultant current because the *electrons* are boundtightly to *atoms* ..."). One explanation for students attending to these individual interactions is that the NetLogo environment displayed a visualization that depicted interactions between individual electrons and atoms. Equations, for instance, do not visualize this interaction.

Navigating multiple ontologies by drawing

The problem described thus far motivates having students visualize individual entities. Drawing in science refers to a representational practice whereby people use paper and pencil to visualize their ideas about a natural system. Drawings depict the systems' physical structures, spatial organization, and causal interactions. This practice proves valuable to educators and researchers because it delivers insight into students' knowledge that we otherwise might not detect from other assessment modes. For example, in writing it is permissible to say, "The forks are *beside* the knives." In drawing, however, a person must specify *left* and *right* relations (Ehrlich & Johnson-Laird, 1982). Moreover, the person must choose to depict the *number* of forks and knives. When assessing students' knowledge of systems composed of multiple physical entities and quantities that interact with one another, drawing often delivers quick insight (Cooper et al., 2015; Cooper, Stieff, & DeSutter, 2017).

This point is relevant to learning from a visual simulation like NetLogo because drawing transforms continuous and dynamic visualizations into static representations. To make this transformation, students must select specific visual features and depict those features at specific moments in time. Prior investigations into students' understandings of the RMP demonstrate that when students draw the RMP, professors assess 90 percent of their drawings as problematic. Moreover, 58 of 74 students sampled failed to depict the RMP, i.e., the electrical potential (Frankel, 2010). To contextualize these results, note that the drawing assessments occurred after some initial instruction—this demonstrates the need to consider alternative instructional modes such as computational environments. This led us to ask how do computational experiences reshape students' drawings of the RMP?

Methodology

Participant population & recruitment

Thirty undergraduate students majoring in Biology or Psychology at the University of Iowa were recruited through university mass mail (n=30; 1 male, 29 female). 25 of 30 students had been enrolled in at least one physiology course that taught them about resting membrane potentials.

Research design and procedure

Here, we report upon aspects of a larger on-going experimental design. First, students were consented to participate in the study. They then took a pretest that included a drawing task (10 mins). Next, we conducted an intervention that guided students to use a computational environment built in NetLogo. Students were prompted to predict, explain, and reflect upon three phases in the evolution of the RMP (10 mins). Participants then took a posttest that contained the same drawing task as well as other writing and calculation items (25 mins). Participants were paid 20 USD and dismissed.

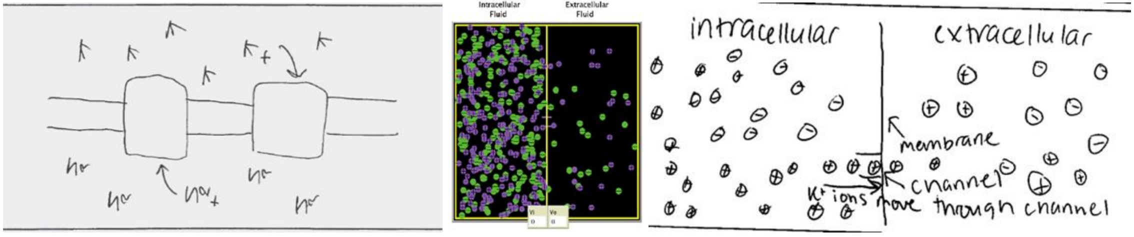
Qualitative analyses of student drawing construction

We analyzed students' drawings at pre- and posttests to assess their overall style and the presence or absence of features that we borrowed from Ryan & Stieff (2019). These include *motion*, *position*, *composition*, and *interaction*. In our context, *motion* refers to an ion's movement. *Position* refers to the configuration of ions and cellular structures. *Composition* refers to the identity or type of ions depicted. *Interaction* refers to the physical cause of an ion's motion. In the drawing task, students needed to illustrate three phases: (1) initial conditions depicting a greater *concentration* of ions inside the cell than outside, (2) the dominant transport mechanism for ions to *diffuse* across the selectively permeable membrane, and (3) the RMP or an electrical potential in *dynamic equilibrium* with a chemical potential.

We first attended to *position*. Position directs attention to the overall *style* of students' drawings. Analyzing posttests first, we found that most drawings resembled the configuration of the NetLogo interface (Figure 1b). This prompted the inductive code *NetLogo inspired position*. In these drawings, a segment of the cell membrane is depicted as a straight and vertical line. On the cell membrane, an open ion channel is depicted near the center of the membrane (Figure 1c). As we attended to *NetLogo inspired* drawings, we noticed that many of them also contained both positive and negative charges (+, -), or particles that carry charges (K^+, Cl^-). Therefore, we next attended to the drawing's overall *composition*. For composition, we attended to each type of entity depicted in the drawings. At posttest, we noticed that most students depicted both potassium K^+ and chloride Cl^- ions. This prompted the inductive code *NetLogo inspired composition*.

After developing our coding scheme, we analyzed the pretests to determine whether our intervention was influential along either of the two dimensions: Position and Composition. At pretest, however, drawing *positions* varied to a greater degree than posttests. Moreover, none of the pretest drawings resemble our NetLogo interface. In contrast to NetLogo inspired drawings, position at pretest consisted of drawings that depicted an entire cell as opposed to a section of membrane. Second, among students who drew a segment of the membrane with straight line, they oriented the drawing along the horizontal as opposed to vertical axis. These stylings prompted the inductive code: *textbook inspired positions* (Figure 1a).

Figure 1
The computational experience inspires students' drawing style and compositions. (a) At pretest: textbook inspired drawing that consists of positively charged ions only. (b) NetLogo visualization window. (c) At posttest: NetLogo inspired drawing that consists of both positively charged ions and negatively charged ions.



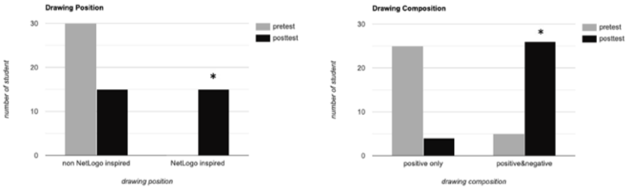
(a) (b) (c)

Results

Computational experience inspires students' drawing styles and derives new drawing composition

When we analyzed the frequency for each category across pre- and posttest, we found that computational experiences changed how students *position* physical entities in their drawing and thus inspires their overall drawing style (x^2=20, n=30, df=1, p<0.0001). Regarding Drawing Style, NetLogo inspired drawings resemble the configuration of NetLogo interface by, for example, positioning the cell membrane to orient along the vertical axis (Figure 1c). This demonstrates that students encoded and recalled the visualization from their computational experience (Figure 2a). Regarding Drawing Composition, we found a significant shift in students' drawing *compositions* (Figure 2b). That is, students incorporated new individual physical entities that possessed distinct identities and properties (x^2=29.43, n=30, df=1, p<0.0001). Students who included new drawing compositions also showed a higher overall score (m= 36.68%) compared to students who did not (m=19%). NetLogo inspired drawings that resembled the composition displayed by the NetLogo interface by, for example, inspired students to draw negative charges (Figure 2b).

Figure 2
*(a) Students' drawing position at pre- and posttest. Frequencies were compared using a chi-square test; *, p<0.0001. (b) Students' drawing composition at pre- and posttest. Frequencies were compared using a chi-square test; *, p<0.0001.*



(a) (b)

To contextualize these results, we tracked interactions between *Position* and *Composition*. Among the 15 students who produced NetLogo-inspired drawings, 14 included negative charges. Among the 15 students who did not produce NetLogo inspired drawings, 12 included negative charges. Thus, only 4 students failed to represent negative charges after experiencing the computational environment. These 4 students failed to represent any charges whatsoever. Thus, although most students readily picked up the physical entities needed to construct multiple ontologies, their use of these entities in drawing demands other requisite science knowledge.

Discussion

Some physical entities display multiple ontologies (Hoehn & Finkelstein, 2018; Duncan & Reiser, 2007). In the case we presented on the resting membrane potential, prior research demonstrated that students attend to physical entities related to a *probabilistic* ontology to the neglect of a *deterministic* one. (Lira & Stieff, *accepted with revisions*). We reasoned that one explanation for this learning phenomenon arose from the fact that students learned with representations—such as equations—that oriented students to the *aggregate* level as opposed to highlighting interactions between *individual* entities (Sengupta & Wilensky, 2009). We therefore implemented a computational learning environment that aimed to guide students to notice the deterministic influence—an electrical driving force that causes ions to move in a direction opposite to the probabilistic influence.

The findings presented illuminate a path for students to recognize two ontologies at play in a complex system. If we adopt a context-sensitive view on how students navigate multiple ontologies during STEM learning (e.g., Hoehn & Finkelstein, 2018), then one possibility is that computational experiences permit students to encode visual elements that corresponds to a given ontology (e.g., probability). This view does not, however, promise that students will construct the ontology—only that students will notice features that represent aspects of it. Moreover, students' construction of the ontology will manifest only if assessment items demand or at least facilitate their use. The drawing assessment we designed aligned with the computational environment's visualization. A context-sensitive view on students' knowledge therefore suggests that students will pick up "pieces" of knowledge from computational environments and that those "pieces" will manifest in unique ways on different assessment items (cf. Sherin et al., 2012).

Drawing therefore granted a small window into how students construct and use multiple ontologies. They incorporated new styles for modeling the cell when they shifted from drawing whole cells to drawing segments of membrane. They also incorporated critical entities—i.e., negative charges—that they neglected before their computational experience. As part of the on-going investigation, we are analyzing how other aspects of students' knowledge manifests in drawing and other assessment modes (Ryan & Stieff, 2019). Future investigations will determine how students learn to represent other physical entities such as the forces that students' drawings neglected to represent after intervention. At present, these results demonstrate that attending to the fine-grained features of students' drawings reveal that students readily pick-up critical pieces of knowledge (i.e., opposite charges) needed for them to construct the *deterministic* ontology necessary for understanding a complex system.

University of North Texas

Abstract: We explored the future plans for teaching of Preservice Teachers (PTs) from marginalized communities at a Hispanic-Serving and Minority-Serving institution. We examined positionality statements to learn how past schooling experiences guided PTs' vision for a future classroom. Our findings show PTs who described positive schooling experiences conceptualized forms of equity-as-inclusion while PTs who described negative schooling experiences articulated desires for transformational classrooms. We propose both forms of equity are valuable, but we examine existing systems as we believe DEI-informed teacher preparation programs can create opportunities for collaborative exploration that prioritize equity-as-transformation and prompt PTs to develop plans for more equitable teaching.

Introduction

Pre-service teachers (PTs) envision what their future classrooms and teachings may look like. Teacher training programs are designed develop PTs' future practice as well as guide their plans for teaching. A central focus of teacher preparation programs is helping PTs develop a deeper understanding for the students they serve including through culture- and race-explicit practices (Jupp et al., 2016) including approaches to explicitly unpack forms of internalized bias (e.g., racism, ableism; e.g., Kohli, 2014). Diversity, Equity, and Inclusion curriculum can help PTs gain perspective on the varied experiences students undergo in the existing schooling system. These efforts are intended to help PTs understand that not all students have the same schooling experiences since existing systems tend to favor those belonging to the dominant group (e.g., white, abled, cisgender, middle class). Our research sets out to understand how PTs from marginalized groups contextualize their own past schooling experiences and make plans for teaching in their future classrooms. We examine their vision for their ideal classroom environment and how their own lived experiences play a role in their future imaginings of teaching.

A framework for an undergraduate teacher prep course and the present analysis

Diversity, equity, and inclusion (DEI) efforts are common across many universities and teacher preparation programs in particular, including the program that was the focus of this study at a Hispanic-Serving and Minority-Serving Institution. In the Learning Sciences for instance, researchers have explored the idea of inclusive and transformative agency (Stroupe, 2014; Keifert et al., 2018, p. 197). We are particularly interested in cultivating transformative forms of engagement as PTs connect learning theory to plans for future disciplinary teaching.

The framework we present comes from the design of a PT undergraduate course exploring the relationship between learning theory (e.g., sociocultural theory, developmental theory) and classroom design. We present this framework as it (a) provided the context in which the PTs were emersed as they wrote the statement that serve as our focal data and (b) demonstrates how we modeled the learning designs that supported transformative futures for PTs as teachers and their future students. Our framework centers humanizing learning designs that position PTs as active sensemakers with the agency to interpret and critique learning theory. We also center horizontality in this work, recognizing that PTs live and learn across a variety of cultural communities and that those experiences should be available as sensemaking tools for themselves and their peers within teacher preparation courses (e.g., Warren et al., 2020). Specifically, we draw on the idea of entanglements—"moments during which participants engaged in collaborative sensemaking make relevant their histories, futures, and ideas about the world" (Keifert, under review)—to understand PTs' sensemaking both in-the-moment as well as through artifact analysis (e.g., assignments). Furthermore, our analysis includes a consideration of intersectionality and relationships between members of a learning community (Collins & Bilge, 2020).

Research methods

The current project is part of a larger design-based research study (e.g., Design-based Research Collective, 2003) studying how examination of prior experience, intersectionality, and sociocultural learning theory supports PTs to create transformative visions for future teaching. The course was taught at a Hispanic Serving Institution, Majority-Minority and in a conservative political climate in the Southwestern region of the United States.

Three instructors' sections of this course were included in the present analysis. All three instructors belong to the dominant community in the US (white, middle class), but were committed to power-explicit conversations about teaching, learning, and school systems through their membership in the dominant community and were recognizing, naming, and disrupting oppressive systems.

The present analysis was conducted by the full research team, including multiple international students, two LGBTQIA+ members, members of neurodivergent communities, and disabled members. This team was led by Denisse Avila: a Hispanic, cisgender female, first-generation college graduate who was in the first half of her doctoral studies. Her work was supported by the senior scholar of the group Dr. D Teo Keifert: a white, European-heritage, disabled, queer, non-binary assistant professor. We share these identities here because the broad range of perspectives of our research group informed the ways we saw and approached our analysis.

To learn more about PTs' future plans for teaching, our research team focused on positionality statements where PTs reflected on how their own personal histories shaped their decision to pursue a career in education. The research team selected statements where PTs identified as belonging to a marginalized group (i.e., race / ethnicity / neurodivergence / socioeconomic status) explicitly. Of 19 consented statements, 12 met the criteria.

Our team followed an open coding process (e.g., Creswell, 2007), looking for phrasing showing key connections between prior schooling experiences and plans for future teaching. All statements were compared to finalize codes and themes. Our lead author identified differences between the assignments in terms of how equity was conceptualized that were connected to stories of past learning. Our first two authors re-engaged with the literature presented to consider how these differences in conceptualization of equity could be understood within the theoretical frames of the course as presented through media. We present our findings according to codes of positive and negative schooling experiences and discuss patterns across that led to our understanding about PTs' conceptualization of equity and equitable learning.

Findings

Positive schooling experiences and future teaching

Four PTs' statements cited primarily positive schooling experiences. Positive experiences included retellings where PTs recall feeling supported, inspired, and even empowered by their educators and classroom environment.

Despite the lack of representation, Tony found support from his educators. His plans for a future classroom included an environment where students feel seen, welcome, and engaged. Vee acknowledged that life seemed to "not be the best at home," but her mother strongly encouraged an education, which led Vee to find comfort and reprieve from her home life in the school environment. Vee expressed finding success in her K-12 classrooms which prompted Vee to seek to provide positive learning experiences to her students similar to those she encountered in her own schooling. Happy wrote that she also did not see much representation growing up, until college, where she had a mentor who was African American. She realized she could bring different perspectives to her role as a teacher and develop deeper connections with her students. Growing up in a single-parent household, Maxwell Steven described their home life as not always idyllic, but they exhibited neurodivergent qualities that enabled them to excel in school. Their plans for future teaching focused on student engagement and ensuring students' likes and dislikes would be accounted for and reflected in the classroom.

Negative schooling experiences and future teaching

Of the seven PTs who shared negative schooling experiences, five spoke of feeling neglected due to having needs or a background that were not like those of their peers. PTs who reported feelings of neglect in the classroom stated feeling "lost", "outcasted", "inferior", and even "belittled". They felt that their teachers "were not equipped or prepared for the students at [the] school", which resulted in PT's neurodivergent and socioemotional needs that were not properly met, were ignored, or even criticized.

While some PTs spoke of feeling neglected in their learning needs, others spoke of feeling shamed due to their learning difficulties and/or cultural differences. Phoebe Bridgers shared she once had trouble spelling the word "abuelito" (Spanish for grandfather) and was made to feel ashamed for asking and not knowing the English word for grandfather instead. Cardinal North retold a time when a teacher laughed at them for asking a question during class. This made Cardinal North feel "cheated of [their] education". Manuel positioned himself in regard to how others reacted or responded to him. For example, he reported being called "faggot" by his peers and cited harassment of "queer Black and Brown students" in his hometown but did not explicitly say he was a member of those groups. As a future educator, Manuel sought to counter "oppressive structures" and feelings of "erasure and exclusion". Soi Kat, shared that she is half Asian and half Black, but did not grow up in a marginalized community.

It was not until she moved to the U.S. that she experienced what she described as a "sharp shift in [her] education experience" and that "for the first time [she] noticed serious discrepancies within the education system." She sought to use her position of power as a teacher to serve as a mentor to students of color and transform the school system into what she referred to as "a safe space for diverse students."

These PTs were explicit in stating the importance of the classroom environment serving as a safe space and expressed their belief that student differences shape understanding. Aligned with readings such as Gutiérrez and Rogoff's (2003) work on cultural repertoires as well as a recorded talk by Tanner (2013) about deficit- and resilience-based models from course work, these PTs did not discuss differences as deficits. Instead, future students were described as multi-faceted individuals whose needs can be expected to be as unique as the students themselves. Individual differences were discussed as strengths, and student input was framed as crucial.

Comparing across positive and negative stories

Commonalities in stories

Across all statements, it was evident that PTs from marginalized groups yearned for a classroom where students from diverse backgrounds were valued, attended to, and understood as holistic individuals. They stressed the importance of having teachers from different backgrounds to develop deep relationships with students who may not always be understood. Many PTs drew explicit connections to their own identity and expressed a desire to make their classroom a place where students of all backgrounds felt welcome and secure. PT statements overwhelmingly showed an intentional effort to seek student opinion, primarily in the belief that this was central to a classroom that is sensitized and responsive to the needs of others. However, it was evident from the statements that the nature of the schooling experiences impacted the depth of exploration that PTs underwent.

Differences across PTs: Conceptualizations of equity and goals for future teaching

Our analysis showed that based on the nature of the stories retold, PTs conceptualized equity differently; PTs who told positive stories conceptualized equity-as-representation, and those who told negative stories of school neglect and harm conceptualized equity-as-transformation within their statements.

Equitable-as-representation vs. Equitable-as-transformation

PTs who cited positive experiences prioritized an equitable classroom specifically as tied to having teachers that represented the race/ethnicity of students in the school. This idea of equity-as-representation was used to argue that their presence in future classrooms, as members of marginalized communities in the US and those underrepresented in the US teaching force, would be valuable to their future students. They used their identity to recognize that the needs of students from marginalized groups may be different from those belonging to dominant groups. However, teacher representation was viewed to develop camaraderie and build community with students who may feel "othered." It may be because these PTs found overall success in the existing system that their focus was consistently to help their students find similar success.

Negative experiences drove PTs to discover deeper issues in existing systems and reject these in their own classrooms, envisioning a transformational classroom. These PTs sought to create student-dictated and student-informed classrooms, where expectations for "normalcy" were not predisposed by society. Their plans for future teaching centered around getting to know students' personal histories and identities and letting students take an active role in their learning, centering ideas from course theory readings, video, and podcasts like cultural repertoires (Gutiérrez & Rogoff, 2003), the role of teachers as serving students and the role of teachers and peers in co-constructing disability and otherness (e.g., Annamma et al., 2013; Tanner, 2013). PTs who did not have positive experiences sought to understand the "whole student" both in and outside the classroom (e.g., horizontality) perhaps in relation to Ramsey's (2004) use of Bronfenbrenner and recognized how outside realities can impact education as the classroom is not a vacuum (Emdin, 2020).

Discussion

In the statements we examined, pre-service teachers with self-named marginalized identities recognized these identities as an area of strength for teaching students from diverse backgrounds. We recognized PTs with positive schooling experiences as conceptualizing forms of equity-as-representation. We also recognized PTs with negative schooling experiences as conceptualizing equity-as-transformation with the need to disrupt "normal" (e.g., Annamma et al., 2013) in favor of centering and cultivating heterogeneity as part of a thriving classroom sensemaking community. Both forms of equity are important, though the first is likely to demand assimilation of learners from non-dominant communities which prior research shows does active harm to learners (e.g., Bang et al., 2012) while also limiting possibilities for sensemaking for students across both marginalized and dominant communities (Warren et al., 2020). Equity-as-transformation takes a more systematic approach to understanding learning in context, systems of oppression, and more accurately reflects critical, sociocultural theories of learning (e.g., Gutiérrez & Rogoff, 2003; Rogoff, 2003; Emdin, 2020). We propose both forms of equity are necessary and valuable. However, equity-as-representation does not adequately disrupt school, and societal norms. Thus, seeding the ground for all students to critically examine existing systems and work towards conceptualizations of equity-as-transformation must be a priority in DEI-informed teacher preparation programs.

Conclusions & implications

Given the divide between PTs who told stories of positive learning experiences and those who told stories of negative learning experiences, a pressing question emerged for our authorship team of how to engage those who told stories of experiencing success within existing K-12 schooling systems in imagining more transformative futures for their own students. From an inquiry perspective, it might be said that these PTs did not encounter the same "felt puzzle" (Keifert & Stevens, 2019) as those PTs who recognized significant harm caused by teachers, other adults, and peers in US K-12 schools as a result of their belonging to non-dominant communities. In this analysis we focus specifically on learners from non-dominant communities who describe positive past learning experiences, though in our broader work we are also concerned about learners from the dominant community. Thus, we wish to pursue two questions in our subsequent work. First, how can opportunities to feel, recognize, and name these problems be presented both to students from non-dominant communities and dominant communities who saw themselves as successful in schooling systems? Second, what kinds of experiences in PT courses might provoke opportunities for recognizing the need to develop a vision for transformative futures without asking for performative or harmful public re-telling of such experiences from members of the classroom community who have directly experienced this harm?

Against “Both Sides” Argumentation: Resisting Dehumanization in Intellectual Community

Tanner Vea, Pennsylvania State University, tvea@psu.edu

Déana Scipio, IslandWood, deanas@islandwood.org

Abstract: In this paper, we respond to an argument that has circulated in the learning sciences in recent years, that it is necessarily advantageous for learners and learning scientists to engage with “both sides” of a debate. While engaging in argument and civic dialogue can be advantageous for learning, its limits must be carefully examined. Drawing on studies of fascism, ideology, and learning toward equity, we suggest that platforming both sides of debate can be a harmful strategy that creates conditions for advancing bad faith arguments, dehumanizing already minoritized communities, burdening people with the work of refutation, and compromising with immoral positions. Without care, engaging “both sides” ultimately threatens the ideals of an open, democratic learning community.

The learning sciences in this political moment

Several years ago, the Politics of Learning Writing Collective (2017) wrote a call to action warning of the rise of right-wing nationalism. In the shadow of Trump’s election to the presidency of the United States and the rise of fascist leaders internationally, they reminded the field of the long history of racist, nationalist, and settler-colonial violence. They called for the learning sciences to take a greater interest in learning as a political act, and over the five years since they published that piece, many of us have tried to heed their call. It is becoming increasingly clear, though, that the tide has not been stemmed, that democracy is in perilous danger, and that along with it attacks and forms of exclusion aimed at trans people; people with uteruses; queer people; migrants; Black people, Indigenous people, and people of color (BIPOC); Jewish people; and disabled people have worsened. Further, in fascist political strategy, agitators foment division through appeals to a mythic national past of purity and order. To secure this myth, they must destabilize collective knowledge of history and attack educational institutions (Stanley, 2018). Observers of recent developments in the U.S. may note the increasing attacks on LGBTQ2S+ educators, on the teaching of the history of racism and slavery, and on intellectual freedom and the institution of tenure in higher education. Left unchecked, these swelling movements threaten every educator and researcher.

Perhaps counterintuitively to some in our intellectual community, “balanced debate” is not an apolitical intervention that always supports productive dialogue; rather, it is one tool being mobilized to advance fascist ideas, policies, and political movements. Calls for balanced debate may be alluring. They evoke images of an even playing field for rational actors, where reasoned argumentation holds sway over ideas that are obviously wrong, or even violent in their implications. Yet, in classrooms, in broadcast media, and on the internet, fascists are working hard under the banner of “free speech” to make space for their repugnant ideas. This year, at one of our universities, known advocates of political violence were invited to speak at campus in supposed defense of free speech, and political violence predictably ensued. We also see advocacy for hearing “both sides” of a debate in some spaces within the learning sciences, including conference plenaries, manuscript reviews, and classrooms. We are concerned both with the environments we study and with our professional community. We write with examples in mind, yet we are opposed to citing specific instances, which could be seen as “calling out” individual community members—such an approach locates the problem in people rather than a system of ideas, which any one of us might invoke. Rather, we draw attention to the ideology that underpins the calls for balanced debate because we have been alarmed by the impacts it has on minoritized members of the community, and because it legitimizes fascist tactics that directly threaten minoritized people, educational systems, and democracy. Supporting heterogeneous viewpoints in learning environments is not the same as considering all perspectives as valid without regard to whether they are moral, logical, or supported by evidence (Rosebery et al., 2020).

In this paper, we make a theoretically grounded conceptual argument against carte blanche support for platforming, listening to, and engaging with “both sides” of an argument, especially as an equity intervention. We argue that the idea of listening to both sides can work against equity and justice, obscure power relations, and harm minoritized people. We look to research on authoritarianism as well as equity studies to propose a conceptual intervention in our field. Our hope is that we will collectively reconsider the perpetual calls for balanced debate, and instead center historicized, evidence-based equity and justice analyses in our calls to platform particular ideas.

Argumentation: Evidence and ideology in learning

Learning scientists have significantly studied the role of argumentation in the classroom as both a pedagogical goal and a tool. While there are many potential models, it is agreed that argumentation can productively support (especially science) learning, but that its effectiveness is highly sensitive to scaffolding and community norms (e.g., Manz, 2015; Schwarz, 2018). Some studies of democratic education have argued that engaging in civic dialogues is a core practice of democracy that should be part of schooling (Mirza & Perret-Clermont, 2009), while other learning sciences research has focused on fostering dialogue across difference (Asterhan & Schwarz, 2016). However, as Curnow (2021) demonstrated in her study of argumentation in a politically contentious space, some "neutral" approaches to argumentation in fact expect minoritized people to "engage with ideas, practices, and ways of knowing and being that fundamentally undermine and seek to degrade their humanity, their civil and human rights, and their ability to participate fully in the world" (p. 281).

Thus, in spaces of argumentation, ideology—not just evidence—is at issue. As Philip et al. (2017) explained, "all sense making that stabilizes (e.g., 'War is inevitable'), challenges (e.g., 'U.S. military action has been mostly in the interest of corporations'), and/or transforms (e.g., 'We should spend as much on a Department of Peace as we do on the Department of Defense') the distribution of material and symbolic resources in society is ideological" (p. 186). In their study of ideology in an engineering ethics classroom during a discussion of drone warfare, debate converged on ideological stances that marked some people as less worthy of moral consideration than others. In another classroom study, Vakil and McKinney de Royston (2019) explored how "politicized trust" was undermined interactionally in a computer science classroom through an absence of shared political understanding, respect, and commitment. When a white student presented on the relative lack of Black students in the school's honors track and reasoned aloud about issues in students' homes and communities, initial solidarity based on an assumption of good intent soon gave way to tension, with one student saying in a follow-up interview about the incident, "Who are you to speak on this?" (p. 562). Intellectual community can be severely undermined when participants invoke ideological stances that bring others' humanity into question.

Fascism and disinformation

The stakes of dehumanizing ideological convergences are further raised in a context where fascist movements are gaining momentum. We draw on fascism here not as an ad hominem attack, but as a political form that can be studied empirically. Stanley (2018) identifies fascism as ultranationalism that uses a common set of strategies, including "the mythic past, propaganda, anti-intellectualism, unreality, hierarchy, victimhood, law and order, sexual anxiety, appeals to the heartland, and a dismantling of public welfare and unity" (pp. xxviii-xxix). Fascists dehumanize marginalized groups to seize power and enforce extreme hierarchy. Stanley (2018) argues that fascists reject expertise and linguistic complexity to undermine the sophisticated debate democracy requires. One strategy used to expand the range of ideas people are willing to entertain in public discourse is to repeat abhorrent ideas and false claims (Arendt, 1951/1973), while framing the ideas that may have once been viewed as extreme as important to consider and debate in the interest of democratic engagement. These patterns from fascist leaders create a dangerous mix with a segment of the population, known as right-wing authoritarians, who are more likely to be submissive toward strong authority figures and act with aggression toward the people those figures target (Altemeyer, 2004). The net effect of this is to shift the range of acceptable discourse such that previously unacceptable ideas can become mainstreamed, at least in some communities.

Conceptual intervention: Against "both sides"

Calls to hear from "both sides" suggest that for analysis or argumentation to be rigorous, both sides of a debate must be thoroughly reasoned through. In the learning sciences, this often takes the shape of advocating for learners engaged in civic discourse to hear both sides of a debate, regardless of what is being debated and powered relationships between the speakers. This view presupposes that all "sides" of a debate are reasonable, put forward in good faith, and rooted in evidence. People advocating for both sides argue that listening to both sides is itself a social good that enables learners to understand the position of their opponent and move toward civil middle ground. Sometimes the "both sides" approach is framed in negative terms, as in, "Both sides (or all sides) carry some (or equal) blame for injustice or polarization." Others express the same sentiment in more subtle ways: "What is most important is to dialogue with one another," or "Valuing heterogeneity means we must weigh and consider all opinions." We presume this begins from a place of good intentions. Dialogue and discourse across differences can result in changed minds and new insights—when those discussing are doing so in good faith and on equal footing. Yet calling for learners to listen to both sides as a requisite strategy for ensuring fairness and quality evaluation of ideas is not commensurable with a justice-oriented framing of how equity is achieved. Justice-oriented scholars and activists have argued that doing so has several problems.

First, prioritizing engaging with both sides creates conditions for advancing arguments that are *not* actually reasonable, put forward in good faith, nor based in evidence. Demanding that scholarship engage with "both sides" works against historicity and evidence. Often in the context of equity debates and discussions, attention to the historical relations of power clearly demonstrates the *lack* of evidentiary basis for arguments against equity. For example, there is a clear scientific consensus that race is not a biological reality, but a social construct (Collins et al., 2003). We would not need to engage a debate about the intellectual capacity of Black people or the inherent greed of Jewish people; we can mark those as intellectually vapid arguments rooted in anti-Black racism and antisemitism without hearing both sides. Engaging both sides in such scenarios actually undermines intelligent debate by creating a sense of false equivalency (Stanley, 2018). "We should therefore claim," Karl Popper (1945/2002) wrote, "in the name of tolerance, the right not to tolerate the intolerant" (p. 668).

Second, the contours of equity and justice discourse mean that this impulse often leads to debates over the humanity of historically minoritized and disempowered groups of people. It requires that community members made marginal through racist, heteropatriarchal, colonial, ableist policies and practices once again be exposed to ideas which undermine our dignity and question our inclusion. We already know these ideas circulate. In fact, we must be aware of them for our daily safety, yet we gain nothing from hearing these ideas again and again, particularly in professional contexts. Is it "good," for example, for trans people to have to listen to and engage with arguments that question their right to exist, to access medical care, and to be safe in schools and society? Entertaining "both sides" directly creates harm for marginalized people. Yet we stress that the primary harms of these debates are not emotional or symbolic at all, but rather material (e.g., Gill-Peterson, 2022). They impact people's well-being through upholding the institutional structures, practices, and policies that threaten our right to life, safety, and full participation in our academic society and in democratic society more broadly.

Third, beyond the emotional and material damage done through the continued exposure to these ideas, marginalized people must also do more work to refute these ideas prior to being able to engage the broader community with their own theoretical and design ideas. As Toni Morrison (1975) has explained:

> [T]he very serious function of racism is distraction. It keeps you from doing your work… Somebody says you have no language and you spend twenty years proving that you do. Somebody says your head isn't shaped properly so you have scientists working on the fact that it is… There will always be one more thing.

In this way, advocating for "both sides" prevents progress on equity and justice issues by requiring a re-litigation of oppression in every meeting and discussion—arguments that disproportionately fall to BIPOC and other minoritized scholars, who must use our time to restate the basics of equity and justice rather than leveraging our expertise to actually design more equitable teaching and learning environments.

Finally, while the notion that equity can occur if we can build common ground through dialogue is an appealing sentiment, a focus on taking a middle position is a strategy that takes us far from a better world. As Tayari Jones (2018) argued, "The middle is a point equidistant from two poles. That's it. There is nothing inherently virtuous about being neither here nor there… What is halfway between moral and immoral?" Focusing on dialogue can suggest that an issue is a matter of reasonable disagreement. When it comes to some equity issues (e.g., police brutality; LGBTQ2S+ youth suicide), affected parties make clear again and again that these issues are urgent and that opposing positions (e.g., it's fine for police to kill people without a trial; LGBTQ2S+ youth are fundamentally broken and perverted) are simply not reasonable. Seeking to meet them halfway in such cases is to espouse an unproductive, and harmful, theory of change.

Conclusions

In sum, demanding we platform both sides advances fascist tactics for sowing disinformation and makes it more difficult for people to evaluate truth claims. In fact, the "both sides" approach is often intentionally deployed by fascist organizations, and taking this approach can inadvertently align with fascist political goals. Indeed, research on fascism and authoritarianism shows that fascists intentionally rely on the framing of "needing to hear from both sides" or "balanced perspectives" as a way to platform ideas which have previously been marked as fringe or extreme (Stanley, 2018). Through repetition, harmful perspectives without an evidentiary base become normalized as reasonable, which effectively shifts the range of viable political possibilities. In many cases, we see how dehumanizing and untrue discourses about queer people, for example, or the biological basis of racial difference, for another example, can become mainstream talking points, such that oppressed peoples' existence and rights become debatable and expungable. Allowing factual and moral untruths to be repeated is itself dangerous! Hannah Arendt (1951/1973) argued in *The Origins of Totalitarianism*: "What convinces masses are not facts, and not even invented facts, but only the consistency of the system of which they are presumably part.

Repetition... is only important because it convinces them of consistency in time" (p. 351). Historical and contemporary analyses show that this strategy is effective; as a field, we cannot let our good faith efforts to listen across difference and to build consensus where possible be used in service to dehumanization.

These arguments require us to take up our field's calls to value heterogeneity (e.g., Rosebery et al., 2010) with nuance and care. Bringing diverse meaning-making practices into contact in our intellectual community can expand the possibilities for human understanding, but only under certain conditions. When we allow dehumanizing positions to proliferate, or worse, when we relentlessly insist on engaging them, we poison the well of dialogue and bring harm upon everyone who drinks from it. This careful and intentional, rather than "anything goes," engagement with multiple viewpoints is what results in more equitable learning environments (Rosebery et al., 2010; Agarwal & Sengupta-Irving, 2019) and more generative moves towards equity in the field. We resonate with Vakil and McKinney de Royston's (2019) conclusion that we must remain "unsatisfied when there is a breakdown of [democratic learning] communities, even when other forms of rich learning and thinking may be taking place" (p. 564). As scholars who care about the relational outcomes of learning (Nasir & Hand, 2006), we hope our field can model these principles in our own scholarly spaces. Finally, we must remember that dialogue is not a substitute for explicitly working towards equity and justice. Such work requires materially shifting our policies and practices toward different outcomes. We have heard enough talk.

Examining Undergraduates' Epistemic Emotions and Discourse Moves That Support Collective Knowledge Advancement in Knowledge Building

Xueqi Feng, Southern University of Science and Technology, fengxueqi@hotmail.com
Jianhua Zhao, Southern University of Science and Technology, zhaojh@sustech.edu.cn
Yuqin Yang, Central China Normal University, yangyuqin@ccnu.edu.cn
Carol K.K. Chan, The University of Hong Kong, ckkchan@hku.hk

Abstract: The purpose of this study was to investigate how undergraduates' epistemic emotions and discourse moves influence collective knowledge advancement in a knowledge-building environment, emphasizing ideation, learning journey design, and collective idea building through learning analytics. Thirty-Five undergraduates studying *Education and Modern Technology* participated. Quantitative ethnography and qualitative analysis were used to analyze student online Knowledge Forum discussions. The findings demonstrate that epistemic emotions such as *curiosity*, *challenged*, *neutral*, and *frustration* might influence collective knowledge advancement via deeper discourse moves. The qualitative analysis indicates how undergraduates engaged in these epistemic emotions to perform sustained inquiry, progressive theory building, and collective idea mapping and creating.

Introduction

Knowledge Building is a major model that intends to facilitate the transformation of education by introducing the concept of knowledge-creating communities (Scardamalia & Bereiter, 2022). Most focus of knowledge building is placed on the ideas that students discuss and the discourse moves they employ to develop those ideas (Chen & Hong, 2016). In earlier research, we utilized the learning analytics tool Knowledge Building Discourse Explorer (KBDeX, Oshima et al., 2012) to evaluate how students' in-depth discourse moves contribute to the advancement of collective knowledge. Students worked in the knowledge-building environment enhanced by their self-designed learning journey and external representations of KBDeX (Feng et al., 2020). Despite years of effort devoted to constructing and analyzing the efficiency of collective knowledge advancement, other aspects (e.g., emotion) in the complex environment may be largely overlooked.

Recent research has focused extensively on epistemic emotion to comprehend the learning process better. Zhu et al. (2021) investigated how knowledge-building practices based on students' feedback affects their emotional engagement. Teo et al. (2022) found that students' epistemic emotions varied during activities aimed at improving ideas. Based on previous investigations, the current project aims to develop a knowledge-building environment using undergraduates' self-designed learning journeys, coupled with representations of KBDeX, and to examine how students' epistemic emotions and discourse moves could support collective knowledge advancement. Seven epistemic emotions were examined: *confusion*, *challenged*, *surprise*, *curiosity*, *neutral*, *frustration*, and *enjoyment.* The research questions are: (1) What was the interplay among undergraduates' epistemic emotions, discourse moves, and collective knowledge advancement? (2) How did undergraduates engage in epistemic emotions and discourse moves towards collective knowledge advancement?

Methods

Participants

Thirty-five students across several majors and grades from a science and engineering university in Shenzhen, Mainland China, participated in this project.

Pedagogy design

The participants engaged in a ten-week inquiry on the topic of the liberal arts, *Education and Modern Technology* on Knowledge Forum. They used epistemic emotion scaffolds when writing each note (Figure 1). In the *Ideation* phase (Weeks 1-3), students initially investigated topics of education and modern technology on Knowledge Forum. In the *Learning Journey Design* phase (Weeks 4-6), each group created a model of the knowledge-building journey on Knowledge Forum for visualization and shared inquiry. In the *Collective Ideas Building* phase (Weeks 7-10), students pursued collective knowledge advancement through learning analytics and the designed journey. Figure 2 depicts how students utilized word networks exported from KBDeX, a learning analytics tool, to map and advance collective ideas. The red and yellow circles represent keywords having or having not been used by the group, respectively. Each group received weekly word networks. For example, a student in group 1 discovered that they had neglected the keyword "talent" (a yellow circle) in the previous week, so they brought it into the current week and proposed new ideas focused on the linkages between educational transformation, social development, as talent demand.

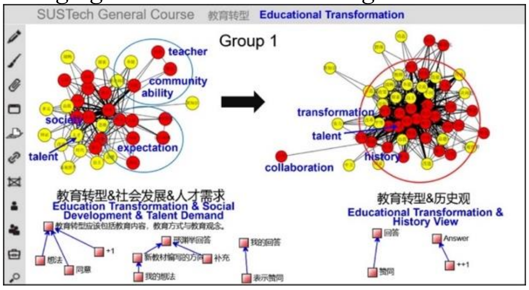
Changing Word Networks Showing Connections among Collective Ideas



Data source

328 Knowledge Forum notes were collected as the data source.

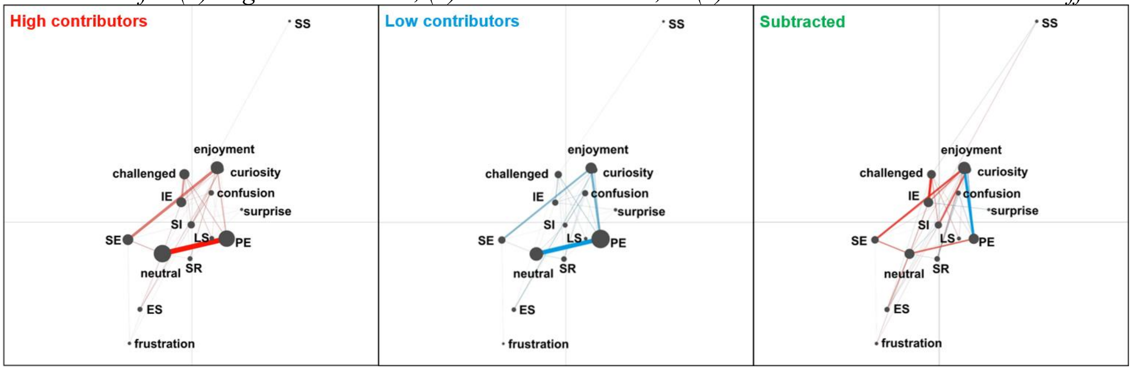
Data analysis and findings

RQ1: What was the interplay among undergraduates' epistemic emotions, discourse moves, and collective knowledge advancement?

We first adopted KBDeX to distinguish undergraduates with high and low contributions to collective knowledge advancement (Feng et al., 2020; Oshima et al., 2020), then we used Epistemic Network Analysis (ENA, Shaffer et al., 2016), an approach in quantitative ethnography, to visualize the associations between epistemic emotions and discourse moves by different contributors (Figure 3 (a) and (b)). The heavier saturation of the edges and nodes indicates that *enjoyment* and *neutral* play essential roles in both networks. However, such epistemic emotions show prominent associations with lower-level *Theorizing* (i.e., *proposing an explanation* and *supporting an explanation*). A two-sample t-test reveals a significant difference in the mean network location in the X dimension between high and low contributors ($t(32.05) = -4.00$, $p < .001$, Cohen's $d = 1.34$). In contrast, there is no significant difference in the Y dimension. The main differences between the two networks are more pronounced in the subtracted network (Figure 3c). The high contributors created a more vibrant network model for the discourse: they have stronger connections between *neutral* and higher-level discourse moves of *Theorizing* (i.e., *improving an explanation*) and *Community* (i.e., *synthesis*); they demonstrated stronger connections between *challenged* and higher-level discourse moves of *Questioning* (i.e., *sustained inquiry*), *Theorizing* (i.e., *improving an explanation*), and *Community* (i.e., *lending support*), and between *curiosity* and *Questioning-sustained inquiry*. More surprisingly, the high contributors have stronger connections between *frustration* and *Questioning-sustained inquiry* and *Theorizing-improving an explanation.* These results suggest that both high and low contributors engaged in *enjoyment* for low-level discourse moves. In contrast, those who engaged in greater *curiosity*, *challenged*, *neutral*, and *frustration* were more inclined to exert collective knowledge advancement through deeper discourse moves.

Figure 3

ENA Models for (a) High Contributors, (b) Low Contributors, & (c) Subtracted Network to Show Differences



(a) (b) (c)

Note. Questioning: ES=explanation seeking; SI=sustained inquiry. Theorizing: PE=proposing an explanation; SE=supporting an explanation; IE=improving an explanation. Community: SS=synthesis; SR=shared regulation; LS=lending support.

RQ2: How did undergraduates engage in epistemic emotions and discourse moves towards collective knowledge advancement?

The qualitative analysis of students' Knowledge Forum activities, reflecting how students advanced collective knowledge by engaging in epistemic emotions and discourse moves, involves the following three themes.

Theme 1: Curiosity, challenged, and frustration for sustained inquiry

Curiosity. When discussing *Educational Transformation*, student s01 first neutrally proposed that the formulation of education policy needs to consider ideas from the educated. Another high contributor, student s31, built on this idea using the discourse move of *Questioning-sustained inquiry* with *curiosity*, focusing on the question of to what extent the educated' ideas are taken into account.

Challenged. When discussing *The Impact of Technology on Education*, student s11 first *neutrally* proposed that technology is the application of objective laws by human beings. Then, an improved explanation of how to extract high-quality information from massive amounts of information, a new challenge for technology and individuals, was proposed by student s29 with the *challenged* emotion. After that, the high contributor student s06 adopted the discourse move of *Questioning-sustained inquiry* with *challenged*, proposing a new question of whether lowering educational thresholds would lead to a decline in the average level of teaching staff.

Frustration. When discussing *What is Education*, student s01 first neutrally proposed that education depends more on one's ownership of learning rather than the teacher's delivery, followed by an improved explanation that education should consider a person's interests and talents. Later, the high contributor student s25 expressed *frustration* that people sometimes could not fully understand themselves. In this case, this student utilized the discourse move of *Questioning-sustained inquiry* to propose a new question of how education could help people identify interests and talents. These results suggest that the high contributor could engage in epistemic emotions of curiosity, challenged, and frustration for sustained inquiry.

Theme 2: Challenged, neutral, and frustration for progressive theory building

Challenged. As noted earlier in the *challenged* case from Theme 1, student s29 adopted *Theorizing-improving an explanation* with the *challenged* emotion to build on the previous explanation and then raised another question for sustained inquiry still with the *challenged* emotion.

Neutral. When discussing *Educational Transformation*, student s27 first neutrally proposed that educational transformation should focus on cultivating talents suitable for current society. Afterward, student s32 used *Theorizing-supporting an explanation* to support this proposal with enjoyment by the example of vocational education, followed by the high contributor s01's improved explanation in neutral.

Frustration. When discussing *What is Education*, student s25 first proposed that one's ultimate ability depends on individual learning approaches. Student s35 supported this explanation that the ideas and approaches brought by education are more important than education itself. Later, the high contributor student s33 improved this explanation to the angle of how to select educational assessment, with the discourse move of *Theorizing-improving an explanation* and the *frustration* emotion. These results suggest that the high contributors could engage in epistemic emotions of challenged, neutral, and frustration for progressive theory building.

Theme 3: Challenged and neutral for collective ideas mapping and creating

Challenged. When discussing *Educational Transformation*, most students focused on the relationships between society, technology, and educators. In contrast, the high contributor student s14 built on collective ideas and pointed out a new direction that educational transformation should consider for future education, with the discourse move of *Community-lending support* and the *challenged* emotion.

Neutral. When discussing *What is Education*, the high contributor student s29 *neutrally* synthesized the group ideas of relationships among education, society, and individual with the discourse move of *Community-synthesis*. The student also summarized group members' ideas of freedom, pointing out the gap between reality and the expectation of freedom. These results suggest that the high contributors could engage in challenged and neutral for collective ideas mapping and creating.

Discussion

This study investigated how undergraduates engaged in epistemic emotions and discourse moves contribute to collective knowledge advancement, supported by a learning environment enriched with students' designed learning journeys and learning analytics in knowledge building. Results from ENA models indicated that undergraduates who engaged in greater *curiosity*, *challenged*, *neutral*, and *frustration* were more inclined to advance collective knowledge through deeper discourse moves such as *Questioning-sustained inquiry*, *Theorizing-improving an explanation*, *Community-Synthesis*, and *Community-lending support.* The qualitative findings revealed three themes about the associations between these epistemic emotions and discourse moves that supported sustained inquiry, progressive theory building, and collective idea mapping and creating. This study evaluated epistemic emotion, which has seldom been studied in the context of knowledge-building, concerning students' usage of discourse moves and collective knowledge advancement. However, more emotions should be researched, as this study only looked at seven epistemic emotions. A significant future effort is also required to explore and examine knowledge-building designs for fostering epistemic emotions and progressive knowledge-building among students.

Decolonizing Climate Change Imagination: An “Engineering Fiction” Learning Experience

Brandon Reynante, Goutham Marimuthu
reynante@stanford.edu, gmarimut@stanford.edu
Stanford University

Abstract: The inadequate societal response to the climate crisis is partly due to epistemological and ontological colonization of climate change imagination. Climate education privileges scientific knowledge (epistemological colonization), which divorces climate change from emotions that typically drive concern and action, and dominant visions of the future obscure the possibility of collective socio-political transformation (ontological colonization). This study examined the effect of a learning experience that integrated engineering systems design and speculative fiction writing to engage 48 high school science students in imagining sustainable climate futures. Students wrote three climate fiction stories: an individually-authored story and a group-authored story during the introductory session, and a final group-authored story. We performed qualitative content analysis of these stories to identify relevant themes. The findings suggest that the intervention decolonized participants’ imaginations about climate change.

Decolonization of the imagination is the most dangerous and subversive form there is: for it is where all other forms of decolonization are born (Imarisha & Brown, 2015).

Introduction

The lackluster societal response to the climate crisis has been called a double failure of imagination (Milkoreit, 2017). First is a failure to perceive the severity of climate change risks since climate change is often construed as *psychologically distant* (i.e., more likely to impact strangers in remote locations and times), which reduces connection to emotional reactions that typically drive concern and action. Second is a failure to envision pathways towards just and sustainable futures.

The first failure of imagination is partly due to epistemological colonization. According to psychologist Jerome Bruner, there are two general modes of thought for interpreting and understanding the world. The first is the logico-scientific mode, which is a rational scientific approach to explain how the physical world works (Bruner, 1986). Western science purports to be the foundation of valid knowledge claims in modern societies, and it splits cognition from emotions in the pursuit of “objectivity,” a legacy of colonial thought imposed on other cultures. Climate change education privileges the logico-scientific mode, and several studies suggest that these approaches have been ineffective in altering youth’s climate change attitudes and behaviors (Rousell et al., 2017). The second mode of thought is the narrative mode, a storytelling approach used to make sense of people and their (inter)actions (Bruner, 1986). Fiction stories are a type of narrative that facilitate cognitive and emotional immersion into an imagined world (Mar & Oatley, 2008). The emerging sub-genre of climate fiction (or cli-fi) allows readers to cognitively inhabit climate-changed worlds and to vicariously experience the emotions of characters that live there (Milkoreit, 2017). The narrative mode thus promises a decolonial epistemology in STEM learning environments (Tzou et al., 2019).

The second failure of imagination is partly due to ontological colonization. Narratives about the future (i.e., ontologies) can generally be classified into four archetypes: continue, collapse, discipline, and transform (Dator, 2009). The continue archetype corresponds to continuation of the status quo. Since fossil fuels are so deeply embedded within our infrastructure, values, and habits, we lack coherent imaginaries of alternative post-fossil futures (Hajer & Versteeg, 2019). The collapse archetype consists of system degradation or failure. Popular apocalypse narratives in cli-fi stories depict this future as a foregone conclusion (Schneider-Mayerson, 2018). In the discipline archetype, behaviors adapt to imposed limits. Environmental education typically emphasizes individual, private-sphere behavior change (e.g., use less energy), but this directs attention away from the need for collective systemic change (Chawla & Cushing, 2007). The transform archetype involves game-changing new models or factors. Transform narratives often come from utopian fiction in the form of an imagined, idealized society. These narratives offer no concrete strategies for connecting future visions to present reality, and those that do typically privilege technological innovation as the primary or only driver of transition (Jovchelovitch & Hawlina, 2018). These Western visions of the future dominate our shared climate imaginaries and shape the boundaries for what is perceived as plausible and desirable through mental colonization that obscures the possibility of collective socio-political transformation.

Intervention design

We hypothesized that it may be possible to decolonize climate change imagination through a learning experience that integrates engineering systems design and speculative fiction writing. With its basis in the narrative mode of thought, speculative fiction expresses a decolonial epistemology. Furthermore, both engineering and speculative fiction are ontological design tools concerned with imagining alternative worlds and their societal implications.

We designed an intervention that tasks students with developing solutions and stories depicting transformation of a socio-technical system (e.g., food, energy) to a future 50 years from now where catastrophic climate change has been mitigated for a vulnerable population. To mitigate techno-utopian visions of the future, the intervention employed the "Systemic Transitions Framework" (Zaidi, 2017). This framework is derived from the worldbuilding practices of science fiction authors and guides the process of constructing an imaginary world by stripping it down to its foundations: philosophical, political, economic, environmental, technological, social, and artistic. The framework involves a "backcasting" process: (1) map the current state of the world; (2) envision a preferred future state of the world; and (3) backcast from the preferred future state to the current state.

The intervention consisted of ten 80-minute sessions. In the first session, students wrote individual and group (pre-intervention) stories. Groups of students were then guided through alternating stages of the engineering design and creative writing processes: define a climate justice problem in their chosen system, build an imaginary storyworld based on their system, analyze stakeholders in their system, develop characters based on their stakeholders, backcast a solution pathway to a desired future, outline a story plot based on their solution pathway, evaluate the potential impacts of their solution, write a draft (post-intervention) story, and share and reflect.

Methodology

This study was guided by the following research question: What is the effect of the "engineering fiction" learning experience on epistemological and ontological decolonization of students' climate change imaginations?

Participants

The participants were students in an environmental science class at a public Title 1 high school in Northern California. There were a total of 48 students split into 12 groups of 3 to 5 students each. Participants self-reported their demographic information (gender: 65% female, 35% male; age: M = 17 years, SD = 0.8; race/ethnicity: 71% White, 12.5% Hispanic/Latinx, 12.5% Asian/American, 2% Native American, 14.5% did not respond).

Data collection

We analyzed participants' pre- and post-intervention stories because they are concrete externalizations of imagination. Individual (n = 43) and Group (n = 12) pre-intervention stories addressed the following prompt: "Picture a person from a group that is at high risk of being negatively impacted by climate change. Write a short story (~300 words) describing who this person is, how they are affected by their situation, and the future world of this person's group 50 years from now." Group (n = 12) post-intervention stories addressed a similar prompt: "Write a story (minimum 2,000 words) depicting the struggle of your protagonist to face a climate justice problem and bring about a desired future 50 years from now." Final stories available here: https://climateimaginaries.com/.

Data analysis

We performed qualitative content analysis (Krippendorff, 2018) to uncover themes related to epistemological and ontological colonization. We used a team-based deductive and inductive coding approach (see Table 1).

Table 1
Codes and descriptions

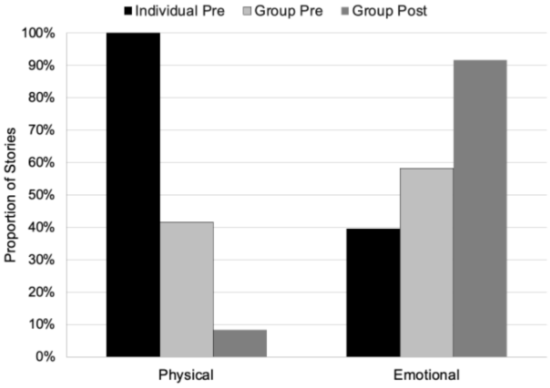
Parent Code	Unit of Analysis	Child Code	Description
Character impacts	Phrase / sentence	Physical	Describes physical impacts of climate change on a character.
		Emotional	Describes emotional impacts of climate change on a character.
Future vision	Story	Continue	Continuation of the status quo.
		Collapse	System degradation or failure.
		Discipline	Behaviors adapt to internal or external limits.
		Transform	Game-changing new models or factors.
Climate justice solutions	Phrase / sentence	Economic	Solutions related to resource management.
		Philosophical	Solutions related to beliefs, attitudes, values, ethics.
		Political	Solutions related to governance, laws, policies.
		Social	Solutions related to behaviors, norms, social institutions.
		Technological	Solutions related to scientific and technological innovation.

Results

The proportions of stories depicting physical or emotional impacts of climate change on characters are plotted in Figure 1. Depiction of physical impacts was common in the pre-intervention stories (42-100%) and decreased significantly in post (8%). As a character in one pre-intervention story states: “When the temperature exceeds 75 degrees…my body reacts in bizarre ways.” Depiction of emotional impacts increased significantly from pre (40-58%) to post (92%). A character in a post-intervention story describes their reaction to being forced away from her family farm due to drought: “I screamed, my world was falling apart, all I have ever known was crumbling in such a short amount of time. I was scared, scared for what’s going to happen to my family, what I’m going to have to do.”

Figure 1

Proportion of stories depicting physical or emotional impacts on characters

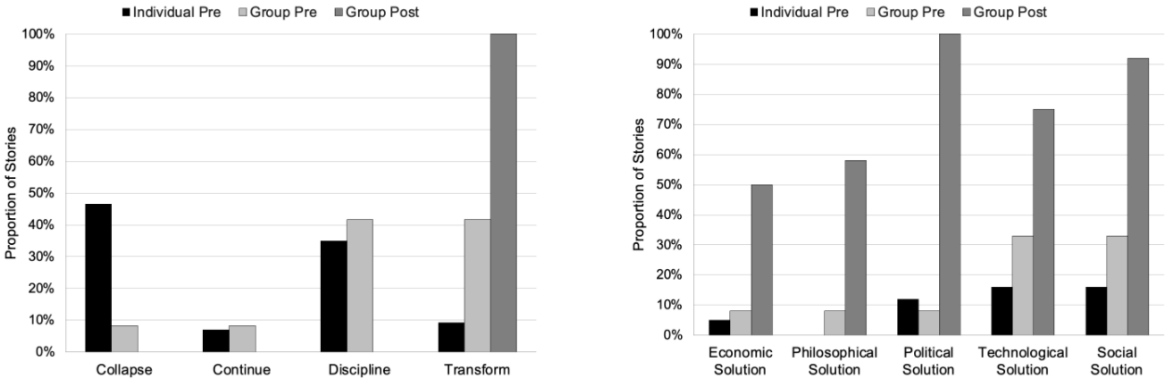


The proportions of stories depicting the various future vision archetypes are plotted in the left-hand side of Figure 2. Individual pre-intervention visions of the future were mostly collapse (47%) and discipline (35%). An example from a collapse story depicts system degradation: “We are left in a world where anyone who cannot afford food simply dies.” An excerpt from a discipline story highlights the need for characters to adapt: “...they would need to find a new environment to live in with less harsh conditions.” The group post-intervention stories were all transform. One narrative describes how: “The people have overpowered the government's will to pump oil for money and went full electric.”

The proportions of stories depicting various climate justice solutions are plotted in the right-hand side of Figure 2. Few pre-intervention stories depicted solutions, and those that did tended to emphasize technological (16-33%) or social (16-33%) solutions. In one pre-intervention story, a character: “...had to adapt to wearing thermal gear that completely protected him from the sun, he looked like an astronaut.” In the group post-intervention stories, there was much greater depiction of climate justice solutions, particularly political solutions (100%). For example, in one post-intervention story: “people took to the streets, all across the nation people were outraged…The capital saw the biggest protest since the beginning of the nation.”

Figure 2

Proportion of stories depicting various future visions (left) and climate justice solutions (right)



Discussion

A large proportion of pre-intervention stories depicted physical mechanisms of climate change impacts on characters, which aligns with the logico-scientific mode of thought (Bruner, 1986). The post-intervention stories primarily centered around emotional impacts of climate change, suggesting that the students demonstrated deeper empathy for the impacted people by imagining their feelings to a greater extent. These results support theoretical arguments that the narrative mode of thought can facilitate emotional immersion into a storyworld and empathy for the characters (Mar & Oatley, 2008), specifically those impacted by climate change (Milkoreit, 2016). Greater emotional connection to climate change may in turn spark greater concern and action (Rousell et al., 2017). This finding suggests that the intervention fostered epistemological decolonization of climate change imagination.

Future visions depicted in the individual pre-intervention stories were mostly collapse or discipline archetypes, which aligns with dominant visions in cli-fi stories (Schneider-Mayerson, 2018) and climate change education (Chawla & Cushing, 2007), while the group post-intervention stories were all transform archetype. Furthermore, most pre-intervention stories lacked details of transitions connecting future visions to the present, which is a common limitation of utopian fiction (Jovchelovitch & Hawlina, 2018). The few solutions depicted in pre-intervention stories were mainly technological, which aligns with dominant Western images of the future (Angheloiu et al., 2020; Jovchelovitch & Hawlina, 2018). In contrast, the group post-intervention stories largely emphasized collective socio-political transformation. These results suggest that the use of worldbuilding techniques that encouraged transformation of multiple dimensions of human culture was successful in mitigating techno-solutionism (Zaidi, 2017). The findings also support the intervention design rationale of engaging participants in "backcasting" and writing "transtopias"—stories depicting transitions between our world and those in fictional futures (Zaidi, 2017). Overall, the learning experience appeared to foster ontological decolonization of climate change imagination, which supports findings from other studies of how writing cli-fi can be an ontological tool for imagining new possible worlds through resistance to the present (Rousell et al., 2017).

Science and Engineering for What? A Large-Scale Analysis of Students' Projects in Science Fairs

Adelmo Eloy, Universidade de São Paulo, adelmo.eloy@usp.br
Thomas Palmeira Ferraz, Télécom Paris, thomas.palmeira@telecom-paris.fr
Fellip Silva Alves, Universidade de São Paulo, fellipalves15@usp.br
Roseli de Deus Lopes, Universidade de São Paulo,roseli.lopes@usp.br

Abstract: Science and Engineering fairs offer K-12 students opportunities to engage with authentic STEM practices. Particularly, students are given the chance to experience authentic and open inquiry processes, by defining which themes, questions and approaches will guide their scientific endeavors. In this study, we analyzed data from over 5,000 projects presented at a nationwide science fair in Brazil over the past 20 years using topic modeling to identify the main topics that have driven students' inquiry and design. Our analysis identified a broad range of topics being explored, with significant variations over time, region, and school setting. We argue those results and proposed methodology can not only support further research in the context of science fairs, but also inform instruction and design of contexts-specific resources to support students in open inquiry experiences in different settings.

Introduction

Participating in Science and Engineering Fairs (SEFs) provide students with an opportunity to showcase the outcomes of inquiry processes, developing a better understanding of science and an increased interest in STEM fields. (e.g., Grinnell et al., 2020). SEFs also offer students a space for authentic participation in "doing science," by engaging with science and engineering practices, as well as taking a sense of commitment and ownership over their projects (e.g., Koomen et al., 2018). Similarly, SEFs are often used to illustrate how students can experience open inquiry, since they can define themes, questions, and approaches in a continuous decision-making process (Zion & Mendelovici, 2012). In particular, while students are able to bring their passions and interests into the scientific inquiry process (Adler et al., 2018), with limited research on how such agency in problem finding manifests in SEFs (LaBanca, 2012). To help address this gap, we propose the following research questions:

1. What are the main topics students participating in SEF choose to explore in their projects?
2. How do those topics vary in time, school settings, and region where they come from?

In this study, we employed topic modeling, a machine learning technique, to analyze data from over 5,000 projects presented in a nationwide science and engineering fair in Brazil. Our analysis revealed the main themes driving students' investigation and design in their projects, and how they are responsive to their context, illustrating how students' interests manifest in their work. We argue these findings can inform designers and teachers on what kind of resources would be most relevant to support students in open inquiry processes.

Methods

Setting: The Brazilian Science and Engineering Fair (FEBRACE)

FEBRACE is a major outreach program of the Universidade de São Paulo launched in 2003 that annually holds the largest nationwide SEF in Brazil, where students from all states showcase hundreds of projects after being selected from over 2,000 submissions per year. To join FEBRACE, teams up to three students from public and private schools submit their projects for evaluation by a jury or are selected by one of the associated regional fairs. The submission materials include a paper/report and a five-minute video presenting their project. Selected students present their project in a synchronous event and undergo a further round of evaluation and feedback. FEBRACE publishes information about the projects selected (e.g., title, authors, institution, abstract and keywords) in annual proceedings available on their website. Outstanding projects are then selected for the International Science and Engineering Fair (ISEF), to which FEBRACE is affiliated.

Data collection and analysis

In this study, we collected information from 5,296 projects accepted and presented at FEBRACE, from 2003 to 2022. Information of each projected included title, keywords, abstract, year presented, school setting, and state/region of origin. FEBRACE proceedings were the main data sources for the dataset (additional information was provided by the organizing committee), which is available upon request.

We used topic modeling to identify major topics among students' projects. Topic modeling is a statistical model that consists in extracting topical patterns within a collection of documents (Egger & Yu, 2022). It has been widely applied to educational research, such as identifying the relationship between the topic relevance of pre-service teachers' journals and their grades (Chen et al., 2016), and identifying major topic from students' essay to support the design of culturally adaptive learning experiences (Coelho & McCollum, 2021).

More specifically, we used the BERTopic (Grootendorst, 2022), which is a deep learning-based model that takes a set of documents, clusters it into topics, and generates representative words for each topic. Before using the BERTopic, we employed text pre-processing techniques, namely *Stopword Removal* (cutting non-significant parts of the vocabulary) and *Lemmatization* (converting nouns and adjectives to their masculine and singular form, and verbs to their infinitive form) (Ferraz et al., 2021).

Two automatic metrics guided the BERTopic: *coherence* (measures an average of the degree of semantic similarity between the words that represent each topic) and *diversity* (measures the percentage of unique words that represents the topics, which means how varied the whole set of topics is) (Dieng et al., 2020). BERTopic managed to assign 58% of the projects in 72 topics with at least 10 projects, which is a reasonable performance given the challenges of automatic categorization (Alcoforado et al., 2022). We manually proposed shorter terms based on the representative words of each topic and reviewed them with external professionals from the FEBRACE organizing committee.

We compared the distribution of topics across three variables: year (grouped into 4-year intervals), region (corresponding to Brazil's 5 macro regions) and school setting (categorized as public or private, which were the most prevalent in our sample). We used the Chi-square statistical test of independence to determine if there were statistically significant differences between groups for each variable. Finally, we identified topics with the highest values of dispersion and described top-5 lists for each variable to expand the findings from the statistical test.

Findings

Using topic modeling, we classified 3,087 projects from our sample into 72 topics (42.9 projects per topic, SD=36.9). Topic coherence was 0.62, which aligns with typical results in the literature (Röder et al., 2015), and topic diversity was 0.72, indicating that the topics are distinguishable from each other (Dieng et al., 2020). Figure 1 shows the distribution of projects across the topics, with the top 10 topics (colored in yellow) containing 1,188 or 38.5% of the projects, while the bottom half of topics (colored in dark gray, each with 30 or fewer projects) represent 765 or 24.8% of the projects. A complete list of topics is available at bit.ly/isls-2023-sef-topics.

Figure 1

Number of occurrences for each topic identified in the model, together with a general top-10 list of topics.

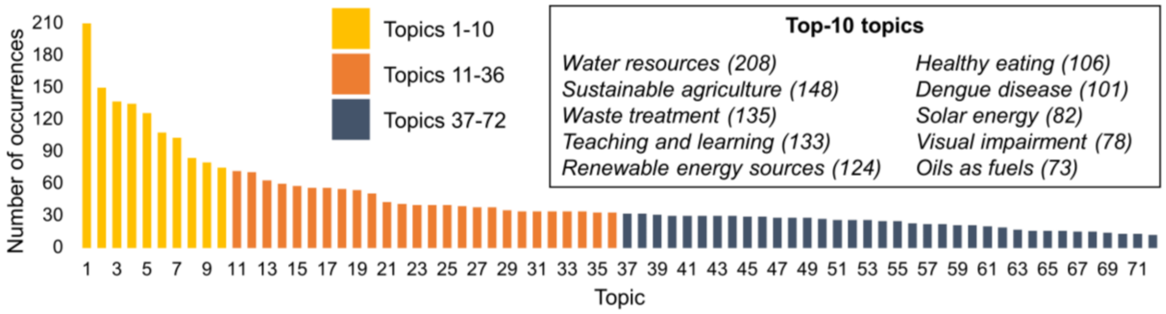

Table 1 presents results from the Chi-square Test of Independence on the topics across three variables: *year* (grouped in 5 four-year ranges, from 2003-2006 to 2019-2022), *region* (corresponding to Brazil's 5 macro regions), and *school setting* (public or private schools). Degrees of freedom (DoF) were adjusted for variables with 5 categories due to the requirement of at least 5 projects in each category, resulting in fewer topics (N_topics). Despite this, p-values ($p<0.05$) and strength of association ($0.1<\omega< 0.3$) indicated the difference between groups are statistically significant with a small relationship between topic proportion and each variable, respectively.

Table 1

Results for the Chi-square Test of Independence with three different variables

Variable	Categories	Dof	N_topics	Chi-square	P-value	Cohen's omega (ω)
year	5	60	16	97.3	0.0017	0.255
region	5	36	10	55.6	0.0195	0.216
school setting	2	42	43	81.0	0.0003	0.179

In addition, we identified the 5 most frequent topics for each variable in their respective categories to help illustrate the relationship between topics and variables. Due to space constraints, we only present the results for the “year” (Table 2) and “region” (Table 3) variables; we used a color scheme to help identify the “intruders”, i.e., topics present only in one or two intervals.

Table 2
Top-5 topics for each year-interval explored in the study.

Rank	2003-2006	2007-2010	2011-2014	2015-2018	2019-2022
#1	Water resources	Water resources	Waste treatment	Water resources	Sustainable agriculture
#2	Robotics	Sustainable agriculture	Water resources	Waste treatment	Teaching and learning
#3	Renewable energy sources	Renewable energy sources	Dengue disease	Sustainable agriculture	Water resources
#4	Teaching and learning	Heritage languages	Sustainable agriculture	Dengue disease	Covid-19
#5	Oils as fuels	Learning of sustainability	Teaching and learning	Renewable energy sources	Healthy eating

Table 3
Top-5 topics for each region explored in the study.

Rank	Southeast	Northeast	South	Central West	North
#1	Water resources	Water resources	Sustainable agriculture	Sustainable agriculture	Water resources
#2	Sustainable agriculture	Dengue disease	Waste treatment	Renewable energy sources	Waste treatment
#3	Teaching and learning	Waste treatment	Teaching and learning	Water resources	Sustainable agriculture
#4	Renewable energy sources	Teaching and learning	Water resources	Waste treatment	Teaching and learning
#5	Visual impairment	Sustainable agriculture	Renewable energy sources	Dengue disease	Traffic accidents

Some "intruders" in Table 2 demonstrate how topics are influenced by the year in which projects were designed. For example, "dengue disease" is the seventh most common topic among all projects but became significantly more frequent in the 2010s due to an increase in cases in Brazil (Nunes et al., 2019). "Covid-19", which became relevant globally, was the fourth most common topic in 2019-2022. Similarly, in Table 3, "dengue disease", is more relevant to students from two regions (Northeast and Central West), which historically have had the highest incidence *per capita* of the disease (Catão & Guimarães, 2011).

Discussion and future work

Our findings illustrate the diverse range of topics that students have explored in their science and engineering projects at FEBRACE (RQ1). Some of the most frequent topics relate to environmental studies (e.g., “water resources”, “sustainable agriculture”, “renewable energy sources”) and indicate some responsiveness to the Brazil’s natural resources and economy; at the same time, they support a more traditional view of scientific inquiry, associated to the Natural Sciences. On the other hand, the list of topics also provides examples from the Social Sciences, such as “teaching and learning”, violence against women” and “heritage languages”. Further in-depth analysis of sample projects focusing on specific topics can provide valuable insights into their relevance and potential impact on students' understanding of science inquiry and the broader scientific field. In addition, the results from statistical tests suggest the topics identified in this study are responsive to their context (RQ2), supporting their description as open inquiry processes (LaBlanca, 2012). Including additional variables, such as city size and HDI, together with the analysis of actual projects from those topics can provide a more nuanced understanding of the relationship between context and scientific inquiry.

This study has limitations stemming from the data sources used. The topic modeling analysis was based solely on projects presented at FEBRACE, as they are publicly available. Including data from all submissions could have led to different results but would still have been limited in terms of representativeness, as we cannot affirm students have equal access to the fair. Additionally, the list of topics is specific to the context of this study and may vary in other contexts. Rather than generalizing our results to any SEFs, we propose that our methodology can support the design of similar studies in different SEFs and open inquiry processes, both within and beyond Brazil. Most importantly, those findings point to the opportunity of providing students with adequate resources to support their inquiry. Open inquiry processes can be mistakenly perceived as independent of teacher guidance and support, whereas teachers play an important role in scaffolding students' inquiry (e.g., Hmelo-Silver et al., 2007). That means, for example, making sure students have access to resources that will enable their inquiry (Zion & Mendelovici, 2012), taking into account context-specific opportunities and constraints. Our results can thus inform both instruction and the design of meaningful resources that support teachers and students' inquiry not only in SEF projects, but in general open inquiry experiences.

Designing for Feelings: Disruptive Beginnings in Youths' Designs of Mixed Reality Activities for Sustainability

Abstract: Dominant approaches to increasing environmental sustainability emphasize anthropocentric, technocentric solutions and definitions of progress, often failing to recognize humans' entanglement with the rest of the world. This study explores how youth conceptualized sustainability when they were positioned as designers of mixed reality activities about environmental issues for younger students. Specifically, we analyze the emotional configurations (Vea, 2020) youth designed for and explore how their designs reached toward posthumanist approaches to science education for sustainability (Jeong et al., 2021).

Introduction

Our current environmental precarity generates several pressing needs for education to foster more sustainable human-nature relations. First, to counter the burden of environmental anxiety that people, particularly youth, feel, we need *forms* of participation that will build hope and agency (Ojala, 2012) and fuel continued participation rather than despair and apathy. Second, to sustain reciprocal rather than exploitative human-nature relations, we need to shift away from didactic science instruction *about* the natural world, which objectifies nonhuman beings, upholds human supremacy, and backgrounds sociocultural and ethical issues behind the veil of objectivity (Gilbert, 2016); toward a recognition of humans' entanglement *with* the natural world (Jeong et al., 2021). And third, recognizing the undue burden on youth to 'fix' environmental problems that they did not create and power hierarchies that often strip youth of environmental agency (Kouppanou, 2020), we need to center youth voices as we fashion collective actions that can express new human-nature relations. New representational media such as mixed reality (MR) offer opportunities to engage in alternate realities and develop new orientations toward action, but their promise to support collective action for environmental good is still unknown. Thus, we asked: *When given the opportunity to design MR learning experiences about environmental sustainability, how do students conceptualize sustainability and their role within it?* In this paper we share findings from a workshop in which 9th graders designed MR activities for middle schoolers on a topic that the 9th graders chose: sustainability.

Design rationale and analytic framework

Participatory simulations have enabled learners to explore the impact of individual (agent-based) actions on the behavior of social-biological systems (Kumar & Tissenbaum, 2019), and contributed to students' empathy toward nonhuman beings and disruption of human-centric relations with nature (Jen et al., 2021). In this study we leveraged MR technologies to facilitate perspective taking to create space for youth to explore relational understandings of and disrupt the anthropocentrism that pervades typical science classrooms. Moreover, we positioned youth as designers of participatory simulations for younger learners which pressed them to elucidate their understandings of sustainability phenomena for others. Our prior experiences with students' emotional engagement in participatory simulations (Jen et al., 2021), recognition of feelings as inherent in science (Pierson et al., in revision; Jaber & Hammer, 2016), and desire to position youth as change agents, led us to center three guiding questions throughout youths' design process: *How do you want participants to feel? What do you want them to think about? How do you want them to act or change their behavior?* When analyzing students' design responses, we realized these questions aligned with Vea's (2020) concept of *emotional configurations,* which refer to interrelationships between emotions, sense-making, and practice in social activity. More specifically, we saw his concept of *guided emotion participation* as one way that youth designed to cultivate emotional configurations for others. Their designs and design process suggest potential *generative* and *exploratory* roles that activities might play in *identifying* emotional configurations, which could complement the *normative* role of guided emotional participation in producing participant alignment to a *fixed* configuration.

We saw students' nascent articulations of emotional configurations as reaching toward an image of social-ecological relations that could move beyond anthropocentrism. Though they had no explicit guidance in this respect, we saw alignment with Jeong and colleagues' (2021) *posthumanist* framework intended to guide science education towards cultivating more sustainable human-nature relationships. Their emphasis on favoring relational rather than humanist ethics, balance instead of progress, and entanglements over "neutral" objectivism aligned with students' emergent conceptualizations about sustainability learning.

Context & methods

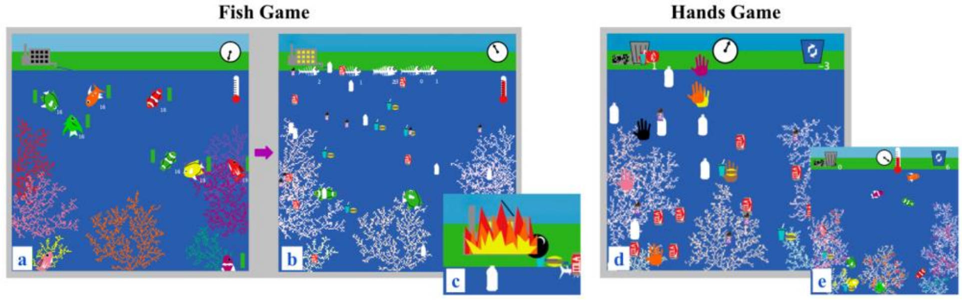
Our data come from a six-session workshop in a STEM program that is a joint venture between a private university and an urban public school district in a southeastern U.S. city. The four-year program brings a racially and economically diverse cohort of high school students to the university one day per week throughout their high school career to engage in research-centered science learning. All of the 9th graders (28) participated in our workshop, working in groups to design and then facilitate sustainability-themed MR activities for middle school participants in another university program. Each author guided one group of students throughout the workshop; this paper focuses on Jen's group. Each of the six sessions lasted 1.5–3 hours. (For session details, see Brady et al., 2022.) Since design, rather than programming, was the focus of the workshop, the research team converted groups' designs into MR using NetLogo (Wilensky, 1999) and a NetLogo language extension (Brady, 2022). This paired NetLogo's visualization capacity with a tag-based tracking technology called Pozyx, which enabled participants' movements around the room to control digital agents in a projected NetLogo model (Figure 1).

Figure 1
The MR environment

While we were initially interested in differences between groups' approaches to design (see Brady et al., 2022), the complexity of each group's work led us to narrow our focus to Jen's group of seven students, because of the nuanced ways they took up guidance to design for participants to feel, think, and act. Jen content logged all video recordings of her group, then transcribed select episodes to explore students' conceptions of sustainability in their initial brainstorming and later reflections on the workshop, as well as the motivation behind their designs and their facilitation with middle school students. Interaction analysis (Jordan & Henderson, 1995) of students' brainstorming led to a focus on students' ideas about agency (who does or doesn't have it) and the emotional configurations at play in their designs and design process. This led Jen to code transcripts from focal episodes as well as students' written reflections with a priori codes informed by emotional configurations (Vea, 2020) and posthumanist science education (Jeong et al., 2021). She reviewed coded excerpts to synthesize understandings of students' conceptions of sustainability and refined these findings through conversations with the other authors.

Findings

Figure 2
Students' MR activities



The focal group designed activities that highlighted impacts of pollution and climate change on ocean ecosystems (Figure 2). They created two games: Fish Game and Hands Game. In Fish Game, participants played as fish trying to survive in a coral reef ecosystem by eating coral (Figure 2a). After ten seconds, a factory turned on and polluted the water with a steady stream of trash, on which fish got caught. The factory also polluted the air (gradually darkening the sky) and emitted greenhouse gases, which raised the temperature of the water (represented by a thermometer). This in turn caused the coral to bleach. It became nearly impossible for fish to survive, so most of the fish died (see fish skeletons in Figure 2b). After Fish Game, the students facilitated a discussion about what happened, how it felt, and what should change, and then played an animation where a wrecking ball destroyed the factory (Figure 2c). Then, in Hands Game, participants played as hands to clean up the ecosystem, picking up trash and sorting it into trash and recycling bins (Figure 2d). Finally, a second animation showed the temperature gradually decreasing, coral regrowing, and fish eventually returning to the ecosystem (Figure 2e).

In brainstorming Fish Game, students developed a core idea of having participants feel and make sense of human impacts from the perspective of a different species. For example, one student shared, “I feel like I would want them to think like about being in… the shoes of the life in the ecosystem. And like seeing, like thinking about that and then seeing the effects [of changes to the ecosystem].” As students grappled with design specifications, such as how much trash the factory should emit, they emphasized making the game feel “overwhelming,” and spurring participants to feel “upset” and “regret for knowing humans contribute to the problem.” Students thus designed for an emotional configuration that linked feelings of stress, anger, and regret to the practice of polluting, and sense-making about the accumulative impact of pollution.

Students’ emphasis on feeling as and for fish demonstrates an expansive ethics of the sort Jeong and colleagues (2021) advocate, recognizing fish as worthy of care. By centering fish’s perspectives, students also decentered humans. Furthermore, they centered entanglement (Jeong et al., 2021) in their facilitation of Fish Game. Though they did not incorporate how humans were affected by the interactions in their game, they touched on this while facilitating a debrief with middle school participants, framing humans as entwined in a larger system. They asked how the death of fish indirectly affected humans and a participant shared how people rely on fish and the ocean for food, concluding, “Basically if you destroy it [the ocean] you’re also kind of destroying yourself.”

At first glance, students’ Hands Game may seem to forward an anthropocentric narrative of humans as saviors. However, the arc of their entire activity sequence, and the emotional configuration they designed for complicates this assumption. While leading a debrief of the two games with middle school students, Uma, described, “I feel like they’re like two contrasts almost like, it like really, makes you think about, wow what are these humans doing to the Earth? And it like makes you think about what you can do to fix it.” Uma’s distinction between “these humans” and “you” distances her from polluting industries and aligns her and her peers with those working to ameliorate environmental degradation. Notably, this frames Fish Game as a critique of capitalist industries. While youth’s ability to ‘fix’ the economic and political systems that cause environmental degradation is limited in the real world, within the imagined space of MR, youth can tear these systems down. The wrecking ball that concludes Fish Game does just this and seems to signify a transition from a scenario modeling the real world to an imagined alternative. In this context, Hands Game can be interpreted as a speculative design of an alternate future, where the factory’s absence enables collective, restorative action. Importantly, rather than a linear narrative of cleaning up the trash to solve the pollution problem, students discussed Hands Game in terms of a *cyclical* relationship between practice, feeling, and sense-making. Xavier reflected, “When [participants] help clean up and see all the good effects they feel excited to help make a difference. We want our audience to think about if someone individually can really make a difference.” He described an interrelationship between the practice of cleaning up, a feeling of excitement, and sense-making about the cumulative impact of individual positive actions. He and his peers saw this emotional configuration as impetus for further environmental practices, and they were adamant about *not* representing a full return to a pre-pollution state. For example, they said coral ought to regrow *on top of* the bleached coral rather than *replace* the bleached coral in the final animation (Figure 2e). Xavier explained, “that shows like this is still here, this is still a problem. You didn’t fix everything. Instead of, ‘Oh it’s all gone, it’s all better now,’ cause once you pollute, it’s not gonna be all better again.” Retaining representations of pollution, students did not simply view humans as saviors. Furthermore, rather than the linear logic that is traditionally emphasized in science education, the emotional configuration students designed for in Hands Game represents a virtuous cycle towards a more harmonious ecosystem (Jeong et al., 2021).

At another level, the sequence of activities students designed suggests the emotional configurations that stabilized for the youth *designers*. A student in one of the other groups reflected, “I always felt like there was pressure towards people our age to fix environmental problems and face the consequences of human activity… I wanted [participants] to not feel this huge amount of pressure… to show them that they aren’t alone.” The weight of environmental problems, frustration with inheriting them, and desire to feel a sense of community was evident in the focal group’s work as well. This feeling was entwined in their representation of negative human impact as a polluting factory, which served as an indictment of power-holding older generations. The practice of designing thus served as a release of their frustration, however it also offered a way to make sense of their agency to sustain Earth and to counter negative emotions with a sense of hope. Students stressed the importance of awareness in efforts toward sustainability. For example, Kareem explained that their activity would make “participants feel surprised for how small impacts can build up to a larger problem… because I don’t believe they have realized visually what impacts that pollution leads to… participants will maybe even be determined to pick up after themselves if they already don’t and even after others that leave their trash behind.” They viewed awareness as potentially spreading beyond their middle school audience as that audience could share with others, who might share with others, and so on and so forth. The importance of working together also came up in their reflections on the process of design. For example, Niles reflected, “Working alone is not easy and having the support and contribution of others can be a great thing.” Thus mirroring the emotional configuration they designed for in Hands Game, the practice of working together to spread awareness was linked to feelings of fellowship and hope, and to a notion of individual actions accumulating to make a difference. In summary, collectively designing for a hopeful emotional configuration generated a hopeful emotional configuration.

Conclusion

Designing for MR encouraged students to consider the interconnections between different elements in a system and to view the system from a nonhuman perspective. In combination with a focus on emotions, it allowed them to gain a felt embodied sense of environmental degradation. It also created opportunities to imagine alternative futures, which in turn created space for hope. Given the importance of cultivating hope to counteract youth’s anxiety around environmental issues (Ojala, 2012), the significance of this should not be understated. Moreover, our study also suggests that designing MR activities for younger peers may offer a compelling setting for exploring and recognizing the importance of emotional configurations. If so, it would offer a *generative* activity structure for *constructing* new emotional configurations, thus complementing the *normative* activity structure of guided emotion participation (Vea, 2020), which aims to *disseminate* existing emotional configurations.

On the other hand, we do not want to overstate the outcomes of the workshop. Undoubtedly, aspects of students’ designs and interactions throughout the workshop demonstrated posthumanist notions of sustainability (Jeong et al., 2021), extending care to nonhuman beings, decentering humans, centering entanglement, and forefronting cycles towards harmony over linear progress. However, notions of human control over nature were also persistent throughout the workshop. So, we do not mean to suggest that the posthumanist conceptions that emerged were necessarily enduring. Nonetheless, the construction of emotional configurations seems to have spurred disruptive beginnings towards recognizing human entanglement with the rest of the world.

Developing Teachers' Contingent Responsiveness in Science Discussions With Mixed-Reality Simulation: A Design-Based Study

Lydia Y. Cao, Harvard University, lydiacao@gse.harvard.edu
Rupert Wegerif, University of Cambridge, rw583@cam.ac.uk
Sara Hennessy, University of Cambridge, sch30@cam.ac.uk
Chris Dede, Harvard University, chris_dede@gse.harvard.edu

Abstract: Orchestrating productive science discussions is challenging for teachers. Little is known about how to support teachers to develop contingent responsiveness (CR), the adaptive expertise in responding to student ideas in the moment to improve the collective dialogue. Using a design-based research method, a professional development (PD) programme that incorporates mixed-reality simulation (Mursion) was co-designed remotely by researchers and practitioners in Pakistan during the pandemic over four iterations. This study found that the PD is effective in supporting teachers to develop CR, which was evident in the shift of teachers' response patterns shown by epistemic network analysis (ENA). Furthermore, conjecture mapping shed light on how the PD works and how teachers learn. It was found that 1) adopting dialogic framings, 2) developing fluency with talk moves, 3) deploying flexible attention, 4) engaging in knowledge-based reasoning, and 5) experiencing metaphoric resonance could lead to CR.

Introduction

The role of talk in science education has long been established – an essential part of learning science is for students to learn to engage in scientific discourse (Lemke, 1990). There is increasing empirical evidence for the role of talk in student learning, including evidence from large-scale randomised control trials (Alexander, 2018; Howe et al., 2019). Nonetheless, productive talk is still rare in the classroom. The rarity of productive talk can be partly attributed to the complexity of dialogic teaching. So far, little is known about how teachers manage the demanding work of moment-to-moment interaction and decision-making in classroom and how to prepare teachers for such a challenge (Lefstein, 2008; Sedova et al., 2014). This study attempted to shed light on how we could support teachers to think and act in the moment and respond to student ideas during science discussions.

What is contingent responsiveness (CR)?

Studies have found that the teacher's response in classroom discourse, plays a vital role in determining opportunities for student sense-making and the quality of classroom discourse (Park et al., 2017). For example, Boyd and Rubin (2006) found that the contingency of teachers' questions mattered more than the nature of the question itself (e.g., open or closed) in terms of extending student talk. However, most of the classroom discourse is characterised by the IRE (Initiation-Response-Evaluation) or IRF (Initiation -Response-Feedback) patterns (Mehan, 1979; Park et al., 2017; Sinclair & Coulthard, 1975) Usually teacher initiate a question, which is responded by student's reponse, followed by teacher's evaluation or feedback. The IRE/IRF pattern of discourse is highly controlled by teachers and limit students' opportunities to engage in sense-making (Howe et al., 2019). In this study, *contingent responsiveness* (CR) is defined as a teacher's adaptive expertise in responding to the dynamic flow of student talk in the moment, with the goal to improve the collective dialogue.

Operationalization of contingent responsiveness

Previous research often focus on the *form* of the teacher's talk rather than its *function* in the dialogue (e.g., Jacobs & Empson, 2016). For instance, often researchers define responsiveness in advance and look for it in teachers' discourse using a predetermined observational rubric (e.g., Lineback, 2015; Pierson, 2008). Indicators of responsiveness include the use of talk moves, such as eliciting a student's ideas and pressing students to elaborate. Boyd and Markarian (2011) noticed that talk could appear dialogic in form, but not dialogic in spirit. O'Connor and Michaels (2019) also found that sometimes talk moves were used in a robotic and perfunctory manner without necessarily advancing the discussion and student thinking. Thus, a teacher's moves should not be predetermined, but rather selected and invented in response to the situation at hand (Chazan & Ball, 1999).

Shifting away from decontextualised indicators of responsiveness, we draw on Bakhtin's (1986) dialogism and view dialogue as relation of voices rather than a tool of mediation (Wegerif, 2008). This shift implies an ontological change from seeing student ideas as individual "things" to mediate to seeing them in relation with each other. Engaging with others in dialogue thus means to de-identify from the individual ideas and instead identify with the whole dialogue to improve the collective dialogue. Wegerif (2010, p. 66) used the metaphor of a space to convey dialogism. Class discussion thus can be conceptualised as a dialogic space where different lived experiences, perspectives, and ways of knowing and understanding are not only acknowledged and respected, but also resonate, merge, clash, to generate new ideas and perspectives. From a dialogic perspective, teacher's role is not to mediate various student ideas, but rather to facilitate the collective dialogue, i.e., to widen, deepen, maintain, or shape the dialogic space.

This operationalisation of CR emphasises the role that the teacher's response plays in the discussion rather than the form of talk. *Widening* dialogic space is defined as increasing the degree of difference between perspectives in dialogue (Wegerif, 2010). In a classroom, the widening of a dialogic space can be enacted by soliciting different student ideas, encouraging students to elaborate, introducing new ideas, embracing a diversity of intellectual resources and multiple ways of knowing, and incorporating students' language and experience into the classroom discourse. *Deepening* was defined as increasing the degree of reflection on assumptions and grounds (Wegerif, 2010). The deepening of a dialogic space in a science classroom often looks like moving from surface observation to underpinning features of the phenomenon, examining evidence, constructing scientific reasoning, questioning the ontological and epistemological assumptions. *Maintaining* is to signal the ongoing nature of dialogic space. In contrast to the conventional practice of wrapping up a lesson or a unit neatly and reaching a conclusion or agreement, dialogic education reveals the messiness and ongoing nature of learning and thinking. Finally, *shaping* a dialogic space is to make visible the expectations and ground rules of the particular kind of dialogue that students engage in and practice of a discipline according to the standard of the community and the disciplinary ways to share their thinking.

Research questions

The goal of this study is to design a professional development programme (PD) that allows teachers to develop CR . The research questions are formulated as the following:

1. To what extent were teachers contingently responsive to students before and after the PD?
2. What are the mechanisms that support teachers in developing contingent responsiveness?

Methodology

This study used a design-based research method to answer both whether the PD works and to understand how it works. Researchers co-designed a PD programme remotely with practitioners in a democratic school in Pakistan during the pandemic. Thirteen teachers initially participated in this study. Four teacher coordinators participated in the co-design and refinement of the workshops throughout four iterations. The PD programme had two components: 1) Four collaborative workshops, where teachers engaged in collaborative and guided inquiry (i.e., asynchronous interactive learning module), collective reflections to develop a conceptual understanding of dialogic science teaching; 2) Four simulation sessions, in which teachers put into practice their learning from the workshops by orchestrating a science discussion in a virtual classroom with avatar students (controlled by a simulation specialist behind the scene), just as a pilot learns to fly a plane in a simulator.

Data sources and analysis

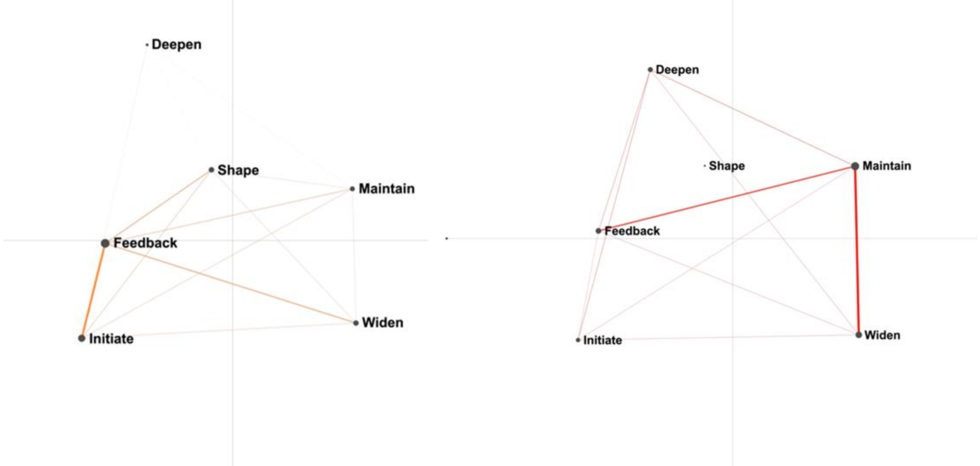
Teachers were asked to record their science classroom discussion for approximately 20 minutes both before and after the PD. There was no specific framing or topic given to teachers. The open-ended nature of the task allowed researchers to capture teachers' practice in an authentic manner when in-person observation was not possible. Thirteen teachers initially participated in the study, but due to pandemic-related attrition and administrative reshuffling at the school level, seven teachers left the school, and four teachers participated in all four iterations. Three teachers provided both pre- and post-PD video recordings of their real-world classroom discussions, which the analysis was based. To measure the extent to which teachers were contingently responsive to students before and after the PD, teachers' pre- and post- PD classroom discussion recordings were transcribed, systematically coded using the dialogic function coding scheme developed for the purpose of this study, and analysed using epistemic network analysis (ENA). An ethnographic method for quantifying, visualising, and interpreting thematic connections across datasets (Shaffer et al., 2016). To understand how the PD works, Sandoval's (2014) conjecture mapping was used. The relations between each mediating process to CR (theoretical conjectures) and the connections to design features (design conjectures) were established based on empirical observation from a variety of data sources, such as video recordings of the simulation session, retrospective interviews, artefacts teachers produced during the workshop, (e.g., note catcher, collective reflections), post-workshop feedback, and post-simulation feedback, and teacher reflections during the simulation. 10% of the dataset was randomly selected and coded by two researchers independently for inter-rater reliability check, which reached substantial or near-perfect agreements.

Findings

RQ1: Assessing changes in teachers' response pattern

ENA showed a significant difference in the response patterns of the three teachers before and after the PD, both visually and statistically. Due to the length of this paper, one teacher's data was presented in Figure 1 as an example. Before the PD, Minahil's classroom discourse was primarily monologic, characterised by IRE/IRF, evident in her response pattern, with the strongest connection being between initiate and feedback (M=0.23). There was also a relatively strong connection between widen and feedback (M=0.13). Minahil's post-PD discussion took place after a field trip, during which students visited a local lake and observed the pollution in the lake. Her post -PD response showed the strongest connections between maintain-widen (M=0.46), and relatively strong connections between maintain-feedback (0.17), shifting towards a more dialogic pattern to improve the collective dialogue.

Figure 1
Minahil's response pattern before the PD (left), after the PD (right)



RQ2: Unpacking the mechanism of the PD

Due to the limited space in this paper, we focused on the emergence of the mediating processes. As a result, we did not elaborate on the relationship between mediating processes and design features (i.e., design conjecture) and or the outcome (i.e., theoretical conjecture). **Adopting dialogic framings:** Teachers shifted from a monologic framing (e.g., interactive lecture) before the PD to dialogic framings of science discussions (e.g., consolidation discussion) after the PD. These findings provided further evidence to support the coherence between framing and response (e.g., Richards et al., 2020; Russ & Luna, 2013), i.e., the teacher's response is coherent with their framings of the situation. Such findings highlight the importance of supporting teachers to recognise their own framings and adopt a variety of dialogic framings in fostering CR. **Developing fluency with talk moves:** Teachers demonstrated fluency with talk moves over time (Michaels & O'Connor, 2012), evident in their increased use of productive talk moves – both in frequency and diversity – in the simulations and pre- and post-PD discussions. **Deploying flexible attention:** All three teachers demonstrated an increase in the frequency of noticing and the diversity of what they noticed in the classroom. What was noticed by teachers include classroom climate, pedagogy, student characteristics, student lived experience, and classroom equity (Luna & Sherin, 2017; Thompson et al., 2016). Overall, the findings suggest that the teachers' attention were flexible and able to encompass a broad range of important features in a multifaceted classroom. **Engaging in knowledge-based reasoning** (van Es & Sherin, 2002): How teachers interpret what they notice is defined by van Es and Sherin as (2002, p. 573) as a form of knowledge-based reasoning: 1) Use one's knowledge and experiences to make sense of what is observed; 2) Make connections between what is noticed and broader principles of teaching and learning. All three teachers demonstrated an increase in the frequency of knowledge-based reasoning during the post-PD interview and diversity of knowledge they deployed, especially in their knowledge about students and pedagogical knowledge. **Experiencing metaphoric resonance**: Metaphoric resonance concerns the recognition of structural resemblances that lead to analogical thinking and reasoning (Mason & Davis, 2013). According to Mason (2002), elements in the structure of the current situation can resonate with a metaphor or structure of previous experience, bringing associated thoughts and awareness to mind. Teachers' experience of metaphoric resonance is evident in their retrospective accounts of their thinking in the moment during the post-PD interview. Metaphoric resonance supported teachers to recognise alternative possibilities in the moment, leading them to diverge from their usual discourse pattern to take up a more dialogic response.

Conclusion

This study illustrated the affordances of a DBR approach to simultaneously produce usable knowledge for practice and advance learning theory. This study also showed the affordance of DBR to move beyond testing 'what works', and understand 'how it works', enhancing the adaptability, sustainability, and potential of scalability of the PD programme. This work highlighted the importance of co-designing with practitioners and leveraging their ground-level wisdom, opening a dialogic space for the emergence of new ideas. It is important to highlight that the result about the effectiveness of the PD in this study is limited by its small sample size in a specific context and thus not immediately generalisable. However, the mechanisms underlying the PD and promising learning pathways were identified, which could be studied, tested, and refined in other educational and cultural contexts. Because traveling was restricted during the pandemic, findings in this study were based on one pre-PD and one post-PD discussion from each teacher. Nonetheless, teachers' consistent tendency towards dialogic practice in the simulations provided some evidence for the sustainability of change. Future studies should therefore further develop and test this preliminary theory of CR in other educational settings and cultural contexts.

“I Will Be Your Informant”: Observing Young People’s Emergent Critical Platform Literacy Development

Charles Logan, Northwestern University, CharlesLogan2025@u.northwestern.edu
Sepehr Vakil, Northwestern University, sepehr.vakil@northwestern.edu

Abstract: Platforms mediate much of modern life. To assist young people in making sense of platforms’ power, researchers have shared different literacy frameworks. In this paper, we build on existing frameworks to outline critical platform literacy. We observe how young people practiced critical platform literacy through engaging platforms’ political-economic model of data capitalism and platforms’ technical surveillance capabilities. Practicing critical platform literacy by making platforms’ visible and hidden dimensions more transparent provides youth with one more way of understanding and responding to platforms’ increasing–and often harmful–influence.

Introduction

Platforms pose a threat to our collective and individual well-being. Through their gathering and use of personal data, platforms entrench historical inequalities, further concentrating power in the hands of a few to the detriment of the many. Responding to platforms’ power is thus increasingly essential.

Platforms are both the hardware and software infrastructures upon which applications are constructed as well as digital spaces where people socialize and conduct economic exchange (Nichols et al., 2022). The urgency to better attend to platforms occurs at a time when education scholars continue to share literacy frameworks, such as critical computational literacy (Lee & Soep, 2016) and personal data literacies (Selwyn & Pangrazio, 2019), as means for helping youth make sense of technology’s potential harms. With so much of modern life mediated by platforms, a pressing need exists for deeper theorizing on the attributes of a literacy framework that specifically engages platforms and their multiple dimensions.

In this paper, we examine how three participants in the Young People’s Race, Power, and Technology Project (YPRPT) demonstrated their emergent critical platform literacy (CPL). YPRPT is a National Science Foundation-funded, out-of-school initiative in a Midwestern metro area in the United States of America that provides a research-based curriculum for high school-aged youth to explore, critique, and reimagine technology. We present evidence of the ways three youth responded to platforms’ political-economic business model of data capitalism, an “economic model built on the extraction and commodification of data and the use of big data and algorithms as tools to concentrate and consolidate power” (Milner & Traub, 2021, p. 4), as well as platforms’ technical surveillance capabilities.

We begin our paper with a genealogy of CPL. We then elaborate our theoretical framework, describe our methods, and share preliminary findings. We argue that observing how young people engage with platforms’ dimensions nuances our understanding of how youth practice CPL and points to potential ways to support their CPL development. We end our paper with future research suggestions.

Literature review

We assemble critical platform literacy from critical literacy, digital literacies, critical digital literacy, and hacker literacies.

We use critical literacy in the tradition of Freire and Macedo (1987), with an emphasis on analyzing the ways power operates through words and in the world. Developing a CPL means engaging visible texts posted on a platform and invisible technical and political-economic systems undergirding platforms’ social functions.

Because platforms include digital spaces, we draw upon digital literacies when constructing CPL. Scholars examine digital literacies in the plural, highlighting social aspects of using technology to connect with others and produce content (Ito et al., 2013). Nichols and Stornaiuolo (2019) advocate for an approach to digital literacies that focuses explicitly on sociotechnical and socioeconomic concerns. We take up these ethical and political dimensions as part of CPL.

Critical digital literacy merges critical literacy’s critique of power with digital literacies’ interest in how people consume and produce media (Ávila & Pandya, 2013). Recently, critical digital literacy scholars have emphasized the need for students to analyze the ways technology is encoded with its creators’ biases (Bacalja et al., 2022). However, conventional critical digital literacy practices may be insufficient for examining platforms’ complexities (Nichols & LeBlanc, 2021). For instance, critical digital literacy practices concentrate on representational forms, yet a technology company’s black box algorithm defies representation.

Finally, CPL grows from hacker literacies. Rooted in critical mindsets, hacker literacies are "empowered participatory practices…that aim to resist, reconfigure, and/or reformulate the sociotechnical digital spaces and tools that mediate social, cultural, and political participation" (Santo, 2013, p. 21). CPL shares hacker literacies' emphasis on empowering young people by making platforms' dimensions more transparent in order to understand and respond to platforms' effects on individuals and societies.

Theoretical framework

We use *critical platform literacy* to denote a singular focus on platforms, while still acknowledging the lingering limitations of a traditional literacy framework for analyzing platforms. We view CPL practices as building upon a platform orientation to critical digital literacy (Nichols et al. 2022) and embedded in a stance of civic media ecology (Nichols & LeBlanc, 2021). If platforms are complex ecologies, then CPL practices are the tools used to navigate and map those ecologies while also charting new courses. Students can develop CPL by studying and responding to a platform's social, technical, and political-economic relations (Nichols & Garcia, 2022). For example, students can strengthen their CPL by analyzing how a platform user's social experience is related to a platform company's political-economic model that relies on content moderators and their labor that is often underpaid and traumatizing (McNeil, 2022).

Our following analysis addresses the research question: How did young people demonstrate their emergent CPL? By addressing our question, we seek to bring into greater focus the characteristics of CPL and possible design considerations to support its development.

Research context and methods

Context

The Young People's Race, Power, and Technology Project (YPRPT) is a community-based social design experiment (Gutiérrez & Jurow, 2016). Our study focuses on data collected during the fully virtual second iteration of YPRPT that occurred during the 2020-2021 school year. The 12 participating groups–from local high schools, community-based organizations, and faith-based groups–completed an application to be considered for the program. Participants completed a 19-week curriculum designed by the research team.

Methods

We first analyzed the Week 3 activity titled "How Do Platforms See Us, and Why?" Each of the 12 groups produced a reaction video in Zoom documenting their responses to viewing and discussing data that Google, Facebook, Instagram, and/or Twitter had gathered about them. We transcribed the Week 3 collective reaction videos by rewatching each until we had accurate transcripts. Next, we began our analysis with deductive coding. We identified instances when a participant demonstrated CPL by articulating and critiquing a platform's social, technical, or political-economic dimension. See Table 1 for more on our coding decision-making process.

Table 1
Operationalizing critical platform literacy using a platform's three dimensions

Dimension of platform	**Example from data**	**Is the example critical platform literacy?**
Social	"Bruh, my former usernames were CurlyHeadedLisa, Flamin_Lisa, PrincessLisa." (Note: usernames are pseudonyms.)	No, because the young person doesn't reflect on a component of the asymmetrical power relationship between herself and the company.
Technical	"Yeah, it's kind of weird that [Google is] tracking such young kids."	Yes, because the young person names and critiques Google's technical capacity to surveil children's behavior online.
Political-economic	"[T]he problem is what the data can do in the future. It can classify certain people in groups, right? It can make them eligible for a loan or not."	Yes, because the young person critiques a key component of data capitalism: companies' use of a person's data to increase inequality.

After deductively coding the Week 3 reaction videos, we used successive rounds of inductive coding (Miles, Huberman, & Saldaña, 2020) followed by writing an analytic memo (Saldaña, 2016) for each reaction video.

At this point, we centered our study on one community-based organization. We call this group Amplify; we refer to the youth participants with the pseudonyms Vicki (Grade 11), Ife (Grade 11), and Sandra (Grade 12). We selected this group for three reasons. First, Amplify members were unique in their collective sensemaking about platforms' technical and political-economic dimensions. Second, Amplify members mostly kept their cameras on throughout the Week 3 recording. Third, of all the YPRPT participants, only Vicki uploaded her Week 4 reaction video. While a limitation to the study, the small sample size also indicates the ongoing challenges of asking youth to complete assignments in addition to their academic and personal responsibilities. As with our other data sources, we completed the same process of deductive coding, inductive coding, and memo-writing to analyze Vicki's Week 4 video.

Findings

Below we share examples from our data that we're examining to understand how youth practice CPL. The data demonstrate how the girls of Amplify engaged two dimensions of platforms: the political-economic dimension of data capitalism and the technical dimension of surveillance.

Platforms' political-economic dimension: Data capitalism

The youth engaged platforms' economic-political dimension in their collective Week 3 reaction video by exploring their ad settings on Instagram and Google. Vicki rephrases a research-team provided question, asking why platforms want to know how many times they open an app or what they search for on Google.

> Ife: I heard that they sell our data to people. [*Vicki raises her eyebrows*.] I don't know why anyone would want to know about me. I'm not important, you know? So why would they sell data? Well, apparently you can use it for different things. I don't know what things, but it's useful.
>
> Sandra: I know a lot of people take data for ads. Basically that they try to, that's the main thing they do. They try to freakin see what we're doing and see what we're looking at and searching up, so they can incorporate ads that they think we might like.

Sandra helps Vicki and Ife fill the gaps in their knowledge by making more transparent platforms' technical capabilities of surveillance and how they reinforce an economic-political model of data capitalism. In this exchange, Sandra uses her more advanced CPL to strengthen her group mates' understanding of why platforms collect and sell data.

Platforms' technical dimension: Surveillance

Vicki begins her Week 4 individual reaction video by saying hello. Then she says, "I will be your informant for some information that I just learned about." Vicki positions herself as an "informant," a whistleblower with explosive news about Google's data-gathering and surveillance.

Vicki's emergent CPL is apparent when she cuts to a screenshot of a map from her Google profile to make concrete the experience of being surveilled. She says, "If you don't have your location turned off, they know every single point that you were at." Unsatisfied by only advocating people turn off their location tracking in Google, Vicki next shows her audience how to do so in the form of an instructional video. She has embraced her role as informant, realizing her agency to push back, even a little, against Google's surveillance.

Discussion

The three girls of Amplify demonstrate their emerging CPL through a process of collective and individual sensemaking. They notice how Instagram and Google gather personal data on their behavior, ask probing questions of the platforms and each other, and share their existing knowledge in order to deepen their CPL. They appear to have a more nuanced understanding of how technology companies use surveillance for profit. This more nuanced understanding isn't neutral, either. As Sandra says, the companies "try to freakin see what we're doing," and in her disgust one can hear a critique that may open opportunities to act and transform if not the platforms then perhaps our relationships with the platforms. In Vicki's case, her individual reaction video illustrates how her growing CPL helped her to develop an identity as a self-determined informant with a need to tell her audience how we too can assert our agency and become more difficult to track and monetize.

Notably, the girls' emergent CPL occurred in the context of making reaction videos. A playful genre, reaction videos evoke a person's surprise, an emotional state repeatedly expressed by the girls as they discover and name the extent to which the platforms extract their data and monitor their movements. Future research can build on existing literature on learning environments that use technology-mediated play to support development (e.g.: Gutiérrez et al., 2019), with a specific focus on reaction videos, to better understand how creating the feeling of surprise might be integral to developing CPL.

Conclusion

The "platformization of education" has arrived (Nichols & Garcia, 2022), and with it, the urgency to work with young people to better understand and respond to platforms' visible and invisible elements. While existing literacy frameworks attend to issues at the intersection of technology and power, CPL centers platforms' social, technical, and political-economic dimensions. Achieving a more nuanced view of CPL and its attending practices is essential if we are to better support young people as they resist, refuse, and reimagine platforms.

Barriers to Reflective Learning: Perspectives of University Students and Instructors

Addisu Leyew Bailie, Engida H. Gebre
abailie@sfu.ca, egebre@sfu.ca
Simon Fraser University

Abstract: Studies have outlined postsecondary students' lack engagement in reflective learning. However, factors affecting students' engagement has not been studied from the perspective of students. This study examined barriers of reflective learning as perceived by students and instructors in a large university in Western Canada. Data were collected from 32 instructors and 161 students through interview and open-ended questionnaire respectively. A qualitative analysis of the data showed four main categories of barriers: emotional, instructional, personal, and structural and contextual barriers. Although instructors and students perceived some common barriers in each category, the findings also showed important differences in the type of instructional and personal barriers.

Introduction

Recognizing the benefits of reflective learning for professional development and everyday life, educators have used various strategies to cultivate and develop post-secondary students' reflective capacity. However, research shows that students' engagement in reflective learning is unsatisfactory (Power, 2016).

Despite instructors' awareness of the benefits of reflective learning and their commitment to incorporate it in their courses, the actual process of engaging with reflective learning could be hindered due to several factors. The literature discusses potential barriers ranging from misconceptions about the nature and process of reflective learning to institutional factors that impact instructors' and students' activities (e.g., Boud & Walker, 1998; Finlay, 2008). For instance, Finlay (2008) expressed concerns that instructors embrace conceptualizations of reflection in uncritical, piecemeal, and reductionist ways. Other explanations of potential barriers focus on instructors' expertise which include poor facilitation skills and lack of knowledge (Platzer et al., 2000) and recipe following (Boud & Walker, 1998). At a more systemic level, efforts to foster reflective learning can be inhibited by factors such as the culture of performativity (Harford & MacRuairc, 2008) and disciplinary framings within which instructors and students operate (Boud & Walker, 1998).

Existing studies on barriers to reflective engagement and learning are limited in their scope and perspective. Both theoretical framings and empirical studies largely focused on the perspectives of practicing educators (Butani et al., 2017). We believe that understanding students' perceived barriers to their engagement in reflective learning is crucial. This study therefore aimed to examine the barriers to reflective learning from the perspectives of both instructors and students at a Canadian university. The research question that guided the study is: *What are barriers to reflective learning as perceived by instructors and students?*

Reflective learning in post-secondary education: A brief overview

There has been a growing interest in fostering reflective learning in post-secondary education because it helps students to develop effective learning strategies (Ertmer & Newby, 1996) and skills and habits of mind essential for living in the contemporary world (Rose, 2013).

Although its benefits are well established in the extant literature, reflective learning is "a complex construct to define, scaffold and develop in the arena of higher education" (Roberts, 2016, p.32). Dewey (1933) defined it as: "active, persistent and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and the further conclusion to which it tends" (p.9). Dewey's conceptualization emphasized thought processes involved in examining experiences based on evidence and rationality. Since then, the concept has evolved to embrace more critical and transformative frameworks (Brookfield, 2017).

The diverse interpretations of the construct itself are considered main constraints on its implementation in higher education. That is, the prevalence of often elusive and vague descriptions of reflective learning may limit the opportunities for practitioners and researchers to foster it adequately. Thompson (2022) discussed internal and external barriers to reflection. Internal barriers are related to the person's experience and beliefs; external barriers come from others or the environment. Notwithstanding the theoretical discussions on potential barriers, however, there is paucity of empirical research regarding instructors' and students' perceived barriers to reflective learning.

Method

Data were collected from instructors and students in the Faculty of Education at a university in western Canada. Education courses that were scheduled to be offered during the time of the study (2020) were first identified. Courses that included reflection in the course descriptions, learning outcomes, or assessment strategies were selected as potential sources of data. We then invited the instructors of the identified courses to participate in the study. As a result, data were collected from 32 instructors who agreed to participate. Instructors announced our study in their respective classes with a link to our survey. A total of 274 students completed the survey. Participants include students from undergraduate, graduate and teacher education programs.

Data collection and analysis

We used semi-structured interviews with instructors and open form survey with students. The general purpose of instructors' interview was to examine their understanding of reflective learning, related instructional strategies they use to foster reflective learning and their perceptions of barriers to students' engagement in reflective learning processes. However, the data used for this study focus specifically on barriers to reflective learning. Interview questions that helped to elicit instructors' perceptions of barriers include: "What things did you find easy or difficult in helping students develop reflective learning?" "What do you think are enabling/ hindering factors for students to engage in reflective learning?" Interviews were conducted both in-person and virtually. Since most of the data were collected during the Coronavirus pandemic, phone and zoom interviews were used depending on the participants' preferences. Interviews were audio-recorded and transcribed verbatim. The length of instructors' interviews ranged from 27 to 56 minutes each. Data from students were collected through survey. The survey included several questions in different forms that were intended to answer the research questions we formulated in the larger project. However, in this paper we used responses to one open form item, i.e., "What were the barriers or challenges to engage in reflective learning in this course?" Among the 274 students who completed the general survey, 161 students responded to this question. Of these, 39.6% were taking preservice teacher education courses, 41.8% undergraduate courses, and 18.6% graduate courses. Data analysis was an iterative process of reading through transcripts, segmenting data relevant to the research question, examining underlying meanings, and comparing and contrasting responses across transcripts. Accordingly, we employed open coding to understand instructors' and students' perspectives of barrier to reflective learning.

Results

Results indicated that both instructors' and students' perceived barriers to reflective learning can be grouped into emotional, instructional, personal, and structural and contextual barriers (See Table 1). It is noteworthy that although both instructors and students' perspectives belong to these four focus areas, specific barriers in each category showed both similarities and differences.

Emotional barriers

Instructors' and students' views indicated that concerns with safety and vulnerability preclude students' reflective engagement. When asked about barriers to reflective learning, many instructors responded using terms such as trauma, safety, being uncomfortable, vulnerability, and fear. One instructor stated, "there's a fear of vulnerability in doing this kind of work and a lot of the topics that we take up evoke a lot of emotion in our students" (PDt24).

Participants pinpointed that creating a safe space is crucial for facilitating reflection since it involves a lot of personal and emotional engagement that may be traumatizing and leading to a crisis. Like instructors, students expressed issues of safety and vulnerability as a main barrier to their reflective engagement. The following excerpt from a student illustrates this point: "there are a lot of sticky topics that can be hard to talk about and see within oneself, like white privilege" (GDs16).

Instructional barriers

Instructional barriers focus on the design and facilitation of instruction. Both instructors and students reported a variety of barriers related to the instructional process. However, the elements of instruction that they emphasize showed some differences. Instructors emphasized the inhibiting roles of assessment and feedback practices, cognitive load, objects of reflection, and remote teaching. GTt16 expressed how course readings inhibit reflection:

> I think too much reading and writing is a hindrance. Obviously, there needs to be a demonstration of understanding and, you know, academic writing. But if there is too much of that I think it hinders engagement. Because there needs to be a balance.

On the other hand, students' views of instructional barriers focus on instructor guidance, language, and nature of reflective tasks. For example, a student illustrated: "Reflective learning is not reinforced in most course activities. Directions are often 'you may reflect on anything that speaks to you', for example. Effective reflection is prompted, not asked for" (UGs13).

Table 1
Instructors' and students' perceived barriers to reflective learning in post-secondary education

Category	Description	Example excerpts
Emotional Barriers	Students' emotions and feelings such as concerns with safety and vulnerability, feeling of shame, trauma etc.	***PDt34 (Instructor):*** "I think one thing that I worry about is that if we're asking people to get personal, but it is also important to understand that people have past traumas that this type of information could be triggering." ***UGs01 (Student):*** "It is emotionally draining. Students who have not done this type of work can default to text-book answers to protect themselves from feeling; most students expect to learn, not to be asked to examine their emotions, thoughts and needs in learning."
Instructional Barriers	Teaching-learning processes which include the nature of learning activities, content of reflection, assessment, grading and feedback.	***UGs10 (Student):*** "Many disparate focuses in the course detracted from extended concentration on reflection. I was too distracted by all a complex syllabus and different criteria to let myself fall into a comfortable reflective state." ***GTt21 (Instructor):*** "they're worried about the grades. And that really gets in the way, worrying about grades really is a problem for students and I do everything I can to discourage them from focusing on the grade."
Personal Barriers	Students' background (e.g., cultural, age, educational background) and prior experience (e.g., limited experience with reflection; life experience)	**UGs09 (Student):** "my own lack of motivation and just do the assignment for a good mark rather than actual learning" ***UTt14 (Instructor):*** "some students are just more naturally inclined with this kind of work than others, right, people who tend to be very concrete thinkers who find such reflexivity difficult might just not be able to do this very well."
Structural and Contextual Barriers	Institutional norms and practices, time, and related contexts.	***GDs06 (Student):*** "Reflective learning requires time and space to marinate on new ideas, merge them with existing ideas and refine understanding . . . but with working full time on top of school it can be difficult to find the time or space to work through ideas." ***GTt02 (Instructor):*** "So a large part of what I'm noticing more is that graduate students and even undergraduate students are having to work more and so the material aspects of their lives leave them less time."

Personal barriers

Participants reported personal background as barriers for reflection although these may be interpreted differently by instructors and students. For example, an undergraduate student explained the role of experience as a factor:

> I am older than those who typically go to university. I have ample life experience and I am not afraid to engage in dialogue. However, my classmates are only able to connect with the readings and dialogues on a surface level. I believe much more reflection and life experience is necessary for those who aspire to become teachers. (UGs15)

In addition to prior experiences, students reported the impact of their lack of motivation including the propensity to complete assignments for grades than actual learning and the lack of honesty and openness to change one's views. On the other hand, instructors emphasized factors related to intellectual capacity and cultural background. For instance, GDt02 claimed that "some students have a greater intellectual capacity than others and thus they are able to ask more in-depth questions." This participant further posited that only some students can pick up on questions, no matter how hard s/he try to get everyone aboard.

Structural and contextual barriers

Most participants, instructors, and students alike, considered time as the main barrier to reflective learning. Lack of having time for reflection was described in relation to students' busy life due to learning, work, and family commitments. Besides time, instructors also reported differences in structure between programs as potential barriers. PDt24, for example, illustrated:

> I think a significant piece of it is the way we've structured school. It's quite jarring for some of them to come into a program where we make reflection so central … And a lot of them have been programmed to not trust that process, not see it as a valid form of personal research and inquiry… It works against our school, or the way we structure schooling and learning.

Although students focus mainly on time, instructors also mentioned barriers such as large class size and expectations of success that focuses merely on acquisition of content knowledge.

Discussion

The results of our preliminary analysis indicated both groups emphasized emotional issues, time, and limited experience as key barriers to students' reflective engagement. On the other hand, differences are observed in instructional and personal barriers. These perceived barriers have implications for designing learning activities. If we aim to foster critical reflection and thereby develop students' agency to make informed decisions, it is important that reflective learning activities are designed as integral parts of education. Doing so would help to overcome the barriers and allow space for its practice. For instance, the perception of time as a barrier implies that participants' understanding focused on retrospective reflection, i.e., reflection taking place after the event. However, designing reflective tasks that can be done during instructional time would help to address time-related challenges. Also, the nature of assessment and grading practices encourage formulaic and superficial approaches to learning thereby inhibiting reflection (Brookfiled, 2017). This can be counteracted by developing assessment criteria inherent to the purposes of reflective tasks.

Abstract: This article examines how fiber crafting can develop mathematics learning and learners. Extending the constructionist paradigm with relational materialist principles, this paper advances the notion of "materialized action," which describes the natural inquiry process that results through emergent patterns between learners and the materialized traces of their actions. This paper takes a qualitative approach, combining a design and intervention phase examine fiber crafts (here knitting) and engagement in a "powerful idea" (i.e., unitizing in multiplicative proportional reasoning) as an illustration of how we can better understand micro-developmental learning processes, and advance constructionist theory.

Introduction

Identifying relatable contexts to practice challenging mathematics topics, such as multiplicative proportional reasoning, remain a challenge in mathematics learning. In this study, we build on fiber crafts a rich context of mathematics learning and examine how fiber crafting can develop mathematics learning and learners. Toward this end, we asked: How does knitting develop mathematics learning and learners and under which conditions? In the context of an out-of-school workshop developed by crafting professionals and mathematics educators, this qualitative study examines knitting as process of creating units and engagement in multiplicative proportional reasoning. This effort combines research on the use of textile crafts for learning advanced mathematics (e.g., Greenfield & Childs, 1977; Peppler et al., 2020) with a relational materialist lens on learning (Hultman & Lenz-Taguchi, 2010) to capture, analyze, and theorize how materials prompt human development and learning. As part of a longer-term qualitative study that focused on capturing evidence of learning via fiber crafts (e.g., Keune et al., 2021), this paper presents a close analysis of the micro-developmental engagement of knitting with youths to show how material changes led to engagement in powerful mathematical ideas of unitizing and proportional relationships. While the full study shows these ideas unfold in three fiber crafts (i.e., knitting, crochet, and pleating) we focus on presenting findings on knitting in this paper. Through this examination, we advance the notion of materialized action as a micro-developmental condition under which epistemic understanding emerges. At its core, materialized action can be conceptualized as the patterns of action in the construction of an artifact. Materialized action allows for the reformulation of ideas (if the physical outcome was not intended) and the co-construction between learner and materials. It has the potential to disrupt in mathematics education.

Proportional reasoning and unitizing in mathematics

This study takes as a starting point the theory of constructionism, which posits that learning occurs best when individuals design physical (or digital) constructions that can be shared, representing cognitive transformations that happen as learners actively engage with domain concepts. Working out reasons for why designs fail and adjusting designs is one important way to deepen understanding of mental models and concepts (Papert, 1980; Kafai, 2006). The types of materials used for learning are not without consequence, as materials, and the relative marginalization of other materials, shape domains in formative ways. Friedman (2018) details how compass and straight-edge produced a range of mathematical techniques and practices that subverted and marginalized other mathematical principles based on paper folding. In a recent workshop organized at the Technical University of Munich and Deutsches Museum, Friedman and Zetti (2023) trouble the immateriality of mathematics by highlighting the distinct role paper played in knowledge production within mathematics and computing contexts. This has manifold consequences for how we conceive of mathematics learning. Additionally, while math learning and fiber craft learning were historically placed in opposition to each other in European and American schools (Harris, 1997), researchers have observed ample connections between textile crafts and math that belie this separation, such as in knitting, crochet, cross-stitch, quilting, needlepoint, and tatting, among others (e.g., Belcastro & Yackel, 2011). Other work demonstrated mathematical learning through textile craft engagement, such as sewing of tents and costumes, knitting, crochet, and weaving (Peppler et al., 2022).

In the constructionist tradition, researchers look for powerful ideas that are persistently difficult as taught using traditional approaches. One such powerful idea, which we examine in this study, is unitizing in multiplicative proportional reasoning (PR). PR is the understanding of the multiplicative part-whole relations between rational quantities and is a predictor of future mathematics achievement (de la Torre et al., 2013; Boyer & Levine, 2015). Persistently, PR has been challenging to learn (Lobato & Thanheiser, 2002); often, young learners try to use additive instead of multiplicative strategies (e.g., incorrectly solving 2/3 = x/6 by adding 3 to both numerator and denominator instead of multiplying both numerator and denominator by 2; e.g., Dooren et al., 2010). Unitizing, the partitioning into composite units, is a foundational concept for multiplicative and proportional reasoning and is difficult for children to develop (Lamon, 1992). There is a powerful possibility in feeling and practicing units across multiple materialities as to "disturb narrow (and perhaps white, western, male) images of mathematics—and to open up opportunities for a more pluralist school mathematics," that draws on different cultural experiences, materialities, and abilities (de Freitas & Sinclair, 2020, p.2). Missing from this prior work is how units can be dynamic and tangibly produced (rather pre-formed) as well as how units build over time.

Methods

This qualitative study explored what features of activities could lead to exploration of proportional reasoning by analyzing data from a three-day fiber crafts camp in which youth performed the craft activities to understand how the crafts supported engagement with PR. The camp took place over the course of three consecutive days (4 hours each). Each day youth learned a new craft and created a project with the craft: 1) Crochet a bag, 2) knit a bag o, and 3) sew a pleated bag. 17 middle-school-aged youths (9-12 years old) participated in the craft camp (16 female, 1 male). This is an age at which PR is typically taught (Common Core State Standards Initiative, n.d.) as well as the age at which girls—and other underrepresented youth—begin to wind down on interest with STEM (Corbett & Hill, 2015). Two participants were joined by their parents to support language translation. For analytical purposes, we focused on three focal youth based on active participation.

The data sources included projects created by the research team. Wideo recording of the youth camp observed the youth-produced proportional reasoning across projects through material unitizing and shaping (40 hours). The video showed youths' hands and faces as they worked on their projects. Data sources also included 231 photographs of youth projects that showed detail of the projects. We first analyzed the projects by the research team through 1) verbal descriptions of the step-by-step craft process, 2) visual representations that showed the emergent material and craft patterns, and 3) corresponding mathematical notation of the RP in the crafts that represented the rules that governed the patterns. As per constructionist philosophy, the abstractions into mathematical notation were not a part of the camp. The analysis of the video recordings of the youth camp focused on how youth produce PR across fiber crafts through material unitizing (i.e., how crafters produced units in the materials). Our analysis of the photographs of youth projects closely observed stitches to reconstruct the mathematical doing that occurred to produce the project. We focused on the differences between planned and implemented projects (e.g., in relation to stitch size) as reference for mathematical processes.

Findings

In contrast to the use of established units as the basis for ratios and proportional relationships, fiber crafting begins with an initial stitch unit that users define through their choice of materials and their body's relationship to their manipulation. Crafters reason with multiplicative part-whole relations as rhythmic and repeated movements of people and materials arrange and multiply stitch units into pattern units, which are multiplied again into a project unit. In this study, we identified three levels of unitizing: *Stitch units* form the basis of proportional relationships when considering the number of stitches per row. *Pattern units* emerge by bringing stitch units in relation. We define a pattern as a form or model used for imitation. *Project units* from through the combination of completed patterns. The project unit shows the mathematical connections even more clearly.

How knitting develops mathematics learning and learners

Katie, a 10-year-old knitter, produced stitch units only to unravel them and to restart 12 times, working to establish a consistent feel for her stitch units. Where initial stitch units were loose and irregularly shaped, as Katie got into a routine, her stitch units became tighter and more uniform. Katie and a neighboring youth also explored stitch units through a conversation about arm knitting, a knitting technique that uses the arms of the crafter in place of knitting needles (see Table 1). Together, the youth determined that the stitches would be gathered on one arm and picked up by the other arm (see Table 1, panel 1 and 2). Through gestures, the youth compared the effects of using different materials (i.e., wooden needles vs. arms as needles) on one's personal stitch unit (see Table 2, panel 3 to 5). Through her body posture and arm gestures, Katie expressed how the size of a needle affected the amount of yarn needed for a stitch as well as the size of a stitch unit (see Table 1, panel 6).

Table 1
Transcript of a conversation about arm knitting that involves stitch units and pattern units.

 1) Katie: "Your arms are like needles." Katie turns to Sarah and lifts her arms. Katie's arms become needles.	 2) Sarah: "Like this?" Sarah lifts her project. Katie drops her arms and nods. Sarah introduces her project as a comparison.	 3) Katie: "I don't know how exactly." Katie lifts her arms and twists them. With arms as needles, Katie explores how arm knitting would work.	 4) Katie: "Now that I think about it, it's like the needles." Katie lifts her project and points at the needles. Katie suggests that arm-needles act similar to wooden needles.
 5) Sarah: "Ah." Katie: "Yes." Sarah lifts her left arm and grabs it with her right hand at three places. Katie nods. Both knit on. Sarah's arm becomes a needle and the grabbing motion becomes stitches on the needle.	 6) Katie: "If you used this arm, it'd be stitches that big." Katie holds her hands one foot apart. Katie shows how the size of the project becomes larger with arms as needles.	 7) Katie: "Lalala" Singing, Katie waves her arms. The waves become stitches and Katie adds a few stitches to her imaginary project.	 8) Katie: "Then you have that much." Katie holds her arm two feet apart. The imaginary project grew over twice in size and, thus, at a faster rate compared to using wooden needles.

Starting over allowed Katie to practice a sense of her personal gauge, reflective of pattern units. With an increasing number of unraveled projects, Katie considered how the number of stitches she cast on would relate to the size she produced, counting the stitches as she cast on her needle. Katie also compared knitting as getting a physical sense of the size of a stitch in relation to the created pattern unit in space, and, more specifically, the length of a row of stitches (see Table 2, panel 7 and 8). This is relevant because needle size is one aspect of how knitters conceive of their personal pattern unit, which shapes the look and size of a stitch unit (i.e., how big or how loose it is). As she worked, each stitch reconstructed the rectangular stitch unit that became the basis for a proportional relationship while this reconstruction was a part of forming the pattern unit. Each pattern of stitches thus formed another unit of the mathematical materialized action. The project unit showed the mathematical connections even more clearly. A knitted stitch unit is rectangular in shape and, thus, the stitch height is unequal to (shorter than) stitch length. This produces a proportional relationship, which in knitting looks like a performance centered on the gauge of a knit. As she worked, Katie noticed the proportional relationship at the site of the project unit, when she realized her project unit did not match the drawn pattern unit and that her stitch unit was not square.

Moving across three units provided space for iterative material exploration (i.e., through the undoing and redoing of stitch units) and drawing relationships across units, which brought about the implementation of proportional reasoning, but in greater complexity than what we would find in traditional classroom exercises. Learning about the epistemic idea is moving between units and is building toward larger constructions. This performative comparison of knitting with needles and knitting with arms was indicative of Katie's developing sense the craft material that affected the production of a stitch unit, the basic element for PR within knitting. Yet, when moving from stitch unit to pattern unit, we start to see intersections and moving back and forth across units.

Discussion and implications

Through our analysis of knitting across units, we can see how learners engage epistemically in mathematical ideas across different levels and complexities. The personalized stitch unit becomes a materialized action that crafters can recognize with hands and eyes. Beyond building units, crafters can zoom in on the combination of units into pattern units as a way to think about what the combination of units can produce that is larger than the unit itself. Taken together, this advances a notion of materialized action, resituating the "doing of" mathematics as a natural inquiry process that results through emergent patterns between learners and the materialized traces of their actions. Types of units can be simultaneously and separately engaged. By working across units, crafters engage materialized actions that provide opportunities for proportional reasoning. Materialized actions integrate (rather than exclude) worldly concreteness into mathematics, promising another way to relate to math. Units do not have to stay the same within a mathematical activity. Materialized actions as a theoretical idea can guide the design of mathematics learning that is embracing (rather than reducing) complex concreteness as part of learning. This holds the promise to engage people with diverse interests in mathematics learning and unsettle what has previously been conceptualized as a canonical source of mathematics activity.

After-School Programs During the COVID-19 Pandemic: Shifting Figured Worlds

Vickie H. Gordon, An H. Dang, Carrie D. Allen
vickiegordon@my.unt.edu, an.dang@unt.edu, carrie.allen@unt.edu
University of North Texas

Abstract: This study focuses on the identity work of after-school service providers within one large state-wide after-school network after the onset of the COVID-19 pandemic. Through the lens of Holland et al.'s figured worlds and self-authoring, we explore after-school service providers' experiences as they made meaning of and negotiated identities within shifting figured worlds of after-school and school because of the pandemic. Findings indicate that after-school service providers engaged in reauthoring within the figured world of the pandemic.

Purpose

The COVID-19 pandemic forced the closure of schools, resulting in unprecedented challenges for students, families, teachers, and staff (Munir, 2021; Lewnard & Lo, 2020). Existing literature suggests that the COVID-19 pandemic has had a profound impact on the identities of educators (Kim & Asbury, 2020), medical students (Byram et al., 2022), and fitness instructors (Andersson & Andreasson, 2021). As a result, many professionals experience pressure to reinvent themselves and find their place in the new pandemic reality (Andersson & Andreasson, 2021; Byram et al., 2022; Kim & Asbury, 2020), including after-school service providers. However, there is a gap in research on after-school service providers' experiences and challenges during the COVID-19 pandemic. In the United States, after-school programs are tasked with keeping students safe, promoting positive social and personal behaviors, and enhancing school attachment and academic achievement (Durlark et al., 2010); thus, after-school providers play a crucial role in delivering high-quality after-school services to students and their families and fostering positive youth development (Durlark et al., 2010; Payne & Eckert, 2010). Viewing after-school service providers' COVID-19-related challenges through the lens of figured worlds aids us in making sense of how the pandemic affected after-school service providers' normacy and the avenues of education access they make through reinforcing learning and socialization for children.

Framework

Figured worlds

Figured worlds are socially and culturally constructed worlds in which people "figure" their identities through social relationships and activities within the world (Holland et al., 1998; Urrieta, 2007). In figured worlds, individuals share reasonably stable understandings, values, and expectations of a certain phenomenon. However, because figured worlds are socially organized, they also produce a web of meaning that divides and distributes people's sense of self across multiple realms (e.g., after-school provider, parent, community member) (Holland et al., 1998).

Within education, figured worlds have served as a tool for studying learning contexts and the identities that are formed within those contexts (Urrieta, 2007). Rubin (2007), for example, explored the figured world of learning and identified the figured world of "smartness" at an urban high school, which involves students studying hard, getting good grades, and completing their assigned tasks diligently. According to Holland et al. (1998), figured worlds are made up of an imagined world in which actors (i.e., members, nonmembers, or a certain kind of members) hold a set of assumptions, beliefs, and norms and act with agency as they author themselves and position their identities. Actors within figured worlds make improvisations strategically through activities using tools of change, such as teachers and utilizing virtual meeting platforms to meet with students.

Hybrid figured worlds of the after-school program during COVID-19

Urrietta et al. (2011) puts forward the idea of "hybrid" figured worlds, in which individuals have to reauthor their identities as they try to make sense of new realms of interpretation, reorganize their roles, and adapt to unexplored performance expectations. For example, hybrid figured worlds in the context of education have explored the worlds of African American males who are in prison and simultaneously attending college (Urrieta et al., 2011); and a the worlds and professional identity of an elementary teacher when their inclusion class was moved online (Naraian, 2009). Furthermore, youth participation in science learning can be understood through hybrid figured worlds as they move across various learning spaces of the science class and out-of-school-time space (Gonsalves et al., 2013).

In this paper, we focus on a hybrid figured world concept, in which multiple figured worlds are integrated jointly, and there are no clear boundaries between figured worlds (Urrieta, 2007). We examine the COVID-19 pandemic's influence on after-school service providers' space and the hybrid space of virtual after-school programming.

Methods

In the current study, we present findings from a qualitative study with providers of an after-school network in California, United States (NSF DRL #1906490). Our analysis includes interview data with eleven after-school service providers. Interviews were conducted virtually from Summer 2020-Spring 2021 and were recorded and transcribed. Interviews lasted roughly one hour. Questions focused on continuous quality improvement (CQI) practices within after-school programming, experiences during the COVID-19 pandemic, the after-school system of support, and Science, Technology, Engineering, and Mathematics (STEM) offerings within the program. Initially, we conducted an inductive thematic analysis of transcribed data and found the emerging themes of service provider identity and changing contexts. In a second-level analysis, we identified figured worlds themes as the providers described their changing identities to accommodate the circumstances of the COVID-19 pandemic shut-down while continuing to provide after-school services through various online platforms.

Findings

The emerging themes in our analysis illustrated after-school service providers' making meaning of and negotiation of new roles in shifting schooling contexts. We find that the after-school network's community formed hybrid figured worlds from their pre-existing after-school figured world pre-COVID and a new figured world of the new normalcy during the COVID-19 pandemic. Negotiating new roles included reauthoring selves through improvisations while expressing hopefulness to return to the before-the-pandemic after-school figured world they previously knew so well.

Reauthoring selves as after-school service providers during the pandemic

Our findings reflect the improvisations many schools and after-school programs made during the pandemic shut-down period to meet their students' physical, social, and academic needs. After-school service providers continued to offer after-school activities virtually and provided the supplies needed to complete the projects at home. Improvisations were made within the after-school network programs by service providers during the shut-down period of the COVID-19 pandemic. These improvisations included: (1) learning new technologies (e.g., Google Classroom, Zoom) to maintain continuity with communication with students during the pandemic, (2) preparing and delivering supplies for learning activities, and (3) maintaining their after-school staff and redefining roles.

Learning new technologies during the COVID-19 pandemic was one of the major themes that emerged from conversations with after-school service providers. Initially, many service providers were unfamiliar with new technologies and the social expectations of delivering services virtually. However, with increased exposure to a new world of technologies, these service providers learned to use new tools (e.g., Google Classroom, Zoom), adjust their practice to align with their professional identities, and meet the expectations of the hybrid figured world of after-school during the COVID-19 pandemic. In the hybrid figured world of virtual after-school programs, these service providers have learned to make sense of and incorporate their work identities as after-school service providers in a casual home environment. Slowly, service providers came to share a stable understanding and ways of operating. As a result, after-school providers could assist students virtually through improvised tutoring through "Pods" in Google Classrooms, Zoom sessions, and virtual field trips. Kim and Sam shared their experience with navigating and delivering after-school services online:

> Also because this virtual world was so new to us, we started doing trainings even a Zoom tutorial training where what's the basics of Zoom? […] and we said, we need to do a Zoom etiquette. [...] Then we also did building rapport with students online because that was something that our staff could definitely benefit from that training (Kim_092420_CA).
>
> Then we have a whole another set of staff that are working in the day; working with Pods of kids in the Internet rooms so that they can access Internet and get assistance during the day (Sam_082120_CA).

Additionally, many after-school services providers recognized that not all students and staff members have access to the devices and supplies they would need to conduct the activities virtually. To make the program more accessible and equitable for their students, these service providers improvise their roles and responsibilities corresponding to the current climate to continue providing support and meeting their students' needs. In short, these providers also became a resource hub for students and their families. Specifically, service providers went beyond their role to assess students' needs, looked for ways to address those needs, and met students where they were at:

> This year, we're also providing them supplies to do the activities. Through the lunch pick-up, they're gonna pick up supplies for their Google Classroom (Sam_082120_CA).
>
> We survey students and staff and see do they even have devices? The after-school team really engaged in supporting with distributions, whether it was food or devices. […] The kids and the staff had all the supplies needed. That was a lot of work. […] We just created assembly lines of work and packages. We had distributions at every site. Every kid that was participating in summer, they got a bag and it was labeled for day 1, day 2. […] They had the tools that they needed, staff and students (Kim _092420_CA).

Our findings indicated that after-school service providers strongly identified with their roles as educators and support staff in supporting students' positive development regardless of the current pandemic situation. They are appreciative and take pride in their work with students. However, these providers also expressed frustrations with the lack of support and recognition for after-school programs and staff members. Some after-school service providers anticipated that their full-time staff would not return due to several factors, including the inability to work with the students in person and difficulties making meaningful connections with students virtually. Moreover, many service providers shared how their work in the after-school program is a huge part of their identities as they hope to continue their work in the future. As Leslie stated: "I live and breathe after-school. I hashtag my life after-school forever and ever." In sum, as multiple figured worlds of home and service became tangled during the COVID-19 pandemic, after-school service providers had to reauthor through repositioning and reorganizing their roles to adjust to the changes. By doing so, service providers can maintain the figured world of after-school programs amid the pandemic.

Significance

Considering a hybrid context of a pre-COVID figured world and reconciling it with the figured world of the pandemic is an important undertaking in this study because it informs the current educational contexts. Our findings suggest that educators and service providers experience tensions in maintaining an identity in one (pre-COVID) world while reauthoring an identity in a figured world of a pandemic. Findings from this study have important implications for policy-making and evidence-based program design to support educators and service providers. These findings are valuable for schools, institutions, and organizations as they consider and develop current programming, type of services, and approaches that can benefit educators' and service providers' overall well-being, growth, and development. Furthermore, educators and service providers can also benefit from the information as they make meaning of and negotiate their identities in the figured words of after-school after the COVID-19 pandemic. Finally, students' education progress and whole-child development are deeply intertwined with educators' and service providers' overall well-being. Thus, support programs that target students' education success and positive development may find this information useful as they provide services for students.

Preparing Teachers to Teach Artificial Intelligence in Classrooms: An Exploratory Study

Helen Zhang, Boston College, zhangzm@bc.edu
Irene Lee, Massachusetts Institute of Technology, ialee@mit.edu
Katherine Moore, Massachusetts Institute of Technology, ksmoore@mit.edu

Abstract: The rapid expansion of Artificial Intelligence (AI) necessitates educating all students about AI. This, however, poses great challenges because most K-12 teachers have limited prior knowledge or experience of teaching AI. This exploratory study reports the design of an online professional development program aimed at preparing teachers for teaching AI in classrooms. The program includes a book club where teachers read a book about AI and learned key activities of an AI curriculum developed for middle schoolers, and a 2-week practicum where teachers co-taught the curriculum in a summer camp. The participants were 17 teachers from three school districts across the United States. Analysis of their surveys revealed an increase in teachers' content knowledge and self-efficacy in teaching AI. Teachers reported that the book club taught them AI concepts and the practicum sharpened their teaching practices. Our findings reveal valuable insights on teacher training for the AI education field.

Introduction

From manufacturing to household automation, Artificial Intelligence (AI) is transforming almost every corner of our lives. This transformation presents a need for developing a generation of citizens who are AI literate so that they can partner with AI technologies in future workplaces and make informed decisions about AI-related civic issues. Meanwhile, youth and adolescents interact with AI-enabled tools in social media on a daily basis without realizing it. They may be targeted by AI-moderated and generated media such as Deepfakes and become persuaded to think that a fake event, image, or text is real, and act accordingly. Thus, teaching K-12 students how AI is used to generate misinformation and how to view information from online sources with essential skepticism is crucial to protecting them from being manipulated by AI-moderated media tools and AI-generated content.

While the need for AI education at the K-12 level is evident and urgent, the field of AI education is in its infancy. Little is known about how to prepare teachers to adopt and offer AI education in regular school day classrooms. This paper helps address this gap by reporting the design and findings of an online professional development (PD) program called Everyday AI (EdAI) PD, which includes two major components to prepare teachers to teach AI: (1) a 20-hour (two hours per week, over 10 weeks) AI Book Club (ABC), and (2) a 30-hour summer practicum. The ABC engaged teachers in reading a book and materials on AI and reviewing and discussing the Developing AI Literacy (DAILy) curriculum, which aimed to develop AI literacy among middle school students through interweaving AI technical concepts, related ethics issues, and the impact of AI on future jobs (Zhang et al, 2022). The practicum engaged teachers in co-planning and co-teaching the curriculum to youth enrolled in summer camps so that teachers can develop pedagogical knowledge and practices. In an earlier study we reported teachers' experiences of participating in the EdAI PD program (e.g., their engagement and attendance) (Lee et al., 2022). This study focused on evaluating the efficacy of the two PD components, with the following research questions: (1) How does the EdAI PD program influence teachers' attitudes toward AI and self-efficacy around teaching AI?, and (2) What do teachers' perceive as the affordances and constraints of the EdAI PD program components?

Rationale

A wealth of research has suggested that the success of educational initiatives and innovations in school depends strongly upon the support and attitudes of teachers involved (McNeill et al., 2016). If teachers believe or perceive an educational initiative as fulfilling neither their own or their students' needs, they are not likely to attempt to introduce it into their teaching and learning. Since AI is new to most K-12 teachers, PD programs offering AI education must take into consideration that teachers may hold mixed feelings and varied views of AI. Thus motivating teachers' interest in AI is of paramount importance. Further, in contrast to many PD programs where teachers possess content knowledge from prior training or education, teachers typically join AI PD programs with limited understanding of AI or experience teaching AI. It is therefore critical that PD programs in AI education develop teachers' content and pedagogical knowledge of AI and foster their self-efficacy beliefs. To address these needs, the design of the EdAI PD program was informed by literature on effective PD components and combined the experience of learning AI literacy as students with experiential learning as teachers.

Characteristics of effective professional development program

Teacher PD programs are crucial to ensuring in-service teachers learn new strategies for teaching and keep up with advances in their fields. Researchers have identified features of high-quality and effective PD programs including: collaborative learning (McNeill et al., 2016); establishment of professional learning communities (DuFour, 2004); adequate time for implementation practice; emphasis on pedagogical content knowledge; and follow-up support for teachers (Garet et al., 2001). In particular, the literature calls for sustained systematic PD programs that unfold as processes over time because they are often more effective than one-time PD events (Harwell, 2003). Yoon et al. (2007) reviewed more than 1,300 studies and found that PD programs lasting 49 hours or more showed a positive and significant effect on teachers and ultimately boosted students' achievement by about 21 percentile points. Informed by these essential findings on PD effectiveness, the EdAI PD program was designed to span approximately five months (over 50 hours) and focus on creating a collaborative environment for teachers to learn AI, become familiar with the DAILy curriculum, and develop implementation strategies and teaching practices.

Experiential professional development

As more and more research started questioning traditional teacher PD models that focus on the transmission of information to teachers through direct instruction (Guskey, 2002), many researchers called for incorporating and extending experiential learning in teacher PD (Marlow & McLain, 2011). Experiential PD engages teachers as active participants in a lived experience upon which they can reflect, think and act (Clarke & Hollingsworth, 2002). Such experience allows for an ongoing process that attends to the personal nature of PD wherein teachers draw upon their own past experiences and what they learn from the PD as a foundation to engage and experiment with the new experience. Experiential PD can be particularly successful in motivating teachers to try new practices and making desired changes to realize the curriculum in their classrooms (Darling-Hammond et al., 2017).

One key component of experiential PD is reflection on action and experience. Teachers who reflect more often were more likely to make changes to their teaching practices than those who reflect less often (Camburn & Han, 2015). Rooted in conceptual models of professional learning which posit that learning begins with a dilemma or problem that one encounters in the workplace (Marsick et al., 2009), reflection should be structured to enable teachers to recognize dilemmas in teaching and should also engage them in attempting to resolve the dilemmas. In the EdAI PD program, teachers were engaged in a daily reflection as a group at the end of every day during the summer practicum. They reflected on the experience of teaching AI, observed student reactions, challenges, and potential solutions. By reflecting and sharing thoughts with peer teachers who have similar experiences of teaching AI, EdAI teachers are expected to identify problems or difficulties and collaboratively develop solutions to better meet the needs of supporting middle school students in learning AI, which is necessary for the adoption of new initiatives and changes in teaching (Van Driel & Berry, 2012).

EdAI PD: AI book club and summer practicum

The EdAI PD program includes a 20-hour AI Book Club (ABC) and a 30-hour summer practicum. The ABC included synchronous online meeting for 1.5 hours and asynchronous "homework" assignment of approximately 0.5 hour every week. Each week featured an AI related topic, such as *What is AI?, Algorithms as Opinions, Ethics in AI, Logic Systems, Perceptions and Machine Learning, Neural Networks and Deep Learning,* and *Generative AI.* The weekly assignment consists of (1) 15 minutes of readings or watching videos that exposed teachers to new AI topic of the week. The readings were chapters from Mitchell's "*Artificial Intelligence: A Guide for Thinking Humans*", a book that interweaves AI concepts, examinations of AI hype versus reality, and ethical concerns about AI. The videos included presentations on how algorithms could be biased, how facial recognition systems failed to recognize darker-skinned females, and a collection of videos about the application of AI in various industries; and (2) 15 minutes of reviewing activities and learning materials from the DAILy curriculum that aligned with the topic of the week. Teachers also participated in an online Slack channel to share their thoughts and impressions of the readings and videos. During the synchronous online ABC meetings, teachers first reviewed what they learned from the assignment and then experienced the AI curriculum activities as learners where the PD instructors and facilitators provided teaching demonstrations and pedagogical tips. They also reviewed student work from previous implementations of the DAILy curriculum and discussed key points, common misconceptions, and how to assess student understanding.

In the summer practicum, teachers formed co-teaching teams to teach the DAILy curriculum in 2-week camps. Each co-teaching team was composed of three or four teachers from the same school district who attended the ABC together. The summer camps were organized by partnering youth-serving organizations that focus on engaging middle school aged youth from underrepresented and underserved groups in STEM. The teachers worked together to apportion the teaching load (each teacher needed to lead eight or nine hours of activities).

When not leading an activity, teachers observed the instruction, supported individual students, and helped lead small group activities. At the end of camp every day, teachers, led by a researcher from the project team, reflected on their experience and discussed how to improve instruction to better meet students' needs and how they will approach teaching these activities in their own classrooms.

Methods

In total, 17 in-service teachers from three US school districts completed the EdAI PD program. The teachers taught a variety of disciplines: 52% Computer Science/Technology, 12% Library/Media Literacy, 12% English Language Arts, and 24% Science. Their school districts serve student populations that are largely from underrepresented groups in STEM and Computing (59%, 90% and 85% respectively). Eighty-eight percent of the participants (n=15) were from groups underrepresented in STEM and Computing education: 82% (n=14) being female, 18% (n=3) male; 35% being African American (n=5), and 12% being Hispanic/Latino (n=2).

Data collected in this study included responses to a survey administered three times among EdAI teachers: before ABC, after ABC (before the practicum), and after the practicum. The survey included 5-point Likert scale questions assessing teachers' (1) attitudes toward AI (Cronbach's alpha=.85) which consisted of 25 questions examining teacher's interest in AI, anxiety toward AI, awareness of AI's impact on future jobs, and perceived relevance of AI to their lives; and (2) self-efficacy of teaching AI (Cronbach's alpha=.85) which included 19 items evaluating teacher's beliefs in middle school students' competency of learning AI, confidence of teaching AI, and community support of teaching AI. The qualitative data collected included teachers' daily reflections and exit interviews upon the completion of their summer practicum. The interview questions asked teachers' experiences during the ABC and the practicum and their views of the benefits and drawbacks of the two components as PD. In this paper we focused on the analysis of teacher interviews.

The data analysis started with a one-way repeated measures ANOVA analysis of teacher survey. We are cognizant that the sample size was not sufficient to reach statistical significance, and therefore the results were used to provide a holistic view of changes in teachers' attitudes and self-efficacy observed between the three measurement waves and to suggest initial codes for the subsequence analysis of the exit interviews. In this paper we reported findings from the analysis of nine teacher interviews. The teacher interviews were purposefully selected to be representative of EdAI participating teachers, which included teachers from the three school districts, taught in different subject content areas, and with mixed demographics (gender, race and ethnicity). The interviews were analyzed using grounded theory. Final themes were emergent based on multiple rounds of coding around teachers' self-described experience and their perceived affordances and opportunities of each PD component.

Findings

The ANOVA analysis showed continued increase in teachers' mean scores of attitudes toward AI (F(2, 20) = 11.32, $p < 0.001$) and in teachers' self-efficacy of teaching AI (F(2, 20) = 12.00, $p < 0.001$) over its time course. Teachers' mean attitude score started with 3.70 (SD=.35, maximum score=5) before ABC, increased to 3.94 (SD=.27) after ABC, and further increased to 4.11 (standard deviation=.37) after the practicum. A similar trend was observed in teachers' self-efficacy score (before ABC: Mean=3.45 (SD=.42); after ABC: Mean=3.83 (SD=.40); after practicum: Mean=4.09 (SD=.39)). This suggests that the ABC and practicum led to continued teacher growth in preparation to offer AI education in middle school classrooms. A closer examination showed that after the ABC, teachers achieved the biggest learning gains in their knowledge around AI's impact on jobs, views of community support in teaching AI, and confidence of teaching AI. After the practicum, teachers became more confident about teaching AI and having community support when teaching AI. They also became more interested in AI and believed more firmly that middle school students are capable of learning AI.

Several themes emerged from the analysis of teacher interviews. For instance, teachers thought that the ABC enabled them to engage with peer teachers from various disciplines across the country teaching AI, e.g., "*I like the idea of getting together with other teachers, especially from different parts of the country. I liked that a lot. I liked the team building"* (teacher FD). They also perceived the experience of learning AI as a student was valuable and helped them gain knowledge about AI, e.g., "*as an adult, I don't want to be embarrassed, but I don't understand it, it [ABC] was like a no pressure zone. The way that you all handle it that those who didn't know participated. So, I can just sit back and listen, but eventually, I was able to participate, that was a bonus"* (teacher RH). For the practicum experience, all the teacher interviewees appreciated the opportunity of teaching and reflecting on their teaching experience as it helped them become more familiar with the curriculum, deepen their understanding of AI, and develop pedagogy, e.g., "*Just like how the lessons work, like being actually asked to teach, it forces you to like, prepare for it and learn from it. And also, the reflections at the end of the debrief, like forces you to think about, how would I do in my classroom? I think that's the biggest thing I learned"* (teacher

HW). Four teachers highly valued the experience of co-teaching with other teachers, e.g., "*You always pick up wonderful tips when you're just in the presence of the teaching of a great teacher... So doing it with other teachers from my district, which would have never happened if it weren't for the practicum, it was great"* (teacher JM). Teachers felt the practicum built their belief that the topic of AI is age-appropriate for their students and motivated them to think about classroom implementations, e.g., "*For me, so coming into this not knowing much, I learned that this is doable with middle school students. Definitely"* (teacher RB). With regard to the constraints of the PD program, three teachers hoped to engage in richer discussions of the readings during the synchronous ABC meetings and felt the online asynchronous discussion was not sufficient. All teachers explained that the practicum required more time and energy to become prepared. On average they spent at least an hour on preparing for the teaching and another half an hour on coordinating with other teachers every day during the practicum.

Conclusions

Bringing AI into classrooms is not easy. This paper reports the design and findings of a PD model that extends learning over time and incorporates an experiential learning component. Our results suggest the PD model was effective in engaging and sustaining teachers' interest in AI and preparing them for offering AI education in classrooms. Learning AI as learners together with peer teachers proved to be a valuable opportunity for teachers; not only did they experience the struggle of learning challenging concepts, they also shared frustrations and started to build a sense of community. The practicum experience sharpened teachers' practices of teaching AI and helped confirm teachers' belief that middle school students are capable of learning AI. The daily reflections prompted teachers to recognize difficulties or problems in their teaching of AI and devise solutions, and motivated them to actively plan for the implementation of AI education in their own classrooms. It was noteworthy that EdAI teachers all voluntarily spent additional time preparing for the teaching during practicum. This expending of time and effort, while demonstrating teachers' enthusiasm, would present a barrier to participation for many teachers.

Abstract: This paper arises out of a need to take seriously interventions on anti-Black racism in the computing education space. We extend the framework of *Politicized Care* to an out of school space to explore how Black femme mentors' pedagogy opens up alternative experiences of computing education. We offer another frame for computing teaching and learning that develops protection and care as a part of deep intellectual work. This necessitates our attention to relationships within moment to moment teaching and learning alongside youth. We offer a vignette from a summer STEAM program that highlight aspects of *Politicized Care*. This paper offers a domain specific example of politicized care that may inform future research design.

Introduction

We urge you to tread lightly. To take care, to proceed with caution, to remember, as we journey towards cultivating more space for Black life. This urgency comes from a tradition of Black school teachers who found moments outside of the gaze of white supremacy to provide their Black students with material no textbook would offer (Givens, 2021). To affirm for children's spirits that there are spaces "they are wanted, where they [can feel] happy and inspired" (DuBois, 1935, p. 5). This work offers an example of how we might tread more lightly with the spirit of Black students within computing. Through the framework of *politicized care* (McKinney De Royston et al., 2017), we offer another frame for computing teaching and learning that develops protection and care as a part of deep intellectual work and as an intervention on anti-Blackness within computing education. This necessitates our attention to relationships within moment to moment teaching and learning alongside youth (McKinney De Royston et al., 2017). McKinney de Royston et. al. (2020, pp. 6-7) define politicized care as a framework that allows us to "further understand how Black educators who work outside of white supremacist and assimilationist frameworks conceptualize the notion of protection to enact it to protect Black children from racialized harm."

This is decidedly relevant within computing where the same techniques that students are taught can be applied to systems that further criminalize their existence (Benjamin, 2019; Browne, 2015; Jones & melo, 2021). Centering technological innovation solely as progress, neglects the reality that youth are being asked and invited into developing algorithms that further oppression (Noble, 2018) and creating large scale surveillance networks that ultimately restrict mobility for their communities (Browne, 2015; Benjamin, 2019). When students' physical, emotional, and psychic safety is taken seriously the educational space is transformed to allow them to expand their imagination around new subject matters. In this paper, we extend the politicized care framework to examine a STEAM summer enrichment program called HubSpace, where the programming activities were led by Black femme mentors. We ask: 1) How does Politicized Care help illuminate ways learners and educators can work together within out of school computing spaces? 2) How does Politicized Care shape how computer science is experienced by learners?

Background

Anti-Black racism (anti-Blackness) is the mechanism through which "Black humanity and human possibility are threatened and disdained "by a racial calculus and a political arithmetic that were entrenched centuries ago."" (Dumas & ross, 2016, p. 6) Anti-Black racism suggests that Black experiences are reducible rather than different and interdependent (Dumas & ross, 2016). Anti-Blackness also operates within the Libidinal Economy "i.e. systems of desire and instincts and fantasies and repulsion around skin tone, hair types, and bodies"(Crockett, 2014). This libidinal economy shapes other aspects of anti-Blackness such as experiences of colorism (Crockett, 2014), and the adultification of young Black people (Nxumalo & ross, 2019). The presence of anti-Black racism in the past replicates itself in the present, and cycles within education. This is demonstrated by a "legacy of federal state and district policies and practices designed to deprive black communities and children of educational resources" (Dumas & ross, 2016, p. 418).

We situate the pedagogies within the HubSpace programming group as demonstrating acts of protection and affirmation for young people through the lens of politicized care. Caring becomes political work due to the stakes teachers understand for their students as adults who have previously experienced the racialized harms of schooling. This framework consists of four main pedagogical themes: Political clarity (Beauboeuf-Lafontant, 2005), Communal Bonds (Morris, 1999), Potential Affirming, and Developmentally Appropriate (McKinney De Royston et al., 2017). These pedagogical themes build upon Culturally Relevant Pedagogies (Ladson-Billings, 1992) to attend to layered educational racialized and gendered values (Apple, 2011) within schools. The pedagogical themes are interrelated due to the way they are co-constructed by one another (McKinney De Royston et al., 2017). For example, data that highlights potential affirming pedagogy may also illustrate developmentally appropriate pedagogy.

This is important in contesting a norm of anti-Blackness within computing, where explicitly denouncing racism is met with a denial of its relevance to a "neutral" field like computing (Jones and melo, 2021). Further, this framework emphasizes acts of care as also political and necessary for rigorous intellectual engagement. Knowing the harms that Black professionals experience in the workplace (Jones and melo, 2021) leads to hesitation in emphasizing career or innovation as a primary goal for these pedagogical interventions. Rather the primary goals are 1) to build up educators to be able to adequately care for and love the students that they work with through addressing anti-Black racism and 2) to create computing education spaces that envision Black life. Educators who might take up politicized care within computing help broaden ways of measuring learning within computing in developmentally appropriate ways as evidenced by learner shifts in political clarity, communal bonds, and self-view.

Research design

Context

The data we analyze in this paper is from a 2019, six-week summer STEAM program called HubSpace where 25 rising sixth-grade Black and Latinx learners from a suburb of a major midwestern city worked in groups to develop apps. Many learners in this program were referred by the district as those who may need additional preparation for the transition between elementary and middle school. The curriculum was developed by the mentors in the space who focused on integrating reading and writing into a creative STEAM summer program. Some of the mentors' goals were for the youth to experience being makers, to offer compliments on learners thinking and participation, to care for the community, and prepare to be in sixth grade while having fun.

The seven mentors within HubSpace were people of white and Black backgrounds. The research team consisted of three people of respectively Iranian, Black, and Latinx backgrounds. Many youths viewed the research team as another set of mentors, as we were readily available as support for facilitating groups and answering questions from the curriculum. Similarly, the mentors were also invited to co-create field notes and participate in the ethnography as a part of a research practice partnership (RPP) (Coburn & Penuel, 2016). The primary mentor was Shai, and the secondary mentor was Stephanie. Both are Black femmes and participated in the research and teaching processes consistent with the team's approach RPP. An important detail about the program is that small teams of learners elected to take on the roles of designer, marketer, and programmer while designing apps. Our analysis focuses on the learners that occupied programmer roles.

Data and methodologies

The vignette is composed of a variety of data and experiences. We received IRB paperwork from 13 learners and 5 staff. We collected 6 weeks of audio, video in addition to images, and final artifacts such as project websites. We also explained to all participants that they could ask us to stop recording at any moment. After the summer we highlighted moments of interest within the data and content logged the co-constructed field notes, expanding their level of detail. The final set of field notes (Emerson et al., 2011) consisted of 24 summaries, 3 specific interactions, and 2 content logged programming sessions. We narrowed this data set to follow the trajectory of the programming group as the primary focus of this analysis. We also completed exit interviews with 11 participants which informed the vignette. In this paper, we highlight a vignette that was created from selected field notes. Pseudonyms were picked by participants and the research team. From the larger data set, we narrowed in on specific interactions that highlighted participants of the programming group who had a variety of experiences. To create this vignette we followed a mixed qualitative approach including content logging and ethnography. This vignette and analysis were member checked (Lincoln & Guba, 1985).

Vignette: Black Beauty

This vignette is an example of how within a research practice partnership a mentor's political clarity was supported. Shai's ability to note colorism supported a brief but intentional moment at the group level and acted as an intervention on a sometimes more subtle anti-Black ideology. The primary mentor Shai, identified as a maker for over 7 years at the time, worked for HubSpace and coded and tinkered in her spare time. She is originally from a nearby midwestern city, and an alum of the city's underfunded public school system. Shai worked with these young girls to identify a pattern of colorism, a prejudice towards preferring lighter skin tones. This form of prejudice can not only shape who is visually incorporated into an app design, but into decision making around who is worthy of friendship, who is beautiful, and who is intelligent. Through this example, we illustrate how the young people's shifts in ideology showed up in their app design.

A group of girls created an app, Black Beauty, that allowed Black folks to see different images of their hair and clothing in a gallery style. They recognized that the media rarely showed images of Black folks and wanted to offer examples of their beauty, and how to take care of it (haircare, skincare, etc). While their intention was to show the diversity of Black Beauty, they initially were more narrow in their selections of images of "Black Beauty." The marketers and designers in the group often stepped into the coding space to gather opinions on what images would be essential to the app.

During debriefs, mentors and researchers would exchange information on how learners might need more support. After observing Black Beauty's progress more closely, Shai said "I am noticing a lot of their images of blackness represent uh lighter skin people." This was echoed by research team member Layla who had noticed similar patterns among other girls in the program. Layla asked "Do you think you want to talk to them about that?" to which Shai replied, "Yeah, I am just now seeing it." This delved into a moment where Layla and Shai discussed a pattern of colorism in an existing beauty app that many of the girls in the program liked to use. Black Beauty's app could be seen as in conversation with this more popular app, filling a need that the girls may have noticed but not yet articulated.

Following the debrief, Shai asked Black Beauty's programmers "Where does your app start? What's the first thing you see?" and a student responded "African Americans." This comment and the earlier debrief affirmed Shai's choice to have a conversation around the topic of colorism, asking them to consider the diversity of Black folks in their app. This is a move that disrupted harm within a societal narrative of what beauty can be for Black folks and resulted in shifts in imagery and language on their final website. By the end of their time, they had created a draft of an app portraying Black folks of all different hues and hair textures.

On their app's website, the "about" section said: "Black Beauty inspires Black people to bring out their inner Black beauty. It starts working once you go to our home page. From there, there will be different categories. You press one of the categories and it'll lead you to different videos and images on that category. Black Beauty inspires black." They included an audio clip of them saying their slogan "Black Beauty inspires Black… period!" In their final presentation, they extended their purpose to say that their app also aims to offer comfort to Black people.

Discussion

This vignette offers insight on how the mentors' political clarity around colorism was able to help the Black Beauty group shift in consciousness around colorism. As a part of a research practice partnership, Shai was affirmed in noticing this form of anti-Blackness and supported in her further explorations with learners. These conversations cannot be held in accusatory ways, but rather in ways that help open learners' perspectives to what they may not have noticed they were participating in. The learners, whose political clarity was sharpened, shifted their app to highlight a variety of skin complexions and hair patterns. Additionally, Shai cultivated space for the learners to utilize African American Vernacular English (AAVE) as they described the work of their app, "Black Beauty inspires Black… period!" The youth's description also highlights how computing has the potential to be transformative of peoples' world views.

In part, Shai's interaction with this group was successful due to the prior communal bonds she had earlier established with the youth in this group. We see how established relationships supported youths' engagement with mentors, as well as mentors' intentions to understand and support these young people. One challenge, therefore, is negotiating between the availability of support for youth, and the need for mentors' rest to be able to sustain healthy relationships with youth. Having ready and available support and community is essential to these young people's learning experiences. Communal bonds are not structured unidirectionally from mentor to learners', rather they are co-created by youth and mentors engaging together.

Shai believed in these young people's desire to represent Black Beauty, and engaged them in potential affirming ways by pushing them appropriately towards disrupting internalized anti-Black racism by interrupting colorism based logic. They detailed that their app intervention "starts working once you go to the home page," and that they hoped it would offer comfort, showing their belief that they could also help others shift and explore differences in Black Beauty. While not placing ceilings on what youth might do for their apps, mentors also needed to discern when it was developmentally appropriate to offer comfort or to step in more technically. These decisions demonstrate care for the learners' spirits and potential.

Conclusion

Through this analysis, we have offered examples of how viewing interactions through the lens of politicized care opens up alternative models for teaching and learning. Models that are focused on treating young Black people as whole individuals, requiring care as a part of their education. We shift the emphasis from app design, in favor of emphasizing the relevance of communal bonds, political clarity, developmentally appropriate pedagogy, and potential affirmation as opening up an alternative experience for computing education. With this, young people were able to wrestle with subject matters that were meaningful to them, while knowing that the mentors were actively wanting to support their thinking.

This paper offers a domain specific example of politicized care that may inform future research design. Through looking at these examples educators might begin to reflect on their own political clarity and the ways they speak about the potential of their learners. As computing educators shape perceptions of future computer scientists, it is important that we begin to hold discussions around ethical computing and open up moments to interrogate anti-Black logics. Through communal bonds, we see how programming is developed relationally, which led to narratives from Black youth around joy, laughter, and realness in computing. In these moments where we center care and tread lightly, we see how Black Life appears.

Abstract: In this study, we used machine learning models to detect the goal setting and planning activities in self-regulated learning (SRL) based on the linguistic features of think-aloud transcripts. Specifically, we trained six types of machine learning models (i.e., decision tree, Gradient boosted decision tree, random forest, logistic regression, support vector machine, and neural network) on 2,792 think-aloud segments of medical students, who were asked to think out loud as they diagnosed virtual patients in a computer-simulated environment. The results suggested that machine learning models, especially Gradient boosted decision tree and neural network, could make accurate predictions. This study shows the possibility of using machine learning to free researchers from the labor-intensive work of coding think-aloud transcripts. This study also informs practitioners about automatically detecting students' SRL activities in real-time as they think aloud in learning, making the provision of timely feedback possible.

Introduction

Self-regulated learning (SRL) is a core competency for students' learning with technologies such as intelligent tutoring system, serious games, and immersive learning environments. The research on SRL over the past 30 years revealed that SRL is a determining factor of student performance across disciplines. To study SRL, researchers have developed a variety of instruments and techniques, among which think-aloud protocols (TAPs) gained a lot of attention. TAPs can concurrently capture the dynamics of students' SRL processes since TAPs involve asking students to verbalize their thinking as they learn (Greene et al., 2011). However, TAPs suffer from the shortcoming of being time-consuming and labor-intensive (Hu & Gao, 2017). There is also a concern about the involvement of subjective judgments when evaluating students' cognitive and metacognitive activities. In this study, we explored the possibility of predicting students' SRL activities in an automated fashion, using machine learning and TAPs. Specifically, we aimed to examine whether machine learning models can predict the occurrences of goal setting and planning activities in SRL based on the linguistic features of think-aloud transcripts. We focused on the goal setting and planning activities since they represented the largest proportion of SRL activities in our research context, which we will describe in the following sections.

Methods

Participant

The participants comprised 34 undergraduate medical students (67.6% females) from a large North American University. The average age of the participants was 23.3 (*SD* = 2.96).

Learning environment and task

In this study, students were asked to diagnose two virtual patients in an intelligent tutoring system (hereafter the system) designed for medical students to practice clinical reasoning skills. Specifically, the system first presents a case scenario, including patient description and symptoms, to the participants. The participants collect and store useful evidence items in an observation list within the system. They can also order medical lab tests to gain more information about the virtual patient. Moreover, the participants can search an embedded library when encountering unfamiliar medical terms, tests, and procedures. They propose one or more diagnostic hypotheses based on the collected information. Students finalize their solutions with a range of scaffoldings, such as ranking, organization, prioritization, and summarization.

Procedure and measures

We trained the participants on how to use the system before the study. The participants were also instructed to conduct think-aloud as they diagnosed two virtual patients. The think-aloud of each participant was recorded in real-time. Students were reminded to think out loud when there was a long silence. It is noteworthy that the order of patient cases was randomized to counterbalance its effect on the participants' problem-solving processes.

Analysis

We used two strategies (i.e., topic representations and verbs) to segment the think-aloud transcripts into units appropriate to our research context. Specifically, the think-aloud transcripts were coded into 2,792 meaningful units. Each unit generally addressed a particular instance of thought, intention, or action. Three researchers performed the segmentation independently, whereby they could ask for help from the group when encountering difficulties. We then coded whether or not each unit involved the goal setting and planning activities. The coding scheme is shown in Table 1. A unit would be coded as one if it involves such activities and otherwise it would be coded as zero. In total, there were 760 units coded as involving goal setting and planning activities. The inter-rater reliability was .813, which was acceptable (Syed & Nelson, 2015). Moreover, we used a text mining tool, LIWC (Linguistic Inquiry and Word Count) (Pennebaker et al., 2015), to analyze the linguistic features of each think-aloud unit. We deliberately chose the most informative features that correlate with the outcome (see Table 2). In doing so, we reduced the computational complexity of building predictive models, and reduced data storage and collection requirements (Brooks & Thompson, 2022).

Table 1
The scheme for coding SRL behaviors of goal setting and planning in clinical reasoning

Sub-Code	Definition
Goal setting	Formulating a superordinate goal
Sub-goaling/planning: Ordering lab tests/	Forming a plan to order lab tests/identify symptoms
Sub-goaling/planning: Searching for information	Forming a plan to search for information in the library
Sub-goaling/planning: Using an external source to get explanations	Forming a plan to request a consult from the system
Sub-goaling/planning: Organizing thoughts about the action plan by self-questioning	Asking questions to oneself in reference to the action plan being formulated

Table 2
The selected linguistic features

Category (words)	Subcategory (words)	Example words
Function words	Pronouns (74)	I, my, myself, we, lets, us, he, she, that, this, it
	Prepositions (83)	to, of, in, for
	Conjunctions (49)	and, but, so, as
	Negations (8)	no, not, never, nothing
Cognitive words	Insight (383)	know, how, think, feel
	Causation (169)	how, because, make, why
	Discrepancy (108)	would, can, want, could
	Tentative (230)	if, any, something, or
	Certitude (131)	really, actually, of course, real
	Differentiation (325)	didn't, although, another, except
Memory words	- (26)	remember, forget, remind, forgot
Conversational words	Assent (50)	yeah, yes, okay, ok
	Non-fluencies (21)	oh, um, uh, ii
	Filters (24)	wow, so, you know

Afterward, we trained six types of machine learning models (i.e., decision tree, Gradient boosted decision tree, random forest, logistic regression, support vector machine, and neural network) to predict the occurrences of goal setting and planning activities, using the selected linguistic features of think aloud transcripts. We chose the six models based on the nature of the problem (i.e., a binary classification problem) and the size of our data. For instance, decision tree and random forest are generally better for smaller data sets. We used the 10-fold cross validation to assess the model performance. The performance metrics included classification accuracy, precision, recall, F1 score, and the value of Area Under Curve (AUC). Classification accuracy is the proportion of correctly classified examples. Precision is the proportion of true positives among instances predicted as positive. Recall is the proportion of true positives among all actual positives. F1 is also an important evaluation metric in machine learning, and F1 score is the weighted average of precision and recall. The formulas were shown in Table 3. Moreover, we evaluated the models' overall capacity for distinguishing between classes by checking the ROC (Receiver Operating Characteristic) curve and the AUC results (Mandrekar, 2010).

Table 3
Performance metrics for evaluating machine learning models

	Actually positive	**Actually negative**	**Performance metrics**	
Predicted positive	True positive (TP)	False positive (FP)	(1) Accuracy = $\frac{TP+TN}{TP+TN+FP+FN}$	(2) Precision = $\frac{TP}{TP+FP}$
Predicted negative	False negative (FN)	True negative (TN)	(3) Recall = $\frac{TP}{TP+FN}$	(4) F1 = 2 $\frac{precision \cdot recall}{precision+recall}$

Results

The performance metrics of the six types of machine learning models are shown in Table 4. The results indicated that the Gradient boosted decision tree (GBDT) is superior to others given that it has the highest values of classification accuracy (.752), F1 score (.718), precision (.726), and recall (.752). Although neural network presents the highest value of AUC (.733), the AUC result of GBDT is acceptable (>.70) (Mandrekar, 2010). Taken together, GBDT is deemed best in predictive modeling, and its performance metrics indicate the feasibility of detecting goal setting and planning activities from think-aloud protocols in general.

Moreover, we compared the performance of the machine learning models when they targeted specifically at think-aloud protocols coded as either involving no goal setting and planning activities (i.e., class 0) or having goal setting and planning activities (i.e., class 1). The evaluation results are shown in Table 5. Considering the uneven class distribution (i.e., a large number of actual negatives), we relied on the F1 score to seek a balance between Precision and Recall. The results showed that logistic regression performed best among the models when class 0 was entered as the target class (F1 = .846). When taking class 1 as the target class, neural network performed best, with F1 = .401 (see Table 5 and Figure 1). The precision and recall metrics suggested that neural network was better than randomly guessing (probability = 760/2,792 = .272).

Table 4
The average performance of machine learning models over classes

Model	**AUC**	**CA**	**F1**	**Precision**	**Recall**
Decision tree	.594	.681	.675	.671	.681
Gradient boosted decision tree	.723	**.752**	**.718**	**.726**	**.752**
Random forest	.690	.729	.702	.698	.729
Logistic regression	.703	.746	.693	.718	.746
Support vector machine	.526	.519	.546	.617	.519
Neural network	**.733**	.743	.718	.716	.743

Note: AUC = Area under curve, CA = classification accuracy.

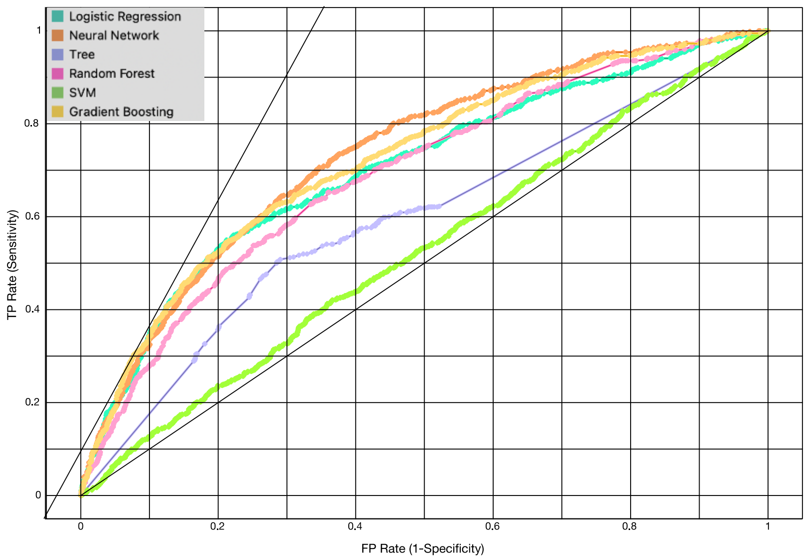
Table 5
The performance of machine learning models of each target class

Model	**Class 0 – No target action**			**Class 1 – Goal setting/planning**		
	F1	Precision	Recall	F1	Precision	Recall
Decision tree	.784	.771	.799	.383	.404	.364
Gradient boosted decision tree	.845	.775	.930	.378	.597	.276
Random forest	.828	.771	.894	.367	.505	.288
Logistic regression	**.846**	.758	.956	.283	.611	.184
Support vector machine	.613	.741	.522	.367	.286	.512
Neural network	.836	.779	.903	**.401**	.548	.316

Note: Target 0 refers to the think-aloud protocols coded as involving no goal setting and planning activities, and target 1 refers to those coded as involving goal setting and planning activities. The scores are computed separately for class 0 as a target class (the middle three columns), and class 1 as a target class (the right three columns).

Figure 1

The ROC of different machine learning models for detecting goal setting/planning



Discussion and conclusion

This study explored the feasibility of detecting the occurrences of goal setting and planning activities in self-regulated learning, leveraging machine learning models and think-aloud protocols. The results suggested that we could accurately predict whether students were engaged in goal setting and planning activities or not since all the performance metrics of Gradient boosted decision tree (GBDT) were larger than .70. Since the primary objective of this study was to detect instances of SRL behaviors related to goal setting and planning activities, we evaluated the performance metrics of machine learning models that aimed to predict the targeted state. We found that machine learning models, especially neural network, performed better than randomly guessing the occurrences of goal setting and planning activities. This study has significant methodological implications. Specifically, this study showed the possibility of using machine learning models to free researchers from the labor-intensive work of coding think-aloud transcripts. Moreover, this study informs instructors and practitioners about the automatic detection of students' SRL activities in real-time as they think aloud in learning, making the provision of timely feedback possible.

This study lays the foundation for future studies. First, it is crucial to explore the relations between SRL activities and the linguistic features of think-aloud transcripts from a psychological perspective. It would also be interesting to expand the features of think-aloud data for predicting SRL activities with machine learning models, such as acoustic characteristics of students' think-aloud. Moreover, the methodology used in this study can be applied to the investigation of other SRL activities such as monitoring and self-reflection.

A Test of Learning Progress Models Using an AI-Enabled Knowledge Representation System

Abstract: This study tested two competing learning progress models - the three-stage and two-stage models - based on an AI-enabled formative assessment tool. Additionally, human-rated scores were used to further validate the models. The data for this investigation consisted of expository essays about a complex problem scenario written by 116 students and 6 experts. The validation analyses, including descriptive statistics, C-LCDM, and group-mean difference tests, demonstrated that the two-stage model was a better framework given the technology. The findings showed the potential of the model to determine learners' conceptual change over time.

Introduction

From an expertise development standpoint, learning is a developmental process toward expert-like problem-solving knowledge and skills (Alexander, 2004; Chi, 2006). Kim (2012, 2015) built on expertise development theories to conceptualize and test learning progress models, shifting the focus of development from long-term change to short-term change in task-level problem-solving in the classroom context. Kim (2012) theorized that learner mental models could represent different levels of understanding of a problem situation, and thus tracking mental model changes could explain how learners develop expertise. A subsequent study proposed computational techniques to extract a knowledge structure from a student's expository essay and leveraged a specific technique, the Continuous Log-Linear Cognitive Diagnostic Model (C-LCDM) method (Bozard, 2010), to test levels of mental models (Kim, 2015).

In this study, we use an AI-based assessment system called SMART (Student Mental Model Analyzer for Research and Teaching) to extract mental models from students' essays and test two competing learning progress models. Since different modeling techniques can produce varying concept maps, it is important to validate relevant diagnostic models. SMART's diagnostic model can monitor students' learning growth over time. The study aims to answer the following questions:

- How do the models explain the stages of learning progress?
- How closely do the computerized diagnostic results align with human judgments?

Learning progress models

Learners' problem-solving abilities can be reflected in their knowledge structure, which is necessary for solving complex problems. Assessing students' problem-solving skills requires examining their knowledge base, which includes ideas and concepts learned from the problem situation (Gijbel et al., 2005). Scholars have introduced three dimensions to understand knowledge structure, known as the 3S dimensions (Kim, 2012): (a) the surface dimension, which concerns the number of constituents of a mental model (e.g., concepts and their relations), (b) the structural dimension, which describes how those components are connected and organized in the knowledge structure (e.g., size and cohesion), and (c) the semantic dimension, which reflects the extent to which students include underlying ideas and concepts used by experts. We use the 3S dimensions to characterize stages of two competing models (i.e., three-stage and two-stage models) as detailed in Table 1. The three-stage learning progress model is based on the Model of Domain Learning (Alexander, 2004) and conceptualizes three stages: acclimation (the initial stage in which most learners experience a lack of pre-structural knowledge), competent (in which learners reconsider and repair their irrelevant preconceptions through teaching and learning), and proficiency-expertise (in which proficient learners construct a sufficient knowledge structure reflecting the problem situation). The two-stage model, called conceptual change, explains that for complex problems, conceptual change from a naïve knowledge model to an informed problem space often requires a shift in fundamental knowledge structure, especially (Chi, 2008).

Methods

Research context and data source

This study collected data from 116 undergraduate students and six professors in the field of instructional sciences. The students were asked to provide their evaluation on the potential factors and variables that led to the failure of a technology innovation project: the implementation of tablet PCs in high-school classrooms that did not result in significant improvements in classroom practices and student performance. The six professors collaborated to develop a reference response using a Delphi research process. To analyze the written essays, the researchers utilized a knowledge-based AI system called SMART. The SMART system performs various core analytics tasks, such as extracting text variables from the essay, eliciting a concept map, abstracting the key knowledge structure from the concept map, comparing the student's concept map to an expert's concept map, and generating multidimensional similarity measures.

Table 1
Competing Learning Progress Models

Three Stage Model	Description	Two Stage Model	Description
Acclimation	(a) All dimensions (surface, structural, and semantic) are quite dissimilar to expert models; or (b) knowledge structures have similar surface dimension to expert models but are missing some structural and semantic dimensions.	Misconception (Novice)	(a) All dimensions (surface, structural, and semantic) are quite dissimilar to expert models; (b) knowledge structures have similar surface dimension to expert models but are missing some structural and semantic dimensions; or (c) Structural dimension might appear to be mastered because mental models, which consist of a small amount of contextual and abstract knowledge, are likely to look cohesive and connected.
Competence	(a) Structural dimension might appear to be mastered because mental models, which consist of a small amount of contextual and abstract knowledge, are likely to look cohesive and connected; or (b) student and expert models are highly similar in semantic dimension but dissimilar in surface and structural dimensions.	Conception (Expert)	(a) Structural dimension shows sufficient complexity while surface dimension is adequate, but not enough to guarantee a semantic fit; (b) knowledge structures are well-featured in all dimensions (surface, structure, and semantic); (c) a significant number of principles (semantic) create a cohesive structure (structural) but with a small number of concepts (surface); or (d) student and expert models are highly similar in semantic dimension but dissimilar in surface and structural dimensions.
Proficiency-Expertise	(a) Structural dimension shows sufficient complexity while surface dimension is adequate, but not enough to guarantee a semantic fit; (b) knowledge structures are well-featured in all dimensions (surface, structure, and semantic); or (c) a significant number of principles (semantic) create a cohesive structure (structural) but with a small number of concepts (surface).		

Data preparation

The SMART analytics system generates concept map indices and knowledge components. Model comparisons result in similarity measures (ranging from 0 to 1) that fall under one of the 3S dimensions, as outlined in Table 2. These hypothetical relationships between the similarity measures and the 3S dimensions were validated by Kim (2015). To further validate the results, two human evaluators used a rubric (Gao et al., 2019) to score the learner responses on four dimensions: content quality, content coverage, content coherence, and argument quality, each of which was rated on a six-point scale. The interrater reliability scores ranged from 0.87 to 0.91 (acceptable ICCs > 0.80; Graham et al., 2012).

Data analysis

We utilized the Continuous Log-Linear Cognitive Diagnostic Model (C-LCDM) method (Bozard, 2010) to identify the stages of mental models and compare the two competing learning progress models. The 3S dimensions are attribute variables in C-LCDM, and each dimension can be considered mastered when its probability is above 0.5 (Rupp et al., 2010). Therefore, the three dimensions ($k = 3$) create eight classes (2^k classes). The mastery profiles of attributes for individuals determine their latent class membership.

Table 2
Model-Based Similarity Measures

Similarity Measure	Definition	3S structure
Number of concepts	Compare the number of concepts (nodes) in two models	Surface
Number of relations	Compare the number of links (edges) in two models	Surface
Density of graphs	Compare the density of two models	Surface
Mean Distance	Compare the mean distances in two models	Structure
Diameter	Compare the largest geodesics in two models	Structure
Concept Matching	Compare semantically identical concepts	Semantic
Propositional Matching	Compare fully identical propositions (edges) between two concept maps	Semantic
Recall-C	The proportion of key concepts that appear in a student summary	Semantic
Recall-P	The proportion of key relations that appear in a student summary	Semantic

Findings

The results revealed the presence of four latent classes: classes 1, 3, 5, and 7, which represented 17%, 31%, 12%, and 40% of the total latent classes, respectively. According to the two learning progress models, these classes exhibited acclimation (29%), competence (31%), and proficiency (41%) in the three-stage model, and misconception (60%) and conception (40%) in the two-stage model (as shown in Table 3). However, contrary to its theoretical assumption, the stages were arranged in descending order, with the second stage of the three-stage model exhibiting lower values in most similarity measures than the first stage. In contrast, the two-stage model displayed an increase in all similarity measures from the misconception to the conception stage.

Table 3
The Estimated Final Class Counts and Proportions

Latent Class	3S Attribute			Three Stages	Two Stage	Estimated Classification (Count)
	S1	S2	S3			
Class 1 (C_1)	0	0	0	Acclimation	Misconception	0.171 (19)
Class 2 (C_2)	0	0	1	Competence	Conception	-
Class 3 (C_3)	0	1	0	Competence	Misconception	0.308 (36)
Class 4 (C_4)	0	1	1	Proficiency	Conception	-
Class 5 (C_5)	1	0	0	Acclimation	Misconception	0.120 (14)
Class 6 (C_6)	1	0	1	-	-	-
Class 7 (C_7)	1	1	0	Proficiency	Conception	0.402 (47)
Class 8 (C_8)	1	1	1	Proficiency	Conception	-

Note. $N = 116$. 3S attributes involve the three dimensions of knowledge structure: Surface (S1), Structural (S2), and Semantic (S3). 0 = absent/non-mastered and 1 = present/mastered.

We conducted an analysis to determine if the two learning progress models could differentiate human-rated scores across the four criteria outlined in Table 4. The results of all group-mean difference tests indicated significant differences between the stages in terms of rubric scores. Consistent with our previous findings, the second stage of the three-stage model received lower scores compared to the first stage. In contrast, the two-stage model aligns with the theoretical assumption, as evidenced by increasing rubric scores from the misconception to the conception stage.

Discussion

An AI-enabled knowledge representation technology can directly influence the way knowledge structures are modeled from students' textual explanations. In this study, the AI-enabled assessment setting demonstrated the potential of the two-stage learning progress model (conceptual change) to characterize the stages of mental models regarding complex problem situations. For example, some students rely on deeply entrenched naive knowledge that is incorrect (misconception), while others leverage sufficient prior knowledge connected to a given problem situation (conception). Pedagogically, the two-stage model, along with the proposed technology-based measurement, can detect students' conceptual change when conceptualizing complex problems. Instructors can use this model to monitor individual students' learning progress and determine when and how to provide instructional remedies, or when to move on to the next assignment. This initial work opens pathways to future studies, and the suggested models and methods should be tested in various technology-based knowledge assessment environments with problems. For example, well-structured problems in closed-world domains or source-based writing tasks (summarization) may produce a new dynamic in the 3S dimensions and a learning progress model.

Table 4
Means, Standard Deviations, Spearman's rho, and Group Difference Statistics for Rubric Criteria

	Three-Stage Model			*F*	Sig.	Two-Stage Model		*F*	Sig.

Tortuga: Building Interactive Scaffolds for Agent-based Modeling and Programming in NetLogo

John Chen, Michael S. Horn, Uri J. Wilensky
civitas@u.northwestern.edu; michael-horn@northwestern.edu; uri@northwestern.edu
Northwestern University

Abstract: Agent-based Modeling and Programming (ABM & P) is widely used in educational settings to promote computational thinking and complex systems thinking. In this paper, we introduce Tortuga, a novel technical system for building interactive scaffolds for ABM & P. Tortuga lowers the threshold and raises the ceiling for constructionist curricular designers. It allows designers to build interactive scaffolds with simple NetLogo commands. These scaffolds can be aware of computational models' emergent behaviors and can react to learners' interactions in modeling spaces. We introduce its technical structure and start to explore how that structure supports learning designs. To understand Tortuga's design affordances, we implemented three types of interactive scaffolds for eight NetLogo models in out-of-school, online learning contexts. Our preliminary quantitative analysis points to potential benefits of content-specific and programming-oriented scaffolds to engage learners with ABM & P.

Introduction

Agent-based Modeling (ABM) investigates scientific phenomena by computationally modeling the behavior of individual autonomous computational agents. This approach is particularly valuable for learners as a way to investigate and understand complex phenomena (Wilensky & Resnick, 1999). Building agent-based models necessitates the learning of agent-based programming (ABP), wherein learners need to program rules for individual agents.

With many studies of ABM & P in classroom environments, less work examined learners' use of ABM & P in informal contexts. In such environments, there is a greater need for technology-enabled scaffolds to support students in engaging with ABM & P. Yet the design of such scaffolds can take significant expertise and effort to implement. The desire to engage learners in online, informal contexts brings opportunities for engaging diverse learners from different socio-economic-cultural backgrounds and further challenges for designers.

To address the challenges, we introduce the design of the first technical platform, Tortuga, that 1) focuses on the learning of ABM & P; 2) lowers the threshold and amount of effort of designing and implementing cross-platform interactive scaffolds; and 3) flexibly supports multiple paradigms of design and diverse learning needs. Through enabling scaffolds to react to the modeling space (i.e., what is happening in the model) and learner interaction, Tortuga naturally invites both learner-adaptable and learner-adaptive scaffolds.

Due to page constraints, we could only briefly explore the affordances of Tortuga. Turtle Universe (TU, Chen & Wilensky, 2020) was launched as a ubiquitous, mobile-first incarnation of NetLogo that aims to engage online, out-of-school learners. On this platform, we implemented sample learning designs on 8 models with 3 paradigms: **content-agnostic**; **content-specific**; and **programming-oriented**. Our preliminary analysis mainly explored: 1) *Were our interactive scaffolds helpful for learners' meaningful engagement with ABM or P?* 2) *Were the impacts of the three paradigms of interactive scaffolds different?*

Related Work

For the past decades, NetLogo has helped educators and learners understand topics of complex systems, such as feedback, emergence, critical parameters, and sensitive dependence (Tisue & Wilensky, 2014). One of the main goals of the NetLogo ecology is to bring ABM & P to a broader audience. The widespread availability of mobile devices for youth brings opportunities for engaging young learners in out-of-school, informal learning contexts (Chen & Wilensky, 2020). Reciprocally, it brings new challenges to scaffold engagement and learning for diverse audiences and generates fresh and urgent needs for technology-enabled scaffolds: learners' time could be more fragmented, their engagement could be more interest-driven, and instructors could be less available.

In this paper, we adopt Collins et al. (1991)'s definition of scaffolding which revolves around experts' support for novices to carry out tasks. The scaffolds will eventually be ***faded***, and learners could carry out similar tasks without them. Extending the notion of scaffolding to support from software, Jackson et al. (1998) discussed two strategies of technology-enabled scaffolds: ***learner-adaptive***, where the design will automatically change to respond to learners' needs; and ***learner-adaptable***, where the design enables learners to initiate the ***fading*** of scaffolds. The scaffolding analysis framework (Sherin et al., 2004) stresses the necessity to compare learning performance between unscaffolded and scaffolded situations. Scaffolds are also relative: while ABM & P are frequently regarded as an approach to scaffolding learning of domain knowledge (e.g., Basu et al., 2015), the learning of ABM & P needs its own scaffolds as well (Sengupta et al., 2013).

NetLogo provides several built-in features for designing scaffolds, but there are also tradeoffs in using them. For example, the scaffolding interfaces of BEAGLE curriculum (Novak & Wilensky, 2007) leads to much more complicated code, limiting learners' capability to understand or build on that model. Introducing the NetLogo language to novice learners is also difficult. Blocks-based interfaces for ABM & P, such as NetTango Web (Horn, Baker & Wilensky, 2021), or CTSiM (Sengupta et al., 2013) were launched to provide a "code-first" or "quickstart" environment to lower the threshold further. However, building those modeling interfaces requires significant technical expertise, and they often come with their own needs for scaffolding as well.

In this section, we briefly presented some related work that discusses the importance of ABM & P and the efforts to broaden its access; that defines the design goals and strategies of technology-enabled scaffolds; and that attempts to scaffold ABM & P through technology design. We believe it is necessary to further lower the threshold for designers to create technology scaffolds that are learner-adaptive and learner-adaptable.

Technological System Design

Anchor Bottom

First Variation of Model

There are two main variations to this model. In the first variation, the "sheep -wolves " version, wolves and sheep wander randomly around the landscape , while the wolves look for sheep to prey on. Each step costs the wolves one unit of energy , and they must eat sheep in order to replenish their energy - when they run out of energy they die . To allow the population to continue, each wolf or sheep has a fixed probability of reproducing at each time step.

What about the population of the grass?

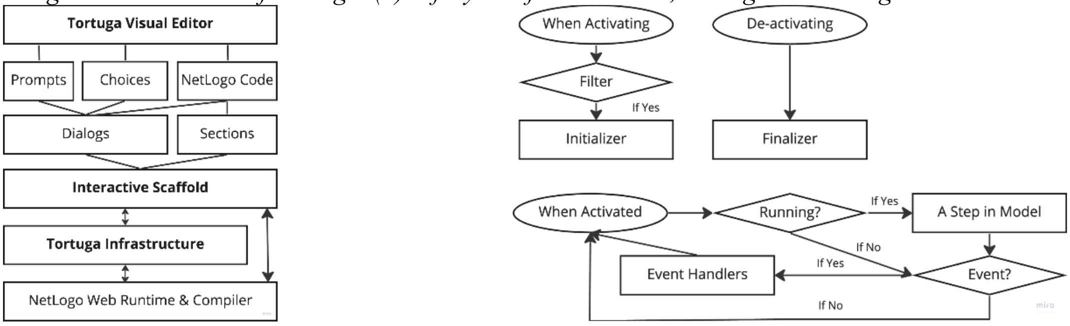
In what condition is this variation well-suited for?

(a) (b)

The technical design of Tortuga aims to bring a low-threshold, high-flexibility way of designing, developing, and implementing technology-enabled interactive scaffolds for ABM & P. Using the NetLogo language and a visual editor (Fig 1a), Tortuga eliminates the need for designers to learn complicated web-based technology for creating scaffolds. The deep integration between Tortuga and NetLogo allows designers to build scaffolds that could capture learners' emergent interactions and the models' emergent behaviors (see the example in Fig 1b). Tortuga is built on the infrastructure of NetLogo Web and works in parallel with NetTango Web (Horn, Baker & Wilensky, 2021), the domain-specific block-based programming interface maintained by the NetLogo team.

Figure 2

(a) The Technological Architecture of Tortuga. (b) Lifecycle of a "Section", the logical building block



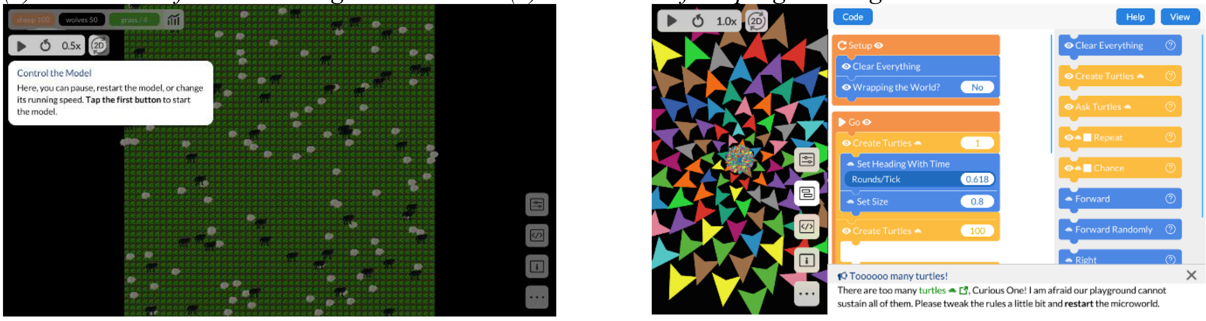
Interactive scaffolds built with Tortuga are capable of interacting with both its own infrastructure and NetLogo Web's runtime and compiler (Fig 2a). By keeping the interactive scaffolds separate from, but running in the same context as the model code, the designers gain access to 1) new customizable and programmable interface widgets such as dialogs and stencils (Kelleher & Pausch, 2005); 2) new capabilities to operate on and take input from most of NetLogo's interface widgets; and 3) new affordances to react to the learner interaction (e.g. changing a certain parameter, or clicking somewhere) and the modeling space (e.g. when the status of agents changes). Fig 2a and 2b demonstrate its main building blocks: 1) Section, similar to a unit or sub-unit in a curriculum; and 2) Dialog, similar to a page or paragraph. The main difference between a traditional curriculum and Tortuga Interactive Scaffolds (TIS) is that while the former is designed linearly, the latter can be designed with a network of triggers.

Sample Learning Design

We designed and implemented 9 sets of TIS. One of them is a content-agnostic interface tutorial. The other 8 sets cover diverse scientific topics, such as biology (Wolf Sheep Predation) or physics and chemistry (GasLab Gas in a Box). Finally, we created a new model (Pocketworld Playground) to introduce ABP through a block-based programming space. All the scaffolds and the Tortuga system are open-sourced.

Figure 3

(a) Screenshot of the content-agnostic tutorial. (b) Screenshot of the programming tutorial.



Control the Model

Here, you can pause, restart the model, or change its running speed. **Tap the first button** to start the model.

Toooooo many turtles!

There are too many turtles, Curious One! I am afraid our playground cannot sustain all of them. Please tweak the rules a little bit and **restart** the microworld.

Fig 3a demonstrates the first paradigm of sample learning design that is **content-agnostic**, mainly to introduce the usage of the software. Here, the stencil-based design asks learners to carry out a specific task and is conceptually similar to Kelleher and Pausch's (2005). The second **content-specific** paradigm comprises 7 tutorials that aim to support first-time learners' exploration at their own pace. Designed with existing learning materials accompanying the models with slight changes of texts, we conducted another embedded experiment: for learners to opt out of the scaffolds, similar texts are still available. Fig 3b shows some design highlights: 1) learners can choose to "learn more" of concepts; 2) learners can choose to "ask questions"; 3) learners can choose to interact with the world instead. In addition, each interface widget receives a question mark that will trigger more information. The third paradigm, the **programming-oriented** tutorial, extends the previous one with several major differences. As the introductory model for ABP, the Pocketworld Playground is designed for learners to explore the space of creativity through programming. Instead of a mostly linear task structure, this tutorial was designed as a network, with 6 major pathways and many branches that fit different levels of prior knowledge and types of personal interest. It also comes with learner-adaptive scaffolds that react to learners' modeling decisions, such as when a learner creates too many turtles in the modeling world (Fig 3b).

Preliminary Study

We implemented all scaffolds in Turtle Universe since early 2021. Then, we collected and analyzed anonymized log data from consented learners during a 14-month period. The timing of user interaction suggests that most were K-12 age learners in out-of-school contexts. Our observation and informal conversations show that most learners had little knowledge of ABM & P before. By filtering the dataset to only include first-time users' first visit to any project, we excluded the effect of learners' prior exposure to Turtle Universe. Learners who spent less than 10 seconds in any model are also excluded. A total of 7,256 learners were left in our study.

Three quasi-experimental conditions were created through TU's design, each with two groups. Each first-time user is presented with two options: "*Free Exploration*", leading to the content-agnostic scaffolds for all but one model; and "*Guided Intro*", leading to the model-specific scaffolds. Learners were free to decide whether and when to stop using the scaffolds. Depending on learners' reaction to the scaffolds, two groups are created out of this situation: learners who engaged with the scaffolds (quasi-experimental); learners who opted out of the scaffolds (quasi-control). Then, we used regressions to compare the effectiveness of each condition on learners' engagement, with fixed effects to control the differences between models. Building on existing studies (Dewan et al., 2019), we used the following metrics from the log data to measure learning engagement:

1. **Time spent in the model (and excluding on Tortuga interfaces)**, to understand learners' engagement and if learners' engagement did increase other than simply reading the prompts;

2. **Total time spent in 8 scaffolded models within the 14-month period**, to reflect the extent of voluntary engagement with ABM & P, which suggests individual interests of learners (Michaelis & Weintrop, 2022);
3. **Number of exploration or tinkering events** (e.g. changed the value of a widget in ABM; added, changed, or removed programming blocks in ABP), to measure learners' deeper engagement with ABM & P.

We found that: 1) While all types of scaffolds improved learners' total time spent in the model, the **programming-oriented** condition performed the best (+223%), followed by **content-specific** (+57%) and **content-agnostic** (+31%). 2) **Content-agnostic** increased engagement mostly through reading prompts (no significant change), while other 2 conditions successfully improved engagement beyond them (+257%/+24%); 3) the **programming-oriented** condition performed the best in helping learners explore or tinker with the model (+666% in event occurences), followed by **content-specific** (+66%), while the **content-agnostic** condition saw a decline (-20%). 4) Learners in **programming-oriented** (+71%) condition engaged more with those models in the long run. All findings are statistically significant ($p < 0.05$).

Discussion

Tortuga is designed as a flexible technology system for developing interactive scaffolds for ABM & P learning activities while lowering the threshold. It could be used to design scaffolds as simple as two-screen prompts, or as complicated as a network. *What could be the cause of the different learning impacts between the conditions?* While the content-agnostic scaffold increased learners' engagement, it likely does that by requiring learners to follow steps. On the other hand, simply turning existing learning materials into interactive scaffolds, with a little bit of story-like framing, could produce significant gains in engagement. The scaffold's understanding of the modeling space, as well as its ability to support open-ended programming activities, could also be powerful, as shown in the programming-oriented scaffold. That being said, our study is limited by a certain learning context (online, out-of-school, informal). To better support learning designers and learners of ABM & P, it remains on us to conduct further studies with learning designers and learners in more diverse learning contexts.

An Investigation of Knowledge-Based AI vs. Human Evaluation in the Context of Academic Summary Evaluation: Similarities, Dissimilarities, and Being Toward Mutual Understandings

Jinho Kim, Golnoush Haddadian, Min Kyu Kim

Georgia State University

Abstract: This study aims to explore the similarities and dissimilarities of knowledge-based AI evaluations vs. human evaluations and discuss how they can be utilized for formative feedback in academic summary writing. Data were collected from 62 students who utilized AI-based formative feedback to make revisions to their summaries. We compared indices on three dimensions (surface, structure, semantic) that were automatically generated through this software with human-rated evaluations. MANOVA results of learners' initial draft and final revision showed learning gains in the semantic dimension and human-evaluated scores. Some significant correlations were observed between automatic and human-rated evaluations. Given that each measure can be interpreted to provide different insights, we suggest combining knowledge-based AI and human evaluations for rich and informative feedback.

Introduction

Instructors have used summary writing to assess reading comprehension and to scaffold students' concept learning (Dunlosky et al., 2013; Kim & McCarthy, 2021). Namely, learners can acquire knowledge while processing the given material, understanding its structures, identifying key concepts, and organizing these into words. To support this process, evaluating learner performance and providing timely feedback is important.

A typical means to evaluate summaries of texts is either through knowledge-based AI systems or human evaluation. The use of knowledge-based AI for evaluation is an emerging field, fueled by the development of natural language processing techniques (Hu et al., 2022). Technology-enabled assessment is perceived as objective, free from bias and stereotypes, able to produce timely feedback to learners, and having potential when there is a lack of human evaluators (Belz & Reiter, 2006; Lewis Sevcikova, 2018; Mithun et al., 2012). However, with many techniques still focused mainly on corpus-based metrics, key concepts have to be identified beforehand and only mathematically calculatable variables are able to be judged (Belz & Reiter, 2006; Mithun et al., 2012). Thus, there have been arguments that automatic evaluations are yet to replace human evaluations (Hu et al., 2022). On the other hand, human evaluation is able to judge summaries holistically, taking argument qualities and aesthetic styles into account (Lewis Sevcikova, 2018). However, human ratings consume much time and effort, and training evaluators is also a challenging task (Brookhart & Chen, 2015; Lewis Sevcikova, 2018). There is also the issue of human raters showing low correlations between each other, especially when no clear rubric exists to evaluate (Belz & Reiter, 2006; Hu et al., 2022; Mithun et al., 2012).

As such, the characteristics of these methods of evaluations differ in many ways. In this study, we aim to use academic summaries to explore the relationship between the two evaluation indices and discuss how they can supplement each other.

Methods

Research context and data source

Data were collected from 62 students across six semesters of an instructional technology course. The course was offered in an asynchronous online format, with learners participating in weekly summary writing, quizzes, and discussions. While learners submitted their summaries directly to the university learning management system for most of the semester, they used a web-based technology that provides knowledge-based AI evaluation and formative feedback for one week. The system provided learners with multimodal feedback, including visual and textual information, and learners were allowed to make as many revisions as they preferred. We used the summaries and indices generated from this interaction for this research.

Knowledge-based AI evaluation

We used the Student Mental Model Analyzer for Research and Teaching (SMART) system to compute knowledge-based AI evaluation indices. SMART is an automated summary evaluator which provides formative feedback on submitted summary by utilizing concept maps as re-represented mental models. Based on graph theory (Wasserman & Faust, 1994), SMART generates concept map parameters for surface, structural, and semantic dimensions (3S). These measures are then compared to a reference model (an expert model) and 11 similarity measures are calculated. The resulting indices are shown in Table 1.

Table 1
SMART-Based Evaluation Indices

Dimension	Similarity Measures	Definition
Surface	S-Number of Concepts	The total number of concepts (nodes)
	S-Number of Relations	The total number of concept relations (links)
	S-Density	The cohesiveness of a concept map
Structure	S-Average Degree	The average number of degrees
	S-Mean Distance	The closeness of concepts (average geodesic distance)
	S-Diameter	Understanding broadness (largest geodesic distance)
Semantic	Concept Matching	Semantically identical concepts
	Propositional Matching	Fully identical propositions
	Balanced Sematic Matching	Propositional matching divided by concept matching
	Recall-C	The proportion of key concepts
	Recall-P	The proportion of key relations

Note. Modified from Kim & McCarthy (2021, p.691).

Human evaluation

Human evaluation was conducted by two researchers based on the rubric introduced by Gao et al. (2019). Each summary was scored on a scale from zero to five in terms of their content quality, content coverage, content coherence, and argument quality. Cronbach's Alpha was used to examine the interrater reliability of the five indices. Content quality ($\alpha = .88$), content coverage ($\alpha = .83$), content coherence ($\alpha = .74$), and argument quality ($\alpha = .90$) showed sufficient levels of reliability (Graham, 2012).

Data analysis

To explore if there are gains between learners' initial and final summary submissions, we conducted one-way repeated-measures multivariate analysis of variance (MANOVAs). A total of four MANOVAs were used to examine the three dimensions of the SMART-generated similarity measures as well as the human evaluation. The relation between the two types of indices were explored using Pearson's coefficient of correlation.

Findings

We conducted a series of MANOVAs to investigate if revisions could lead learners' summaries to become similar to the reference (Table 2). Surface level indices showed some improvement in terms of descriptive data but were not statistically significant (Wilks' Lambda = 0.95, p = 0.35). This could have been due to the assignment having clear guidelines about the length of the summaries, leaving little room for change. There was also no significant difference for the structural measures (Wilks' Lambda = 0.95, p = 0.35). As with surface measures, having a clear restriction on the number of words could have limited structural changes from taking place. In terms of the semantic dimension, there was a significant difference (Wilks' Lambda = 0.32, $p < 0.001$). Univariate repeated-measures ANOVAs showed statistically significant gains for all semantic measures. Learners' revisions were focused on the semantic area, showing clear changes in the use of key concepts and relations. As SMART provides feedback focusing on terms and relations that should be included in summaries, learners seem to have been able to add such information through revisions. Human-rated indices also showed significant gains (Wilks' Lambda = 0.52, $p < 0.001$), with univariate repeated-measures ANOVAs confirming that these were present in all four indices. The findings suggest that from a rubric-based human view, learners performed better through revisions.

Table 2
Similarity Scores and Human Rated Descriptors: Means, Standard Deviations, MANOVA Results

Descriptor	Mean (SD)		(F – I)	*F*	Sig.	η^2
	Initial (I)	Final (F)

Structure						
S-Average Degree	0.95 (0.04)	0.95 (0.04)	0.007	3.27	0.075	0.50
S-Mean Distance	0.91 (0.07)	0.91 (0.06)	<0.001	0.01	0.916	<0.01
S-Diameter	0.84 (0.12)	0.84 (0.10)	0.005	0.08	0.779	<0.01
Semantic						
Concept Matching	0.26 (0.12)	0.36 (0.13)	0.10	69.59***	<.001	0.53
Propositional Matching	0.06 (0.05)	0.11 (0.08)	0.05	44.29***	<.001	0.42
Balanced Semantic Matching	0.21 (0.13)	0.28 (0.13)	0.08	26.08***	<.001	0.30
Recall-C	0.42 (0.16)	0.70 (0.22)	0.28	120.45***	<.001	0.66
Recall-P	0.29 (0.16)	0.61 (0.28)	0.33	113.68***	<.001	0.65
Content Quality	2.73 (0.58)	3.12 (0.61)	0.40	35.64***	<.001	0.37
Content Coverage	2.73 (0.58)	3.21 (0.56)	0.48	47.91***	<.001	0.44
Content Coherence	1.84 (0.49)	2.06 (0.59)	0.23	17.79***	<.001	0.23
Argument Quality	2.74 (0.56)	3.10 (0.62)	0.35	32.41***	<.001	0.35

Note. N = 62. ****p* ≤ .001

Pearson's correlation coefficients were calculated between the SMART-generated 3S similarity measures and human evaluations to explore their relationships (Table 3). For the initial summary scores, a statistically significant correlation was observed between Recall-P and content quality, Recall-C and content coverage, and Recall-P and content coverage (r(60) = .25, .27, and .30 with p = .05, .04, and .02, respectively). In the case of final summary scores, we observed significant values with structure and semantic indices. Specifically, the mean distance similarity values showed correlations with content coverage and content coherence (r(60) = .32 and .26 with p = .01 and .05, respectively). For semantic indices, concept matching, propositional matching, balanced semantic matching, and recall-C (r(60) = .35, .42, .43, and .25 with p = .005, .001, <.001 and .05, respectively) showed relations with content quality. There were also significant correlations between balanced semantic matching and content coherence, propositional matching and argument quality, and balanced semantic matching and argument quality (r(60) = .27, .29, and .30 with p = .03, .02, and .02, respectively).

In summary, some significance was identified, with a few within the range of previous studies on such relations (Jonsson & Svingby, 2007). While initial submission evaluations had few significant values, the final scores showed more semantic indices showing significance. Such differences could have stemmed from the characteristics of automatic assessment. SMART's indices measure similarities with a more micro view, focusing on if the certain concept or relation is explicitly stated within the text. On the other hand, human evaluators can have a more comprehensive view and are able to understand underlying meanings. Thus, this could have caused a discrepancy between SMART and human rater's judgements in initial summaries. As learners utilized SMART's feedback for revision, they could have been encouraged to identify more key terms and to state them clearly. This could have led to the higher levels of correlation between SMART indices and human evaluations and would be in line with the explanations given by Dang & Owczarzak (2008), who stated automatic evaluations could lead to low scores when differently phrased information is not correctly recognized.

Discussion and implications

This study aims to explore the relationship between knowledge-based AI and human in academic summary evaluation. To this end, we compared SMART-generated indices alongside rubric-based human evaluations. We found that system-generated evaluation is quite different from human judgements. While knowledge-based AI can be objective, focuses on micro-level changes, and looks for explicitly expressed information, human generated measures are more subjective, comprehensive, and holistic. As such, each measure needs to be interpreted accordingly. Furthermore, knowledge-based AI and human evaluations can supplement each other to provide insights the other cannot. Thus, we believe that using both measures collectively would allow for more informative formative feedback.

Expanding and Focusing Infrastructuring Analysis for Informal STEM Education

Ronni Hayden, University of Colorado, Boulder, Ronni.Hayden@colorado.edu
Stephanie Hladik, University of Manitoba, Stephanie.Hladik@umanitoba.ca
Ricarose Roque, University of Colorado, ricarose@colorado.edu

Abstract: In our efforts to build transformative informal STEM learning environments, we must consider how innovative educational practices and tools are adaptable, sustainable, and equitable. The lens of infrastructuring allows us to attend to the ways that people, practices, and objects already present in these environments can be leveraged and redesigned to support equitable learning outcomes. Through qualitative analysis of 16 facilitator interviews across three informal STEM organizations, we determined six types of infrastructure that support engagement with computational tinkering in informal learning environments: institutional routines and resources, social and facilitation practices, institutional and facilitator values, facilitator expertise, tools and materials, and physical space. We also point out some critical gaps or challenges within these categories that can serve as points for reflection and redesign. This work has implications for researchers, designers, and facilitators/managers who work in informal STEM settings and aim to engage learners with STEM in new ways.

Introduction and purpose

Informal learning environments, such as museums, libraries, and after-school clubs, can support expansive ways of engaging with STEM, especially for learners from communities marginalized in STEM education (Calabrese Barton et al., 2017; Rahm et al., 2022). While informal spaces operate outside of some constraints of the formal school system, such as a government-mandated curriculum and strict training and evaluation protocols, informal learning environments have their own structures, policies, and practices that can either support or constrain learning opportunities. Studying infrastructure allows us to attend to the invisibilized and relational work at play within these local systems, practices, and environments (Star, 1999), which has implications for how we can effectively design educational practices and tools that are adaptable, sustainable, and equitable.

In this paper, we offer a study of infrastructure across three informal STEM learning organizations. We aim to understand how existing infrastructures at these sites can support facilitator and learner engagement with what our project team has termed “computational tinkering,” a novel approach to computing education that prioritizes relationships, joy, and creative explorations of physical and digital materials to create personally meaningful artifacts. We also looked for infrastructure gaps or challenges that hinder engagement with computational tinkering at each of the sites. Our work adds to the existing infrastructuring literature by focusing on informal learning environments as opposed to school classrooms. We also highlight how using a particular approach to computing (i.e., computational tinkering) as a lens for infrastructure analysis brings to light the ways that epistemologies are implicated in both the support systems and the infrastructure gaps.

Theoretical framework: Infrastructuring

Star and Ruhleder (1996) proposed the notion of infrastructure as a way to examine moments in which local practices and solutions intertwine with larger-scale structures and technologies. They argue that infrastructure is inherently relational due to its ties to people, practices, and things - an argument echoed by Bielaczyc (2013) in her social infrastructure framework. In this way, infrastructures are resources in a learning environment that should be designed around and with. Critically, infrastructures are not static, but can be redesigned and renegotiated by the people within a system - an action known as “infrastructuring” (Karasti & Syrjänen, 2004). In a formal education setting, Penuel (2019) uses infrastructuring to discuss efforts that are focused on creating the conditions of support for educators around educational innovations. Studying infrastructure means paying attention to how, where and when resources are taken up, and allows designers to understand how innovations can be implemented equitably across an educational system and be sustainable long term (Penuel, 2019).

Our work continues to build on these theoretical conceptions of infrastructure in design work and brings them into informal STEM environments. Informal learning environments can potentially engage youth and communities that have been systematically marginalized and excluded from traditional STEM learning spaces, particularly by creating a supportive environment that helps learners develop their interest and identities as people who are capable and motivated to pursue STEM fields (Bell et al., 2009; Bevan & Michalchik, 2013; Ito et al., 2009). Touted as spaces with great transformative potential outside of the constraints of formal education, it is important to recognize that these informal learning spaces also have their own deeply contextualized tensions, contradictions and gaps in infrastructure that designers engaged in design projects must recognize in order to design and implement sustainable and consequential learning innovations (Hladik et al., 2022). To that end our work proposes an initial framework of types of infrastructure that might be analyzed and reimagined in these environments, informed by the perspectives of facilitators within these spaces.

Research design

Context

This work stems from a multi-year collaboration between research institutions and informal STEM learning environments in the US, including a museum makerspace on the West Coast, library makerspaces in the Mountain Region, and community-based technology centers across the US. The purpose of the partnership is to collaboratively design, implement, and evaluate activities for "computational tinkering." To guide the co-design of our interventions, our project team articulated particular values as being central to the design of computational tinkering activities: engaging entry points, supporting multiple interests, allowing for deepening complexity within activities, the use of both digital and physical materials, experimental and playful practices, projects that are culturally and personally meaningful, positive affect in the learning experience, and a desire to create a sense of belonging in STEM for all participants. As part of this work, we wish to understand the relationship between this particular approach to computing and the infrastructures in these learning spaces.

Participants, data collection, and analysis

We aimed to examine infrastructures from facilitators' perspectives, as their professional practice requires daily interactions with these infrastructures. Based on nominations from institution leadership, we invited facilitators to participate in 90-minute interviews via the video conferencing software, Zoom. We interviewed 16 facilitators: 5 from the museum makerspace, 6 from the library makerspaces, and 5 from the community technology centers. Through a semi-structured interview, we asked them about their role, their organization's goals, their views on equity, and what they were excited to try in the future. We also asked them to bring an example of a computational activity, share how it was designed and facilitated, and detail the challenges that facilitators or learners faced during the activity. Interviews were recorded, downloaded, and transcribed.

While these interviews did not specifically ask facilitators about infrastructures for computational tinkering, we were able to gain some insight into infrastructures by looking for things that support their work, or challenges they are facing, across their responses. We drew upon grounded theory and constant comparative methods (Glaser, 1965) for this analysis. First, authors 1 and 2 engaged in open coding of three transcripts, looking at the data through the lens of infrastructure that supported facilitators' work in computational tinkering. We organized these codes into broader categories of infrastructures for an initial codebook. We then coded two additional transcripts separately and met to refine the codebook. We then coded the remaining nine transcripts individually, resolving any questions through discussion.

Findings

Our analysis revealed six types of infrastructure that support design and implementation of computational tinkering activities in informal STEM environments:

1. *Institutional routines and resources*: Institutional practices or rules that impact activities and how facilitators engage; resources that can be accessed by the wider institution
2. *Social and facilitation practices:* Learner and facilitator interactions that support engagement
3. *Institutional and facilitator values:* Values that align with ideas of computational tinkering
4. *Facilitator expertise:* Knowledge and attitudes of facilitators that impact activity design and implementation
5. *Tools and materials:* Procurement and use of computational tinkering materials; specific material properties that support engagement
6. *Physical space:* Arrangement of resources within the physical environment

Our framework is applicable to any STEM learning approach when its materials and values are made explicit. To illustrate our findings, we next highlight examples from two different categories of infrastructure: (3) institutional and facilitator values and (5) tools and materials.

Institutional and facilitator values

Drawing on Bielaczyc's (2013) notion of cultural beliefs as a form of social infrastructure, we suggest that institutional and facilitator values around computational tinkering can either support or hinder the design and implementation of these activities in their organizations. More specifically, alignment between the values that made up the core of computational tinkering (as described in the context section) and established values of the space was an important factor in implementation and continued engagement.

For example, as computational tinkering is premised on the idea of both physical and digital materials being meaningfully integrated into a final project, spaces that already valued this diversity in materials were also more easily able to support CT in their spaces. However, this valuing of physical and digital materials was not always balanced; Primo (note, all facilitator names are pseudonyms) pointed out that families and youth within the CTC loved to have something to take home with them, making solely digital projects less exciting for their participants and possibly excluding some CT activities that do not lead to a final physical product. Another value that both supported CT and at times constrained that work was the desire for positive affect. Facilitators wanted youth to have joyful experiences working with computing, and at times, they perceived their learners' frustration in an activity as a barrier that hampered their engagement, such as an activity where a girl was not able to "immediately figure out" the "complicated vision for what she wanted the [Scratch] sprite to do" (Amy). Trying to determine the fine line between "true frustration" voiced by Amy and a productive struggle as part of learning something new (Warshauer, 2015) can be challenging, possibly leading to moments where facilitators step in to solve a problem or pivot to a different activity, leading to decreased engagement with computational tinkering.

Finally, a value that both supported facilitators in CT and also constrained their work at times was the desire not to mirror formal education settings. Facilitators spoke about wanting to encourage learning without strict outcomes or grades, instead aiming to get youth deeply involved in the iterative process of learning in a safe way. (Diego, Daniel, Eric). This aligns well with computational tinkering, where process is valued over a final product. However, the spread of popular computational tools into formal education settings where they may be introduced in more instructivist ways led some facilitators to avoid these tools in their spaces. As Diego said, "I just struggle when there are a lot of activities that are already offered in most of the school systems, so a lot of kids, they don't see it as something new, they see it as part of like, "Oh this is schoolwork." Several facilitators (Diego, Leonardo) mentioned that they rarely designed activities which used the creative block-based programming language, Scratch, because children associated it with their school settings - even though many youth already had some knowledge of Scratch and it is known to be a tool with the potential to promote creative, personally-meaningful learning experiences, especially for youth and families from marginalized communities (Roque, 2016).

Tools and materials

Perhaps unsurprisingly, having access to computational tools and materials was a significant part of the infrastructure to support computational tinkering activities at these organizations. Our analysis showed however, that *availability* was not the same as *accessibility*; Amy pointed out that "some of it is in very deliberately setting up a space in a way that materials and equipment, it's just open, it's just available and just out [in the space]," accompanied by explicit facilitator explanations and invitations to try it out, such as relating a Raspberry Pi microcontroller to a regular computer (Amy). Tensions also emerged between giving participants the opportunity to use computational tools and materials that they would not typically have access to, such as a laser cutter, versus ensuring that the tools and materials could also be used at home, such as looking for free software (Diego). However, even if the software was free, many facilitators spoke about how some of their visitors did not have access to computers or high-speed at home, revealing another infrastructure gap in how they could extend their impact beyond their organization's walls. Facilitators also mentioned that having different tools or software packages that could be used across different projects, such as using a digital illustrator software that could be used on its own or to create designs for a vinyl cutter (Eric), helped learners to be more comfortable with a variety of tools and take on new projects.

One of the most significant infrastructures related to tools and materials were the supporting resources, such as guides, videos, instructions, and example projects. In many cases, existing supports were not meeting the needs of their learners, due to a lack of detail or relevance to their particular project, or not including instructions in learners' home languages. Facilitators frequently filled these infrastructure gaps themselves, highlighting their agency in creating their own infrastructures. For example, Amy discussed how learners were having trouble understanding what a breadboard is and how the various rows are connected, so he decided to break one apart, "open it up and show the guts" so that learners could see, touch, and understand how to connect electronic components. Facilitators also created activity cards and visuals to spark project ideas (Eric), cards to explain basic coding principles (Jenna), sample projects (Emilia), practice sheets (Emilia), and instructional videos (Daniel, Eric, Katie). These resources were especially helpful when facilitators did not have the time to sit down and walk a learner through an activity 1-on-1 for an extended period of time, something that was very common across the library makerspaces and CTCs. In this way, facilitators designed their own infrastructures to deal with day-to-day operational challenges that occur in busy, drop-in, and under-staffed settings.

Discussion and conclusion

This work aims to expand our capacity to build equitable informal STEM learning environments by better understanding how infrastructure can be considered and leveraged in the design and implementation of educational innovations. We specifically highlighted two categories, facilitator and institutional values, and tools and materials, to show the complexity of systems and practices that may support or constrain uptake in the case of computational tinkering activities.

Our findings also show the impact of considering the role of epistemologies of STEM in an analysis of infrastructure. By using our specific lens of computational tinkering, we can make the epistemologies of STEM — that is, what STEM *is* or *should be* — visible. Values are built into approaches to STEM learning within the activities, pedagogies, materials and goals. We must be especially mindful when we are trying to promote or create space for new approaches to computing, because it may or may not be supported by the organization. Our work builds on previous scholarship about infrastructures in formal learning environments (e.g, Penuel, 2019) to highlight that informal learning spaces have their own affordances and constraints with respect to infrastructure that must be considered by researchers, designers, and practitioners in these spaces. We also highlight the important perspectives of facilitators in this work, further making visible the complexity of informal facilitator practices (Hladik et al., 2022).

We also want to make clear that this framework was built from data across distinct informal learning spaces. Our goal is not to collapse these organizations into a monolith, but rather to offer a framework to help designers use infrastructure as a lens to see the nuances of the spaces they are working with. In our future work we plan to more deeply investigate the agency of facilitators with respect to infrastructures: what infrastructures do facilitators have the power to redesign, and what more constraints remain. We will also continue to validate this framework through in-person observations of infrastructure as well as infrastructure-specific interviews with facilitators.

Learning as Emergent Practice in the Transdisciplinary Civic Learning Collaborative

Abstract: Conceptualizing learning as emergent practice, we explore the political learning of teachers in a teacher learning community. Drawing on data from two years of monthly virtual meetings, we identify four emergent practices that have come to cohere in the group: multi-vocality, interrogating boundaries, identity inquiry, and affective attunement. After a brief summary of these practices, we trace their negotiation in one interactional episode.

Introduction

As the world continues to stumble forward from the global pandemic, the jury remains out on how schools today may function as locations for pursuing education's liberatory potential (Ladson-Billings, 2021). Though central in this work, already overburdened teachers can hardly be charged with the added feat of transforming the school itself. Yet, teachers continue to work, often against the grain of schooling, to create conditions that support the learning, thriving, and meaningful participation of children. The Transdisciplinary Civic Learning Collaborative (TCLC), a voluntary teacher learning community, provides one example of how teachers work to transform learning possibilities for students, and in doing so, challenge the very nature of schooling. Contributing to questions about the political learning of teachers (Cochran-Smith & Lytle, 2015), and to better understanding the possibilities and potential of teacher learning in transdisciplinary, multi-grade teacher communities, this paper reflects early inquiry into the learning of this group, theorizing learning as emergent collective practice. Analysis asked: 1) What is being learned in and by the TCLC as evidenced in emergent practice? 2) How are these practices learned and negotiated in interactional moments of tension or conflict?

Theoretical framework: Learning as emergent practice

We draw on social practice theory (Holland & Lave, 2009) to frame learning as a fundamentally social endeavor through which individuals and groups make meaning and come to participate in shared practices that emerge both through moment-to-moment interaction and through the accumulation of these moments over time. Building from Freirean "culture circles" as a model (Freire, 1971), we conceptualize TCLC as an emergent community of practice (Wenger, 1999). Unlike more established communities of practice such as a trade or professional community, the practices of TCLC are immanently emergent precisely because there is no existing tradition of transdisciplinary, multi-graded, teacher-researcher design collaboration communities. Rather, TCLC reflects the coming together of highly diversified learning ecologies and experiences. Still, drawing from this literature, we conceptualize learning as the emergence of practice (Holland & Lave, 2009; Lave & Wenger, 1991). Rather than following the trajectories of individuals, we focus on the collective practices of TCLC as they emerge and are negotiated. We see the emergent nature of these practices as reflecting the early learning of participation—ways of being and knowing together—in the collaborative.

Transdisciplinary civic learning collaborative: History and context

In January 2020, a group of English Language Arts (ELA) and mathematics teachers convened virtually for the first time, brought together for their varied commitments to the liberatory potential of teaching, to articulate the possibilities of *quantitative civic reasoning* – the pairing of quantitative and literary practices to engage civic questions. Building from an expanded conception of civics as inclusive of all human activity that works to build democratic communities (Westheimer & Kahne, 2004), and responding to the provocation, "all teachers are civics teachers" (Nicole Mirra, personal communication), participants shared examples from their own practice and sought resonances, at times unexpected, between mathematics, ELA and civics. After the writing, production, and public launch of a teacher guide (Gargroetzi et al., 2020), many desired to continue meeting.

In response, participating teachers each invited a colleague from their own school to join the group, adopting our current name, the Transdisciplinary Civic Learning Collaborative. Currently, 12 teachers and researchers across content, location, and grade level meet monthly (virtually) to collaborate in a social design-based experiment (Gutiérrez & Jurow, 2016). Together we generate and examine new possibilities for youth transdisciplinary civic learning, designing for and reflecting on learning and practice in each of the three school sites. We believe the pursuit of radical new possibilities for identities, engagement, and creation, likely requires no less than the transgression of traditional boundaries of academic disciplines, grade levels, and institutions.

Methods

The TCLC social design experiment includes multiple layers of design, implementation, and reflection, with much focus on designing for student-facing learning activities. The analysis presented in this paper, however, is a qualitative analysis of the TCLC meetings, examining the meeting space itself as a space of learning for TCLC participants. Taking discourse as a primary site for learning, we analyzed transcripts and artifacts from 14 90-minute virtual meetings spanning January 2021 – November 2022. The research team began with open coding and collaborative refinement of codes (Emerson et al., 2001) to identify recurrent TCLC practices. As both participants and researchers in TCLC, we layered this data-centered analysis with analytic memo writing (Emerson et al., 2001) focused on our own experiences in TCLC. Through this process, we identified and began to articulate the nature of four emergent practices reflecting the learning of TCLC. Ongoing analysis will include comprehensive coding of the data with further code refinement and the mapping of these practices as they emerged in and over time.

Theorizing social practice as emergent not only over time, but also in moment-to-moment interaction, for this paper, we selected for analysis an episode of tension that arose in the third meeting of the group (May, 2021). The selection was based on the understanding that conflict often indicates that a norm was transgressed (Goffman, 1971), and that the norms of a community may become salient in moments of conflict. Here we make use of episode analysis to illuminate the texture and negotiation of emergent practice as TCLC learning.

Preliminary findings

Four emergent practices were identified as reflecting the learning of TCLC over the first two years of collaboration. Each of these is briefly described below. Then, episode analysis illuminates each of these practices *in vivo* as they were actively negotiated, becoming immanently familiar and expected TCLC practice.

Multi-vocality as anti-hierarchical: Multiple perspectives and experiences were explicitly stated as valued in the initial "agreements" of the group: 1) Everyone is coming with *lots* of expertise; we need everyone's voice; and 2) We are here to build from and across different experiences and perspectives. In this sense, the design of the group was anti-hierarchical from the outset. Over time, this has come to be expressed in the multi-vocality presumed in conversational patterns wherein it is common for multiple contributors to provide insight on a topic before anyone speaks twice. Multi-vocality is also evidenced in the production of shared ideas wherein neither consensus nor majority-rule guides uptake; rather, ideas are often left open with multiple possible enactments.

Challenging boundaries as critical work: The collaboration is framed around transgressing boundaries; this includes the boundaries of academic disciplines such as civics, mathematics, or literacy, as well as the boundaries erected around our classrooms and schools as we seek to build intellectual and pedagogical collaborations across spaces and places. The practice of surfacing boundaries and challenging them, asking whom these boundaries serve and what it means to cross or bend them, became embedded lived practice as evidenced in discourse as well as in the design of the learning units and teacher collaborations at each site.

Identity inquiry: The practice of locating and inquiring into identity as an essential component of considering the purpose and impact of our work emerged in multiple forms, coalescing into a driving component of what we eventually articulated as the student-facing guiding question for learning units across sites: *How can we leverage our individual assets and identities to collaboratively imagine, create, and sustain thriving communities?* In settling on this shared guiding question, teachers observed that student-facing work must start with opportunities to explore individual identities in relation to their diverse communities.

Legitimate attention to affect and emotion as part of learning and human development: Throughout group interactions, and reflected in discourse about student learners, consistent attention and care are given to human emotion, affect, and experience. Reflected in the fourth "agreement," "care for yourself and the group," as well as in the opening check-in questions such as "What color(s) are your emotions today?" (9/27/2022) that launch each meeting, personal affective states are taken seriously in organizing the work of the group around trust and care, and are mirrored in attention to the same in the lives of students.

Learning shared practice in a moment of tension

During the third TCLC meeting, a literacy educator and group facilitator, Antero, asked if mathematics teachers might approach a moral quandary using quantitative thinking. Evan, a math teacher, responded by sharing a lesson in which his high school algebra students consider a scenario where a police chief concludes from a set of data that one group of people needs to be policed more than another group. Students then consider the data and make two opposing arguments based on the statistics. Evan explained,

> Without getting into all the math, if you look at it based on the number of people committing crimes total, uh, one group has a much higher incidence of people committing crimes. If you look at it as proportions within the populations, the other group is committing at a much higher rate. So, you've got two opposing arguments that can be effectively made with statistics. And the reality is that there are a lot of unanswered questions here. Students have come up with great responses, right? These are just the people who are being arrested and convicted, but is that actually who's committing these crimes? Is there some bias going on in terms of who's being arrested? A lot of this might depend on the crime, and the particular populations involved. The way the problem is set up, it's not based on race, but clearly, that's the mindset that is kind of intended… It definitely speaks to that idea that you can use quantitative reasoning to make arguments and prioritize, and answer ethical questions. But you can also do it well and you can do it poorly and ideally, it's going to bring up more questions than it answers.

Evan's example evidences his own emerging work to challenge the boundaries of what traditionally happens in math classrooms by not only using current statistical data, but tying it to a prevalent social, political, and racial issue. In presenting a situation that is initially posed as a mathematical problem, but then encouraging his students to articulate challenges to the premise of the problem and the data itself while connecting it to their daily lives, Evan pushes traditional borders of mathematics education into the civic realm. He likewise poses a challenge to the efficacy of mathematical problem solving without attention to the moral or political context of the problem.

Responding to Antero's prompt, Emma followed Evan's comment with another example of a mathematics task that pushed students to articulate underlying ethical dilemmas. Then, she indicated it was time to change topics. At that point, Min, a third math teacher, spoke up:

> I don't want to drag this on, but I was very uncomfortable reading Evan's slides, maybe the title and maybe the quote that was in it. It just like spiked my heart rate in, um, in reacting to it. And I think, Evan, you clarified like, we're not directing this project at any particular race, but you don't mention explicitly races in the project, but like I know what you're trying to get at. And, I think Emma said, not everything that we can quantify should be quantified. I think in the same way, not every intersection of quantification and civics should necessarily be brought into the math classroom. Um, and I, I'm just, I'm trying to capture how uncomfortable I am right now, and I don't quite know why. Like, maybe I do know why and I can't articulate it. Um, but that's, that's where my emotional space is right now.

Min's disruption of the flow of the meeting to announce her affective experience – the bodily discomfort produced in learning about the lesson Evan shared – was, at this early phase of the group's work together, a potentially high-risk contribution. Yet, she was compelled to do so, perhaps because it felt safe to do so, or perhaps because she knew if this group was going to be a safe and productive space to continue critical work, she had to find out if it was a safe place to do so. At this moment, the emergent practice of treating affect as a legitimate component of participation was tested. Instead of rejecting it, pursuant responses cemented this as an enduring shared practice. Kyra, an ELA teacher, was the first to respond.

> I really appreciate that Min. I struggle with this, generally, but part of the reason why I really liked it is because if that isn't happening- I'm thinking about my students, if nobody is breaking down the math, that that actually happened- Maybe part of what I am feeling, in terms of what you brought up is that it was left open, right? When really, we're talking about Black people, like Brown and Black people. But I want my students to know how people who get on the news are saying that this is real based in math. Like, my kids don't know that. Like, I'm a hundred percent sure. So, I think for me, there is this question of, yeah, I don't want to do this work because it does seem there's something inhumane about it. And like with my Brown and Black students, if we're not doing that work, there's some students that are going to walk out thinking that the math is backing up what folks are saying. So, I wonder, I mean, I don't know, I think that that's a question then. Do we do it, do we not? I don't know.

Kyra started by appreciating what Min shared, implicitly affirming rather than rejecting the affective pause that Min had counseled of the group. She then returns to the question of the implied, but not explicit, racial identification of the groups of people in the original problem. She connects this to the importance of considering the identities of the students in the room when also considering the potential value and impact of engaging with this or other complex racialized statistics. Invoking her own Black and Brown students, Kyra asserts that they have the right to learn what's behind math, even if it might feel "inhumane" to explore such topics. Kyra's insistence on moving identity – here in terms of racial categories – from the sidelines into the foreground reflects the emerging practice of centering identity inquiry. Her concluding words leave unresolved questions open, respecting both voices already shared, garnering alternative perspectives from others, thus reflecting emergent practice of anti-hierarchical multi-vocality.

The conversation continued for just over 17 minutes; contributions were shared by six of the nine participants. Antero brought up discussions regarding what types of questions should be considered up for debate. Janice, another ELA teacher, raised the importance of learning more about traumatizing issues paired with potential opportunities for taking action. Evan added a comment about providing choice and "opt-out" possibilities for lessons on sensitive topics.

When Antero spoke again, he pointed to the importance of Min's original comment where she voiced her discomfort, "It could have been really easy for us to move past this conversation, I think, Min, if you hadn't voiced anything. So, trying to recognize that might have been uncomfortable to voice… I'm really grateful… Maybe we can also just check in and see how are you feeling with the nature of this conversation? Not closing it either, but just to check in." At this moment, Antero validates and lifts up the importance of Min's pausing the group. He positions what she did as generous and expresses sincere appreciation. He checks in with Min to see how she's feeling now, and finally, he leaves the conversation open to continue as needed, affirming multi-vocality alongside the importance of the inherently affective dimension of work that considers painful social issues such as anti-Black police violence. Min responds, "I'm glad I named it. I think the fact that we discussed it for a bit, um, I think I'm able to move on now and thanks folks for engaging in that."

Discussion & conclusions

The preliminary findings from analysis of learning as emergent practice in the TCLC over its first two years, with attention to a critical moment of tension, begin to jointly illuminate both what might be learned in such a critical and transdisciplinary teacher-researcher collaborative space and also how it is learned through talk and interaction in each moment, and over time. Ongoing analysis will attend to how emergent practice is both immanently negotiated and accumulates over time to thicken into cohering practices of the group as we contribute to questions of teacher political learning.

Supporting Framing Agency with the Wrong Theory Protocol in a Youth Radio Camp

Madalyn Wilson-Fetrow, University of New Mexico, mefetrow144@unm.edu
Vanessa Svihla, University of New Mexico, vsvihla@gmail.com
Sherry Hsi, BSCS Science Learning, shsi@bscs.org

Abstract: STEM instruction commonly constrains learners' agency as a means to focus attention to specific content. One consequence of this is much more research has investigated problem *solving*, rather than problem *framing*. This study investigated how learners negotiate framing agency—that is, making decisions about how to frame a design problem. Set in the context of a coding camp, learners worked with micro:bits and paper template my:Talkies to pose a community problem that could be solved via radio systems. Noticing their fixation, we guided learners through an ideation technique that prompts them to generate humiliating, harmful ideas before generating beneficial ideas, which resulted in divergent designs. Interaction and discourse analysis of video recordings highlights how learners (re)framed.

Introduction

A persistent challenge in the design of instruction is learner agency. Instruction necessarily constrains agency as a means to focus attention to specific concepts. Out-of-school settings provide an opportunity to engage learners in meaningful design, creative making, and disciplinary inquiry activities that can relax some of these constraints, shedding light on how learners negotiate agency. The goal of this research is to foster learner agency and creativity during engineering design and making activities by understanding the potential barriers to generating divergent ideas. Learners wrestle with framing and reframing design problems, in part because they have typically had few opportunities to engage these practices. Teachers and informal educators working need more strategies for facilitating generative design activities, especially in maker-oriented environments. While these environments afford a wide range of tools, materials, and possibilities, informal educators have limited guidance on facilitating problem framing processes. This paper shares an analysis of a creative engineering task in which informal educators and group of novice designers—learners in a summer STEM camp—negotiated agency while working individually and together on a problem in their community. We examine how an ideation technique supported framing agency, guided by a research question: How might an ideation technique of generating bad before beneficial ideas support learners to negotiate their agency to frame design problems?

Theoretical framework

While much research has investigated learning through *problem solving*, a key part of design comes before this, *problem framing*. Problem framing involves gathering information, including about/from stakeholders, the context and design requirements—providing abundant learning opportunities (Dorst & Cross, 2001). Problem framing is also dependent on the designer, who brings unique preferences and judgment to bear as they use what they learn to make decisions that bound the problem space (Dorst & Cross, 2001). The ability to make consequential decisions about the problem frame is termed framing agency (Svihla et al., 2021). Designers use their framing agency responsively as they consider how possible solutions meet design requirements. Thus, in addition to learning about the problem, novice designers learn how to direct their framing process. In order to shift between framing and solving a problem, designers typically generate ideas. Common techniques suggest designers should generate many ideas, yet this probabilistic argument has failed to find support in research, in part because of design fixation—inadvertent adherence to flawed solutions (Alipour et al., 2018). Because fixation creates a narrower problem space, it also limits learning. One method for overcoming fixation, the Wrong Theory Protocol (WTP), tasks designers with generating harmful and humiliating ideas prior to generating beneficial ideas (Svihla & Kachelmeier, 2022), resulting in empathetic and creative solutions.

Methodology

We report on one iteration of a design-based research (DBR) study (The Design-Based Research Collective, 2003) in a radio communication camp that positioned learners as designers capable of framing and solving a problem. Radio crafters camp is five-day, museum-hosted summer learning experience designed to introduce a socio-technical topic: radio frequency communication. They use BBC micro:bits (programmable microcontrollers (Austin et al., 2020)) to build a conceptual model of radio and use craft materials and papercraft templates (my:Talkies, (Yu et al., 2022)) to build a radio communication system model to solve a problem. The first activities introduced radio communications and the paper my:Talkies and an initial framing of the design problem—create a system of radio communications that serves a newly-developed neighborhood west of the city, with the constraint that their solution needed to communicate with another local radio system. We prompted learners to consider problems that could be solved by having access to radio communications (contacting friends, getting announcements for the community) and to identify a list of stakeholders (kids, police or fire departments, businesses, etc.). Following the steps of the Wrong Theory Protocol (Svihla & Kachelmeier, 2022), we prompted learners, as a group and documenting their ideas on a large sheet of butcher paper, to create "the worst ideas for community radio, actively harmful." Next, they individually imagined beneficial ideas, planning for what they wanted to design with the micro:bits and my:Talkies. The camp concluded informal design presentations.

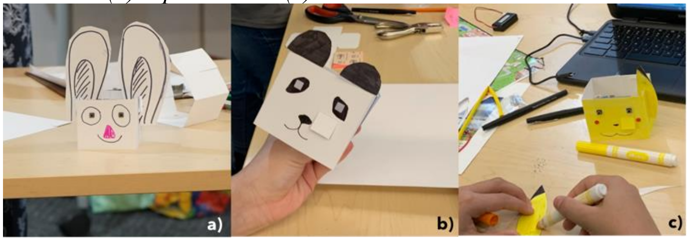
Two girls and four boys (ages 11 to 15) participated in the camp. Four identified as Hispanic/Latinx. Two reported some prior experience with block-based programming. Sessions lasted three hours over five contiguous days in a discovery-focused museum in the American Southwest. We collected short video and audio recordings from the camp, field notes, artifacts created by learners, and documentation from whole class discussions. We initially transcribed video and audio using Otter.ai, then corrected these, adding filler words, tone, and pauses. We used two analytic techniques to examine how learners used and distributed their agency. First, interaction analysis provided a way into the data (Jordan & Henderson, 1995), with particular attention to turn-taking, participation structures, and access to space and materials. We repeatedly discussed and reviewed data to test conjectures about fixation and problem framing. We used a discourse analytic approach to characterize agency in talk (Svihla et al., 2021), with particular focus on the subject and verb types in verbal clauses. In this way, "I" denotes individual agency; "we" denotes shared; third-person subjects denote attributed agency; modal verbs such as "going to" and "could" denote tentativeness characteristic of framing agency; and modal verbs such as "can't" and "have to" denote offloading of agency.

Results and discussion

In early pre-ideation activities, we saw evidence of fixation from the learners. One created a version of the Titanic (which was part of the initial framing of the camp about possible disasters of radio communication) while others mirrored the examples—a rabbit and a duck—creating Pikachu, a swamp monster, and a panda (Figure 1).

Figure 1

(a) Example of my:Talkie presented to the learners; designs subsequently made by learners: (b) a panda and (c) Pikachu

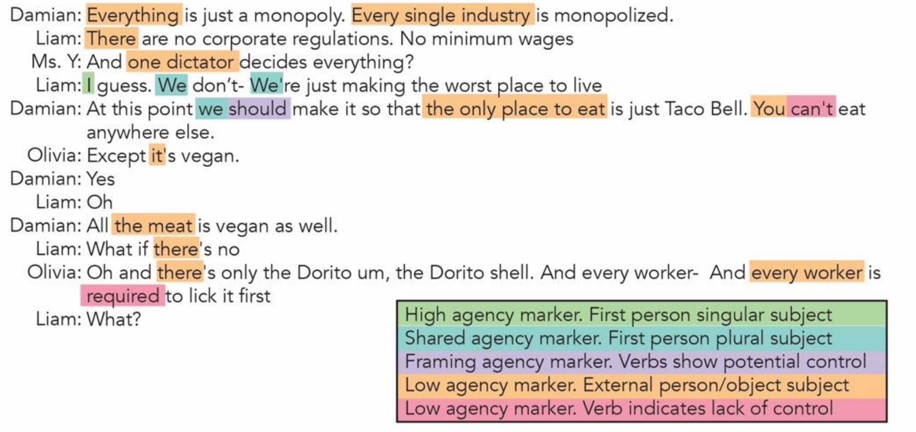


Thus, the learners seemed influenced by prior solutions, suggesting design fixation was at play and could limit the creative learning opportunities (Alipour et al., 2018) by limiting their framing agency. Responsive to indications of fixation, we implemented the Wrong Theory Protocol. We prompted learners to generate harmful and humiliating ideas related to the problem. Although the facilitators attempted to bring them back to the more specific problem space (radio communication), the learners framed the problem much more broadly as the "worst place to live," a framing that served as fertile ground for their problems and designing. After an initial period of tentativeness, one learner came up with the idea of faulty wiring causing electric shock and fire. They revisited the idea of fire throughout the whole session. At one point in the discussion, learners discussed a "nuclear football" (delivered to the president via faulty Amazon drone delivery) that would lead to nuclear holocaust, but decided there would be nothing left to harm nor humiliate, so they returned to fire again. As the learners developed more dystopian ideas on the large shared paper, they went back to scribble red marks over them to depict objects in the community, trees, and buildings catching on fire. This focus on fire is particularly important as during the camp, wildfires raged across the state, leading to smoke in the air.

Learners also drew on locally-salient societal issues. They considered ways Amazon could be used to facilitate specific harm, including delivering unwanted packages by drone and providing harmful working conditions, a local concern considering an Amazon distribution center had recently been built in the community they were designing for. Olivia suggested, "everyone has the same rights as an Amazon worker" and Liam showed his understanding of issues Amazon workers might face, adding "They don't ins—install toilets in houses anymore." Building on this, Damian and Liam discussed monopolies and removing regulations (Figure 2). In response, Ms. Y, a facilitator, suggested a dictator. However, Liam showed high individual agency over his evaluation that a dictator did not fit their dystopian vision, then shared agency with his peers over the framing. Damian then tentatively shared new direction—making Taco Bell "the only place to eat," and restricting envisioned community members' agency, a storyline picked up by his peers. This interaction illustrates how students drew upon their understandings of localized issues like wildfires and worker rights, using their agency to reject an idea as out of frame, before more playfully exploring a topic they may have suspected the facilitator would not be able to contribute to. In a classroom, such a shift in focus may have been discouraged or labeled "off task," but we interpret it in this context as a display of framing agency.

Figure 2

Vignette 1: Framing a harmful, humiliating design of an Amazon monopoly, determining that the idea of a dictator raised by the facilitator doesn't fit.



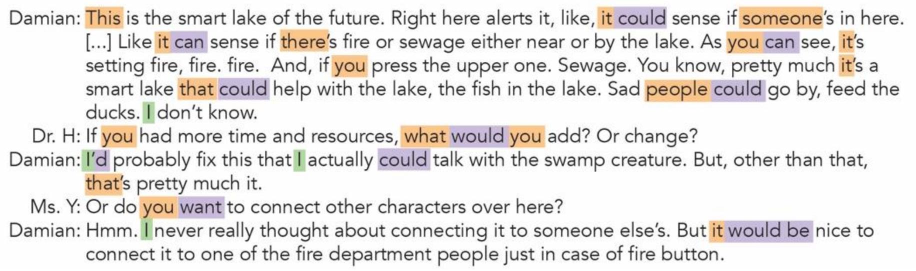
Damian: Everything is just a monopoly. Every single industry is monopolized.
Liam: There are no corporate regulations. No minimum wages
Ms. Y: And one dictator decides everything?
Liam: I guess. We don't- We're just making the worst place to live
Damian: At this point we should make it so that the only place to eat is just Taco Bell. You can't eat anywhere else.
Olivia: Except it's vegan.
Damian: Yes
Liam: Oh
Damian: All the meat is vegan as well.
Liam: What if there's no
Olivia: Oh and there's only the Dorito um, the Dorito shell. And every worker- And every worker is required to lick it first
Liam: What?

🟩 High agency marker. First person singular subject
🟦 Shared agency marker. First person plural subject
🟪 Framing agency marker. Verbs show potential control
🟧 Low agency marker. External person/object subject
🟥 Low agency marker. Verb indicates lack of control

After generating terrible ideas, learners generated ideas individually and developed these into their projects, which were diverse, empathetic solutions. Damian's smart lake showed empathy for community members' needs and varied uses of a lake. He emphasized the importance for privacy for someone who is unsheltered (and who had a need for bathing in the lake), respect for a family on an outing (who would be alerted if the lake was occupied), and solace for people who come to the lake to feed ducks when they are sad. The smart lake had the capability to take care of itself, monitoring sewage and the fish's home. Damian, in explaining his final project (Figure 3), demonstrated framing agency through his use of potential control verbs, like "could" and "would," demonstrating how he continued to consider possibilities. This reflects how designers treat their early solutions as tentative and as revealing much about the problem and whether needs have been met (Dorst & Cross, 2001). When a facilitator made a suggestion, he considered it but did not automatically take it up, indicating that while he was willing to take other ideas into account, he retained control over his design and the problem he had framed.

Figure 3

Damian retained framing agency as he considered possible changes

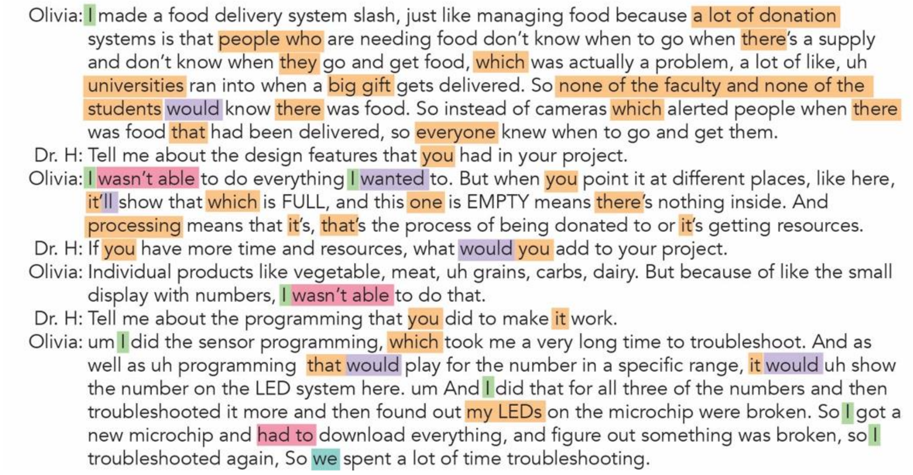


Damian: This is the smart lake of the future. Right here alerts it, like, it could sense if someone's in here. [...] Like it can sense if there's fire or sewage either near or by the lake. As you can see, it's setting fire, fire. fire. And, if you press the upper one. Sewage. You know, pretty much it's a smart lake that could help with the lake, the fish in the lake. Sad people could go by, feed the ducks. I don't know.
Dr. H: If you had more time and resources, what would you add? Or change?
Damian: I'd probably fix this that I actually could talk with the swamp creature. But, other than that, that's pretty much it.
Ms. Y: Or do you want to connect other characters over here?
Damian: Hmm. I never really thought about connecting it to someone else's. But it would be nice to connect it to one of the fire department people just in case of fire button.

Olivia created a system for alerting the community for needed food donations and availability of food for distribution. In describing it (Figure 4), she showed high individual agency over the problem, which she situated as an existing problem. When asked about design features, Oliva offloaded her agency, a shift that speaks to her disappointment in not fully delivering what she envisioned. Rather than suggesting she lacked framing agency here, we interpret this as an indication that she maintained a clear frame, but because of time spent troubleshooting, did not develop the solution she aimed to make. Concern about failure in ambitiously-framed problems can prompt educators to limit learner agency. Allowing learners to envision and tackle ambitious problems means being prepared to coach them through failures, positioning problems and learning as more important. Dr. H's response shifted attention away from what was not, to what Olivia accomplished—a positioning Olivia took up as she displayed high individual agency ("I did...").

Figure 4

Olivia showed high agency in describing her creation



Olivia: I made a food delivery system slash, just like managing food because a lot of donation systems is that people who are needing food don't know when to go when there's a supply and don't know when they go and get food, which was actually a problem, a lot of like, uh universities ran into when a big gift gets delivered. So none of the faculty and none of the students would know there was food. So instead of cameras which alerted people when there was food that had been delivered, so everyone knew when to go and get them.

Dr. H: Tell me about the design features that you had in your project.

Olivia: I wasn't able to do everything I wanted to. But when you point it at different places, like here, it'll show that which is FULL, and this one is EMPTY means there's nothing inside. And processing means that it's, that's the process of being donated to or it's getting resources.

Dr. H: If you have more time and resources, what would you add to your project.

Olivia: Individual products like vegetable, meat, uh grains, carbs, dairy. But because of like the small display with numbers, I wasn't able to do that.

Dr. H: Tell me about the programming that you did to make it work.

Olivia: um I did the sensor programming, which took me a very long time to troubleshoot. And as well as uh programming that would play for the number in a specific range, it would uh show the number on the LED system here. um And I did that for all three of the numbers and then troubleshooted it more and then found out my LEDs on the microchip were broken. So I got a new microchip and had to download everything, and figure out something was broken, so I troubleshooted again, So we spent a lot of time troubleshooting.

Conclusions and limitations

We find support for using WTP to mitigate the impacts of fixation and help learners use their agency to (re)frame problems—itself a learning process. WTP opened space for learners to draw upon their assets and understanding, sharing their awareness of everyday events and experiences, in turn shaping a broad problem space—far broader that the radio systems context that the facilitators envisioned. The learners' broad problem space served as fertile ground for them to frame diverse problems with empathy. When the facilitators tried to alter the scope, the learners displayed ownership over the problem space. We also identified examples of learners displaying framing agency as they reflected on their work, both as they treated their solutions as tentative.

Emotion and Emotion Regulation Matter: A Case Study on Teachers' Online Teaching Experience During COVID-19

Abstract: This study explored higher education instructors' emotional experience and regulation strategies as they shifted to online teaching during COVID-19. The purpose of this study is twofold: (a) to gain insight into teachers' perceptions of emotional experience in reacting to the transition from in-person teaching to online teaching during COVID-19, and (b) to investigate the strategies teacher adopted to regulate emotions when they teach remotely. Data for analysis involved in-depth semi-structured interviews. All interviewees were Canadian university instructors from a wide range of backgrounds. A deductive thematic analysis procedure and text mining technique were applied. Findings for (a): supportive relationships/good cooperation with colleagues promote teachers' positive appraisals; lacking connections with students/colleagues facilitates the feeling of isolation. And for (b): teachers applying reappraisal strategies in response to perceived challenges in online contexts enables them to manage negative emotional experiences. Implications for higher education in online contexts are further discussed.

Introduction

Due to the Pandemic, instructors in higher education were required to fast convert to online instruction, and these unprecedented changes may have elicited a range of emotional responses. It is not uncommon for teachers to report negative emotions such as frustration and anxiety in complex teaching tasks (Sutton, 2004). Emerging research examines the causes and consequences of teacher emotions (Donker et al., 2018); however, research on teachers' emotion regulation strategies in online contexts is relatively new.

Emotion regulation enables us to comprehend how people deliberately and unconsciously affect the strength, diversity, and duration of their emotions. The two most frequently studied emotion regulation strategies are cognitive reappraisal and expressive suppression (Gross & Thompson, 2007). Cognitive reappraisal interprets a potential emotion elicitor in a way that lessens the negative emotional impact, whereas expressive suppressive includes suppressing an emotional experience once it has been activated (Hagenauer & Volet, 2014). In high stake achievement situations, emotions can both help and hinder performance, therefore it is better to make efforts to regulate them. For example, teachers who perceived less control in achieving their instructional goal in the online context may experience negative emotions, which in returns, could impeded their instructional activities. However, if they appraise the tough situation differently, they might adapt to positive emotional experience as well.

This study is guided by the integrated model of emotion regulation in achievement situations (Harley et al., 2019) and seeks to answer the following question: what are teachers' emotional experience and how do they cope with negative emotions in response to challenges in online teaching during COVID-19?

Methods

Participant

The data are part of a larger study of teachers' online teaching experience in higher institutions during COVID-19. IRB was obtained and informed consent was obtained from all participants. Ten Canadian university teachers participated in the interview section. Among them, one case was tested for pilot study and it was not included in the further analysis. As shown in Table 1, the participants represented a cross-section of the subject areas (e.g., Engineering, Education, and Physiology) and various teaching experiences (1- 46 years).

Table 1
Interviewee Information

ID	Gender	Age Range	Domain	Teaching (Yrs)	Online Experience
2	Male	25-30	English	8	No

3	Female	45-50	Engineering	10	Yes
4	Female	30-35	Educational Policy	6	Yes
5	Female	25-30	Nutrition	1.5	Yes
6	Male	35-40	Educational Psychology	1	No
7	Male	60-65	Indigenous Teacher Education	42	Yes
8	Female	30-35	Educational Psychology	6	No
9	Female	35-40	Physiology, Biochemistry	15	Yes
10	Female	65-70	Educational Psychology	46	Yes

Interviews and data collection procedure

Ten semi-structured interviews were conducted remotely (Table 2). The interviews were audio-recorded and transcribed verbatim. Among the transcripts, nine use the language of English and one was conducted in French, according to the interviewees' preference. The second author interviewed the teacher in French and later translated the French interview transcript into English. Each transcript was assigned a unique code to ensure anonymity.

Table 2
Sample Interview Questions

Example questions	Example follow-up prompts
Have there been any particular changes to your course(s) with the transition to online courses?	Did you have to change the content, design, learning activities, assessment, …?
When you first learned that you might have to change something of your course, how did that go?	How would you describe your emotional state at that moment?
Could you briefly describe a specific challenging moment that you experienced in this online environment?	How did you respond to that?
How would you describe your comfort using technology for teaching and learning?	Would you say that you value a particular teaching and learning format more than another?
How has it been since? How do you feel about the way things are going now?	Can you tell me your feelings about teaching in remote instruction?
Did this experience change the way you do things or perhaps the way you plan on doing things in the future?	How did this experience change the way you do things? The way you think about online teaching?

Analysis

An in-depth qualitative analytic method was used to examine the participants' emotions and emotion regulation strategies related to online teaching experiences. Data analysis followed a deductive thematic analysis approach (Braun & Clarke, 2006) and a text mining technique to identify and interprete content relavant to the research question. In this case study, we adapted to Hagenauer and Volet (2014)'s qualitative analysis processes: initial coding of emotions, identifying emotion regulation strategies, and identifying themes.

The first and second researchers extracted text content containing relevant information about teachers' reported emotions. Teachers' emotions were divided into 'positive tone' and 'negative tone' (Hagenauer & Volet, 2014) and contained codes labelling distinct teacher emotions (e.g., stressful, angry, happy). This analysis step was undertaken using the software MAXQDA (version 20.4.1), which assists in data management and coding. Within minimum code overlapping rate of 90% at the segment level, two coders coded 20% of the emotions individually, and the coefficient kappa (Brennan & Prediger, 1981) of the interrater reliability reached 0.82.

To better understand teachers' both explicit and implicit negative emotions and how they cope with them, we applied text mining on the transcripts to identify and extract abscure negative expressions. Specifically, we used the meaning extratction method of the Linguistic Inquiry and Word Count (LIWC, Boyd et al., 2022) tool to locate relevant content by color coding words with negative tones from interviewees' transcripts. As a result, words with negative tones were identified two hundred and ninty-six times from the transcripts and we used these colorcoding scripts as a complmentary evidence to our emotion-related pool.

The next stage involved scrutinizing the adjacent segments within each emotion-related code. The answers to this question were first paraphrased from the interviewees' narratives and then brought to significant broader patterns of meaning (Braun & Clarke, 2006). The last stage of analysis involved identifying overall themes. The themes served as a reflection of the content of the entire data set. By delving into the situations where teachers' negative and positive emotions were mentioned, specifically teachers' appraisals related to achievement of instructional goals, we identified three general themes that are subsequently used to organize the findings.

Results

In the interview section, most interviees expressed more negative emotions than explicit positive ones while recalling their online teaching expereince. Particularly, they mentioned negative emotions in specific teaching situations (e.g., anger when students lack of engagement). Furthermore, they expressed more types of distinct emotions (e.g., stressful, scared). Specifically, one interviewee claimed that she found it easier to talk about specific emotional experiences through interviews than answering in the emotion scales. Additionally, three themes were identified in terms of teachers' emotional experience and coping strategies in online teaching: (a) supportive relationships/good cooperation promote teachers' positive appraisals; (b) lacking connections with students/colleagues facilitates the feeling of isolation; (c) applying cognitive reappraisal strategies in response to challenging moments enable teachers to manage negative emotional experience.

Table 3 extracts interpretation on concrete examples where teachers applied emotion regulation strategies. Regardless of teachers' teaching experience and domain, most of them reported negative feelings (e.g., panic, traumatic) when the Pandemic hit and expressed negative emotions (e.g., exhausted, nervous) towards challenging moments in online teaching. Besides, teachers' positive experiences were also reported when good connections were built with students:"Through that individual feedback, I noticed that we started to develop like individual dialogues, individual conversations, you know. So I was very surprised that at the end, like how connected I was with the students, although I had never seen them in person" (I6).

One frequently mentioned challenge that leads to teachers' negative emotional experience is the lack of connections with students and colleagues. One interviewee described challenging situations where students do not engage in the instructional activity: "I feel like it's very impersonal, like you are not connecting with the students" (I5). Another interviewee mentioned: "I feel less effective like you need to connect with students, it's so much harder to have it happen over like a screen rather than like in person...Because they can't really see my body gestures and all those things that go into like communication are kind of blocked in a way" (I4). Besides challenges in teacher-student interaction, lacking cooperation with colleagues can also lead to feelings of isolation. For example, the virtual class makes teaching more "independent" and "like I was in less collaboration which is essential to be a real person." (I2). Fortunately, we also received positive responses from teachers that they were able to manage these negative emotions. For instance, one interviewee positively appraised the situation in facing and overcoming this challenging moment as a precious story to tell in the future. Besides, some lower their expectancy and attribute teaching outcomes to other causes, thus drawing attention away from their emotionals.

Table 3
Extract of Types of Emotions and Emotion Regulation Strategies

Tone	Emotion Code	Sample Transcript	Paraphrase	Interpretation	Emotion Regulation
Positive	Appreciative	*Like I really (think) the pandemic has just kind of made me think, what makes me appreciate my life a lot, and in the teaching. I thought it's actually a really cool way to have one to have an excuse to do things a bit differently and to really think about teaching and assessing.*	Teachers manage to think of the positive side of the transition to online teaching.	Thinking positively towards the change and take the transitioning of teaching and assessing as a good opportunity to learn and think in a new and better way.	Cognitive Reappraisal
Negative	Angry	*I feel angry when students don't engage or have the cameras off. But like we do have to keep in mind that everybody in their home...You can be living with 50 other people, exaggerating, but*	Teachers view from the students' perspective and think of possible explanations that might lead to their	Standing from the students' side, understanding that they had their camera off for some personal reasons	Cognitive Reappraisal

	all other people in the background moving around... Those things like they cannot unmute and, you know, and have the cameras all at the same time just be distracting.	less engagement and camera off are able to manage their anger.	and forgive their lack of engagement in learning.

Discussion and conclusion

This study support previous research that continuous dialogue in a community benefits online learning environment (Regan et al., 2012). Furthermore, good cooperation with colleagues allows teachers to perceive more control of online instruction activities which resulted in more positive emotions. Supportive relationships may lead to teachers' valuing the situation more as their opinions are accepted and supported. On the contrary, lacking connection with students and colleagues leads to teachers' negative emotional experience. This finding is partially aligned with previous studies indicating that teachers' emotions, to some extent, depend on the relationship teachers build with their students (Hagenauer & Volet, 2014). Additionally, instructors successfully coped with negative emotions by reevaluating the situations that could potentially lead to undesirable emotions. This finding reveals that this group of teachers practice cognitive reappraisal strategies that appear to be more effective than expressive suppression (Gross & Thompson, 2007). Examples of the interviews revealed that cognitive reappraisal allowed them to handle unpleasant experiences, to think more neutrally, and arguably more positively to continue moving forward in their day-to-day work.

To conclude, the study provides empirical evidence for the need to address teacher emotions and emotion regulation in remote teaching/learning settings. The identified themes have implications for teacher education to help teachers understand and manage their emotions in online teaching. Supportive relationships and good cooperation are proved important and teacher community initiatives could be developed to help teachers share encountered emotional experiences and instructional concerns. These initiatives could also include cognitive reappraisal emotion-regulated strategy workshops for online teaching settings to maintain positive emotions. This study also replies to the call for empirical studies on emotions that highlight the importance of field studies and qualitative data. It delves into teachers' emotional experiences, including those expressly mentioned (explicit) and those implied (implicit) during in-depth descriptions of lived experiences. The study also investigates how teachers manage their negative emotions in online teaching contexts. It is one of the few papers that focus on teachers' emotions in online settings, particularly in response to the COVID-19 pandemic.

Curriculum as Seed: Designing and Supporting the Use of Open Education Resources to Promote Teacher Agency and Innovation

Mon-Lin Monica Ko, Arturo Cortez, William R. Penuel
monlink.ko@colorado.edu, arturo.cortez@colorado.edu, william.penuel@colorado.edu
University of Colorado Boulder

Abstract: As open education resources (OERs) continue to proliferate, teachers will likely utilize these freely available resources to design and enact disciplinary instruction. While OERs have transformative potential in shaping classroom instruction, their open-access and availability also introduces new questions about how teachers will learn to take up and utilize these curriculum materials. In this conceptual paper, we build on a metaphor introduced in the field of human-computer interaction to reconceptualize the relationships among OERs, teachers, students, and the local context. We expand on how this new metaphor foregrounds aspects of curriculum use that have been backgrounded in previous conceptual frameworks, including the timescale and evolution of curriculum use, teacher creativity and agency, and the role of educational systems in shaping curriculum use.

Curricula as tool for education reform

Designing and disseminating high-quality curricula has historically been a main vehicle for supporting large-scale reforms to transform mathematics and science learning in K-12 classrooms (Stein & Kim, 2009). While curricula such as NextGen Storylines and OpenSciEd (OSE, 2022) are examples of such an effort within science education, there are also other disciplines, including Artificial Intelligence (AI) education, that are taking similar approaches to curriculum development. Curriculum materials can be a key lever for supporting disciplinary learning because they serve as boundary objects between reform initiatives (e.g., NRC Framework, NGSS) and the design of classroom instruction (Penuel et al., 2011). The tasks, tools, and representations that constitute the curriculum communicate what aspects of the discipline are worthy of pursuit in the classroom, as well as (potentially) new visions of teaching and learning (Sherin et al., 2004). Teachers play a pivotal role in bringing these curriculum materials to life by using their actions, ideas and experiences in ways that transform the written curriculum into the enacted curriculum (Ball & Cohen, 1996).

Open education resources (OERs) are materials that can be freely shared and, with many licenses, freely adapted. As they become more prevalent in the educational landscape, there are new opportunities and challenges for using materials as resources for supporting disciplinary instruction. For example, OERs remove financial burden as a barrier to accessing high quality materials. However, materials tend to represent a specific approach to disciplinary instruction and cannot be designed to meet the needs and interests of all students across various education settings. In addition, many embody visions for teaching and learning that may be unfamiliar to many educators. Thus, teachers will need to engage in professional learning experiences that help highlight the principles underlying these materials to enact them in sustainable and responsive ways within their classrooms. Teachers, curriculum materials, students, and local contexts must be considered together for curriculum materials to become a lever for both teacher and student learning (Short & Hirsh, 2020).

Our conjecture is that the proliferation of OER resources opens up new opportunities to engage with different metaphors that can help us transform the relationships among teachers, students, curriculum materials, and the contexts in which they are enacted. One prominent conceptual model in both science and mathematics education foregrounds different orientations of teachers with respect to how they engage with curriculum materials (Remillard, 2005). Remillard's framework outlines the knowledge that teachers and curriculum materials bring and how these forms of knowledge interact to transform the designed curriculum into the planned and then enacted curriculum. In this framework, the students and contexts are seen as inputs that shape the enacted curriculum (see Figure 3, Remillard, 2005). New metaphors are needed, both in the age of OERs and given what we know about curriculum adoption and sustainable change to practice of teaching. First, teachers orient in different ways to and learn from curricula in different ways, and their use of curriculum materials is varied and dynamic (Arias et al., 2016). While curriculum designers have been increasingly and intentionally embedding educative features (Davis & Krajcik, 2005) to support teacher learning in the context of curriculum use, attending to all these features each time curriculum is used is unfeasible. Supporting teachers' use of educative features must be supported intentionally through professional learning, and yet, we seldom acknowledge that this process takes time, as teachers utilize and become more familiar with the materials themselves. One would expect that the relationship between the teacher and curriculum would shift over time, as each additional use is an opportunity to better understand how the teacher can leverage their knowledge and experience and attend to different curricular features when enacting the curriculum materials.

Second, existing frameworks do not provide guidelines or account for how teachers might become more agentive in their use of the curriculum materials over time. Current forms of professional learning around the use of OER materials largely focus on guiding teachers through a curriculum storyline, although recent efforts have shifted to emphasizing local adaptations that explicitly address the lived experiences of students. Understanding how teachers make sense of the design principles that undergird curriculum materials and learn to make principled adaptations (DeBarger et al., 2013) in alignment with these principles is a timely and critical issue to take up within the learning sciences community.

Finally, current frameworks do not sufficiently account for the role of contexts in shaping curriculum use. Teachers make sense of curriculum materials through (and not in the absence of) the lens of the policies, practices, and instructional routines that are at work in their teaching contexts (Allen & Heredia, 2020). Moreover, students' sensemaking of the curriculum is shaped by the experiences they build within their community. Decades of learning sciences research suggests that disciplinary instruction ought to leverage and build on these robust and localized experiences for disciplinary learning to be meaningful (Barab & Luehmann, 2003). In other words, local contexts are not just backdrop in which curricula are enacted; they should inform the design of the curriculum if they are to be used in responsive and locally relevant ways (Buxton, 2010). For these reasons, the field needs new metaphors to help us rethink the ways in which teachers, students, curriculum materials and the local context work together to create new opportunities for expansive disciplinary instruction.

A new metaphor: Curriculum as seed

We draw on Fischer's work (Fischer et al., 2002; Fischer 2007; 2011) from the field of Human-Computer Interaction and propose *curriculum as seed* as a new metaphor for the relationship between teachers, curricula, students, and the local instructional context (see Table 1). We draw on literature from HCI because of its focus on generating novel technological tools that can expand the potential for human functioning and learning (Bannon, 2011). In contrast to the grammar of schooling that typically frames the curricular tools as static objects that are handed to teachers to use, HCI scholarship acknowledges that design problems in the real world require designing for open systems that end users inevitably modify and adapt to fit their needs (Fischer, 2007, 2011). The *curriculum as seed* metaphor similarly acknowledges the open-ended nature of the design space; curriculum materials are viewed as starting points (*seeds*) for greater innovation that materializes through the hands of teachers and students. Seeds, unlike germ cells, have a specific potentiality when they are cultivated in conditions that allow them to thrive. They also hold specific trajectories for adaptations, based on its survivability in various environmental conditions. For example, large seed size is advantageous for growth under low light conditions, but, due to their weight, large seeds cannot be borne on small plants (Linkies et al., 2010). Likewise, curriculum materials embody the collective inheritance (e.g. design principles, approach to teaching and learning) that were brought forth in their creation, and yet their survivability and thriving depends on the ways in which these materials are taken up by teachers and students' to address the needs and goals of the local environment. Teachers are local users who drive its growth and evolution because they have the agency, ownership, and knowledge that is needed to deliberately restructure, enhance, and "remix" the starting materials in ways that best address the needs and interest of their students. The *curriculum as seed* metaphor challenges the notion of teachers as enactors and conduits through which curricula get "delivered" into the classroom. Rather, teachers are seen as the innovators and designers, drawing on their knowledge of their instructional contexts, their students, and their funds of knowledge in ways that can enrich and transform the materials and the design of disciplinary instruction (Brown, 2002). This view of the teacher is directly related to the emerging scholarship around teachers as co-designers, and the value of co-design as a valuable space for expansive learning (see Ko et al., 2022).

Table 1
Curriculum as Static Object vs. Curriculum as Seed

Curriculum as Static Object	Curriculum as Seed
Curriculum designers have all the knowledge	Teachers have the knowledge and agency to creatively adapt curricula
Curriculum materials are over-designed to include all possible supports for teachers and students at the outset	Curriculum materials are under-designed, and become well cultivated seeds that evolve into a localized version of the curriculum that is

	realized in the hands of teachers and students
Curriculum use remains more or less the same over time	Curriculum use is dynamic and continuously evolves in response to the local context
Curriculum enactment is evaluated based on alignment with original intent	Curriculum enactment is used to deliberately restructure and enhance existing curricula
Teachers use curriculum "as intended" by designers	Teachers are informed participants who actively contribute to the evolution and creation of new curricular designs
Initial curriculum = intended curriculum	Initial curriculum = starting point for building new sociotechnical infrastructure within the school and/or district

What does this new metaphor enable?

Fischer expands on the *curriculum as seed* metaphor by describing the process of design and redesign as *seeding, evolutionary growth,* and *reseeding* (SER). *Seeding* comprises a largely planned set of activities, such as developing tasks, identifying phenomena, and embedding instructional routines into a unit. From an Indigenous perspective, seeding also involves collecting, growing, and sharing seeds to promote cultural diversity for future generations (Native American Food Sovereignty Alliance, 2022). The initial seed then undergoes *evolutionary growth*. During this phase, designs are treated as open systems that users can tweak, adapt, and play with. Depending on their effectiveness in supporting student learning, adaptations may lead to more permanent deliberate modifications and enhancements to the original materials – leading to a *reseeding* of new materials. To us, SER reflects a more expansive conceptualization of curriculum design and use. Curriculum materials are positioned in the larger context of instructional systems and *expected* to evolve in response to the needs and desires of that system. This conceptualization also blurs the boundary between the practice of design and the use of the curriculum materials. Instead of packaging materials to include all possible supports, curricula are intentionally open systems that teachers are expected to modify (and not "adhere to" or enact "with fidelity"). It also leaves room for – and explicitly encourages – customization and transformation.

One might push back on the "idealistic" vision of curricular uptake and innovation that are implied by this metaphor, arguing that "lethal mutations" (Brown & Campione, 1996) will result when teachers are left to their own devices. We respond to this by arguing that a corollary of the *curriculum as seed* metaphor is that new forms of professional learning are required to support teachers in this complex, long-term endeavor. We need professional learning opportunities that support principled improvisation (rather than fidelity of implementation approaches) to promoting teacher learning. Teachers cannot engage with a "one size fits all" professional development (PD) in which they are walked through the curricular sequence and expected to adhere to the curriculum as a script. Instead, we draw on prior scholarship to conceptualize teachers' curriculum use as one that requires *principled improvisation* (e.g. Philips, 2019). This metaphor creates new demands for teaching: teachers can make principled adaptations to curriculum materials (and other technological innovations) only when they understand its underlying architecture and the principles that undergird the design of lessons and the arc of the unit (Frank & Zhao, 2003). Moreover, different approaches to PD may be needed, depending on one's familiarity with the innovation being introduced (Frank et al., 2011). Teacher educators and PL designers will need to design opportunities to make the purpose and curricular structure visible and invite teachers to adapt the curriculum materials in ways that align with and address the needs of their local context (Penuel et al., 2009). What counts as "curriculum" is not just the initial seed, but instead encompasses the sociotechnical infrastructures that arise to support the design and use of the modified curriculum. The resulting curricular innovation and evolution is evidence that the seed has been taken up, cultivated, and carefully nurtured.

Supporting High School Science Teachers in Developing Pedagogical Content Knowledge for Data Literacy

Katherine Miller, Susan Yoon
kmiller@gse.upenn.edu, yoonsa@upenn.edu
University of Pennsylvania

Abstract: As the world becomes increasingly awash in data, there is a growing need for greater focus on data literacy at the K-12 education level. Since high school teachers are often trained in one specific subject, they need additional support to teach data literacy as an integrated STEM topic. In addition to providing subject matter knowledge of data literacy, this support must focus on pedagogical content knowledge (PCK) which connects the content to the pedagogy for teaching it. As there is a major dearth of research on PCK for data literacy this study seeks to apply existing strategies and design mechanisms that can support teachers in developing their PCK to the subject of data literacy to better understand how a new conception of PCK can be surfaced and understood.

Introduction

While the field of data science has expanded over the last few decades to address the explosion of data and the way it permeates so many aspects of life, K-12 education has not yet caught up, resulting in strong calls for greater focus on data literacy at all levels (e.g., Wolff et al., 2016). As the need for data literacy grows, the way we seek to teach students to interact with data also needs to change to promote a broader relationship with data that prepares students for working with the big, messy data sets that imbue research, industry, and society (Kjelvik & Schultheis, 2019; Lee & Wilkerson, 2018). Teachers need additional support to develop knowledge and tools for integrating that type of data into their classrooms, including both subject matter knowledge about data and knowledge about how to teach with it (Lee & Wilkerson, 2018). Pedagogical content knowledge (PCK) encompasses the professional knowledge that teachers hold about how to teach particular topics to particular groups of students (Shulman, 1987). While research on PCK for data literacy is mostly lacking, research on PCK for STEM integration has shown that in order to successfully integrate STEM learning in their classrooms, teachers need to understand how students learn and apply ideas in topic-integrated contexts and be able to ground the varied STEM concepts in the learning context and prior knowledge of their students (Vossen et al., 2020). This suggests that pedagogical strategies for data literacy implementation, are unique from teachers' existing PCK for the subject they teach. Therefore, any professional development (PD) that seeks to improve teachers' data literacy implementation should explicitly teach and model these strategies (Aydin-Gunbatar et al., 2020). However, the lack of research on PCK for data literacy makes it difficult to determine how to support teachers in developing it. As such, this project explores how to support teachers in developing their understanding of PCK for data literacy. Through a semester-long workshop with four in-service high school science teachers aimed specifically at examining their PCK for data literacy, this study asks, how did the components of the PD workshop support teachers' surfacing and development of PCK for data literacy?

Background

Data literacy is an emerging concept without a clear definition, and the overlap between data science, data literacy, computational literacy, and statistical literacy is still nebulous (Wolff et al., 2016). In an attempt to distinguish data literacy from some of the other fields, Kjelvik and Schultheis (2019) chose to define data literacy as existing in the overlap between quantitative reasoning and data science where data is grounded in an authentic context. This framework is useful in outlining some of the important components of data literacy, namely that it involves applying mathematical principles, working with computers and other technologies, and understanding the context of the data. The need to ground data literacy in real-world contexts and focus on *using* data rather than simply analyzing it is a common component across data literacy research (Rubin, 2020; Wolff, et al., 2016). However, authentic real-world data is often complex, messy, and unlike most of the data typically used in secondary school classrooms and teachers haven't always been taught how to engage with this data or the pedagogical strategy that is required to teach it (Kjelvik & Schultheis, 2019).

In order to engage teachers with pedagogical practices specific to teaching with and about data, we applied the framework of PCK to better support teachers' knowledge and learning. PCK is a distinct form of knowledge separate from subject matter knowledge (Gess-Newsome et al., 2019; Vossen, 2020). In the case of data literacy, the subject matter knowledge needed in the development of PCK draws from multiple disciplines across science, statistics, and technology. For this project, the subject matter focus included a knowledge of the context of data, the role and purpose of data visualizations, and how to build inferences from data (Rubin, 2020). While most teachers have extensive PCK for subjects they received training in and have experience teaching, considering data literacy as explicit subject matter rather than a tool for teaching math or science is often new to teachers and they may need to develop additional PCK for data literacy in order to enact it successfully in the classroom. While PCK can develop through experience alone, studies have shown that PCK development can be guided and enhanced through PD that aligns with teachers' learning needs and goals (Aydin-Gunbatar et al., 2020; Gess-Newsome et al., 2019). However, there has been little to no empirical research published on PD specifically for developing knowledge for teaching data literacy. The theoretical research on potential strategies for teaching data literacy (e.g., Lee & Wilkerson, 2018) have been developed without engaging teachers with those strategies during PD. As such, this study relied on a method shown to develop PCK within PD interventions (e.g., Loughran et al., 2012) and applied those strategies to the development of knowledge for teaching with and about data.

Methods

This research engaged in an early-stage or exploratory study in which the goal was to examine how the knowledge teachers held about teaching for data literacy could be surfaced and developed.

Designing for PCK development

The intervention relied on a common method for engaging teachers in building and refining their PCK: Content Representations (CoRes, e.g., Loughran et al., 2012). CoRes were originally developed by Loughran and colleagues (2012) as a way to guide teachers to think about their practice in creating PCK around a particular big idea. A CoRe is a template which prompts a teacher or group of teachers to think about teaching a particular subject through big ideas with questions such as: *Why is it important for students to know this? What else do you know about this idea that you do not intend students to know yet? What is your knowledge of students' thinking which influences your teaching of this idea?* Loughran and colleagues (2012) found that CoRes could be used to develop PCK by enabling teachers to make their practice, and their thinking on their practice visible in a way that allowed them to then reflect on that knowledge. While teachers often struggle to construct big ideas for a subject and answer the questions in a CoRe individually, when building knowledge collaboratively they have more success (Aydin-Gunbatar et al., 2020). Using a CoRe as an artifact allows teachers to develop a shared language around the content knowledge and the PCK for teaching a particular topic (Loughran et al., 2012).

Context and participants

This study took place within the larger context of an intervention designed to support teachers in implementing a STEM-integrated unit on bioinformatics in their existing secondary school science classrooms (Yoon et al., 2022). An extension workshop was conducted with a subgroup of four teachers in which participants met virtually for about 20 hours over the course of five months while implementing the bioinformatics unit in their own classrooms. The workshop sessions relied on a number of different strategies, including explicit discussion of PCK, implementation discussions, and review of data literacy content components. During the workshop, four CoRes (and framing for a fifth) were discussed. The four participants all taught in the same large urban school district in the northeastern U.S. Three of the teachers (Hallie, Will, Manisha) had over ten years of teaching experience, while the fourth (Mary) was only in her second year in a formal classroom but possessed over 15 years of experience teaching informal science education. Two of the teachers (Hallie & Manisha) were teaching biology, two were teaching environmental science (Manisha & Will), and one (Anna) was teaching agriculture.

Data sources and analysis

The data for this paper came from transcripts of the workshop sessions and post intervention interviews. The nine sessions of the extension workshop series were conducted over Zoom and each session was recorded using Zoom's built in recording feature. A total of 15 hours, 20 minutes of video was captured and transcribed. Additionally, at the end of the workshop series, a semi-structured interview was conducted with each participant. The interviews asked teachers about teaching data literacy (e.g., *In your view, is data literacy important to teach in a science class, why or why not?*) as well as asking them to reflect on the components of the workshop series and how they affected their knowledge and learning (e.g., *What parts of the workshop series did you find most supportive of your growth as a teacher?*) The interviews ranged in length from 40 minutes to 58 minutes with an average length of 49 minutes and a total time of 3 hours and 19 minutes.

The transcripts of the workshops and interviews were organized in Delve Tool, a qualitative data analysis software and a constant comparative analysis (Glaser, 2008) was conducted to generate themes related to participants' perceptions of the intervention and its design components.

Findings

While the larger project that this paper is a part of focused on understanding what the components of PCK for data literacy are (Miller, 2022), this paper focuses on the process by which they were developed. The most valuable and tangible shift in teachers' PCK was simply becoming more aware of the knowledge they already held and being able to articulate it in a way that made it easier to apply to their implementation. To that end, the primary theme from the design of the workshop is that the CoRes, and especially the development of big ideas provided a successful framework for surfacing and organizing PCK for data literacy.

The CoRes served as a framework that allowed space for reflection. All four participants thought the CoRes were a useful component of the workshop series. They primarily reflected in their interviews about how the CoRe Template provided them a specific framework that allowed for more nuanced and focused reflection. Hallie and Will both reflected during their interviews about the usefulness of the conversations engaged around the CoRes. Hallie spoke to how being forced to articulate her own thinking to fit into the framework of the CoRe led to deeper thinking for her. She said in her interview, "So, I'll say just the brainstorming around what to do and how to do a thing because it's a lot easier for me to think deeply about a thing when I'm trying to express it to someone else than it is when I'm just trying to turn it around in my own head." Similarly, Will focused in his interview on how listening to other people articulate their thoughts in response to the CoRe framework was useful for him, reflecting during his interview, "I was more looking at what the other teachers were talking about. Seeing what other teachers were focusing on and what they knew opened my eyes: oh, I hadn't thought of it that way. So that was very beneficial to change my thinking in how I was going to present this." In this reflection, Will was talking about how the discussions around the CoRes and the ideas that the other teachers came up with and the knowledge they surfaced helped him to grow his own knowledge. They opened his eyes to new concepts and new strategies that he hoped to employ in his own classroom going forward.

While the CoRe template was useful for guiding discussions and reflections on teaching with and about data to be more focused and nuanced, perhaps the most useful part of completing the CoRes was identifying the big ideas for data literacy. Teachers were not used to thinking about data literacy as subject matter that needed to be explicitly taught rather than as a tool to be used to teach other concepts in science. There was extended time in the workshop sessions for discussing and identifying big ideas before building each CoRe, yet it was often still not enough. Simply coming up with big ideas that were appropriately specific but also appropriately generalized was a challenge for the teachers but a challenge that led to a lot of growth and recognition and articulation and refinement of knowledge that the teachers already held. One example of this is in attempting to develop big ideas for the concept of data in context, teachers landed on a big idea of interest: *interrogating data is useful and necessary*. The identification and refinement of this big idea led to the surfacing of PCK in that teachers then connected this to what they knew about how students' perceive data and strategies for teaching it. Specifically, they identified that students are not used to questioning data, and that therefore students would need to be explicitly taught how to interrogate data through tools such as employing text analysis to data representations.

The teachers came up with many more big ideas than they ended up focusing on in the CoRes they built, however having the CoRe as a framework allowed them to decide which of the big ideas were the most important or salient. So, while the brainstorming process for the big ideas was a crucial piece of surfacing knowledge about teaching data literacy, the CoRes allowed the participants to focus on specific big ideas and connect those to knowledge about students' understanding and specific teaching strategies, important components of PCK.

Discussion and implications

While the exploratory nature of this study did not allow for an exploration of the extent to which teachers developed additional PCK as a result of this intervention, it was clear that they became more aware of the concept of PCK and more inclined to reflect on their practice within the PCK framework. Engaging in development of big ideas for data literacy and subsequent completion of CoRes for those big ideas supported teachers in developing a better sense of the strategies they were using, language to describe them, and tools to reflect on them more productively. Unpacking the components of data literacy in order to determine the big ideas led teachers to, if not increase their subject matter knowledge of data literacy, certainly approach it with a different perspective. This supports previous research that shows CoRe development can support teachers' knowledge growth (e.g., Aydin-Gunbatar et al., 2020) However, most previous studies were conducted within disciplines that had well established big ideas and frameworks for PCK. The field of data literacy does not have that. So, while one implication of this research is to suggest that these tools continued to be used to help teachers develop knowledge and confidence for teaching data literacy, another implication is that the field needs to engage further with teacher knowledge for teaching data literacy. As Hallie reflected in her interview it would be nice if teachers had an established set of knowledge about students' preconceptions for data and teaching strategies to engage those preconceptions, but the field is not there yet, partly because there has been so little research conducted on teacher knowledge.

The use of CoRes in PD can guide teachers towards best practices for using authentic complex data in their classroom, but first a set of best practices needs to be established so that teachers can be supported in using those best practices to teach data literacy. Previous research has found that teachers often lack the content knowledge to engage in integrated STEM activities such as the use of complex authentic data (e.g., Aydin-Gunbatar et al., 2020) and this study supports that research. However, the larger struggle for the teachers in this study was not the subject matter knowledge of data literacy but the strategies for how to teach it. While the teachers already had knowledge of strategies for teaching science and engaging with data in the context of a science class and were able to reframe that knowledge in a way that applied to data literacy, most of them still felt at the end of the intervention that they were in need of additional support to grow their strategies for teaching with and about data.

"TERFs are a Thing. And I F*cking Hate Them": Developing Solidarity Through Emotion and Ideology

Dylan Paré, University of Calgary, dylan.pare@ucalgary.ca

Abstract: In this paper, I investigate gender marginalization and the desire for belonging from similar (non-binary) and divergent (misgendered male versus female) experiences. The study occurs within an immersive virtual reality experience designed to deepen understanding of gender and sexuality-based marginalization. My analysis extends Sara Ahmed's queer phenomenological concept of orientations, bringing it into conversation with learning sciences theories of ideological stance-taking and emotional configurations. I highlight moments of emotional-ideological sense-making where learners reflexively negotiate between themselves and marginalized people and engage in *reorientations* that support new kinds of solidarity for participants. An analysis of the interaction between the narrator's story, Clare, and the researcher reveals how differences in experiences of marginalization, despite a shared identity, can produce divergent emotional configurations and ideological stances. Further, the analysis shows that interactions with the VR experience and the researcher supported the development of shared ideological stances and emotional-ideological *reorientations* toward solidarity.

Introduction

In this paper, I investigate gender marginalization and the desire for belonging from similar (non-binary) and divergent (misgendered male versus female) experiences of non-binary people. I use the term non-binary when referring to the identities of the participant, researcher, and VR narrator. I also use the term trans (short for transgender) as an umbrella term that includes non-binary people. Trans is defined as having a current gender that is different from the gender assigned at birth.

This study occurs within an immersive virtual reality (VR) experience designed to deepen understanding of gender and sexuality-based marginalization in science, technology, engineering, and math (Paré et al., 2021). The VR narrative features a nonbinary but societally-assumed female, queer individual's emergent and cumulative experiences of exclusion and marginalization. The purpose of this paper is to offer a close analysis of the learning processes and outcomes of an interaction between the participant, the researcher and a section of the story told by the VR narrator that highlight a moment where differences in experiences of marginalization, despite a shared identity, can produce divergent emotional configurations and ideological stances.

I draw attention to how experiences of identity difference go beyond the categorical and are deeply rooted in the phenomenological, where who we are is not simply what we call ourselves, such as "non-binary." Rather, our identities are embodied life histories that are always in the process of becoming (Paré et al., 2019). Our identities shape how we experience ourselves, how others see us, and how we are allowed to extend ourselves into spaces (Ahmed, 2006). I argue that reorienting ourselves toward the marginalized other involves emotional-ideological sense-making processes where learners reflexively negotiate between themselves and the marginalized person. This paper highlights how equity and justice-seeking work in the learning sciences can be strengthened by attending to critical, queer phenomenologies of being and becoming and *reorienting* processes toward solidarity and care.

Rising fascism and trans-antagonistic politics

Access to women-only spaces is a complex political issue. Women's spaces are typically created to address the barriers women face to accessing men-dominated spaces in learning and careers. However, they have intentionally and unintentionally excluded trans and non-binary people who experience gender marginalization and could benefit from similar support. The issue has been further politicized by explicitly trans-exclusionary radical feminists (TERFs), who expressly argue for excluding trans people, especially trans women, from women-only spaces. In the past decade, TERFs have acquired global media attention through highly visible TERFs such as the well-known British author of the Harry Potter series, J.K. Rowling and British-Australian theorist Sheila Jeffreys (Bassi & Lafleur, 2022).

Bassi and Lafleur (2022) draw upon Traverso's (2019) description of postfascism to explain the connections between the current cultural moment of neoliberal individualism, enduring fascist discourse, and trans-exclusionary ideologies. For example, trans-antagonism is propagated through the fascist and neoliberal concern with women's safety and the constructed, transphobic discourse that "transgender identities allegedly offer an excuse for 'predators' to infiltrate women's spaces" (2022, p. 315). Bassi and Lafleur (2022) explain that in these discourses, trans women are portrayed within neoliberal individualizing frames as an "example of individual behavior that is perverted and deviant" (p. 315). Conversely, cisgender women are portrayed in neoliberal discourse "as an ontological state whose normativity derives from its putative naturalness" (Bassi & Lafleur, 2022, p. 315). Bassi and Lafleur (2022) connect this to the similarly framed ideologies of Fascist Italy, where fearmongering about women's proper roles was used to pressure women to "conform to state-sanctioned femininities deemed natural, chiefly that of the fascist housewife and mother" (p. 315).

Trans and non-binary people's access to supportive learning environments that address all forms of gender marginalization is a critical issue in education (Keenan, 2022). In the United States, 200 anti-LGBT bills were introduced in the first five months of 2022, with many of the bills aiming to limit transgender students' access to educational facilities and activities (Mangin et al., 2022). Rhetoric in support of these bills takes the form of what Elster (2022) terms "insidious concern" that is centred on the "moral policing of the reproductive order" (p. 416). Elster (2022) juxtaposes the concern shown for children generally, who "often symbolically represent heteronormativity, the family, and whiteness" while "actually existing trans children are simultaneously configured as imperilled subjects requiring protection and dangerous actors in need of regulation" (p. 412).

Research questions & methods

I researched the following question: How do the reorienting experiences in the VR experience allow for new kinds of solidarity for the participants?

The VR experience was designed by myself and my team at Queer Code (queercode.org). See our design-focused paper for further details about the VR application design (Paré et al., 2021). This ethics-approved study was conducted over Zoom for 1-2 hours, in which seven participants (recruited via social media) were interviewed while they played the VR experience and shared their game screen and included a pre and post interview. The only inclusion criterion was that people have VR systems because people who are new to VR can become distracted by the novelty of VR. Participants self-selected based on interest in participating in a study on learning about gender and sexuality in VR. I present the case of Clare (pseudonym), a non-binary person in the United States who is in their early fifties and is misgendered by society as male. Like the VR narrator, the facilitating researcher is a non-binary person misgendered by society as female. Although all three share a marginalized identity as non-binary, how society misgenders each person differently significantly affects their sense of belonging in learning spaces that are not inclusive of non-binary people. I chose this case because a close analysis of the interaction between the narrator's story, Clare, and the researcher reveals how differences in experiences of marginalization, despite a shared identity, can produce divergent emotional configurations and ideological stances. I recorded and transcribed videos and identified emergent themes further refined through my theoretical focus on identifying occurrences involving reasoning about gender and sexuality through ideological stance-taking and emotional configurations.

For my analysis, I extend Ahmed's (2006) queer phenomenological concept of orientations with complementary learning sciences theories of ideological stance-taking, where "every stance exists in a triangular relationship among the stance taker, the object that is being evaluated, and other subjects" (Philip et al., 2018, p. 196), and emotional configurations, the "situated and reciprocal interrelationships between feeling, conceptual sense-making, and practice (including linguistic practice) that give emotion social meaning (Vea, 2020, p. 315). I highlight moments of emotional-ideological sense-making where learners reflexively negotiate between themselves and marginalized people and engage in *reorientations*–meaning recognizing and resisting normative enforcements of docility and reorienting toward counter-hegemonic and non-normative actions and people (Ahmed, 2006; Paré, 2022; 2021) that support new kinds of solidarity for participants. In particular, the case study in this paper demonstrates a form of solidarity between trans people, called trans care (Malatino, 2020), in which transgender people show up for one another when socio-political systems fail.

Findings

I present an illustrative case of Clare's reflection upon the narrator's story of seeking to belong to a women's coding group. Clare initially struggles with the narrator's reluctance to access a women-only space because Clare desires this access to feminine friendship and belonging but is denied because they are misgendered as male.

> **Turn 1 Researcher:** So how did that last story kind of sit with you?
> **Turn 2 Clare:** Is it possible to die of wistfulness? … Like, It's kind of relatable in a certain way, except like it's, so like, my experience is so different because. The person who's narrating the experience, it's like clearly, is someone that people would tend to code as female. Right? [**Researcher:** Yeah]

In turn 1, I asked Clare about their reaction to the story because I had noticed Clare both agreeing during the story, saying "Yeah," but also in some parts saying that it was not like their experience as someone seen by others as a cisgender man. I also interpreted Clare's heavy sighs as a sign that this story was emotionally difficult for them. In turn 2, Clare explains their sense of difference by checking with me about the narrator's identity as societally "coded" or misgendered as female, which I confirm.

> **Turn 3 Clare:** That's how they would be clocked. And, umm, you know, [sigh] maybe it's just my own projecting or something, but I've long thought that that would be easier. You know? So it's like, I felt empathetic for what they were going through. But at the same time, there is a part of me that was like, "Wow, you're so lucky that people see you as female so that you can just be in those spaces." And like I find, I tend to find women-dominated spaces more supportive and safe. So like. [sigh] I can see how it would be difficult for them, but it seems like it would be easier that way than the opposite. Which is sort of more my scenario.
> [**Researcher:** Right.] [**Clare:** Yeah]
> **Turn 4 Researcher:** Yeah, that makes sense from your own perspective. You're in this position of like, how can you take for granted? The narrator, how can you take for granted that you have access to these supportive spaces? When you're like, you want that, you know, that's where you'd like to be.
> [**Clare:** Right.] [**Researcher:** Yeah, that's really understandable.]

In turn 3, Clare expresses that while they felt empathetic for the narrator's experience, their ideological stance was that they thought it would be easier to be societally seen as a woman, even if one is non-binary. Clare explains that they believe, based on their experience, that women-dominated spaces are more supportive and safe. In turn 4, I hesitated before answering because my own experience as a non-binary person who is misgendered as a woman (like the narrator) informed my ideological stance that neither men-dominant nor women-dominant spaces are more safe or supportive. Despite my disagreeing, I wanted to stay with Clare's experience because I recognized that while my experience was represented in the narrator's story, Clare's experience of marginalization was not represented and needed to be heard. I affirm Clare's experience by reflecting aloud on how Clare might feel upon hearing how the narrator can access the spaces that Clare is denied. I empathize with Clare's desire to belong and frustration with the narrator when they seem to take this access for granted.

> **Turn 5 Clare:** But at the same time, I know that it's not perfect, right? I mean, like TERFs are a thing. [**Researcher:** Yeah.]
> **Clare:** And I fucking hate them. [**Researcher:** Yeah.]
> **Clare:** You know, and it's like. [big sigh] So it's pretty easy to imagine by analogy. Somebody being like, OK, either they're assuming things about this person that are not true and that could hurt, or if they sort of came out and were like, "Hey, I'm nonbinary," then I can imagine some people having the reaction like, "Oh, well, this is a space for "real" women." And then it would be like, "Well, fuck you, then," you know?
> [**Researcher:** Right Yeah.]

In turn 5, Clare then reasons about the socio-political systems that fail us as non-binary people. They draw upon their socio-political knowledge of TERFs (trans-exclusionary radical feminists) and how society fails non-binary people by propagating or allowing the propagation of gender essentialist beliefs about "real women." Clare's emotional configuration toward the narrator shifts from "wistfulness" for the narrator having access to something Clare does not toward a redirected anger at TERFs for making women-only spaces exclude gender-marginalized, non-binary people.

Clare thus reorients toward a shared experience with the narrator and researcher by leveraging this ideological-emotional stance against TERFs as a resource to establish this shared experience with the narrator of being excluded from women's spaces by gender essentialist beliefs and trans-antagonist actions. Despite their initial emotional disconnection with the narrator's experience, Clare reorientates toward a new kind of solidarity that does not rely on a shared interpretation of women's spaces as safer. Clare ultimately demonstrates trans care (Malatino, 2020), a kind of preservative love, where the commitment to showing up requires acknowledging how socio-political systems fail us and how "recurrent, habitual, and mundane" trans care work is integral to our survival (p. 70).

Summary and discussion

Reorienting ourselves towards a marginalized person's experience involves emotional-ideological sense-making processes where learners reflexively negotiate between themselves and the marginalized person. A phenomenology of reorientation can support analyzing solidarity as a *turning* or *reorienting* process (Ahmed, 2006; Paré, 2022; 2021) that supports new kinds of solidarity for participants. This reorientation toward the marginalized other involves negotiating emotional configurations (Vea, 2020) and ideological stance-taking (Philip et al., 2018) with the marginalized person (or VR narrator). Further, identifying how reorienting processes occur between marginalized people with different marginalizing life experiences demonstrates how solidarity is an accomplished interaction, not a state of being, even among those with shared marginalized identities.

The participant, facilitator-researcher, and narrator share a socio-political experience as non-binary/trans people threatened by the global rise of fascist ideologies and the intertwined trans-antagonistic discourse and action. The growing threat to trans survival informs the facilitator's reorientation toward Clare's experiences of marginalization and need to be heard. It also informed and reoriented Clare's ideological stance-taking from a focus on difference to a shared struggle against gender essentialist ideology and toward the shared emotional configuration expressed in their statement, "TERFs are a thing. And I fucking hate them," to which the researcher agreed. This analysis highlights how trans people show up for one another by acknowledging how socio-political systems fail us and how "recurrent, habitual, and mundane" trans care work is integral to our survival (Malatino, 2020, p. 70). I believe that this preliminary analysis demonstrates how equity and justice-seeking work in the learning sciences could be advanced with further empirical analysis using a phenomenology of *reorientations* to analyze how solidarity is achieved in social interactions and how emotion and ideology coordinate sense-making toward these reorientations. This case could also inform how educational researchers and practitioners might practice care for their trans colleagues and students by becoming informed of political contexts of trans-antagonism, creating space for hearing diverse trans experiences, and affirming and supporting trans people.

Abstract: In this paper, we investigated the activity systems in two contrasting upper-elementary classrooms and drew on analyses of discourse between teachers, researchers, and students during an AI curriculum intervention. We examined the role teachers' practices played in setting the stage for classroom discussions and interaction. Despite the teachers appropriating different components of the same curriculum depending on their teaching strategies and classroom cultures, to attain the learning objectives, pre- and post-assessment results revealed that both teaching approaches led to similar student learning outcomes indicating that there are multiple ways to teach a pre-designed curriculum.

Introduction

AI education has begun to gain prominence in K-12 education (DeLyser & Born, 2021). However, there is little work exploring how classroom interactions influence students' understanding of AI concepts. Our project explores approaches to AI education along with the development of PrimaryAI, a curriculum for upper elementary-aged students (Glazewski et al., 2022). The curriculum has multiple resources, activities, and discussion prompts to foster classroom interactions. Differences in how teachers use these tools and resources can lead to varying forms of classroom engagement (Hmelo-Silver et al., 2015), which raises the question of the impact that these different enactments may have on student learning depending on how the curriculum resources are used to mediate learning. We provide a comparative case study between two classrooms where the teachers taught the same unit of the AI curriculum regarding teaching practices, mediators and tools, and learning outcomes. We observed how depending on teacher practices and classroom cultures, the same lesson from a unit in the curriculum was delivered in a different manner and yet yielded similar student learning outcomes.

Method

Our team collaborated with two teachers in the Midwest to design an AI curriculum to introduce AI learning experiences into their upper-elementary classrooms, 35 4th graders and 27 5th graders. The pre-and post-tests were administered at the beginning and end of each unit respectively. Implementation of Unit 1(computer vision), Unit 2(machine learning), and Unit 3(AI planning) were completed in both classrooms over three weeks.
This study investigates two primary questions:

1. What is the impact of different teacher practices on discourse and students' understanding of AI concepts?
2. What are teachers' perceptions of the AI curriculum, and what is the relationship between these perceptions and teacher practice?

Theoretical framework: Activity theory

Activity theory (AT) was used to understand the role of the teacher's instructional strategies aligning with the idea that learning always occurs in social and cultural contexts (Levinson et al., 2000). Our focus was to understand how the teachers use different resources as mediators to facilitate learning. Viewing the two classrooms as complex activity systems, our goal was to compare these two systems to explore how learning was mediated in these two contexts and to understand its impact on student learning outcomes. Activity theory offers a conceptual framework for studying human behavior and provides a framework for conceptualizing different social interactions, materials, resources, and norms that enable and constrain what individuals and a collective group can accomplish (Leont'ev, 1978). The six core components of an activity system include subject, object, mediating artifacts or tools, rules, community, and division of labor (Engestrom, 1987). In this study, we compared the two activity systems that represented the different entities and interactions in the two classrooms.

Data sources and analysis

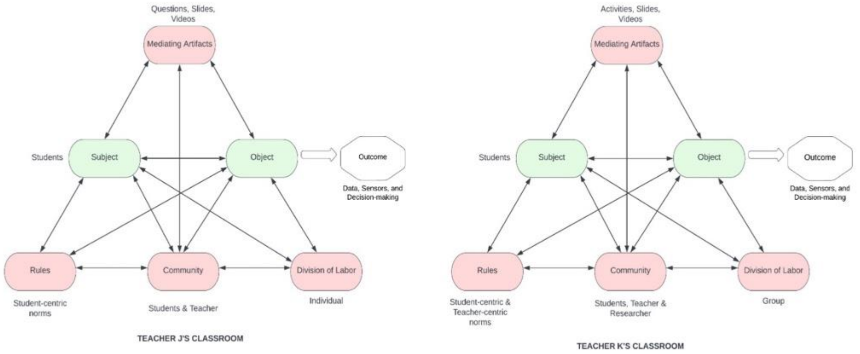
To understand the student interaction, discourse, and teacher role in the two classrooms, we examined a total of 8 hours of video data from both classrooms. Field notes were also used for analyzing classroom interactions and teachers' pedagogical practices. To evaluate student learning gains in both classes in this study, we calculated descriptive and within-group inferential statistics. We applied mixed methods to analyze the pre-and post-test data quantitatively and analyze representative clips from the video data qualitatively. For the video data, we conducted a moment-by-moment analysis to investigate the discourse during the learning process, mainly focusing on teacher-student and teacher-researcher-student interactions. To further understand the teachers' mediating and discourse practices, we attempted to gather their perspectives through semi-structured interviews. We qualitatively analyzed the data inspired by thematic analysis to find evidence relevant to understand the teachers' strengths and how they leveraged them to mediate classroom interactions and appropriate the curriculum.

Results

Activity system comparison

We analyzed the classroom videos and our field notes from two classrooms and observed that they varied in context, classroom culture, and the role of the teacher, leading to different student interactions and discourse. Both teachers taught the same lesson: data, sensors, and decision-making from Unit. However, they differed greatly with respect to the way they introduced the concepts and engaged with the curriculum resources and materials. This had a subsequent impact on classroom dynamics including the different teacher-student and student-student interactions. We compare the two activity systems representing the classrooms for similarities and differences as shown in Figure 1. We summarize the classroom interactions between teachers and students in these two activity systems, by each component, where the teachers taught a lesson from Unit 1(Computer Vision), which was designed with the objective that the students will leave with the idea that "humans use data to see or create an informed decision, and computers also behave similarly when it comes to gathering data through different sensors to make decisions."

Figure 1
Activity System Comparison



<u>Mediating artifacts</u>

The key mediator that Teacher J used to her strength was the leading questions from the curriculum that she posed to encourage student interactions and discourse. A moment-by-moment analysis showed how students interacted with the teacher and engaged with the content through conversations. The first question she posed was: "*How does a computer learn?*" A few open-ended student responses that were based on their prior knowledge included "*maybe a human teaches it," "some program," "maybe it is programmed to do that," "it has a thing inside it that allows it to change the program and learn new things."* These responses revealed that although the students did not have a clear understanding of how computers learn, they knew that there was some training involved –*" a human teaches," "some program"* and that it is a continuous process– "*allows it to change."* Teacher J summarized these responses and introduced a new concept "*computers learn using data..*" She talked about the different types of data and presented examples on slides to help students visualize these different types. She first introduced the new concept and then used the slides from the curriculum resources to further build on it. By weaving multiple student responses and the content from the curriculum, she gradually built their understanding of each new concept that was introduced.

She did not feel comfortable with a lot of the activities and curriculum resources due to her lack of familiarity with the content. In her interview, she talked about how she did not understand how to facilitate learning through many of the activities in the curriculum because she was not convinced about the concepts that they were meant to address as she was not a content matter expert, and the activities did not have enough guidance for novice AI teachers:

"Again, sometimes I think I wasn't able to explain AI very well. So maybe if the teacher did have a little more guidance. When we started getting to examples of what is AI or what is not AI, sometimes I wasn't sure if they were or not. We aren't experts on it. When you are trying to explain or teach it, a little more scaffolding "

Instead, she leveraged her strength of leading classroom discussions and facilitated learning by eliciting student answers to the questions and then introducing the new concepts after gauging their level of understanding at that moment. She guided student thinking by asking these questions and modeled how to critically think about AI concepts.

Teacher K, on the other hand, used classroom activities, curriculum resources, and the researcher on-site's assistance as the main mediators to facilitate learning. She introduced a couple of AI concepts together using the slides, and instead of asking questions from the curriculum resources, she relied on classroom activities to help students get involved with the content. These concepts included “*AI computers learn and make decisions,”* “*They learn through data,*” and *“How computers get data, let's think about how animals and humans get data.”* After introducing three new concepts she posed her first question to the class, “*how do they get this data?*” She got a few responses like “*books,” “google,”* and “*other adults.*” She acknowledged these responses, but instead of building on them, she moved on to an activity to delve deeper into how humans use their senses to get data: "*We're going to play a game, with make-belief scenarios to help us think about how humans get data. Once we see how humans get data, we can see how computer scientists mimic these processes in computers. The best ideas come from nature. We are going to create groups for this activity.”*

She was comparatively more comfortable using the curriculum resources like the videos and activities to facilitate learning. There are two factors emerging from her feedback interview that can be attributed to this: One, for activities that had underlying AI concepts she was not too confident about, she used the researcher-on-site’s help to clarify the area of confusion:

> “This is the part where we had to ask her (the researcher) a lot of questions and she had to study and answer them”

Two, she was more comfortable depending on the videos and the activities because she wasn’t the only one talking, and sources of information were distributed, and this helped when she was not too confident about her AI knowledge:

“I loved the little bits of information because me being you know..a little uncomfortable with it but also it's not me talking the whole time..I learned something new as well”

We observed how Teacher K introduced new concepts from the curriculum, and instead of having conversations about these concepts, she engaged the students in activities to further understand these new concepts by leveraging her strength in science teaching.

Community

In Teacher J’s classroom, the community members included the students and the teachers. However, in Teacher K’s classroom, there was an additional member, a researcher from the curriculum development team who assisted the teacher with resources, co-teaching AI concepts, and answering student questions.

Rules and division of labor

Teacher J’s classroom was more teacher-centric where the conversations were mostly initiated by the teacher and the interactions were between the teacher and the individual students. There was not much student-student interaction unless the classroom activity required them to work together.

In Teacher K’s classroom, there were more classroom interactions between the students. Even when they were engaged in a discussion, we observed students building on each other’s answers, agreeing with or disagreeing with each other’s responses. It was more student-centric and the teacher encouraged students to express their freedom with how they decided to take part in an activity. Students walked around and enacted the scenario from the activity in their groups.

Learning outcomes

We analyzed the pre-and post-test scores quantitively. There was an overall increase in the average scores in the post-tests across both classrooms in comparison to the pre-tests. Paired t-test scores for all the comparisons for two out of three of the constructs were statistically significant ($p<0.001$). Cohen's *d* values for the first two content areas were >1.0 across both classrooms indicating a large size effect with no differences between the classrooms.

Discussion and conclusion

Teachers' instructional strategies and practices play a critical role in helping students engage in conversation and build an understanding of the content being taught. Our results support the notion that the same curriculum with the same set of resources and materials can be taught in different ways depending on an individual teacher's teaching practices and strengths. Although the PrimaryAI curriculum had multiple resources, activities, videos, and discussion questions, our findings revealed that while one teacher relied more on the discussion questions and slides as resources to mediate learning, the other used more of the activities and the videos to do so. The presence of an onsite researcher who had content matter expertise in the second classroom (Teacher K), helped her leverage curriculum resources that addressed AI concepts she wasn't too sure of. While Teacher J in the first classroom did not have this support, she used her years of teaching expertise to her strength and used guiding questions to mediate learning. The interaction in this classroom was almost always initiated by the teacher, but it was not didactic. Instead, it was more inquiry-based, helping the students to think critically about the AI concepts one at a time. Pre- and post-test results revealed that there was a considerable gain in students' understanding of AI concepts across both classrooms, indicating that there are multiple ways to teach a pre-designed curriculum. The two teachers leveraged their strengths to ensure that the outcome was met. Activity theory, with its emphasis on mediation, provided a useful lens for identifying what these strengths were and how the classrooms were viewed as complex systems. Contrasting classroom cultures could be visualized with the help of the framework and let us identify the different social and cultural interactions that took place between the teachers and the students. Teacher interviews helped us recognize ways in which we can refine the curriculum by adding support for the teachers and provided us with their perspectives on how they and the students interacted with the curriculum. The curriculum offered multiple resources, activities, discussion questions, and additional material to teach each AI concept that was introduced which provided the teachers with the choice of working with whatever they were comfortable with and best suited their teaching styles. Unfamiliarity with the content led to both teachers not feeling confident about explaining many of these concepts.

Both teachers in this study discussed challenges with the content matter they had to deliver highlighting the need to prepare teachers through professional development courses. Further future research should explore how to build teachers' capacity and capabilities for AI education, which includes pedagogical knowledge and understanding of AI and AI ethics. Future efforts could also be directed towards understanding how these strategies to support teachers with AI knowledge can influence teachers' outcomes such as confidence and motivation, and hence impact student engagement and learning outcomes. This program highlighted teachers' experiences and challenges while teaching an AI curriculum providing researchers with the opportunity to develop teacher development programs to address these challenges and improve the curriculum.

Improving Technology- Enhanced Immersive Learning With Design-Based Implementation Research

Eileen McGivney, Harvard Graduate School of Education, eileen_mcgivney@g.harvard.edu

Abstract: While research on learning with immersive virtual reality (VR) to date has primarily focused on technology-focused or media comparison experiments, the field of learning sciences increasingly calls for research that accounts for classroom constraints to better translate findings to practice and instructional design. This paper describes the benefit of design-based implementation research (DBIR) as a method for studying immersive learning technologies and a work-in-progress study of VR that employed DBIR to illustrate its application. The process surfaced learning outcomes and instructional methods that would have been difficult to find in a lab experiment, including the benefit of knowledge-building discourse for students' development of curious dispositions about scientists' work.

Introduction

The field of learning sciences increasingly recognizes the value of research accounting for implementation in education systems to better impact policy and practice and advance our understanding of learning. For example, McKenney (2018) invited more research focused on collaboration between research and practice, attending to issues of implementation to better impact learning at scale. Learning scientists have pointed to design-based implementation research (DBIR) as a fruitful method to advance research and practice (Yoon & van Aalst, 2017). Such methods may be particularly useful for technology-enabled interventions with transformative aims to be effective and usable in education systems at scale (Fishman et al., 2004).

Despite this call for research that centers collaboration and implementation, learning with immersive virtual reality (VR) is most often studied in laboratory experiments leading with questions about the technology rather than problems of educational practice. Reviews point to the prevalence of hardware-focused (Jensen & Konradsen, 2018) or media-comparison studies (Mayer et al., 2022), comparing VR to another device or value added by a specific feature. Many of these studies are conducted in laboratory experiments, and those conducted in classrooms are often in response to a brief experience (Markowitz et al., 2018) or unrelated to the curriculum (Petersen et al., 2022). Much research on VR has been conducted with state-of-the-art technologies to understand people's behavior in these environments, not as learning tools (Bailenson, 2018; Slater & Sanchez-Vives, 2016). While this research points to important issues of VR learning design to account for issues like cognitive load and avatar choices, their translation into classroom practice is a challenge. Questions that remain include the impact of the technology as its novelty wanes, appropriate instructional designs incorporating VR in lessons, assessing learning outcomes beyond content knowledge gains, and navigating constraints such as limited internet connectivity, time, and space. DBIR offers a useful framework to study learning with VR in authentic contexts and can be implemented systematically, what can be referred to as "state of the actual" (Southgate, 2020) or "state of practice" research (McKenney, 2018). This paper describes DBIR as a research method, its applicability for improving research on VR in authentic educational environments, and describes a study that is currently in progress to illustrate the benefits of conducting DBIR on technology-enhanced immersive learning.

Theoretical background

DBIR has four guiding principles, described in Table 1 (Fishman et al., 2013; Research + Practice Collaboratory, n.d.). These principles describe a collaborative research process to address problems of practice, design studies around classroom constraints, iterate implementation of interventions, and build capacity. In VR research, such approaches have not yet been widely used to study its impact on learning: most studies identify technology-focused research questions rather than problems of practice and focus on isolating causality with controlled experiments outside of classrooms. Using DBIR can benefit the study of immersive learning technologies by focusing on instructional designs that illuminate effective implementation and provide a better understanding of their impact on student learning in an authentic context.

A DBIR study of learning with VR

To illustrate the applicability of DBIR to VR learning research, this paper describes a work-in-progress study of VR field trips in two high school engineering classes and preliminary findings about students' learning that guided implementation. The study was conducted in 2021-22 at an urban public charter high school in the greater Boston area serving primarily low-income and minority students. Participants were 30 (5 female) 11th and 12th grade students from two engineering classes. 28 students were second-generation American, and one first-generation, primarily from Latin American and Caribbean countries.

Table 1
DBIR Principles and Applicability for Immersive Learning Technology Research

DBIR Principle	Description	Benefit for immersive learning technologies	Differences from typical VR learning research
Deciding on a focus for joint work	Teams form around a focus on persistent problems of practice from multiple stakeholders' perspectives.	Immersive learning interventions are developed within a curricular framework to address the needs of educators, making them more usable and useful in classrooms.	Focus on meaningful learning experiences rather than features of the technology.
Organizing the design process	To improve practice, teams commit to iterative, collaborative design.	Research findings include optimal instructional designs for immersive technologies by iterating their implementation, making the interventions more effective and scalable.	Research design adapts to the constraints of schools and classrooms, resulting in interventions in addition to evidence on learning with VR.
Doing research in DBIR	As a strategy for promoting quality in the research and development process, teams develop theory related to both classroom learning and implementation through systematic inquiry.	Research attends to questions of implementation, individual learning, and opens areas of inquiry valuable for classrooms including group dynamics and collaborative learning.	Research informs design but does not drive it. Findings provide thick description and insight into mechanisms in authentic environments.
Developing capacity for continuous improvement	Design-based implementation research is concerned with developing capacity for sustaining change in systems.	Educators and students get sustained exposure to technologies and develop modes of implementation.	Control of the technology given to educators and students.

The VR field trips addressed a challenge identified by the teacher and aligned to NGSS engineering standards: students struggle to identify and articulate problems engineering could solve in open-ended tasks. By exploring virtual environments and observing scientists working in extreme conditions, students could practice problem-finding and improve their ability to write problem statements, the first step in engineering design. The primary research questions were how the VR experiences engendered students' sense of agency (control over their learning) and presence (feeling of "being there" in the environment), and how their problem statements varied over time or by type of VR used. Students used Quest headsets over 4 lessons, two with 360-degree videos (filmed footage of the environment and people), and two interactive graphical applications (videogame-like environments to move and interact with objects). Two lessons were on Antarctica and two the International Space Station (ISS). Figure 1 depicts the VR applications and implementation. Students took a pre-survey one month before the first lesson and post-surveys after each VR application (measuring sense of agency, presence, and intrinsic motivation), and 8 students were interviewed. To assess learning, students wrote engineering problem statements about the VR experience. Class discussions and field notes were recorded.

Figure 1
Left: VR Applications (Clockwise from top left: National Geographic Explore, Mission:ISS, Space Explorers, Polar Obsession). Right: Students using interactive environment (left) and immersive video (right)

Lessons used a "plan, act, reflect" experiential learning model (Dede et al., 2017): students completed a pre-work activity, used the VR application, then participated in written reflections or discussions before writing problem statements. We iterated the lesson plan after the first lesson was rushed and students struggled to make meaning of what they had seen and learned. Figure 2 illustrates how students largely did not write statements (e.g. “I don’t know”), wrote about problems with the technology (e.g. vision difficulties), or wrote what the narrator had told them about the environment (e.g. climate change is impacting Antarctica). To address this, lessons 2-4 spread activities across multiple lessons and added small group discussions to scaffold student meaning-making before the assessment. Figure 2 illustrates how these discussions shifted the focus of students’ problem statements: in lessons 2 and 3 they focused on problems the people face (e.g. difficulties working on the ISS) which had been the focus of the discussions. Following lesson 4 many students wrote technology-focused statements, likely because the teacher also led a concluding discussion to reflect on the four VR experiences.

Deciding on a focus for joint work

The focus of the lessons and the research design were developed collaboratively by the author and the educator through their shared interest and multiyear partnership. This required designing a series of lessons that addressed the problem of practice the teacher faced (supporting students in writing problem statements) and the research questions that interested the researcher (how interactivity and embodiment in VR affect student experience and learning). The collaboration around dual goals led to several decisions that differed from controlled experiment designs, especially the need for all lessons to be experienced equally and for each VR application to provide a meaningful learning experience. Rather than restrict experiences of a control group, we varied the order in which they used immersive video or interactive applications, allowing for comparisons in response to varied interactivity and addressing space constraints, as only half of students in a class period needed space to move in VR (see Figure 1). To ensure VR was used in a meaningful way we used high-quality 360-videos rather than isolating interactivity in VR by giving some students a recording of an interactive application (e.g. Johnson-Glenberg et al., 2021). The result was the development of meaningful learning experiences with two different types of media, as well as a holistic understanding of students’ resultant learning and subjective experiences.

Organizing an iterative, collaborative design process

Implementing the lessons required flexibility from the teacher and researcher to make changes to the lesson plan and timing, rather than adhering to an inflexible controlled design. The most significant iteration came after lesson 1, when we saw in practice how the lesson did not address students’ need for more time and discourse to make sense of the VR experiences. We observed that students were eager to discuss what they saw and did in VR with their peers, but written reflections did not capitalize on this enthusiasm. When given the opportunity to participate in a facilitated small group discussion, they articulated more problems related to the scientists who work in these environments. The result was lessons that maximized learning and were practical for classroom implementation. This also revealed how the discussions can make concepts more salient for students, as the varied focus from lessons 2 and 3 (challenges facing scientists) to the final discussion (reflecting on VR) revealed.

Figure 2

Content of students’ problem statements by lesson

Doing research in DBIR

The iterative design process highlighted benefits for research on VR to understand group dynamics and assessment. The study intended to use students’ problem statements to assess learning outcomes. However, after recognizing students’ struggles to write the statements, using small group discussions as reflective activities provided a rich source of data on how students learned with the VR in ways not demonstrated on the assessment. While this analysis is ongoing, preliminary findings suggest students developed curious dispositions about what it means to do science and be a scientist. This suggests learning with VR is better understood as a collaborative exercise in meaning-making aligned with a knowledge-building framework (Scardamalia & Bereiter, 2005), than an individual endeavor. The compromises made by being flexible and suiting the intervention to learning rather than maintaining a controlled experiment therefore provided fruitful insights about how VR field trips can engender a rich learning experience, particularly when peer collaboration is engaged.

Developing capacity for continuous improvement

Conducting DBIR in classrooms required giving control of the technology to the teacher and students. While its novelty waned as students used the technology over time, their mastery increased. With each lesson, the students more easily set up and put away the equipment, navigated to the applications, and operated the controllers. In interviews and discussions, they shared critiques for how VR experiences could be improved. The teacher gained an understanding of VR's affordances and applications that would be valuable in his classroom. This points to the ways doing research in classrooms with teachers and students can help build their capacity to improve the implementation of emerging technology in education.

Discussion

While this study illustrates the benefits of using DBIR for studies of learning with VR, it also has several limitations. Future research should investigate longer-term implementations with multiple iteration cycles and capacity building such as training teachers to create and school-wide integration. The flexible and iterative process provided holistic description of student learning with immersive technology, but limits claims about causality and generalizability to other media or populations. However, collaborating with an educator to use VR to tackle a persistent problem of practice and answer the author's research questions about how young people learn with VR over time led to a set of lessons using VR field trips that are meaningful and feasible in classrooms, as well as research findings that would have been difficult to uncover in a more controlled experiment. Pivoting from individual written work to knowledge-building discourse revealed students' curious dispositions about what it means to do science, a learning outcome not captured on the individual assessments. The iterative collaboration also helped highlight the ways VR field trips need to be scaffolded to support student learning.

Gamebooks for Environmental Education: Designing for Content and Pedagogy

Jonathan Halls, Shaaron Ainsworth
Jonathan.halls2@nottingham.ac.uk, Shaaron.ainsworth@nottingham.ac.uk
School of Education, University of Nottingham

Abstract: The goal of this project is to design gamebook-based lessons, which include an interactive gamebook (a non-linear, branching narrative) and supporting dialogic lessons, to increase children's (7- to 11-years-old) engagement in pro-environmental behaviours. A design-based research approach was used to optimize the design, focusing on both the content of the gamebook and the supporting pedagogical methods. This paper details the early design processes, not typically covered in DBR papers.

Introduction

Although many individuals are aware of climate change and preventative measures, actual behavioural change is limited (Pruneau et al., 2010). To effectively tackle climate change, a more educated and action-oriented public is necessary, focusing on preventative and adaptive societal changes (Williamson et al., 2018). Developing early education materials can help promote pro-environmental behaviours in children and prepare them for a future where their behaviour must change regardless of personal desire. This paper reports the development, in relation to content and pedagogy, of educational materials that aim to increase children's engagement in pro-environmental behaviours (PEBs), defined here as any decision that leads to an action with a positive impact on the planet (e.g., walking instead of driving or recycling).

Gamebooks

Existing educational materials cover the scientific aspects of climate change but rarely aim to support children in undertaking PEBs (Lundholm, 2019). Educational gamebooks are proposed here to address this problem. Gamebooks are non-linear, branching narratives that allow readers to make choices that shape the book's ending (e.g., Choose-Your-Own Adventure™ books). Gamebooks provide readers with agency and may effectively demonstrate the potential impact of their actions, supporting education for behavioural change.

Theoretical background

This project utilizes the Reasoned Action Approach (RAA) to predict and change social behaviour (Fishbein & Ajzen, 2010). RAA has been effective in modelling predictors of behavioural intention and developing behavioural change interventions, including encouraging PEB (Steg & Vlek, 2009). The RAA model proposes that behaviour is predicted by intention, which is, in turn, influenced by three constructs: attitude towards the behaviour (i.e., consequences of the behaviour), perceived behavioural control (i.e., skills and agency to perform the behaviour), and perceived social norms (i.e., the behaviour of influential others). Each construct is formed from corresponding beliefs: attitude is based on behavioural outcome beliefs (e.g., by recycling, I reduce landfill), perceived behavioural control on control beliefs (e.g., I know how to recycle), and perceived social norms on normative beliefs (e.g., my friends recycle).

The RAA model suggests that behaviour can be changed by challenging influential beliefs through discussion, reflection and the use of implementation intentions (IIs). IIs are action plans that draw on environmental cues to support behavioural change (Gollwitzer, 1999). They focus on a specific behaviour in response to a specific trigger, usually with an IF-THEN structure (e.g., IF I am brushing my teeth, THEN I will turn the tap off between rinsing). Designing educational materials based on RAA involves targeting specific beliefs, as different beliefs may vary in their impact on the formation of intentions to undertake PEBs. De Leeuw et al. (2015) found that perceived behavioural control (based on control beliefs) had a strong effect on high school students' intentions to undertake PEBs, while attitude towards the behaviour (behavioural beliefs) had a smaller but significant effect.

Gamebook-based lessons

Drawing on the RAA, the educational materials were designed to target behavioural, normative and control beliefs, with behavioural beliefs reflected in different gamebook endings, control beliefs reflected in reader choices, and normative beliefs addressed through supporting dialogic pedagogies. Furthermore, it was necessary to consider the language used in the gamebook (Cleaver, 2010*),* risk of causing eco-anxiety (Pihkala, 2020), and how to integrate an engaging narrative with learning content to support intrinsic motivation (Habgood &

Ainsworth, 2011). Regarding the last element, the core mechanic of gamebooks is user choice, in this instance choice in carrying out PEBs, which reflects the educational aim of encouraging children to choose to undertake PEBs.

While the gamebook serves as the central resource, in practice, it is supported by teacher-led pedagogical approaches. As discussed, implementation intentions effectively support behavioural change, therefore, represent a suitable supporting activity. Another approach shown to be effective in similar contexts is dialogic teaching (Alexander, 2006), supported by talk moves (Michaels & O'Conner, 2012), where teachers facilitate group discussion to critically reflect on concepts and collaboratively develop a shared understanding. In the gamebook supporting lessons, dialogic teaching would allow children to explore the beliefs of others and develop a shared understanding of appropriate behaviour, which could positively affect normative beliefs. Taken together, these are referred to as gamebook-based lessons. In developing these gamebook-based lessons, careful consideration needed to be given to the content of gamebooks (e.g., creating a fun narrative) and the design of pedagogical approaches (e.g., design of suggested talk moves).

Research approach

This project used a design-based research (DBR) approach to develop and evaluate the gamebook-based lessons. The paper reports the first two cycles of material design, which cover the often underreported phase 1 of design-based research studies: preparation and design of materials (Bakker, 2018).

Conjecture mapping (Sandoval, 2014) was used to inform the design of the gamebook-based lessons. The following provides an overview of the conjecture map based on concepts discussed in the introduction. The high-level conjecture is that children's intention to engage in PEBs can be improved by increasing the three predictive constructs (attitude towards the behaviour, perceived behavioural control and perceived social norms) through challenging the associated beliefs (behavioural, control and normative). This conjecture is embodied in both the design of the materials and structures. Materials include the gamebook, the core mechanic of which allows for intrinsic integration of learning content, and the creation of implementation intentions to support behavioural change. Regarding participant structures and discursive practices, the gamebook is used alongside dialogic lessons. In these, children collaboratively reflect on choices made in the gamebook, supported by talk moves to help teachers guide discussion. The design conjecture between embodiment and mediating process is if children engage with the activities (reading the gamebook and forming implementation intentions) through the environment (dialogic lessons), they should: a) explore the impact of PEB; b) develop a shared understanding of what are appropriate PEBs; and c) generate personal action plans (implementation intentions). Mediating processes are theorized to lead to four related outcomes: understanding the importance of individual PEB; improved predictive constructs (e.g., perceived behavioural control); ability to review what are appropriate PEBs; and increased engagement in PEBs. The theoretical conjecture between mediating processes and outcomes is if mediating processes occur: i) influential beliefs are challenged, leading to increased PEB intention; and ii) environmental cues, via implementation intentions, increase engagement in PEB.

The following reports six research activities across two overlapping cycles of iteration completed in phase 1: cycle one focused on designing the content of the gamebooks, and cycle two covered the design of supporting pedagogical activities. Given space limitations, only the aim and outcome of studies are reported.

Cycle one: Designing for content

C1.1: Initial design of gamebook-based lessons

This section presents the initial design of the gamebook-based lessons. The gamebook's narrative is set during a week of school holidays, where readers take on the role of a child going on various days out. Each day includes choices about minor narrative content and pro-environmental choices grouped by areas of environmental action:

- Day A – Area of Action: material consumption; Act 1: clothes shopping; Act 2: visit the fair.
- Day B – Area of Action: travel and mobility; Act 1: visit the park; Act 2: trip to the cinema.
- Day C – Area of Action: food and diet; Act 1: explore the zoo; Act 2: go food shopping.
- Day D – Area of Action: heating and cooling: Act 1: visit the beach; Act 2: plan a holiday.

Days can be experienced in any order, after which it is revelated in a twist that readers were acting as 'time agents': individuals sent from a future badly impacted by climate change and tasked with carrying out PEBs. Readers are then shown one of two futures based upon their choices about engaging in PEBs. These futures depict the impact of climate change in 2050, based on current predictions, and show either 1) a worst-case scenario; or 2) a best-case scenario. The gamebook is written in *ink* (inkle, 2021), with the UI created using *Unity*. In theory, the gamebook challenges and encourages reflection on behavioural and control beliefs. A demo is available at www.enviroedgamebooks.co.uk.

In practice, gamebook reading is followed by two learning activities. Firstly, a book club where children, in small groups, discuss choices made in the gamebook. This acts as a dialogic lesson where children can co-construct understanding of PEB. It is supported by a set of generic talk moves to focus discussion on underlying beliefs and the rationale for behavioural change. Secondly, children create implementation intentions they can use in the following weeks. These are revised and refined each week. These activities target normative beliefs, as children collaboratively discuss their experience of the gamebook and develop a shared understanding of what are appropriate and practical PEBs.

C1.2: Determining viable pro-environmental choices

To integrate learning content through the core gamebook mechanism of reader choice it was essential that gamebook PEBs reflected actions that children would carry out in the real world. Consequently, a survey of 32 UK-based parents/guardians was conducted to develop a homogenous set of child-friendly PEBs. The analysis resulted in 40 child-friendly PEBs for which children would be at least *somewhat likely* to carry out.

C1.3: Affective reactions to gamebook content

To design engaging gamebook content for children and address concerns of eco-anxiety, a study was conducted to investigate emotional reactions, reading difficulty and narrative engagement. 18 children (7-14 years old) read shortened versions of the gamebook and completed a questionnaire. Results showed minimal adverse emotional reactions concerning eco-anxiety. However, parts of the narrative (e.g., the visit to the beach) required revision for greater engagement. The gamebook was suitable for the target age range in terms of reading level, and there was reported increased intention to engage in PEBs.

Cycle two: Designing for pedagogy

C2.1: Expert group review

A wider design team, consisting of 11 academics with expertise in initial teacher education, science education, computer-supported collaborative learning, design-based research, and gamebook writing, provided feedback on the design and use of educational materials at various stages throughout the project. In phase 1, they provided feedback on early narrative storyboards and reviewed the gamebook and lesson plans in focus groups and individual interviews. Feedback from the team in initial teacher education suggested supplementary materials should accompany the gamebook-based lessons. The group also suggested using visual indicators when readers faced PEB choices and highlighted the opportunity to increase inclusion and diversity in gamebook imagery, particularly disability representation. Changes to gamebook imagery were made in all following iterations. The group also called for more exploration of the emergent structure of learning to inform dialogic activities.

C2.2: Teachers' use of materials

A study evaluated the practicality of the gamebook-based lessons and adaptions made by teachers (two teachers and 53 children) using the gamebook-based lessons in classrooms across three lessons. Lesson 1: read the first half of the gamebook. Lesson 2: finish reading the gamebook, take part in a 'book club' to discuss choices made and book endings, and create individual implementation intentions that can be used across the following week. Lesson 3: review children's records of individual implementation intentions. Results showed that readers only received the better ending of the book (due to following PEB visual indicators), necessitating a mechanism for readers to view alternative endings to better facilitate group discussion. Teachers noted it was difficult for children to reflect on and revise their IIs. Like the expert group, teachers requested supplementary materials to extend children's environmental education. Finally, neither teacher was a science specialist. Still, they did not feel out of their depth discussing climate change issues or running the activities, suggesting that the intervention does not require additional subject-specific or pedagogic knowledge.

C2.3: Facilitating group discussion

While talk moves were designed for teachers to support children's discussion, predicting the types of questions children will raise and the prompts needed to guide discussion can be challenging. An exploratory study was conducted with 16 children (10-13 years old). The aim was to explore the emergent structure of learning activities. That is, what questions children raised and what talk moves were needed to focus group conversation. Participants read the gamebook, were observed participating in book club discussions and creating IIs, then provided feedback on gamebook design. The results produced a set of targeted talk moves to highlight the underlying position that all PEBs are beneficial. This ensures that IIs are both possible for children to conduct and focus on a specific PEB and introduces the time travel mission at the beginning of the book to act as a narrative hook. Finally, reliance on PEB visual cues was observed, as participants noted they signposted when to think about their actions.

Revision of materials

The six studies reported here demonstrate the need to design for both content of the gamebook and the supporting pedagogical approaches. The results highlighted the need to evaluate initial assumptions about child-friendly content design (see C1.2, C1.3, C2.3); for example, moving the time travel mission to the beginning of the book as a narrative hook. In terms of pedagogical revisions, targeted talk moves were developed (C2.3) to ensure they anticipated children's questions and better-guided reflection. Implementation intentions were found to be difficult for children to develop and revise. To support II development, children now create IIs in Lesson 1 (linked to school-based behaviour), in addition to those created in Lesson 2 (linked to out-of-school behaviour), with the two contexts covering different social norms (school and home). Lesson 3 now involves group discussion of PEB vignettes where children evaluate pro-environmental choices of fictional others and design IIs for them. Consequently, the initial conjecture map was updated to include PEB vignettes as additional material, leading to a new mediating process of reflecting on the behaviour of others.

The results of the studies led to two design conflicts. Firstly, both the expert group (C2.1) and classroom teachers (C2.2) wanted supplementary climate change materials to use alongside the gamebook-based lessons. A suitable pack has been developed; however, potential variations in use pose methodological problems that must be evaluated in future efficacy tests. Secondly, the use of visual cues (C2.1) within the gamebook to flag potential PEB may have guided children to predominantly select PEBs (C2.2, C2.3), limiting the experience of alternative endings and potential loss of reader agency. The use of such cues will be investigated in future studies.

Conclusion

Educational gamebooks are an under-explored resource that can be used to show individuals the impact that their actions can have. The studies reported here illustrate how to design for both content and pedagogy in developing gamebook-based lessons, including underpinning conjecture mapping. Such steps are crucial for others creating gamebooks for environmental education and other areas that focus on belief revision or behavioural change.

Abstract: Despite the importance of socially shared regulation of learning (SSRL) in collaborative learning success, there remains a paucity of evidence on how it could be detected and supported effectively. In this paper, we present an experimental study with a systematic analysis approach that utilizes facial expression recognition technology to examine emotional triggers for collaborative learning regulation. The study involved high school students (N=27) working in groups of three with a collaborative learning task. During the learning process, the collaborative groups were intervened with a controlled cognitive trigger followed by three emotional triggers. AI facial expression recognition was utilized for analyzing students' continuous valence and changes in emotions throughout the collaborative learning task. Cross-recurrence quantification analysis (cRQA) approach has been employed to examine emotional synchrony through regulatory triggers. Our findings present evidence for the regulatory trigger concept and offer novel insights into how the regulatory triggers facilitate emotional synchronization among learners in collaborative learning. Furthermore, the study also demonstrates the use of AI technology for examining collaborative learning regulation. The study further discusses not only the potential role of the trigger concept in generating a better understanding of the regulatory processes but also its contribution to establishing foundations for designing support for regulation in collaborative learning.

Introduction

There is a growing body of literature that acknowledges the importance of learning regulation in collaborative learning. Self-regulated learning (SRL) theory and socially shared regulation of learning (SSRL) framework have offered an understanding of the regulatory processes in collaborative learning through which group members negotiate goals, planning, and strategies for purposefully carrying out learning activities. It involves groups taking metacognitive control of the task together through negotiated, iterative fine-tuning of cognitive, behavioural, motivational, and emotional conditions as needed (Hadwin et al., 2018). Besides their ideas, knowledge, and skills, group members also bring their emotions and interpretations of other learners' emotions. Research has pointed out learners' need to control also their collective emotions in collaborative learning (Lobczowski, 2020).

Recently, research in (S)SRL has recognised the role of emotional and cognitive triggers for regulation and understanding small-scale adaptation in collaborative learning. Events and/or situations which may inhibit learning processes and, thus, require regulatory responses are defined as trigger events (Järvelä et al., 2023). Since measuring SRL and SSRL has been challenging (Winne, 2010), empirically identifying trigger events as markers for the regulation of cognition, motivation, emotion, and behaviours has great potential for advancing the field. Whilst some research has been carried out on triggers for collaborative learning regulation (Nguyen et al., 2022), no controlled studies have been reported for examining trigger events for regulation. In addition, the existing accounts to identify the trigger event in collaborative learning are limited.

The recognition of regulatory triggers and examination of learners' responses to them are essential to progress the current understanding of collaborative learning regulation and design appropriate and effective support for the learners. Nonetheless, SSRL's cyclical adaptive nature, high levels of interactivity, and dynamics make it difficult to measure, capture, and analyze the regulatory triggers and SSRL processes (Winne, 2010). The emotional and cognitive processes at the core of regulation are unobservable by humans, and it is difficult to capture these processes using traditional approaches. Fortunately, recent advances in Artificial Intelligence (AI) and machine learning have enabled new means to trace and analyze learning behaviors (Cukurova et al., 2020). Accordingly, this study attempted to examine the use of AI techniques to analyse emotional synchrony through regulatory triggers in collaborative learning.

Accordingly, in this study, we utilise AI facial expression recognition technique to assess emotional synchrony through cognitive and emotional triggers for SSRL. Particularly, this study aims to answer the following research questions: 1) How do regulatory triggers facilitate emotional synchronisation among learners in collaborative learning? 2) How do the learners' emotions change over time throughout regulatory triggers in collaborative learning?

Learning analytics and AI for socially shared emotional regulation

In collaborative learning, emotional regulation refers to the capability to recognize others' emotions and modify those emotions in social interaction, as well as regulate one's own feelings. Emotion is individually enacted but socially constructed. Emotional regulation involves the active utilization of various regulation strategies in interaction (Lobczowski, 2020). An effective regulator adjusts their strategic regulation accordingly to match the situational needs and ensures the most appropriate possible strategy to address the challenges and ensure solid emotional foundations for group functioning. In socially shared emotional regulation, awareness and sharedness of emotion among the group members invites for shared regulation. However, despite the learners' perceived emotions and overall learning experiences being evident, much less is known about individuals' short-term emotional states and the group's shared emotional states in SSRL. Emotional synchrony among short-term emotional states has been demonstrated to be a sign of individuals' affiliative bonding and empathy (Dindar et al., 2020). By capturing and understanding these temporal cycles of emotions and emotional synchrony, we would better identify SSRL's pain points and timely support the learners. Recently investigators have examined the shared emotional processes during collaboration by analyzing shared physiological arousal events (SPAE) (Dindar et al., 2022; Nguyen et al., 2023). To date, there are few studies that have investigated emotional synchrony with facial expressions in SSRL. From a methodological point of view, the use of AI facial expression recognition technologies facilitates the accurate frame-by-frame detection of emotional states for a granular analysis of emotional synchrony in SSRL.

In the context of learning sciences research, learning analytics and AI machine learning have offered exclusive methods for analysing and predicting learners' performance and their learning behaviours (Cukurova et al., 2020). For instance, Nguyen et al. (2022) utilised multimodal deep learning techniques automatically detect interactions for regulation in collaborative learning. Moreover, learning analytics and machine learning could identify and extract human cognitive and emotional activities, such as facial expressions of emotion (Dindar et al., 2020). Nevertheless, the gap between those who understand AI's methods and techniques and those who know how to improve learning and teaching remains significant. Prior research highlighted the challenges associated with aligning learning theories with technology to provide new insights and to provide real-time learning and teaching support (Cukurova et al., 2020). The implementation of time-stamped video-based facial expression recognition methods would be promising in the collaborative learning context for identifying temporal and cyclical emotions (Dindar et al., 2020). It provides fine-grained details, including, for instance, the exact moment when changes in facial expressions occurred, matching to the learning events confronted by the learners. Accordingly, this paper adopted learning analytics and AI machine learning as the methodological approach to examine socially shared emotional regulation in collaborative learning.

Research methods

To address these research questions, this study involved an experiment with regulatory triggers. The experimental setting was designed with 10 small groups of three high school students (N=30) working with a collaborative learning task for 30-40 minutes. Nevertheless, trigger time recording was missing for two groups, thus 8 groups were included in this analysis (N=24). After the first half of the learning task, the treatment groups will be presented with manifested emotional triggers in 3-minutes time intervals and up to three times in total. High-resolution video data was collected for facial expression analysis using Insta360 Pro video cameras placed in the middle of each group, and each student was equipped with an individual microphone.

To extract emotion, the faces are first detected and cropped from the videos based on Dlib, a toolkit containing machine learning algorithms. The emotion recognition from cropped faces is based on EmoFAN, built on a face-alignment network with two Unet followed by five 2D convolutional layers and a fully connected layer (Toisoul et al., 2021). EmoFAN provided one model pre-trained on the large facial dataset in the wild. The discrete emotions of five categories (neutral, positive, sad, fear, and surprise) were obtained and aligned so that their affective states could be analysed.

In this study, cRQA was conducted to compute the level of emotional synchrony among learners within the same collaborative learning group. In particular, the drpfromt method was employed to compute the diagonal profile of the recurrence plot for each pair of learners before and after the regulatory triggers. To validate the role of cognitive and emotional triggers in facilitating emotional synchronisation among learners in collaborative learning, we conducted paired sample t-tests to compare the means of maximum recurrence rates before and after regulatory triggers. In addition, Pearson's Chi-Squared and Cramér's V tests were applied to examine the distribution of emotions among different time periods (before and after each regulatory trigger). Furthermore, this study utilises visual analytics using Tableau, a commonly used data visualisation tool, to examine how learners' emotions change over time throughout regulatory triggers in collaborative learning.

Results

RQ1. How regulatory triggers facilitate emotional synchronisation among learners in collaborative learning?

Figure 1a shows the cRQA results with each maximal recurrence rate (MaxRR) observed and the delay (MaxLagAbs) at which it occurred from each profile. MaxRR denotes the alignment between two time series, i.e., the alignment between the learners' facial expressions of emotion in this case. High MaxRR implies that two learners had similar facial expressions of emotion over time. The paired-sample t-test showed a statistically insignificant difference with the cognitive trigger, $t(26) = -1.58$, $p = 0.13$, whereas there is some evidence for an increase in emotional synchrony after the emotional trigger, $t(26) = -2.70$, $p = 0.01$. The present study raises the possibility that different types of regulatory triggers have distinct effects on corresponding aspects of learning regulation. Whilst we found no significant effect of the cognitive trigger on learners' emotional synchrony, our findings suggest that a potential link may exist between emotional triggers and emotional synchrony in collaborative learning.

RQ2. How do the learners' emotions change over time throughout regulatory triggers in collaborative learning?

For the second research question, Pearson's Chi-square test shows a significant difference in the distribution of emotion among different periods (before and after each trigger), $\chi 2(12) = 268.00$, $p < .001$. However, a note of caution is due here since only a small effect size is reported with a weak Cramér's V, 0.06. To further inspect the change in emotion distribution before and after each trigger, we visualise this distribution over time, as shown in Figure 1b.

We observed a noticeable increase in negative emotions after the first and second emotional triggers. This could indicate the role of the emotional triggers pushing the groups to complete their task early. Nevertheless, a rise in positive and surprise emotions was noted toward the end of the collaborative learning task. This may be explained by the fact that they were happy with their products and had been waiting for the time up. Further research may investigate the effects of different types of emotional triggers.

Discussion and conclusion

This study set out to examine emotional synchrony through regulatory trigger moments in socially shared emotional regulation by applying AI facial expression recognition techniques. These results play a role in confirming our theoretical predictions and determining the role of regulatory triggers in facilitating regulatory processes in collaborative learning (Järvelä et al., 2023). Furthermore, the study evicted the effects of different types of regulatory triggers on emotional synchronisation, one of the key facets of SSRL. The study also contributed to the contemporary discourse regarding the use of advanced technologies to further progress methodological and theoretical development in learning sciences.

This study continues the collaborative efforts in utilising AI and advanced techniques in examining SSRL in collaborative learning. It was designed to determine the effect of cognitive and emotional triggers on learners' socially shared emotional regulation in collaborative learning. By using AI techniques, we examined the learners' emotional synchrony via facial expressions of emotion. Our results indicated that emotional synchrony among the learners in a group was not significantly affected by the controlled cognitive trigger but by the controlled emotional triggers. Hence, it could conceivably be hypothesised that different types of regulation (i.e., cognition, emotion, and motivation) could be prompted by corresponding types of regulatory triggers. Further research should be undertaken to investigate the effects of various regulatory triggers on different SSRL aspects. A better understanding of the triggers for regulation will establish the foundation for the development of effective methods based on advanced technologies such as AI that will allow real-time detection of these "invisible" events to support the regulatory process. The study also highlights the potential of AI and learning analytics to advance learning theories.

The generalisability of these results is subject to certain limitations. First, with a small sample size, caution must be applied to the findings of this study. Further work is required to establish the generalizability of these results for different larger cohorts of learners. Second, the study is limited by the missing values from facial expression recognition due to the segments that learners' faces were covered in the video recording. Notwithstanding these limitations, the study offers valuable insights into the process of socially shared emotional regulation in collaborative learning. Moreover, this study has provided evidence for validating our proposed conceptual framework of regulatory triggers (Järvelä et al., 2023). A greater focus on cognitive, emotional, and motivational triggers for regulation could produce interesting findings that account more for understanding and supporting SSRL in collaborative learning.

Abstract: Past research shows that teacher noticing matters for student learning, but little is known about the effects of AI-based tools designed to augment teachers' attention and sensemaking. In this paper, we investigate three multimodal measures of teacher noticing (i.e., gaze, deep dive into learning analytics in a teacher tool, and visits to individual students), gleaned from a mixed reality teacher awareness tool across ten classrooms. Our analysis suggests that of the three noticing measures, deep dive exhibited the largest association with learning gains when adjusting for students' prior knowledge and tutor interactions. This finding may indicate that teachers identified students most in need based on the deep dive analytics and offered them support. We discuss how these multimodal measures can make the constraints and effects of teacher noticing in human-AI partnered classrooms visible.

Introduction

Teacher noticing of noteworthy events in the classroom is argued to be a key teacher competency for effective pedagogical practice (Blömeke et al., 2015) and has been shown to matter for student learning and experience (Kersting et al., 2012). At the same time, research on human perception suggests that teachers may be limited in their attentional capacity when focusing on the multitudes of events happening in a classroom at a given point in time (Kahneman, 1973). Classrooms with artificially intelligent tutors (AI tutors) that collect moment-by-moment data on student learning and experience offer new opportunities for AI-supported teacher noticing. Through analytics derived from these data, teachers can react to classroom events that they otherwise might not have been aware of. Accordingly, AI tools designed to improve teachers' real-time awareness and sensemaking have been effective in improving students' learning (Holstein et al., 2018). However, we are yet to fully understand how teachers distribute their attention across students when provided with analytics that extend their current knowledge about classroom learning. These settings offer novel opportunities to study how teacher noticing and intervention relate to student learning and engagement with AI tutors. Besides being interesting in its own right, this kind of understanding could be helpful in designing better tools that support teachers' in-the-moment noticing and ultimately support reflection on their own practices. In this study, we relate three multimodal measures of teacher noticing to student learning in an AI classroom with a mixed reality teacher tool. We showcase how these measures can be used to better understand and quantify teacher noticing and its relationship to student learning.

Multimodal measures of teacher noticing in human-AI partnered classrooms

In this paper, we measure teacher noticing using multimodal data collected from a mixed reality teacher awareness tool. Lumilo is a smart glass system that sends real-time analytics about student learning and engagement (i.e., idle, rapid attempts, hint abuse, low or high local error rates, many errors after hints, hint avoidance, and unproductive persistence) to the teacher via indicator icons (Holstein et al., 2018; Holstein & Aleven, 2022). In addition to providing teachers with real-time analytics, the smart glasses are instrumented to gather multimodal measures of teacher interaction. We investigate three such measures: 1) the number of visual fixations teachers allocate to students (*gaze*), 2) how often teachers use the deep dive function of Lumilo to obtain more information on a student's progress in the AI tutor (*deep dive*), and 3) how often teachers visit students in person (*visit*).

According to the framework proposed by van Es and Sherin (2021), teacher noticing involves *attending* i.e., recognizing important aspects of classroom interactions and ignoring others, *interpreting* i.e., reasoning about what is observed using contextual knowledge and past experiences and *shaping* i.e., gathering additional information by constructing new interactions with the students while continuing to notice. We argue that our three multimodal measures (i.e., gaze, deep dive, visit) operationalize key components of van Es and Sherin's (2021) noticing framework in a manner that applies to the targeted classroom scenario. First, visual attention in the form of gaze is unequally distributed among students; it tends to be focused particularly on students who exhibit undesirable behavior (Wolff et al., 2017; Yamamoto & Imai-Matsumura, 2013). Prior work also suggests that students with low academic performance are more often in the teacher's visual focus (Chaudhuri et al., 2022). Based on these findings, teachers' gaze represents a coarse-grained measure of teachers' visual focus to identify noteworthy events (akin to *attending* in van Es & Sherin, 2021). Second, to gather further insight into noteworthy events, the Lumilo mixed reality tool, which generates the data analyzed in the current study, allows the teacher to open a deep dive analytics screen. This screen shows in-depth analytics on the given student's progress and instructional needs (e.g., areas of struggle; Holstein & Aleven, 2022). These real-time analytics augment teacher sensing, particularly concerning *interpreting* noteworthy events (van Es & Sherin, 2021). Still, teachers must connect multimodal analytics with contextual knowledge (e.g., prior knowledge of the students) to draw meaningful conclusions and guide further action (Deunk et al., 2018; Holstein & Aleven, 2022). Third, we view the use of the deep dive function and visit as forms of *shaping*, as defined by van Es and Sherin (2021). Shaping helps teachers amend and confirm assumptions gathered via attending and interpreting by gaining access to additional information.

We posit that it is worth investigating teacher noticing through multimodal measures for three reasons. First, multimodality offers a quantified lens into noticing. Second, multimodality offers a more complete representation of teacher noticing facets through multiple measures compared to a single measure. Third, multimodality allows for a lens into different levels of noticing, relating to theoretical stages of teacher noticing (cf. van Es & Sherin, 2021). In our context, we conjecture that gaze fixations, deep dives analytics lookups, and visits can be understood as stages of increasingly focused noticing of student needs for attention and extra help. Whereas the teacher's gaze wanders through the room or can be directed specifically to a student, calling up the deep dive function might indicate (perhaps especially when it involves a student just gazed upon) a heightened form of teacher noticing as the teacher proactively seeks further information about a student. In the same vein, perhaps visit can be understood as an action resulting from the preceding noticing events (attending, interpreting) to gather more information from the students directly. More research is needed to understand how teachers use different forms of noticing and how they relate to student learning. Hence, the guiding question for our analysis is: *how do multimodal measures of teacher noticing relate to student learning with AI tutors?* We hypothesize that physical teacher visits represent the most salient mode of teacher noticing from a student's perspective and is, therefore, most strongly related to students' learning gains compared to gaze and deep dive.

Methods

We analyze previously collected data from an intervention study investigating the efficacy of the mixed reality teacher awareness tool Lumilo (see previous section; Holstein et al., 2018). Our study sample included 173 students from ten classes taught by six teachers. Between pre- and post-test assessments of students' skills in the relevant mathematics (i.e., equation solving), students practiced math with the linear equation tutor Lynnette while being monitored by their teacher and supported when necessary. Each student worked with Lynnette for approximately 60 minutes across two classroom sessions. Their problem-solving behavior was recorded in the form of time-stamped log data. Lynnette has been reported to significantly improve students' equation-solving abilities. Teacher noticing variables were exported via Microsoft Hololens (see previous section). They include the number of times the teacher looked at a particular student (i.e., gaze), how often they used the deep dive feature to gather in-depth insight into a particular student (i.e., deep dive) and how often teachers entered the physical proximity of a student, defined as within a radius of four feet (i.e., visit). If a teacher entered the proximity of multiple students simultaneously, proximity was coded for the student closest to the teacher. From the tutor log data, we aggregated the following student-level variables: (1) tutor interactions, such as the average time students take for correct, incorrect, and all steps when working with the AI tutor, (2) in-system performance, such as ratio of correct to incorrect attempts, and (3) engagement behaviors, such as tutor misuse, estimated using previously-developed machine learning models for the AI tutor (cf. Holstein et al., 2019). Grade level, prior student knowledge, and class size served as control variables. As our outcome, we analyzed the association of these variables with students' learning gain after working with the AI tutor. Learning gains were operationalized as the difference between normalized pre- and post-test scores.

Results

We investigate whether a teacher visit is most strongly related to learning gains among our three multimodal noticing measures as it could be the most salient mode of teacher noticing from a student perspective. We employ an automatic feature selection procedure (AIC-based backward feature selection) for a linear regression model of learning gain, adjusting for prior knowledge, grade level and student-tutor interactions. Contrary to our hypothesis, deep dive, not visit, had the strongest association with learning gains after controlling for contextual factors and students' tutor behavior ($\beta = 0.19$ [0.07, 0.31], $p = .001$; Table 2). Dive explained 3.1% of the variance in learning gains beyond the other variables featured in the selected model. As deep dive was the only noticing measure selected by our procedure, gaze and visit did not explain a significant amount of variance in learning gains beyond deep dive.

Table 2
Linear model of learning gain selected via backward search based on AIC with deep dive being the only noticing measure that explained variance in learning gains beyond control variables.

(a) (b)

Next, we check heterogeneous effects of teacher noticing across students by plotting the most associated noticing variable (i.e., deep dive), tutor variable (i.e., average time spent per tutor step), and control variable (i.e., prior knowledge) in Figure 1. We observe three main trends. First, we find a significant positive (albeit small) association between deep dive and learning gains and a significant negative association between the average time per tutor step and prior knowledge. Second, teachers performed significantly more deep dives on students who spent more time per tutor step, while students with longer tutor steps had significantly lower prior knowledge. Third, a small (non-significant) positive correlation was found between deep dive and prior knowledge.

Discussion

The current study investigates how multimodal teacher noticing measures relate to learning in a human-AI partnered classroom. We hypothesized that physical visits would be most strongly related to students' learning. Contrary to that hypothesis, deep dive had the strongest positive association with learning gains. This finding may indicate that teachers identified students in need based on the deep dive analytics and offered them support, potentially acting upon diagnosed struggles and difficulties students experienced. However, since visits were less strongly associated with learning than deep dives, the support prompted by deep dives would, apparently, not always be in the form of an actual visit, consistent with field observations that some teachers using Lumilo would frequently provide feedback to students from across the room, without physically visiting them (Holstein et al., 2018; 2019). Perhaps other purposes of teacher visits not immediately related to student support, for example, looking over a student's shoulder without interacting with the student, celebrating the successful completion of a problem, or other social interactions might dilute the current signal for teacher support for learning captured by our visit measure. Another potential explanation is that teacher visits were actually helpful, but that visits nonetheless did not correlate positively with learning gains because these visits were infrequent. As teachers tended to perform deep dives on students with higher prior knowledge, mechanisms other than support could also explain the lack of association between visit and learning. For example, teachers' selection of students to perform deep dives might have been influenced by top-down selection effects (i.e., decisions informed by teachers' prior knowledge of the student rather than noteworthy classroom behavior; Chaudhuri et al., 2022). From post-study interviews with teachers during data collection, we know that teachers report using the deep dive feature on multiple high-achieving students in a row to calibrate their assessment of class progress (Holstein et al., 2019). Thus, the use of deep dives may sometimes represent teachers' efforts to gather classroom-level data rather than sizing up the extent of a student's struggle. Future research may look at how deep dives with different purposes might be distinguished (e.g., their duration might be different), which may re-inform or help extend prior conceptualizations of teacher noticing. In conclusion, our multimodal measures offer novel lenses into the study of teacher noticing in classrooms with AI tutors that we believe would have implications to designing tools for teacher orchestration and reflection.

Abstract: Social Perspective taking (SPT) is the aptitude to consider others' thoughts, feelings, intentions, and motivations in a particular situation. Our goal was to gain a deeper understanding of SPT by focusing on its dynamic and social nature. Qualitatively analyzing small group dialogues in an 8th-grade humanities classroom, we explore the interplay between the level of *SPT acts* and dialogical moves. Our findings indicate that SPT in a group dialogue context is a complex practice in which students engage with different perspectives and evaluate how their perspectives differ (or do not differ) compared to the perspectives of others. Specifically, higher levels of *SPT acts* stemmed from explaining one's own perspective by inviting peers to put themselves in someone else's shoes.

Introduction

Social Perspective-taking (SPT) has long been acknowledged as an essential feature of human interaction (Selman, 1981). At its core, SPT entails "the active consideration of others' mental states and subjective experiences" (Todd & Galinsky, 2014, p. 374) and has been identified as a vital component in a variety of social and academic processes such as overcoming conflicts, productive collaboration, and reading comprehension (see Gehlbach & Mu, 2022 for a recent review). Paradoxically, although SPT is inherently an other-oriented process, most research has (implicitly) relied on an individualistic understanding of SPT, which focuses on the interaction between an individual and a novel perspective introduced in a text. The same is true for educational contexts, where it is rare that "students in social studies classrooms view their peers as valuable sources of wisdom" (Gehlbach, 2011, p. 316). To address this lacuna, we examined how students engage in SPT when collaboratively studying texts that elicit the need to engage with other perspectives. We collected data in one middle-school humanities classroom where students conducted small group dialogues around texts. Our goal was to deepen our understanding of SPT by focusing on this process's dynamic and social nature as we uncover the interactions between *SPT acts* in this context.

Theoretical background

Social perspective taking

SPT has been recognized as fundamental to the ability to reflect on and behave in line with the needs of others and to the development of empathy (Batson et al., 1997), and as a means of understanding members of other social groups (Wang et al., 2014). In addition, SPT has been identified as a key part of vital skills in today's world, such as collaboration, communication, and argumentation (Sadler, 2006). Finally, ongoing political polarization has highlighted the urgency of facilitating interactions across social groups, which necessitates transcending one's own perspective (Dishon & Ben-Porath, 2018). However, engaging in SPT is neither simple nor automatic, requiring motivation and continued practice (Lin et al., 2010). Moreover, researchers have distinguished between levels of *SPT acts*: (1) The *acknowledgment* of other actors and perspectives; (2) *Articulation* concerning the thoughts, feelings, preferences, and orientations of other actors; and (3) *Positioning* – which involves integrating the situational and personal factors that shape an individual's perspective (Diazgranados et al., 2016).

SPT is usually referred to as a cognitive process in which an individual tries to adopt or imagine another person's point of view. However, critiques have stressed the need to examine SPT through a social-relational lens, exploring interactivity, intersubjectivity, and metareflective forms of sociality and interpersonal negotiation (Martin et al., 2008). Yet, despite the rich body of research on SPT's potential benefits, little is known about how perspectives shift through social interaction.

Dialogue and argumentation in small groups

Though not explicitly focused on SPT, productively engaging with multiple perspectives is a fundamental tenet of research on dialogue and argumentation in education (Asterhan & Schwarz, 2016). Such efforts have been identified as indirectly contributing to the development of SPT by facilitating opportunities for discussion around engaging questions and dilemmas that require students to examine a given issue from various perspectives (Hsin

& Snow, 2017). More specifically, the transition from whole-class discussions instructed and guided by the teacher to small group interactions without teacher mediation can change the SPT dynamic as it shifts the structure of the conversation and the patterns of participation (Hofman & Mercer, 2016). In such contexts, interpersonal aspects related to student dynamics become more central.

Researchers have identified practices such as using specific *talk moves* (Michaels & O'Connor, 2015) that are vital for promoting discussions that are conducive to engagement in SPT (Hsin & Snow, 2017). Research shows that for group discussion to be productive, students should share their ideas as they support them with reasons, discuss different views, and resolve them to achieve group consensus (Hofmann & Mercer, 2016). To study group talk, researchers have developed different coding schemes that aim to support a systematic analysis of different types of *talk moves* in dialogical contexts (e.g., SEDA, Scheme for Educational Dialogue Analysis; Vrikki et al., 2019).

However, few studies have examined the connections between dialogical moves and the levels of SPT in small group work. Accordingly, rather than looking at how the discussion supports SPT via pre- and post-assessments, our research questions focused on studying (1) if and what level of *SPT acts* emerged during small group dialogues; and (2) whether there were connections between students' *talk moves* and *SPT acts*.

Methods

This study was conducted in one 8th grade humanities class, studying a unit centered on moral dilemmas over two months. The curriculum was built by the teachers and modified with the help of the research team to facilitate engagement in SPT. The intervention centered on integrating different dialogical practices and included seven sessions of small group work. During this time, we observed ten lessons and audio recorded five groups' discussions within the classroom (later transcribed). In this paper, we discuss findings from one group that included two girls and two boys. This group was chosen due to technical and substantial reasons. First, as data were collected during an uptick in the COVID-19 pandemic (January-March 2022), many groups suffered from inconsistent participation. Second, this group was characterized by relatively rich conversations in which participants presented diverse positions. In this respect, this group is not necessarily representative of the class as a whole and is not generalizable, but it allows us to bring into focus theoretical relationships that may apply to other contexts (Eisenhart, 2009).

Data includes transcripts of six group discussions with a total of 990 utterances. In each conversation, the teacher instructed the students to discuss a different text that reflects various moral dilemmas that the characters struggle with (stealing or lying for a morally noble cause) and one real-life example exploring the topic of euthanasia. In all cases, weighing the dilemma potentially involved SPT and our analyses explored if and how students practiced SPT within this learning activity. To account for the interplay between *talk moves* and the level of *SPT acts*, we developed a coding scheme (see Table 1) including three levels of SPT. Any utterance that indicated one's awareness of the perspective of the fictional character/classmate was coded as a case of SPT. We also coded *talk moves* that students performed to analyze students' dialogical process and argumentation as they engaged in SPT (based on Vrikki et al., 2019).

Table 1
Coding scheme based on Diazgranados et al. (2016) for SPT acts and SEDA (Vrikki et al., 2019) for talk moves

Code	Sub-code	Definition	Example
SPT Level	Acknowledgement	The act of identifying the various actors involved in a given social situation.	*"He said he had cancer."*
	Articulation	The act of describing the thoughts, feelings, or orientations to the action of distinct actors in a given social scenario.	*"He thought it was the right thing for him."*
	Positioning	The act of identifying the roles, circumstances, or attributes that qualify the position distinct actors hold in a social scenario.	*"A person who wants to commit suicide won't [...] go to work because he doesn't like his life."*
Talk Moves	Build on ideas/ Revoice	Building on, adding to, reformulating, or clarifying one's own or other's contributions.	*"What you are saying [is] that we need to respect the man's choice."*
	Challenge	Challenging / confronting others' view / assumption / argument. The challenge must be evident through verbal (or nonverbal) means, including questioning.	*"If you were given the money, would you take it?"*

	Invite	Invite others to build on or respond critically through explanation, justification, argumentation, analogy, use of evidence or speculation.	*"Do you have a way to convince us?"*
	Guide	Take responsibility for shaping and directing dialogue or activity, including encouraging student-student dialogue, offering thinking time, providing informative feedback or other scaffolding strategies.	*"Joni, what do you think? […] what dilemma are they facing?"*
	Reflect	Explicit self or group evaluation or metacognitive reflection on purposes/ processes/ value/ outcome of learning or activity or invitation to engage in this.	*"This is supposed to be a discussion."*
	Agree	State that one or more participants agree with others.	*"Yes, exactly."*
	Disagree	State that one or more participants disagree with others or acknowledge differences.	*"With this I agree less."*

Findings and discussion

We found SPT in a group dialogue context to be a complex practice in which engaging with different perspectives is constantly intertwined with social dynamics and interlocutors' argumentative concerns. Thus, students repeatedly evaluate how their perspectives differ (or not) with respect to their peers. First, with respect to the manifestation and level of SPT, we identified 356 *SPT acts* (out of 990 turns), of which 228 were at the most basic level of *acknowledging*, 84 were coded as *articulation*, and 44 as *positioning* (see Table 1 for examples). We focused on the highest level of SPT (*positioning*) due to its importance and high complexity (Kim et al., 2018). The use of *positioning* acts led us to conduct a more fine-grained qualitative analysis revealing that these SPT acts were motivated mainly by the effort to "put others in the other's shoes": to explain their own perspective, students often invited other group members to take on the fictional character's perspective while highlighting situational aspects they thought were vital. For example, *"think that your sister was dying and that you had the money [for the medicine], but he [Heinz] stole it."* Here, the student invited his peer to "put herself in someone else's shoes," a person whose sister is in a life-threatening situation and needs a particularly expensive and rare medication. Later, he explains that it is wrong of Heinz (the main character) to steal the medicine. Thus, an argumentative act of trying to challenge his peer and convince her of his perspective is pursued via a *positioning* act.

To examine the interplay between *talk moves* and *SPT acts* more closely, we examined the co-occurrence of SPT *positioning moves* with the various *talk moves* outlined in the SEDA framework (Table 1). Our findings indicate that *positioning* acts (overall 44) co-occurred with the high use of the two *talk moves*: *Build on Ideas/Revoice* (33 acts) and *challenge* (9 acts). We suggest that this indicates that SPT is a process of understanding, explicating, and communicating one's perspective as one positions it in relation to other perspectives (building, challenging, or coordinating perspectives). For example, *"Can you say that you personally knew this man? Do you know what he's been through?"* Here, the student is challenging his peer to recognize that she is not aware of the other's perspective, nor does she understand it. He demands her not only to acknowledge the other individual but also to position herself in his place. Thus, we uncover how students used a higher level of SPT to explain their perspective to their peers as an argumentative move. However, students did not take on their peers' perspectives; instead, they focused on explaining their *own* views in relation to those of others.

Our findings highlight the social nature of *SPT acts*. Students refined and expressed their perspectives as part of a conversation in which they tried to convince others to understand and adopt their own perspectives. Put differently, students practiced their social understanding of themselves in relation to the perspective presented in the text and to group members' diverse perspectives. This implied that individual SPT processes are already social: they include considering how one's understanding of a given situation stands in relation to another person's perspective (a fictional character and/or a classmate). Moreover, this highlights how *perspective taking* processes are entangled with *perspective making:* the process in which one develops and frames their own narrative of experiences (Boland & Tenkasi, 1995).

Conclusions

Our case study broadens the existing literature on SPT in educational settings by examining the manifestation of SPT in dialogical contexts and the connections between the level of *SPT acts* and students' *talk moves*. Our findings indicate that engagement in high levels of SPT could be potentially supported by opening the class to more student opinions, thus fostering student engagement as they relate to additional views. Also, exposing students to more perspectives on a given dilemma allows them to practice SPT as they better understand their peers. Moreover, we highlight that a central aspect of *SPT acts* revolves around *perspective making* – forming and communicating one's own perspective while positioning it in relation to others. This highlights that SPT is not merely an individual cognitive process but also a social effort that supports personal exploration within a group dialogue. Yet, in our data such perspective making acts often came at the expense of attentiveness to interlocutors' perspectives, an issue that should be further explored in future research. In this respect, though exploratory in nature, this study could offer a conceptual roadmap for future research that examines the social processes underpinning engagement in SPT.

Virtual Reality Induces Awe but Possibly Not Accommodation

Cesar Delgado, Tyler Harper-Gampp, Matthew Peterson, Karen B. Chen
cdelgad@ncsu.edu, twgampp@ncsu.edu, mopeters@ncsu.edu, kbchen2@ncsu.edu
North Carolina State University

Abstract: Awe is a transformative emotion associated with positive educational and psychological outcomes, and is caused by experiences of *vastness* that induce *accommodation*. Vast VR scenes have been found to elicit awe. We examined self-reported causes of awe among grade 3–8 students — a previously unstudied age group regarding awe — in a virtual environment portraying entities over 20 orders of magnitude from atom to Sun. Most students reported feeling awe, around half specifically enough to be coded based on *a priori* categories drawn from the literature. *Vastness of scale* (including both large and small entities, and large differences in scale) was the most common cause of awe. Surprisingly, no student responses were related to accommodation. *Vastness of evolution* and *degree of immersion* were identified as novel causes of awe. Thus, even young children can experience awe in VR, opening possibilities for productive VR in education at the elementary school level.

Introduction

Awe is a transformative emotion that can induce positive psychological and physiological changes (e.g., Piff et al., 2015; Rudd et al., 2012; Yang et al., 2016). The consensus view is that awe is caused by vastness and accommodation (Chirico et al., 2018; Cruz, 2020; Keltner & Haidt, 2003; Shiota et al., 2007; Valdesolo et al., 2017). Researchers have recently begun assessing whether and how experiences in immersive virtual environments portraying vast scenes induce awe (Chirico et al., 2018).

Understanding what elicits awe is important because awe has been found to drive scientific discovery, support science learning, and elicit constructive science behaviors (e.g., Jones et al., early view; Chirico et al., 2018; Gottlieb et al., 2018; Keltner & Haidt, 2003). However, the literature on awe is either theoretical or involves college-age or older participants, and little is known about how and why younger students experience awe; furthermore, there is little literature on awe and virtual reality (VR).

Our NSF-funded project has developed an immersive virtual environment called *Scale Worlds* that allows students to interact with virtual entities as they seemingly shrink or grow themselves over 20 orders of magnitude from atom to Sun. We studied whether grade 3–8 students experienced awe in this virtual environment, and what caused that feeling, guided by the following research question: What factors within a virtual environment induce awe among middle school and elementary students?

Theoretical framework

Awe

Keltner and Haidt (2003), in their foundational work, posit a prototype perspective where awe is characterized by two features: *vastness* and *accommodation*. "*Vastness* refers to anything that is experienced as being much larger than the self, or the self's ordinary level of experience or frame of reference. Vastness… can also involve social size such as fame, authority, or prestige" (Keltner and Haidt, 2003, p. 303, emphasis added). *Accommodation* refers to the Piagetian process of modifying existing mental schemas during new experiences that cannot be assimilated (Piaget & Inhelder, 1966/1969). In particular, "awe involves a *need* for accommodation" (Keltner & Haidt, 2003, p. 304, emphasis retained). If accommodation successfully takes place, then it may result in "feelings of enlightenment and even rebirth" (p. 304). If accommodation does not take place, feelings of confusion, disorientation, powerlessness, and fright may result instead (p. 304).

Yaden et al. (2019) developed the Awe Experience Scale (AWE-S). Their exploratory factor analysis identified a six-factor structure: *accommodation, vastness, connectedness, self-diminishment, time dilation,* and *physical sensations*. Like several other papers, their scale does not distinguish among causes (e.g., vastness) and consequences (e.g., time dilation) of awe.

Virtual reality

Virtual reality is a computer-generated environment that combines multisensory stimuli, affording users the ability to interact as they would with natural environments. Among VR systems are the Cave Automatic Virtual Environment (CAVE) and head-mounted displays (HMD). The CAVE is a small room size space with 3–4 projecting walls, a projected screen floor, and sometimes a ceiling; while the HMD includes a visual display for each eye. VR systems are immersive to varying degrees — high for HMD as the headset blocks out the external world, and medium for CAVE. Of the many conceptualizations of *immersion,* Witmer and Singer (1998) describe it as feeling "enveloped by, included in, and interacting with an environment that provides a continuous stream of stimuli and experiences" (p. 227). They posit that there are three characteristics of VR that induce immersion: its ability to isolate the experience from the real-world, the user's self-inclusion, and a user centered interaction (1998). Unlike merely watching images on a computer screen, VR allows embodied interaction, as users can change their positions by walking, and can sense sizes relative to their own body (CAVE) or avatar (HMD).

Awe and virtual reality

Chirico et al. (2018) demonstrated that virtual environments for HMD that portray vast scenes induced awe more than non-vast scenes, attributing it to the immersive experience that elicits a sense of presence.

Methods

Participants

Participants (n=69) consisted of middle school (n=20) and elementary school (n=49) students participating in a STEM summer camp serving students of historically underserved and underrepresented groups. Students were recruited via our collaboration with the institution organizing the camp. We had one session for the middle school students, and split the elementary-age students into two sessions. Each session was approximately two hours long.

Student experience

All students experienced the CAVE-based *Scale Worlds* in groups of 3–5. Up to four at a time used the CAVE and the fifth student rotated in. Middle school students also experienced the HMD version, with groups of 3–4 alternating among two headsets. Each experience lasted 15-20 minutes and involved navigating across the 20 orders of magnitude from atom to Sun. The elementary students were guided during the CAVE activity by the first author; for example, he encouraged them to walk around the virtual entities, identify continents on the virtual Earth, compare their own size to the entities displayed, and keep track of the sizes in powers of ten. The middle school students were encouraged to freely explore. Students not in the CAVE or HMD rotated in their groups among other stations with educational technology (e.g., Sphero Robots), attended by graduate students.

Data source

To assess the impact of the educational experience and inform our research initiatives, we created a survey centered around the CAVE, scale cognition, and situational interest. The survey was administered immediately following the student's experience in the CAVE. The CAVE was chosen as the focus over HMD because its version of *Scale Worlds* was further developed. The survey consisted of various questions; the one analyzed in this paper was "Did you experience feelings of awe (amazement, astonishment, or wonder) during your *Scale Worlds* experience? If so, what caused those feelings? Please describe." The survey was administered on iPads.

Analysis

The first author analyzed the literature for previously-identified factors related to awe. The first two authors independently divided these into causes and consequences of awe, and discussed their analyses until they achieved consensus. The second author then constructed an *a priori* codebook that included definitions from the literature for each code. We added an example response for each as we encountered them while coding. An abridged version is presented in Table 1.

To obtain inter-rater reliability, seven questions (10% of the data) were selected at random using a random number generator and coded using the codebook, resulting in 50% agreement. To improve reliability, both authors discussed each statement to clarify definitions, and selected examples to add to the codebook. Hypothetical example statements were also generated to further increase clarity. Another seven questions (10% of the data) were randomly selected and coded, resulting in 86% agreement. With this level of agreement, the remaining student responses were coded by the second author.

Findings

Of the 69 students, 68 (98.5%) responded to the prompt about awe. Of those, 65 (95.6%) acknowledged feeling awe, while 3 (4.4%) indicated no feelings of awe. Over half (53.8%) of the responses (n=35) simply reworded the prompt (e.g., "it was cool") or were too general or vague to code (e.g., "Being in 3D and seeing it was super awesome sauce gamers!", "It was cool", "It was weird"). The remaining 30 (46.2%) responses did indicate cause(s) of awe, and were coded as follows: 16 vastness (24.6%), 5 sublime (7.7%), 3 gap in knowledge (4.6%), 2 novelty (3.1%), 1 violates expectations (1.5%), 1 incomprehensible (1.5%). Two responses cited a cause not in the codebook (3.1%). Of the student responses, 90.7% were single coded and 9.2% were coded for two categories.

Vastness

Responses coded for vastness included both very large and very small entities. One student indicated the size of the Sun while another student identified the size of the coronavirus as awe inducing. Another student indicated a difference in scale as awe inducing, referencing that "ants are so small but planets are so big." We propose reconceptualizing this cause of awe as *vastness of scale* rather than simply vastness.

Other causes

The second most common category (8.7%) was sublime. These responses included: "Yes it was so well engineered and very realistic," "the effort people put into the technology," and "only 6 people designed a VR masterpiece." The third most common category (7.2%) was a gap in knowledge (e.g., "I never knew the worlds were that big"). Students also reported a sense of novelty (e.g., "I had never done something like that"), violation of expectations (e.g., "amazing that people really made these things"), and incomprehensibility ("surprised you could do all this stuff with small glasses")" as causes of awe. No students identified explanatory power or social importance as a cause of awe. Some students' responses resulted in novel findings. One student expanded the idea of vastness, indicating that the evolution of humans over time was a cause of awe ("caused by me realizing how much humans have evolved"). Another student discussed the degree of immersion of the technology ("It was honestly how immersive the VR and the 3d screens were").

Accommodation

While a few students referenced a gap in knowledge, no students expressed any form of Piagetian accommodation. For example, a student indicated that they "never [knew] the worlds were that big," which induced awe. However, they provided no evidence that this resulted in the revision of their mental schemata, drawing attention only to the gap in knowledge. This is interesting because Keltner and Haidt (2003) identified accommodation as a prototypical cause of awe, and most subsequent authors are aligned with this idea.

Table 1
Abridged version of codebook of a priori codes for causes of awe developed from the literature.

Cause	Definition
Vastness	"Vastness refers to anything that is experienced as being much larger than the self, or the self's ordinary level of experience or frame of reference." (Keltner & Haidt, 2003, p. 303)
Incomprehensible	"a direct and initial feeling when faced with something incomprehensible or sublime." (Reinerman-Jones et al., 2013, p. 298); "difficulty in comprehension, along with associated feelings of…surprise." (Keltner & Haidt, 2003, p. 303)
Accommodation	"Awe… entails an inability to assimilate information into existing mental structures and a resulting need for accommodation" (Valdesolo et al., 2017, p. 217)
Violate Expectations	"awe is triggered by an unexpected event… awe seems to be evoked by major violations of expectations" (Valdesolo et al., 2017, p. 217)
Novelty	"when we are faced with a vast, novel stimulus that does not fit our current image of the world" (Cruz, 2020, p. 6)
Gap in Knowledge	"awe… involves the salience of a gap in knowledge" (Valdesolo et al., 2017, p. 217)
Explanatory Power	"it may also be elicited by more conceptual contents, such as great works of art and 'grand theories' (i.e., the theory of relativity)" (Chirico, 2018, p. 1)
Sublime	"we defined awe as a direct and initial feeling when faced with something incomprehensible or sublime" (Reinerman-Jones et al., 2013, p. 298)
Social Importance	"social size such as fame, authority, or prestige… symbolic markers of vast size such as a lavish office" (Keltner & Haidt, 2003, p. 303)
Overcoming Challenges	"However, a novel finding is that teachers perceived social aspects of awe experiences. Teachers described being awed by students' social behaviors or dealing with adversity or challenging situations." (Jones et al., early view, p. 21)

Discussion

Our work contributes to the literature by clearly identifying causes of awe (as distinct from consequences), and then operationalizing them into a protocol for qualitative analysis resulting in a codebook with definitions, sources from the literature, and examples. This codebook can be used by other researchers.

Most student-described causes of awe aligned with prior literature, with two notable exceptions. First, the total absence of *accommodation.* From our data we cannot distinguish between the possibility that students did not experience the need to accommodate their mental structures, the possibility that they did experience the need but lacked the metacognition to write about it, or other causes. We do believe that even young students should be able to voice the need for accommodation using phrases like "it blew my mind" or "I realized I had to change what I thought about [one or more entities]," but perhaps they did not feel that this constituted a legitimate "cause." Future research should address this gap, by conducting interviews with students of this age group, and researching older students to observe at what age they begin to generate descriptions of accommodation.

The second exception involved student responses beyond previously-identified causes of awe. One student indicated that the *degree of immersion* in VR induced awe, suggesting a unique technological affordance. This is consistent with Chirico et al.'s (2018) finding that the general effect and sense of presence simulated by virtual environments was associated with feelings of awe. Another student indicated *vastness of evolution.*

While vastness has long been identified as a cause of awe (Keltner & Haidt, 2003; Shiota et al., 2007; Cruz, 2020), our findings suggest a reconceptualization of this cause is needed. Rather than just considering entities, spaces, distances, or experiences (whether physical or metaphorical) that are larger than one's frame of reference, *vastness of scale* including tiny objects or large differences in scale may cause awe as well.

Our study shows that even young children can experience awe in VR, opening possibilities for productive use of VR in education even at the elementary school level.

Teacher Reflective Noticing and Scaffolding for Student-Driven Knowledge-Building Inquiry

Hyejin Park, Korea Institute of Science and Technology Information, hpark7@kisti.re.kr
Jianwei Zhang, University at Albany, SUNY, jzhang1@albany.edu

Abstract: This study investigates a teacher's noticing and scaffolding in two Grade 5 science classrooms based on knowledge building pedagogy. The teacher observed students' inquiry and collaboration in the classrooms and online and kept weekly reflective journals to write about her noticing, reflection, and planning to scaffold deeper knowledge work. Qualitative analysis of the teacher's journal entries in connection with classroom data generated a detailed temporal view of the teacher's ongoing noticing, envisioning, and classroom actions, which responded to and further reshaped student-driven inquiry efforts. Through engaging in reflective noticing and envisioning of students' knowledge building progress, the teacher can devise responsive support to scaffold ever-deepening inquiry processes in which students enact epistemic agency.

Introduction

Reforms in education prioritize the need for students to develop deep knowledge and authentic practices by which knowledge is constructed (National Research Council, 2012). To cultivate authentic practices for knowledge building in science classrooms, teachers face the challenge of how to scaffold expansive inquiry processes in a way that enhances student epistemic agency for charting and reshaping the course of improvisational inquiry in a collaborative community (Scardamalia & Bereiter, 2006; Zhang et al., 2022). Existing studies have documented a wide range of scaffolding moves teachers take to facilitate students' knowledge building conversations (e.g., Hmelo-Silver & Barrows, 2008). Further research needs to better understand their ongoing pedagogical judgment and decision-making underlying their classroom moves (Horn, 2020; Watkins & Manz, 2022). Thus, the current study investigates a teacher's noticing and scaffolding in two parallel Grade 5 classrooms that implement Knowledge Building (KB) pedagogy with technology (Scardamalia & Bereiter, 2006). This study aims to produce a comprehensive and temporal account of the teacher's reflective noticing that informs her scaffolding of student collaborative inquiry. Our research questions ask: (a) What aspects of students' knowledge building work did the teacher attend to in her reflective journals? (b) In what ways did the teacher interpret the changes in student knowledge building and envision responsive classroom moves? And (c) how did the teacher scaffold student knowledge building based on her ongoing noticing and envisioning?

Conceptual and design framework

We propose a framework to guide our design and analysis of teacher noticing and scaffolding for student-driven knowledge building. Based on this framework, investigating teachers' reflective noticing and envisioning for knowledge building may demystify how teachers navigate the emergent changes and opportunities in students' inquiry work and make strategic choices to catalyze deeper conversations and sustain iterative idea improvement.

The key elements of the framework are elaborated on below.

First, teachers' reflective noticing and scaffolding revolve around student-driven knowledge building processes, treating students' authentic problems and evolving interests and ideas as the center of classroom dynamics (Scardamalia & Bereiter, 2006). Teachers use an open-ended approach to classroom planning: identifying *big ideas* and challenging issues in a curriculum area, sketching an overarching picture of how the collective inquiry may get started and evolve while leaving the detailed actions and processes open to be co-improvised with students as they step in the scene (Zhang et al., 2022; Zhang & Messina, 2010). Second, our framework highlights three interconnected elements of reflective noticing and scaffolding: Attending, Interpreting, and making pedagogical Moves (A-I-M). While these elements have been identified in the literature on teacher noticing (Barnhart & van Es, 2015), our framework further aligns such teacher efforts with student-driven action and agency for deepening collaborative inquiry and discourse. Specifically, in a knowledge building community, teachers need to (a) attend to students' evolving ideas and inquiry practices to detect dynamic information about what is going on and what is new and emerging; (b) interpret the classroom information to understand how students are thinking now, in relation to their work in the past and potential idea development in the future; and (c) in response to the evolving landscape of ideas, envision strategic pedagogical moves (choices), which catalyze or leverage student-driven efforts to further their collaboration and inquiry. Third, teachers' attention, interpretation, and pedagogical moves are guided by the core principles of knowledge building. For example, guided by the principles of *authentic problems, real ideas*, and *continual idea improvement*, teachers are attentive to students' evolving problems and ideas generated in personal and collaborative works. Capturing such information helps teachers make timely and intentional moves to advance students' knowledge building efforts.

Classroom context

This study was part of a larger project to explore classroom designs and technology for student-driven knowledge building in science at a public elementary school in the Northeastern U.S. The participants included one teacher, Mrs. G, who taught science in two Grade 5 classrooms, including her homeroom class (classroom G) and Mrs. W's class (classroom W). Mrs. G taught for over 20 years and was in her third year of teaching science based on KB pedagogy. There were 21 students in each classroom (20 boys and 22 girls), who were 10- to 11-year-olds and came from diverse ethnic backgrounds. In the school year of this study (2015-2016), Mrs. G worked with the students to study human body systems over eight months as part of their science curriculum. There were two science lessons every week, each lasting for 40 minutes.

In mid-September, students participated in the kick-off activities, each of which required them to complete a challenging task about various body parts. In the following science lesson, students from each classroom participated in a reflective conversation called a metacognitive meeting (MM), in which they shared a wide range of questions and, as a whole class, built shared interests in understanding the functions of the human body. Then, students with interrelated interests and questions worked together to formulate an overarching question to guide their inquiry in a shared "wondering area." As their discussion proceeded, they formed a spontaneous group with those having similar interests and conducted personal and collaborative inquiry activities. Major questions, ideas, and findings generated through the face-to-face activities were contributed to Knowledge Forum for online discourse. In the classrooms and online, Mrs. G worked as an attentive listener to understand students' interactive questions and ideas while offering support to help students further their inquiry and refine their collaboration. She kept a weekly reflection journal designed based on our conceptual framework to record her observation ("I notice…"), interpretation ("I think…"), and responsive planning ("In the following week(s)…").

Data source and analysis

The core data source was Mrs. G's weekly reflective journals. The teacher recorded 27 reflective journals to reflect on student inquiry in the two classrooms. Her journals contained 172 journal entries, including 92 entries reflecting on the inquiry work in her home class (classroom G) and 80 for classroom W. We analyzed Mrs. G's journals in connection with several other data sources, including classroom observations of students' inquiry activities and the archive of student online discourse in Knowledge Forum. We observed each science lesson during the human body inquiry and video/audio-recorded the major classroom activities, such as whole class metacognitive meetings.

To address the first two research questions, we analyzed Mrs. G's reflective journals using a grounded theory approach to understand what aspects of student inquiry the teacher attended to, how she interpreted, and the classroom moves she envisioned in response. Each entry (row) of reflection (i.e., an A-I-M set) was considered a unit of analysis. The first author read the journals multiple times to develop a general sense of Mrs. G's reflection. Then, she worked with the second author to develop initial open codes (raw codes) using a subset of reflection journals as applying open codes to characterize Mrs. G's reflection. The two co-authors then discussed the open codes and the related examples, reflected on the meaning and consistency of the codes, and refined the labels and definitions better to capture the teacher's points of observation and thinking. Through multiple rounds of discussions, the authors compiled an initial codebook and then reviewed all the open codes and examples to formulate salient themes that characterized Mrs. G's attention, interpretation, and planning of classroom moves. In the final analysis phase, the authors searched for connections across the themes of A-I-M sets, identifying how Mrs. G interpreted the observed knowledge work and considered various pedagogical moves. To address the third research question, we further examined Mrs. G's noticing points and scaffolding moves in the temporal context of student knowledge building processes in the actual classroom events, discovering patterns of teacher scaffolding that built on and further shaped student inquiry actions.

Results

What aspects of students' knowledge building work did the teacher attend to?

Through coding Mrs. G's writing in the column of "I notice...", we identified six salient categories (themes) representing what the teacher attended to when observing and monitoring student knowledge work as individuals, groups, or a whole class. As the most salient points of noticing, Mrs. G observed students' individual and collective efforts of ongoing idea improvement in existing lines of inquiry (A-2, 37.21%) while paying attention to the emergence of new inquiry interests and directions (A-1, 23.26%) and monitoring gaps in inquiry and contribution (A-6, 2.33%). She was also attentive to students' specific inquiry activities, emotions, and needs (A-3, 16.28%), their use and generation of resources and tools to support inquiry (A-4, 6.98%), and the meta-talk among students about knowledge building practices and norms (A-5, 2.91%).

In what ways did the teacher interpret new changes in student knowledge work and envision responsive moves?

The teacher's interpretation and sense-making of what was going on

Nine themes emerged from the coding of the teacher's journal writing in the "I think…" section, which recorded her interpretation and analysis of what was going on in student knowledge work. Mrs. G's pedagogical analysis and sense-making centered on understanding students' personal intent, needs, and emotions (I-6, 30.23%) while comprehending and appreciating their progressive ideas (I-1, 25%) to discern emergent opportunities and needs for further idea improvement and collaboration. As the related considerations, Mrs. G also reflected on specific gaps in student inquiry and idea contributions (I-9, 5.81%), analyzed potential opportunities for deepening ideas (I-2, 2.33%), expanded collective inquiry (I-3, 0.58%), and assessed the clarity of student ideas (I-5, 1.16%). She examined potential connections between different concepts and areas of inquiry (I-4, 3.49%), reflected on how students used and created resources/tools in their knowledge work, including their needs for support (I-7, 3.49%), and analyzed student knowledge building practices and norms reflected in the classrooms and online discourse for possible improvement (I-8, 2.91%). In her pedagogical sense-making, Mrs. G often positioned the specific events she had observed in the larger context of the core disciplinary ideas in the curriculum area, the past and future of the human body inquiry of the whole classroom community, and the knowledge building principles and norms.

The teacher's planning of responsive classroom moves

In light of what was going on in student work, Mrs. G envisioned ways to enhance student knowledge building in the coming week(s). Nine categories of classroom moves that the teacher envisioned. The most salient moves focused on (a) supporting students' needs to improve their learning experiences and enhance their knowledge building practices (M-6, 19.19%), such as by offering suggestions to individual students on note writing or meeting with a small group to address their needs, and (b) facilitating idea connection and collaboration among students (M-4, 12.79%), such as by highlighting a student's Knowledge Forum note during a metacognitive meeting for further discussion or pairing students who had posted interconnected questions to work as a group. As the relative classroom moves, she envisioned specific ways to continually trace students' inquiry progress and contributions and explore the further directions of the community's inquiry (M-9, 8.72%); to foster students' deeper understanding of concepts through continual inquiry efforts (M-2, 8.14%); to form new inquiry directions with students (M-1, 6.98%); to broaden the sharing and spread of inquiry progress (M-3, 4.65%), while supporting student use of resources/tools (M-7, 4.65%), knowledge building practices and norms (M-8, 4.07%), and misunderstanding (M-5, 2.33%) as needed.

How did the teacher scaffold student knowledge building based on her ongoing noticing and envisioning?

Our analysis investigated the dynamic links between what the teacher captured from student work, her envisioning/planning of responsive teacher moves, and the actual classroom processes that followed. For a temporal view, this analysis zoomed in two time periods: (a) from October to November 2015, when students were initiating their inquiry works on the various human body topics and establishing their knowledge building practices as a whole community; and (b) in December, when the classroom members continually reflected on their ongoing inquiry and worked on new opportunities to deepen and expand their knowledge. For each period, we identified and traced the co-occurrence of various themes of A-I-M associated with each row (entry) in Mrs. G's reflection journal.

For instance, we unpack one of the patterns: tracing ongoing student efforts in the unfolding lines of inquiry to enhance idea improvement, build connections, and address knowledge gaps. Students in each classroom co-formulated an initial set of wondering areas at the beginning of the human body inquiry, which guided students' personal and collaborative knowledge building. Mrs. G continued observing how student thinking deepened in each inquiry area (A-2), attending to student-generated inquiry interests, ideas, and activities. Anchored in what she had observed, Mrs. G engaged in pedagogical sense-making to understand students' progressive ideas and questions (I-1) and analyze potential opportunities/needs for students to further deepen their thinking (I-2). Based on that, she (a) facilitated deeper inquiry and understanding of concepts (M-2); (b) facilitated student collaboration and idea connection (M-4); (c) spotlighted the inquiry progress and ideas of an individual or a group of students to facilitate broader sharing and discussion (M-3); and (d) addressed misunderstandings reflected in students' work (M-5). From December, the teacher continued to observe students' ongoing efforts in the existing lines of inquiry to understand students' evolving ideas (I-1) while pondering their intentions of inquiry and needs for support (I-6). Such pedagogical analysis and sense-making helped the teacher to envision responsive moves to support student idea improvement and build connections across the various lines of inquiry (M-2, M-3, M-4) while addressing students' specific needs (M-6). As Mrs. G monitored students' ongoing progress, she also detected missing concepts yet to be incorporated in student discourse (A-6) and reflected on possible ways to bring such concepts to student attention (I-9), building on the questions and ideas they had generated online or in classroom-based activities. Instead of redirecting students to teacher-specified directions, the teacher built on student ideas and inquiry practices to introduce her responsive input. Students' inquiry works and artifacts were used as examples to facilitate meta-talks about how they should carry out their knowledge building as a community, leading to more elaborate inquiry practices, tools, and classroom norms.

Conclusion and implications

This study suggests that principle-informed reflective noticing and envisioning may function as a dynamic process that teachers can leverage to support student-driven knowledge building practices in science and potentially other content areas. Ongoing reflective noticing of student knowledge work, guided by the core principles of knowledge building pedagogy, reveals ever-emerging opportunities for further advancing students' inquiry and collaboration. Teachers then interpret and respond to such opportunities by devising possible classroom moves, which help catalyze students' epistemic efforts to develop deeper inquiry and discourse on an ongoing basis. Following each major classroom effort to reshape the community's inquiry works in specific ways, teachers co-engage in the subsequent knowledge building activities and discourse with students to observe how student inquiry efforts further evolve. Thus, teachers' reflective noticing and responsive scaffolding unfold as an iterative and recursive process over time as students' knowledge building proceeds (cf. Watkins & Manz, 2022). Given the challenging nature of teacher noticing in a constantly changing classroom environment, it is important to design classroom-oriented analytical support that can enhance teachers' ongoing noticing of students' dynamic inquiry in a collaborative community (van Leeuwen et al., 2019). The conceptual framework and empirical of this research may inform designs of the support and professional development resources aimed at helping teachers master the art of reflective noticing and scaffolding for collaborative knowledge building.

Abstract: This is a work-in-process research project aiming at examining the design of Knowledge Building professional development (KBPD) to foster university instructors' conceptions of teaching and learning and teaching practices. 10 instructors from the same university joined this study. Multiple sources of data were collected, including surveys, classroom and online artefacts, and interviews. Analysis of pre- and post-surveys showed that the participants hold more constructivist conceptions about teaching and learning after attending KBPD. The classroom reflection artefacts showed that they were more inclined to apply the KB principles in their own classes, and that they regarded the epistemological role of their students have shifted more towards knowledge constructors/creators in their classrooms after attending the KBPD. Interview analysis further showed in what ways they have changed their conceptions and perceived practices. Implications for future design of KBPD were discussed.

Introduction

This is a work-in-process research aiming at examining the design of Knowledge Building professional development to foster university instructors' conceptions of teaching and learning and teaching practices.

Knowledge Building is one of the computer-supported collaborative models in education (Scardamalia & Bereiter, 2014), emphasizing students taking collective cognitive responsibility to advance their community knowledge (Scardamalia, 2002). Knowledge Building has been widely studied and researched in K-12 education. Many existing Knowledge Building research has focused extensively on the role of Knowledge Building in fostering students' collaboration, learning, and cognition (Chan, 2013; Lin & Chan, 2018; van Aalst & Chan, 2007; van Aalst & Truong, 2011; Zhang et al., 2009; Zhao & Chan, 2014), whereas comparatively less is known about how Knowledge Building might support teacher learning. Even though there are initiatives to foster Knowledge Building teacher communities (e.g., Chan, 2011; Teo et al., 2021), and some also examined the role of Knowledge Building discourse in supporting pre-service teachers' learning (e.g., Chai & Tan, 2009; Hong & Chai, 2017), few studies have examined the design and impact of professional development (PD) on Knowledge Building for university instructors.

Teacher PD plays an important role in enhancing the teaching and learning in higher education. Effective PD could improve teachers' conceptions and practices, and therefore enhance students' learning (Fishman et al., 2014). In this project, we designed a Knowledge Building professional development (KBPD) program for university instructors, and we aimed to examine its impact on their conceptions and perceived practices. Specifically, we addressed two research questions: 1) Did the instructors change their conceptions of teaching and learning and views of Knowledge Building after attending the KBPD? 2) To what extent have the instructors changed their perceived teaching practices after attending the KBPD?

Methods

Participants and contexts

Participants are 10 university instructors (full-time faculty staff, N = 3; part-time instructors, N=7) in a public autonomous university in Singapore recruited through an invitation email sent to all instructors. The participants' age ranged from 31 to 65 years old ($M = 51$, $SD = 11.6$), with 3 female instructors and 7 male instructors. They had varied disciplinary backgrounds (e.g., Business, Law, Humanities and Social Sciences) and education levels (33.3% bachelor's degree, 33.3% master's degree and 22.2% PhD). Their teaching experiences ranged from 4 to 23 years. All participants did not have prior experience with Knowledge Building, but they had used other asynchronous learning tools in their classes (e.g Padlet, Miro).

Instructional design

The design of KBPD program was informed by Knowledge Building pedagogy and experiential learning, with the aim of fostering a Knowledge Building community. It included three successive synchronous sessions (each

3 hours) and asynchronous learning in-between, covering theory, practice, and reflection. Besides Knowledge Building principles (Scardamalia, 2002), a few other principles have also guided the design of KBPD program: 1) Activate prior pedagogical stances. Similar to the general conceptual learning where articulating prior knowledge is important, to help instructors change their conceptions of teaching and learning, it is important to let them articulate their prior pedagogical ideas. 2) Articulate epistemic goals for teaching. Epistemic goals are fundamental in influencing one's practices (Chinn, et al., 2011). To help instructors make sense of knowledge building, we tried to link their own epistemic goals with the epistemology of Knowledge Building. 3) Situated learning. KB is a principle-based approach, and it does not have predefined fixed steps for teachers to follow (Hong & Chai, 2017; Scardamalia, 2002). Therefore, to help instructors learn about Knowledge Building, we drew upon situated learning theories (Lave & Wenger, 1991) and engaged them in the Knowledge Building process themselves, including posting questions, constructing explanations, building on each other's ideas and continually improving their ideas online and offline.

The first session started with instructors' reflection of their current teaching practices. They were asked to articulate and elaborate where they were and where they wanted to move in terms of students' epistemological roles, ranging from learners as knowledge receivers to learners as knowledge co-constructors and creators. This led to the common goal of achieving idea-centred knowledge creation. Then KB was introduced as a pedagogy to achieve the common goal. The trainer discussed the rationales of KB, what KB looks like, and the principles of KB. Four principles were highlighted throughout the workshop, including authentic problems, improvable ideas, constructive use of new information, and epistemic agency. While only four principles were highlighted, other principles were infused and embedded across the PD process. The participants were also provided with a worksheet which asked them to rate the extent to which they thought the principles were important and were applied in the classroom. Following this self-reflection, they discussed in small groups about how they could use these principles to tweak their current teaching practices. Knowledge Forum, a computer supported platform for supporting Knowledge Building, was introduced to support their collective online inquiry.

In Session two, participants were asked to identify the promising ideas/questions in their online and offline inquiry, and then they engaged in a Knowledge building talk (Reeve et al., 2008) to further pursue inquiry on the identified questions. Knowledge building assessment (Lee et al., 2006; van Aalst & Chan, 2007) was also introduced, and the participants were asked to write portfolio notes to reflect on their collaboration and community knowledge based on the four KB principles. In the second half of the session, they worked in small groups to redesign a regular course (provided by participants) into a KB class informed by KB principles.

Session three focused on practice and reflection. There was a two-week gap between Sessions 2 and 3. Between which, the participants were expected to apply some of the KB principles and strategies in their own classroom. For the participants who were not teaching during that period, they were asked to redesign one of their courses with KB pedagogy and bring the redesign back to session three to share. During session three, two guest speakers who had extensive KB experiences were invited to share their KB practices with the participants. Building on the learning points from the workshop and the guest speakers, the participants worked in small groups to share and finetune their own KB designs. In the end, the participants were asked to reflect on their current teaching practices similar to what they did in the first session.

The participants were encouraged to write on Knowledge Forum between the sessions. Considering they are working adults who have various commitments, we also provided opportunities for them to write on Knowledge Forum during the sessions.

Data source

Conceptions of teaching and learning

To assess participants' conception of teaching and learning at pre- and post-tests, we adopted Teaching and Learning Conceptions Questionnaire (TLCQ) from Chan and Elliott's (2004). The TLCQ has 30 Likert Scale items (1-5) which measures two major dimensions: Traditional Conception of teaching and Constructivist Conception of teaching.

Views of Knowledge Building

As mentioned, participants were given a worksheet to reflect on their understanding of KB in the first and last sessions. The worksheet was both a reflection tool and also a measurement of their views of KB. It was adapted from Hong et al's (2011) instrument for measuring students' views on the importance and feasibility of KB (Likert scale: 1-5). As our participants were instructors, we changed the feasibility to application. In other words, instead of asking participants to rate the extent to which they think the principle is feasible, we asked the participants to rate the extent to which they have applied the principles in their classes. The pre- and post-worksheet were collected to understand the change of their views of KB.

Perceived teaching practices

In both the first and last sessions, participants identified where they were in their teaching practices, and these data were collected to examine the change of their perceived teaching practices. In addition, we also conducted individual interviews one month after the KBPD to understand how the program has impacted their teaching practices. We also asked them to elaborate further on why they put themselves in a certain place in the spectrum in the first and last session, and how their current teaching is different from their previous teaching (before attending KBPD). Thematic analysis was conducted to identify the themes and patterns associated with the change.

Preliminary findings

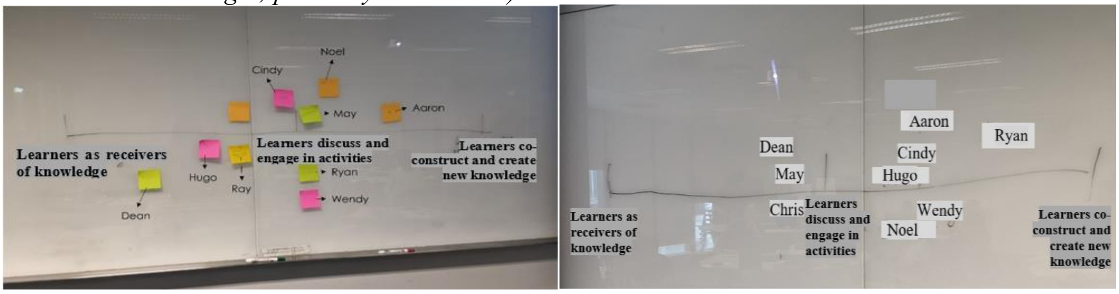
We conducted paired sample *t*-tests to analyse participants' conception of teaching and learning before and after the PD. There was no significant change in traditional conceptions before (M = 2.22, SD = .36) and after (M = 2.15, SD = .43) the KBPD. However, the participants' constructivist conceptions were significantly higher after the KBPD (M=4.21, SD=.40) as compared to before the workshop (M=4.06, SD=.42), $t(8) = -2.71$, $p < .05$. These findings demonstrated that the participants held more constructivist conceptions about teaching and learning after the KBPD, while their traditional conceptions remained the same.

We also conducted paired sample *t*-test to examine participants' views of KB principles, results showed that there was no significant difference in the perception of the importance of the knowledge building principles before (M = 4.17, SD = .47) and after (M = 4.25, SD = .50) the workshop, $t(5) = .79$, $p > .05$. However, a significant difference was found in the perception of their application of the knowledge building principles before (M = 3.57, SD = .13) and after (M = 3.88, SD = .26) the KBPD, $t(5) = 3.80$, $p < .05$. This indicated that they were more inclined to apply the KB principles in their own classes after the KBPD workshop, however, their understanding of the importance of the KB principles remained unchanged. This is probably due to their extensive teaching experience in higher education and they have already perceived KB principles as important prior to the KBPD program.

We also compared their perception/reflection of their teaching practices in the first and third session of the KBPD. As Figure 1 shows, most of them moved themselves towards the right side of the spectrum to a certain degree, except Noel and May. In the follow-up interview May clarified that she misunderstood the question asked and she should put herself in the same place as the first one. This suggested that in most of the participants' classroom, the epistemological role of their students have shifted towards active participants and knowledge co-creators.

Figure 1

Participants' reflection of their teaching practices in the first and last session (first session on the left and last session on the right; pseudonym were used)



Our preliminary interview analysis also showed in what ways they changed their conceptions of teaching and learning and teaching practices after the KBPD. While each of them perceived different changes, these changes showed that they were more aligned with constructivist approach and Knowledge Building. For example, while asked to describe their previous and current teaching practices, Cindy mentioned: "*[before] We[I] wanted students to participate and to answer questions. But I think, after the workshop you[I] realize that it's actually better if you[I] ….[encourage] students to think on their own and come up with their own questions".* This excerpt suggested Cindy has just started to realize the importance of students' questions in learning. Before it was mainly her asking questions, and now she planned to give more agency to students and encourage them to ask questions. Another participant (Hugo) mentioned how the KBPD has transformed him from merely one-way lecturing to providing students with opportunities to learn from each other: "*You know. We just teach, teach and tell, tell and lecture, lecture… I think being students they have to rely on whatever is given… but with this new methodology in place, the students not only learn from me but also from other students. So they sort of inevitably expand their sources and their levels of information that they can receive...*"

For participants who have been using constructivist approaches in their classes, they have even further deepened their understanding of constructivism and knowledge building. For example, one law lecturer mentioned that while he learned about the principle of "authentic problem", his immediate thought was that he had been using it in his classroom as they had lots of authentic law cases. Later he was questioning himself, "*the problem is very authentic but do the students see that it is authentic*". Soon he started to realize that if students could come out with problems they have seen or experienced, it would be even more authentic.

Discussion and conclusion

This study provided some preliminary insights about the impact of designed KBPD on university instructors' conceptions and perceived teaching practices. Previous studies that examined the role of KB in teacher learning mainly focused on teachers' online discourse (e.g., Chai & Tan, 2009; Hong & Chai, 2017). Our study extended previous studies by focusing on examining the design of PD on Knowledge Building and its impact. These university instructors are working adults who mingle between work and life and have various responsibilities and commitments. They usually have limited time for continual professional development. Our study showed the possibility of enhancing their conceptions and perceived teaching practices with three intensive KBPD sessions across one month.

Even though our PD focused on Knowledge Building, each participant seemed to have their own pace and their own ways of moving towards Knowledge Building. While their changes were not huge, we still regard the results as quite promising as they only went through a short intervention. As mentioned, this is a work-in-progress research project. Moving forward, we will further examine these instructors' learning process (e.g., online and classroom dynamics), to unpack how their change took place and how the designed learning environment had facilitated their change.

What If Interaction Fails?
A Comparison of a Virtual and a Physical Learning Environment for Learning About Areas of Parallelograms

Eva-Maria Ternblad, Dept of Cognitive Science, Lund University, eva-maria.ternblad@lucs.lu.se

Abstract: In what ways do virtual and physical interactive learning environments differ, what type of affordances or constraints may affect the use of them, and might this use influence learning and understanding? To address these questions, a physical material, designed to teach areas of parallelograms, was translated into an application with virtual manipulatives. The material (a virtual/physical frame and a virtual/physical deck of cards) was tested on 71 adults with different levels of prior knowledge in geometry. The participants followed instructions and performed exercises during a 15-30-minute session and thereafter took a test. The results show that many novices failed with one specific virtual interaction, which in turn had a significant negative effect on their learning outcomes. The findings also indicate that a material's effectiveness may not necessarily depend on if it's virtual or physical, but instead on the learner's prerequisites to use it and succeed with critical actions.

Introduction

Over recent years, and especially during the Covid-19-panedmic, there has been a rapid increase in virtual learning environments. But despite the perceived overall potential of such tools, their effect on learning is still unclear (Rau, 2020; Stull, 2013). Apparently, which material is most appropriate for learning depends not only on the medium itself, but also on the academic or work-related subject, the specific design, its content, and so on. Here, digital tools can afford valuable qualities, visualizing attributes and relations that are hard to perceive in reality, but also constraints, where irrelevant aspects of the real world (color, texture, size etc.) may be filtered out. At the same time, by digitalizing concrete artefacts, some properties (weight, force, dimensions, and so on) are infallibly lost. This changes the prerequisites for perception, interaction, and knowledge building.

A specific type of learning material is so-called *instructional manipulatives,* often used in STEM education (Pouw et al., 2014; Rau, 2020; Stull, 2013). Even if such material often is concrete, some researchers claim that it is not the actual *physicality* of these manipulatives that is important, but the possibility to interact with representations in a meaningful way (se for instance Sarama & Clements, 2009). However, with a more embedded perspective on cognition and learning (Kirsh, 2010; Pouw et al., 2014; Sawyer & Greeno, 2009), we may argue that physical manipulation offers a perceptual richness that not only may off-load working memory but also strengthen multimodal memory traces – all important aspects when we are trying to learn.

In this experiment, we have chosen to study understanding of geometry – an important subject where learners develop a series of skills, such as spatial reasoning, logical argumentation and proof (Battista, 2007; Jones & Tsekaki, 2016). School geometry is often taught by letting students interpret, measure, and draw standard figures with basic tools (pen, paper, ruler, compass, protractor). But, as several theorists and researchers have pointed out (Battista, 2007; Leontiev, 1978; Piaget & Inhelder, 1945), reshaping and reinterpreting geometrical objects may also be fruitful for learning. And since geometry – or at least Euclidian geometry – is profoundly anchored in our physical and spatial reality, one might expect that this subject would benefit from manipulating this reality (or virtual copies of it).

Being interested in how the understanding of geometrical relations can be mediated through transformations of a structured material, Sayeki and colleagues (1991) tested a method for teaching middle-school students about areas of parallelograms. In this study, students worked during 5-6 lessons with two manipulatives: a tile of paper sheets and a paper frame, reshaping them into different parallel figures. The students hereby learnt that the formula for the area of a parallelogram was the same as for the area of a rectangle (that is, the base times the height). This teaching method was concluded to be very effective, leading to a deep understanding of areas of parallelograms with different shapes (ibid.). A question that arises, in the present era of digitalization, is if this kind of manipulatives could be transformed into virtual ones without losing the supportive effect with respect to the learner's geometrical comprehension. Subsequently, the main goal of the present study was to evaluate such a transformation, by formulating the following research questions: i) Does the interaction with physical and virtual manipulatives, aimed to teach about areas of parallelograms, differ? In what way? ii) Do the materials mediate learning and conceptual understanding of the geometrical principle that is being taught? And does one material succeed better in doing so?

Method

The research questions were addressed by setting up an experiment with two variants of a stimulus – one physical and one virtual – inspired by Sayeki et al's (1999) material described above. The GUI was tested on a Swedish 6th grade in fall 2020 with interesting findings (Ternblad, 2022). However, due to the Covid19-pandemic, no visits at schools were allowed after this pilot. We therefore decided to address a broader adult population and to conduct the study in a controlled laboratory setting – well aware of the risk with attracting participants with too much prior knowledge. But, even if the concept of area often is taught as early as elementary school, many adults seem to struggle with understanding basic geometrical rules (Ojose, 2011). In addition, studies on adults' geometric knowledge are rare, and exactly how well these skills are preserved later in life is not well known (ibid.). Hence, studying this target group could also be of interest, even if the original material was designed for younger students.

Materials

In the physical condition, the participants used a concrete material (Figure 1) together with written instructions on paper and a set of papers with the correct answers. The participants started with interacting with the deck of cards, shaping different figures, drawing two-dimensional pictures, answering questions and correcting them. They were then given a frame with articulated corners with the same base as the cards but a bigger height. The participants inserted the cards inside the frame and were asked if they thought it would be possible to tilt the frame so that the cards would fill it. After guessing, they were instructed to try it out. The lesson ended with more questions regarding the properties of the frame and the deck of cards and how to calculate areas of parallel figures.

In the virtual condition, the application consisted of a two-dimensional digitized version of the card-and-frame-materials described above (see Figure 1), specifically designed for this project. The test persons interacted with the virtual frame and the virtual deck of cards, saving the figures on the screen. They completed the same exercises and answered the same questions as in the physical condition but received immediate automated feedback (right/wrong).

Figure 1

Presentation of the physical material (left) and the virtual interface (right).

Do you think it it would be possible to tilt the frame so that the cards would fill it entirely?

Participants and procedure

Participants were recruited online, where the experiment was described in loose terms without any references to geometry and mathematics (trying to avoid scaring people off). All participants filled in an informed consent at arrival, before taking part in the study, but after being informed about its specific content (i. e. geometry calculations). The entire experiment contained 4 parts: a pretest, a session with the learning material, a post test, and a brief interview. The participants interacted with the material at their own pace. Hence, the time for the procedure varied between 40 and 60 minutes depending on the participant's interest, carefulness, and expertise.

Pre- and posttest

All participants conducted a pre-test with questions on formulas for standard figures as well as questions aiming to assess their overall geometrical understanding, such as "Is it possible for two rectangles to have the same area but different perimeters?". The post-test contained area calculations for parallel figures (64%), checks for over-generalization (18%), and questions on how a frame – slightly different from the one in the exercises – could be tilted (18%).

Data gathering

The experiment was conducted from February to September 2021 in Sweden, during the Covid-19-pandemic. At this time, all experiments had to be conducted with only one test person and one researcher present. No body-mounted equipment was allowed, and the researcher and participant had to maintain a minimum distance of 2 meters. Since the screen activities in the virtual condition were impossible to observe from where the researcher was seated, these participants were told to speak out if they had any problems with the virtual interaction. The observations in the physical condition were simplified to a hands-on-protocol, writing down time slots (minutes) for different tasks, number and type of interactions etc. In the virtual condition, all screen activities were recorded.

Results

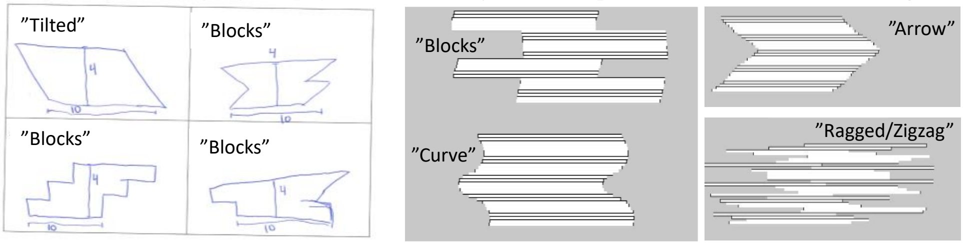
In total, 71 test persons (31 males and 40 females), with an age between 20 and 50 years (*median* = 35) participated in the study. No data had to be excluded. The result on the pre-test for the virtual condition were normally distributed, as per Shapiro-Wilk's test ($W = .95$, $p = .14$), but the result for the physical condition was not ($W = .86$, $p < .001$). The physical group (N=36, *mean* = .75, *median* = .83, SD = .25) also contained more participants with higher scores than the virtual group (N=35, *mean* = .72, *median* = .75, SD = .17). However, a Mann-Whitney's U-test revealed no significant difference between conditions ($W = 515$, $p = .21$).

Interactions with the deck of cards

The interactions differed between conditions in several ways. The participants in the physical condition produced fewer shapes with the deck of cards (N=36, *mean* = 4.7, *median* = 4) than the participants in the virtual condition (N=35, *mean* = 6.0, *median* = 5). The number of shapes for the virtual condition were close to normally distributed, as per Shapiro-Wilk's test ($W = .94$, $p = .07$), while those for the physical condition were not ($W = .89$, $p < .01$). A Mann-Whitney's U-test revealed a minor but still significant difference between conditions ($W = 825$, $p < .05$). In addition, the two conditions resulted in slightly different types of figures, and not all drawings of the physical deck of cards were perfect (see Figure 2).

Figure 2

Examples of drawings of the physical cards (left) and shapes with the virtual cards (right).



Interactions with the frame (and cards and frame together)

When analyzing the screen activities, it became clear that several participants in the virtual condition had problems with interacting with the frame, and in some cases, they gave up tilting it. This behavior was even more articulated when the virtual deck of cards was inserted into the virtual frame, and some participants treated the partly filled frame as a rigid object. In contrast, the physical group interacted with the frame very easily, and often pressed it quite far down, both when it was empty and when the cards were in it.

In sum, 40% of the participants in the virtual condition failed with properly tilting the frame and cards together, compared to 8% in the physical condition. A chi-square test of independence revealed a significant relationship between a successful tilt and condition: $\chi^2(1, N_{Dig,} = 35, N_{Phys} = 36) = 9.8, p < .01$. When looking at the participants failing with the tilt (or choosing not to perform it properly), these had a pre-test score on 0.63 (on average). This is clearly below the mean value for pre-test scores in both conditions.

Result on post-test

The result on the post-test was, as per Shapiro-Wilk's test, barely normally distributed for the virtual condition ($W = .95$, $p = .13$), but not for the physical condition ($W = .87$, $p < .001$). And even if the proportion of correct answers were slightly higher in the physical group (N=36, *Mean* = .80, SD = .19) than in the virtual one (N=35, *Mean* = .71, SD = .20), a Mann-Whitney's U-test revealed no significant difference between conditions ($W = 471$, $p = .07$).

To investigate if the performed interactions and/or the pre-test scores could have had an impact on the result, the following independent variables were used to formulate a linear regression model with post-test scores (*PostScore*) as dependent variable: Pre-test scores (*PreScore*), physical or virtual condition (*Cnd*), number of interactions with cards (*CardInt*), successful tilt of frame and cards together (*CardFrame*), as well as interaction effects between *Cnd*, *CardFrame* and *PreScore*. The best linear regression model was then fitted to the data set in a step-wise-step up procedure and resulted in the following: $PostScore = 0.33 + 0.44 \times PreScore + 0.15 \times CardFrame$. The overall model was statistically significant, but had a weak fit ($R^2 = .39$, $F(2, 68) = 21.4$, $p < .001$). Apparently, to succeed on the post-test, the participants had to i) have enough prior knowledge in geometry, ii) succeed with tilting the frame and cards together. If not, they learned less about areas of parallelograms during the session.

Discussion

The goal with the present study was to test the hypothesis that a virtual and a physical material – designed to mediate the understanding of the areas of parallelograms – would lead to different learning outcomes. We based this idea on an embedded perspective on cognition and learning, claiming that multimodal actions in the world may off-load cognition (Kirsh, 2010), as well as facilitate the understanding of abstract concepts (Pouw et al., 2014). Consequently, different types of interfaces could, due to different constraints and affordances, make the learner reshape the materials in different ways, but also give him/her different perceptual input from the materials themselves. Both these aspects might affect cognition and learning.

In this particular case, some of the virtual interactions differed from the physical ones, and several participants – significantly more so in the virtual condition – failed with tilting the frame and cards together. Such unsuccessful interactions had a negative impact on the participants' understanding of parallelograms and how to calculate them. The difficulties with tilting the virtual frame were primarily due to flaws in the design of the virtual interface, but a lack of prior knowledge in geometry also seemed to have an influence. Still, these failed interactions led to insights about how certain manipulations of a material may have a strong impact on the understanding of a concept, and thereby overshadow the significance of other variables – such as the number of shapes created with the deck of cards and the concreteness of the material as such (virtual or physical).

According to theories on embodied cognition, multimodal perceptual traces (including sensory input, motor schemas and body posture etc.) constitute core entities of human thinking and understanding. However, it might be the case, that the main function of such processes is to facilitate interaction, not the mere perception per se. The conclusion that the actual physicality of a material might be less important than its manipulability is in line with previous studies (Sarama & Clements, 2009; Stull, 2013). In the study by Stull et al. (2013), however, the lack of constraints in the physical condition (compared to the virtual one) lead to less learning gains. Thus, exactly when and how different affordances may support learning ought to be further investigated.

It also appears as if the interactions with the frame (and the frame and cards together) functioned as a necessary *complement* to the interactions with the deck of cards alone, giving the learner an additional perspective on parallelograms. This highlights the value of using more than one representation for describing the same concept – which is in line with theories on the value of multiple analogies (Gick & Holyoak, 1983). This would be of interest to study in more detail too. Finally, the results of this study reveal learning as a multifaceted process. Hence, research scrutinizing the use of instructional manipulatives could not only teach us more about how to design and utilize interactive learning environments, but also provide insights about human cognition as a whole.

Taking and Getting Perspectives on Controversial Topics: How Does It Change Attitudes and Affect Learning?

Paulo J. M. Santos, Armin Weinberger
p.santos@edutech.uni-saarland.de, a.weinberger@edutech.uni-saarland.de
Saarland University

Abstract: Scenarios of argumentative knowledge construction often challenge learners to argue for perspectives dissonant to their own and are geared to prepare learners for debating divisive topics on text-based social media. Perspective-related approaches that aim to evoke empathy for the other side of the debate have a potential impact on learning and on attitudes in such scenarios. With this 2×2-study ($N = 421$), we investigate the near and far-transfer impact and interaction of perspective-getting (with vs. without) and perspective-taking (with vs. without), in a text-based medium, on subjective learning gains, argument elaboration, attitude change, speciesism value, health and environmental beliefs, as well as attitudes towards outgroups and towards other eating habits. Results show significant main effects of perspective-taking for attitude change, self-reported learning, and argument elaboration. No effect of perspective-getting or interaction effects were found.

Controversial topics and attitude change in education

Socio-scientific topics of interest are often controversial and society tends to be divided on them (Kauppi & Drerup, 2021). Present days' controversies are, for instance, the need for vaccination, climate change, use of nuclear power, the right to abortion, immigration policies, or vegetarian eating habits – the topic of the study at hand. These rich debates find a place in informal as well as in formal civic education, i.e., in school curricula within deliberative democracies (Hess & McAvoy, 2014; Oulton et al., 2004). Argumentation practices have been found to not only facilitate comprehension, but also promote epistemic growth, conceptual change, and attitude development on these debates (Chinn et al., 2021; Valladares, 2022; Vosniadou, 2012). Promoting argumentation around controversial topics can be relevant for fighting misinformation, avoiding oversimplification of complex issues, and promoting an open frame of mind that allows for productive outcomes from debating them.

In persuasive domains, some strategies have been devised for changing strong attitudes. Dual-mode processing models of persuasion propose that the receivers of a persuasive message process information in differently engaged ways (Chaiken, 1980; Petty & Cacioppo, 1986). However, research done in the context of strong attitudes has shown that interventions aiming at attitudinal change have often limited impact or are short-lived (Paluck et al., 2021). Recently, there is evidence showing the efficacy of *deep canvassing* and certain perspective-related narratives in facilitating attitude change with a more durable impact (Kalla & Broockman, 2021).

Deep canvassing and perspective-related strategies

Since the beginning of the 2000s, a group of activists, especially in the US, started experimenting with a new approach to political canvassing that is now being termed *deep canvassing*. Deep canvassing emphasizes dialogic, non-judgmental conversations, sharing different perspectives on life (Demetrious, 2022). It has been used for fostering open discussions on different controversial topics and it became more salient in the context of impacting exclusionary and discriminatory attitudes, such as intergroup prejudices, and transgender rights.

Deep canvassing employs different perspective-related narrative strategies, among them *traditional perspective-taking* and *perspective-getting.*

Traditional perspective-taking involves actively imagining oneself in the place of another. Here, one creates a narrative about someone else's experiences, trying to go through the story or event as if one were the other person – usually an outgroup. Studies on perspective-taking have shown that perspective-takers are likely to manifest empathy and feel emotions that resembled those of the targets, which is also referred to as self-other merging (Todd & Galinsky, 2014). Its effectiveness in persuasive contexts has been investigated, with mixed results regarding attitude change – sometimes working, sometimes not, sometimes even backfiring (Galinsky & Moskowitz, 2000; Skorinko & Sinclair, 2013).

Perspective-getting is defined as listening to or reading about someone else's experience, without the need to imagine oneself in the place of the other. Being exposed to one individual's experience, in contrast to a generalized experience from a group, was also found to promote reactive empathy (Lee & Feeley, 2016; Slovic, 2010). This is a more passive exercise in comparison to the other narrative strategies, and less active processing can result in more short-lived attitudinal changes. However, recent studies suggest that perspective-getting alone, rather than the full set of deep canvassing elements, has a consistent and relatively durable impact on attitudes (Kalla & Brookman, 2021).

This present study serves to investigate the impact of these two strategies, not only on attitudes, but also on learning, specifically in a text-based online environment (differently from deep canvassing's face-to-face conversational settings). Considering the context of an activity of reading and writing arguments, our main research question then focuses on the extent to which perspective-getting (with vs. without), perspective-taking (with vs. without), and their combination have near- and far-transfer influence on a) subjective learning gains, b) attitude change, c) elaboration of arguments, d) speciesism value, health and environmental beliefs, e) attitudes towards outgroups and f) towards other eating habits.

Methods

Study design, procedure, and participants

To test the influence of the perspective-related strategies on attitudes towards (vegetarian) eating habits, we designed a 2×2 study with the factors *perspective-getting* (with vs. without) and *perspective-taking* (with vs. without).

The sampled population consisted of 421 participants (54.2% female), native English speakers with a mean age of 45.2 (SD = 10.9). Their educational backgrounds were as follows: 25.5% primary and secondary education, 18.3 vocational higher education degree, 45.2% university bachelor's degree, and 11% master's and PhD degrees. The majority (92.1%) reported eating meat. Time on task was used as a criterium for exclusion, and accordingly, 43 participants were excluded since they finished the study in less than 10 minutes – a threshold established using pilot data.

Procedure

The current study involved two stages, separated by a gap of 5 weeks. In the first stage, the participants first filled out a pre-questionnaire with demographics, their eating habit, and the attitude-related, value and beliefs instruments. Then they got one counter-attitudinal argument to read, i.e., participants reporting to be vegetarians would be confronted with reasons in support of a meat-including diet and vice versa (with or without perspective-getting). After which they were asked to formulate an argument (with or without perspective-taking). The number of words was limited by the system (min. of 100, max. 500 words). Following this writing activity, participants filled out a post-questionnaire consisting in the self-reported learning and the attitude-change instruments.

After 5 weeks, the participants were again surveyed for their attitudes, values, and beliefs, and were asked to produce a text which would summarize the eating/not eating meat issue.

Perspective-getting and perspective-taking

The argument presented to the participants consisted of 3 main reasons, preceded or not by a personal, emotional narrative for *perspective-getting*. Subsequently, participants were asked to construct an argument consonant or dissonant with their own attitude for *perspective-taking*. Participants were randomly assigned to the four experimental conditions.

Self-assessed learning was measured by asking how much the participant considered to have learned on a scale from 0 to 100. With a scale of four items ($\alpha = .87$), measured in a 7-point Likert scale, we assessed attitude change, i.e., how much the participant considered to have changed attitudes related to the topic after the near-transfer reading and writing exercises. The behavior-change intention scale comprised of 5 items, administered before the intervention ($\alpha = .78$).

Results

Near-transfer effects on attitude change and self-reported learning

A multivariate analysis of covariance was conducted to assess significant differences in the linear combination of *attitude change scores* and *self-stated learning scores* between the levels of *perspective-taking* and *perspective-getting* after controlling for *behavior-change intention*.

The multivariate model showed a significant effect of perspective taking, $p = .008$, $\eta^2_{\mathrm{p}} = 0.02$. The covariate, behavior-change intention, was also significantly related to the dependent variables with a large effect size, $p < .001$, $\eta^2_{\mathrm{p}} = 0.24$. No statistically significant effects were found for perspective-getting, nor the interaction of perspective-taking and perspective-getting.

Attitude change

Regarding attitude change, no significant effect was found for perspective-getting nor for the interaction of perspective-taking and perspective-getting. The main effect for perspective-taking reached statistical significance showing a small effect size, $F(2, 414) = 9.07$, $p = .003$, $\eta^2_{\text{p}} = 0.02$.

Self-reported learning

Regarding self-reported learning, no significant main effect was detected for perspective-getting nor for interactions. The main effect for perspective-taking reached statistical significance showing a small effect size, $F(2, 414) = 5.63$, $p = .018$, $\eta^2_{\text{p}} = 0.01$.

Far-transfer effects on attitudes, values, and beliefs

A mixed model multivariate analysis of covariance was conducted to determine whether significant differences exist among the two time points for the targeted variables (beliefs on environment and health, speciesism values, and attitudes towards outgroups and towards other eating habits) between the levels of perspective-taking and perspective-getting after controlling for behavior-change intention.

No main effect of perspective-taking and perspective-getting was observed in the 5-week period for any of the dependent variables. The main effect for time in the model was significant $F(1, 228) = 4.04$, $p = .002$, , $\eta_p^2 = .081$, indicating there were significant positive differences (t2-t1) in pro-vegetarianism health beliefs $F(1, 232) = 12.148$, $p < .001$, $\eta_p^2 = .05$, and negative differences in attitudes towards other eating habits, $F(1, 232) = 4.373$, $p = .038$, $\eta_p^2 = .02$. (See Figure 2). No time-related effects were detected in the other variables, speciesism value, environment beliefs, and attitudes toward outgroups.

Effect of perspective strategies on argument elaboration

Argument elaboration was measured by counting the number of words in the participants' near- and far-transfer arguments, controlling for interest in the topic, which was measured by one item: "How much interest do you have in the debate of consuming vs. not consuming meat?"

Near-transfer

No significant effect was found for perspective-getting nor for the interaction of perspective-taking and perspective-getting. There was a significant main effect for perspective-taking, so that participants in the perspective-taking condition wrote less than participants without perspective-taking $F(2, 414) = 4.02$, $p = .046$, $\eta^2_{\text{p}} = 0.01$.

Far-transfer

As in the near-transfer, no significant effects were detected for perspective-getting nor for the interaction of perspective-taking and perspective-getting. The perspective-taking condition again showed to be significantly different, this time with the perspective-taking group writing significantly more than the without perspective-taking participants, $F(1, 228) = 4.46$, $p = .036$, $\eta^2_p = .02$.

Conclusion and discussion

Practices of argumentation that include taking and getting others' perspectives hold an interesting potential for civic education on controversial topics, as it can positively influence learning, as well as changes in attitudes and behaviors. We explored the impact of perspective-taking and perspective-getting in an online argument, which could bring us initial insights on the extent to which these strategies could be applied in formal and informal educational settings.

We had hypothesized that perspective-getting, as operationalized here, could impact the variables of interest, especially those related to attitudes, but it did not show any effect. Perspective-getting's effects may depend on circumstances that contribute to developing empathy for the other side. In this vein, perspective getting seems to strongly build on the face-to-face, dialogic interview situation in deep canvassing. Perspectives may be less easily conveyed in single online arguments.

Perspective-taking, however, showed to be an important element in such a text-based online context. Here operationalized as writing a counter-attitudinal argument, it revealed an impact on attitudes and self-reported learning. More than only reading, having to write the other side's arguments can imply that people, in the process of having to reason and elaborate on them, are led to reflect and engage with those arguments more actively, which could be the cause for the attitude change. This could be explained through the lens of dual process models of persuasion, such as the elaboration likelihood model and the heuristic systematic model (Chaiken, 1980; Petty & Cacioppo, 1986).

Perspective-taking also influenced participants' engagement in writing. Perspective-taking participants wrote less when asked to argue for an opposing side, as hypothesized with people having less arguments for the other side. But perspective-taking participants produced more comprehensive essays in the delayed writing task. Hence, taking perspectives by constructing attitude-dissonant arguments may facilitate comprehension and engagement of learners in reasoning about a controversial topic in the long run. Future research is needed to determine the validity of this claim.

The results on the self-reported learning gains provide first pointers to an untapped potential of perspective-taking for fostering learning in informal online contexts.

The differences in the health-related beliefs as opposed to the attitude towards other eating habits develop in opposite directions. Charity seems to begin at home when it comes to the health benefits of a vegetarian diet, which are being understood and accepted, but dealing with eating habits other than one's own may remain a nuisance.

Knowing Together With Materials in Collaborative Creative Making

Alekh V, Chandan Dasgupta
alekhv@iitb.ac.in, cdasgupta@iitb.ac.in
Indian Institute of Technology, Bombay

Abstract: Making is characterized by intricate flow of creative acts that promotes deep investigations and material explorations, inciting meaningful knowledge construction. This paper expands the focus of Making beyond humans; towards material entities, to understand learning by making, and emergent creativity in collaborative networks. In this study, we examine the epistemic aspects of materiality in collaborative creative making, by specifically looking at data from two making contexts: 1) a medical device innovation camp, and 2) a maker activity-centered workshop, as ideas emerge and evolve as makers get involved in design problem-solving scenarios. Our findings suggest that the knowledge-building pursuit in the creative collaborative making is sociomaterially entangled, and shapes the course of subsequent creative actions. The emergent epistemic entities such as shared conceptual and design artifacts conditioned ideation, refinement, and further materialization.

Introduction

Making opens up learning opportunities, unexpected modes of play with material resources and drives creative movements as makers engage in invention projects (Dougherty, 2012). With the flattened ontology where matter is no lesser than humans, making becomes a dynamic exchange of agencies between humans and other-than-human actors, through which learning and creativity emerge (Latour, 1996). When makers come together and utilize the available material resources, knowledge transfer happens via building shared understanding and translating abstract ideas into various forms as visual, conceptual, and material artifacts. These shared design artifacts can serve as the anchor points around which further refinement in the pursuit of inquiry and collaborative processes takes place (Knorr Cetina, 2001). Also, the creativity emerging out of these sociomaterial encounters cannot be reduced to individualistic accounts but distributed across social, material, and temporal dimensions of the situated context (Sawyer & Dezutter, 2009). Prior studies on knowledge-building postulate ideas and conceptual artifacts as objects that materialize in a world where knowledge is shared and inspected by the community (Scardamalia & Bereiter, 2014). In making situations, makers approach materials with preconceived material properties, and materials 'talk back' to makers (Schön, 1983). Materials cannot be considered as dormant entities (Pickering, 1993), not only responding to the actions performed by makers but also directing the makers to creative actions. Even though researchers have argued the centrality of tools, artifacts, and the associated embedded knowledge to thought and action, characteristics of these entities are obscure and complex (Engeström & Blackler, 2005). The materialist and posthuman frameworks can be used to look into learner-learning environment entanglements which traverse the human and other-than-human entities of the situated context in a non-hierarchical fashion (Barad, 2003).

In this paper, we take an *epistemic standpoint to look at how sociomaterial entanglements influence collaborative creative making*, by specifically looking at data from two collaborative making contexts: 1) a medical device innovation camp, 2) a maker activity-centered workshop, as ideas emerge and evolve as makers engaged in design problem-solving scenarios. We consider making as a collaborative practice between human and nonhuman entities and position the related creative aspects as emergent (Sawyer & Dezutter, 2009).

Methods

For this study, we looked at two collaborative making contexts: 1) a medical device innovation camp, 2) a maker activity-centered workshop. The five-day medical device innovation camp was organized by the Biomedical Engineering & Technology Incubation Centre at a leading engineering institute in India. The organizers facilitated team formation to form a total of 16 teams around a predefined set of twenty medical problems generated by multiple doctors. The audio and video data along with field notes and observation logs for day 1 and day 2, of two teams - Team A and Team B- formed the data set from this setting, as the rest of the data was not available due to hard-disk storage failure. Team A consisted of a doctor- Subject Matter Expert (SME) (male), designer (male), mechanical engineer- M.E (male), and an electrical & electronics engineer- E & E. Engg (female). Team B consisted of a doctor - Subject Matter Expert (SME) (male), designer (male), software engineer (male), and market expert (male). Teams were provided with knives, scissors, screwdrivers, hand drill, pillar drill, pens, pencils, rulers, drawing chart papers, plastic sheets, tapes, glue, sticky notes, breadboard, LEDs, jump wires, battery.

The one-day maker activity-centered workshop was organized at a leading engineering institute in India. The participants comprised eight second-year mechanical engineering undergraduate students who responded to an open invitation. Four teams were formed based on the order of their response with each team consisting of two members. After the introductory session, participants were given a design challenge to conceptualize and model a semi-automated assembly line with static and dynamic robots using the resources available in the makerspace. A facilitator was present during the making sessions to support the teams with technical assistance. We followed the making activities of teams- P, Q, R, and S. Team P consisted of one female student (G1) and one male student (B1).Two male students (B2, B3) constituted Team Q, Team R had two male students (B4, B5) and Team S with two male students (B6, B7). The workshop was conducted at a makerspace with a work table, a whiteboard, a computer, and a desktop FDM 3D printer. The teams had access to two Lego Mindstorms EV3 kits, a 3D printing pen, knives, scissors, screwdrivers, cardboards, pens, pencils, chopsticks, play-doh modeling compounds, cable ties, tapes, glue, styrofoam sheets, a box with used cables, wires, defective electronic devices like earphones.

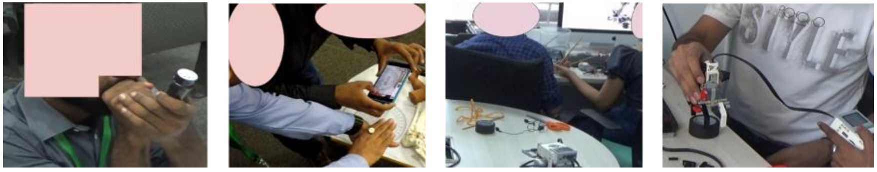
We used video data along with transcripts and field notes to unpack the moment-by-moment emergent actions during collaborative making by following the case study methodology (Merriam, 2007). We began the analysis by content logging and segmenting the data into phases of the making process - ideating, information seeking, sketching, prototyping, testing, and refining ideas, to get an overall understanding. We used the content logs to conduct interaction analysis (Jordan & Henderson, 1995) looking at talk, use of artifacts and technologies, turn-taking and participation structures focusing on maker-material agency (Svihla et al., 2020). The unit of analysis is idea units - episodes during various making phases bounded by idea entry, evolution, and exit.

Findings

We found that the making episodes were constitutively entangled with human and non-human elements of the situated making contexts. We present few representative instances from the making contexts to illustrate how different epistemic entities emerge and how ideas get shaped during the course of making, driving creative actions.

Figure 1

Designer testing PVC pipe prototype (a), Designer measuring angular values using the mobile prototype (b), Team P checking the Lego Mindstorms EV3 manual (c), Team Q testing gripper (d)



(a) (b.) (c) (d)

Case 1: Medical device innovation camp

Team A worked on developing solutions to remove the sputum from patients' respiratory systems. The particular episode discussed below is from Team A's prototyping phase where makers are concretizing the initial ideas of building a blowing unit.

SME: We use similar things like spirometer.. you know.. to check the patient's breathing .. I will show you something that I made.. [takes the PVC pipe prototype]..
Designer: How did you make this? [inspects the PVC pipe prototype]
SME: [Points to PVC pipe prototype] it's just a PVC pipe bent.. and this is a PVC pipe end cup. Then drilled a bigger hole in the end cap over which the marble is resting..
Designer: [Blows through the PVC pipe prototype] I can feel a resistance .. kind of vibrations
SME: Yeah.. these vibrations should go inside the lungs.. patients'..
M.E: Kind of.. maybe perforated balloons can be added at the end for more vibrations
Designer: Can I use something like .. placing a vibrating belt on my chest .. see same principle

In the above excerpt, the SME shared his experience with similar existing devices and introduced a crude PVC pipe prototype. As the designer tested the prototype, and experienced resistance against blowing (see Figure 1(a)). The feedback offered by the PVC pipe prototype prompted the makers to think about how the prototype functioned and shaped further questions. The shared understanding of the guiding principles related to air column vibrations developed from SME's inputs and encounters with the prototype, helped the makers to build on the core idea with that of perforated balloons and vibrating chest belts. The instance shows the entanglement of SME's prior experience, features of existing devices, PVC pipe prototype, guiding principles like air column vibrations and resistance in the path of knowledge inquiry, and the moment-to-moment evolution of the collaborative making.

Team B worked on the problem of quantifying the patient's clubfoot deformity, to arrive at a portable measuring system for monitoring the degree of deformity. The SME built an intermediate prototype using a mobile phone, transparent sheet with angular markings and tapes, by which photographs of deformed feet can be taken and processed to get angular measurements. As illustrated below, the prototype became crucial in developing a shared understanding of the guiding principles related to angular measurement. Here, the designer was not convinced by the property of constant angular measurements with heights. But the rest of the team members followed the concept, eventually pushing the designer to test angular measurements (see Figure 1(b)). The designer proceeded with testing, and acknowledged the concept of constant angular measurements with heights. The intermediate prototype thus becomes a shared entity through which the human and other-than-human entities expressed shared agency. The knowing is found to be materially grounded as the conceptual artifacts, material resources and related design artifacts acted as vehicles for the pursuit of knowledge and creative solutions.

Designer: I think we will have angular measurement problems with height..
Market Expert: No.. no, height will not change the angular measurement
Designer: No, the measurements will be different.
SME: Ok.. do one thing, check yourself.
Designer: [Draws an angle on a paper, uses the mobile phone prototype to take readings at different heights]..Yeah, measurements are same.

Case 2: Maker activity-centered workshop

For the design challenge, Team P started with the idea of a static parallel robot to perform the package pickup and place task. The following episode from Team P's prototyping session shows the intertwined states of maker-material elements that determine the making process as the makers attain insights on various design instantiations.

G1: I don't think it will work.. not enough.. support structure.. drop?
B1: Drop?.. mm .. then we will have to check the crane one.. search..
G1: [Opens Lego Mindstorms EV3 Classroom application] there are some models.
B1: Hey.. we can do that [points to serial robot model in the manual]
G1: mm.. but look here [points to manual diagrams].. these got some gear systems.
B1: Yeah.. but we can make these.. [picks up and shows gear parts from kit]
B1: but all these should hold together.. the stability thing
G1: mm.. we can make a bigger base this time.. rectangular ones..

The team tried to materialize the parallel robot idea by combining mundane materials like chopsticks, threads, tapes, and lego parts, but the resultant prototype probed the queries related to structural stability as it continued to break down. The makers were forced to drop the idea, check for alternatives, searched online resources and Lego Mindstorms EV3 construction manuals (see Figure 1(c)). They found a serial robot model in the manual and discussed the adoption of design features, looked at the available resources and gear arrangements by reminding themselves about the structural stability. The episode is an example where material entities resisted makers' actions and pushed the makers to search for other solutions. Initially, the makers didn't take into account the notion of structural stability in building the robot but became cognizant of the same with responses from the prototype.

In Team Q, a static two link serial robot was conceptualized along with a dynamic robot inspired from a forklift. The following episode from Team Q's making session shows how the construction manual and the gripper built, paved the way for evaluating and refining makers' understanding of gear mechanisms. Here, the makers worked on the problem of picking up the package. While testing (see Figure 1(d)), B2 pointed out the malfunctioning of gripper arms. Since B2 followed a few design ideas from the Lego Mindstorms EV3 Classroom manual to build the gripper, the exact functioning know-how of the gear combinations remained hidden. Although the makers had a basic knowledge of gear mechanisms, the incomplete prototype threw questions related to gear combinations, motion transfer and logic in the block program. These questions directed B2 and B3 to closely follow the functioning of gear combinations and links, to get deeper insights and modify the design.

B2: [Points to gripper arms].. not closing enough [gestures gripper arm movements]
B3: [Takes the gripper and inspects] lot of gears.. block program?
B2: Some are from the manual [refers to Lego Mindstorms EV3 Classroom manual]
B3: So.. this gear is connected to..one spur .. and here is the rack, pinion [points to different gear combinations used in the gripper]
B2: Ok.. then the shaft rotates and .. arms open up.
B2: [checks other gears from the kit] I think these can be used [takes larger spur gears]

Discussion and conclusion

We have presented few instances of collaborative making from two making contexts: 1) a medical device innovation camp, and 2) a maker activity-centered workshop, to show the ways in which states of design ideas evolve in relation to the social and material elements of making, focusing on the emergent epistemic entities. While looking at the maker-material encounters, we placed materials as more than dormant entities or mere mediators, and included non-human agencies, which revealed the active role of materiality in creative collaborative making, as various material resources involved in the process influenced the knowledge–building process and the moment-to-moment unfolding of the proceedings. The study highlighted the active roles of human and other-than-human entities in collaborative creative making in the respective contexts, which reiterates the distributed notion of collaborative creative emergences (Sawyer & Dezutter, 2009) The makers and material entities are found to be intertwined in cycles of inquiring, answering, and raising queries as the making progressed (Knorr Cetina, 2001). The material resources acted as springboards in the evolution of ideas and arriving at guidelines, which directed the next course of creative actions. For example, Team A makers' encounters with the PVC pipe prototype lead to the understanding of air column vibrations, and the ensuing generation of connected ideas. The design artifacts played a crucial role in idea stimulation, refinement, and advancement, as the incomplete nature of these entities continued to pose questions for the makers, and augmented shared understanding. For example, the incomplete dynamic robot design that emerged during Team Q's making actions raised questions related to gear combinations and motion transfer. The design artifacts actively helped in settling certain design aspects and transforming others, via temporary instantiations. As the Team B makers engaged with the mobile phone prototype, the concepts of angular measurements and the experimentations contributed to the realization of portable measuring devices. These material entities are in a constant relational flow of changes and can be considered to have an unfolding ontology. Notably, material references, metaphors, and features of existing devices came into play as makers recalled prior material experiences. SME of Team A recalling his experience with the spirometer and referring to the material features, and B1 of Team P referring to cranes can be pointed as such instances. Although the two settings differed in design challenges, resources available, and participant expertise, we see makers thinking, knowing, and making *together* with the material entities. Further studies are required to expand our understanding related to the sociomaterial entanglement in creative making contexts.

Mechanistic Reasoning and Ethics of Caring in Engineering Contexts for Educators

Amy Voss Farris, Anna Eunji Kim, Gözde Tosun
amy@psu.edu, aek5559@psu.edu, gjt5160@psu.edu
Pennsylvania State University

Abstract: Contexts of introductory engineering education hold potential to situate engineering within the cultural and sociotechnical dimensions of being and becoming, thus highlighting the transformative roles of engineering. In this paper, we pursue an articulation of care as a key learning outcome for preservice teachers in their first formal experiences in engineering disciplines. We present two explanatory themes, originating from (1) an extended bridge design task and (2) an investigation of machine learning image recognition processes. In both studies, preservice teachers engage in a process through which mechanistic explanations about sociotechnical systems give rise to an ethic of care (Silvis et al., 2022), narrowing the relational distance among the engineering contexts, themselves, and perceptions of students. We highlight affective connections between undergraduates' experiences in engineering and their trajectories of becoming teachers and explain how mechanistic sensemaking supported articulations of an ethic of caring concerning both engineering and learners.

Introduction

Reasoning about the underlying processes that give rise phenomena—especially in contexts of science and engineering—is often called *mechanistic reasoning* (e.g., Krist et al., 2019; Russ, 2008). In engineering education, learning to reason about systems also requires attention to the social, ethical, and political impacts of engineers' scientific and technological pursuits (Gupta et al., 2019; Philip et al., 2018). As recently argued by McGowan and Bell (2022), learners' critical and affective engagement in studies of sociotechnical phenomena *deepen* science learning opportunities, supporting learning to make sense of "the impacts of engineering and technology on their own communities and everyday lives" (p. 982) while also working toward more socially just futures for the learners themselves and their communities. This is consistent with recent studies of learning that conceive of affective dimensions of learning as a target of instruction (Vea, 2020) and meaningfully enmeshed with other disciplinary goals.

We examine how preservice teachers make sense of mechanistic relationships in both a traditional engineering education context (e.g., a truss bridge design unit) and in reasoning about artificial intelligence (AI) and machine learning. Our inquiry is guided by our desire to understand the relationships among preservice teachers' mechanistic reasoning (e.g., Russ, 2008; Krist et al., 2019) and the development of ethics of care (Farris & Tosun, 2020, Silvis et al., 2022) that impacts their teaching in relation to their students and technologies.

Mechanistic reasoning, modeling, and emotion

Reasoning about mechanism has longstanding attention in the philosophy of science (e.g., Bechtel & Richardson, 2010), in theories of cognition (e.g., Machamer et al., 2000), and in educational research (e.g., Krist et al., 2019). An affordance of mechanistic reasoning as an analytic frame is its fundamental commitment to systems perspectives—that is, the processes that underlie relationships within a system, including how components of one part of a system give rise to emergent behaviors of the system (Bolger et al., 2012; Russ et al., 2008; Machamer et al., 2000). Studies of mechanistic reasoning have often been concerned with ecological systems (e.g., Dickes et al., 2016), kinetic toys (e.g., Wineberg, 2020), and computational models of invisible processes in physical systems (e.g., Jacobson & Wilensky, 2006).

We seek to contribute to a deeper articulation of the connections between sensemaking and the affective and justice-seeking outcomes of that sensemaking, for self and others. In a recent example, McGowan and Bell (2022) illustrate how biology students' systems perspectives and modeling work about climate change and oceanic temperature ultimately supported learners' greater ownership of ecological care. In their study, the affective dimensions arise from figuring out the relationships among factors contributing to the prevalence of disease in sea stars. In our study, we examine a similar pattern with non-science major preservice educators. We ask, "What are the affective entanglements between preservice teachers' sensemaking in engineering contexts and their articulations of the work of teaching engineering?

Learning contexts and analytic approach

We have selected two contrasting disciplinary contexts for preservice teachers: (1) a truss bridge design unit in which students worked in and sustained collaborative teams, and (2) an explanatory modeling unit about image recognition AI systems. We position both as sensemaking in and about engineering contexts, however, the cases are contrasting in terms of the degree to which the societal impacts of the engineered systems were considered by the students. The truss bridge design project was intended to support students in an extended process of redesign around introductory mechanics concepts in a collaborative team, while the social implications of bridge design were given little attention. In contrast, in the AI example, we designed the learning activities to invoke preservice teachers' more examined awareness of AI in everyday life, as most laypeople do not conceptualize their daily interactions with AI in ways that are consistent with the dynamic nature of how those systems operate (Royal Society, 2017; Fiebrink, 2019. We were interested in how the teacher candidates could become more critically aware of applications of machine learning in their everyday lives. For example, we speculated that critical recognition of the unjust failures of AI—such as image recognition tools that consistently fail to recognize photos of dark-skinned people (Metz, 2021)—requires an informed explanation of how these image recognition systems are designed and trained.

Figure 1

a. b. c.

Data were collected from two different undergraduate courses within two design-based research studies (Cobb et al., 2003;) The first course is an introductory engineering course for educators—a science content course for beginning students in the College of Education who aspire to become elementary grades teachers. This course focused on the interaction among physical science concepts and engineering design principles and was designed to foster Figueiredo's (2008) four epistemic dimensions of engineering, which position engineering as a social science, basic science, process of design, and a problem-solving process. It included three science content modules (structures, simple machines, and electricity), each of which had an associated engineering design project. All 23 students who completed the class consented to participate in the study. The second course is a science teaching methods course. The methods course is for teacher candidates in their 7th semester of study who are seeking professional teaching certificates for middle level grades and are non-science majors. Data sources include artifacts and assignments teacher candidates produced as part of their coursework and instructor/researcher field notes. The analysis began with the student responses to within key assignments, which were coded using open and axial coding (Strauss & Corbin, 1990) and triangulated with other assignments and researcher notes. We constructed themes from the codes, in relation to the research question and established knowledge (Vaismoradi et al., 2016) related to affective dimensions of learning in engineering contexts.

Thematic analysis

We focus on two outcomes of mechanistic explanations in engineering contexts and their potential entailments for preservice teachers' orientation toward ethics of care as aspects of engineering education:

Theme 1: Participation in iterative engineering design gives rise to empathy

Theme 1 is concerned with empathy for youth's feelings of failure in sustained engineering design projects. In the introductory class bridge design unit, we focus on Natalie, a member of a four-person team that had a particularly challenging time designing a bridge that met the minimum stability criteria. An early iteration of the bridge is shown in Figure 1a. The entire team often stayed after class to continue working on their bridge. In Natalie's bridge design report, she explained that the way her bridge snapped "almost upward when it broke," informed her about the compressive forces acting at the point of failure. She wrote, "Our bridge held half of the necessary weight without bending, so we were very optimistic. We decided that if we added more support to the middle of the bridge (where the force would be pulling it down), we would have a better chance of being able to hold the full amount of weight." Natalie and her teammates were paying attention to the bridge as a system of balanced forces and eventually designed a bridge that met minimum criteria. In her end-of-term reflection, Natalie wrote about how her experiences in the course would become helpful in her future teaching: "I went through the processes that I will be asking them to when I am teaching. I learned the hardships that come out of designing and creating the things we did in this class and I feel as if working through them myself will help me better be able to understand my students or assist them when they face similar issues" [Natalie, Week 15 Reflection]. Across the course, Natalie thinking shifted from an initial emphasis on content knowledge alone (e.g., "... If I could answer some of these questions for children" [Natalie, Week 1 Reflection]) to perceptions of engineering that include supporting students' design process as an emotive process and learning and teaching engineering as emotionally entangled (Farris & Tosun, 2020). This is important in relation to our research question because Natalie made connections between learning explanatory mechanisms in (for example, in stable truss bridge design) though immersion in the design process, and this experience influenced on her thinking about her teaching practice towards understanding and attending to elementary children's emotions about engineering design.

Theme 2: A mechanistic view of training data situates criticality about the social impacts of AI

Theme 2 addresses the teacher candidates' development of a critical consciousness of how bias arises in machine learning systems and the need to design more equitable systems. In the 7th-semester science methods course, several members of the class built an image recognition game called Snap! using an environment called *Machine Learning for Kids* (Lane, 2021, Figure 1b). To create the game, students made hand drawn playing cards based on standard suites (hearts, diamonds, clubs, spades), then used their own drawings as the training data. The game flashes a card for the player to match and times the player as they search for correct card to hold up in front of their computer camera (Figure 1c). Across the students' work, we observed that first-hand experience training a simple image recognition model was very important for understanding how the model recognizes images. Here, we focus on Annabel, who selected this game to use in a lesson planning assignment.

Annabel wrote about the importance of students' experience in trying out their own training data for students' evaluation of their own computational models. She explained that students will be training their models "to guess [the meanings of drawings] based off of their/their partners' drawings. Hopefully, through this process and our discussion, students will be able to understand how computers can learn and be trained to interpret and make guesses [about image data]." She explicitly connected her own experience of reasoning about the system, explaining that she will support students the think about "why some [models] worked better than others" and will "show the positive and negative effects in other aspects of life where computer guessing can be good or harmful."

In her reflection, Annabel wrote that applications of science and technology can be important to students' life and teachers' work because, "Recognizing the potential for models and systems to be better, and diagnosing those problems, is important in the lives of students. I see this concept being used in this activity as they get experience with code, machine learning, and modifying their projects for improvement." [Annabel, Lesson Plan]. In sum, in Annabel's work, her mechanistic reasoning about training in image recognition AI supports her emergent criticality about the impacts of AI and her desire to support students to reason about training processes. She considers how modeling machine learning can support students to better make sense of the biases in machine learning and the broader impacts to sociotechnical and sociopolitical systems in which those systems operate.

Discussion and implications

The university students in our studies encountered their first formal experiences in engineering education in the contexts of teacher preparation. Similar to engineering courses for engineers (Gupta et al., 2019; Philip et al., 2018) students in the College of Education had disciplinarily meaningful affective responses to the technical and sociotechnical implications of engineering, for example, the teacher candidates' own recognition of how machine learning systems perpetuate injustices, and the frustration of balancing unknown compressive and tensile forces in bridge design.

Furthermore, our paper expands existing conceptions of engineering as emotional practice in two ways for contexts of teaching children and youth: Preservice teachers' responses were deeply connected to educational contexts and the work of teaching, and these were emergent from their own intellectual engagement with mechanistic sensemaking processes. Specifically, teacher candidates in the cases reflected on pedagogical impacts of emotive dimensions of engineering: Natalie, while involved in engineering work that had minimal direct implications for society, reflected on how deep participation and frustration in the engineering design process motivated a different kind of empathy for young learners in the process of designing engineered systems. Annabel started from reasoning about patterns in training data as mechanisms that give rise to image recognition in machine learning. She identified how patterns in data inform biases that are built into machine learning systems. In both cases, teacher candidates' experiences within the mechanistic and sociotechnical complexities of engineering—alongside their considerations of the pedagogical dimensions of teaching engineering content—led to expressions of engineering education that were entangled in care for others.

Abstract: This qualitative study examines the use of math walks with middle grade students and adult facilitators at a local zoo. Drawing on situated learning and participation frameworks, we used interaction and stance analysis to compare two contrasting cases: In the first case, the adult chaperone asked more questions and evaluated student responses. In the second case, the adult chaperone intervened less frequently, leaving more room for student discourse. Findings support efforts to design informal math learning activities which amplify student voices, towards increased mathematical interest and learning.

Introduction

Despite the growing popularity of informal STEM learning environments, there is little research about how students learn mathematics in these spaces (Pattison et al., 2017). Additionally, facilitating mathematics learning in informal STEM environments can be challenging. Many adult facilitators do not have formal pedagogical training (Hmelo-Silver & Barrows, 2008) or may have difficulties with recognizing mathematics in informal settings (Peck et al., 2022). Therefore, we aim to investigate how adult facilitators and students collaborate to recognize and discuss mathematics in informal learning environments. To address this, we analyzed video footage of adults and students participating in math walks (Wang et al., 2021) at the City Zoo (a pseudonym). Our research question was: *What are different dynamics for adult-student interactions during informal math activities and what implications do these dynamics have for student learning?* Drawing on interaction analysis (Jordan & Henderson, 1995) and stance analysis (Goodwin, 2007), we identified and analyzed two contrasting cases (Schwartz & Bransford, 1998) to highlight how context and student-adult dynamics shaped the mathematical discussions.

Theoretical and analytical framework

This study is theoretically grounded in situated perspectives on learning, which recognizes that all learning is the development of participation structures specific to the setting, (Greeno, 2006). When considering mathematics, it is important to note that learned participation structures may not be especially useful or appropriate in other settings For example, based on their participation in “school math” students may come to believe that participation in a mathematical activity is constituted by obtaining answers to short, self-contained problems requiring repetitive calculations, with no larger goal or purpose for which the answers have meaning. Authentic participation practices in mathematical activities in real contexts (like designing an animal enclosure for a zoo) may bear little resemblance to how students are used to seeing mathematics in school. We believe the difficulty for students and adults to ‘see’ mathematics and negotiate mathematical meaning together in informal settings stems from this tension. To analytically map this tension, we draw on Goodwin’s (2007) construct of participation frameworks which describe how participants publicly organize conversations through a series of stances. Goodwin describes five stances: instrumental, epistemic, cooperative, affective, and moral. We use Goodwin’s stances to trace how adults and students together recognize and discuss mathematical ideas while participating in math walks. Here we only use the first three stances (instrumental, epistemic, and cooperative), because conversations in our dataset rarely involved affective and moral stances.

Table 1
Interactional Sequences

Stance	Definition	Example
Instrumental	Drawing attention to entities (objects, materials, etc.) that are necessary to complete the in-progress activity	Referring to an object (i.e., video) when posing a question
Epistemic	Positioning in a way that promotes the experience through perceiving or understanding the activity	When students discuss mathematical or science content
Cooperative	Organizing one’s body in the direction toward others, as well as the environment, to sustain the activity	Involving other members in the group during a discussion

Context, data sources, and analysis

We partnered with informal educators from the City Zoo to design three math walks, in various locations within the zoo. These math walks highlighted the mathematics of animal behavior, enclosure size, and coat patterns. We demoed the math walks with 20 middle grade students enrolled in a three-day City Zoo camp. Students were in six groups and paired with one adult. Students explored the City Zoo, participated in math walks, completed worksheets to summarize their thinking, and created their own math walks. Each small group was video recorded by the adult participant, using a hand-held video recording device. We began analyzing the video recordings by creating content logs (Jordan & Henderson, 1995). This allowed us to explore the data at a high-level to scope out patterns in interactions and mathematical questions. We created minute-by-minute content logs which documented the turn taking patterns between adults and students, the artifacts used or things referenced in the physical space (e.g., the worksheet, animals in the zoo), and the types of mathematical questions being asked and answered. At this point, we discovered the prevalence of some adult-driven small group discussions. We marked the content logs where adult questioning was most pronounced and compared the set of interactional sequences. For this manuscript, we selected two interaction sequences from the first day to transcribe, compare, and further analyze. With the two cases in hand, we turned to Goodwin's participation framework (2007) to describe how adults and students go about engaging in the math walk stops. Working line-by-line, we annotated each turn-at-talk as to whether it was an instrumental, epistemic, or cooperative stance. Our annotations described *how* a particular sequence of talk achieved a particular stance. In many cases, participant's talk functioned as more than one of the interactional stances (ex. a turn at talk could be coded as both instrumental and epistemic). In the sections ahead, we synthesize our annotations in order to 're-tell' these conversations, with an eye towards the contextual and interactional features that made these cases different.

Case a: Exploring animal walking patterns

Our first case demonstrates how adults and students reproduced canonical mathematical classroom dynamics. This case involved three students and one adult. All three students were middle grade girls, two of the students were Latina (112 and 111) and one of the students was African American (116). The group of students was led by an adult member of the research team (RR) who was a South Asian man. At the start of the recording, the group was seated in a circle on the floor. The group had just watched a short video which explained the walking pattern of all quadrupedal mammals. The video recording began with RR asking the students what they found interesting about the video. Students 116 and 112 briefly mentioned "the walking patterns" and recalled the numerical code '3-1-4-2' which described the order in which legs strike the ground. RR prompted 116 - who was holding the clipboard - to record her group mates' answers. After a short silence from the group, RR began questioning the students to clarify what was interesting about animal walking patterns (below).

Table 2
Transcript from Case A

Line	Participant	Talk
A.1	RR	So for this one you could - like how else would you describe what's being answered though? The video is about walking patterns but
A.2	116	Like how the walking patterns work
A.3	RR	But we're trying to find a pattern between which animals
A.4	112	All of them?
A.5	RR	or not all animals, but what type of animals?
A.6	112/111	(simultaneously) mammals
A.7	RR	Mammals, but
A.8	112	It's called something I remember at the beginning.
A.9	RR	So, I know it's a complicated word.
A.10	112	(It is)
A.11	RR	(But) what is it? What's like a dumb like definition of that word?
A.12	111	Animals that walk on four legs
A.13	RR	Yeah, yeah, there you go. four legged animals.
A.14	116	Quad - quad - quadra
A.15	RR	quadrupeds

RR breaks the silence by asking the students "how else would you describe what's being answered though" (line A.1). Instrumentally, he drew students' attention back to the video. Cooperatively he faced the entire group, panning the camera back and forth to see all the students. Epistemically he signaled that students' initial interest in 'animal walking patterns' was not enough. Then, RR and the students engaged in a series of back-and-forth questions and responses until they had reached the correct answer - one that RR determined was sufficient. Student 116 took up RR's cooperative and epistemic stance, responded first, and said "like how the walking patterns *work*" (Line A.2). RR ignored her epistemic clarification (work), and instead posed a new question: "but we're trying to find a pattern between which animals?" (Line A.3). We interpreted this new question as both an epistemic stance (redirecting what types of mathematical questions should be asked) and a new cooperative stance (continuing to ask students to provide him answers - just not the one 116 had provided). RR led the students, through iterative questioning, to the scientific term 'quadruped.' The discussion ended when RR made two final statements. First, he made an epistemic stance by summarizing their conversation: "So it's trying to find a walking pattern between quadrupeds right - and then we we figured out that they all walked the same across - every single animal." Then, he made an instrumental stance by instructing student 111 to complete the worksheet: "you can - you can just write that - what are walking patterns? Or how do you - how do four legged animals walk - right?"

We interpreted this sequence as a reproduction of canonical mathematical classroom dynamics. The mathematical discussion was epistemically and cooperatively led by RR. Students participated only by taking up RR's cooperative stance and attempting to provide correct answers. When students did not provide correct answers, they were either ignored (as with 116) or redirected with a new question (as with A.10). Furthermore, instrumental stances were limited to references to either the worksheet or the video.

Case b: Exploring giraffe coat patterns

Our second case demonstrated how adults and students engage in a more distributed dynamics relations and student-led talk. This case involved three students and one adult. All three students were middle grade boys, two of the students identified as multi-racial (117 and 118) and one identified as Latino (120). The group was led by an adult member of the research team (AM) who was a white man. The students watched a short video about giraffe's coat patterns. The recording began with the AM asking the students to recall the mathematical content from the video. Student 118 mentions that "you can measure the patterns of a giraffe." From there, Student 117 poses a question after observing the giraffe's behavior (Table 3).

Table 3
Transcript from Case B

Line	Participant	Talk
B.1	AM	okay, we can make a question or that hold that thought okay, let's think about that. So, what else from the video part?
B.2	118	Um that oh that you can make pattern that you can make pattern that well that you can **measure** the patterns of a giraffe
B.3	117	Why are their tongues so long?
B.4	AM	Why do you think so
B.5	118	to get the grass from the trees to get from the high trees (jump)
B.6	AM	What did you? What can you summarize what the video is saying?
B.7	117	Basically, that giraffes' patterns are math mathematical that you can solve them
B.8	120	They have different types of patterns.
B.9	117	Yeah, they have big patterns and small patterns
B.10	120	and different types of shapes
B.11	AM	OK
B.12	117	like squares, triangles, circles.
B.13	AM	Yeah
B.14	117	they can come in different sizes and different shapes.
B.15	AM	OK
B.16	117	Like that one has a lighter in different colors. There's a lighter one and that one has a darker one
B.17	AM	Yeah,
B.18	117	and she has hers a little bit more space a little bit more smaller. Like we're closing, like closer, like not so far away.
B.19	AM	Yeah, that's a good observation

The sequence this case follows is the progression of the conversation related to math patterns. AM begins the discussion in line B.1 by taking an instrumental stance by referring back to the video, epistemic stance by indirectly considering the mathematical concepts from the video, and a cooperative stance by encouraging all of the students to consider the question. Unlike in the first case, the adult facilitator allows the students to pose their own questions based on their observations from the giraffe exhibit and responds in an open-ended manner. In line B.3, student 117 notices the giraffes eating a lettuce leaf from zoo patrons, and poses the epistemic question, "why are their tongues so long?". Immediately, AM answers using a question, which instrumentally indicates that AM took up the students' idea, and epistemically places the agency and ownership on the student. However, AM also took a cooperative stance, based on his positioning toward all of the group members, which led another student (118) to take an epistemic stance and provide an answer to the group (B.5). After allowing the space for the students to consider their observations, AM again, takes instrumental, epistemic, and cooperative stances to have the students recall and summarize the video (B.6). The remaining conversation within this sequence is guided by the students. The students take an epistemic and cooperative stance by building on each other's responses. AM only contributes to the conversation using an instrumental stance, to affirm each students' contribution to the discussion around giraffe's coat patterns. This interaction sequence ends with student 117 taking an instrumental, epistemic, and cooperative stance, by facing and pointing to the giraffes and describing the pattern differences between the giraffes within the exhibit (B.16 and B.18). Finally, it concludes with AM taking an instrumental stance by saying, "Yeah, that's a good observation" (B.19) by acknowledging 117's epistemic stances. We interpreted this sequence as a more equal distribution of power between the adult facilitator and the students. The majority of the discussion was epistemically and cooperatively led by the students. AM's participation during the discussion was taking an instrumental stance to affirm each students' contribution.

Discussion

Our analysis traced the importance of adult facilitators in mediating student mathematical discussions in informal settings. In case A, we found that mathematical discussions were epistemically and cooperatively led by the adult facilitator, thus limiting the students' contributions. In case B, we found that mathematical discussions were epistemically and cooperatively driven by the students, thus enhancing the variety of mathematical questions which were posed. Furthermore, the environmental context differed greatly between the two cases. In case A, the adult facilitator and students were seated in a room away from the rest of the zoo exhibits. This provided a narrower field of possibilities for the students to reference when ideating possible mathematical questions. In contrast, in case B the adult facilitator and students were standing along the giraffe exhibit as they watched associated videos and discussed possible mathematical questions. This provided a broader range of possibilities for the students to explore their natural curiosities through observations, as well as from the videos. Implications for this initial analysis, suggest supporting the adult facilitators so they can better prompt open-ended and student-led mathematical discussions to connect the mathematical content to the present sites. It also suggests that the physical location in which informal mathematics learning discussions take place has important implications for the mathematical discussions that ensue. Finally, it highlights how tensions between academic and everyday mathematics can arise for facilitators in informal learning environments, and suggests that strategies should be developed to explicitly address these differenting participation structures.

Play as a Site for Children's Construction of Internally Persuasive Mathematical Discourses

Amy Noelle Parks, Michigan State University, parksamy@msu.edu
Candice Love, Vanderbilt University, candice.love@vanderbilt.edu
Madison Knowe, Vanderbilt University, madison.l.knowe@vanderbilt.edu

Abstract: This study explores the relationship between play and authoritative discourses (Bakhtin, 1981) in a kindergarten mathematics classroom. Drawing on interpretive methodological traditions, the research team video recorded and took field notes on a week of geometry lessons following a professional development session in which teachers co-designed playful geometry lessons with the researchers. Our findings demonstrated that engaging in play allowed children to construct their own internally persuasive discourses about mathematics.

Introduction

When children experience mathematics as a set of rules to memorize, they come to see mathematics as something they do not have the authority to question or create, such as when children execute procedures like "borrowing and carrying" without conceptual understanding of place value (Laupa, 2000). In contrast, mathematical play can allow children to engage in mathematics in ways that allow them to explore, reason, and rely on their own authority (Wager & Parks, 2014). In this study, we were interested in identifying qualities of mathematical play in a kindergarten classroom that made it possible for children to challenge authoritative discourses about mathematics. For example, rather than seeing mathematics as primarily requiring the memorization and recitation of correct answers, we hypothesized that certain kinds of mathematical play might allow children to raise mathematical questions of their own, form and test mathematical conjectures, and engage other children and even teachers in mathematical arguments. In defining play, we drew on definitions that emphasized play as providing opportunities for pleasure, chosen repetition, creativity, social engagement, and use of attractive materials, whether or not individual children took up these opportunities (Burghardt, 2011). To guide our study, we asked the following research question: What qualities of play-based tasks support children's meaningful sense-making about mathematics and to engage with mathematics as more than an authoritative discourse circulated by the teacher?

Theoretical frame

In exploring the potential of play in a kindergarten classroom during mathematics, we adopted a discursive perspective on authority, heavily informed by the work of Bakhtin (1981). Bakhtin (1981) differentiated between authoritative and internally persuasive discourses. He called authoritative discourses "acknowledged truths," and "the word of a father, of adults and of teachers" (Bakhtin, 1981, p. 342), while he defined internally persuasive discourses as those we believe to be true even though they are "backed up by no authority at all" (Bakhtin, 1981, pp. 342-344). In mathematics classrooms, authoritative discourses circulate around appropriate behavior—for example, sit criss-cross applesauce, raise hands before speaking, obey the teacher—and around mathematics—use proper vocabulary, perform procedures correctly, memorize rules. An authoritative discourse "demands that we acknowledge it, that we make it our own; it binds us, quite independent of any power it might have to persuade us internally" (Bakhtin, 1981, p. 343). In contrast, we hypothesized that play could provide a site for children to develop their own internally persuasive discourses about mathematics.

Methods

This study, which is part of a larger project, draws on interpretive ethnographic traditions (Erickson, 2004). The site of the study was a school serving a racially and socio-economically diverse population. Kindergarten teachers at the school participated in a week of professional development (PD) on mathematical play during the summer as well as four daylong sessions focused on adapting lessons from the mandated mathematics curriculum throughout the school year. This smaller study focuses on one kindergarten classroom with two co-teachers and 26 students during the week of geometry lessons planned during PD. Data collection included video of the week's lessons with four video cameras. In addition, at least one member of the research team observed each lesson. In the weeks before the play-based lessons, a member of the research team observed typical mathematics lessons one or two times each week and took written fieldnotes. For this analysis, the research team viewed video from four recorded lessons in one classroom to identify moments of mathematical play. Additional viewing of the videos focused on identifying authoritative mathematical discourses and moments when children challenged these discourses. These moments were then analyzed to identify differences in children's and teachers' participation in playful mathematics activities as well as to differences in the quality of play and the content of the mathematics (e.g., social engagement, creativity, open and closed problems, etc.) across the playful activities implemented during the week.

Findings

In the weeks leading up to the play-based geometry lessons, children's engagement in mathematics was largely directed by Ms. Lane, who provided explicit instruction and typically assigned independent tasks to children. For example, after first introducing an activity to students in which they counted objects on cards and recorded their counts on a number line, referred to as a "game board," Ms. Lane and her students had the following exchange:

Ms. Lane: Is it time to play?
Students: (*loudly and in unison)* No!
Ms. Lane: Is it time to work?
Students: Yes!
Ms. Lane: "Is it time to learn?
Students: Yes!
Ms. Lane: Is it time to talk to your neighbor?
Students: No!

In typical lessons like this one, Ms. Lane reinforced authoritative discourses about mathematics by focusing on the production of correct answers, acting as the authority in determining correctness, and giving explicit directions about tasks. During these lessons, children typically worked independently after the whole-group introduction. During the week of play-based instruction, Ms. Lane added in group activities co-developed during the PD by the research team and the kindergarten teachers, such as pattern block puzzles, shape sorts, and making shapes on geoboards. During the exploration, children rotated through centers chosen by Ms. Lane.

Authoritative task, authoritative discourse

On the first day of the geometry unit, in addition to using the play-based tasks developed in the PD, Ms. Lane provided the children with a a game that they had played during the previous unit. This game challenged children to unlock a toy by correctly matching a picture with a numeral. The task of the game was relatively closed, supporting only one kind of play with not many opportunities for improvisation. When Ms. Lane engaged with children at this center, she focused their attention on the production of correct answers, as in the episode below:

Layla: *(Counts to 14).* Fourteen! Where's fourteen? (*Picks up a key and smiles at Ms. Lane*).
Ms. Lane: Is that fourteen on the key?... I can't see the number.
(Layla shows Ms. Lane the number 15 key she is holding. Ms. Lane smiles.)
Ms. Lane: FOURRRteeeen, is that FOUUURRRRteeeen? Find FOURRRteeen
(Layla shows key number 13.)
Ms. Lane: FOURteen? Is that FOURteen?
Layla: (*searching for the correct key)* Four....teen

Even though this moment was playful for both Ms. Lane and Layla—they both smiled, Ms. Lane's voice was teasing, and Layla seemed to find pleasure in handling the locking toys—Ms. Lane focused her questions on getting Layla to repeat that the numeral was fourteen and not fifteen rather than exploring Layla's thinking.

Opportunities for improvisation and internal persuasiveness

A center where children used stencils to draw polygons and then mark vertices with dot paints seemed to provide more opportunities for children develop internally persuasive discourses about mathematics. Children could make choices about which shapes to draw and how to mark the vertices, and the blank paper used for the activity supported children in going beyond the authoritative directions for the task. For example, Will and Nicholas wrote numerals inside of a circle they traced, making a connection between the number and geometry. In addition, Ms. Lane's interactions in this center also seemed less focused on reinforcing the authoritative mathematical discourse. For example, when Ms. Lane saw the children writing numerals, Ms. Lane asked the children to explain:

Ms. Lane: What are y'all doing? What's that? *(Points at Will's paper.)*
(Will and Nicholas look at Ms. Lane silently.)
Ms. Lane: Why are you putting those numbers in the circle?
(Will and Nicholas look down at papers, look at each-other, and then smile at Ms. Lane, still silently.)
Tiana: (*Interjecting.)* I didn't put numbers in the circle, but I put a smiley face.
Ms. Lane: No, I am talking to these two. What is that? What are you making?
Will: I'm making a clock.
Ms. Lane: You're making a clock?
Nicholas: Yeah.
Will: Out of the circle.
Nicholas: We are making a clock.

In this episode, the two boys played with the rules of the activity by not just identifying vertices, but also creating pictures out of the shapes. This improvisation allowed them not only to connect shapes and numerals but also to make a connection to a mathematical tool in their ordinary lives. The more open task and the playful social context, which allowed the children to talk freely and build off each other's ideas, supported the children to engage with mathematics as something they had the power to manipulate. In addition, Ms. Lane seemed to adopt a slightly more playful stance in this interaction than in the matching lock interaction, perhaps because the drawing of the clocks inside a shape was both not incorrect and was mathematically relevant.

Authoritative discourse, internally persuasive discourse

Beyond the importance of open activities (e.g., those that supported choice, exploration, and multiple answers), spaces where children could interact outside of the watchful eye of the teacher provided important opportunities for children to develop internally persuasive discourses about mathematics.

One morning before centers, Ms. Lane led a whole group discussion about the orientation of triangles, asking the children to decide if triangles of various shapes and orientations were still triangles. Some children said no, and she talked about how orientation did not determine if shapes were triangles. She prompted children to count all the sides and vertices to determine if a shape was a triangle.

Following this discussion, Will, Nicholas, and Tiana were assigned to a geoboard activity during centers. Each child had a geoboard, stack of shape cards, and some rubber bands. Ms. Lane had asked children to choose a card that had a shape on it and to recreate that shape with rubber bands on their geoboards. As Will, Nicholas, and Tiana begin the geoboard activity, Ms. Lane joined the group to continue the conversation about orientation. She presented the group with a square shape card turned so the square stood on a vertex. Will and Nicholas both claimed that the shape was a diamond while Tiana was insistent that the shape remained square, regardless of its orientation:

Ms. Lane: *(Addressing Nicholas.)* What is it this way?
(Ms. Lane turns the card three different ways and repeats her question. Nicholas continues to call the shape a square only when a side was parallel to the table; otherwise, he calls it a diamond.)
Ms. Lane: *(Addressing Nicholas and Will.)* How does it change from a square to a diamond? It's still the same shape.

In this exchange, Ms. Lane maintained her commitment to reinforcing the authoritative discourse about shapes—orientation does not matter—even though Nicholas disagreed. Ms. Lane continued to press her point by grabbing a board eraser and turning it in multiple directions, asking what it was at each turn. The children agreed it was always an eraser, but when Ms. Lane returned to the square example, both Nicholas and Will still insisted it was a diamond. Throughout this interaction, even in the play-based context, Ms. Lane maintained a commitment to guiding children toward authoritatively correct answers. However, the playful context of the center and Ms. Lane's own smiles seemed to have made Will feel comfortable in reiterating his own position— the square is a diamond—even though it was backed up by "no authority at all." Ms. Lane left the group before she convinced Will and Nicholas to adopt her position. Not long after Ms. Lane left, Will, looking at a square, exclaimed, "It's a diamond! I know it is!" Then, after about a minute of individual work, Tiana reintroduced the orientation conversation:

Tiana: (*showing the square card to the group)* What is this everyone?

Both boys: *(without really looking)* A square.
Tiana: *(changing the orientation of the card)* If I flip it over like this, what it is? *(looking frustrated)* How does this change, but... what if you had a triangle? When you flip it over it still looks like a triangle because all of the sides are the same. *(shows Will a triangle card)*
(Will repeatedly affirms the shape is a triangle as Tiana turns it.)
Tiana: *(shows two different square cards turning them to be different and then matching orientations)* Then how does this one change? They are both the same thing!
Tiana: *(attempting to build a hexagon on her geoboard by making two trapezoids)* I'm making the same shape you teached me.
Will: *(making a square on his geoboard)* I got a diamond. Did you know, if it's a square sideways or diagonal then it's a diamond. Do you see the difference? Nicholas, do you see the difference? *(Taking a breath and pointing to his square turned on a vertex)* This is actually a square! Look! It's just facing diagonally.
Tiana: That's what I just told you.

In this independent interaction Tiana advanced an idea she seemed to find internally persuasive—that the orientation of the shape did not change how it was identified. No doubt, hearing this argument from both Tiana and Ms. Lane helped Will reach a similar conclusion. However, it was his own play with the geoboard that brought his own internally persuasive discourse about shapes in line with the authoritative discourse. The atmosphere of play, where children were able to make shapes on their own, to talk as they worked, to argue and disagree with the teacher supported their exploration of mathematical ideas.

Discussion

As with previous research, introducing playful spaces into the kindergarten provided opportunities for children to construct their own internally persuasive discourses about mathematics; however, some characteristics of play seemed more important to children's sense-making than others. While children found the matching numeral and quantity locking game pleasurable and talked with each other and the teacher while playing with it, the play did not allow them to do their own sense-making, but rather pushed them toward accepting authoritative discourse. In contrast, the tracing shapes and geoboard activities allowed children to alter the tasks in ways that let them explore questions of interest to them and to develop their own understandings. This suggests that closed playful tasks—even if they are pleasurable, social, and low-stress—may not provide the kind of support necessary for children to do their own sense-making around mathematics.

“I Guess My Question is Like”: Problematizing in an Introductory College Physics Lab

Sophia Jeon, Ian Descamps, David Hammer
Sophia.Jeon@tufts.edu, Ian.Descamps@tufts.edu, David.Hammer@tufts.edu
Tufts University

Abstract: There are beginnings of research studying how college students manage the experience of not-knowing in instructional laboratories. Previous work in introductory physics focused on student problematizing has had mixed results in activities designed to guide students to recognize and address an apparent discrepancy. Here, we study an instance of a student’s successful problematizing, starting from her initial puzzlement during her group’s exploration of a Newton’s Cradle. We highlight the idiosyncrasy of the instance and suggest it raises questions for curriculum design.

Doing science in lab entails being puzzled by natural phenomena

For more than a century, physics educators have called for reforms in instructional labs to encourage students to observe and interpret natural phenomena, rather than to confirm known results (Otero & Meltzer, 2017). Recent work has provided new motivation for these reforms, finding confirmatory labs do not result in any measurable gains in students’ conceptual understanding (Smith et al., 2020). As well, the shift toward objectives of students’ *doing science* has had support in national standards (National Research Council, 2012) and in strands of research on how students learn to appreciate and engage with experiences of *not-knowing* (Watkins et al., 2018).

A number of researchers (Chen & Qiao, 2020; Manz, 2018) have focused on feelings of uncertainty, “the uneasy sense that something is missing or amiss” (Phillips et al., 2017, p. 1), as the beginnings of scientific inquiry. While much research has focused on student learning about *measurement* uncertainty, we consider the broader construct of *epistemic* uncertainty: the feeling and assessment that there is some gap or inconsistency in one’s understanding. Taking that sense seriously entails the often-difficult work of *problematizing*: “identifying, articulating, and motivating a problem or clear question” (Phillips et al., 2018, p. 983).

Recent lab reforms have designed activities guiding students to experience a planned surprise or discrepancy—their data in conflict with their expected results. Part of the goal of these activities is students taking up the opportunity to problematize and construct their own knowledge. These efforts have sometimes led to success (Sundstrom et al., 2020), but the outcomes are highly variable (Descamps et al., 2022; Phillips et al., 2021). The diversity of findings in previous research motivates further study of how students come to problematize in lab. Here we examine an instance of successful student problematizing in a context of an open-ended lab activity.

The students were enrolled in an introductory physics lab as part of a course taught by the third author. There were four lab activities in the course, each lasting 2 or 3 weeks with progressively reduced structure, designed to encourage students to problematize. The lab activity presented in this study was the final and most open-ended of the semester.

We collected video data as a part of a larger project that studies what shifts or sustains undergraduate students’ framing in physics labs (Descamps et al., 2022; Phillips et al., 2021). Here, we studied an episode of one group’s exploration of a Newton’s Cradle and selected it as an instance of successful student problematizing. This clip interested us because of the sudden onset of confusion that a student expresses in the activity. Our analysis of this clip followed Derry et al. (2010)’s video research methods and had iterations of the following process: we viewed the clip, gathered multiple interpretations, and watched it again to refine our initial interpretations. The first author wrote the interpretations and revised them after discussing with the other two authors. Here we present a moment-to-moment analysis of an emergence of student problematizing.

A student problematizing in a physics lab

There were three students in the lab group, Esther, Abby, and Anita (pseudonyms), all first-year undergraduates in the school of engineering. Demographic course data informed us that all three students identified as women, Esther and Anita as Asian, and Abby as White. Leading up to the episode in this paper, the students start their final activity of the semester, with the assignment to arrange some form of collision and study it, and the students were free to ask whatever empirical question they choose. After some initial exploration, this group decides to build and study a simplified Newton’s Cradle comprised of three pendula.

Anita and Abby try to make it work the way it is "supposed to": an outer ball hits the middle ball, which does not move but hits the other outer ball up in the air, which falls back to make the first ball go up again and so on. Esther is with them at first and then retreats to her laptop. When Anita and Abby finish setting up the apparatus, they see that all three pendula swing after the first collision—they do not behave as they are "supposed to."

Anita proposes adding more mass to the middle ball, and explaining, "if it's more massive then it'll have more inertia, will be more resistant to acceleration." Neither Abby nor Esther takes up this bid; Anita decides to do it herself. She hangs a hook with masses on the string that holds up the middle ball, and she watches the first couple of collisions: The middle ball stays relatively still after it gets hit by the first outer ball, and the other outer ball swings up farther than before. Abby and Anita see this, and Anita immediately expresses her confusion, the moment at which the transcript begins. The entire episode occurs over two minutes.

01 Anita: Why does it do that? I don't get that. [looks at the setup]
02 Esther: What?
03 Abby: What?
04 Anita: Why it, why it {[unclear]} [points at the middle ball]
05 Esther: {'Cause it's} harder to, to resist. [releases the left ball] It's
06 harder — {It can resist}
07 Anita: [Points at the middle ball, left ball, and back to the middle ball]
08 {But wait these,} wait, it [left ball] went all the way back up. Right?
09 Wait wait wait.
10 Abby: It should. {It should.}
11 Anita: {It [unclear].} But why? [in a whisper, looking to Abby]

Anita becomes puzzled by how the outer ball bounces off a stationary middle ball. She points at the middle and left balls and articulates the source of her confusion, that the outer ball goes "all the way back up" (line 08). Keeping her eyes on the apparatus, she is struck by the outer ball's clear bounce that happens after she adds mass to the middle ball to make it more stationary.

We are struck ourselves that Anita expresses confusion about the phenomenon that she has been trying for some time to arrange. Seeing it happen seems to shift her into wondering: Why does the outer ball bounce up in the air when the middle ball is stationary? While Anita has focused on adding mass to the middle ball until this moment, she now notices the phenomenon is puzzling, which she tries to identify and articulate. Esther and Abby ask Anita to clarify (lines 02 and 03), and they try to answer her questions (lines 05, 06, and 10). Their responses, however, do not seem to address Anita's confusion, as she points at the left ball (line 07) and emphasizes "why" (line 11) in a whispering tone. Their efforts to respond apparently supports Anita to articulate her question further, perhaps because they do not seem to understand what troubles her.

Anita's efforts to problematize continue

About thirty seconds pass, during which Anita suggests making the middle ball even more massive. Abby points the group's attention to the first collision, and Esther and Anita raise questions about its underlying mechanism.

12 Abby: 'Cause like, it, although because it's, it's not perfect, it's not perfect,
13 but like, [releases the right ball] we have the first one.
14 Esther: But why is it, why is it working?
15 Anita: [Leans in closer toward the apparatus, remaining in her kneeling
16 position] Yeah, I don't know why that the ball is [unclear]
17 Abby: 'Cause it's supposed to be
18 Esther: But why put an extra mass there?
19 Abby: 'Cause it makes it not move. Just because of our error and have it
20 [unclear] collision
21 Anita: I don't understand why
22 Abby: 'Cause the energy
23 Anita: How like, how the – the energy is being transferred
24 Abby: I wanna see if it works. [releases the right ball]
25 Esther: The energy is transferred.
26 Abby: The, the only thing it does is make sure it stays still. It stays in the
27 middle.

Esther's question (line 14) seems to support Anita's confusion, as Anita agrees and continues (line 16). She reiterates her uncertainty (line 21) and revises her question in terms of energy transfer (line 23). In the group's earlier discussion with the TA, Esther explained that she expects full transfer of energy between the balls, which may be what Abby and Anita recall at this moment. What remains unclear for Anita, though, is *how* the energy transfers. She refines her question from wondering about why the outer ball bounces up in the air (lines 07-11) to wondering about how energy transfers (line 23).

In this way, Anita formulates her question in a collaborative effort with her peers: She reiterates Esther's question (line 14), and she asks about energy after Abby mentions it (line 22). Throughout this interaction, Anita is kneeling on the floor, at eye level with the apparatus, and pointing at different features. The materiality of the phenomenon drives her curiosity.

Anita further refines her question

Still thinking about energy transfer, Anita clarifies her question further.

28 Anita: But I guess my question is like [takes hold of the middle ball], when
29 this stays still how does the energy
30 Esther: Transfer?
31 Anita: Yeah. Do you know? [points at Esther with her finger]
32 Esther: Yeah. It [left ball] hits this [middle ball] and it goes through, hits
33 that [right ball]. Passes through.
34 Anita: But, but what if this. What if this [middle ball] is, this [middle ball]
35 stays completely still. It [middle ball] won't do anything?

Anita takes hold of the middle ball, and she asks, how does the energy transfer when the middle ball "stays completely still" (line 35)? That the middle ball stays still, and the outer ball bounces, does not make sense: How can the middle ball transfer energy if it stays still?

She begins her question with the words, "But I guess my question is like" (line 28), which show her effort to arrive at a question. She is still crouched on the floor with her eyes on the apparatus, holding the middle ball in her hands. Anita's physical handling of the apparatus continues to drive her wondering about it. Esther also contributes to Anita's problematizing, as she helps to finish the question (line 30) and offers the idea that "it goes through" (line 32)—probably to mean the energy goes through, or "passes through", the middle ball (line 33). Esther's explanation does not satisfy Anita, who articulates her question again: If the middle ball "stays completely still" would the phenomenon still happen (line 35)? Anita and Esther's different understandings of the mechanisms that underlie energy transfer afford Anita an opportunity to further refine her question.

Contextual dynamics of a student problematizing

To review, Anita's wondering begins with her seeing the very phenomenon that she has tried to make happen. The physicality of the event—the clear bounce of the outer ball off the middle ball, which she watches closely—is the initial trigger. Her effort to articulate what troubles her is supported by her peers, although they do not seem troubled themselves. This suggests social features of the context also played a role (Appleby et al., 2021): The three students have worked together for months and developed a social rapport, evident in their frequent banter and laughter, that supported their attention to and caring about each other's thinking. Of course it also matters that the students were working within instructional labs designed to encourage sensemaking (Etkina et al., 2010). There is evidence here of Esther's framing lab as about their making sense of their data, and in other moments, it is Esther who presses the group with questions.

This moment, in sum, was idiosyncratic. No one could have anticipated these particular dynamics. It is also difficult to imagine a lab design that could have guided Anita to her question. So, what if idiosyncrasy is an ordinary feature of students' problematizing? Perhaps the mixed results in prior accounts of when and how undergraduate students problematize in physics labs reflects the complexity of the dynamics (Descamps et al., 2022; Phillips et al., 2021; Sundstrom et al., 2020). This case, with others, motivates that consideration. Many efforts to support problematizing in the literature involve designing a specific experience of discrepancy into the phenomenon students are to explore. It is clear that these approaches can be successful; we do not propose abandoning them. We suggest, however, that many instances of students' problematizing will arise outside of such specific plans. One implication is that the guided-discovery approach to *problems* has similar challenges to those of the guided-discovery approach to concepts (Hammer, 1997), and so enactments of such curricula should leave room for instructors' discovery of students' productive thinking the designs did not anticipate.

More broadly, instructional labs to support student problematizing would benefit from diversity of approach, including designs to engender idiosyncrasy. This of course argues for student projects, although within introductory courses there may be tension between the various ideas that students want to explore and the shared features of experience in their thinking about similar topics. At another level, labs can pay more attention to student framing of laboratory experiences, including their expectations for how they may be agentive in their learning within the activities. In that regard, Cherbow & McNeill (2022) introduced the possibility that curricula may be *too successful* at anticipating students' thinking, if students come to expect that of the materials: if the course already knows what they are going to ask, why should students bother asking? For instructors and researchers working to prioritize students' agency, the challenge is to designing labs that create space for students' emergent ideas and idiosyncratic questions. Students need opportunities to experience and take up puzzlement of their own.

Abstract: Computational Thinking (CT) is a vital and multi-dimensional skill for all learners. Understanding the development of CT's different dimensions is essential to refining educational experiences that best support it. In this study, we investigated the development of three aspects of CT: Self-Perception of Computational Ability, Modeling and Simulation, and Computational Problem Solving, as students engaged in collaborative game design and programming practices within a game-design platform, *WearableLearning* (WL). Through their engagement with WL and its accompanying curriculum, we show preliminary evidence for developing two CT dimensions, Modeling and Simulation and Computational Problem Solving, and discuss the challenge of developing Self-Perception of Computational Ability. We found an increase in students' ability to understand machines and their processes and an improved capacity to think algorithmically as they constructed models, debugged, and iterated through their designs. Student Self-Perceptions of Computational Ability, however, did not change significantly.

Introduction

Educators recognize that Computational thinking (CT) is an essential skill to master within STEM fields (Wing, 2006). Considered a key aspect of Computer Science (Grover & Pea, 2018), CT is now understood to more broadly encompass the thought processes and practices necessary for systematic problem-solving, such as iterative testing, algorithmic thinking, and troubleshooting, among others (Weintrop et al., 2016; Shute et al., 2017; Resnick et al., 2009). In particular, there is limited work that explores CT within environments that leverage game design to teach critical CT skills and concepts. Our work describes the results of engaging students in a six-stage curriculum (the WearableLearning curriculum) that teaches CT through programming and playing games on a web-based game design platform.

The *WearableLearning* Platform (WL) aims to develop students' CT skills by having K-12 students and teachers create, administer, and play multiplayer games using mobile devices (Arroyo et al., 2022). In this work, we sought to understand the impact of the WL curriculum that involves gameplay, game design, programming, and testing. We thus explore the following research question in this work: *what aspects of Computational Thinking does the process of game playing, game ideation, and programming/implementation impact*? We hypothesized that the aforementioned processes would yield an increase in students' CT abilities, in particular: how students see their abilities to solve problems (self-perception of computational ability), their understanding of machines and models that represent their functioning (modeling and simulation), and their capability to generate correct solutions that use logical reasoning (computational problem solving).

Background

Computational Thinking has become an umbrella term that refers to a broad set of early Computer Science skills essential to thrive in our increasingly digital world (Wing, 2006). Many scholars have grappled with the different definitions of CT and have contributed different, highly context-driven answers. Most definitions include the aspects of problem decomposition, pattern recognition, data representation, generalization and abstraction, systems thinking, and algorithm-building (Grover & Pea, 2018). Another one of the most thorough analyses of CT at the K-12 level (Weintrop et al., 2016) suggested the following practices within CT: analyzing and logically organizing data; data modeling, abstractions, and simulations; formulating problems so computers may assist; identifying, testing, and implementing possible solutions; automating solutions via algorithmic thinking; and generalizing this process to other problems. We agree with the reflection by Román-González et al. (2019), which suggests that the term *Computational Thinking* has helped to extend Computer Science Education beyond computer programming, and helped to lower the barriers to entry for learning computer programming, in part, due to an increase in the number of visual block-based programming languages. In addition to developing cognitive skills, engaging in CT offers the opportunity to develop noncognitive aspects related to attitudes and 21st-century skills such as persistence, self-confidence, tolerance to ambiguity, creativity, and teamwork (van Laar et al., 2017).

Thus, the uses and applications of CT have evolved and grown beyond strictly CS education (Kalelioglu et al., 2016).

Exploring the different dimensions of CT enables us to identify distinct mental processes during problem-solving tasks in contexts within and beyond coding and programming. Game design emerges as a context that is rich with opportunity to develop CT because students are tasked with creating a sequence of interfaces while keeping scale, difficulty, individual differentiation, and complexity in mind (Kafai et al., 2015). Engaging in CT often results in a logic-based computational solution to a problem that is defined at various levels of abstraction. CT involves a cyclical process where a problem is explored at a high level of detail and precision, with multiple possible solutions. These solutions need to be articulated and implemented to varying degrees, tested according to a success criterion, and revised or redefined.

The WearableLearning platform

The WL Platform is a browser-based platform that enables users to create and deploy active math games without prior programming experience (Castro, 2022). The programming interface (see Figure 1) consists of *states* and *transitions* that users drag and drop onto a canvas on the screen to create a game flow. *States* contain specific game content that are displayed to a game player, such as text (e.g., questions, prompts), images, sound, and videos. Movement from one state to the next depends on the *transitions* that connect states. A player can enter text, color codes, or press buttons corresponding to choices to transition from one state to the next. WL's Game Creator functionality includes a debugger, which runs a simulated game instance to show what a Game Player would see on their screen as they progress through the game, allowing users to troubleshoot, debug, and fix errors as they develop their game.

The WearableLearning curriculum

The WL curriculum consists of a series of guidelines and materials to support teachers in guiding their students through a six-stage process of playing, creating, and modifying games. The overarching goal is to design an active, educational, collaborative math game aided by mobile devices for learners to play, learn, and practice math skills. Students work through an iterative design process and engage in designing, prototyping, and testing/evaluating their game designs, and redesigning after feedback from other students. Students follow a six-stage design process: (1) playing games, (2) brainstorming and designing a game on paper, (3) drawing finite state machine diagrams, (4) programming the games on the WL platform, (5) playing a math game made by peers, and (6) observing others play their math game and iterating on their game based on these observations.

Methodology

To address our research question, we conducted a study with 47 students (11–13 years old), across two after-school programs in Eastern and Western Massachusetts in the United States, where students experienced the six-stage WL curriculum over 8-10 hours of contact time. Across both programs, 22 (46.8%) of students self-identified as male, 18 (38.3%) self-identified as female, and 7 (14.9%) preferred not to answer.

Instruments

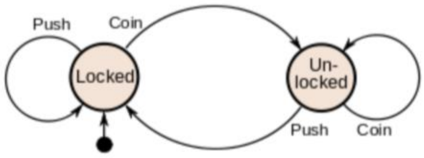
We designed pre- and post-tests to measure three different aspects of CT: Self-Perception of Ability, Modeling and Simulation, and Computational Problem Solving, before and after students engaged in the WL curriculum. The full curriculum and instruments are at https://osf.io/tx9ab/. The first section of each test gleaned students' self-concept of how adept they considered themselves at computational tasks and the use of computers. This section was adapted from Angeli et al.'s (2016) work on CT perspectives where they describe what students at different grade levels should know to have CT. We created a test of CT self-concept by adapting these notions to feelings of knowing CT skills into seven 5-point Likert scale questions (5="Strongly Agree" to 1="Strongly Disagree").

The second part of the test posed questions related to modeling a machine (Figure 2 shows sample items on a finite state machines assessment). According to Wilensky et al. (2016), CT activities in various capacities include learners designing, constructing, and evaluating models as part of their educational activities. We thus assessed students' modeling and simulation ability by assessing their ability to interpret abstract models of finite state machines, what kinds of machines they represent, and how they function, especially given the heavy focus of the WL curriculum and platform on finite-state machines. We created items on Finite State Machines from beginner material given to students in tertiary education as part of Computer Science classes.

Figure 2

The three items that assessed students' knowledge of Finite State Machines

This is a visual model of how a machine works.



1. Can you tell what kind of machine this could be? What does it remind you of and why?
2. According to this model, what would happen if you put three (3) coins in?
3. The machine is currently locked. What would you have to do to get this machine to go "unlocked" and then back to "locked"?

The final part of the test had multiple-choice items from the Computational Thinking test (CTt) by Roman Gonzalez et al. (2019) relevant to algorithmic thinking concepts, such as sequencing and loops, to measure computational problem-solving skills. According to Wilensky (2016), this involves a variety of skills, such as preparing problems for computational solutions, choosing tools, assessing approaches/solutions to a problem, and debugging. The CTt addresses some of these aspects; we adapted from the CTt and included only the preliminary concepts of algorithmic thinking, excluding the more complex nested loops and conditionals, as those were not part of the topics covered in the instruction for the after-school programs.

Results

We computed a total score for each student for the pre-/post-tests, with the score for self-perception as an average of the Likert scale scores for each student and the FSM and CTt components being sums to indicate correctness. We computed descriptive statistics for the collected data and analyzed the difference between pre- and post-test scores using a two-tailed paired-samples t-test (significance compared to an alpha level of 0.05).

We found a statistical significance in the CT measures for Modeling & Simulation (t=2.01, p=0.05) and Computational Problem Solving (t=2.62, p=0.01) from pre to post-test. Modeling & Simulation showed a small to medium effect size, suggesting that exposure to the WL curriculum activities positively impacted students' skills in creating models and understanding finite state machine concepts. The Computational Problem Solving section showed a small to medium effect size, suggesting that students' engagement with the content and process positively impacted their problem-solving skills. We found no statistical significance for average scores on Self-Perception (t=0.74, p =0.46).

Discussion and conclusion

Students showed improvement in two out of three different measurements of Computational Thinking after being exposed to the WL curriculum and platform for 8-10 hours of contact time. They improved in Algorithmic Thinking/Computational Problem Solving Practices and Modeling/Simulation practices, as reflected in their learning gain. They also developed complex models for their games and debugged those models as they built their games, which had branching and distinct levels of difficulty, using concepts such as loops and parallelism.

Students did not improve in their Self-Perceptions of their CT abilities, which probed students to think about the level of comfort and ease with which they can engage in computational practices and use digital media for problem-solving. There are multiple possibilities why there was no significant improvement in their self-perceptions of their CT abilities. This might be because of the steep learning curve experienced during the 8-hour curriculum or because it was their first experience as active creators of complex games. This experience might have challenged their self-perception of their technology/digital skills. These findings reflect similar results in active vs. passive STEM learning that suggest novice learners are inaccurate in their judgments of how much they learned; this "feeling of learning" can be negatively correlated with actual learning (Deslauriersa et al., 2019). Future work may include increasing student exposure or contact hours with the curriculum, which could make students more comfortable with the learning curve. Another possibility would be to add specific reflection prompts that encourage students to think about what skills they have developed as they participate in this game design and creation process, thereby deliberately building their awareness of the skills they are developing.

The results of our study show that a curriculum based on game design and play can impact the development of different dimensions of CT. Our findings invite discussion for a more granular analysis of our curriculum activities and their impact. Different measurements and instruments of Computational Thinking, focusing on different aspects, could yield different results, as they capture only a portion of what constitutes thinking computationally. Therefore, assessing CT through a multi-dimensional assessment that looks at CT skill development holistically will lead to a clearer understanding of where our students stand and what remains to be improved upon.

Supporting Mathematical Problem Posing Through Representations

Francine Athias, University of Franche-Comte, francine.athias@univ-fcomte.fr
Gerard Sensevy, University of Brittany, gerard.sensevy@inspe-bretagne.fr

Abstract: In this paper we show how problem posing can be organized in the classroom. The decisions were made in a team of teachers and researchers: to use mathematical representations, to choose worked examples and to elaborate a tool called repertoire-instrument. Thus problem posing can be based on concrete representations, on the one hand, and on worked examples on the other. This case study focuses on a dialogue between a teacher and a student. The results concern the potentialities and effects of this device in the implementation in a class. The study is intended to be continued, with statistical analyses of the students' performance and qualitative analyses of the practices implemented.

Purpose of the study

Mathematics and representations

When considering elementary school mathematics, we often find that students see mathematics as a collection of rules and procedures that must be remembered (Richland *et al.,* 2012). However, the essential purpose of mathematical activity, both in the classroom and for mathematicians, is to understand mathematics.

We argue that the construction of mathematical knowledge is a cultural process. In saying so, we hypothesize that we need to understand patterns of culture (Benedict, 2019). These patterns institute certain ways of seeing-as, of doing, certain practices as specific ways of doing things, with a specific jargon. We argue that culture is embedded in representations, that are ways of concretizing culture. Goldin (2020, p. 556) developed these ideas in mathematics education: « *mathematical representations* are visible or tangible productions – such as diagrams, number lines, graphs, arrangements of concrete objects or manipulative, physical models, written words, mathematical expressions, formulas and equations, or depictions on the screen of a computer or calculator – » . These different representations embody mathematical ideas or relationships. In our perspective, the fundamental means of becoming familiar with culture is becoming familiar with representations. This work on representations is based on a national research project DEEC (Determining the Effectiveness of Experiments which are Controlled in teaching and learning), in France. It is devoted to build a set of mathematics lessons at first, second and third grades (6, 7 and 8 years old students). This project is grounded in a cooperative work between teachers and researchers (Sensevy & Bloor, 2020).

Problem posing

Among mathematical and scientific activities, problem posing is one fundamental part, more important, in fact, than problem solving itself (Kilpatrick, 1987). The most crucial thing for doing science is to know how to pose a problem before trying to solve it. Thus, familiarizing students in the process of problem posing is an essential goal for teaching. Problem posing has been recognized as an important intellectual activity in mathematics education (Cai *et al.,* 2015). By giving students the power to pose their own problems the teacher has to share mathematical authority in the classroom. Problem posing work in mathematics has been studied in different classrooms. For example, Singer & Moscovici (2008) described a learning cycle that includes problem posing as an extension of problem solving. Ellerton (2013) proposed a theoretical framework that situates the process of problem posing in a broader process. Zhang and Cai (2021) analyzed specific problem posing teaching cases. They tried to understand the nature of problem posing tasks used by the teachers. They were interested by the ways teachers led students to pose their own problems. These different studies aim to a better understanding of what teaching through problem posing entails for the teacher and the students. In other words, it means that there are two kinds of practice: the practice of the teachers (what they do in the classrooms) and the practice of the researchers (how they analyze it).

Based on Cai's perspectives (Cai *et al.*, 2015), we define problem posing as the following specific intellectual activities. Students pose mathematical problems based on given problem situations which may include mathematical expressions or diagrams. Teachers generate mathematical problem posing situations for students to pose problems. Teachers are able to predict the kinds of problems that students can pose based on a given problem situation.

Problem posing through a work between teachers and researchers

Teachers and researchers work together to understand what is problem posing and what is the practice of problem posing.. The purpose of this paper is to provide an understanding of what teaching mathematics through problem posing could look like. Students have to write mathematics thanks to representations and problem-posing (Richland et al., 2012). For example, they use symbolic writing (135 – 119= 16) and at the same time the number line, a box of numbers (see table 1).

Table 1
Different representations

119 + **16**= 135 135 – 119= **16**		135 119 **16**

In the classroom teacher and students study problems in a problem posing activity. They keep track of these problems. These problems are considered as emblematic examples, they are categorized according to their mathematical structure : change, combine, compare (Riley *et al.*, 1983). These emblematic examples of the practice can be seen progressively as exemplars, in Kuhn's sense (Kuhn, 1977).

The repertoire-instrument for problem posing

We focus on the fundamental fact, in the teaching-learning process, that students learn by relying on a previous set of meanings, that we may call a "*déjà-là*" (*already-there,* Sensevy **2014)**. In order to teach, a teacher has to gain a deep understanding of this *already-there*. For doing that, we argue that a promising avenue consists of organizing the teaching-learning process on the basis of specific examples of the way problems are posed and solved. The use of analogy is common in the posing/solving problem activity. Thus, the teacher works on problems with students, have them study solved problems, which can be understood as worked examples (Sweller, 2006). The set of these studied problems constitutes a repertoire-instrument for the class. Its "repertoire" function consists of the institution of a memory of emblematic problems of the class which will be considered as *exemplars* (Kuhn, 1977). Another function "instrument" corresponds to the use that students make of it to solve or pose new problems. This repertoire-instrument is a notebook available at each moment. The teachers and researchers team has developed the idea of this notebook as a way to support problem posing sessions. Teachers and researchers share this idea: a repertoire-instrument must contain problems that each student can solve.

Research question

Grounded on the previous analyses, our research question is the following: in the classroom, how the repertoire-instrument that the teachers and researchers team designed can help students pose problems and solve them ?

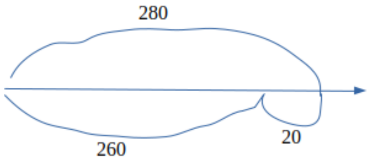
Methods

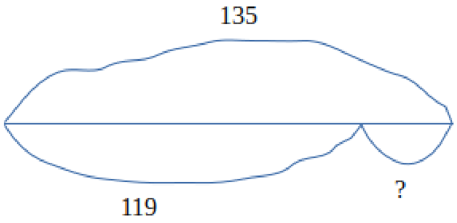
To try to answer this question we rely on various data collected during the implementation of the problem posing phases and in particular on classroom videos. In this paper we have chosen to describe and analyze what happens in the classroom of one of the teachers who is part of the team of teachers and researchers. This class, while being specific, is part of the team's culture and the culture of posing/ solving problem based on representations. The teacher and his students worked on posing problems early in the year. For example, they developed an example of each category (Riley et al., 1983). These categories were named by the team of teachers and researchers and these names were repeated within the class. We will focus on two categories, comparison and combine. This jargon captures a part of thinking in the classroom: each student is able to say what they are doing, thanks to the repertoire-instrument. In the classroom the teacher organized the same process during problem-posing session. The students are on their own to pose problems: they use a slate, on which one can easily erase and rewrite. The teacher is there but he doesn't help. The specific session was video-recorded and transcribed. We have identified three phases: reading the repertoire-instrument together in the classroom, individual work on the slate, intervention by the teacher with different students. We look at the exchanges between one student and the teacher. We selected this moment in particular since the teacher's role in this discussion exemplifies some central principles for using the repertoire-instrument and mathematical representations.

Results

As a result we will focus on the place of the repertoire-instrument during the exchanges between the teacher and a student called Andreas. Andreas wrote a problem: "I've got 260 marbles. Chloe has got 20 marbles. How many marbles are there altogether?" and made a number line (see table1). He explained that he wanted to compare the number of Chloe's marbles and the number of his own. The teacher asks the student to look at his number line. The teacher then brings up the page of the repertoire-instrument (see table 1), which he places next to the number line produced by Andreas.

Table 1
Both number lines

The Andreas'number line	The number line on the repertoire-instrument
	




He then explains to the student that in his problem, he was looking for what was "at the top" of the number line (280). He then adds that it is not the same thing in the comparison problem, without specifying further. After these exchanges around the number line, the teacher rereads the student's statement aloud. The teacher then asks the student about the meaning of the question in the student's problem: "What are you looking for in the problem? ". Without hesitation, Andreas answers that he is looking for the whole and names the problem category (combine). He has now correctly identified the type of problem he has posed. The teacher confirms, but he does not stop there: "Yes, but you wanted to write a comparison problem. He rereads the beginning of the problem: "I have 260 marbles. Chloe has 20." He asks again about the type of questions to ask for a comparison problem. The student then asks: "How many marbles does Chloe need to have the same number of marbles?"

Let's analyze this particular moment. The student has correctly posed and solved a problem that he finally recognized as a combination problem. But as the student indicates that he wants to pose a comparison problem, the teacher helps him to investigate. The teacher's expertise here can be understood in the following way. The teacher does not accept this problem, even if it is correctly recognized, now by the student as a combination problem. He encourages the student to start from his initial choice: the student wanted to compare the number of his marbles to Chloe's - not to know the total number of marbles. It is a question of posing and solving a problem that the student poses to himself; and not of posing and solving "mechanically" a problem by imitating the representation that appears in the repertoire-instrument. The teacher helps the student in this sense, by comparing the representations used by the student (the number line) and the one of the exemplar of the repertoire-instrument. He wants the student to compare the place of the number sought in the two number lines. In Andreas's number line, the teacher simply states that it is the number "at the top" (280) that is being sought. He does not say that in a comparison problem, the number to look for is "down" In the classroom, the number being sought is usually represented by the question mark. Then the teacher directs the student's attention to the problem question. Andreas's quick responses show his knowledge of the problem categories (combine and compare), responding to the teacher's prompts. We know that the repertoire-instrument is next to the student, with the question, "How many centimeters does Chris need to be as tall as Hana?". We cannot determine whether the proximity of the question of the repertoire-instrument is an aid or not.

Discussion & conclusion

The problem posing requires that the students be able to pose and represent a problem, and to solve it by relying on relevant habits. We tried to show the crucial role of the teacher. He is able to lead the student thanks to these habits, the *already-there*. His help focuses on the exemplar of the repertoire-instrument, a shared exemplar that students can imitate and can build on, only after a sufficient study of it. Through this case study, we can see that the teacher leads the student to understand the problem posing task and the role of the exemplar to pose himself new mathematical problems thanks to the repertoire-instrument. On one hand, student succeeds in designing concrete word problems he is able to solve. On the other hand, an abstract theoretical thinking enables the student to move beyond the words and numbers presented in the problem. The student becomes familiar with an appropriate mathematical structure. For example, the student is able to say that he had written a combine problem when he wanted to write a comparison problem. At the same time, the teacher does not let him in posing a "simple" mathematical problem, which answers a problem posing task. But he leads him to pose a problem that matters to this student. The students involved in this sequence seem to do better on the problems in the national assessments, because they know how to represent problems (Fischer *et al*., 2019). To go further, we want to combine two types of analyses: on the one hand, statistical analyses to identify what is effective in these classroom practices on the basis of students' performances (Evidence Based Practice); on the other hand, a documented joint analysis of these practices, by the members of the team, which determines the reasons for the effectiveness of these practices (Practice Based Evidence, PBE).

Unpacking the Complexity in Video Artifacts: Visible and Audible Dimensions of Teachers' Noticing

Sarah Larison, Northwestern University, slarison@u.northwestern.edu

Abstract: Video artifacts can support teachers in learning to notice phenomena like students' mathematical thinking (van Es & Sherin, 2002) and participation (Wager, 2014). Less is known about the physically visible and audible dimensions that teachers attend to while viewing video. Here, I characterize what teachers noticed in videos of classroom interaction in terms of the visible and audible features of their noticings. Teachers noticed four dimensions in video: *Talk, physical artifacts, time* and *bodies*. Teachers noticed seven dimensions of talk in video: *Students' words, teachers' words, interactions, prosody, distribution of talk, background talk,* and *silence*. I argue that these dimensions can add to our understanding of the affordances of video for supporting teachers' noticing. Further, mapping the physically visible and audible dimensions that teachers attend to when viewing video can contribute to our understanding of the conceptual contours of what teachers notice when viewing video.

Introduction

Video has been shown to support veteran and pre-service teachers' (PSTs') noticing and learning to notice (Amador et al., 2021; Santagata et al., 2021), or their attention to and interpretations of facets of classroom interaction (Sherin et al., 2011). Video artifacts uniquely afford teachers the opportunity to examine the complexity of authentic classroom interaction while providing time for careful examination (Sherin, 2004). How video supports that examination has been less explored. One related question is, what do we mean by *complexity* when we describe what is available to be noticed by teachers via video? While the field has begun mapping the conceptual contours of what teachers notice when they notice via video, we know less about the physically visible and audible dimensions of video to which teachers attend.

Research on teacher noticing via video has explored how teachers notice different phenomena such as students' thinking (van Es & Sherin, 2002), strengths in students' thinking (Jilk, 2016), students' ways of knowing that may differ from normative conceptions of "smartness" (Roth McDuffie et al., 2014), and their participation (Wager, 2014). One study, for instance, characterized what teachers noticed about students' thinking along teachers' interpretive dimensions, finding that teachers noticed things like "indicators of learning" and "problems to be addressed" (Colestock & Sherin, 2015). Teachers often attend to what students say as evidence of their thinking (e.g. Sherin & Han, 2004; Goldsmith & Seago, 2013). But what about students' talk do they *see* (e.g. facial expressions or accompanying gestures) and *hear* (e.g. prosody or volume)? What interpretations do teachers draw related to those dimensions? And based on their interpretations about what they saw and heard, how do teachers decide whether a student "learned" or that there is a "problem to be addressed?" These are open questions related to how teachers notice students' thinking. The same questions can be asked about other phenomena that teachers notice, like students' participation.

Exploring what teachers notice in terms of what they physically see and hear via video is important theoretically and practically. Theoretically, beginning to index what teachers notice in terms of what they see and hear can contribute to the field's unpacking what it means or can mean to notice a given phenomenon, or the range of phenomena teachers notice. Practically, we can begin to develop criteria from which teacher educators and teachers can draw to more purposefully record, choose, or segment video for learning purposes, key to the work of facilitating video-based learning opportunities (Kang & van Es, 2019) and itself fertile ground teacher for learning (Richards et al., 2021). As a foray into exploring what we mean by *complexity* (Sherin, 2004) when we describe what is available for teachers to notice via video, I ask: When discussing video of classroom interactions, what did PSTs notice, in terms of what they physically saw and heard?

Methods

These data are part of a larger study designed to explore how first-year elementary mathematics teachers make sense of video artifacts together *without* heavily structured facilitation. Seven PSTs, all recent graduates of the same master's degree program at a mid-sized university in the Midwestern U.S., participated in the meetings. All PSTs intended to teach mathematics in an elementary or middle school setting in the U.S. in the 2022-2023 SY. All PSTs identified as women. Six identified as white and one as biracial: Black and Caucasian. I facilitated two meetings for participants to get comfortable viewing and discussing video together, asking, "What did you notice?" and "What implications can you draw for your practice?" Data sources include the transcripts of the two meetings in which teachers discussed video clips after viewing them together. In total, teachers discussed classroom video for ~42.5 minutes. All videos teachers viewed were publicly available on Teachingchannel.org. I selected videos that showed raw footage of classroom interaction, and chose each clip based on what I imagined might encourage varied interpretations. I did not contribute my own thinking to teachers' discussions about the video, only occasionally interjecting to ask teachers to clarify their thinking.

Phase 1 of analysis included segmenting teachers' talk turns (n=55) by idea unit (Jacobs & Morita, 2002), or the topic of their talk (n=158), and then again by whether teachers were noticing, or attending to and interpreting moments from the video, rather than ideas or experiences outside of the video (e.g. Sherin et al., 2011). Phase 2 of analysis included coding noticing segments (n=90) along the lines of the visible and audible dimensions of video teachers' noticing, using the constant comparison method (Charmaz, 2005). Phase 3 of analysis included coding for dimensions of the category of talk (n=52), one dimension of video that emerged in Phase 3, using the constant comparison method (Charmaz, 2005).

Findings

Teachers noticed four visible or audible dimensions of video: Talk, physical artifacts, time, and bodies

When discussing clips of classroom interaction, teachers talked about what they noticed in the video in about 57% of their total talk turn segments (90 of 158). Across their noticings, they made explicit the physically visible and audible dimensions to which they attended about 84% of the time (76 of 90 noticing segments). Each of these segments were characterized as either talk, physical artifacts, time, or bodies. In these data, teachers attended to talk more often than all of the other visible or audible dimensions of video they attended to combined, ~58% (n=52) of the time. I will further unpack the dimension of talk in Finding 2. Following talk, teachers noticed physical artifacts most often (n=12). They discussed pattern blocks and a ten frame with magnets, as well as papers and whiteboards showcasing student work. When teachers noticed time (n=7) they noticed teachers' wait time, the allotment of time, and the fleeting nature of moments. When teachers noticed bodies (n=5) they noticed gesture and the physical arrangement or physical movement of bodies.

These dimensions of video that teachers noticed can function as an initial framework to explore to what teachers attend, visually and auditorily, when they interpret moments of classroom interaction. We can use these dimensions to explicate what we mean, in physically visible and audible terms, when we describe phenomena that teachers notice, like students' thinking or their participation. We can also explore these dimensions of video that captured teachers' attention to construct and define the range of phenomena that teachers notice via video.

Teachers noticed seven dimensions of talk in video: Students' words, teachers' words, interactions, prosody, distribution of talk, background talk, and silence

Within the category of talk, teachers attended to seven dimensions: Students' words, teachers' words, interactions, prosody, distribution of talk, background talk, and silence or the absence of words (Table 1). While research on teachers' noticing students' thinking has discussed that teachers notice students' talk (e.g. Sherin & Han, 2004; Goldsmith & Seago, 2013), less work has explored the particulars of talk to which teachers attend. We can use these dimensions to explicate what we mean, in physically visible and audible terms, when we describe what teachers notice about students' thinking. Notably, students' thinking is not all that teachers made interpretations about. They made interpretations about pedagogy and relational issues in the classroom, as well. Drawing from the physically visible and audible dimensions of video and talk in video to which teachers attended, we can construct and define the range of conceptually-defined phenomena that teachers notice via video, contributing to the body of research that has begun to map the conceptual contours of teachers' noticing via video.

Table 1
Visible and audible dimensions of talk teachers attended to on video.

Dimension	Description	Example Segment
Students' words	Words, phrases, and questions students used to make their thinking public.	One student saw the equivalent fraction as being like a smaller division of the same amount sort of. *Because she said small triangles would make up the bigger ones.*
Teachers' words	Words, phrases, and questions teachers used to	I really appreciated…the way the teacher affirmed students' sensemaking especially at the end when *he like told the girl, "wow I didn't think about it that way."*

	frame tasks and respond to students.	
Interactions	The order or amalgamation of different speakers' talk turns.	*She's (the teacher) like, "Does anyone think it's false?" and he (a student) wasn't afraid to be like "Yeah I think it's false," even though no one else seemingly felt that answer… and none of the other students were like "How would you think it's false?"*
Prosody	The stress and intonation audible in students' and teachers' words, phrases, and questions.	*I didn't hear in her tone any kind of like shame, you know what I mean? Like it was very much just, "Where'd you make that mistake?"*
Distribution of talk	The amount of words, phrases, and questions offered by different students and teachers.	*I'm still kind of thinking about how much the one girl kind of over here in the video like directly across from the one kid didn't talk as much.*
Background talk	Overlapping and quieter words, phrases, and questions made audible while others were speaking.	*Other kids were immediately like, "Yeah yeah," there is that sense of camaraderie or understanding… a sense of communal understanding without a sense of shame or "you're wrong," you know.*
Silence	The length of pauses between talk turns, and moments without words, phrases, or questions.	*She left a lot of silence while the student was explaining their thinking… until she understood, without asking more questions.*

Discussion and implications

This study contributes to our understanding of how video supports teachers' noticing. By characterizing what teachers noticed along physically visible and audible dimensions, I have begun to unpack how video is uniquely suited to support teachers' noticing and map what we mean by *complexity* (Sherin, 2004) when we refer to the affordances of video for noticing. This study also contributes to our understanding of teachers' noticing via video. The dimensions presented here begin to unpack, in physically visible and audible terms, what teachers attended to in video. These dimensions can be used to further explore what teachers notice when they notice students' thinking (e.g. Colestock & Sherin, 2015) or other phenomena. They can also support the field in continuing to map the conceptual contours of what teachers notice when viewing video, by using the physically visible and audible dimensions of video to which teachers attend as a novel starting point.

Future research can enumerate and refine these dimensions to work toward outlining a more comprehensive framework to represent to what teachers notice via video, and in turn, the unique affordances of video for supporting teachers' learning to notice. Practically, I hope this framework can be expanded and used to further develop criteria from which teacher educators and teachers can draw to more purposefully record, choose, and/or segment video for teacher learning purposes.

The Black Love Framework: How Remembering Leads to Reimagining STEM Pedagogy

Ti'Era Worsley, The University of North Carolina at Greensboro, tdworsle@uncg.edu
Rasheda Likely, Kennesaw State University, rlikely@kennesaw.edu

Abstract: STEM learning spaces have necessitated assimilation for students from minoritized communities. Humanizing pedagogies within STEM learning spaces can serve as an opportunity to broaden participation for historically marginalized youth. Attending to the racialized and gendered intersections of Black students, researchers, and educators, the Black Love Framework provides an opportunity to remember and reconnect cultural ways of knowing and doing within STEM learning. The focus of this research is to highlight the ways Black Love can serve as a pedagogical frame for STEM learning. We argue that community and relationship-building should take precedence beyond the content as the authority within the STEM learning space. Remembering such racial and cultural experiences cultivate a space within education that celebrates and affirms various identities rather than separates or isolates.

Introduction

STEM learning spaces reflect larger aspects of American society such that who is identified as a scientist and science doing is informed by settled hierarchies that privilege Whiteness (Calabrese Barton & Yang, 2000). Students are expected to simultaneously assimilate to cultures of power and thrive in spaces that do not celebrate, encourage, or affirm their culture including language, clothing, and ways of doing (Bang, Warren, Rosebery, & Medin, 2012; Brown, 2006). Science education supports "historically privileged ways of knowing, talking, seeing, and acting shaped by European American practices and values" (Rosebery, Warren, & Tucker-Raymond, 2016, p. 1574). Sense-making and cultural processes are severely undervalued, inaccurately assessed, and overlooked within STEM education. Specifically, minoritized students and teachers such as Black women and girls within science learning spaces contend with assimilation and perforation of who they are and cultures they represent. Collins (2002) theorizes these intersections as a "matrix of domination" (p. 18), due to the multitude of organized structures and systems operating across racial, classed, and gendered boundaries. Particular to STEM, these matrices have been conceptualized as a "double-bind" (Ong et. al., 2011), where women of color experience matrices of domination within STEM workplaces and educational settings because of perpetuated Whiteness (Morton & Parsons, 2018). Therefore, Black girls in STEM at times experience othering and separation, erasure, disinterest, isolation, and irrelevance (Keller, 1985; Ireland, et. al, 2018; Rosa & Mensah, 2016; Roth & Lee, 2004.).

Literature review

STEM tends to be taught from a westernized perspective directly making these spaces rooted in anti-Blackness. Jenkins (2021) defines anti-Blackness as "the socially constructed notion that Black people are non-human, inherently problematic, and disposable, structures the spatial arrangement and social imaginaries of every facet of American society" (p. 111). Ultimately, we consider the question "What does it mean to reimagine the ways in which youth are provided opportunities to engage in science" (Wright, 2016, p. 25)? Considering the call for additional research focused on "integrating the experiences, beliefs, and cultural awareness of Black teachers within spaces of professional learning" (Watkins et. al, 2020, p. 2185), we are presenting a pedagogical framework developed by a Black woman tinkerer and educator while working with Black youth in an informal STEM community-based program. This framework utilizes students' and teachers' experiences inside and outside of the classroom for pedagogical strategies for STEM learning. Essentially, the framework operationalizes experiences in the community and at home for learning (Ladson-Billings, 1992). The act of remembering "refers to the process of bringing to mind a particular event, feeling, or action from one's past experiences and the process of actually putting those memories back together in the present" (Dillard, 2008, p. 91). Remembering and connecting these intimate, deeply complex racialized, gendered, and cultural experiences can support expansive learning experiences and pedagogical practices in STEM. The guiding research question for this work is: *What are humanizing pedagogical practices that affirm (celebrate and recognize) Black students in STEM?* To answer this question, the authors turned to radical remembering to support the development of the Black Love Framework.

Methods

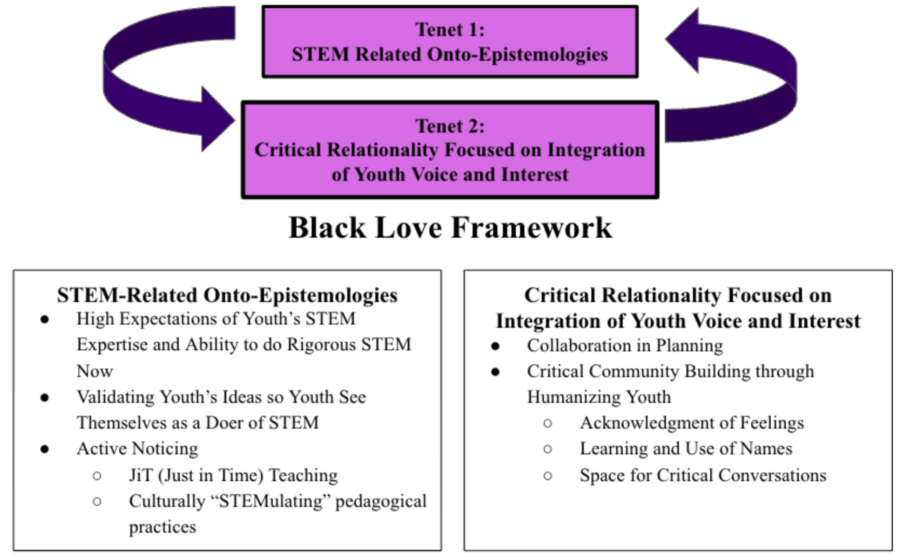
The focus of this paper is to highlight the ways Black Love as a pedagogical frame intentionally attends to the racialized and gendered experiences of Black women in STEM. In an effort to avoid further proliferating and separating deeply woven together experiences that are capable of informing science learning curriculum and instruction, this project makes an attempt to move toward considering whole experiences of Black women and their pedagogies. Crenshaw (1991) argues that "the intersection of racism and sexism factors into Black women's lives in ways that cannot be captured wholly by looking at the race or gender dimensions of those experiences separately" (p. 1244). The authors are two self-identified Black women with undergraduate and graduate degrees in biological sciences and agricultural engineering and currently hold doctorate degrees in STEM education. Previous STEM experiences for both of them have suggested separating these very complex and intertwined identities as a part of science teaching and learning. Worsley reflected on STEM experiences such that "I wondered what the possibilities could have been if I had educators who created spaces for me to engage in STEM in the ways that I wanted" (Worsley, 2022, p. 124). Likely expressed "I wanted [science learning] that could be more applicable to daily scenarios and reflective of cultural practices. But how was I to do that when I had not experienced it?" (Likely & Wright, 2022, p. 149). Reconnecting racial and cultural memories associated with being a Black woman, who self-identifies as a tinker, and science education researcher informed the choices made in the development of the Black Love Framework.

Findings: Development of Black Love

Black Love (Figure 1) pushes against canonical norms that are embedded in science/STEM spaces by fostering, restoring, and humanizing of Blackness within STEM spaces. Black Love is emergent from lived experiences within formal and informal STEM settings, on the ground work within the community, and current facilitation of STEM to Black youth. The framework follows two tenets that are in dynamic relationship with each other: STEM-related onto-epistemologies (Tenet 1) and critical relationality focused on the integration of youth voice and interest (Tenet 2). Black Love is a pedagogical frame that supports the interaction between disciplinary content and relationships between the students and teachers. Each tenet is further expanded in the next sections.

Figure 1

Black Love Framework consists of two tenets that dynamically interact.



Black Love Tenet 1: STEM-related onto-epistemologies

The focus of Tenet 1 is on content through actively engaging in the doing of science and activities. Using an asset-based approach to students' capacity to engage in the STEM doing and learning provides the opportunity for youth to participate in disciplinary learning. SROE are the intersections of who someone is (ontology) and how they develop STEM-related knowledge (epistemology) (Barajas-López & Bang, 2018). When engaging in STEM there are multiple ways to reach solutions and they are informed by youth's SROE. High expectations set a norm that youth put forth the effort and take pride in their work because it is an extension of themselves and follows their interests. Through utilizing various methods. youth begin to see themselves as a doer of STEM.

Black Love Tenet 2: Critical relationality focused on youth voice and interest

Critical relationality means that "my humanity, my integrity, and my dignity are rooted in my willingness to safeguard your humanity, secure your integrity, and protect your dignity" (Olivares & Tucker-Raymond, 2020). This reduces power dynamics and gives youth the agency and confidence to speak up and advocate for their learning (Bettez & Hytten, 2010). Pedagogical practices to support youth interests are collaboration in planning and critical community. Collaboration in planning requires being flexible and also includes receiving feedback from youth, and using it to improve programming (Escudé et al., 2020). Within the learning space, the educator acknowledges feelings, learns and uses names, and makes space for critical conversations that are informed by students' livelihood (Calabrese Barton & Tan, 2020; King & Pringle, 2018).

Implications

Settled hierarchies within science point toward the content being the authority within the learning space. We argue that community and relationship should take precedence beyond the content as the authority within the STEM learning space. By connecting STEM learning with critical community, we remember and reconnect practices to "help us create more affirming and loving spaces of education and personhood for our students, especially Black and Brown students" (Dillard, 2022, p.32). Implications for such radical remembering by people within the margins who have been required to assimilate could serve as the catalyst for change needed in STEM education. The Black Love Framework honors the wisdom in creating learning opportunities, sustained engagement to reimagine possibilities, and developing politicized trust and critical relationality through remembering what science learning has tried to proliferate. The pedagogical strategies supported by Black Love support the wholeness and vulnerability needed for effective teaching (hooks, 2014). Instead of separating identities for specific learning goals, we argue that it is imperative to incorporate a more holistic approach to teaching and learning in STEM pedagogy using strategies such as the Black Love Framework.

Conclusion

Reconnecting racial and cultural experiences within STEM education can cultivate a learning space that celebrates and affirms rather than separates or isolates. "We have to learn to remember the things we have learned to forget" (Dillard, 2022, p.5). When seeking to integrate and leverage students' cultural wealth as a part of learning, we must make it a practice to engage with our memories beyond the classroom to support "expertise as they live and narrate life from their perspectives without censorship or apology" (King, 2021, p. 3). Ultimately, focusing on the intertwined knowledge that is experienced and expressed through culture plus content knowledge are instrumental and necessary for good teaching. Black Love suggests that instructors be prepared to do the active work to support students' learning experiences and build a trusting community. Black Love provides support for Black youth to find joy in STEM-rich making while loving themselves, especially their Blackness, throughout the process (Love, 2019; Worsley & Roby, 2021). Black Love persists beyond the written text of the curriculum and is evident through the pedagogy and assessment to support students' interests in content, scientific vocabulary, phenomenon, and process.

Abstract: Self-regulated learning (SRL) is essential while learning with a game-based learning environment (GBLE) to effectively interact with instructional materials, monitor and regulate SRL strategy use, and increase domain knowledge. The field of SRL has had little progress in understanding how learners temporally deploy SRL operations, including Searching, Monitoring, Assembling, Rehearsing, and Translating (SMART; Winne, 2018) , during game-based learning. This study recruited 56 undergraduate students to play Crystal Island, a GBLE focused on increasing microbiology domain knowledge. Using both log-file and eye-tracking data, learners' SMART operations were captured as they completed the game. Results found that learners engaged in Searching and Assembling/Rehearsing significantly more than any other operations. Transition matrices revealed that while some transition sequences were detrimental to learning, directly monitoring after assembling/rehearsing information were positively related to learning gains. These results have implications for designing GBLEs whose features simultaneously promote and discourage the sequential deployment of SMART operations.

Introduction

Given continued developments in advanced learning technologies (ALTs) accompanied by dramatic changes in learning environments over the last decade, researchers and practitioners have increasingly turned to game-based learning environments (GBLEs) as an approach for increasing learner engagement and improving learning outcomes, with generally positive results (Taub et al., 2019). Despite the growing acceptance of GBLEs in the classroom, few studies have examined how learners' interactions with GBLEs are related to their self-regulated learning (SRL) and deployment of SRL strategies within GBLEs (Dever et al., 2021; 2022). Self-regulated learning (SRL) may be viewed as an ability (Dever et al., 2022), a complex system of recursive events (Taub et al., 2017), and a phenomenon (Winne, 2018; Winne & Azevedo, 2022) in which learners implicitly and/or explicitly monitor and regulate by enacting strategies to control their own cognitive, affective, metacognitive, and motivational (CAMM) processes during a goal-directed learning activity (Azevedo et al., 2019; Molenaar et al., 2023; Winne, 2018). Specifically in this study, we operationalize SRL as learners' behaviors within the GBLE (e.g., opening/closing instructional materials) aligned with Winne's (2018) **c**onditions, **o**perations, **p**roducts, **e**valuations, and **s**tandards (COPES) model. The focus of the current work is on the function of SRL SMART operations – searching, monitoring, assembling, rehearsing, and translating – learners' cognitive processes (i.e., searching, monitoring, assembling, rehearsing, translating) that facilitate SRL strategy use and on how learners deploy these SMART operations during learning with a GBLE and their relationship to learning gains.

Prior research with GBLEs in the context of SRL has focused on the use of multimodal data, including both log-file and eye-tracking data, to develop models predictive of learning outcomes (Cloude et al., in press; Dever et al., 2020; Geden et al., 2021). However, there have been calls for a broader application of interdisciplinary methodological approaches and analytical techniques toward understanding learners' deployment of SRL strategies during gameplay (Taub et al., 2017), and specifically, a need to use multichannel data to identify when and how learners enact specific SRL processes within GBLEs. Therefore, in this work, we collected eye-tracking and log-file data to examine the frequency of and transitions between learners' SRL processes while using a GBLE (i.e., Crystal Island) to provide actionable insights for the design of adaptive interventions to induce better learning outcomes through supporting learners' SRL.

Current study

Current SRL literature does not examine how learners deploy the specific SRL operations during learning with GBLEs. Specifically, it is not studied how learners transition between Searching, Monitoring, Assembling, Rehearsing, and Translating operations as they learn with a GBLE. Within the current study, we aim to use multimodal data to examine the frequency with which learners use SRL SMART operations and the transitional relationships between these operations during learning with a GBLE. To begin addressing this gap, we ask three research questions: (1) Are there differences between the frequencies in which participants deploy SMART operations with a GBLE?; (2) How do learners generally transition from one SMART operation to another?; and (3) To what extent do the probabilities of learners' SRL operation transitions relate to learning gains?

Method

Participants and experimental procedure

Undergraduate students ($N = 56$) aged 18 to 26 ($M = 20.1$, $SD = 1.54$) were recruited to play Crystal Island, a GBLE focused on increasing microbiology knowledge. Prior to the start of the experimental session, participants provided informed consent and were calibrated to an eye tracker. Participants then completed a series of questionnaires including a microbiology content knowledge pre-test. Afterwards, participants started Crystal Island in which eye-tracking and log-filed data were collected as learners interacted with non-player characters (NPCs), read instructional materials, moved around the environment, scanned food items for diseases, completed concept matrices, and filled out a diagnostic worksheet. Upon completion of the game, participants were asked to fill out post-test questionnaires including several self-reports and a microbiology content knowledge post-test similar to the pretest. Participants were thanked and compensated for their time $10 an hour up to $30.

Coding and scoring

SMART operations consisted of one or more activities that were directly related to and captured by the Crystal Island environment (see Table 1). These operations were recorded using both log-file and eye-tracking methods where the order in which participants engaged in activities were captured. All participants engaged in each activity and SMART operation.

Table 1
Activities Captured in Crystal Island and their SMART Operation Classification

Activity	Capture Method	SMART Operation Classification
Movement across Pre-Defined Areas	Log File	Searching
Completing Concept Matrices	Eye Tracking	Monitoring
Viewing Posters	Log File	
Filling out Worksheet	Log File	
Reading Books and Research Articles	Eye Tracking	Assembling/Rehearsing
Conversing with NPCs	Log File	
Scanning Food Items & Hypothesizing	Log File	
Submitting Final Diagnosis	Log File	Translating

Learning Gains were calculated using normalized change scores developed by Marx and Cummings (2007). The set of equations calculated the differences in participants' pre- and post-test scores on microbiology content knowledge while controlling for their prior knowledge.

Results

Research question 1: Are there differences between the frequencies in which participants deploy SMART operations?

A within-subjects ANOVA was conducted to examine the differences in the frequency of participants' use of SMART operations. There was an overall significant difference between the four groups, i.e., Searching, Monitoring, Assembling/Rehearsing, and Translating, where participants engaged in Searching and Assembling/Rehearsing operations the most followed by Monitoring and Translating ($F(1.86, 102.22) = 169.9$, $p < .001$). A pairwise t-test with a Bonferroni correction found that all groups were significantly different except for Searching and Assembling/Rehearsing. Participants engaged in Searching and Assembling/Rehearsing more often than any other SMART operation. This is followed by Monitoring and then Translating. For descriptive statistics, refer to Table 2.

Table 2
Means, Standard Deviations, and Pairwise T-Test Scores

Variable	*M*	*SD*	Searching	Monitoring	Assembling/ Rehearsing

Searching	132.5	56.42			
Monitoring	95.8	43.5	-4.54**		
Assembling/Rehearsing	137.91	48.1	0.70	23.2**	
Translating	8.8	4.4	17.3**	15.2**	20.8**

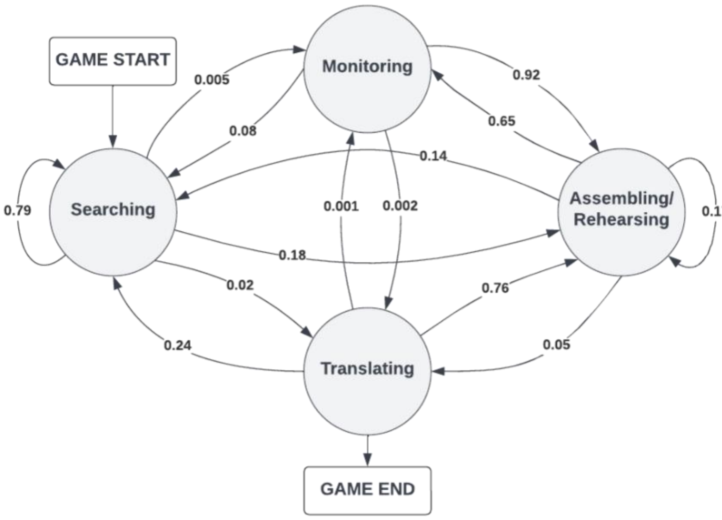
Note. * indicates $p < .05$; ** indicates $p < .01$.

Research question 2: How do learners generally transition from one SMART operation to another?

A transition matrix was calculated to identify the probability each participant would transition from one SMART operation to another. Each participant received a probability across 16 possible transition states. Each transition probability was averaged across participants to create Figure 2, a diagram depicting the average probability that specific state transitions could occur. From the transition probabilities, participants are most likely to transition from Searching to Searching, Monitoring to Assembling/Rehearsing, Assembling/Rehearsing to Monitoring, and Translating to Assembling/Rehearsing. However, it is essential to contextualize the meaning of these transition probabilities in relation to their effectiveness for learning outcomes to fully understand how to better promote learning through participants' deployment of SMART operations.

Figure 2

Diagram showing the average probability a participant would transition from one SMART operation to the next



Research question 3: To what extent do the probabilities of learners' SRL operation transitions relate to learning gains?

Multiple linear regressions were conducted to examine each transitions' relationship to learning gains. Results found that the greater the likelihood a participant had of transitioning from Assembling/Rehearsing to Assembling/Rehearsing ($t = -2.16$, $p < .05$; $\beta = -1.44$) as well as Translating ($t = -2.35$, $p < .05$; $\beta = -3.58$), the lower the learning gains. Conversely, the greater the likelihood a participant had of transition from Assembling/Rehearsing to Monitoring the greater their learning gains ($t = 2.15$, $p<.05$; $\beta = 0.54$). In sum, sequential and recurrent engagement in an Assembling/Rehearsing operation during game-based learning had a detrimental effect on learning gains along with transitioning directly from Assembling/Rehearsing into a Translating operation. However, when participants engage in a Monitoring operation directly after Assembling/Rehearsing more often, learning gains increase.

Discussion and future directions

The purpose of the current study was to examine how learners deploy SMART operations during game-based learning using multimodal data. Findings from this study support the assumptions of SRL models while enhancing Winne's (2018) SMART operations model. Specifically, this study examined how learners temporally engage in SMART operations and how transitions from one type of operation to the next support learning. This study serves as the baseline for future studies to examine the relationships between SMART operations across different GBLEs and domains. From the results, we identify a need to expand this study regarding learners' more detailed use of the SMART operations as well as GBLE design implications. For example, does the duration of each SMART operation influence which operation is next initiated, its quality, and is this related to learning outcomes? Can we identify accurate versus inaccurate SMART operations and does the transition between these (in)accurate SMART operations use relate to learning outcomes or reveal learners' lack of SRL skills? Does the spatial layout of the GBLE influence how SRL SMART operations are deployed through an embedded cognition perspective? Could an analysis of transitions between observed SRL strategies provide more insight than an analysis of observed SRL operations? These questions and future directions elicited by the current study have the potential to better support our understanding of SRL and how GBLEs can be used as a tool to detect, measure, and support SRL processes.

Abstract: Reforms in science education have called for students to engage in scientific practices. A scientific practice that has received increased attention is modeling. Part of the practice of modeling is the development, use, and evaluation of epistemic criteria which are the standards scientists use to evaluate the validity and accuracy of scientific models. For students to effectively engage with epistemic criteria, they need to be given collective cognitive responsibility, or epistemic agency. This study investigates how the design and implementation of a fifth-grade model-based inquiry unit supported students' epistemic agency to revise an initial class criteria list for scientific models. The findings indicate that reflecting upon peer critique of their scientific models in a written task, and the ways that teachers engaged students in a class discussion to revise the initial class list, supported students' epistemic agency to revise an initial class criteria list for scientific models.

Introduction

Current standards in science education emphasize students learning core scientific ideas through engagement in scientific practices (NGSS, 2013). A part of the practice of scientific modeling is the development, use, and evaluation of epistemic criteria which are the standards that scientists use to evaluate the validity and accuracy of scientific models (Pluta et al., 2011). Examples of epistemic criteria for good scientific models include models should fit the evidence, be conceptually coherent, fit with other established theories, and be parsimonious (Kuhn, 1977). Engaging with epistemic criteria (as an aspect of modeling) provides several benefits to students. First, students will be involved in the analogous scientific reasoning and evaluative processes that are part of the development of scientific models (Chinn & Buckland, 2012). Second, class criteria lists can be scaffolds for communities of learners (Pluta et al., 2011). Third, engaging students with epistemic criteria and understanding how they guide the practice of scientific modeling can build trust and commitment to them.

For students to authentically engage with epistemic criteria in scientific inquiry environments, it is helpful to have collective cognitive responsibility, or *epistemic agency*, which is the responsibility to shape knowledge and practices of a community (Damsa et al., 2010; Stroupe, 2014). Epistemic agency is an emergent characteristic of a group which enables the group to make progress on a shared knowledge object (Damsa et al., 2010). Epistemic agency is visible in the ways that the members of a group jointly negotiate the collective collaboration of a shared knowledge object. Fostering epistemic agency in students is important because, "…we assume, both individual learners and groups with a higher sense of agency should have a greater potential to engage in productive collaborative activities that generate new knowledge" (Damsa et al., 2010, pp. 146). The purpose of this study is to show how students were afforded epistemic agency to revise an initial class criteria list for scientific models through reflecting on peer critique in a written task and teachers' supportive discursive moves in a class discussion.

Theoretical framework

Epistemic criteria

Pluta et al. (2011) found that students *generated* a range of normative criteria for scientific models that were categorized as goals of models (i.e., models explain or describe), model constituents (i.e., pictures, words, diagrams etc.), communicative elements (i.e., clarity, focus, organization, etc.), evidential criteria (i.e., explicitly references evidence), and epistemic elements (i.e., accuracy, interest, realism etc.). However, prior research has not focused on students' revision of a class criteria list which can reflect students' valuing of criteria by which criteria they choose to add, revise, or remove from the initial class criteria list.

Epistemic agency

Prior educational research has shown ways that students' have been afforded epistemic agency in science classrooms. Teachers can position students as epistemic agents with effective discursive moves such as an epistemic press which is a public statement about a scientific idea, for example, requesting evidence; asking questions to clarify a point, solicit information, encourage participation, or probe metacognitive understanding; publicizing private ideas by revoicing or summarizing students' statements; dismissing or extracting students' science ideas during discussion; and providing space for tangential talk (Stroupe et al, 2014). Stroupe et al. (2018) positioned students as epistemic agents by inviting them to cocreate the space therefore attributing value to their ideas. Students suggested areas of research, and designed methods and knowledge products, therefore using their epistemic agency to guide the unit in new directions.

Prior studies have made gains in promoting students' epistemic agency in science classrooms, but they have focused on students' agency in terms of what to study, which methods to use, and which questions to ask (Stroupe et al., 2018). There had not yet been an investigation into students' epistemic agency regarding students' considerations about a good explanation or necessary evidence, or how to facilitate students' development of robust criteria. A study of this kind would be significant because students' valuation of criteria can affect how they engage in scientific modeling (Ryu & Sandoval, 2012). The aim of this study is to extend prior research by asking *how does the design and facilitation of a model-based inquiry unit support students' epistemic agency to revise a class criteria list for scientific models?*

Methods

Participants and context

The unit was taught in a public charter school in the Northeast of the United States. The school performs above average on standardized state tests on Mathematics, Language Arts and Science. The demographics of the school were 60% White, 22% Asian, 9% African American, 7% Latinx, and 2% other; 5% of students were eligible for free and reduced lunch. The study was conducted in a fifth-grade classroom, Class A, during a five-week model-based inquiry unit with 25 students. Students made models in a new modeling software called MEME (Model and Evidence Mapping Environment) (Danish et al., 2019) that enabled them to create components and link them with arrows (mechanisms) to provide a causal account of why fish were dying in a local pond (a eutrophication phenomenon). Students reviewed evidence in the form of reports and simulations to develop the model and linked the evidence to support the various parts of the model.

At the start of the unit, each class developed an initial class list of criteria for scientific models which scaffolded model development, evaluation, and revision. At a mid-point in the unit, students provided critique to each other's models in a gallery walk. Students displayed their models in MEME and used the "comment" box to give feedback to peers. The gallery walk was positioned to occur before the revision of the initial class criteria list to inspire students to think about criteria. By providing critiques, students assessed how well the models met the class criteria and how useful the criteria were in evaluating the models. After the gallery walk, students reflected on the critique in a written task in which they wrote down with a partner which criteria they thought should be added, revised, or removed from the initial class criteria list. In a class discussion immediately following the written task, teachers drew on students' suggestions to revise the class criteria list. The class ended up with a final class criteria list composed of five shared and agreed-upon criteria for good models.

Data collection and analysis

The data for this study are from the written task and class discussion. The written data was categorized into which criteria students thought should be added, revised, or removed, and then by the type of criteria they referred to. For example, whether the statement suggested a revision to a criterion about evidence or understandability. We then counted the frequencies of statements that referred to each type of criteria. The class discussions were audio and video recorded from multiple angles and there were microphones on students in two focus groups in each class. The videos of the class discussions were viewed multiple times to identify the kinds of suggestions students gave for what criteria should be added, revised, and removed, and how classroom discourse between students, and between students and the teacher, shaped the final class criteria list. We used content analysis to code the class discussions (Schreier, 2012). A students' suggestion marked the start of an episode. We coded the discussion moves as supporting students' epistemic agency if there was uptake of students' ideas that preserved and built upon the meaning in the students' statements. For example, a teacher asked a clarifying question to ensure she properly understood what the student said and thus retained the meaning of the students' statement. A discussion move was coded as not supporting students' agency if it diverted away from the meaning of the students' statement. For example, a teacher reframed a students' contribution which introduced new language and took attention away from the meaning in the students' contribution.

Results and discussion

The written task, in which students reflected upon peer critique, and the class discussion, in which students' suggestions were supported in various ways, prepared students to revise the initial class criteria lists (Table 1).

Table 1
The initial and final class criteria lists in Class A

Class A: Initial Class Criteria List	Class A: Final Class Criteria List
1. Be on topic with accurate information	1. Model should *make sense*
2. Include a main focus supported with reasons and evidence	2. Components and mechanisms should be *clearly* ordered and labeled to show a start to finish
3. Be neat and organized	3. Each component and mechanism should have a *clear* explanation supported with reasons and evidence
4. Use a specific order	4. The mechanisms should be *understandable* sentences
5. Have labels within a visual representation of data	5. Model should have a main focus that includes all components and mechanisms

Students' written data reveals a theme: models being understandable. 11/14 students' statements about which criteria should be added and 12/19 statements about which criteria should be revised were about models being understandable. Four students suggested adding a criterion about a clear start and three students stated to add a criterion about models making sense. Five students wanted to combine "*neat and organized*" with "*use a specific order*" and four students suggested replacing both these criteria with "*models should make sense.*" Students' ideas, that models should be understandable, are shown in the final class criteria list in the language "make sense," "clear," and "understandable" in the following criteria: "*models should make sense,*" "*components and mechanisms should be clearly ordered and labeled,*" "*each component and mechanism should have a clear explanation,*" and "*mechanisms should be understandable sentences*" (Table 1). The written task supported students' epistemic agency because students reflected on which criteria they valued. They developed good quality knowledge (criteria) which shows they had the responsibility to shape knowledge and knowledge products in their classroom community. Students had agency over their lists because they generated the criteria based on their own (and not the teacher's) ideas and they held each other accountable by their critiques.

The teacher facilitated the class discussion in ways that supported students' epistemic agency to revise the initial class criteria lists. The teacher supported Lily's epistemic agency to include a criterion termed, "*fully evidenced.*" Lily's reason for suggesting this criterion was that one group had included a mechanism in their model that said, "which makes this" (e.g., nutrients "makes this" algal bloom). Lily's explanation (line 3) shows that she did not think the label on the mechanism, "which makes this" adequately explained how the two components were connected. Note: square brackets provide clarification.

1 Lily: Like, I think it [the class criteria list] should also have one that says, like, "*fully evidenced*" because, like, some… one of the groups, they wrote, like, something… they didn't really write anything, but… they wrote something, but they didn't write anything that related to the mechanism.
2 Teacher: Like clear explanations?
3 Lily: For mechanism, they wrote umm… "which makes this" and then had a component and it didn't really say anything like how they [the components] connected to each other.
4 Teacher: So, was the explanation not clear or was the evidence not linked? I feel like you're saying two different things. Or was it both?
5 Lily: Both.
6 Teacher: So, we have "include a main focus supported with reasons and evidence". Do you want to revise that? [Lily nods.] What do you want it to say?
7 Lily: That it should have like understandable evidence that makes sense.
8 Teacher: So, each component and mechanism should have a clear explanation with appropriate evidence? What do you guys think? Does that make sense? Is that a little more specific? Okay. So, each component and mechanism should have a clear explanation- Lily, is that what you want to say?
9 Lily: Yeah.
10 Teacher: Supported by reasons and evidence [end of episode].

The teacher in Class A interacted with Lily in specific ways which supported Lily's agency when revising the class criteria list. The teacher asked Lily a clarifying question, "Like clear explanations?" to better understand Lily's suggestion (line 2). Lily explained that the mechanism did not explain how the components were connected (line 3). The teacher followed up with another clarifying question (line 4) in which the teacher rephrased what she thought Lily said to identify multiple aspects of Lily's statement and bring attention to each. The teacher then draws attention to an existing criterion and asks Lily if she wants to revise it (line 6). Here, the teacher highlights that Lily's suggestion is like an existing criterion, but she asks Lily if she wants to revise the existing criterion and what she wants it to say, thus preserving Lily's agency to direct the way her suggestion will alter the initial class list. Finally, the teacher asked what the class thought and asked Lily what she thought of the criterion, thus seeking confirmation from Lily and consensus from the class (line 8). This episode resulted in the criterion, "*each component and mechanisms should have a clear explanation supported by reasons and evidence.*"

Conclusion and implications

This study shows how the design and implementation of a fifth grade MBI unit supported students' epistemic agency to revise a class criteria list for scientific models. The findings build on prior research by showing not only which kinds of criteria students develop (Pluta et al., 2011), but the criteria they value by how they revise an initial class criteria list, and how to afford students with epistemic agency, not only by asking questions, selecting what to study, or designing methods (Stroupe et al., 2018), but by building a knowledge product that reflects students values about the standards (criteria) for scientific models. Providing students with the opportunity to reflect upon critique in a written task, and the ways that the teacher engaged students in a class discussion, supported students' epistemic agency to revise a class criteria list for scientific models. Teachers can support students' epistemic agency in class discussions by asking clarifying questions, paraphrasing in a way that retains the student's meaning, checking with the student to ensure the meaning has been adequately captured, seeking class consensus, and giving students choice on how they want their suggestion to alter the initial list (by being added as an additional criterion or revising an existing criterion). The findings have implications for design research because they suggest ways that students' epistemic agency can be supported to develop criteria for epistemic products such as scientific models. The findings have implications for teacher practice because they show ways that teachers can support students' epistemic agency during class discussions to revise a criteria list.

Studying Whether Expansive Framing and Authorship Impact Transfer Using Statistical Discourse Analysis

Joshua D. Quick, Indiana University, jdquick@iu.edu
Daniel T. Hickey, Indiana University, dthickey@indiana.edu

Abstract: We analyzed the relationship between the engagement strategies of expansive framing and authorial positioning with the transfer of online learning. Mixed methods were used to analyze 1154 discussion posts and 156 ePortfolios in a semi-synchronous graduate course on educational assessment. Open qualitative coding and statistical discourse analysis modeled the influence of peer and instructor interactions on the display of authorship, accountability, and transfer strategies. We found evidence of sustained roles of authoritative and accountable positioning by participants and the use of strategies presumed to foster generative learning that transfers readily and widely. These findings are discussed in light of the theoretical explanations of why expansive framing should support transfer.

Introduction

The engagement strategy known as *expansive framing* assumes that broader social and linguistic connections within learning activities can promote the development of learners' capacity to generate and adapt disciplinary knowledge in subsequent engagements (i.e., transfer, Engle, 2006; Engle et al., 2012). Engle et al. (2011) conducted a one-on-one tutoring experiment where tutoring interactions used expansive framing or bounded framing. The expansive condition pushed students to make numerous connections with outside people, places, topics, and times and positioned learners as "authors" who were respondents to the texts. The bounded condition did not push learners to make connections beyond the tutoring context. Students in the expansively framed tutoring condition were more likely to transfer and adapt learned concepts and knowledge to new problems. More recently, Tierney et al. (2020) conducted several studies in a design-based research project on developing students' connected identities within an environmental sciences course. Their initial study examined a detailed case analysis of students and their teacher's development of agency and connected identities. Two follow-up studies used comparative analyses of expansively framed activities across course design iterations. Their findings indicated initial support for the relevance of expansive framing in developing broader, more connected disciplinary identities for learners.

A systematic review by Hickey, et al. (2021) confirmed that expansive framing has been employed in dozens of interventions. But expansively framed engagement remains largely unexplored and has yet to be examined using learning analytics. For example, the actual processes by which expansively framed engagement promotes transfer remain unproven. This study seeks to explore these connections in relation to proposed explanations linking authorship and expansive framing in Engle et al. (2012).

Expansive framing, accountability, and authorship

Engle et al. (2012) proposed five explanations for how expansively framing engagement might support the transfer of knowledge. The first two explanations deal with how connecting settings within learning tasks promotes the expectations of transfer and prioritizing previous knowledge as relevant to current and future learning tasks. The third explanation focuses on the links between authorship and prior settings in promoting the transfer-in of knowledge. The fourth and fifth explanations, however, center on how authorship promotes accountability to disciplinary knowledge and promotes the generation and adaptation of knowledge in new contexts.

These last two explanations are the focus of the current study. The development of authorship should be recognized by peers and instructors in collaboration with a student. This recognition of authorship should lead to further authoritative positioning by students. This authoritative positioning also enables participants to hold each other accountable to disciplinary practices, thereby leading to social "pressure" for participants to regularly hold themselves accountable as authors of disciplinary knowledge. Here, we explore these two explanations in the context of an online course on educational assessment. Specifically, we seek to answer the following question: does peer and instructor collaboration enable students to position themselves as authors accountable to disciplinary standards? If so, does this continued positioning support the development of transfer strategies such as generating examples, making generalizations, and making comparisons?

Course design, context, and hypotheses

This course has been iteratively refined and developed as part of a decade-long ongoing design-based research project (Hickey & Rehak, 2013; Hickey et al., 2020). The course design facilitates learners' development of disciplinary knowledge and practices in educational assessment through agentic engagement. This is accomplished through students regularly responding to prompts that guide them in problematizing course content from the perspective of a personally relevant curricular aim and context. These responses are shared on public (to the class) ePortfolios where peers and the instructor comment on a student's engagement in the assignment. We posit that if the explanations on authorship and transfer in Engle et al. (2012) are viable, then links between previous authoritative engagements should occur and such engagements should contribute to enhanced transfer.

Participants, data, and methods

Fifteen students who completed the course in 2020 were asked to participate or opt-out of having their data used in this study. No students opted out. This study examined 162 distinct ePortfolio assignments and their corresponding threaded discussion posts (n = 1475) by peers, the instructor, and the ePortfolio author.

Methods & analysis

This study occurred in two stages and incorporated a mixed-method design. In the first stage, we conducted qualitative coding of students' ePortfolio responses and discussion posts. Next, we used statistical discourse analysis (Chiu & Fujita, 2014) to model relations between these coded posts.

Coding procedures

Codes for expansive framing, authorship, and accountability were adopted from Andrews et al., (2019). Codes for transfer strategies were developed from general transfer processes (i.e., generating examples, making generalizations, and making comparisons) that are widely assumed to promote transfer (National Research Council, 2000). The transfer codes were attributed as evidence of a post's author adapting or generating knowledge across contexts. All codes assigned were binary indicators for whether a participant's response exhibited a coding category. Coding was conducted transparently and openly by the first author through three audit sessions (Cresswell & Miller, 2000).

Statistical discourse analysis

Statistical models of conversations present several challenges to the assumptions of independence of observations and the homogeneity of variance in standard regression techniques. Chiu & Fujita (2014) developed procedures under the umbrella of statistical discourse analysis to mitigate these issues. First, talk is clustered in terms of specific conversational instances through multi-level models (i.e., models that include fixed and random effects to contend with clustered or repeated data). Second, lagged variables are included through vector autoregression, which deals with the sequenced dependency of conversational turns. Following Chiu & Fujita, sequencing posts in terms of their threaded replies rather than temporal order in the discussion is also required for asynchronous discussion forums. This reduced the modeled data to 1145 posts that were replies to prior comments in 156 ePortfolio assignment responses. Codes from the t-1 variables (i.e., the immediately prior posts) were used in the model along with codes from the ePortfolios (as t-2) variables. All code variables were binary. Post-authorship (i.e., peer and instructor roles) were also used as regressors.

Using ePortfolio discussion posts as units of analysis, we constructed multi-level logistic regression models with codes for authorship, accountability, and transfer strategies as dependent variables. Models were fitted in R using mixed effect and Bayesian mixed effect models where evidence of partial to complete separation (see Heinze & Schemper, 2002) was observed in parameter standard errors or indicated by issues in model convergence. All R cleaning and analysis scripts are available within an OSF repository (https://osf.io/w4rnv) for replication.

Results

Table 1 presents the exponentiated model parameters for the relationship between previous displays of expansive framing, authorship & accountability, and a given post's display of authorship and accountability. While no statistically significant relations were generally observed in the expansive framing variables, the presence of authorship and accountability within the ePortfolios increased the odds that a comment would display authorship and accountability by an average of 1.86 and 2.11, respectively. The prior comment's display of expansively framed participants (i.e., individuals outside the class context) was also borderline significant within an alpha level of 0.05, though these results should be considered in relation to type-1 errors. Additionally, if the previous comment displayed evidence of accountability, the next comment had an average increase in the odds of it displaying accountability by a factor of 2.24. It also seems that comments made by the instructor were much more likely to display authoritative positioning. When a comment was made by an instructor, it increased the odds of authoritative positioning in a comment by a factor of 4.15 relative to comments made by peers with a factor of 2.59, both significant. These observations suggest evidence for authorship and accountability as being promoted socially, thereby providing support for Engle et al's (2012) fourth explanation.

Table 2 presents the exponentiated parameters for each transfer strategy model. Given the lack of influence of expansive framing in prior posts in the previous models, only authorship and accountability in previous comments were used as lag variables along with the ePortfolios' display of expansive framing codes. No statistically significant relationships between expansively framed engagement and transfer strategies were observed. However, the ePortfolios' display of experiences prior (times past) to the course reduced the odds of a post displaying generalizations. ePortfolios' display of expansively framed participants was borderline significant for a post's likelihood to display generalizations with an average increase in the odds of 2.8. Prior comments from the instructor also increased the odds that the subsequent post would display generalizations by a factor of 4.33. These results, therefore, present a somewhat mixed account of the explanation of positioning students as accountable authors enabling them to adapt or generate new knowledge.

Discussion

These initial findings provide some evidence of the explanations of the importance of authorship and accountability in Engle et al. (2012) contributing to participants' sustained authoritative positioning. However, the presence of accountability and authorship was not directly observed to contribute to the display of transfer strategies. Furthermore, we observed few relationships between the use of expansive framing and transfer, as evidenced by the use of transfer strategies. Importantly, Engle et al. noted that positioning learners as authors need not involve expansively framed activities to encourage the transfer of knowledge. However, we found little indication from these observations that such adaptations occurred, at least in terms of the codes used in this study.

These outcomes suggest several possibilities. First, modifications to the coding analysis may be called for. Specifically, modification of the coding scheme to reflect more nuanced descriptions of both expansive framing, authorship & accountability, and transfer rather than simple binary indicators may reveal more insights. Alternatively, it is possible that the explanation of linking authorship and expansive framing may be incorrect. Alternative mechanisms of transfer, such as concreteness fading (see Goldstone & Son, 2005), posit that increased use of concrete representations may interfere with the later transfer of knowledge. In such a framework, expansive framing may present complications in the ability of students to adapt knowledge due to an increase in information a learner needs to engage with. While such a perspective presents alternative theoretical and epistemological commitments to knowing and learning, comparing these frameworks' utility in learners' transference of knowledge may reveal further clarification on what is being transferred and how such adaptations occur. Future work, then, will seek to make these modifications and extend these comparative analyses through experimental designs.

Giving Voice to Kosovar Teachers: Experience and Reflections on Play-Based Math Learning in the Classroom

Abstract: According to PISA results, Kosovo students performed worst in Europe and in the bottom three out of all 77 participating countries. It may be due to the discrepancy between PISA's focus on problem-solving and Kosovo's explicit pedagogical mode of instruction. Here, we present initial findings from an ongoing project, which aims to support educators in fostering students' active participation and more play-based learning in early childhood math education. We conducted an interview study in three schools to evaluate what active and playful learning looks like to Kosovar teachers, considering the specific challenges and affordances of the local educational context, as well as unique challenges posed by COVID in a developing European country. Student-driven, playful learning is welcomed but rarely implemented digitally. Lack of resources and skepticism about digitization were major barriers to broader implementation.

Context and background: Kosovo

In this short report, we present a part of an ongoing project with Kosovar teachers exploring challenges and opportunities in transforming early math education in a developing European country. Kosovo, once an autonomous region in former Yugoslavia, experienced drastic transitions since the 1990s. After recent civil wars and armed conflicts, Kosovo now ranks among the poorest countries in Eastern Europe (World Bank, 2022). These events had a devastating effect on the educational system, with closings of state-funded early childhood education institutions and a sharp decline in enrollment (Ibra-Zariqi, 2019). There are now numerous systemic challenges to providing high-quality early education, including a lack of teacher training, difficulties in recruiting qualified teachers, high workloads, and underpayment (Haxhikadrija, 2019). Unfortunately, government expenditures on education are low, with only 0.1% of GDP allocated to early education (Ibra-Zariqi, 2019).

According to the 2018 Programme for International Student Assessment (PISA) test results, Kosovo ranked well below average overall, and below all participating European countries—ranking 75th out of 77 surveyed countries (OECD, 2019). Math was the subject in which Kosovo performed lowest. Because mathematics is a particularly good predictor of later life prospects (Ricthie & Bates, 2013), there is an evident need for more effective math instruction. Indeed, research indicates that instructional approaches in Kosovar schools are typically limited to explicit instruction, often based on learning by rote memorization. Researchers previously noted a lack of awareness and knowledge of more child-centered pedagogical approaches in Kosovo (Kadriu & Gougeon, 2014; OECD, 2017). Unfortunately, recent evidence indicated no progress in educational quality, despite this being an area requiring significant improvement (EU Progress Report, 2020).

A major impediment to educational progress in Kosovo is the challenge of digitizing its educational system (Government of Kosovo, 2016). No national distance learning system existed at the start of the COVID19 pandemic in 2020. Moreover, internet access is not widespread. Consequently, the pandemic caused severe disruptions to education with some children left without schooling for several months (UNICEF Kosovo Programme, 2022). UNICEF supported Kosovo in setting up the e-learning platform shkollat.org; other existing platforms have also been used to ensure learning continuity, such as public television and YouTube, yet, among teachers, there is an overall sense of this being "too little, too late."

Within the math context, the best predictor for future achievement are basic mathematical skills that underlie early numerical learning (Gashaj, Oberer, Mast, & Roebers, 2019). Despite a lack of agreement on the best pedagogy, one promising direction comes from play-based instructional approaches, which come with strong scientific support (e.g., Ginsburg, 2006; Hirsh-Pasek, Golinkoff, Berk, & Singer, 2009). There, scaffolding through appropriate materials coupled with expert guidance appears to increase learning and foster a more positive attitude towards learning. A fundamental step towards enhancing early math education in Kosovo is to better understand its current state. The present study focused on understanding the current use of play-based instruction in math learning. Preschool teachers in Kosovo seemed interested in play-based activities but preferred nondigital over digitally supported ones (Gjelaj, Buza, Shatri, & Zabeli, 2020). As this was pre-COVID, we were interested in whether and how Kosovar teachers embraced digitization after pandemic-related educational disruptions.

Method

Participants were teachers in primary schools instructing children from kindergarten to 5th grade. By design, the schools differed in terms of resources. One of the schools was a private institution (commonplace in Kosovo), and two were public. The schools were selected due to their willingness to participate. When writing this article, 12 teachers were interviewed by the first author in their native language. The semi-structured interviews (average length of 90 minutes) explored teachers' beliefs, practices, and challenges in implementing play-based mathematics learning. Questions were taken from Russo, Bragg, and Russo (2021), Allsop and Jessel (2015), and Jesmin and Ley (2020). All questions were adapted and translated into one of Kosovo's official languages by the first and senior author. These preliminary results reflect Albanian-speaking schools.

We report on survey responses complemented by a discussion of selected teacher responses. The selected excerpts, identified through inductive analysis of the interview data and discussion among the authors, reflect three distinct viewpoints on play-based learning. The names of contributing teachers were anonymized. Ermond is a male teacher in his early forties in a rural area with two years of teaching experience. Zanfina is a female teacher in her early twenties, teaching in a private institution in the capital, with one year of experience. Finally, Anduena is a female teacher in her fifties with three decades of teaching experience in rural areas.

Results and discussion

All participants reported using play-based activities "all the time" or "often" during math instruction. The teachers agreed on when play-based activities should be used, stating they would "use play-based activities mostly to introduce new math concepts, to consolidate learning, and add variety to their classes." When asked about the effectiveness of these play-based activities, teachers agreed that they are "effective for engagement and on-task behavior, but also to acquire general skills." Additionally, play-based activities were generally perceived as "supporting the understanding of and connections between math concepts, as well as facilitating problem-solving skills." Despite this, the teachers disagreed on a number of important points, as seen below.

Use of play-based activities

When we asked teachers "How frequently do you play math games in your classroom, and what materials do you mostly use?" The following answers were given. According to Ermond, there were few opportunities to employ play-based activities, and he practiced more direct instruction than he would like to:

> I lack materials and time… All materials must be bought by the teacher, that's why I usually use verbal quizzes and let one student summarize what we learned while the other students can elaborate on it. So, we teach a lot of theory, but it can't be practiced. If our students can't practice what they learn, they can't learn in higher levels. Low salaries and insufficient materials make it very difficult to switch from direct instruction to more child-centered approaches.

The most used materials were blank papers used as pretend money, or cards for card games. Less frequently, teachers also used traditional mathematical manipulatives (such as Cuisinaire rods) and commercial games (such as Ludo). Anduena told us she used "cards for a game for multiplication, Dominos, self-made money from paper, PlayDooh to make the numbers or magnitudes and enhance fine motor skills." Zanfina also reported using "different kinds of dice, cards with numbers, blocks in the form of numbers."

Anduena was undeterred by a lack of available materials. She mentioned:

> I connect math with physical education, use gestures for learning the signs smaller than, greater than, equal, tell the children to build groups of *x* students, so they learn numbers and magnitudes by building groups for a team. For example, a football (soccer) game—when they play football or other known games, they have to count the goals. Sometimes I make them count their steps, estimate how far away their friends are standing, and so on.

Many of the teachers described creative examples of play-based activities. For instance, using hoola hoop rings that were held by some children while another one had to throw a ball through them to be awarded points. As children earned different numbers of points from throwing the ball through different rings, they had to count/calculate to come to their final score. When we asked them "Where do you find ideas for math games in your classroom?" most reported being inspired by colleagues, but also social media, and Anduena's response seems typical: "Nowadays, I use social media; there is nothing you can't find on Instagram and Pinterest!"

The broad trend for surveyed teachers was that they valued play-based activities, and believed that these activities are beneficial and effective, but also perceived a lack of (digital) resources, both in terms of training and materials. This scarcity issue became utterly apparent during the pandemic when digital services were the primary means to ensure at least basic schooling. As such, we also investigated teachers' teachers' attitudes and experiences with digital technologies and as digital games.

Digitization during and after the pandemic

Anduena taught first graders during the pandemic and reflected on the negative consequences due to the lack of digital resources during that time:

> The horror! Most of the students and teachers did not even have a laptop. I did use zoom and wanted to be able to see all my students. I am lucky that my sister [in a more developed country] brought a laptop for me to use; otherwise, I would have done the same as my colleagues did. They left the students watch the educational TV program, where for each subject, there was a ten-minute recording. The recordings were of good quality, but can you imagine first graders learning from a ten-minute TV program? Horrible, there was no active participation of the students, no play or engagement.

To the question of how digital devices and tools like games are or were used before and after the pandemic, we received similar responses expressing skepticism about the benefits of digitization.

> Ermond: There is no IT equipment for digital games. I do not own a private computer either.
> Zafina: We do not use equipment for digital games. It is possible that the children play at home with the parent's phone, but not in kindergarten. We practice imaginative and role play the most.
> Anduena: We have projectors, we have a computer in the school, but we prefer to use books, board and card games, and more social activities.

Such scarcity may well affect educational achievement as reflected in PISA results. Therefore, we explored potential changes in response to PISA in another set of questions described in the following.

PISA response

Because PISA results were shocking, we asked teachers "Have you or your school adapted the educational approach since 2018? If so, please explain." Ermond perceived no change:

> No, not even in theory… The decision-makers do not have any experience with teaching and do not see the reality of the classroom. They do not understand that teachers need materials and students need an appropriate environment to have the possibility to do activities… Action plans are taken from other countries [Scandinavia], but these plans are for whole-day classes and our students only come in the morning or the afternoon. There is only half the time to achieve the same goals. If there were additional classes in the afternoon… the students would get to practice and consolidate their knowledge.

In contrast, Zanfina, who started teaching during the pandemic, perceived positive and effective change in her private institution in the capital:

> Based on multidisciplinary cooperation (educators, psychologists, and speech therapists) within our institution and working within the framework set by the Ministry of Education, the realization of all educational goals has been successfully achieved.

Anduena had a more differentiated perspective that provides some more context:

> No. Maybe in big cities [capital city]. The teachers, if they wanted to deal with logical math, they changed it themselves by finding ideas on their own, searching for PISA-similar tasks to

> practice with. The books we use for education have changed, they support a more active learning approach, but the teachers decide for themselves whether they want to buy new ones or not.

Conclusion

This contribution presents data from an ongoing investigation into challenges and opportunities for integrating play-based activities to support children's early math learning in Kosovo. At this stage, we focused on teacher surveys and interviews to better understand the educational landscape from the practitioners' side.

Kosovo has attempted to reform and improve its educational system by adopting policies and practices from more economically advantaged countries (such as Finland, Shala & Grajcevci, 2018). However, our findings highlight the need to consider the specific local political and economic context when implementing educational reforms. Regarding play-based instruction, it seems crucial to ensure that teachers are trained to implement the required activities, to provide actionable evidence to guide teachers in improving their practices, and not to require resources beyond what is available in the average classroom.

We found that teachers welcome integrating play-based learning into the primary school math curriculum. They believed that play-based learning is more built on enjoyment and that children are more likely to stay engaged when actively involved. Arguably, these perspectives are remarkably progressive—even though their implementation seems to remain a challenge. Teachers tend to use the physical materials in their classrooms as tools for playful learning. At the same time, there appears to be skepticism towards digital games or digital technologies in general. It may be necessary to address this skepticism before further commitments are made regarding digitizing the existing curriculum. Despite this skepticism, teachers reported widely using social media to spark inspiration for play-based activities.

Despite these challenges, there is an eagerness and an opportunity to guide the next steps towards a more modern curriculum in Kosovo. We hope to report these and future findings to a broader audience of learning scientists and gather feedback on what actionable steps may be taken in the near future. Yet, these findings already indicate that play-based learning does not have to be an either-or proposition, even in situations with limited resources. Creating eagerness for math from earliest education may inspire children to see mathematics as mathematicians do: difficult but rewarding and playful.

Scaffolding Middle School Children's Coding Experiences in an Open-Ended Social Robotics Program

Rabia Ibtasar, Sylvia Joseph, Sarah Athar, Joseph E. Michaelis

University of Illinois-Chicago

Abstract: Social robots and collaborative open-ended learning may help expand perceptions of computing and develop computational thinking to build skill and interest in Computer Science. We designed pre-programming activities to scaffold middle school children's learning in a collaborative and open-ended social robotics program. In this work, we report on how this scaffolding influenced children's computational thinking and perceptions of computing by describing children's experiences in the program. We conclude with theoretical and practical implications of these results.

Introduction

Learning computing through robotics, has demonstrated how working with robots reified abstract computing concepts, including *computational thinking*, and increased student interest and enjoyment (Rusk et al., 2008). *Social robotics*, where robot actions intentionally use human social cues and norms to interact with people and its surroundings, may further expand options for connecting youth to computing. Research addressing harmful stereotypes about the nature of computing has shown how learning computing in a collaborative environment can increase their confidence and change perceptions that computing is a solitary activity (Bowman et al., 2021). In our work, we believe there may be a unique benefit to computational thinking and addressing stereotypes by connecting learning in the context of social robotics with an open-ended and collaborative learning environment. Our goal is to investigate how working on open-ended collaborative social robotics projects with pre-programming scaffolds impact children's computational thinking and perceptions of computing.

Background

Perceptions of computing

Research on stereotypes of computing has identified negative perceptions of the discipline as boring, asocial, and disconnected from student's personal interests (Fisher & Margolis, 2003). We have seen an increase in computing programs to address these negative perceptions by utilizing collaborative learning approaches such as pair programming (Bowman et al., 2021) and creating new computational materials such as educational robotic kits (Xia and Zhong 2018). An approach that has been helpful in broadening participation in computing has been promoting computing as a way to help (Ross, 2007). Thus, expanding student's perceptions of computing through *social robotics* can be useful in emphasizing how computing is integrated within our daily lives and can contribute to modern society.

Computational thinking and robotics

Computational thinking (CT) encompasses skills and practices that use the concepts of computer science to formulate and solve problems (Wing, 2006). Computing practices and concepts can be supported through lessons and programs that often use block-based programming tools to support or *scaffold* students with a range of abilities to quickly begin programming projects (Bers et al., 2014). These block-based programming environments have often been combined with robotics as physical representations that may benefit learning (Merkouris & Chorianopoulos, 2015). Robots as physical objects can be personally meaningful to learners and designed to communicate with their environment so are noticeable by others providing opportunities for rich social interactions and collaboration. As such, using *social robotics* for introducing students to computing can be a more effective method compared to traditional programming as it involves students systematically applying computing concepts and practices within complex coding needed to program a robot that interacts with the environment around it.

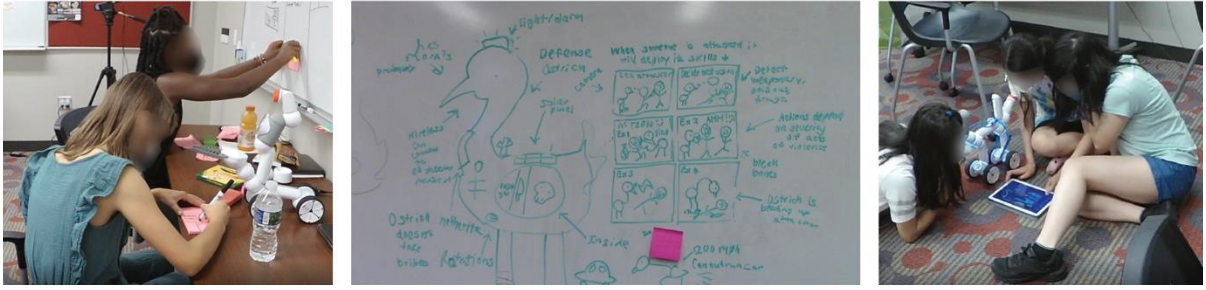
Open-ended learning environments

Supporting open-ended programming projects is challenging as instructors don't know what ideas students will have and what problems they might face (Hannafin et al., 1999). Research has shown that scaffolding around open-ended learning environments can benefit student learning by calibrating an optimal balance of autonomy and support, where students explore their own ideas and receive support to learn and use new programming features to be successful in developing that idea. Pre-programming activities, are designed to support student's conceptual understanding of programming concepts to better apply programming skills later in their project. However, this type of pre-activity support is seldom used in computing education. Well-designed pre-programming activities for social robotics can scaffold students' learning of abstract computational practices, including problem identification, decomposition, problem solving and testing where students are supported through the process from initial idea generation to building and then coding their robots.

Program design

To investigate how working on open-ended collaborative social robotics projects with pre-programming scaffolds impact children's computational thinking and perceptions of computing, the first author co-designed a summer computing camp for middle-school girls with four female undergraduate Computer Science majors. Activities were designed to promote collaboration and included paired participation, facilitated whole group discussions, informal share-outs, gallery walks, scaffolded computational activities, a mentored social environment, and a technology showcase for family and friends (see Figure 1).

Figure 1
Activities in the social robotics program including children working in pairs on their designs(left), a sample storyboard (center), children working across different groups to problem solve (right).



We selected the context of social robotics for program activities as it required children to deeply consider the role of creating and coding computational artifacts that would have impact on society. In this paper, our goal is to understand how students experienced the collaborative open-ended projects, social robots, and pre-programming scaffolds. Specifically, we ask the Research Question: *How does an open-ended and collaborative social robotics program influence computational thinking and perceptions of computing?*

Method

The MyTurn summer camp took place at a large midwestern university. Participants (N = 17) all identified as female, were between the ages of 10 and 14 (*M* = 11.3), and were from a diverse racial and cultural backgrounds including Asian or Asian American (n = 6), Asian or Asian American and White (n = 1), Black or African American (n = 3), Black and Latinx (n = 1), Latinx (n = 1), Mexican and Puerto Rican (n =1), and White (n = 4), were introduced to the topic of social robots and provided a modular social robotics kit, ClicBot (Keyirobot, 2022), to design, build and code their own social robots. We ran two one-week sections of the camp with eight-hour sessions for five days. The first week included rising 5th and 6th graders and the second included rising 7th and 8th graders. In each camp section, students worked in pairs with a mentor to design robot interactions using storyboards and pseudocode and program the robots using block-based programming on a tablet with the ClicBot App. The last day of camp included a Showcase for parents and family members where the campers shared their work and demonstrated their social robots. Campers completed daily surveys and pre/post surveys in computing and completed post-camp interviews. Exit Interviews took place on the last day of camp, followed a semi-structure qualitative interview protocol (Blandford, 2013), and were video recorded and later transcribed verbatim. We conducted a Thematic Analysis (Braun & Clarke, 2022) to analyze the interview transcripts. Data familiarization through notes on videos was followed by a process of open semantic coding on a subset (20%) of the data. The data was then organized within major categories of latent codes based on these semantic codes. All four authors used these codes to iteratively and collaboratively propose and refine themes that developed from the analysis and determined final themes through consensus. The findings below are presented according to these themes.

Results

Our analysis of the interview transcripts revealed two main themes that help us understand the experiences of children in the social robotics program. For clarity in reading quotes, ellipses were added to connect ideas in responses, bracketed words indicate intended objects, and interjections or fillers were removed when not impacting the meaning.

Theme 1: Children related the pre-programming scaffolds to integrate their planning in problem solving with understanding and applying block codes.

Children referred to the pre-programming activities as being very helpful to their process of learning Specifically, children explained how their learning was supported by: (1) storyboards that helped them organize their ideas and sequencing the robot's interactions (2) pseudocode that simplified selecting and planning for block code and built explicit connections between block code and informal descriptions of their function.

First, children explicitly stated that using the block code directly to implement their ideas for the robot would have been challenging for them. For example, P2 said, "I think that [the activities] helped because if we just jumped to the block code, I think we would have a hard time of how its gonna work." Our inclusion of storyboarding activities seemed to address this issue by helping children work out their ideas as they could "piece it together into what we're doing," where if they, "didn't do[the storyboard]…I think that would be very challenging" (P2). Specifically, the storyboard assisted in planning the robot's actions as they had to "brainstorm with the storyboard, what it was gonna be able to say and do since we couldn't speak to it" (P17). Thus, we found that the children were able to use storyboards to engage in procedural thinking to plan a successful program for the robot by sequencing the actions they wanted the robot to perform.

Second, the pseudocode activity reduced the complexity of using the block code by helping students select code blocks for the actions they want their robot to do. one student shared "[the pseudocode] was beneficial because if they just took us straight to the block coding, we would be like, oh, what are we making the robot for? Or, oh, what does the robot do? How do we use these blocks and code?" (P11). The pseudocode guided students in making a connection between what they planned for the robot to do, from the storyboards, and how they were going to implement that plan in their code. Pseudocode also seemed to help children make explicit connections between their daily or natural language use and the verbiage and nomenclature in the block code they needed to program the robot. Children were able to connect the pseudocode activity to the design of the algorithm to be used by the robot by seeing it as a simplification of the actual coding. Children felt that implementing their ideas for the robots and subsequently programming them was supported through the progression of these scaffolded activities. P17 commented on this process, "helped us simplify it [their ideas] into almost block code".

Theme 2: Open-ended and collaborative learning supported creativity, problem solving, iteration, and expanded perceptions of computing.

Students described instances where they were engaged in key CT practices such as, creativity, problem solving, testing/iteration, and related them to the open-ended and collaborative nature of the program.

First, the open-ended learning environment let children practice computing as a creative discipline by incorporating their personal interest into defining the problems and solution paths that they work on. This freedom to make choices in the problems to work on enabled students to include their own interests into their work that demonstrates how computing requires creativity. P10 said, "I mean that we get to really be creative of what we do and kind of choose, we get to choose what we want to create." The diversity of concerns and approaches that students could take and the creativity they were able to experience impacted their perceptions of computing as a discipline. Comments about figuring things out were frequent and demonstrated that children were actively engaged in problem solving through a process of iteration. P4 reflected that, "if you get something wrong you have to problem solve to figure it out and try different methods."

Second, the collaborative nature of the program allowed children to exchange ideas and knowledge within and across groups to help them build on each other's programming solutions. For example, collaborating lead to children making improvements in their work, "it was a lot of fun to implement other people's ideas and use them to create the robot and make the robot better"(P17) or assisting in issues with coding, "we could talk about each other's work and also give each other ideas or help them out with the code" (P13). Children attributed across groups interactions as helping them in the generation of ideas. P19 shared, "I got to look at other people's robots and sometimes it would give us ideas or I'd be like, 'oh, hey, this is a nice way to write their code." Children were continuously seeking help, sharing ideas and communicating around computing with each other and the mentors and this prompted a shift in perceptions of computing from a solitary endeavor in front of a computer screen to a more collaborative image of the discipline that requires interacting with people to generate ideas for problem solving.

Discussion and conclusion

Our results demonstrate that (1) children felt to be successful they needed scaffolds as a bridge between conceptualizing the interactions in their project and coding with block code and (2) practicing computing as an open-ended and collaborative activity broadened students' perceptions of computing disciplines.

First, we found that children felt their learning was supported through the pre-programming scaffolds in ways that helped them connect conceptualizing, planning, and programming the social robot interactions. The progression of activities let students convert their initial, unorganized thoughts for their social robot designs into a concrete set of instructions that they could then implement with the block code. Children in our study benefitted from the additional scaffolds in pre-planning their code to make the block code more interpretable and help structure interconnected block programs. Our findings indicate that the designed scaffolds seemed to help reduce the complexity and that allowed learners to write more complex and sophisticated robot programming. In this way, our scaffolds supported CT concepts involved in creating specific elements of their programming as well as higher order CT practices where children learned to decompose problems and iterate on solutions.

Second, the open-ended activities approach may provide students a perspective of computing that is not just focused on programming but problem-solving. Social robotics helps with this perception shift as children problem solve in a social context, related to their everyday lives, that requires considering how the robot interacts with its environment. The collaboration students engaged in also may have helped to change their perspectives about computing to demonstrate how interactive problems solving can be in the field (Bowman et al., 2021). Thus, integrating social robotics in the collaborative open-ended learning environment may be an effective way to support key CT practices where students' problem-solve in creative ways and in doing so provide an expansive understanding of computing.

In summary, we found that children related their learning of coding and computational practices to the pre-programming scaffolds where the positive experiences changed their perceptions of computing as a creative and collaborative discipline. We found social robotics to be a powerful context for learning CT.

Comparing Virtual and Augmented Reality: Learning and Interaction Effects in Astronomy Classrooms

Taehyun Kim, James Planey, Robb Lindgren
thk4@illinois.edu, planey@illinois.edu, robblind@illinois.edu
University of Illinois at Urbana Champaign

Abstract: There is growing interest in the educational applications of immersive virtual reality (VR) and augmented reality (AR). However, there have been scarce empirical studies that directly compare the learning affordances of AR and VR. This study examines how AR and VR versions of the same astronomy simulation affected learning and collaborative behavior in undergraduate astronomy classrooms. Results showed that both environments were effective for supporting student understanding of key astronomy ideas and problem-solving strategies (e.g., determining one's latitude and longitude). Students who used AR had stronger learning gains on the more challenging assessment items compared to the groups of students who used VR. Additionally, students who used AR made explicit attempts to reconcile their viewpoint with their group members' viewpoints through gesture and referencing each other's perspectives, whereas VR users relied more on verbal coordination.

Introduction

Immersive technologies like virtual reality (VR) and augmented reality (AR) have attracted attention because they have the potential to engage students in active learning by allowing for direct manipulation of virtual objects and altering their perspectives in ways that can potentially enhance their understanding of complex phenomena (e.g., Checa & Bustillo, 2019; Papanastasiou et al., 2019). While both VR and AR technologies show promise for collaborative activities, more research is needed to understand their respective affordances and tradeoffs in small group contexts. AR allows students to engage with real-world problems in familiar contexts (e.g., in-class group work around a table) while experiencing augmented digital information (Klopfer & Sheldon, 2010), whereas VR provides full immersion (Bowman & McMahan, 2007), a sense of presence (Slater, 2009), and embodiment (Johnson-Glenberg 2018) in a simulated environment, enabling natural interaction without real-world distractions. Both types of immersive technologies have potential to enhance student perspectives in ways that may benefit group learning and problem-solving practices, but efforts to understand the effects of these technologies on collaborative learning processes are still limited and the results so far are inconclusive (Ke & Carafano, 2016).

A multi-year research project on collaborative learning with undergraduate astronomy students presented the opportunity to compare the relative affordances of AR and VR technologies for supporting learning on the same task, addressing questions related to learning effectiveness, collaboration experiences, and differences in usage between the two technologies.

- *RQ1*. How effectively do students in the VR and AR groups learn the astronomy concepts and procedures?
- *RQ2*. What differences were observed in how students used the VR and AR headsets in the context of small group problem solving?

Methods

Participants & design

A total of 68 students (39 in the VR groups, 29 in the AR groups) from a midwestern community college introductory astronomy course participated in this quasi-experimental study. The software system and task outlined below were integrated into the course's existing 120-minute lab time. Leading up to their engagement with the system, students were introduced to both the AR or VR headset as well as the features of the software across immersive and tablet platforms during portions of their lab time leading up to the study session.

Software design, VR, and AR environments

The software environment, designed to facilitate sharing night sky perspectives and stellar information across immersive devices and tablet interfaces, provides users with three main perspectives shown in Figure 1. As groups explore the sky, they can share star selections, draw annotations, and viewing locations on both immersive devices and tablets.

Figure 1
The three main views accessible in the software environment: "star view" (a full celestial sphere accessible without any Earth horizon), "horizon view" (a situated first-person view of the sky as if standing at a location on Earth), and "Earth view" (an orbital perspective facing Earth).

In the VR headset (Oculus Quest), participants access shared interface panels with information about selected stars, networked group members, and controls to manipulate location, date, and time. Figure 2 (Left) shows a group working together within the VR implementation. The AR implementation (HoloLens 2) required interface changes to accommodate hand-tracked gestures, which were also carried over to tablets, as seen in Figure 2 (Right). Data representations were made more visible, buttons enlarged for easier use, and interface panels in AR could be moved in 3D space around the user.

Figure 2
The left image illustrates a VR-based learning environment and the viewpoint of a student using VR, while the right image likewise displays a learning environment utilizing AR.

Task design

For both the VR and AR implementations, a problem-solving multistage task "Lost at Sea" was created in collaboration with the introductory astronomy course educators. The overarching goals addressed by the task were to facilitate students with building on their existing knowledge and apply it in a novel context, as well as provide a foundation to promote collaborative interaction via task goals and distributed resources (each group had one AR headset, two tablets, and assorted paper materials). "Lost at Sea" is a problem-based collaborative task that places students in the role of a space capsule recovery team attempting to determine the location of a splashed-down capsule. Working in groups of 3-4, students are tasked with using observations of the night sky within the software to: 1) Determine the hemisphere of the crash site and support their decision with identified stars or constellations, 2) Identify additional constellations they recognize to orient themselves to the cardinal directions, and 3) Calculate approximate latitude and longitude of the crash site location based on night sky information.

Measures

We conducted pre and post questionnaires for both implementations. The pre-questionnaire was designed to check pre-existing characteristics of each group's students. It asked students to rate their interest, confidence, and knowledge of astronomy on a 5-point scale from "Very Low" to "Very High". The post-questionnaire asked students to make self-ratings on their own group collaboration. In addition to the self-rating items, open-ended questionnaires asked participants what tasks they completed while they were using each device. The first and second authors classified open-ended post-questionnaire items using the coding scheme, which was applied to all device types (VR, AR, and Tablet). Developed coding scheme classifies how students used technology into four levels: Level 0 - not used, where students didn't use the device; Level 1 - adjusting to the technology, where students focused on understanding the device rather than problem-solving; Level 2 - exploring, where students used the device to explore the night sky and interact with stars and constellations; Level 3 - measuring, where students used the device to calculate or measure for task completion, such as changing locations, tracking time, and finding constellations.

Pre and post assessments measured students' knowledge of calculating latitude and longitude after the intervention using an open-response prompt: "Write as much as you know about the steps for calculating latitude/longitude based on the stars visible in a given location." The first and second authors scored students' answers using a co-developed rubric. The rubric classified responses as Basic (1) or Advanced (2); if there was no response, it was scored as a 0. Basic responses included height or distance of a star from the horizon for latitude and time as a calculation component for longitude. Advanced responses added using degrees for measuring the height of a star and identifying Polaris as a target star for latitude, and measuring two time zones and understanding 15 degrees equals one hour of Earth's rotation for longitude.

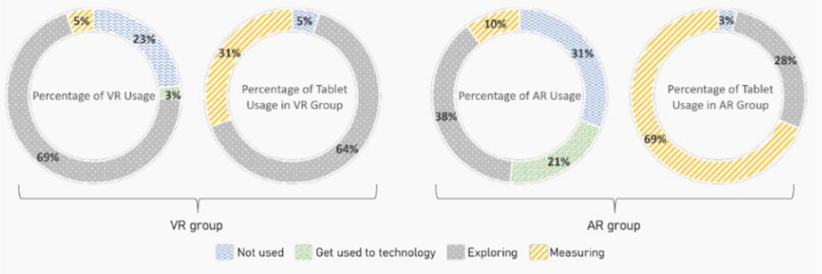
Results

We first examined whether there were any pre-existing differences between the groups in science interest, confidence, and astronomy knowledge. The t-test result shows that the two groups did not differ in the mean scores ($p=0.18$). Furthermore, from the pre-test scoring result, Wilcoxon signed rank test revealed that there were also no significant pre-existing knowledge differences between the two groups (latitude: $p=0.63$; longitude: all students were at 0 points). Therefore, we can conclude that there were no significant pre-existing differences between the two groups.

Our first research question concerns whether students learned the desired content after the intervention. We conducted Wilcoxon signed rank tests for both groups' pre- and post-test scores and the results show that both groups' post-test results were significantly higher than the pre-test for both learning outcomes (VR group latitude: $Z = 4.31$, $p < 0.001$; VR group longitude: $Z = 2.99$, $p = 0.004$; AR group latitude: $Z = 3.78$, $p < 0.001$; AR group longitude: $Z = 3.98$, $p < 0.001$). In addition, we conducted a Mann-Whitney test to compare which group performed better. The results show that there was no difference in latitude calculation between groups. However, the AR group performed significantly better on the determining longitude task ($p = 0.009$).

Our second research question investigates whether students used each device differently. According to students' device usage self-report responses, 69% of the students in the VR group used VR devices to explore the night sky, whereas only 38% of the students in the AR group used AR for exploring (See figure 3). We also found that more students were at the "get used to technology" level while they were using AR devices (VR = 3%; AR = 21%). In addition, both groups' tablet usage also looked different. The VR group mainly used tablets for exploration (64%), while the AR group used tablets mostly for measurement (69%). Interestingly, VR group students used both VR and tablet devices mainly for exploring, whereas AR group students used each device in diverse ways.

Figure 3
Each device usage comparison.



To get a better sense of how each immersive device affected students' approaches to device usage, we picked the group who scored highest on the post-test from each immersive platform and compared their collaborative discourse. Reviewing the video recording data from the two groups, we found that students in the AR group communicate more efficiently in establishing shared knowledge than students in the VR group. For example, there were episodes in which a student wearing an AR device looked at both the AR environment and a tablet screen (used by other group members) simultaneously to make sure they were all on the same page. On the other hand, students using VR devices had to undergo more turn-by-turn verification processes to ensure they were looking at the same object as their group members, since VR users could not see the tablet screen simultaneously and vice versa. However, once shared knowledge was established between students using VR devices and students using tablets, the exchange of related information took place very quickly and efficiently.

Discussion

In this study, we compared two multi-platform collaborative learning environments in astronomy classrooms to investigate students' learning outcomes and device usage. The analysis shows overall positive learning outcomes in both environments measured via pre- and post-knowledge assessments. AR group students performed better on a more difficult and complex task (calculating longitude) compared to VR group students. This may indicate that

AR devices provide a similar immersive perspective as VR devices without completely blocking students from the physical learning environment, facilitating communication between AR and tablet users. However, both groups' self-rated collaboration scores did not differ significantly, warranting examination of how they used each device during collaboration.

We intentionally designed tasks to require different levels of device use: the latitude task focused on exploring, while the longitude task involved measuring. One possible reason AR group students performed better in the longitude task is that they used tablets more for measuring, while most of the VR group students focused on exploring. This suggests that AR devices encourage higher-level tablet usage, and learning outcomes may depend on the combination of device use and collaboration. AR users coordinate their understanding by viewing both AR and tablet displays, while VR users engage in longer discourse exchanges. These technological affordances may impact collaborative discussion, particularly for the longitude task, which requires significant information exchange. However, this does not imply that AR is superior to VR in every situation or tasks. When designing tasks for multi-device immersive learning environments, researchers should consider each device's unique characteristics and how they may impact students' learning.

We expected students to have more difficulties with AR devices due to (bare) hand-tracking interactions and provided a short technology introduction session before the intervention day (not the case for the VR intervention). Nevertheless, many students had difficulty adapting to technology usage. To apply AR devices in classrooms, it is appropriate to consider long-term use instead of single sessions, allowing students enough time to acclimate to the novel technology. We acknowledge that the data analyzed and discussed here came from students' self-reporting and selected video recordings and as a result has limitations on the ability to draw broader conclusions beyond the context of this study. However, the trends toward use across the different immersive platforms uncovered here lays the groundwork for a more structured and targeted qualitative analysis of group discourse and action based on the full data corpus.

Finding Life in Data: Datafication and Enlivening Data Towards Justice-Oriented Ends

Angela Calabrese Barton, University of Michigan, angiecb@umich.edu
Edna Tan, University of North Carolina at Greensboro, e_tan@uncg.edu
Tamara Clegg, University of Maryland, tclegg@umd.edu

Abstract: We investigate the process of "enlivening" data and what it entails for youth vis-à-vis its relations, mechanisms, and purposes. Using vignettes, we explore enlivening data and datafication as nested concepts. While enlivening data gives learners agency to take action, datafication affords new ways to collect, analyze and present data about oneself. Educators must be attuned to the socio-political historical aspects of learners' experiences and as informed, be willing to make changes to their shared environments.

Introduction

Data are intentionally manufactured and they act to order and construct the world (Sadowski, 2016). Lupton (2016) characterized "lively data" as how people are "living with and by our data" (p. 709). That is, lively data is personally meaningful and consequential to how one is making decisions in daily life. In this paper, we attempt to map how minoritized youth "enliven data" which we operationalize as a datafication process involving larger data sets, embodied data, and lived data in myriad combinations shaped by historical and contemporary social interactions. We are interested in investigating what happens during the data enlivening process, who it involves, how, when and what justice-oriented trajectories such data enlivening might initiate, including new datafication directions. Using vignettes across our research-practice-partnership work, we explore the following overarching question: What are the relations, mechanisms, and purposes for datafication and enlivening data?

Theoretical framework

Datafication, lively data

A focus on data science education assumes a centrality of datafication in everyday life. That data, and questions of when, how, and why people engage with data, matter in the world. Datafication involves how experiences are rendered in data (most often quantified) and mediated by data with intentionality, purpose, and direction (Beraldo & Milan, 2019). Datafication is always a social, historical, and political project, often geared towards economic and political gain (Sadowski, 2016).

Datafication in society has been given authority in ways that lives/stories do not. And yet, datafication is *contingent on lives and stories*. Processes of datafication often make data lives invisible, as experiences in the world become quantified. However, datafication is not static, it is always enlivened, whether acknowledged or not, with pasts, presents, and futures. We draw upon Lupton's notion of lively data to theorize on the intersections between datafication and enlivening data. Lively data focuses on humanistic entanglements with data, including people's personal data, big data sets, and daily interactions with technology. It involves how people "live with, by, and through data" (Lupton, 2016, p.1) in their everyday lives, practices and decision making. Thus, making sense of how lives are made visible in datafication is an important practice for young people to be engaged in. We view processes youth engage in to *enliven* data as a way of theorizing the possibilities for justice in data science education.

Data justice, data agency

Our work is grounded in theories of data justice as a way to help us to make sense of how youth call attention to how their lives have been datafied in non-neutral ways. These theories remind us that people are made visible, invisible or hypervisible, represented or misrepresented, treated or mistreated in data (Taylor, 2017). Data is always racialized, gendered and related to socioeconomics (Philips et al., 2015). Engagement with data, and data infrastructures is thus always power-mediated (Vakil, 2016). As Acker & Clement (2019) remind us, meaning-making with data is never "innocent work."

Datafication does not impact all people equally. Theories of data justice tell us that engagement with data always takes place in sociohistorical and political contexts, shaping what data is made **visible and makes visible**, who and what is **represented** in data, and the **stories told** with and about data. All of these shape youths processes of coming-to-know and act in the world -- whether it be decisions on how to stay safe during a pandemic or taking action against forms of systemic racism such as environmental injustice, or make decisions related to athletics.

Youth not only act with data, but also act on data –to contest, re-appropriate and transform how datafication shapes their lives. Studies show that youth view data as a powerful force for social transformation and justice, and seek to mobilize more just data arrangements. For example, Kahne & Bower (2018) illustrate how youth have used social media in both the Black Lives Matter and the DREAMer movements to increase visibility, share resources, raise critical awareness, exert pressure, and organize action. How youth curate and distribute data sources can be viewed as a response to systemic asymmetries in data access and knowledge production, shaping what the public is able to know (Lehtiniemi & Haapoja, 2020). Data agency thus extends beyond data fluency by emphasizing youths' understandings of data and their efforts to actively control and manipulate information flows, wisely and ethically.

Research question & methodology

Our overarching research question is: What are the relations, mechanisms, and purposes for enlivening data? Specifically, we focus on these sub-questions: 1) What is the process of enlivening data for youth? 2) How do we know that data has become enlivened for youth? What indicators from youth reveal that data has become enlivened for them?

In a *Community-Based Critical Data Practices (CCDP) Collaborative*, involving researchers from three institutions, we collaboratively analyzed data across three extant projects to study youths' critical data practices (see Calabrese Barton et al., 2021, Tan et al., 2019, Clegg et al., 2022). This study takes an abductive analytic approach, which refers to "an inferential creative process of producing new hypotheses and theories based on surprising research evidence" (Timmermans & Tavory, 2012, p.170). Our approach to abductive analysis sits within an historicized and future-oriented design-based participatory orientation where we give witness to and learn with youth and community (Villenas 2019). Our approach is guided by participatory knowledge building approaches within research practice as we intentionally bring analyses into dialogue with partner youth and adults, as critical to the meaning making process. In monthly workshops we identified and explored data/cases that either intrigued us or challenged our thinking in relation to our framework of data justice and critical data to build possible explanations for enlivening data processes. We looked across these projects, drawing on existing analyses from the three projects noted above. We then used the framing of lively data (Lupton, 2016) and data justice (Taylor, 2017) as a lens to look across the cases specifically with a focus on understanding how data became enlivened for participants in our studies and the indicators for such.

Findings

First, we suggest that the work that it takes to enliven data requires people to be attuned to the social political parts and be willing to make changes based on such sociopolitical data-integrated insights. Enlivening data orders and constructs the world in particular ways and how we understand it with particular consequences and actions. Second, the relationship between enlivening data and datafication is dialogic, nested and "live". These processes are not merely taking existing data and giving it life. A generative outcome of enlivening data is new ways of datafication that lends further insights and a wider stakeholder buy-in to the issue being datafied and enlivened. Third, we propose three practices by which youth enliven data, including: a) Re-performing lived experiences; b) Building hybrid forms of data (e.g., community survey data + personal lived, embodied data, takes place through fleshing out data - with stories, range of examples); and c) Recruiting powered stakeholders for sociopolitical allyship towards a shared justice-oriented purpose.

Vignette 1: Collegiate athletes' enlivened experiences with data on their teams

In interviews with NCAA Division I athletes across sports, focused on critical data practices in their sport, we found that athletes on low-revenue teams collected their own quantitative and qualitative data from their training (e.g., heart rate, distance, pace, video). We conjecture that these data became enlivened for them as they integrated them with their own "felt" data (i.e., sensory-oriented reflections from their experiences). For example, Lei, a middle-distance runner on her university's track and field team mapped her speeds and heart rate to her own sense of "felt" exertion during runs, "Let's say I'm running four miles at a 7:30 pace. I'm feeling good, and my heart rate is 150... By the end of the season let's say I'm running that same four miles, but the 7:30 pace feels like I'm jogging and my heart rate is 130 average. That feels good because you feel like you're improving." However, Lei carefully about how she could and would leverage data on her team with her coaches. While she did not verbally leverage the aforementioned data integrations with her coaches, she and her teammates used them to determine when to collectively speed up or slow down from coach-set paces.

On the other hand, athletes like Omar on high-revenue teams had less agency on these metrics of data collection because of extensive staff set and implemented data practices on the team. However, Omar became animated in interviews when he realized film review counted as a data practice, "Because it's everything. Film shows you how an offense operates, their tendencies, how they line up to tell you if it's a run or a pass." This data, we conjecture, was so enlivened for Omar because this was a data practice that required Omar's agency and because he brought his unique "felt" experience to bear on when, and how, to use insights from film review in games. For example, Omar described the importance of appropriately weighing film review insights with the felt data of reading his key, "*…the most important thing they emphasize is, 'Read our key,' each position has a key. My key is the shoulder of the linemen, if he's turning down, I know it's a run block and then someone else is coming at me, so I got to play differently… It's good to have tendencies but you can't rely on that, you always have to trust and rely on your key.*" These findings suggest that while datafication abounds on Division I athletics teams, these data become *enlivened* for athletes as they integrate it with their unique felt experiences during training and games and as they leverage this data to enact change on their teams (e.g., in training or in game-time decisions). Yet, athletes needed to be socially and politically attuned to navigate the complex power dynamics of athletics (e.g., knowing how they could and could not advocate for and with their data).

Vignette 2: Mood board

In a 6th grade STEM classroom, a group of students engineered "a mood board" to address concerns about classroom morale they documented through surveys and interviews. Sage stated the mood board was important because, "Students normally don't have a way to express their feelings and show how they feel. Normally you can only talk to someone or use your body language. Some people don't feel comfortable doing that. When someone's using the Mood Board, it's easier for them to express their feelings." Layla pointed out that she is sometimes sleepy in class because she stays up late to greet her mom coming home from her night shift. Her sleepiness causes her to feel cranky and get in trouble.

The mood board was a light-up board where students could call attention to how they were feeling that day. As Sage explained: "Students can put their hand in the box and pick a mood that fits how they're feeling. Then they put it on the board. If students want to light up the board, all they have to do is turn the hand crank." Layla further explained that they switched to a parallel circuit instead of a series circuit because they wanted to light up many lights, supporting them in calling attention to their mood because: "if a student sees someone share that they are feeling angry or sad", then "you can practice empathy and try to make them feel better in some way or show you understand." In this way, the students pushed for the importance of recognizing and making visible a range of student feelings as important in school science. Students also handed out "mood board cards" to their peers, school personnel, and family members to encourage use of their design.

These findings suggest that students *enliven* their analyzed survey data through layering their own embodied experiences onto them, such as when Sage described how being sleepy caused her to be cranky and get in trouble. By making visible how their embodied experiences shape their lives in classrooms, they could orient their data towards having consequential impact on their classroom culture. Additionally, the mood board itself offered a process by which students' moods were *datafied*, making them visible and learnable by their teacher and peers through a new communication platform – via the physical operations of the mood board. As students posted their moods, new ways of *datafication* and learning became possible, as the teacher tracked differences in moods across the school day and week, and among student groups. As students *datafied* their experiences, then cranked the lights, they invite others into their experiences. Such *enlivening*, through performance provided spaces for youth to engage agency to do the things they needed to foster better classroom morale, e.g., I want to use this board so that people know how to interact with me in class today.

Vignette 3: Black youth vaccine resistance

As the pandemic unfolded and Black communities were disproportionately impacted by poor health outcomes, the Black youth with whom we work in our weekly community-based STEM programs recalled mental anguish caused by accessing statistics on COVID rates in their cities and states and hospitalization and death rates in the Black community through the CDC and the WHO. Such *datafication* positioned them as a statistic—*hypervisible* in a demographic group with higher infection, hospitalization, and mortality rates. However, when vaccines became available, datafication rendered their lives *invisible* as their experiences were not fully considered in how vaccines were tested or made accessible to the public. Many of the youth articulated their reluctance to get the Covid vaccine when it was finally approved for children 5 to 18 years old. The youth invoked historical abuses on Black bodies in Western Science and medicine, saying that "they experimented on Black people" as ample reason to not trust CDC (Center for Disease Control and Prevention) guidelines. One Black youth, Selena explained why she refused to get the Covid vaccine: "I have sickle cell [anemia] and they did not test the vaccine on people with sickle cell. They think I don't know science, I know science!"

However, even for those youth who wished to be vaccinated, information and access was limited. Fourteen-year-old community member and research participant, Jazmyn, shared her experience as she navigated tensions of a) standing up with her community by leading a Black Lives Matter protest but also b) wanting to avoid COVID-19 exposure: “I had to decide whether to protect myself and my family against injustice by protesting, or to protect myself and my family by not going.” It is because of navigating realities like Jazmyn’s that our participants did not anticipate a vaccine rollout to serve them in a just manner. First, vaccine distribution has been chaotic, and well-known statewide structures to reach communities who need it most are glaringly absent. Jazmyn wondered where were “the televised PSAs and billboards, phone banks, citywide text/email alerts,” along with volunteers, and centralized resource access locations that seem so readily available during “political campaigns”? In both cases youth observed their lives datafied – as statistics in a pandemic.

Implications & tensions

Enlivening data has the potential to lead to new territories and possibilities when youth and young adults experience how particular kinds of data might be salient to their lives now and inform their lives in the future. Sociopolitical allyship with more powerful others is an important element of enlivening data, both in the enlivening process and in the setting into motion new modes of datafication. As we can see from the mood board in vignette 2, Layla and her teammates had the support of their science teacher to pursue and create their engineering project which datafied and enlivened data on students’ moods, with concrete social-relational outcomes in the classroom. There are also tensions that arise out of the data enlivening process, with implications for sociopolitical allyship. For example, Omar’s data agency in vignette 1 with how he enlivened film data is contingent on how he negotiates the information from this data with the data apparatus and coaches within his Division 1 team. In vignette 3, while Selena was wise to consider historical exploitation on Black bodies in western Science, how she then couched current covid vaccine data against that historical backdrop was problematic. Jazmyn was highly insightful when she articulated the tension between prioritizing what kinds of safety for her community, as a Black youth committed to Black lives. Given these insights, how do we move forward in mapping the affordances and constraints of datafication and enlivening data? How might we design more student-agentic, justice-centered learning experiences for youth concerning critical data literacy?

“The Answer is Your Thinking…:” One Teacher’s Role in Helping Students in Navigating Their Epistemic Vexation

Sierra Morandi, Florida State University, smorandi@fsu.edu
Claudia Hagan, Georgia State Unvierstiy, chagan1@student.gsu.edu
Victor Kasper, Florida State University, vkasper@fsu.edu
Sherry A. Southerland, Florida State University, ssoutherland@admin.fsu.edu

Abstract: Current understandings of science learning revolve around students’ developing the ability to use science concepts and practices to “figure out” aspects of the natural world. One emerging area of focus in this new vision of learning is the emotional work required in students’ participation science sense making. This research focuses on how one teacher supports student reframing of moments of epistemic vexation. After reviewing classroom video, and interviews, three themes emerged: (1) Productive meta-affect is more likely to occur when students understand why the teacher allows for failure to connect ideas or understand scientific concepts, (2) Without explicit attention from the teacher during moments of epistemic vexation, students can disengage from sense-making and (3) When the teacher does not adequately attend to students’ epistemic vexation, students can build solidarity and reach out to each other for emotional support in developing meta-affect.

Introduction

Science Education has transitioned from a portrait of science learning as one driven by the recognition of “facts" to that of science proficiency--in which students are to gain the ability to engage in sense-making about the natural world (National Research Council [NRC, 2012])- learning to “figure things out” (Passmore, 2014). An emphasis on authentically engaging in the discipline of science asks students to share, discuss, and refine thinking about scientific phenomena in a classroom community (Bamberger & Davis, 2013; Berland & Reiser, 2009; Manz & Suarez, 2018; McNeill et al., 2006).

Many aspects of this disciplinary engagement have been widely studied and continue to be a focus of ongoing investigation. One emerging area of focus is that of the emotional work involved in science sense-making. Davidson, Jaber and Southerland (2020) and others (Arango-Muñoz, 2014; Jaber & Hammer, 2016a, 2016b) argue that epistemic affect-- learning how to *feel* as scientists do when engaged in their work-- should be recognized as a central component of meaningful disciplinary engagement in science. Epistemic affect includes “the emotional responses, feelings, and dispositions that emerge as one participates in the construction of knowledge through figuring things out about the natural world” (Davidson et al., 2020, p. 1009). Additionally, meta-affect (feeling about feelings), also plays an integral role in construction of knowledge and beliefs (Goldin, 2002). There is a growing recognition that these emotions are not just unnecessary by-products of scientific work, but rather they are part-and-parcel of doing science, as these emotions are part of what “instigates and stabilizes disciplinary engagement” in scientific pursuits (Jaber & Hammer, 2016b, p. 189). From this position, epistemic affect is recognized as an essential aspect of scientific research and thus needs to be considered as students are learning to engage in science practices (Davidson et al., 2020; Jaber & Hammer, 2016a). The work presented here is an extension of this line of inquiry, as we examine a teacher’s response to his students' epistemic vexations.

Research question

While this is an emerging area of inquiry, much work remains in terms of understanding how teachers can support their students as they learn to manage the emotions inherent in disciplinary engagement. Toward those ends, this work provides a description of a teacher’s efforts in supporting his students in navigating these emotions. The question at the center of this research is: What is the teacher's role helping students navigate moments of epistemic vexation, so students maintain their engagement in sensemaking?

Study design

Data for this study comes from a larger four-year professional development (PD) project focused on supporting teachers in their work to foster student sense-making through productive science talk (Southerland et al., 2017). Danny was our focal teacher, was intentionally selected because of (1) his teaching approach that focuses on helping students to be agents of their own learning, (2) his focus on students’ reasoning and deepening of this reasoning in his course, and (3) his long-term participation in the PD. For this study we selected to follow his

Advanced Placement (AP) chemistry classes in year one and four of the PD. A diverse group of students' interviews and classroom observations were coded to support initial themes.

Data sources for this study include classroom video and audio recordings, teacher interviews, and student interviews. After analyzing these different data sets in terms of their alignment around epistemic vexations and the ways in which Danny's efforts allowed students to reframe moments of epistemic vexation, the research team conducted final interview to capture Danny's perspective of students' epistemic vexation boundaries.

We employed a constructivist grounded theory approach (Charmaz, 2017) to analyze the data, where patterns were identified in both Danny and his students' perceptions of his teaching. The first author adapted the coding scheme from Radoff et al. (2019) to identify common themes in the student interviews, as well as the themes presented in Danny's final interview. The second author drew out common trends in Danny's four post lesson interviews and two end of year interviews to identify how he framed student emotions when teaching.

Findings

Theme 1: Productive meta-affect is more likely to occur when students understand why the teacher allows for failure to connect ideas or understand scientific concepts.

Danny prioritizes giving his students experiences where they have the responsibility to determine the meaning to be derived from their experience, which may lead to students experiencing emotions similar to those of scientists and create space for student agency of their own learning. Students are given opportunity early on in the course to share their thinking as a way to build resiliency as they reason through their ideas. Danny explained how he set up expectations to support agency and resiliency in his course:

> [L]ike setting the expectation, that regardless of your comfortability level, like you are going to share at some point, but at least having them start off with the experience of sharing in the lower stakes setting of a group of four people is a place to start off, where they don't instantly feel like the entire class is watching and judging…

This goal of providing students experiences, to "be like a scientist", which was necessary for their own sense-making, was not unnoticed by Danny's students. As Candice stated in her end of year interview:

> It definitely felt more like we were the scientists, not the students, I guess, let's put it that way. It felt like we were, we were scientists and not like we were making a discovery, although it was already proven, but like, still felt a lot more interesting.

However, students did not understand why Danny would not answer their questions or give them closure on concepts, and in turn students experienced frustration that in some students became anger. In Candice's understanding she continued:

> You would ask him like, "Well why does this happen?" He'll be like, "I don't know, figure it out" and you're like, "I need help! I am 16 years old! Okay? I am not a chemist. I don't know. Please help!" Um, the [task] just frustrating cause I never got closure on anything...With this one [chemical equilibrium investigation], we weren't getting it so he was frustrated with us and we were mad at him and it was just a really toxic environment because everyone was mad at everyone."

Throughout the year Danny continually pushed his students to rely on their own ideas, and toward deeper sense-making. At times he kept students productively engaged in that effort through careful questions, and in other times those questions push students past their vexation boundaries, causing them to become frustrated and disengage in sensemaking.

Themes 2 & 3: When the teacher does not reframe moments of epistemic vexation, (1) students will disengage from sense-making or (2) students will build solidarity and reach out to each other for emotional support in developing productive meta-affect.

Danny sees questioning as a way to "get [students] onto that train of thought", as he focuses students on the sensemaking portion of a lesson as students grapple with their explanations. Wanting students to "at least attempt to grapple" with ideas as he addresses questions to entire groups but expects students to engage, even if at the very least they are passively engaging. Danny states:

> So, usually I always focus on the "why". My kids will tell you that "Why?" is my favorite question. And if they can't answer that, I'm not gonna let them not, so I'll just keep pressing them until eventually they tell me what they know.

It is evident that Danny's students are also aware of his consistent presses as he questions and probes their thinking. Hannah stated, "Even whenever he's teaching, if someone has a question, he asks them like, okay, well how do you think this will happen?". Likewise, Emily had mentioned in her end of year interview, "He would never give us a direct answer and even when I had like come to him and ask him a specific question, he would make me work myself to the answer."

In one moment during implementation of a lesson, Danny asks one small group member, Kyle, to make a relationship about the elements on the periodic table. While Kyle appears to be confused on the relationship in the periodic table (shuffling papers in his hands while staring at Danny without saying anything), Ryan, another group member, speaks up to address Danny's question and further the train of thought that is being built. Students look to Danny for answers, and while he realizes this he does not comply. Instead, Danny uses the building of ideas within the group to help students make sense of their own observations. Danny knows students become frustrated by his constant questioning instead of answers, as students look to him as an authority in the classroom. He stated in one of his end of year interviews:

> [Students] are probably going to be frustrated. This is what we're going to do in this class. I would advise you to not try to read answers off of my face, because I typically don't change my tonality, and I don't change how my face looks. So just trying to guess if you're right or wrong by looking at my facial reaction, that's not gonna go well for you.

In another classroom moment during a whole class discussion with a student named Carol, Danny asks "Why was green the one with the highest energy?" This question is the turn in conversations that began to lead Carol away from the idea she was initially trying to express. The frustration that Carol exhibits (identified by her flushed face nervous tone to her voice and putting her head in her hands) is observed by others in the classroom This moment provides a common experience which later helped build solidarity amongst students. During student interviews, students were asked to watch this moment and talk through their feelings and recall what was happening with a researcher. Hannah speaks about solidarity in her interview, "During that lesson, I didn't feel as bad cause I think I felt like, okay, like majority of the class isn't getting it either. So it's not just me." This solidarity helped students be more empathetic with each other's sense-making which in turn led them to emotionally supporting each other when they experienced feelings of frustration or confusion. Students expressed their gratitude for their peers throughout the interviews.

> But I always had partners so we could talk about it together. So, it wasn't just me like figuring out the answers. -Emily
>
> Yeah, well I think it's like the whole class having that discussion, it just makes it a lot easier because it's not just you and even if it was just you and your group, you know sometimes you and your group really might not know the answer. Some when it is the whole class. At least one person's bound to get it right or like at least one person at least somewhat understands and can help explain it. -Hannah

While student support and solidarity can build a sense of community, this solidarity is not always enough. In the moment with Carol and Danny, the lack of substantial guidance from the teacher when a student so obviously has been pushed beyond her vexation boundary can have a lasting impact. Rose stated in her end of year interview, "Yeah, I think like, I don't know, I don't know like [Carol] especially like towards the end of the year, like stopped talking as much as she used to."

Contributions

This work offers insight into the case of one teacher and his students' perspectives on moments when students are tittering at their epistemic vexation boundaries. Danny views epistemic vexation as a necessary part of student sensemaking. For sake of disciplinary connections, Danny forgoes attention to students' emotions and his own in order to make space for empirically driven sensemaking. This does not mean that Danny is not aware of these emotions but given his teaching goals he chooses to not forefront in science learning for his students.

While this is only one teacher and his role in helping students navigate epistemic vexations, it speaks to a need to attune teachers to the need to recognize and find techniques to help students navigate students' epistemic vexations. If we are to successfully engage students in the thinking of the discipline, teachers will need to learn to recognize, value, and support students' emotions involved their wrestling with uncertainties (Jaber et al., 2022; Manz, 2015; Manz & Suarez, 2018)

Abstract: Supporting minoritized students' participation in a science requires designing expansive notions of what counts as doing and learning science. We present the design of a middle-school biology unit about stress and body system interactions that challenges the boundaries of disciplined science and promoting social change making through consequential learning. Four core axiological commitments shaped the design of the unit: a) expanding disciplinary practice by entangling mind, body, and environment; b) supporting students' rightful participation and expertise; c) recognizing the environment as politicized across scales; and d) supporting social change through allied political struggle. We describe how we embodied these commitments in the unit design and how they played out in the context of a 7th grade urban science classroom. This work provides another example of consequential learning environments and contributes to the theory and practice underlying their design.

Introduction

Over the past two decades Learning Sciences has increasingly attended to issues of equity and justice by recognizing that all learning environments are inherently political and thereby serve to either maintain the status quo and (re)produce inequities or disrupt historical and ongoing injustices and redress them (Esmonde & Booker, 2017). In the context of science education there have been ongoing efforts to promote a more expansive view of desirable aims that include using science to identify, investigate, and address injustices (Basu et al., 2009; Morales-Doyle, 2017). Such efforts have emphasized the importance of learning that is consequential to students in that allows them to participate in science through knowledge and practices that are relevant and meaningful to them and their communities (Tan et al., 2019). Designing for consequential learning therefore entails attending to and disrupting settled and powered participation structures in order to expand disciplinary boundaries (what counts as science) and allow for new aims and new forms of participation. A core and valued aim of consequential learning is to make visible and address locally meaningful injustices that are, invariably, rooted in broader sociopolitical injustices (Tan et al., 2019).

In consequential learning environments legitimate participation extends beyond being included and supported in sanctioned disciplinary practices and entails rightful presence-- the ability to reauthor rights, make injustices visible, and shift normative power relations and expectations. The *Rightful Presence* framework (Calabrese Barton & Tan, 2020) challenges traditional notions of equity as inclusivity and argues that legitimate participation needs to afford changing those very rules and expectations by challenging guest-host powered relations. Traditionally, students in science classrooms function as guests learning new normative disciplined practices (ways of doing, being, knowing) from the teacher or adult hosts. Given the (still) prevailing view of science practice as relevant to yet unaffected by broader social and political struggles, students' own experiences of historical and ongoing injustices are not made visible as part of science learning nor made welcome in the classroom. Rightful presence therefore entails making sociopolitical struggles visible in the classrooms as a legitimate form of participating in science, and places responsibility on those who hold power in these spaces (e.g., teachers) to leverage their positions, as sociopolitical allies, for change towards more just outcomes.

Examples of consequential learning environments in K-12 science education, while compelling, are rare and the field would benefit from additional efforts (National Academies of Science, Engineering, and Medicine, 2022). Here *we discuss the design of a middle school life science unit aimed at addressing science standards in the U.S. (NGSS Lead States, 2013), while also challenging the boundaries of disciplined science, and promoting* *social change making through consequential learning*. Our aim with the unit was to address science standards through investigation of a health issue that was of concern to the local community through a unit that involved sociopolitical change making at the local level. This design work was guided by commitments to and intentional design towards: a) expanding disciplinary practice by entangling mind, body, and environment; b) supporting students' rightful participation and expertise; c) politicizing the environment across sociopolitcal levels (national to local); and d) supporting social change through allied political struggle.

We present a middle school biology unit-- Bio4Community: *Stressed Out- How our bodies interact with our environments,* as a design case with the hope that it can contribute to the field in three ways. First, as an example of expanding disciplinary practice in the context of life science adding to the small, but growing, collection of exemplars of consequential and justice-oriented science units available for researchers and practitioners. Second, as an example of connecting structural oppressions at the larger sociopolitical level to their local manifestations. Third, and following from the prior point, as an example of student-developed solutions that are, in turn, aimed at transforming inequitable structures and policies at the local level (but that are embedded in the larger sociopolitical context) in ways that will benefit their community.

The Bio4Community design team and the Stressed Out! unit

Our team was engaged with design in multiple configurations, some of which included youth and teachers from the school district with which we collaborated (Krishnamoorthy et. al., 2021). As a research team we hold different positionalities (in terms of racialized and gendered identities, ethnic backgrounds, and their intersections), we have different lived experiences and expertise. Team members also brought experiences and perspectives informed through their identities as immigrants (voluntary and involuntary), settlers on colonized lands, and as members of the queer community. The collaborating teachers who enacted the unit were a Middle-Eastern immigrant woman who has been teaching in the urban district for multiple years and a Black woman who recently joined as a special education teacher in the 7th grade classroom and also had extensive experience teaching in urban and marginalized settings. This district itself serves a majority Hispanic community (85%) with over two thirds of families socioeconomically deprived.

Briefly, the unit included six lesson sets each lasting multiple days. The first lesson set introduced students to the phenomenon of stress grounded in their embodied experiences, through testimony from community members their age, and through quantitative data from their community. In the second lesson students engaged in community ethnography and developed a survey about causes of and solutions to stress in their community. The survey was sent out to the school community. Results from the survey were analyzed later in the unit to inform students own solutions in the stress-in-our-community problem space. The third lesson set engaged students with evidence from, predominantly, Eurocentric scientific research about the short-term stress response (fight-or-flight) to support the construction of a class consensus model of this phenomenon. In the fourth lesson set students investigated long term stress through a set of stories. The fifth lesson set focused on the ways in which injustices structured into the environment act as ongoing stressors. In the sixth and final lesson set students developed "proposals for change" that honed in on a particular cause of stress in their school (based on analysis of the survey done earlier in the unit), identified the existing structure or policy that was at its root, and advocated for a solution at the policy level (e.g., universal bathroom policy). Students presented these to the principal, faculty, and staff.

Axiological commitment I: Expanding disciplinary practice by entangling mind, body, and environment

Much of school science is grounded Eurocentric ways of knowing that separate humans from the environment and mind from body. In the *Stressed Out* unit we learned from Indigenous scholars by taking a more expansive and holistic view of human biology that focuses on the relations between and within the mind, body, and the MTH (Bang et al., 2012; Kimmerer, 2013). Throughout multiple activities were encouraged to express physiological sensations (heart rate, sweating, shaking) and mental sensations (overthinking, anxious, crying) as entangled, legitimating a holistic view of how we define stress in our bodies.

To engage students in exploring the effects of chronic stress on our minds and bodies we used an approach we term story-driven investigations that presents students with a story that includes evidence and that explicitly weaves the sociopolitical. We endorsed an expansive view of evidence that included community-based knowledge from elders and respected community members (along with normative scientific evidence). For example, one of the stories involved a high school student- María- who struggles to focus in class and is frustrated by this. María's abuela (grandmother) suggests that she may be unable to focus due to stress setting María (and the students) on a journey to find out whether stress can actually affect your focus. Throughout this journey María leverages the expertise of multiple individuals including family, teachers, and scientists who provide her with resources that serve as evidence in her quest for an explanation.

María's story was intentionally designed to entangle feelings, thoughts, and the neuronal networks in the brain with her school and home environment. Taking an adaptive, rather than deficit, view of the impact of stress on the brain, in the story María finds out that stress increases connections in the brain's fear networks making the mind constantly "on alert", and reduces connections in the attention network making it hard to focus on cognitively challenging tasks such as taking a math test. Both sides of this response, are adaptive but in the context of schooling become a problem. Entangling feelings, mind, body, and environment was an intentional decision that was embodied and made explicit in all three stories.

Axiological commitment II: Supporting students' rightful participation and expertise

Throughout the unit students' experiences and expertise served as crucial and valued levers in driving the investigation forward. Students' experiences also served as proxies for the experiences of the larger middle school community and informed community ethnographies. In this sense, students' personal experiences informed theoretical construals of the phenomenon—how stress shows up in the community and what are its causes. The proposals for change (Lesson set 6) that were informed by the community ethnography data also intertwined disciplined science knowledge (model of long term stress) and community knowledge. The legitimated presence of local and personal knowledge shaped the problem space and made salient the importance and relevance of that knowledge; students were able to reauthor what kinds of contributions, problems, and solutions were valued.

In an effort to encourage youths' rightful presence through valuing their worlds as consequential to their learning, all three stories featured family and community members as integral to the main character's sense making journey, such as the positioning of elder wisdom (María's abuela) as culturally relevant (Ladson-Billings, 2021) to and explicitly *not* less important than disciplined science knowledge. As this part of the unit unfolded, abuela's role in youths' sensemaking expanded beyond the words on the page. When explaining their model of "stress and focus" to the class through a skit, the youth prominently featured María and her abuela's relationship as central to the model of long-term stress. Acting as a sociopolitical ally, the teacher (host) ceded power to the students (guests) in authoring their rightful presence in the space through legitimating social interactions in which one student began identifying himself as 'abuela' (and was referred to as such by the teacher). Finally, the consensus model-making activity, was led by 'abuela' (the student), who was called on to evaluate the model. 'Abuela'. The class positioned their consensus model as being storied, by abuela - thus weaving disciplined science with culturally valued expertise (abuela) and practices (story telling).

Axiological commitment III: Politicizing the environment across sociopolitical levels

We wanted students to understand that minoritized communities are not at fault for being stressed, and while they are agentive in their own survival, they do not have much control over the stressors in their environment because those are intentionally structured into the environment. Towards this aim, we interrogated our positionalities and ways of knowing (Austin, 2023) with regard to the disproportionate impacts of white supremacy on our lives. This resulted in a more nuanced presentation to the students of data about perceived stress in their town, disaggregated by race and income level, in the very first lesson set, to position health disparities as ultimately caused by the environment. The stories included many details about the characters' environments in terms of the unjust structures and policies. For example, one of the stories featured Felix and Josue a young gay couple living in a segregated and economically disadvantaged neighborhood with limited access to health facilities and robust grocery stores, yet with a culturally vibrant and supportive community.

We have used the language of unfair structures, policies, and procedures to support students in seeing and naming these elements in the environment. This framing helped us illustrate: a) the designed nature of injustice in the environment (i.e., targeted racial policies such as redlining); b) that these environments are not neutral in that different groups of people experience them differently; and c) that these environments are therefore not benign, they cause inordinate harm to some groups of people. Students then applied what they learned about unjust structures, policies, and procedures at the larger societal level to their own local context—i.e., what structures, policies, and procedures in their school stress them and their community of peers.

Axiological commitment IV: Supporting social change through allied political struggle

Social change making requires understanding and disrupting the structures operating to propagate and entrench inequities. Successful efforts depend on the support and allied struggle of others in the community, and in particular those in positions of privilege and power (Calabrese Barton & Tan, 2020). The teachers, a highly regarded elder in the community, and the researchers worked with and alongside the students in their advocacy efforts. Several curricular activities in the last two lesson sets supported this allied political struggle. First, the teachers and the elder created and shared their life-lines of stress depicting stressful events in their lives from middle school to adulthood, making an effort to explicitly connect the stressors they experienced to unfair structures and policies. Second, the students interviewed the elder (another form of community ethnography) about her experiences with racism and her sense of unfair structures in the school environment and what has been done about them. The elder shared advocacy and activism efforts she had participated in the school to allow students to wear hoodies. She emphasized the importance of "being right" and doing due diligence on researching and understanding the inequities and their root causes (structurally) and then intentionally developing allyship and support in activism that aims to disrupt them. Third, the principal was invited to the presentation of students' proposals for change and, in turn, was able to provide the students with an opportunity to present to all the school faculty and staff during a faculty meeting. This was not a trivial opportunity to bring to fruition and required substantial effort on the principal's part- another example of allyship.

Concluding remarks

Here we have attempted to explicate the axiological commitments undergirding our equity conjectures (Lee al., 2022). Centrally, we attempted to take an overt political stance by developing materials that engage students with the historical and political nature of the injustices experienced by marginalized communities. Understandings about racism at the broader sociopolitical context were then leveraged to make sense of and advocate against local institutionalized oppressions and inequities as experienced by the students. The science ideas and explanations students' developed in the unit motivated the urgency and need for the sustainable solutions students proposed. In this sense the disciplined science, local knowledge, and embodied experiences were brought together, consequentially, to problematize and push against the status quo.

Abstract: Postsecondary science education has been shaped by Eurocentric ideologies that center science as a set of culturally neutral, color-blind, and meritocratic systems designed to exclude underrepresented groups from positions of power and knowledge production. Nationally, white faculty still predominate senior faculty positions, resulting in few opportunities for students of color to take courses from faculty who share their racial or cultural backgrounds (Haynes & Patton, 2019). At the same time, there is a need to diversify the predominantly female and white elementary teacher workforce as the K12 student population is rapidly diversifying (Januszyk, et al, 2016; NCES 2103). This paper will describe white STEM faculty learning around race, culture, and STEM teaching/learning in a design-based research project in which we are designing science and engineering modules for preservice elementary teachers that deeply integrate scientific concepts and practices, racial equity, and examinations of the history of racist research practices within science itself.

Introduction

Increasingly, the natural sciences are recognizing the need to address social theories in the study of natural systems (Schell, et al, 2020; Graddy-Lovelace, 2017). For example, Schell, et al's review (2020) argued for conceptualizing social inequality as a key driver in the ecological and evolutionary outcomes of more-than-human species in urban environments. Residential segregation and redlining have resulted in a legacy of racially segregated geographies that correlate with decreased biodiversity, canopy cover, and increased heat islands. To understand how these factors affect genetic diversity of species in urban ecosystems, then, racial inequity needs to be taken into account as a driver of these processes. Redlining, comorbidity factors, dense housing, and inequitable access to health care--all stemming from institutional racism--have been implicated in the disproportionate suffering of Black and Latinx people in the current global pandemic. Caplan, et al (2015), argue for the need to consider racial justice implications of CRISPR and gene editing technologies. These considerations include historic distrust of communities of color of the medical community because of studies such as Tuskegee, and because of the underrepresentation of people of African descent and Indigenous peoples in genetic databases, which can differentially affect the types of therapies available to people of color and poses a real threat to the rise of eugenics. In these examples, racial inequity are key variables in the actual doing of the science.

However, postsecondary education–in particular, science learning environments– has been shaped by Eurocentric ideologies that center science as a set of culturally neutral, color-blind, and meritocratic systems that invisibilize eugenicist practices to exclude underrepresented groups from positions of power or from knowledge production (McGee, 2020). Nationally, white faculty still predominate senior faculty positions, resulting in few opportunities for students of color to take courses from faculty who share their racial or cultural backgrounds (Haynes & Patton, 2019). Studies of the development of race consciousness in white faculty have found that they may miss many opportunities to address historicized patterns of racial oppression, or to center culture in their teaching through pedagogical choices they make in micro-interactions with students (Haynes & Patton, 2019). There is a need, therefore, to understand how instructors in higher education develop *political clarity*, or coming to see the teaching of science as an inherently political endeavor (Madkins & MicKinney de Royston, 2019), in order to connect science with the sociopolitical realities of their students.

At the same time, there is a need to diversify the elementary teacher workforce. Elementary school teachers in the United States are predominantly female and white, even though the K12 student population is rapidly diversifying (Januszyk, et al, 2016; NCES 2103). Although a majority of elementary school teachers are over 40 years old, one-third of them report having 5 or fewer years of experience teaching science. Elementary teachers have taken limited college courses in physics, chemistry, and engineering, and only one-third have had coursework in all areas of science recommended by the National Science Teachers Association. Curriculum materials give some guidance in helping teachers learn content but are often not enough to support teachers in teaching complex ideas such as climate change–especially as related to intersecting issues of racial justice.

Teachers feel much more prepared to teach math and literacy than science or social studies. When asked about different aspects of science pedagogy, they do not feel well-prepared to support students engaging in the practices of science, providing science instruction based on students' ideas, or incorporating students' cultural backgrounds into science. In addition, almost 25% of elementary teachers have never attended a professional development focused on science (Plumley, 2019).

Informed by these bodies of scholarship, this paper will describe white STEM faculty learning in a design-based research project in which we are designing science and engineering modules for preservice elementary teachers that deeply integrate scientific concepts and practices, racial equity, contemporary scientific tools, and examine the history of racist research practices within science itself. We are a group of learning scientists and interdisciplinary STEM faculty who are co-designing a 2-quarter undergraduate course sequence that engages preservice elementary school teachers in project-based, interdisciplinary science content that incorporates contemporary issues (ethical engineering and algorithmic justice, gender inclusive biology, socioecological constructs of time, soil contaminants and redlining), science and engineering practices (computational modeling, GIS), and ethics ("should we"? vs "can we"?) of science, situated within the economic, social, and political contexts in which science and science decision-making always live. We are designing anti-racist pedagogies to highlight the ways in which science has been used as both a means of oppression of Black, Indigenous, and other people of color (BIPOC) and as a tool for advancement.

We argue that shifts in preservice elementary teachers' understandings of science begin with the instruction, modeling, and positioning they receive in their undergraduate STEM courses. This portion of our research asks:

(1) *What shifts occur in STEM faculty learning around the connection between their disciplines and racial equity during the design and re-design process? and*
(2) *How do these shifts show up in faculty instruction and course design?*

Framing

The recently released consensus study from the National Academies (NASEM, 2021) outlined a framework for understanding equity in terms of four "discourses" of equity and adopted from Philip & Azevedo (2017). These equity discourses are: (1) increasing opportunity and access to high-quality science education, (2) emphasizing increased representation and identification with science, (3) broadening what counts as science, (4) connecting science and engineering to social justice movements.

We also use Philip's "ideology in pieces" framing (2011) to study how faculty's ideas around racial justice as it pertains to their disciplines evolve over the course of co-design. The "ideology in pieces" framing allows us to track the "naturalized axioms", or commonsense ideas, that faculty have about their students, their disciplines, and their teaching practices. We study how those become articulated, or increasingly connected and systematized within and across contexts of use. This allows us to make sense of how a faculty member might simultaneously hold, for example, the connections between racism and the teaching of stoichiometry when reading and discussing an academic paper, but center dominant chemistry discourses that center whiteness while co-designing instructional sequences in our course, as emerged with one of our case study faculty.

Methods

We use a case study method (Yin, 2017) to understand the learning trajectories of four STEM faculty partnered in a multi-year co-design effort to collaboratively redesign the undergraduate science course sequence for pre-service elementary education majors at a public university in the Pacific Northwest. Data included recordings and transcriptions of bi-weekly design team meetings and quarterly design summits (72 hours), 3 interviews with each faculty member across the first year and a half of project work (14 hours), exit tickets from quarterly design summits (16), and artifacts (such as syllabi and course modules) related to course co-design. We used grounded theory (Straus & Corbin, 1994) to iteratively code data related to science teaching, racial justice, connecting to family/community practices, and course design, and we triangulated our findings across data to find common themes and patterns (or ideologies) that emerged for faculty over time and space. There were a total of 17 emergent codes related to faculty ideological stances.

Findings

A major part of our co-design work has been joint study and reading together around connections between science learning, Indigenous sovereignty, refusing anti-Blackness, power and historicity, ethics, and complex systems theory. We are also using educator frameworks from the Learning in Places project (Learning in Places

Collaborative, 2021) to understand issues of power, historicity, culture, ethical deliberation, and nature-culture relations in science.

Emerging findings indicate that faculty have shifted from processing their understandings about the four equity discourses to thinking about how to operationalize justice-oriented science and engineering design and teaching. In this paper, we will present the shifts in one faculty member's [Leah's] thinking about the connection between racial justice and teaching physics over the course of our first year of co-design work. Outside of our project, Leah has been engaged in a yearlong professional development project in which she supports a cohort of teachers incorporating equity into their physics courses. During our design meetings, Leah would frequently share how she tried out ideas from our co-design with her high school teachers. The shifts in thinking that we noticed in Leah are exemplified in her responses below: The first two responses are from exit tickets after two co-design meetings, and the third is from an interview with her after our first year of co-design.

> January 2022: The Azevedo framework for equity is exciting to me and aligns well with my current work with high school teachers - that was fun to learn about.
>
> May 2022: My thinking about honoring Indigenous presence continues to grow and evolve as a result of this project and others. I'm trying to remind myself of the option to decenter humans, think of humans in the context of plants and animals and lands and waters, think of the more-than-human as also mattering. In my work with high school teachers, I am trying to teach about place-based education, introducing them (and myself...) to the Learning in Places framework.
>
> October 2022:
> It's not my experience so far that, like different demographics of students have different science ideas…I mean, they think all different things. But you know…I feel clear that there must be different things that students are bringing to my class than their science ideas that I am barely um tuned into, if at all. I'm a lawyer's daughter. Argumentation is how you say I love you in my family right like we um spar for fun. So like that translates super easily to a science context for me, and I'm theoretically aware that that's probably not true in everybody's family. But um, I don't really know what's going on with my students about that. I'm just sort of theoretically aware that that is probably a thing that is not the same as me for many of my students.
>
> I'm still in a learning area about like what physics concepts are, can serve social justice and the best area. So far like one of the really good areas, so far, is power plants. Power plants are great [for]understanding the energy transfers and transformations that happen in a power plant [and] can help you engage with the impact the relationships that the power plant has with its environment, with the human communities and the more than human communities, the lands and water and air and plants and animals that um that is in relationship with…there's always some kind of community decision making happening around it… How are they engaging with the tribes? And what should they do about the salmon? I'm planning to make the whole course be about power plants and…maybe have someone from the utility company come and talk to the class to make that more community based. But, like everybody, has a utility company, right? Everybody pays a utility bill right? And so like learning more about that seems like a good idea.

Over the course of 10 months, we see Leah form a gradually more concrete operationalization of ideas connected to her course design and pedagogy. In January, she has just learned about the four equity frames (Philip and Azevedo, 2017) and is connecting it to her work with high school teachers. Her May response shows that she is reflecting on the frameworks that we read around *nature-culture relations* and seeing humans as a part of natural systems (rather than apart from and dominant over natural systems). By October, Leah is starting to articulate these ideas into her course design. She is starting to consider the role that her students' cultural practices might play in the knowledges and practices they bring to physics learning, and that some of those practices may be more aligned to science than others, though, at the same time she dismisses the idea of culturally-based ways of knowing. We also see her beginning to incorporate the "equity and justice" framing and begins seeing humans as part of the physics concept of power by making connections to power plants, human decision making, and more-than-humans. Through these brief episodes, we see the different pieces of Leah's emerging ideology around the connection between race, culture and science and how she applies them to different contexts, including community partnerships, research, and course design.

Significance

Research has found that co-design is a powerful learning mechanism for teachers and researchers to both make sense of scientific knowledge and also gain more clarity on design and pedagogy (Penuel, 2022). In this work, we conceptualize co-design as a set of practices that include reading relevant research, engaging with and re-designing pre-existing tools, data analysis, and designing new materials for student and faculty learning. While research on co-design within K-12/university/community partnership has shown productive shifts in learning for co-designers, more work needs to be done in postsecondary education to understand how university faculty become attuned to issues of racial justice in their STEM teaching. Given findings in the literature about both the reluctance of STEM educators to acknowledge the importance of race and culture in their teaching (Morales-Doyle, 2021) and the structural racism embedded within postsecondary STEM education (McGee, 2020), this work contributes to our understanding of how to support faculty in shifting the design of their courses and their pedagogy towards more culturally sustaining and anti-racist practices.

Acknowledgments

This work was funded by the National Science Foundation, grant number DUE2111261. We would like to thank our partners, including teacher collaborators and participating students and their families who shared their stories and knowledges with us to make this work possible.

Abstract: Relating evidence to explanations is a critical epistemic practice for productive engagement with evidence in the science classroom and beyond. However, research examining students' reasoning about what makes for stronger and more robust evidence is limited. In this study, we explored students' justifications for their judgements regarding whether evidence supports, contradicts, or is irrelevant to a causal explanation. We worked with 4th-grade students in the context of an after-school virtual science club. Students examined evidence in relation to simple causal explanations using an adapted Model-Evidence Link (MEL) Matrix as a scaffold for coordinating explanations and evidence. Evidence varied in whether it included a mechanism, whether the mechanism was similar to that of the explanation, and whether the entity (organism) involved in the mechanism was similar or not. Analysis of students' choices and justifications revealed a preference for evidence that includes a mechanism, and for similar mechanisms over similar entities.

Introduction

The ability to comprehend and evaluate evidence in terms of its relevance and strength is vital in both science practice, science learning, and for a science literate society (Duncan et al., 2018) and is an explicit aim in science education (NRC, 2012). However, the research examining students' reasoning about what makes for good evidence, is limited. Children can recognize weak explanations (e.g., circular explanations; Mills et al., 2017). However, children may struggle to link evidence with explanations in different contexts (Sandoval et. al., 2014). Typically, reasoning with evidence in the classroom involves evidence that is directly relevant to the explanation, whereas reasoning with evidence outside the classroom is often much messier as evidence is more complex and may not directly support or contradict an explanation (Duncan et al., 2018).

To better understand students' reasoning about evidence relevance and strength, Danovitch and colleagues (2021) examined children's judgments of the helpfulness of different types of evidence in supporting a simple explanation. They presented children with an explanation for an animal's behavior and then provided them with several pieces of evidence that varied along two key dimensions: whether the evidence was about the same organism or a different one (i.e., same organism/different organism), and whether it pertained (and supported) the same causal mechanism postulated in the explanation or was not relevant. Danovitch et al. (2021) found that elementary students recognized when a piece of evidence was clearly relevant to a proposed causal explanation. However, children's ability to recognize that evidence involving the same organism as the explanation is sometimes causally irrelevant was tenuous or inconsistent. Thus, students were better able to recognize relevance in terms of the causal mechanism when it involved the same entity (i.e., same organism).

Danovitch et al. (2021) did not ask students to explain why they found evidence more or less relevant; children were simply asked to rate the evidence's helpfulness. In this study, we further explored students' justifications for their judgements regarding whether evidence supports, contradicts, or is irrelevant to a causal explanation. Specifically, we asked what are students' epistemic considerations when reasoning about the relationship between evidence and a causal explanation?

Grasp of Evidence Framework

We draw on the evidence interpretation dimension of the *Grasp of Evidence* (GoE) framework to inform our analyses of students' justifications of evidence-explanation relationships (Duncan et al., 2018). The GoE framework describes five dimensions of evidentiary practice that addresses the understanding of expert's use of evidence and laypeople's use of evidence. A grasp of scientific evidence involves epistemic knowledge about evidence as well as practical skill in thinking about evidence individually and collaboratively. In this study, we specifically focus on the *evidence interpretation* dimension of the framework, which emphasizes coordination of explanations and evidence. The interpretation dimension of GoE describes the epistemic aims, ideals, and reliable processes involved in relating evidence to one or more explanations. These constructs are drawn from the AIR model of epistemic cognition (Chinn et al., 2014): a) *Aims* are valued goals that individuals and communities set to achieve, b) *Epistemic Ideals* are the criteria used to evaluate the quality of resulting scientific products such as evidence or models; and c) *Reliable epistemic processes* are the diverse methods used to achieve epistemic aims, such as protocols for carrying out observations or conducting experiments. The aim associated with interpretation is to determine explanation validity using evidence. Several ideals are associated with this aim, including having a model that is supported by relevant, strong, and diagnostic evidence. Several reliable epistemic processes can be used to achieve the aim while meeting the ideals, such as systematically coordinating alternative explanations with the available evidence and analyzing which parts of the explanation are supported (or not) by the available evidence. In thinking about the relationship between a simple causal explanation such as the snapping turtle standing on its hind legs to scare away predators and evidence such as predators swimming away from a blowfish that expanded to double its size, one would argue that the evidence supports the explanation because the underlying mechanism, of making oneself bigger to scare predators, is common in the animal kingdom. In contrast, evidence about where snapping turtles live is irrelevant because despite it being about snapping turtles it does not relate to the mechanistic core of the explanation. Obviously, evidence that posits that predators do, in fact, run away from turtles that stand on their hind legs would be even stronger as it supports both the mechanism and its instantiation in the organism.

Using the GoE framework, in this study we examined elementary (4th grade) students' reasons for why particular evidence supports, contradicts, or is irrelevant to a simple causal explanation. To support students' engagement with coordinating evidence and explanation we used the Model-Evidence Link (MEL) scaffold (Rinehart et al., 2016), which juxtaposes (in table form) one or more explanations in relation to multiple pieces of evidence and helps students systematically relate, using specific types of arrows for support/contradict/irrelevant, each evidence to the explanation/s thus supporting a reliable epistemic process. We asked students to justify their choices of arrows and we analyzed the epistemic considerations evident in their justifications.

Methods

Study context

20 fourth graders (9 boys, 11 girls, M_{age}= 9.64 years old) voluntarily joined a virtual science club that met for an hour once a week for four weeks. Note that some students missed some sessions or parts of sessions and hence the sample sizes shown below (for various claims) are at times less than 20. The students worked in groups of 3-4 students with a researcher acting as facilitator. During the first meeting, students were introduced to the activity of deciding whether pieces of evidence support, contradict, or are irrelevant to two competing claims (e.g., are dolphin's mammals or fish?) and providing reasons for their choices. In the second meeting, students were introduced to the phenomenon of the bad smelling corpse flower and provided with explanation I: The corpse flower smells like rotten meat to *attract* pollinators that like eating rotten meat (i.e., flies). Students were then given, one at a time, four pieces of evidence: a) turtle evidence (same mechanism/different organism) involved a similar causal mechanism of attraction but did not involve smell b) skunk evidence (different mechanism/different organism) involved smell but the mechanism was of deterring predators c) rose evidence (i.e., no mechanism/similar organism) did not provide any mechanism d) lily evidence (same mechanism/similar organism) involved smell in a similar mechanism of attracting pollinators. Students were asked to decide if each piece of evidence supported, contradicted, or was irrelevant to explanation I (attracting pollinators) and to justify their choice. In the third week, we provided a different explanation II: The corpse flower smells like rotten meat to *scare away* predators who don't like the unpleasant smell. Students were shown the same four pieces of evidence as the prior week and asked the same questions. Note that, for week three, the nature of the evidence-explanations relationship changed: a) turtle evidence was different organism/different mechanism (attracting instead of deterring), b) skunk evidence was different organism/same mechanism (smell as deterrent), c) rose was similar organism/no mechanism, and, d) lily evidence was similar organism/different mechanism (attract rather than deter).

Data collection and analysis

Videos and chat responses were transcribed and coded first in terms of the relationship noted (Support, Contradict, or Irrelevant) and then in terms of any justification provided by the students. Justifications were coded in terms of whether the reasoning emphasized the similarity/difference in organism, or the similarity/difference in mechanism. We noticed that sometimes students parsed "mechanism" into two distinct elements: referencing the function (e.g., deter or attract) or referencing the means of the mechanism (e.g., smell). We considered justifications based on the means of the mechanism alone (smell) as less compelling than justifications based on function (deter/attract), and justifications that included both function and means as the most compelling (comprehensive). We also considered a justification that focused on any aspect of the mechanism as better than a justification based solely on similarity (or difference) of organism. We refer to similarity and difference of organism as an "entity-based" justification.

Results and discussion

Students' interpretations of evidence: Mechanism and entity considerations

As noted above, the evidence varied in whether it included a mechanism, and we found that students were able to recognize this difference and preferred mechanistic evidence. When the evidence did not include a mechanism, most students (12 of 15) found it to be irrelevant. Six and seven of 15 students claimed the no-mechanism evidence was least helpful overall when evaluating Expl. I or II respectively. When the evidence included any mechanism at all (same or different), students were more likely to see it as supporting or contradictory rather than irrelevant.

The picture is somewhat more complex when we look at whether the mechanism was the same or different than the one proffered in the explanation. When the evidence had a different mechanism (and pertained to a different organism) students tended to see it as contradictory for Expl. I (11 of 17 students) and all explicitly noted the difference in mechanism in their justification. There were five students who claimed that the evidence was irrelevant, and, of these, four argued that the evidence was irrelevant because the organism was different. Interestingly, for Expl. II, the majority of the students (13) claimed the different-mechanism evidence was irrelevant (9 because of the different mechanism and 4 because of the different organism). Only six claimed it was contradictory and all based it on differences in mechanism. Thus, overall students privileged differences in mechanism over entity.

When the mechanism in the evidence was the same as the mechanism in the explanation, most students preferred evidence in which the organism was also similar as supporting the explanation. In fact, the majority of students claimed evidence with the same mechanism, but a different organism was irrelevant rather than supporting (12 compared to 6). It may be that having the same mechanism in a different organism made that evidence more cognitively difficult to connect back to the claim as students would need to ignore the organism information and just focus on the mechanism.

When we compared how students reasoned about evidence that had the same or different mechanism as the target explanation, yet involved different organisms s, the findings were a bit puzzling. For Expl. I, six students saw the evidence featuring the same mechanism and a different organism (Evidence a) as supporting and 12 students claimed that it was irrelevant. For Expl. II, nine students saw this type of evidence as supporting and only five saw it as irrelevant. Why was there such a discrepancy in how students perceived evidence involving the same mechanism? In both cases, students had to "ignore" the information about the different organism, so the different treatment cannot easily be attributed to differences in the organism. However, there is another "hidden" difference between these evidence pieces—the similarity or difference of the function versus the means of the mechanism. That is, for these pieces of evidence the function of the mechanism (deter or attract) was the same but the means were different. If students attend to the means aspect more so than the function then what we considered to be the "same mechanism" in Evidence a was actually not that similar, and that may explain why 12 students saw this evidence as irrelevant. In fact, 4 students who claimed it was irrelevant also explicitly noted smell as a point of difference. If students attend to function more than means, then the mechanism would likely appear the same to them if they could successfully ignore the different organism information, and they would see it supporting (which 6 students did). When the evidence involved the same mechanism in terms of both function and means. this was less confusing and more students saw it as supporting (9) with fewer students being "sidetracked" by the different organism and seeing it as irrelevant (5).

A similar pattern emerged with when we compared evidence that had a different functional aspect of the mechanism with or without a reference to means and alluded to a different organism. Note that the different functional aspect makes the evidence diagnostic- smell can attract or deter but not both (i.e., when the evidence supports an attraction mechanism, it by default contradicts a deterrent mechanism and vice versa). Here we expected evidence with a different means for the mechanism to be seen as contradictory rather than irrelevant. We found that the majority of students found the no-smell evidence to be irrelevant with 6 others claiming it was contradictory. In contrast, 11 students found the evidence with reference to smell contradictory and only 5 found it irrelevant. Again, we see that when both the means and the function of the mechanism are explicitly mentioned, likely increasing the saliency of the difference in function, students may see the evidence as relevant (and contradictory). When the function is different and no means are noted, it may make the saliency of the difference less clear, and students may tend to see it as irrelevant. Given that students did not always explicitly note the presence or absence of means (smell) as part of their justification, we do not have strong evidence to support this assertion in terms of their reasoning.

Conclusion and implications

In this study, we examined students' engagement with the evidence interpretation dimension of the Grasp of Evidence Framework (Duncan et al., 2018). Our findings suggest that students attend to both the context of the evidence-entity involved and the underlying mechanism of the evidence, and that they prefer evidence that includes a causal mechanism. Moreover, students differentiated between the function and the means of the mechanism.

The causal explanations and evidence we provided to students featured very simple causal mechanisms that included entities (turtle, rose), their properties (the turtle's tongue movements, the skunk's glands), and activities (releasing odors, mimicking worms) towards a final outcome of either deterring or attracting other species. Our findings suggest that students attended to entities and activities and that the nature of the activities, such as whether or not they involved smell, mattered.

Lastly, we wish to highlight another interesting finding: students' attention to the diagnosticity of evidence. The GoE framework posits diagnosticity as an epistemic ideal that can be used when interpreting evidence. That is, evidence that supports one explanation while ruling out an alternative ought to be considered stronger evidence (Haack, 2007). Our design made it such that evidence with a different functional mechanism acted as diagnostic. We speculate that students attended to this attribute of the evidence. We suggest that developers of learning environments and teachers should attend to this epistemic ideal in design and that even elementary students may be ready to attend to diagnosticity if given the opportunity to do so when reasoning with evidence.

Abstract: In public education forums people create and contest implicit theories of learning and society. We study a community education council meeting where participants address mask mandates, selective admissions policies, and school violence. We used critical discourse analysis to trace how speakers mobilized emotional configurations about children to guide emotion participation. To influence councilmembers' votes, speakers contested which children should get to learn, under which conditions, and toward what futures. By invoking ideas such as innocence and rationality, meeting participants engaged the racist underpinnings of U.S. society in calling for individualist or collectivist approaches to learning in schools.

Introduction

Public education forums are key sites where the public engages policy and contributes to decision-making, contesting far more than the children and their learning they are ostensibly there to support. For example, organized groups have contested racist and colonialist national history, self-determination, and bodily autonomy by advocating particular policies at the local school board level. Since discourse in and about public education decision-making offers implicit theories of learning and society (Philip & Sengupta, 2021) that index powered contestations, attuning to collective action in such forums is a necessary part of studying politics and learning (Curnow & Jurow, 2021; The Politics of Learning Writing Collective, 2017). In the New York City (NYC) Community Education Council (CEC) meeting we analyze here, participants articulated visions of the future by sharing multivocal positions for the public record and to shape decision-making. As part of sensemaking, *emotional configurations* are constructed *in* and form learning targets *of* the practices of activism (Vea, 2020). With the potential to garner support through "productive cultivation and unethical manipulation" (p. 340), emotional configurations and *guided emotion participation* are powered practices that shape which (and whose) contributions are taken seriously. Toward this end, we ask: *How do participants in a public education meeting create and mobilize emotional configurations about children and childhood? With what consequences?*

Situating powered practices of public education engagement

We analyze the situated activities of participants in a CEC meeting to highlight how participants contested meanings as part of racialized histories (Curnow, 2022). As Curnow describes, "these ongoing historical processes assign power to people in dominant groups via institutions and practices, enacted by people in daily life" (p. 4). We focus on how participants engaged histories of racialized power relations in the emotional configurations they mobilized and whose arguments were taken up or dismissed. As Vea (2020) describes, *emotional configurations* are "situated and reciprocal interrelationships between feeling, conceptual sense-making, and practice (including linguistic practice) that give emotion social meaning" (p. 315). How emotional configurations are oriented, what racialized and powered meanings such configurations draw from, and what futures they move toward, matter. People learn to participate in valued emotional configurations through *guided emotion participation* where "experienced practitioners engage in a provision of opportunities, along with normative pressure, for others to participate in particular ways of feeling" (p. 332). Deliberately or not, the participants' calls to action engage racist histories and practices in US public education. We illuminate three interrelated concepts that participants frequently relied upon (childhood, innocence, and whiteness) in relation to whom they have historically served.

First, *childhood* is a contested construction. Racial ideologies guide *which* children are recognized as being innocent, by whom, and in which moments. Such constructions of childhood have consequences for minors and non-minors, such as distributing the negative impacts of carceral systems like increased surveillance and policing (Meiners, 2016). As Meiners (2016) highlights, however, simply "claiming nonwhite youth as children or juvenile does not allow for critical exploration of the conception of innocence… [nor] unpack the underlying nexus of other associations tied to childhood." (p. 62). Therefore, attending to who is allowed to be a child and thereby granted innocence, victimhood, and/or safety can illuminate the power relations (re)produced in public education forums. Second, the workings of *innocence* in political appeals show how "morally ennobled victimization has become the necessary precondition for determining which grievances we are willing to acknowledge and authorize" (Wang, 2018, p. 278). Determining who is innocent, victimized, or safe implicates some people as not-victims and, therefore, as deserving of harm. Tracing attributions of innocence, victimhood, and purported deservingness of safety reveals the ideological positions underlying the emotional configurations that participants mobilized in their testimonies, because "the invocation of personal security and safety presses on our affective and emotional registers and can thus be manipulated to justify everything from racial profiling to war," (p. 282). Finally, innocence has long been connected to *whiteness* in the U.S., and racialization has historically been predicated on determining who is and is not eligible for the privileges and protections of whiteness. Racialization, however, often happens without explicit articulations of race. Bonilla-Silva (2018) illustrates, for example, how "contemporary racial inequality [is explained] as the outcome of nonracial dynamics" (p. 2) through abstract liberalism, an ideology that draws on ideas of political and economic liberalism (e.g. equal opportunity and individualism). It allows participants to contest whether public education should serve public or private interests without explicitly mentioning race or racism, enabling the (re)production of racial inequality. Considering which children are entitled to innocence makes visible the histories of power indexed by emotional configurations. Specifically, we attend to how conceptions of childhood are dynamically constructed and contested; how ideas about innocence distribute harm in racist, carceral, capitalist, and neoliberal systems; and how racial ideologies sustain and conceal this distribution of harm.

Research methods

NYC schools are divided into 32 community-based districts, each with an elected CEC that shares decision-making with the Department of Education (DOE). Since 2020, CEC meetings have been held virtually, recorded, and posted for public record. We analyzed a recording of a 2022 CEC meeting from one of NYC's largest and most socioeconomically diverse districts. This 5+ hour meeting included public speaker sessions where the public signed up to speak for two minutes each and sessions where councilmembers discussed and voted on resolutions: a non-binding resolution on making facemasks optional (masking was mandatory in schools at the time); a student-proposed school name change; sibling and borough priority for school admissions; and academic screening for school admissions. Many participants also spoke about a middle school which had recently been the subject of high-profile news stories about instances of violence. We take this meeting as a case of participants in public education forums mobilizing emotional configurations toward contested futures. We analyzed turns of talk to "identif[y] the ways that social actors express–through their language and material activity–the relations between feeling, sense making, and practice" (Vea, 2020, p. 238) in relation to powered histories. We began with five speaker turns that elicited strong emotional responses from the research team; for example, one turn began with a measured and calm tone and shifted to something one researcher described as leaving her heart pounding. Noticing asymmetries in how these turns framed issues led us to select additional sets of turns that spoke to the same "issue" within the meeting to highlight implied symmetries in their framing while illuminating the actual asymmetries of consequences (Philip et al., 2018). Informed by critical discourse analysis (Blommaert, 2005), which attends to how language constructs power, dominance, and control, we engaged in cycles of group viewing sessions, individual analysis and memo-writing about specific turns and about connections and contrasts across turns, and group discussion of hotspots and themes. In total, we closely analyzed 14 turns from parents, council members, and other community members. In what follows, we use pseudonyms for all speakers and schools.

Findings

Meeting participants mobilized emotional configurations about children that engaged powered relations in education in four ways. First, participants constructed *safety as a condition for children's learning*, using fear and a desire to protect children from fear to persuade the council. Some participants focused on children's safety from physical violence, while others emphasized safety from emotional discomfort. Safety is treated as an important condition for learning and yet mobilized to argue for practices that erode public safety, particularly for children and communities of color. This reproduces long standing associations between "public safety" and white safety, and it reinforces neoliberal notions of responsibility in civic institutions such as schools. Second, some participants *imagined troubling futures for imaginary children* if their preferred policies were not enacted. Three speakers described how hypothetical children would suffer from eliminating academic screening, from failing to implement carceral policies, or from making facemasks optional. Although these speakers worked towards different ends, each of them (and others) engaged in rhetorics of care that promote whiteness to guide emotion participation. Third, participants recruited unspecified "data" to lend *an air of rationality* to false equivalences and righteous arguments. The participants guided emotion participation by implying parity between the consequences of illness and consequences of preventing illness, and by appealing to "data" to argue that, for children, the latter were more dangerous than the former. Finally, participants contested who falls within the *dynamic bounds of childhood*, and therefore innocence, as a precondition to granting victims time, attention, and policies in their favor. Next, we elaborate on a constellation of turns in which speakers did the latter while engaging schooling practices with racist histories and consequences, forming competing conditions for learning.

Contesting (the significance of) who counts as a child

Mobilizing protection for white childhood

Isabella, who had recently participated in a news segment about violence at M.S. 100, positioned herself and her spouse, Esteban, as parents of an innocent child victim of violence. She mobilized fear by framing M.S. 100 as especially violent and "not normal," dynamically bounding the protections of childhood. In describing their son's experiences, Isabella omitted his actions, portraying him as a passive recipient of unprovoked violence. She reported they transferred schools to protect him from peers who "have stolen [his] innocence with all the words he's learned at that school, in the playground, in the bathrooms, in the hallways, in the stairways." She animated this "profane" language with a racialized shift in voice as she named a Snapchat group called "yo we on drugs." Isabella positioned these students as like-adults who "weigh the same as [she does]," and their actions as threatening "safety issues." By contrast, she indexed her son's adult-like actions (e.g. traveling to school alone) as examples of "independence." The pair shared their histories of migration to NYC from Bolivia and Spain, claiming that their "multicultural" background along with "liv[ing] in Hell's Kitchen" made them "not racist" and thus accusations "taking out the race card" were unwarranted, ultimately positioning themselves as victims. "We're taxpayers here…" she says; "If the DOE is not going to defend our children… and you're not going to keep a safe environment, and you're not going to put NYPD [Police] in there… then allow the money to follow the kids…" Isabella appealed to *their* innocence from racist practices while making a racialized appeal to white victimhood for their son. She spoke of "defend[ing] the children," but the context of her argument and demands for increased policing and voucher systems (which are known to harm communities of color, especially Black communities) makes clear that this does not mean all M.S. 100 students. Those whom she constructed as violent are not offered the defense that childhood offers some children–overwhelmingly those racialized as white. Through appealing to relational feelings bolstered by institutional practices of whiteness and white victimhood, Isabella and Esteban sought to guide participants' emotional participation in their favor.

Refusing innocence

Naomi, the M.S. 100 PTA co-president, spoke before Isabella in the meeting but responded indirectly to Isabella's participation in a recent public news story and took a distinct approach, refusing innocence. As co-president, Naomi saw participating in educational decision-making as a practice that encompasses "the good, the bad, the beautiful, and it's hard," in contrast to Isabella's participation only in this particular situation. Her position as a woman of color is relevant, too, in her efforts to name and shift racist practices. Naomi drew on the more full set of activities and debates within educational decision-making and activism to claim that the actions of those who painted M.S. 100 as especially violent and unsafe "reek[ed] of fear and racism." In contrast to guiding emotional participation toward reproducing racist stratifying practices, Naomi declared that "children make mistakes," framing the claimed incidents of violence as within an expected realm of mistakes that schools are meant to support a community in working through. From the position that the school is a "true microcosm of New York City" that "represent[s] every child in [this] district" and all "640 students at M.S. 100," she was proud of students, parents, teachers, and the principal "doing the hard work, the equitable work, the fair work, the work that everyone in [this] district and New York City asked [them] to do." She invited participants to "please lean in and ask us how you can help us doing this work." By positioning members of the community as doing their jobs to support each other, Naomi offered an emotional configuration that moves away from litigating innocence, deservingness, or victimhood to instead consider what the school community might need. Attending to how Isabella's, Naomi's, and others appeals were taken seriously, or not, makes apparent which emotional configurations were valued. For example, later in the meeting Naomi responded to a councilmember who referenced her prior turn, contrasting his claims of racism in calling for screening policies with her not having her "truth [in naming racism] honored."

Who is a victim? (Il)legibility of (mother's) suffering

The enforcement of two-minute turns was inconsistent. Many speakers, including Isabella, spoke for over two minutes, which became contentious. Mia presented a poem about how students' suffering due to the intertwined pandemics of COVID and structural racism should be met with compassion, not merit-based screening. After two minutes, Council President David Rumford repeatedly interjected to end Mia's turn. Councilmember Carmen Ramirez pointed out that "we let someone go over two minutes [previously]," and Councilmember Brooke Donegan countered that "that was the mother of a victim." She differentiated between Isabella, whose racialized constructions of innocence were heard as coming from "a mother of a victim," and Mia, whose speaking about structural racism (and about her child with long COVID) was not granted similar status. Councilmember Ramirez pushed back that Mia "is also suffering," but the council did not recognize her plea. Contemporary discourse on mothers of/as victims allows white mothers to parlay their grief into advocacy; Black mothers, however, face the burden of humanizing their children and litigating their innocence (Carew, 2018). So whose children are victims? Which mothers get to move others with their stories, and in what ways? How does this work in relation to children subject to peer-imposed violence, whose 'innocence' has been stolen and who are victims, while children subject to institutional violence are not? Our analysis shows how relying on appeals to innocence and victimhood to guide emotion participation continues enduring racist relations.

Discussion

Throughout the meeting, participants invoked powered relations in configuring and guiding emotion. Speakers contested which children should get to learn and under which conditions to influence votes and differentially allocate particular futures. Participants' invocations of ideas like innocence and rationality engaged the racist underpinnings of US society while calling for individualist or collectivist approaches to learning. Furthermore, by inconsistently wielding the two-minute turn limits, councilmembers legitimized particular claims about who was seen as victims, innocent, deserving of safety, and whose suffering mattered, and thus, who was not: or, which relationships between feeling, meaning and practice the council valued. Feeling is a powerful part of making appeals. As Vea (2020) cautions, given "the dual capacity of bodies both 'to affect' and 'to be affected,' guided emotion participation entails a form of participation that is not under fully autonomous control" (p. 340). Authoritarian groups increasingly use public education forums to advocate for racist practices, often through rhetorics of protecting children's innocence (e.g., the weaponized white motherhood of Moms for Liberty). Attending to which children are and are not included in constructions of childhood within public education forums illustrates how emotional configurations (re)produce powered relations. Participating in collective action *against* oppressive forces within public education forums, then, might require cultivating different sorts of emotional configurations than those that rely on the terms of childhood, innocence, and whiteness. What might we learn, for example, from Naomi's expansive construction of community or Councilmember Ramirez's explicit naming of suffering, and how might we mobilize emotional configurations toward different ends?

Exploring Youth Critical Collective Futuring as Learning

Melissa Perez, University of Michigan, perezme@umich.edu

Abstract: Youth critical collective futuring (YCCF) is a constellation of practices and ways of being that come together to shape and refigure the future through actions in the present. Using current literature on relational learning and STEAM making, we present an analytic vignette from a critical ethnography in a middle-grade out-of-school online STEAM makerspace. We argue for exploring YCCF as a form of learning that is relationally constructed across space and time.

So like, [adults] tend to underestimate people depending on their age, skin color, [...] or just anything, but honestly we are all people. Just because you are a child doesn't mean you don't know things, so if people choose not to listen, that's kind of annoying. Like, how they just think 'oh you're a child so you don't know anything, adults know more, adults know more than you do,' so like it's kind of annoying how that's how some people think. But honestly, anybody can know anything; it just depends on what research you do, or like, what you are trying to learn about. - Lily, age 12, Black maker of cat hats

Introduction

In this opening quote, Lily (pseudonym), a member of the Green Club (GC) pushes back on deficit orientations of how she is positioned as a young Black girl who is concerned about the unfolding global climate disaster and COVID-19 pandemic. She states explicitly that "anybody can know anything; it just depends on what research you do," referring to how she feels left out of discourse at multiple levels due to her age and not her capacity for knowledge building. Her statement not only describes the present state, but her ability (and the ability of others) to learn and become in the future. If "anybody can know anything" by conducting research depending on "what [they] are trying to learn," she refers not only to herself as a youth, but herself as a teenager, an adult, and others as long as they are "trying to learn."

We take seriously the concerns raised by Lily and her peers in the GC, and seek to understand the ways in which they attempt to recreate their positions to each other and the world via their work together. Therefore, the basis of this paper aims to answer the following questions: 1) What are the constellations of practices that Black youth engage in as participants in a STEAM-makerspace? 2) How do Black youth embody these practices, and what do these practices say about what they think STEAM can be? 3) What do these practices tell us about what they think the future can and should be? We address these questions with attention also to the conditions that surround Black youth as they work to be and become learners/makers/doers in STEAM, such as anti-Blackness (Jones & melo, 2021) and underrepresentation in STEAM. Taken together, we begin to conceptualize Youth Critical Collective Futuring (YCCF) as a response to these questions, and set the groundwork for future exploration of YCCF as learning.

Background & conceptual framework

Making spaces are often sites for youth futuring practice to occur. Not just in the sense of innovation and production, how the "maker movement" is often positioned (Vossoughi, Hooper, & Escudé, 2016), but in how people come together to organize practice around "making" (Calabrese Barton & Tan, 2018). In this way, relationships are at the core of what drives the making, despite the mainstream emphasis on the tools. Focusing on relationships in making departs from normative views of what it is and who can participate in it (Vakil, & McKinney de Royston, 2019). Through a focus on relationships, we can pay attention to how a learning environment can be (re)organized. Foregrounding youths' moves to "be with" (Villenas, 2019) each other in the online format, we build on work that views STEAM learning as relationships, practices, and discourses that ultimately position them as knowledgeable and creative STEAM makers. Understanding youth's work as a way for them to live out their politics adds dimension to how we understand the relationship between youths' politics and their actions (Curnow & Utttamchandani, 2022; Uttamchandani, 2021). Taken together, we can see how youths' relations push forward their collective work, and in what ways that can impact what their work becomes (Uttamchandani, 2020). Using this framework for making, we discuss how YCCF fits in as part of the relational emphasis on what learning can look like in a making space.

To begin to unpack what we mean by YCCF, we address each term individually. By *futuring*, we refer to the practice of envisioning and enacting the future, and argue that youth often take up futuring practices that are not recognized and therefore not seen as important and actively positioned as deviant. Through *critical futuring*, youth not only take up these dominant practices and invent their own, but they do so in ways that also express political clarity (Vakil, 2018). *Collective futuring* takes into account the multiple different perspectives, backgrounds, and abilities of those who participate in it. *Critical collective futuring* refers to how people come together to not only envision a future, but to bring it into practice through the ways that they interact with each other. This sort of practice is rooted in Black feminist praxis (Combahee River Collective, 1986), in that they recognize that the future is something that is brought about through living it into existence, not waiting for something to happen. Finally, the "youth" in *youth* critical collective futuring is a recognition of the particular ways that youth take up critical collective futuring. Through critical collective futuring, youth come together to be and bring about the changes that need to happen for their survival.

Context, methods, & analysis

The Green Club is an after school STEAM program for middle school-aged students. It is part of a larger after school space located in a predominantly Black neighborhood in the U.S. Midwest. In the 2020-21 school year, this program was online. The work youth did over the weeks and on the different days of the club was varied, yet the through lines included making and sharing, and discussion of their interests as they relate to what we do together. This meant that, although each day of the week had a different purpose, these boundaries were fluid and changed based on the needs of the youth, both anticipated and in the moment. During the 2020-21 year, there were 10 youth total.

The data that we generated during this year consisted of recordings of sessions, field notes taken after each session, artifact interviews with the youth at half way through the year and the end of the year, informal reflective conversations with the youth, debriefs amongst the research team, and meeting notes – documents from co-planning sessions with youth during the year that helped not only shape the club, but helped inform the moments that we looked into for the analysis. The primary data used in the analysis and the basis for analytic memos were the field notes generated by the research assistants.

Starting from field notes, we identified multiple "openings" (Halle-Erby, 2022) that were of interest and worked from those moments to 1) find the contexts that built up to those moments, including the types of actions/activities that allowed for it, 2) identify similar moments and record them to create a "strand" of insights, and 3) what happened because of those moments. We wrote analytic memos to record each moment, and as a team discussed insights from the memos in order to present the initial analysis. In the findings we present the work of Lily, who we argue enacted YCCF through her making practices. We present this as an extended vignette, which focuses on her project work over time.

Findings: Lily's project

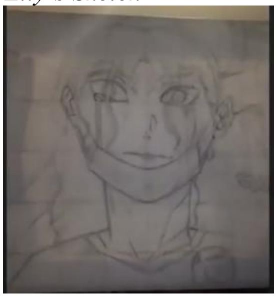
Lily, at the time of this online year, was a sixth grader at a school which had gone completely remote. She is Black, and a fan of many different anime. Her passions were and are drawing, reading, and making animations. The work that Lily takes up in telling her "2020 story" had implications for what it means to be and become in STEAM. Through her work, we can see how the context of a STEAM makerspace, and the expectations of the people in it, affects how she is able to express herself and her ideas.

One fall day in our after school program, our goal was to think about what kind of projects we wanted to do. The larger theme, "2020 stories," was already set, but most of the youth did not yet know what it meant to tell their 2020 stories as they lived through them. It took time for her work to take shape, and we highlight a pivotal moment for her as she developed her project.

A few months into the project, Lily was ready to share an update about her work with the group. She held up the sketch of her painting, which ended up slightly cut off by the Zoom framing. She covered her face so she could point, though she had to move it constantly so she could see what part of the picture she was describing (Figure 1). Front and center on the image was the face of a young girl, while the background and her clothes all held distinct meaning. She highlighted the most important parts: the tree in the back for the Australian and California wildfires, the "I voted" sticker the character wore, "mask because covid," "crying because why not, it's good to cry sometimes," and a "scrunchy because why not." Lily received praise from her peers and the adult mentors verbally and in the chat.

Maria, one of the adult mentors, asked Lily if she was going to make her painting "colorful," to which Lily responded that she would. Maria then asked if she was going to add any lights, by which she meant LED's or similar STEM artifacts, which she was given in a kit at the beginning of the year. At this point, Lily's face lit up, and she responded emphatically with a yes. She then described her idea to paint blue and red lights reflecting off the character's face, representing the police violence against Black people that has become more publicized. In this idea, she took the question as an invitation to think about something she wanted to say about her life, not as a suggestion to add a commonly recognized STEM artifact to her art. While she turned the question on its head, this moment represented a possibly overlooked phenomenon that occurs in STEAM: that ideating on a creative project in the vicinity of STEM tools and resources, youth can come up with powerful representations to express themselves that may not have been open to them before. If Maria had not asked about LED lights (STEM) and Lily interpreted it, that dimension of her work might never have surfaced.

Figure 1
Lily's Sketch



Lily developed her ideas in conversation with others, and in sharing her project ideas she informed others' work. Viewing YCCF as learning leads us to ask us why her process should be overlooked, and challenges us to picture what the youth are envisioning when they take part in futuring. Lily is envisioning a world in which her learning is not defined by the product, but the process. A world where having fun with her friends is as much a part of being in a makerspace as learning the tools involved with it. A world where being in conversation with multiple disciplines counts as engaging with it, rather than just the outcomes of that engagement. The form of making she engages in is an example of how youth challenge and expand the boundaries of STEAM learning, and in doing so create a future where those boundaries become suggestions rather than limits.

Discussion & conclusion

The context of the 2020-2021 school year was unpredictable: youth in this program were navigating the new stresses of online school, not seeing their friends and family as much, and the effects of knowing people who had been lost to COVID-19. Moving school and extracurriculars to a virtual format would have been difficult without a public health pandemic going on in the background, or the resurgence of public attention to racial justice movements arisen from the murder of George Floyd.

These conditions surfaced how youth future in the learning space, and how in doing so they made room to talk about their substantive concerns about the world we live in. YCCF allows for a shift in how we approach education so that it is less tied to neoliberal logics of production, innovation, and competition in favor of developing relationships, exploring new processes, and collaboration. YCCF is an attempt at a "sustainable praxis" (Salo & Heikkinen, 2018), which focuses on experience and developing practices around learning, rather than relying on testing or other assessments to see if learning has been "achieved." The focus on outcomes is de-emphasized in favor of more relational forms of learning and being together (Patel, 2014). In doing this, the logic of a set curriculum that follows a strict, linear time scheme is disrupted.

We see youth futuring in Lily's example in how she sees the future, and how she brings it about now. We can see her in the work of critical collective futuring: she is both reimagining what it means to do a STEAM project about her experiences, and offering what she knows as something that her peers can draw on as well. Further, Lily's work across her project example embodies how she wants her maker practice to look like, and asks us to value her work for what it is rather than what it could have been. Seeing YCCF as a form of learning is to see possibility in all youths' ways of being and doing, not just the ones that are currently valued. It requires meeting youth where they are and working from there, rather than the other way around.

In this paper, we describe how youth take up critical collective futuring in an informal, remote, makerspace, but this has implications even as the pandemic context shifts over time and space. Lily and the rest of the youth in GC continually show us, as adults, researchers, and fellow STEAM-makers, how critical collective futuring is not just a means to continue what we were doing "pre-pandemic." It is an opportunity to figure out what matters most to the people in a learning environment, and take that chance to value relationships and create something new. Through YCCF, we see that the importance of content knowledge expertise in STEM is always there, but with changed emphasis. Youth have expertise in how they want to engage with each other and know how to elicit thought provoking activities/discussions from the group. In this way, they take moments to engage in CCF, and show us how we can learn and become within STEAM without "sacrificing" STEM learning or treating arts as merely a vessel for STEM learning.

Ultimately, YCCF in a STEAM context offers a lens through which we can understand youths' projects, relationships, and interactions that does not center the end products of their work. Youth demonstrate how, when we take the time to recognize the multimodal youth work and conversations that take place in an online environment, new and innovative projects can take shape. It is exciting to see how this can be done, though it is important to take into account the virtual world is not without its challenges and power dynamics. It is important to consider these, given that the potential implications of this work could extend on and offline.

Understanding How Resettled Refugee Youth Bridge Funds of Knowledge With Science Learning

Qiuyan Wu, Minjung Ryu
qwu41@uic.edu, mjryu@uic.edu
University of Illinois Chicago

Abstract: Refugees' knowledge and experiences are often rendered invisible. Building on an asset-based view, our study investigates the practices of resettled refugee youth bridging funds of knowledge with science learning in an afterschool STEM program. We present findings of how the youth bridged funds of knowledge with science learning about weather, climate, and climate change and how bridging practices mediated their engagement with the science topics.

Introduction

Learning is not limited to school but is expanded across multiple contexts of people's everyday lives (National Research Council, 2015). School learners naturally connect their knowledge and skills developed from diverse contexts outside school to those learned in school. However, students' everyday knowledge and experiences are often either viewed as non-scientific and therefore are not at all utilized or are only superficially referred to (Gutiérrez et al., 1999). These issues are even more salient for learners who come from non-dominant backgrounds. Only dominant (European, White, middle-class) ways of knowing are centered in classrooms, while others are ignored and rendered marginal (Calabrese Barton & Tan, 2020). An alternative view has been suggested to consider diverse ways of knowing as assets (Gutiérrez et al., 1999). Building on this view, we examine learners' participation, engagement, and STEM learning in contexts where non-dominant experiences and knowledge are leveraged. In this study, we focus on science learning of refugee youth who resettled in the United States. Narratives about resettled refugees overwhelmingly focus on their interrupted schooling experiences, trauma, and limited proficiency in the languages of their resettled country (Ryu & Tuvilla, 2018). While providing support for these challenges is an important task of our education system, our work intends to leverage refugee background learners' unique knowledge and experiences from their transnational experiences.

Theoretical framework

We aim to understand what cultural assets the resettled refugee youth brought to science learning space and how doing so mediated their science learning. *Funds of knowledge* and *bridging practices* guided our investigation.

Funds of knowledge

Moll et al. (1992) define *funds of knowledge* as "historically accumulated and culturally developed bodies of knowledge and skills essential for household or individual functioning and well-being" (p.133). Originally funds of knowledge refer to knowledge from households, including family members' employment, occupation, or household activities (Moll et al., 1992). More recent research has extended funds of knowledge to include knowledge and skills developed in communities, from media, and with peers (Calabrese Barton & Tan, 2009; Moje et al., 2004). As this study specifically focuses on Chin (an ethnic group in Burma) refugee youth's participation in science learning, we pay extra attention to their funds of knowledge linked to their lived experiences in the countries they had lived.

Bridging practices

We are interested in understanding not only what funds of knowledge the refugee youth brought into science learning, but also how they connected the funds of knowledge with science learning. We use *bridging practices* as a metaphor to emphasize that connecting funds of knowledge with science learning is more than bringing the two in contact but also making them integrated. Like building a bridge, making two pieces of construction in contact is not complete; they must be riveted together to become a whole bridge. Using *bridging practices,* we emphasize our focus on understanding how the youth integrated funds of knowledge with science learning in the current, situated learning context. We analyzed to what degrees, in what ways, and for what outcomes, the youth participants bridged funds of knowledge and science learning. We also examined how bridging practices mediated the youths' engagement with science topics. We paid close attention to the youths' sensemaking of the topics and their affects shown in the learning processes. Previous studies found that students drew on everyday knowledge and experiences to make sense of science concepts and populated science understanding onto familiar everyday phenomena (Rosebery et al., 2010). When these processes happened, new understandings were generated (Moje et al., 2004). Other than helping with conceptual understanding, drawing on everyday knowledge and experiences also resulted in emotionally engaged participation (Rosebery et al., 2010). For example, nondominant participants positioned themselves as experts when they could connect everyday knowledge to academic learning (Calabrese Barton & Tan, 2009).

Study context

This study analyzed data from Project RESET. The project was part of a community-based afterschool program offered for resettled Burmese refugee youths in a Midwest city (1) in the United States. Project facilitators collected a rich set of data, including video recordings of weekly sessions, audio recordings of small group discussions, student artifacts, and interviews. The project has yielded publications focusing on the youths' self-narratives (Ryu & Tuvilla, 2018), design principles for engaging the youths in critical STEM literacy practices (Ryu et al., 2019), and how the youths negotiated their identity work (Ryu & Daniel, 2020). In the current study, we revisited part of the data (session video, audio recordings, and learner-generated artifacts) to answer two research questions: 1) What funds of knowledge did the resettled refugee youth bridge with science learning? 2) How did bridging funds of knowledge and science learning mediate the youth's engagement with science topics?

Curriculum

Project RESET consisted of 24 weekly sessions (90 minutes each) during the school year of 2016-2017. 10-20 youths participated in each session. The project addressed weather, climate, and climate change. The topics were chosen because of their high relevance to the youths' lived experiences. In the first 18 sessions, the participants learned about the topics through videos, pictures, personal stories, and maps. Learning activities included lab work, drawing, presentation, small group discussions, online research, and creating stories. Facilitators encouraged the participants to apply multimodal and multilingual literacy practices when making sense of the topics. In the last 6 sessions, the participants created videos in small groups to share their learning.

The youths left Chin State, Burma, at the ages of 5- to 11-year-old. They moved to a first asylum country, most of them to Malaysia and others to Thailand, Singapore, or India. They then resettled in the United States. At the time of participation, the youths were sophomores or juniors at local high schools and had lived in the United States for varying periods from 3 years to 9 years. Most of the youths spoke English, Burmese (the official language of Myanmar), and Hakha-Chin (a lingua franca in most parts of the Chin State), with different degrees of proficiency. A few students speak other Chin languages (e.g., Hakha, Falam, Zophei).

Data analysis

We analyzed data from the first 18 sessions because no adequate data were collected in the last 6 sessions. Our data analysis methods were inspired by the grounded theory approach (Strauss & Corbin, 1990). We primarily analyzed the video recordings and referred to the audio recordings and student artifacts to zoom in on interactions and discourses. In initial open coding, we identified episodes where the youth brought in their lived experiences of weather, climate, and climate change in the places where they had lived. Through the comparison of these episodes, we identified nuanced categories of family and community funds of knowledge. We then moved to axial coding, watching the episodes repeatedly to surface the themes of how the youth bridged funds of knowledge with science learning and how bridging practices mediated their engagement with the science topics. Throughout the process, we discussed the codes and reached agreements on interpretations.

Findings

The resettled refugee youth brought into science learning family and community funds of knowledge. Family funds of knowledge are linked to their life in Myanmar and their family's migration history. Community funds of knowledge include their childhood experiences and Chin farming and cultural practices. The youth demonstrated bridging practices in the following ways. They drew on funds of knowledge to concretize scientific concepts. They also applied newly developed scientific understanding to reinterpret funds of knowledge and began to see what was familiar in new ways. While these findings align with those of existing studies (Moje et al., 2004; Rosebery et al., 2010), our findings revealed more nuanced ways of how the resettled refugee youth bridged family and community funds of knowledge with science learning and how bridging practices mediated their engagement with the science topics. We explained our findings in the following three episodes.

Episode 1: Surprising climate differences between countries

When learning about climate, each group received a set of pictures of flora, fauna, natural landscape, and architecture. The youths were asked to identify the country in which their set of pictures was taken. The facilitators marked six countries on the world map as options. After providing some time to discuss in small groups, Facilitator 1 revealed the correct answers and gave them climate data (temperature, precipitation, and wind speed) graphs of each country. The two groups who had pictures of Sri Lanka and Spain were surprised to find out that the patterns of monthly mean wind speed were distinctly different between the two countries. In Sri Lanka, the monthly mean wind speeds stayed pretty much constant throughout the year, whereas in Spain they were higher in January and May through September than in the other months. Pointing at the world map, Joe talked out loud that both Spain and Sri Lanka are surrounded by oceans. The other group members echoed, "Yeah! They are!" Talia said, "Didn't we discuss earlier that places near oceans usually have similar climates and are usually windy?" She continued, "Remember when we were sharing our experiences of weather in Yangon, Kuala Lumper, and Singapore? These places have very similar climates – windy, rainy, and hot." The participants were expecting that Sri Lanka and Spain, both close to oceans, should have similar climates, based on their experience of similar climates in the multiple coastal cities and countries they had lived in. The data graphs of Sri Lanka and Spain contradicted their expectations. The disparity led them to discuss other factors that could shape a place's climate.

In another group, the youths started to examine Australia's climate data graphs. To their surprise, they noticed that the coldest months they experience in the U.S. are Australia's warmest months, and vice versa. The group members started to talk to the group that had the U.S. weather data. A youth described, "They are inverted from each other." Other youths commented, "Interesting," "Weird," and "Why?!" They suggested that maybe this pattern is due to time zone differences. They moved from Southeast Asia to the U.S. and experienced both time and climate differences. They searched online and learned that Australia and the U.S. have time differences as well. Hence, they reasoned that the time zone differences might be the reason why the two countries have climate differences. Facilitator 1 shared that though her home country and the U.S. are in different time zones, they have overlapping months of the four seasons. The facilitator suggested the youths locate the U.S. and Australia on a globe. They identified on the globe that the two countries are on the northern and southern sides of the equator. Facilitator 1 explained to them why the U.S. and Australia have opposite seasons.

As this episode demonstrated, the youths tried to make sense of an unfamiliar country's climate based on their experiences of climates in regions they had lived in. When their predictions turned out to be far from reality, they were surprised, confused, and intrigued to find out why. The contradictions made them aware that climates are influenced by more factors than they had thought.

Episode 2: Commander Leo's adventure story

After learning about climates in several different countries, the participants created their climate stories tied to their experiences of climate in one or more regions. Leo built his storyline along several places he and his family went through when they were migrating from their hometown to the United States. He produced a mini storybook telling an adventure story of a troop marching from Myanmar to the United States. He made himself the commander of the army. After leaving Chin State, the army first arrived at Mandalay and then marched all the way south until they reached a coastal city near Rangoon in June. There they seized all the supplies they needed. Because the army's target was to capture Rangoon, it kept marching despite the non-stop rain and resulting muddy roads. When the army finally reached Rangoon in August, the weather turned sunny - as Leo described, "The sun was all over." Then it took the army less than one month to capture Rangoon. Leo exclaimed, "Think about that! In less than one month! How spectacular it was!" Putting a range of stickers representing a castle and people in his storybook, Leo explained, "Here is the Commander's castle. Everyone is happy because they just captured the capital Rangoon." However, the army did not stay in Rangoon for very long but continued their adventure toward the United States. After a long journey, the army eventually reached America in December. "It was very cold and snowy there as you can see the snowmen and cookie houses," said Leo while he was adding different stickers.

Leo turned his family's migration route from Myanmar to the United States into the journey of his army's adventure. He kneaded into the climate story his experiences and knowledge of climates in different cities of Myanmar and in the United States. Bringing in his lived experiences of family migration and of weather and climates in multiple cities along the migration journey, Leo was engaged in personally meaningful and emotionally rich climate storytelling. He provided rich details of what the weather was like in those places at those times of the year. With the knowledge, he made strategic planning and decisions for his army as they moved along from place to place. Creating and sharing the climate story made it explicit to himself and other participants how weather and climate are different in different places at different times of the year.

Episode 3: Myanmar farmers' farming practices

In the reading materials on extreme weather events including drought, the word "desertification" was mentioned.

Facilitator 1 approached one of the groups and asked the youths to explain "desertification". Simon jumped in, "It means that the land turns into a desert." The facilitator further asked why that could happen.

Pointing at the words "poor farming methods" in the text, Leo explained, "If you grow corn every single year, then you know for sure that your ground is going to be messed up. The Great Plains used to be rich in minerals. But since farmers know nothing about farming methods, they just grow the same crops every single year. That is how it turned into a desert." Leo continued, "You must change crops every season. Potatoes, for example, are good for the soil." Later in another group, Rosa, who had overheard Leo' talk, explained how poor farming methods could result in desertification. Tom in the same group exclaimed, "That [crop rotation] is what farmers in Myanmar do! When it rains a lot, farmers plant rice. In summer when it does not have a lot of rain, they grow peas."

When making sense of desertification and drought, Leo brought in his understanding of how different farming practices impact lands. Tom shared his knowledge of Myanmar farmers' farming practices. Leo and Tom made the science concept concrete by relating it to their knowledge and experiences of farming practices. They were emotionally charged when explaining the knowledge to others. A sense of pride was evident in Tom's emphasizing tone when claiming Myanmar farmers' farming practices as an example of "good farming practices". He enthusiastically described how farmers change crops based on weather and climates in different seasons.

Conclusion

In this study, we identified that the resettled refugee youth bridged family and community funds of knowledge with science learning. Bridging practices helped the youth both make sense of the science topics and develop new interpretations of the funds of knowledge. What is more, bridging practices mediated the youth's engagement with the science topics in emotionally charged ways. The youth positioned themselves as experts who were contributing relevant knowledge and experiences to the science learning community. They merged family stories and community practices into learning tasks and discourses, with a sense of pride. When bridging funds of knowledge with science learning caused wrong predictions and surprises, they were intrigued and motivated to learn more about the concepts. These findings call for engaging refugee youth's life stories, experiences, and wisdom as productive resources for teaching and learning.

Abstract: Though the medium of computational modeling presents unique opportunities and challenges for science learning, little research examines how teachers can effectively support students in this work. To address this gap, we investigate how an experienced 6th grade teacher guides her students through programming computational, agent-based models of diffusion. Using interaction analysis of whole-class videos, we define a construct we call *ontological alignment* in which the teacher facilitates discourse to surface, highlight, connect and seek supporting or contradictory evidence for student ideas in ways that align with the level of analysis available in the modeling tool. We identify two practices reflecting this construct; the teacher 1. primes students to orient to interactions between particles and 2. strategically selects evidence to help discern between student theories. We discuss the pedagogical value of ontological alignment and suggest the identified practices as exemplary for supporting students' learning through computational modeling.

Introduction and background

Modeling is a central practice in scientific work and involves explaining a phenomenon by representing its key elements and their underlying behaviors, relationships, and interactions. Computational modeling, and specifically, domain-specific agent-based modeling (ABM), has emerged as an important practice that can simultaneously support students in science and computing (e.g., Kahn, 2007; Wilkerson-Jerde et al., 2015).

Teachers play a critical role in facilitating student engagement with modeling (Ke & Schwarz, 2021). However, uncertainties and challenges persist around teachers' roles in supporting students' computational modeling work. As with any modeling work, teachers must navigate between modeling as a practice for content learning vs. a practice for generating, exploring, and validating or refuting yet unknown scientific knowledge (Guy-Gaytán et al., 2019). As a relatively new representational medium and practice, computational modeling offers unique opportunities and challenges that merit more focused research. Many aspects of programming computational models can be challenging for students, as it requires them to identify relevant content, manage programming structure and syntax, and map content onto the ontological structure of code (Basu et al., 2016). Teachers need to respond to these challenges with tailored support. Incorporating any new epistemic tool or practice into a classroom can be a complex task; teachers and students require time and space to negotiate between their goals and the tool's functionality (Wilkerson et al., 2022) before settling on productive engagement practices. However, despite the central role of teachers in guiding modeling activities, most existing research focuses on the efficacy of diverse teaching approaches using *pre-built models* (Hmelo-Silver et al., 2015) rather than on how teachers can support students in *computational model building* for learning.

In this paper, we investigate how an experienced 6th grade science teacher guides her students through a computational, agent-based model-building unit about diffusion. Specifically, we pursue the following research question: *How does an experienced science teacher support students in expressing and representing their ideas through a computational modeling unit?*

Based on our analysis, we identify a construct called *ontological alignment* that we define as a lens the teacher adopts in facilitating discourse to elevate student ideas that align with the level of analysis available in the tool (in this paper, particle-level behaviors and interactions). We see ontological alignment as important to supporting discourse when using new epistemic tools and practices in science classrooms.

Methods

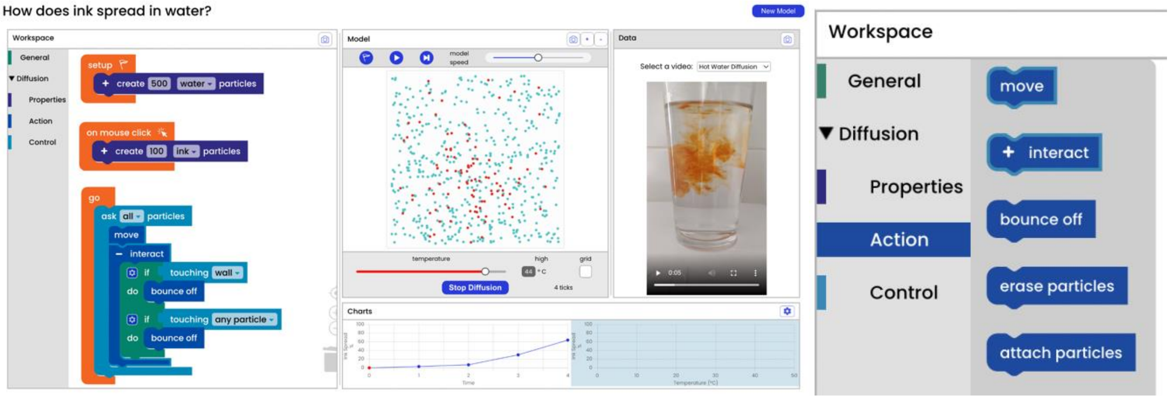
Materials

The computational modeling unit studied in this paper was enacted in MoDa, an agent-based, domain-specific, block-based environment that puts a computational model side-by-side with real-world data of the target phenomenon (Fuhrmann et al., 2022; Wagh et al., 2022). MoDa includes a coding workspace, a space to run simulations, and a real-world data area with video of the phenomenon (Figure 1, left). The code library for this unit includes blocks to define particle-level interactions such as “bounce off” and “attach” (Figure 1, right).

Over 5 days (1 hour/day), students investigated how ink diffuses in water. They ran an experiment comparing the diffusion rates in hot and cold water (Day 1), drew models to explain observed differences (Day 2), and presented their ideas to the class (Day 3). They used MoDa to program models representing their theories about diffusion (Days 3 & 4) and compared their computer models with video data (Day 5).

Figure 1

MoDa with coding, modeling, and data areas (left) and diffusion-specific code blocks (right).



Data collection & analysis

Ms K is a 6th grade teacher at a public school in the Bay Area, CA. She was selected for this analysis based on her 8+ years of experience teaching computational modeling curricula in which students explored pre-built models. This was her second year teaching a computational modeling unit using MoDa in which students programmed their own models. Of Ms K’s two classes, one class was randomly selected for analysis. Data sources include observation notes and whole-class video recordings.

Based on observation notes and video review, we identified 4.5 hours of video of teacher-led, whole-class discussions in which Ms K introduced, reviewed, or contextualized the computational modeling activity. Following interaction analysis methods (Jordan & Henderson, 1995), members of the research team reviewed the videos independently and collaboratively to identify the teacher’s high-level pedagogical practices around supporting her students’ computational modeling work. In mapping the relationships and goals of those pedagogical practices, we developed the construct of *ontological alignment*, which we define as facilitating discourse in ways that surface, highlight, connect and seek supporting or contradictory evidence for student ideas that align with the level of analysis available in the tool (in this case, particle-level behaviors and interactions). Through discussion and comparison, we clustered the initial set of pedagogical practices into two moves critical to establishing ontological alignment, presented below in the Findings.

Findings

We present two ways ontological alignment was visible in Ms K’s facilitation of classroom discourse: 1. underscoring student ideas about particle-level interactions and how those relate to ABM; and, 2. strategically selecting evidence to discern between student theories about interactions.

Underscoring ideas about particle interactions and how they relate to ABM

Ms K emphasized particle behaviors and interactions in ways that aligned with the representational infrastructure of MoDa, an ABM platform. On Day 2, she organized students’ paper models into five groups of “theories” about how ink spreads in water. Words representing MoDa blocks are bold; words used by students in discussions and drawings are underlined: 1. “The water particles are infecting, consuming, soaking in, capturing, dissolving the ink particles"; 2. "Water and ink particles are mixing but not **attaching**"; 3. "The water particles are **bouncing off** the ink particles to cause the spreading of the ink"; 4. "The water particles are combining, growing or coming together, **attaching** to the ink particles"; and, 5. "The compactness or density or space between the particles affects the spread of ink in water." Each theory either highlighted an interaction between particles (e.g., #2 or 3) or flagged the kind of outcome students would expect to see when they run their model (e.g., "not attaching"). Notably, the language for these theories came from students and reflected the block library available in MoDa (e.g., "attach" and "bounce").

In the whole-class presentations that day, Ms K supported students in thinking about how to translate their ideas into computational models. For instance, during Parker's presentation of his paper model, Ms K asked students to consider how they might code their explanation:

> *Parker: In this one, the ink was far apart. In a little bit more time, it was closer together.*
> *Ms K: Did the ink particles increase or break apart? How did there get to be more ink particles?*
> *Parker: It slowly increased because the ink particles were splitting apart.*
> *Ms K: So that'll be super interesting to think about when you make this computer model, like how can you take an ink particle and split it apart?*

Parker explained that the ink spreads in water because the ink particles split apart, but there is no block in MoDa for splitting particles. Aware of the challenge of translating this explanation into a computational model, Ms K asked students to think about how they would represent that idea in their computational model.

On Day 3, after student pairs programmed their first MoDa models, Ms K pulled up four student models representing those theories or combinations thereof. Introducing one pair's model, Ms K said "They're doing kind of an interact and **attaching** theory. So watch what happens to the particles here [*plays simulation*]" (emphasis added). Here, Ms K labeled a student model (#4) and supported students in noticing how the model represented this interaction. Specifically, she instructed students to "pick an ink and water particle and watch what happens to them." After a few moments of watching the simulation, one student commented, "What the heck, the particles are **attaching**" while another student noticed that "only the water seems to be **attaching**, not the ink." In these instances, students saw how each theory, even ones they may not have programmed, could be programmatically encoded and simulated.

Strategically selecting evidence to discern between student theories

When using MoDa, students support or refute the explanations encoded in their models by running the simulation and comparing it to video data of the target phenomenon. By Day 4, the "infect theory," the idea that ink particles change the color of water particles to cause the spread, was popular in the class but could not be invalidated using the video data available in MoDa. Outside class, Ms K discussed at length with the third author what kind of evidence would help students refute the infect theory. On the last day, Ms K asked students how they could test their idea that "the water has been fully infected." Students suggested that "you could evaporate it" or "you could use a microscope." On a projected slide, Ms K showed the class an experimental setup in which water mixed with blue dye was evaporated from a dish covered with plastic wrap (which she referred to as "Saran wrap"). When she asked students to discuss with their partners what color the water on the plastic wrap would be, some students predicted it would be blue.

> *Ms K: Ok, it would be blue if the infection theory is correct. If the water is not blue on top of the Saran wrap, what does that mean?*
> *A few students: That that theory is incorrect.*
> *Ms K: That the infection theory is incorrect. (Shows next slide with clear droplets on Saran wrap)*
> *Ms K: What color is the water?*
> *Multiple students: Not blue.*
> *Ms K: It's not blue. It's clear. So does the ink infect or get captured by the water?*
> *Multiple students: No.*

Ms K strategically brought evidence that helped students discern between their ideas and brought in new evidence to invalidate a theory that could not be disproved within MoDa itself. Here again, Ms K operated from an understanding of the strengths and limitations of the computational modeling possible within MoDa and found ways to support students where the code and simulation fell short. She situated computational modeling as one tool for scientific sense making and exemplified for students how to best pair that tool with other science practices and techniques to advance their theory-building work.

Discussion and conclusion

This paper addresses a pressing gap in the literature about how teachers can support computational model building in the classroom. It defines a construct, *ontological alignment,* to characterize the teacher's work of guiding discourse to highlight the representational infrastructure and level of analysis in the computational tool being used. We present two manifestations of ontological alignment in Ms K's practice: 1. underscoring student ideas about particle-level interactions and how they map onto ABM; and 2. strategically selecting evidence to discern between student theories about particle-level interactions. Collectively, these practices required the teacher to adopt an ontological lens of particle-level interactions and, throughout the unit, to elicit student ideas about interactions, support them in translating these ideas into a computational medium, and find evidence that would help students discern between the different theories. Space constraints exclude our ongoing analysis of how students take up these practices. The paper contributes to research on teachers' roles in computational modeling by illustrating how ontological alignment can guide a teacher in supporting classroom discourse around computational modeling. The focal teacher's understanding of MoDa went beyond simply knowing how to use it; she was intimately aware of its strengths and limitations, which informed how she guided students in her class. Ultimately, our findings highlight the importance of teachers seeing computational tools as supporting the expression and refinement of particular forms of students' existing ideas and facilitating discourse from that perspective. We see ontological alignment as important to supporting discourse when using new epistemic tools and practices in science classrooms.

Cultivating Historical and Political “Truths”: How Designing for Collective Relationalities and Critical Reflexivity Supports Expansive Historical Thinking

Ava Jackson, Boston University, abj12@bu.edu

Abstract: This paper offers preliminary results from a project exploring the cultivation of historical and political ‘truth’ in a critical history classroom. As questions of truth and knowledge production continue to shape public discourse, more work is needed to explore how critical pedagogies can influence disciplinary learning processes and knowledge production. Drawing from critical sociocultural perspectives of learning, I share one vignette from a year-long collaborative ethnography of a U.S. history high school class to understand how the teacher’s critical history pedagogy shaped students’ historical thinking. Based on ethnographic, interactional, and discourse analyses, I highlight how a history class grounded in values of relational collectivity and critical reflexivity invited new conceptions of truth as ever-changing and spatially, temporally, and culturally situated based on new information, perspectives, and re-narrating specifically in history education. Potential implications include nuancing our theorizing, conceptualizing, and design of disciplinary learning by incorporating critical pedagogies.

Introduction

Whether in response to re-imaginings of schooling structures during COVID-19 or ongoing battles over ‘CRT,’ contestations of knowledge production and expansion face new considerations. I explore a microcosm of these grander questions with a case study of an11th-grade U.S. history class in which the teacher engaged an expansive disciplinary pedagogy. The teacher and I wished to understand how his pedagogy informed the history learning students took up over the school year. Based on ongoing ethnographic analysis, I offer initial findings on how his pedagogy ,grounded in values of *relational collectivity* and *critical reflexivity,* invited new student conceptions of truth based on *new information, perspectives,* and *re-narrating*. I share one vignette to demonstrate these constructs and how they became foundational to student thinking. These findings can support nuanced insights into what expansive disciplinary education can look like, how we can achieve such learning initiatives, and why this expansiveness is necessary for current and future envisioning of education.

Literature review

Relational mediation & collectivity

Learning is highly dependent on the quality and care of the relationship between teacher and student (Bang, 2017; Vossoughi et al, 2020). Through foundational frameworks like culturally responsive pedagogy (Ladson-Billings, 1995), cultural modeling (Lee, 2001), and Third Spaces (Gutiérrez, Baquedano-Lopez, Tejeda, 1999), we have built the groundwork to help teachers create positive social interactions with students. Building a relational ethic of trust, dignity, and respect can open rich moments of transformative learning, particularly for young people contending with various forms of oppression (Espinoza et al, 2020; Jackson, 2021). Paying attention to relationship building offers insights into the varied ways relational mediation shapes the teaching experienced by students (Vossoughi et al., 2020). A collective relationality centers multiple subjects as *working together*, each contributing their own conceptual resources and expertise, to accomplish activities that would not be possible without the dialogical attunement to one another (Shotter, 2015). These forms of relating prefigure the world as it could be through just and dignifying co-relations.

Expansive disciplinary learning

Powerful research grounded at the intersections of disciplinary education and critical pedagogical theories offers insights into the nuances of learning made possible through an expansive disciplinary perspective. Across these works (Vossoughi, 2014; Gutstein, 2016; Rosebery et al, 2010), learning was more robust and meaningful to students than normative didactic approaches to disciplinary teaching and inspired new ways of thinking and participating in the disciplines. The valuing of heterogeneous onto-epistemologies alongside the interrogation of the power systems can cultivate the conditions for knowledge-building and social dreaming (Warren et al, 2020). Scholarship exploring expansive approaches to history illuminate unique forms of learning: historical argumentation that directly engages the ideological foundations of historical inquiry (Freedman, 2015), the potential of supporting students' critical receptivity of evidentiary sources (Bain, 2006), and the value of historical sense-making that centers students' cultural and political knowledge and histories as legitimate knowledge sources (Goldberg et al, 2011). How does this happen? What does expansive history learning look like in the moment and? These are the questions my research aims to address.

Theoretical & conceptual framework

I define learning as the shifts in participation and thinking supported within and across cultural activities (Nasir & Hand, 2008; Rogoff, 2003). These shifts often leading to the participation in new, expansive activities (Engeström, 2001), are embedded in sociopolitical systems and ethical assumptions, "articulating the 'how,' the 'for what,' the 'for whom,' and the 'with whom ' (Philip, Bang, & Jackson, 2018) of participation. My approach to seeing teaching and learning requires attuning to the design principles and approaches of learning activities, capturing the moment-to-moment interactions of people within these activities by attuning to the shifting form & function (Saxe & Esmonde, 2005) of learning as a situated experienced.

Project overview & methods

The project I drew from was a year-long ethnography of Mr. Nottingham's 9th-period U.S. history class. During the school year, I visited Mr. N's class three times a week, gathering jottings, field notes, video recordings, interviews, surveys, and student work. My units of analysis were the practices and ways of being designed for and taken up by students; special attention was given to student verbal and embodied communication to trace shifts in thinking participation over time.

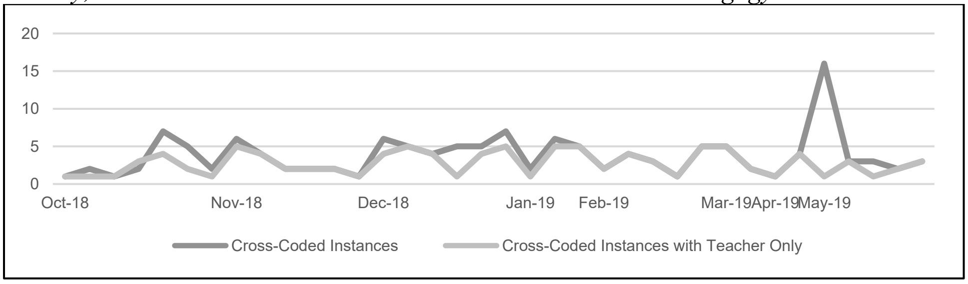
Drawing on ethnographic, discourse, and interaction analyses, I analyzed this large data corpus through iterative coding, conceptual matrices, and memo-ing (Erickson, 1985). I open-coded all jottings and field notes across the school year and synthesized codes into conceptual matrices around unifying themes. I have completed the pedagogy portion of the analysis, focusing on Mr. N's most prominent pedagogical practices (see Table 1).

Table 1
Pedagogical Practices Definitions

Pedagogy Practices	**Asking questions**	**Explaining**	**Encouraging**	**Modeling**
Definition	topics with no clear answer and/or to encourage conversations	class topics and teaching; a story framework using disciplinary, personal, and political	discursively motivate practices or habits of mind	embodying or acting out practices and habits of minds

I then used process coding to further analyze the immediate the longer-term interactional impact these pedagogical practices had on student participation in class. As a result, three primary categories emerged: history (786 coded instances), relational (837 coded instances), and political practices (812 coded instances). We can see the overlap of all moments students engaging in history, relational, and political practices with the teacher's pedagogical practices in Figure 1 (1).

Figure 1
History, Relational and Political Practices Cross-Coded with Pedagogy Practices



Looking more concretely at these moments of student engaging history, relational, and political practices together, initial analysis has illuminated characteristics that student participation in these moments is characterized by an historical thinking grounded in engagement with new information, new perspectives, and re-narrating historical and political narratives.

Initial findings

Initial findings indicate that organizing a history class around values of *relational collectivity* and *critical reflexivity* invited new conceptions of truth as ever-changing and spatially, temporally, and culturally situated based on *new information, perspectives,* and *re-narrating***.** Relational collectivity was the process of understanding oneself as embedded within collectives; the individual is always shaped and shapes the larger world, whether individuals, artifacts, or social norms/beliefs. Critical reflexivity was analyzing new and known information within disciplinary, political, and ethical lenses to refine information based on an ever-changing world, a continuous process of knowing and re-knowing by recognizing the impact sociopolitical systems have on ways of knowing. Mr. N wished to support students in historical thinking grounded in assumptions that history is an ever-changing narrative based on one's sociopolitical status and beliefs. Mr. N's encouragement of collective inquiry primed students to engage in historical thinking as a collective endeavor versus an individual investigation. This led students to conceptualize historical and political truths as determined by new information, perspectives, and re-narrating.

Take this discussion from the middle of the school year. The class was starting a new unit on the Gilded Age and Mr. N wanted students to think about the underlying themes that resonate across U.S. history. He asked students a simple question–what is ownership? This question inspired an almost 20-minute conversation on how to define and conceptualize ownership. I offer a brief vignette from the discussion to demonstrate how students attuned to the perspectives and information offered to one another, shaping their collective inquiry:

> Mr. Nottingham said, "after reconstruction, we were looking for ways to make more money…common theme around ownership, what does it mean to own?" Bolaji, a young Black man, said, "to legally own." Mr. Nottingham followed up, "but what does that mean? What do you actually own?" Borna, a young White man, said, "a house." Sarah, a young White woman, said, "you own your body." After students started to discuss these ideas, Mr. Nottingham asked again, "what does that mean?" Borna added, "you control it."
>
> As more students offered suggestions, Mr. Nottingham repeated the ideas he heard, such as Sarah's response: "I'm hearing 100% control of one's body" At first, Bolaji said no, and Sarah responded, "yes, really." Sarah and Bolaji went back and forth a few times before Bolaji said, "not if you are in the military." A few people said, "oh!" while another asked what Bolaji said. After a few seconds, Sarah repeated, "he said, 'not in the military." There was a discussion about body ownership in the military, with Sarah nodding her head, now agreeing with Bolaji.
>
> Mr. Nottingham said, "y'all are talking about really interesting ideas." Laquantre, a young Black man, referencing another student who seemed to be laughing around this conversation, said, "y'all laughing, but Bolaji is lowkey right."

Students' back-and-forth on body ownership highlights the ideological intricacies embedded in the notion of "ownership." As a young white woman, Sarah's claim could have emerged from many intellectual histories. She could be just using her intuition that since she can move her body, she owns it. She also could be drawing on her experiences of being a woman, particularly during a political moment in which bodily autonomy is effervescent in news media and discourse. The stance for body ownership was still presented as a given because, to Sarah and others, this information aligned with a perspective many already shared, a perspective of being young white Americans. The resulting narrative of people owning their bodies makes logical sense in this framework.

Bolaji challenged this. Bolaji was a young Black man who emigrated to the U.S. from Nigeria when he was 12, resulting in a limited understanding of U.S. history. Although some students knew Bolaji's background, many did not; this often made Bolaji feel insecure about asking questions or raising points that may be 'obvious' to others but not to him. This insecurity is important to remember when reading Bolaji's challenges to Sarah's position. Although most of the class supported Sarah's argument that one own's a body, Bolaji was drawing from different conceptual and historical resources, perhaps not privy to Sarah. Young Black men, whether in Nigeria or U.S., are often discursively positioned as politically disposable resources for national militaries (Corcione, 2019). Bolaji's introduction of this new information not only necessitated adopting a perspective of young Black men but also a re-narration of body ownership in this new context.

Once Bolaji introduced this new information, Sarah's position immediately shifted. She did not negatively receive Bolaji's pushback but acknowledged it to others in the class, ensuring everyone heard his point. This inclusion of new information introduced a new perspective that she and many others in the class may not have had because of their social positioning. Laquantre's further affirmation of Bolaji's point reflected the relational collectivity valued in Mr. N's class. Knowing the precarious status Bolaji held in the class, Laquantre leveraged his role as a legitimate participant to raise Bolaji's argument, just as Sarah did by repeating Bolaji.

The discursive moves by Sarah, Bolaji, and Laquantre invited, responded to, and affirmed new information while they negotiated their perspectives, and thus narratives, on what constitutes ownership. Furthermore, the consensus on Bolaji's information did not negate Sarah's perspective either; rather, you can own your body depending on one's sociohistorical positioning regarding race, gender, and economics. This was affirmed by Mr. N, who didn't say whether one was right or wrong but acknowledged that "y'all are talking about some really interesting things." The new narratives emerging around ownership were neither right nor wrong. Still, they reflected the complexity of using an all-encompassing term to make sense of historical and political questions.

Implications & conclusions

I aim to highlight the conditions and moments in which students introduced and engaged new information, perspectives, and re-narration in their pursuits of historical and political 'truths.' Just from this example we can see how, through pedagogical mediation characterized by collective relationality and critical reflexivity, practices of including new information, perspectives, and re-narration invited students to engage in more expansive historical thinking that is socio-politically situated. Offering detailed profiles can help us 1) recognize how students are unpacking complex ideas through lived experiences, 2) trace the conceptual practices they draw upon to unpack complexity, and 3) the pedagogical practices that create the conditions for take-up of these practices, positioning students to be political and historical actors. This research can contribute empirical insights on what constitutes disciplinary knowledge production and participation, on how to see this knowledge in action, and how to support teachers in this knowledge cultivation (Vossoughi & Gutierrez, 2017).

Endnotes

(1) This is evidenced by the spike in student practices in May. On this day in class, Mr. N asked students to lead their discussion about WWII. We see students engaged in the history, relational, and political practices even more than usual to create and sustain the kind of learning environment they co-created with Mr. N, demonstrating the usefulness of the practices.

At-Home Engineering: Caregivers' Support During Problem-Solving

Lauren Penney, Indiana University, lapenney@iu.edu
Kelli M. Paul, Indiana University, kelpaul@iu.edu
Jungsun Kim, Purdue University, kim929@purdue.edu
Adam V. Maltese, Indiana University, amaltese@indiana.edu
Amber Simpson, Binghamton University, asimpson@binghamton.edu

Abstract: The home environment is a critical context in which children engage in STEM activities. Caregivers serve as key influencers on their children's engagement in these activities. This case study of four families explored how caregivers support their child(ren) during moments of problem-solving while completing engineering activities at home and illustrated the variation in caregiver support, caregiver participation/child agency, problem-solving strategies used, and integration of activities into the home. Our findings suggest we need to be purposeful in designing kit activities and supports for caregivers that will contribute to meaningful interactions during STEM activities that draw upon the unique relationship between caregivers and their children in the home.

Background

There is growing recognition of the importance of engaging in engineering practices and processes for young children, both in formal settings (e.g., schools) and informal settings (e.g., home). Caregivers significantly influence children's engagement in engineering and STEM activities, shaping their children's experiences, attitudes, identities, interests and practices (Ing, 2014; Maltese & Harsh, 2015; Šimunović & Babarović, 2020; Vedder-Weiss, 2018). Research in informal environments looking at family STEM engagement often occurs in museums (Callanan et al., 2017; Zimmerman et al, 2010) or workshops (Simpson et al, 2021). Researchers have studied home science practices (Strickler-Eppard et al., 2019; National Research Council, 2009) and have retrospectively interviewed families about open-ended engineering design (e.g. Dickens et al., 2016). However, compared to other informal settings (e.g., museums), the home environment is understudied. We argue that the home is a critical context in which children engage in STEM activities. Within this context, caregivers play an important role, serving as key influencers on their children's engagement in STEM activities. In this study, we seek to add to the scholarship by answering the research question: *How do caregivers engage with and support their child(ren) during moments of problem-solving while completing engineering activities at home?*

Methods

This study was part of an NSF-funded project to (1) engage children and their caregivers in engineering, (2) increase awareness of engineering, and (3) spark or sustain childrens' interest in engineering. We created several engineering design challenge kits for 8-12 year old children. This paper focuses on the Watercolor Bot kit, which contained instructions with video links to more information and examples, a facilitation guide for caregivers with optional question prompts, a variety of materials (e.g., Q-tips, cotton balls), two lithium coin cell batteries (Figure 1a), and two 10mm vibrating disc motors (Figure 1b). Instructions were to design a motorized bot that "paints," which required families to build a bot body, connect the battery to the motor (Figure 1c), attach the motor to the bot, test on various surfaces, and redesign as needed (Figure 1d-e shows sample bots). Caregiver guidance was minimal and focused on supporting the design cycle (research, plan, create, test, improve). The library website hosted a welcome video with kit instructions, including the statement "while you may be tempted to let your children complete the activity on their own, we encourage you to actively participate with them." Kits did not indicate a time estimation for the activities. A watercolor bot could be created in 20-30 minutes, but we expected families to engage in design iterations which would extend the activity.

Figure 1
Examples of Components of and Completed Watercolor Bots

Participants and data collection

We partnered with our local library to distribute kits to families as part of their annual summer reading challenge or to families who participated in Saturday workshops offered to families. Kits were offered to families with no expectation of participation in the research project. A majority of families expressed interest in the research study (26 of the 33 families from the summer reading challenge, three of the eight families from the Saturday workshops). Families who expressed interest in the research study were emailed information about the study, including a unique Zoom link that auto-recorded when the room was opened. We asked families to record their entire making process, instructing them to open the link whenever they engaged in the kit activities together. When confirming their participation, some caregivers expressed discomfort with recording (e.g., concerns about low level of scientific knowledge, recording arguments within family interactions). Families had full control over the recording, deciding when to start and stop the recording and whether to have their video on/off. Researchers were not physically or virtually present during the recordings. Four families recorded their work on the Watercolor bot. Pseudonyms were used for all caregivers and children (see Table 1).

Table 1
Participant Families

Family	Caregiver(s)	Child(ren)	Video Duration
		Name (Gender, Age)	
Harris[a]	Mom and Dad	Ethan (M, unknown)	64 min.: 2 sessions on same day
Williams[a]	Mom and Dad	Bella (F, 6); Charlotte (F, 9)	38 min.: 1 session
Cadshaw[b]	Mom and Dad	Harper (F, unknown)	65 min.: 3 sessions across two different days
Gupta[a]	Mom	Arnav (M, 7); Priya (F, 10)	48 min.: 2 sessions on same day

[a]Participated in the Saturday workshops. [b]Participated in the summer reading challenge.

Data analysis

We utilized a case study approach to showcase interactions between caregivers and children in natural, everyday contexts as they worked through creating the movement for their watercolor bot at home. For each caregiver-child dyad, we were interested in examining the ways caregivers supported their children during moments of problem-solving while completing the task of the engineering kit. For each video in the selected corpus, we used interaction analyses (Jordan & Henderson, 1995) to inductively code segments related to families problem-solving through not knowing something and figuring it out together. After open-coding the full videos, we identified segments that demonstrated moments of problem-solving, specifically focusing on the following: connecting the circuit, maintaining the connection of the circuit, and vibrating the bot. We re-coded those segments with the lenses of participant attention (Vossoughi et al, 2021), caregiver roles (Simpson et al, 2021), and strategies used to solve problems (Cardella et al, 2013). These lenses informed our understanding of how caregivers support their kids during problem solving.

Findings

We present a brief showcase of each family's interactions that highlight differences in caregiver support, caregiver participation/child agency, problem-solving strategies used, and integration of activities into the home.

In the Harris family, Mom helped Ethan get started but then left him to explore and create on his own while she and Dad engaged in other activities nearby. Ethan made comments that pulled Mom and Dad into his exploration as he expressed his success, frustration, and ideas. Mom positioned herself as a novice but continually checked on Ethan, asking him questions about his progress. When Ethan said, "How is this thing supposed to work? I don't know how this thing is supposed to work," Mom told him to "Ask Daddy" and Dad offered advice and referenced the given materials. By the end of the recording, Ethan's bot vibrated around on its Q-tip legs, though Ethan never used the watercolor paint on the Q-tip feet during the video.

Both girls in the Williams family were engaged in the watercolor activity. When Bella switched to painting on her own (rather than making a bot do it), Mom focused on collaborating with Charlotte who was redesigning her bot. Mom suggested ideas, pulling in her knowledge of circuits and balance as she supported Charlotte. Mom celebrated successes, calling Dad over to see their work. Dad also supported by providing his knowledge of electrical circuits when Charlotte struggled to maintain the connection between the battery and vibrating motor wires. Mom, Dad, and Charlotte all theorized why the bot was not moving, wondering if there was too much friction, had too much watercolor paint on it, or the vibration was not happening in the right place. As the recording ended, they celebrated as the bot vibrated the tinfoil across their floor.

In the Cadshaw family, Mom helped Harper get set up and started on the activity. Mom provided resources (e.g., read text from the guide), referenced informational videos, and asked questions to guide Harper in the planning, design, and creation of the watercolor bot. Multiple times across the series of videos, Mom redirected Harper to focus attention on the questions Mom was asking her or rebuked Harper for her behavior, even stopping the recording at one point. Mom admitted that she did not know how to connect the battery and motor and that they would have to figure that out. Harper got the motor to vibrate by pressing the wires hard against the battery and brainstormed many creative ideas to generate "more pressure" to connect the wires to the battery. Eventually, Mom stripped plastic coating off the wires to help make a better connection. Mom was simultaneously caring for baby brother and balancing other family obligations (e.g., friends arrived to drop off dinner), telling Harper, "At some point I need to go get something else done besides this." When Mom asked Harper questions from the materials, Harper slumped in her chair and did not respond. Their sequence ended with Harper having a watercolor bot that painted a bit but still had stability and vibration connection troubles.

Both children in the Gupta family worked on their own watercolor bots for their whole session. Mom sat at the table the entire session and provided hands-on help to both children when they struggled to realize their bot using the materials available to them. Arnav finished his design first but struggled to attach the battery and vibrating motor to his bot body. When he was unable to solve the problem, all three worked together to get the motor to vibrate using available resources (e.g., kit guides, videos, internet searches) and by manipulating the motor, wires, and battery in trial-and-error fashion. They frequently wondered aloud, offering suggestions, ideas, and questions, as they built their knowledge together. After more than ten minutes of problem solving, Mom decided to stop the video while they figured out how to connect the battery. The second video began with Mom announcing they had figured out the connection and held the bot up to the camera. Mom continued providing hands-on help to both children, responding to requests when they ran into issues. Their video ended after they successfully tried their watercolor bots on various surfaces.

Discussion

The four families illustrated variation in problem-solving strategies used, caregiver support, caregiver participation/child agency, and integration of activities into the home. The families encountered each of the three identified problems (making the initial connection, maintaining the connection, and getting the bot to vibrate) to greater and lesser degrees with each family utilizing a mixture of observation, ideation, and testing to solve the problems. Caregivers positioned themselves as a supportive resource, scaffolding the activity when their child got stuck, experienced frustration, could not physically manipulate the materials, or did not know how to proceed. At times physical (e.g., attaching a rubber band), facilitative (e.g., helping child persist when he/she said "I give up"), or collaborative (e.g., offering design suggestions), this scaffolding allowed children to access a larger range of actions and behaviors than would have been possible on their own. Throughout all interactions, caregivers drew on their prior content knowledge (e.g., circuits) and familiarity with their children (e.g., behaviors) as they adjusted the support they provided.

Through their actions and words, caregivers positioned themselves as co-learners and facilitators, working alongside their children in their attempts to support their child's success in the activity. Caregivers positioned the activity as owned by the child who had full agency and ownership of their created watercolor bot. While they at times inserted their ideas and help, caregivers did so in support of their child's vision. Caregiver participation varied on a continuum from being on the periphery nearby but only engaging when the child needed assistance, to participating for the entirety of the activity as co-learners and collaborators. This continuum was evident in the Harris family where Ethan completed the activity entirely independently (except when he requested help) and in the Williams family where Mom could be heard suggesting her ideas but giving Charlotte the agency to make all final design decisions.

Finally, our findings illustrate challenges with integrating and engaging in STEM activities within the home context. The segments of time families chose to record provided a glimpse of the balancing act required by caregivers to provide their children opportunities to learn new things against the constraints of daily life (e.g., caring for younger siblings, household tasks). Some caregivers took a consistently active role in the activity while others popped in and out as they attended to their child as well as other tasks. Additionally, kit completion often occurred across multiple sessions, stopping and starting based on these family obligations as well as the behavior of the child. All of this demonstrates the uniqueness of challenges faced in the home context.

Conclusions and implications

Our examination of four families engaged in completing one at-home engineering kit activity offers a glimpse into family engagement in STEM activities at home. The findings suggested that families draw on different background knowledge, patterns of interaction, and strategies when working together during STEM activities, all while balancing the integration of these activities into existing family activities. All of these factors influence whether and how STEM kits and activities are used in the home context. We need to be purposeful in designing supports specifically for caregivers, many of whom are not confident in their ability to support their children in STEM activities (Knox et al, 2022). Such support could include supplemental materials that provide entry and expert level activity support, strategies to engage caregivers as co-learners and collaborators while fostering children's agency in STEM activities, and tips for adjusting support based on their children's individual needs. Additionally, since the home context allows for more time and flexibility in completing activities (e.g., across multiple days), activities should be designed to easily accommodate occasional stops/starts and varying levels of caregiver participation as they are pulled away to do other tasks. Continued work is needed to understand how best to support children through moments of productive struggle (Warshauer, 2015) which often is an aspect of the problem-solving required during open-ended STEM activities. Attention to these design features may contribute to more impactful interactions during STEM activities that draw upon the unique relationships between caregivers and their children.

Abstract: Machine Learning (ML) is integrated into many of the technologies we use daily. However, biased training datasets have shown to be harmful for marginalized populations. As future consumers and producers of technologies, children should have the technical and social expertise to engage with such issues in ML. In this study, we describe a series of activities designed for elementary and middle-school aged children to learn concepts of machine learning (ML), bias, and the sociopolitical implications of ML. Grounded in critical constructionism principles, we describe how children engage in reflective discussions, tinker with existing ML tools, and build an ML-based robot for social good.

Introduction

Machine Learning (ML) is integrated into many of the technologies we use daily. However, the socio-ethical implications that arise due to biased training data sets have shown grave implications, especially for underrepresented minorities. For example, while working as an MIT computer scientist, Joy Buolamwini, uncovered racial and gender bias in artificial intelligence (AI) services from companies such as Microsoft, IBM, and Amazon (Kantayya, 2020). With other numerous documented instances of ML bias (Piano, 2020), it is essential to equip youth, as future consumers and designers of technology, with the technical expertise and experience necessary to engage with ML. To broaden youth engagement with ML, a number of studies have developed programs and curricula that teach young learners basic ML concepts and operations (Chan, 2019). However, few studies have integrated AI ethics (Payne, 2020) and sociopolitical issues in educational programs. To address this gap, we co-designed with learners between 3rd-5th grade and implemented a critical machine learning (CML) program that attempted to integrate teaching concepts of ML with sociopolitical issues in ML. In this paper, we describe critical constructivist activities that children engaged in and provide examples of how youth integrated ML concepts with sociopolitical issues. This paper is a part of a larger study on critical constructivist activities designed to enable children to think critically about the sociopolitical implications of ML and design ML applications for social good (Arastoopour Irgens et al., 2022). This paper presents a description and analysis of critical constructivism and an application of its active-learning principles to developing a CML program for elementary and middle school youth in afterschool programs.

Designing for CML education with a critical constructivist lens

Our design and pedagogical approaches for facilitating children's critical engagement with machine learning (ML) were based on critical constructionist perspectives (Holbert et al., 2020; Kafai et al., 2020). The critical constructionist design framework promotes a learning environment that builds upon learners' lived experiences and provides tools that mediate learners' development of creative ideas and artifacts that reflect and challenge their lived realities. In this framework, educators connect concepts to personal and communal structures of inequities that shape the meaning and application of such concepts. Learners reflect, tinker with tools, and design futures that challenge the identified structures. Holbert et al. (2020) argue that engaging students in a cycle of connection and critical reflection about knowledge gives learners the opportunity to infuse their own perspectives and values into their creation. Moreover, learners play an agentic role in reducing or creating awareness about systems of inequalities in society and the critical nature of knowledge-building leads to a better understanding of the content (Holbert et al., 2020).

Methodology and CML program design

The activities described in this paper were designed and implemented with youth from two after-school centers in the United States consisting of Black, Latinx, and White children with a mix of those who presented as girls and boys and ranged between 9 - 13 years of age. The goal of the program was to provide children with learning experiences that enable them to understand ML bias, critically reflect on the harmful effects of ML bias at the systemic level, and design ML systems while attempting to mitigate bias. The activities, inspired by MIT's AI + Ethics Curriculum for Middle School and AI Ethics Education Curriculum (Payne, 2020), have been designed and tested in three iterations with forty-four children and three staff counselors from two separate after-school youth programs. Each iteration lasted approximately seven weeks and the activities with the youth occurred 2-3 days per week and lasted 1-2 hours each. Through these bi-weekly sessions, the researchers evaluated and amended the activities in light of the children's behaviors, conceptual grasp, direct and indirect input, and observed level of involvement (Arastoopour Irgens et al., 2022). The children's input, perceptions, values, and needs were taken into account and contributed to re-designs during implementations and between iterations. In this way, the children engaged in the co-design process as testers, and informants (Druin, 2002). We describe the set of activities implemented in the third iteration of the project following the changes that were implemented in the first and second iterations (for examples of the iterative re-designs in this study, see Bailey et al., 2023). The section that follows describes the CML program activities in light of the program goals: 1) engage children in reflective discussions on bias in ML algorithms, 2) engage children in 'tinkering' with existing ML tools with adult guidance, and 3) promote opportunities for children to use their gained knowledge and experience to design and build an ML-based robot for social good. Alongside the activities, we present qualitative data from interviews with children and researcher observation notes to provide some context of learners' engagement in activities.

Engaging children in reflective discussions on bias in ML algorithms

The goals of the following discussion-based activities—*Harmful/Helpful Technologie*s, *Pizza Algorithm*s, and *Coded Bias*—were to guide children in critical reflections regarding the advantages and disadvantages of ML technologies, as well as understanding that algorithmic bias may exist within these technologies.

Harmful/Helpful Technologies: The children worked in groups of 3-5 participants to create a list of technologies they use. They were asked to document whether the identified technologies are helpful or harmful. Each group used large poster boards and markers to illustrate or list technologies within the categories of helpful or harmful (see Figure 1a). The youth worked in small groups and then in a whole group discussion with program facilitators.

Pizza Algorithm: We introduced the children to the concepts of algorithms and bias and the children worked in groups to write or draw a set of instructions on how to make the "best" pizza using markers and large posters hanging on the wall (see Figure 1b). They explored what represented the "best" pizza to each group and according to our observations, voiced how their preferences were reflected in their algorithms.

2. need the dough
3. spread tomato sauce on the dough
4. Sprinckle chesse on pizza
5. Put PEPPORONI ON THE PIZZA
6. Put pizza in the oven
7. Bake pizza until ready
8. Take the pizza out and slice it
9. Enjoy your tastey pizza!

(a) (b)

Coded Bias: Children watched the Coded Bias film trailer (Kantayya, 2020), which featured Joy Buolamini's realization of racist facial recognition technologies. Subsequently, children critically reflected on the concepts of bias, facial recognition technologies, and the socioethical implications of such bias with the researcher's guidance. In a group discussion, children responded to prompts such as: *What was interesting in this video? Who was being mistreated in this video and how? Who was creating the technology that was harmful?* During the discussion, one child commented: "*What I thought was interesting is a lot of people's life could be changed by, what the cameras [facial recognition software]…, on the streets pick up…*" Another child in the same group added, "*Just because of the software the person wasn't recognized to a certain, like house or where they live, they could get locked out of their house or they could be denied housing.* Statements made such as this one suggest engagement in the discussions around how technologies can be biased and the socio-ethical implications, such as AI making mistakes and people being denied housing.

Engaging children in tinkering with existing ML tools with adult guidance

The goals of the activities—*Google Search*, *Quick, Draw!*, and *Cat and Dog Teachable Machine*—were for children to tinker with tools and explore concepts of testing and training data, outputs, and algorithmic bias.

Google Search: To explore how algorithms have the creator's biases and opinions embedded within them, a researcher used a laptop and projector to guide the children through a group activity that required running a Google image search for words such as "basketball player." The search returned images of men and the researcher asked: *Who might not be represented in this group? Why do you think we are seeing the images we are seeing? Who or what decides what we see?* During the discussion that followed this search, one girl stated "*If you look up basketball… you should be able to see both of them [men and women]. If you look up anything,* ***you should see women and basketball.****"* After completion of the program, another girl revisited the activity in her post-interview: *"Like, when we did the Google algorithm… When we searched up the basketball player, I liked how we could like to express our opinions on if it should be male or female."* Here, the girl liked expressing her opinions about the output of the search algorithms. These girls felt comfortable in the space to provide their opinions and display a critical lens towards existing search algorithms.

Quick, Draw!: The children explored Google's "Quick, Draw!" to see an example of how a neural network predicts in real time. The application randomly assigned six drawing prompts. The user draws the object and after 20 seconds the AI guesses the drawing by extracting from a database of drawings that other players had contributed to the application in the past. In their post-interview, when the researcher asked what children liked best about the entire program, one child stated "*Oh, the Quick Draw! I thought that was interesting."* Another child answered, "*I really like the drawing thing like where you gotta draw something and then you had to guess it."* These responses suggest they enjoyed the drawing and that this type of hands-on activity could initially engage children to participate in learning activities around ML.

Cat and Dog: Children built, trained, and tested ML models as they tinkered with Google's Teachable Machine (GTM). This web-based tool allows users to develop simple classification models using images, audio, or video. Children were given photographs of both cats and dogs to use as a training and testing set for their models, but they were unaware that the researchers had given them a biased dataset that contained images of more cats than dogs. The goal was for children to discover the bias in the training dataset and then retrain their machines with new and less biased datasets. One child directly connected concepts of biased data sets from this particular activity with her final project. In her post-interview, she remarked, "*I don't think my [final project] machine is biased because I tried to get the same amount of pictures so it could, like, make it even. So, it wasn't biased, like the cat and the dog one."* Here she was comparing her final project with the cat and dog activity.

Using gained knowledge and experience to design an ML-robot for social good

The goals of the three final activities—*Build your own GTM, Superhero Robot Story, and Build Superhero Robot*—were to design an ML-based robot machine through storytelling and block-based programming. The children were given the challenge to identify issues in their communities and apply concepts of what they had learned in previous activities to create an ML robot for social good.

Build a GTM: After introducing the children to supervised ML in the cat and dog activity, children were challenged to create their own machine that recognized images, poses, or sounds using GTM. One child described her machine saying, *"I did a lot of pictures of guinea pigs and hamsters because they look alike. And I tested it… And it didn't work as well. So, I just added more pictures of different hamsters and different guinea pigs… I think 16 each… from the web. I put a lot of different pictures of different hamster and different guinea pigs and not just like one type of hamster and one type of guinea pig."* Here, the child explained how she applied her knowledge of how to mitigate bias in ML algorithms by using a balanced training set of a variety of both hamsters and guinea pigs.

Superhero Robot Story: Children created narratives about robots that could help their community. They used large poster boards to visualize their imagined superhero robot. Afterward, they shared their Superhero Robots story with the group by responding to prompt questions such as: *What does your robot do? Who does your robot help? Why did you decide to design this robot?* Children told stories about robots that could contribute to social good in a way that they could relate to in their own lives. For example, when describing her robot design, one girl stated, "*My cousin, when she was growing up, she didn't have the opportunity to watch TV shows that teach her colors and stuff… So I thought to myself that could be happening to multiple other kids all over America. So, I thought, I could make a machine that can help kids with that."*

Build a Superhero Robot: Children worked in groups to build a minimal viable prototype of their superhero robot. By integrating the principles of training and testing data, the children built their ML models using GTM and linked their model with block-based programming (see Figure 2a) with a micro:bit robot. For example, one group described "Ted" as a helpful robot that answers questions and helps with household chores (see Figure 2b). Using this baseline story, the girls created a minimum viable version of Ted (see Figure 2c) by training a ML algorithm that combines with a micro:bit robot to ask a question: "Are you happy or sad?" The robot then responded to the answer by making movements, displaying lights, and playing a sound depending on the feedback.

In this activity children designed an artifact that incorporated their own perspectives and values while also practicing ML concepts and, in some cases, mitigating bias.

Future study and redesign of the CML program

We observed children as they engaged in what Holbert and colleagues (2020) described as "cycle of connection and critical reflection about knowledge." Children critically contributed to discussions in activities like Coded Bias and Google Search and integrated their personal experiences while creating their superhero projects and building ML algorithms. They used knowledge gained from prior activities for building and evaluating their designs for bias, with some youth making reference to the earlier activities. The final activity; *Superhero Robot Story* helped us realize storytelling is a powerful way to help young learners engage actively with CML concepts and integrate a critical lens with their design projects (Chan, 2019). Thus, future work includes designing a narrative-driven role-play experience that incorporates ML bias activities but is a more cohesive set of activities and requires a critical lens for *every* activity. We believe these efforts are vital for children to develop a critical consciousness as the future generation of consumers and producers of technologies.

Learning Through Play at the Intersection of Problem-Solving, Epistemic (Un)certainty, and Emotion

Zack Carpenter, University of Minnesota, carpe787@umn.edu
David DeLiema, University of Minnesota, ddeliema@umn.edu

Abstract: Although play is often viewed as a buffer against failure, our nascent work in this paper argues that play is teeming with emotional and epistemic complexity. Based on the epistemic cognition, emotion, and problem-solving literature, we are developing a coding scheme for exploring how people learn in puzzle video games. Preliminary findings revealed a significant negative relationship between self-reported confidence and time spent on a level ($r = -.52, p < .001$). In addition, players' problem-solving moves showed different co-occurring patterns with epistemic stance and emotional valence. The study's initial results demonstrate its potential for enhancing understanding of what it means to learn from playing video games by conducting a fine-grained process analysis and bridging literatures.

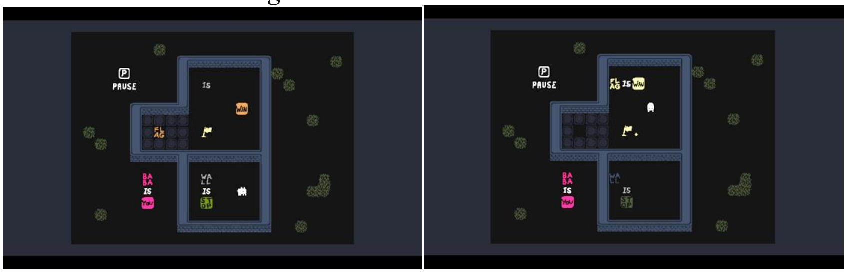
Introduction

Engaging in any kind of learning entails experiencing fluctuating certainty about what you know, surrounded by a wide range of emotions. Indeed, science education researchers have argued that both epistemic (un)certainty and emotion play a pivotal role in learning (Watkins et al, 2017; Radoff et al, 2019). Alongside this context of learning science, rich literatures illuminate how uncertainty and emotion influence learning processes and outcomes. For example, many models of epistemic cognition (EC) include a component focused on differing levels of certainty, some focusing on it as a characteristic of knowledge (Hofer & Pintrich, 1997) and others focused on the epistemic stances (ES) one can take towards knowledge (Chinn et al., 2011). Furthermore, researchers have shown that emotions are inseparable from learning processes (Pekrun et al., 2017). Bridging these research topics, our work in this paper explores how ES and emotion work in tandem alongside the problem-solving processes that shape learning in a puzzle video game. Learning in a puzzle game requires problem-solving, a process that involves noticing when you get stuck, understanding why you're stuck, and trying to get unstuck (DeLiema et al., 2022). However, we know very little about how problem-solving processes, which drive learning in play, are laden with epistemic experiences of (un)certainty and emotion (e.g., joy, frustration). To bridge the cognitive and affective divide that still resides in much work on learning, we argue it is essential to understand the dynamic, moment-to-moment interactions between these processes. Our work here is guided by the following question: How do emotional valence and epistemic (un)certainty relate to problem-solving *while* players learn the mechanics of *Baba is You* (Teikari, 2019), a challenging puzzle game? To answer this question, and to allow for more granular claims about the interconnectedness of ES and emotion, we use eye gaze along with talk-aloud data and game actions to provide a process-based account of learning.

The learning context: Baba is you

Baba is You, and many games in general, create generative spaces for micro-longitudinal, process-based analyses of the dynamic expressions of ESs and emotions because players must grapple continually with moments of failure and uncertainty (Juul, 2013). This game was chosen in part because it offers a unique blend of ill and well-defined problem elements, and the rules structuring the game are explicitly shown on the screen, which affords the use of eye gaze to support inferences about what the player might be thinking. The game's structure also resembles programming, which makes possible a connection between computer science education and a playful learning space. The game has over 200 levels spread across worlds with different themes. Figure 1 shows that the different elements of each 2-D puzzle—such as text blocks (e.g., WALL-IS-STOP) and objects (e.g., the little, white sheep character Baba)—are presented to the player in a one-screen format. Players are given control of a character and move around the play space by using the keyboard's arrow keys. The game's core feature is that players change the text-based rules (e.g., breaking off WALL from WALL-IS-STOP) to change the objects in the space (e.g., making the wall permeable). By either creating or breaking text-based rules, players can turn one object into another object, change the physical properties of an object, or even change which character they are controlling, among many other possibilities. For example, a player could complete the level shown in Figure 1 by combining the two text blocks, "IS" and "WIN", with another text block to create a winnable game state. If the player uses Baba to push the text blocks around to form the sentence "FLAG-IS-WIN", the flag object would sparkle, allowing the player to win when they move over the flag object. The game also affords numerous other ways players can change the nature of objects in the game by rearranging the text-based rules.

Figure 1
The left picture shows the initial game state of a Baba is You level, and the right picture shows the WALL-IS-STOP rule deactivated and the FLAG-IS-WIN rule formed. The player wins when Baba moves over the Flag.



Method

18 undergraduates participated in the study. Both play sessions consisted of a short setup period to calibrate an Eye Link II (SR Research) eye tracker and a 40-minute play period (the eye tracker was recalibrated after the first 20 minutes). While students played the game, the first author remained in the room staying silent except to inform students of the general game controls and ask the following confidence question when a level was completed or skipped: "On a scale of one to ten how confident did you feel over the course of that level?" In the first session, players were told to imagine themselves as a Twitch or YouTube streamer and describe what they were thinking out loud. Screen recordings of the play sessions were captured, and players filled out a demographic questionnaire at the end of the second session. Due primarily to equipment failure and three cases of attrition, the data from eleven participants are used in the analysis here.

Overview of coding scheme development

Our exploration of the above-described confidence measure led to the discovery of a significant negative correlation between player confidence and time spent on a level ($r = .51, p < .001$). Though perhaps unsurprising, this finding prompted us to ask what the player experienced during the level that culminated in that confidence rating pattern. Our prior interaction analyses (Jordan and Henderson, 1995) showed that players frequently gave clues about their knowledge states and emotional experiences (e.g., "I do not know what to do" and "That is so annoying"). We conjectured that players' end confidence rating might be related to their level of certainty concerning the knowledge they were gaining (e.g., their ES) and their emotional experience of the game (Melander Bowden, 2019). We consider players' level of certainty toward their generation of knowledge to be centered on four aspects of knowing: (1) I know that I am stuck, (2) I know how I am stuck, (3) I know why I am stuck, and (4) I know what to do. Instead of labeling specific emotions (an analytical move fraught with complexity), we focused on valence. Valence is the intrinsic pleasantness (e.g., joy) or unpleasantness (e.g., sadness) of emotion, and it is argued to be a salient component of emotion (Barrett, 2006).

We used a prior problem-solving coding scheme built around *Baba is You* (DeLiema et al., 2022) as a point of departure. The framework is theoretically grounded in literatures such as play, problem-solving, self-regulated learning, productive failure, and debugging; it focuses on how players notice or describe something deviating from their approach (Noticing deviation, ND), how they propose a cause of an observed deviation (Causal explanation, CE), and how they describe a plan to revise and enact a new approach (Action revision, AR). When players revised their approach and deemed it a success, we labeled it a successful revision (SR). We also added a code called "Action" (A) because we wanted to differentiate between players enacting a new approach not following a deviation. An action that is determined by the player as successful was also labeled a successful action (SA). Table 1 shows how we build off the existing coding scheme by including binary ES codes (certain/uncertain) and emotional valence codes (positive/negative) that we *only coded together with* a problem-solving move. For example, one player experienced their character "dying" on a level. The player said "No!" followed by a short sigh (negative valence) while their eye gaze moved quickly away from the site of the deviation and they restarted the level. Together, these provided evidence that the player was certain that something in the game deviated from their preference, what we labeled in our framework an epistemically *certain* ND layered with negative valence. This is distinct from players suspecting or being uncertain about whether something went wrong. Another player treated an outcome as misaligning with their preference (e.g., undoing an action), but did not vocalize anything; we coded this only as an ND. Thus, ES and valence were coded only when a problem-solving move was coded, and when the player made a vocalization. An additional note is that epistemic stance and emotion are complex constructs that almost certainly exist outside of binary classification, but we opted for a simplified approach as an initial exploration of these constructs in play.

Table 1

Overview of the coding scheme. Each problem-solving code can be layered with epistemic stance and emotional valence.

Problem-solving move	**Action revision (AR)/(A)** Definition: The player revises their approach after experiencing a deviation (AR) or enacts an approach without experiencing a deviation (A).	**Noticing deviation (ND)** Definition: The player signals recognition of an outcome misaligning with their preference.	**Causal explanation (CE)** Definition: The player proposes a potential cause of the deviation.
Epistemic stance	**Certainty** Definition: The player's conviction that they understand and/or can plan game actions. Markers: saying "I know …", "I am going to do …", "oh". Speaking confidently. Taking directed action and moving without hesitation. Gaze can help determine what the player is referring to when language is vague.	**Uncertainty** Definition: The player's lack of conviction that they understand and/or can plan game actions. Markers: saying "I don't know …", "I am not sure…", "I think…", "um", "uh". Speech has questioning prosody. Moving aimlessly and/or with hesitation. Gaze can help determine what the player is referring to when language is vague.	
Emotional valence	**Positive** Definition: The player signals an overall evaluation of a game event as pleasant. Markers: Saying things like, "I am so proud of myself", clapping, cheering, smiling, laughing.	**Negative** Definition: The player signals an overall evaluation of a game event as unpleasant. Markers: Saying things like, "I am frustrated", "I don't like this", "Ugh", etc. Sighing.	

To explore patterns across varying levels of confidence and experience, we selected a subset of the data. We chose game levels where players reported the highest, lowest, and widest range of confidence (i.e., the highest standard deviation); we also chose some levels that were further into the game and levels that most players attempted. This selected data consisted of three levels from the introductory overworld ($M_{Confidence}$ = 4, 7.04, 5.73; $SD_{Confidence}$ = 2.49, 1.27, 2.8) and three levels from the first unlockable world ($M_{Confidence}$ = 3.1, 7.63, 4.32; $SD_{Confidence}$ = 1.66, 1.2, 2.5). The subset includes a total of about 5.5 hours of video across 66 clips. We then randomly selected 18 clips to use for interrater agreement checks. We iteratively checked and adjusted our codes after coding three clips at a time. Currently, we are still in the process of coding, but our interrater agreement has been charting toward strong agreement (overall simple percent agreement was equal to 74.6, 75, 89.7, and 95.3 across the first four checks). Because our agreement was quite high in our last check, the final check will include the six remaining clips.

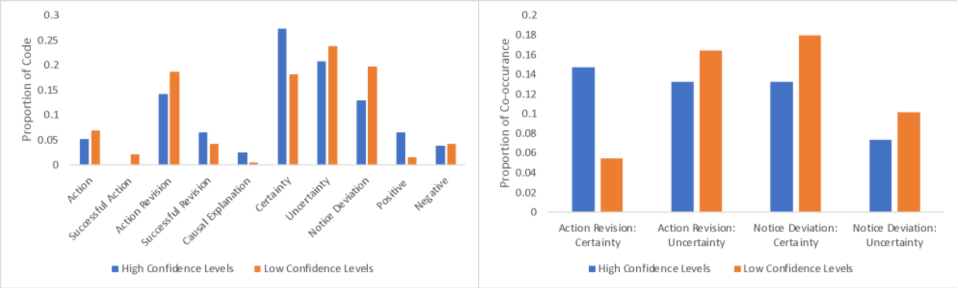
Initial findings and next steps

In addition to the confidence findings showing a significant negative relationship between time and confidence, there are two other initial findings described below. First, an unexpected pattern emerged regarding the coding scheme's granular representation of problem-solving processes. More specifically, we were able to capture dynamic switching between epistemic stance and emotion *while* players were enacting a problem-solving move. For instance, one player experienced a deviation and said, "what" and studied the deviation for a moment (this would be coded as uncertainty). Then, after gathering evidence and/or retesting their approach to explore if the same outcome occurs, they said, "oh, I see", (coded as certainty) and then revised their approach. This means it is possible to code each problem-solving move multiple times as players attempt to find their footing and shift back and forth between being certain/uncertain or experiencing positive/negative valence. Although we do not go into these patterns in detail here, we think they will further our understanding of what it means to study students' reasoning as they engage in a task.

We also explored the overall distribution of the codes in the currently analyzed data and what codes co-occur. We use proportions to compare high and low confidence levels because low confidence levels tended to be played for much longer, increasing the likelihood that more codes would be applied to them. Two emergent trends are shown in Figure 3. First, the most applied codes were ARs, NDs, Certainty, and Uncertainty, with higher confidence levels showing higher rates of certainty and lower rates of uncertainty. This suggests that the more certain players are about the knowledge they are generating, the more confident they will be. Second, the graph on the right provides more nuance than the graph on the left by providing what codes co-occurred with another code. We chose to focus on the level of certainty paired with ARs and NDs because they were the most salient. The most noticeable difference here is that high confidence levels showed higher rates of certainty and lower rates of uncertainty co-occurring specifically with ARs, suggesting players' certainty about their actions in response to deviations is a core piece of their sense of confidence. Overall, these initial results suggest that higher confidence may in large part relate to students knowing what plan they want to pursue after getting stuck.

Figure 2

The graph on the left shows the distribution of codes across high and low confidence levels, and the graph on the right shows codes that most often co-occurred with ARs and NDs across high and low confidence levels.



Our goal in this short paper was to present some initial findings from an exploratory study that used multi-modal data to inform an extension of a prior coding scheme. By connecting ES with emotional valence, our initial results showed that learning in *Baba is You* is a process that involves problem-solving while shifting between (un)certainty intermixed with positive and negative emotion. These initial results have the potential to move beyond the results of previous work showing emotion and uncertainty impact learning (e.g., Ozcelik et al., 2013) by exploring how these constructs emerge in problem-solving moves, which can apprise teachers of when to intervene in a student's problem-solving process. Beyond the small sample size, there are at least a few noteworthy limitations. First, we rely on outward expressions of ES and emotion, which could either be misinterpreted or misaligned with subjective experience. Second, since we are only coding ES and emotion with a problem-solving move, we are likely missing much of players' private, internal experiences of these dimensions. With these limitations in mind moving forward, we still hope to expand on the results presented here, deepen connections between constructs, and apply what we have learned in this study to other settings. A few next steps of the project are to finish coding the data and to continue to explore different qualitative and quantitative analyses.

Orchestrating Students' Systems Thinking About the Rock Cycle

Amanda Provost, Toni York, Su San Lim, Nicole Panorkou

Montclair State University

Abstract: This study examined middle school students' development of systems thinking as they explored the rock cycle in an interactive diagram. In this paper, we focus on the analysis of a design experiment with two students to discuss the teacher orchestrations that supported their reorganizations of meanings about the rock cycle's chain of materials and processes.

Background

Teaching and learning about the rock cycle, or the interconnected processes that change the earth's rocks over time, has been a concern of science educators for decades. Traditionally, the rock cycle is considered to include five materials, three of which are different types of rock, and the processes that transform them (Table 1).

Table 1
Processes and Materials of the Rock Cycle

Process	→	Material Created
Weathering and Erosion	→	Sediment
Compacting and Cementing	→	Sedimentary Rock
Heat and Pressure	→	Metamorphic Rock
Melting	→	Magma/Lava
Cooling	→	Igneous Rock

The teaching and learning of the rock cycle has been difficult due to its complexity (e.g., Vasconcelos et al., 2019). To support students' learning, diagrams have been used to show how the same processes can affect each of the types of rock and may also include the depiction of physical locations such as mountains as contexts (Peloggia, 2018). Research has also focused on developing students' systems thinking of the rock cycle, which involves (a) understanding the various materials and the processes producing them, (b) understanding causal relationships among specific processes and their input and output products, and (c) understanding the rock cycle system as a whole by recognizing that each output product of one process may serve as an input product for another resulting in an endless chain of processes and products (Kali et al., 2003). To support students' systems thinking, Kali et al. (2003) turned to the use of a digital learning environment that fostered students' reflection upon the interconnectedness of the rock cycle's processes and materials. In this work, students were found to have a static view of the rock cycle and struggled to internalize the idea of the rock cycle as a dynamic and cyclic system. However, students' development of systems thinking about the rock cycle was not described or how the teacher influenced that development. By looking at students' systems thinking from these perspectives we can understand how to best facilitate students' development of reasoning about the rock cycle within a technological environment. Thus, we aimed to explore: *(a)* How may students' systems thinking about the rock cycle progress as they interact with a technological environment?, and *(b)* How may the teacher orchestrate this development?

To study the students' development of thinking by interacting with a technological medium, we situated our study within the theory of instrumental genesis (e.g., Rabardel & Bourmaud, 2003). Through their interaction with an artifact, the student builds an *instrument,* which consists of both artifact and cognitive schemes. Each new instrument becomes part of a system of interlinked instruments developed earlier, which is constantly reorganized. To assist students' reorganizations, the teacher engages in *instrumental orchestration* (Trouche, 2005), a plan of action that involves forming conjectures based on the affordances and constraints of the artifact and acting as an orchestra conductor to engineer opportunities for them to reflect on their activity and reorganize their meanings.

Methods and design

We conducted a whole-class design experiment (Cobb et al., 2003) in a sixth-grade classroom in a large suburban district in the Northeast U.S. We created a new rock cycle diagram (Figure 1) that uses visual aids to depict a separation between processes and materials and clear connections between them. For example, all three of the melting process boxes are grouped near the magma/lava material oval to support students in noticing that the melting of any rock transforms it into magma/lava. We then designed an interactive computer simulation based on the metaphor of the earth as a rock cooking machine that allows students to select an ingredient (a rock cycle material) and a rock cycle process in order to build a recipe at the bottom of the screen. By clicking the Cook button, students can view the results of their selected recipe. If their selection is invalid, the result box will display a red X. A valid result is displayed both in the recipe and by the relevant path being highlighted in blue.

We prompted students to examine one process at a time and experiment with different possible recipes to determine which process belongs in each location. We conjectured that this focus on the processes would support their reasoning about the relationships between different processes and materials. This paper focuses on the retrospective analysis (Cobb et al., 2003) where we identified excerpts that illustrated the elements of systems thinking about the rock cycle described by Kali et al. (2003) and examined the teacher's orchestrations that facilitated students' constructions and reorganizations.

Findings

In this paper, we focus on one student, Laura, to present constructions and reorganizations of meanings that are possible when students engage with our specific instrumental orchestration.

Reasoning about various materials and the processes producing them

During a few minutes of free exploration, Laura tried combinations of materials and processes that presented her with both valid and invalid results. She was asked questions, such as "What two things do you control in this simulation?", "Which of these are processes that you can use to make recipes?", and "Which of these are materials that you can use as ingredients to make recipes?" Laura identified the variables of the diagram and distinguished between the two inputs. She stated, "You can choose the processes and the ingredients, to make a rock or sediment or magma." When asked to identify the non-rock materials she replied, "Because sediment and magma/lava are used to make certain types of rocks. They're not actually rocks themselves."

Reasoning about causal relationships among processes and their inputs/outputs

Next, Laura was prompted to explore relationships between the materials and processes. Laura discussed weathering and erosion when she was asked what process turns each rock into sediment. By trying this process with other ingredients in the diagram she explained, "To make sediment, it has to have other rocks eroding and weathering away." This showed the construction of the relationship that *other rocks + weathering and erosion* → *sediment*. Later in the investigation she was asked what patterns she noticed and she responded, "I noticed that all of the rocks, if you choose weathering and erosion, they turn into sediment," illustrating the relationship that *all rocks + weathering and erosion → sediment*. The researcher then asked her to clarify what she meant by "all rocks" and she explained, "Igneous, sedimentary, and metamorphic. If you choose all of them." Laura concluded, "If any type of rock weathers and erodes away it can turn into sediments," illustrating the relationship that *any rock + weathering and erosion → sediment*. The orchestrated questioning by the researcher encouraged Laura to reorganize her meanings into a more precise relationship.

When Laura was asked what patterns she noticed in her exploration, she talked about cooling: "Like ingredients, you can't cool some stuff because, you can't cool sediments, you can't cool sedimentary rock." Her reasoning shows that she identified that not all materials could be cooled, for example, *sediment, sedimentary rock + cooling → X*. When she was prompted to explain further, she stated, "You can cool magma and lava, you can't cool sediments or metamorphic rock, sedimentary, igneous." We interpret Laura's statement to show that *only magma/lava + cooling* was valid without focusing on a specific output. Laura was again asked about patterns she noticed and responded, "When magma is cooled, it turns into igneous rock," showing that she reorganized her meanings about cooling into the specific relationship that *magma/lava + cooling → igneous rock*.

When asked about other processes she explored, Laura stated that "Igneous rock turns into magma." Here she identified a valid relationship between an input ingredient and an output product, *igneous rock → magma/lava*, but did not note the process that was used to 'cook' the rock. The researcher then asked whether all the rocks turn into magma/lava and Laura responded, "No, I don't think so." She continued to try different combinations, and discovered, "Oh, they do. Sedimentary rock and melting can turn into magma and lava if it's hot enough." Her reasoning showed the construction of another relationship: *sedimentary rock + melting → magma/lava.* The researcher then prompted her to examine if all the ingredients turned into magma/lava when melted. Laura used the diagram to test out different combinations as she explained, "I think so. Oh nope. Because sediment, if you melt sediment, I think it's because it's like it's too small to turn into magma and lava. And you can't really melt lava. … Because magma's already melted." Laura's reasoning shows that she constructed a more precise relationship: *all ingredients except sediment and magma/lava + melting → magma/lava*. Laura's reorganization of meanings was orchestrated by the researcher's questioning that required her to reconsider the material and process combinations.

The researcher asked Laura about compacting and cementing and she explained that "If you compact sediment it turns into sedimentary rock." Laura's statement, *sediment + compacting and cementing → sedimentary rock*, was further questioned by the researcher, who asked if it was possible to compact other rocks. Laura used the simulation to test out other combinations before stating, "No. … When you compact sediment and it's like pressure when it's compacting it, over like millions of years, it turns into sedimentary rock."

Laura was asked how metamorphic rock was made and she stated, "Metamorphic rock is made out of compressed magma and lava. I'm not sure if that's igneous or, I mean, metamorphic." The researcher brought her attention back to the diagram and asked the question again. Laura responded, "Igneous and heat and pressure," illustrating that she reorganized her meanings into the relationship that *igneous rock + heat and pressure → metamorphic rock*. Laura was then asked if heat and pressure on all other rocks would produce metamorphic rock. She tried combinations on the diagram and replied, "Yes. So, I think it's created with heat and pressure." We interpret this as a statement of the relationship that *all rocks + heat and pressure → metamorphic rock*. Laura was later asked about the possible things that can happen to rocks. She explained that "if igneous or sedimentary rock has heat and pressure applied to it, it can turn into metamorphic," demonstrating the relationship that *igneous rock or sedimentary rock + heat and pressure → metamorphic rock*. The researcher questioned Laura about whether it was possible for metamorphic rock to undergo heat and pressure and encouraged her to use the diagram. Laura answered, "It stays to metamorphic rock," illustrating the relationship, *metamorphic rock + heat and pressure → metamorphic rock*. Through the researcher's orchestrated questioning, her meanings about the heat and pressure process were reorganized to a set of more specific relationships.

Reasoning about the system as a whole

After the Cooking Rocks lesson, students explored the life of a rock using a different simulation (https://acmes.online/htmls/bobslife/bobslife.html) that illustrates what material form the rock is in but does not show the related processes. When asked what she noticed in this simulation, Laura explained: "[It] turns into igneous, then it breaks down to sediment and turns into sedimentary rock because it gets compacted and then the pressure increases so then it turns into metamorphic for most of it. Once it reaches the lava it turns back into magma." Her reasoning shows that she was able to describe one complete path through the rock cycle by describing the processes the rock would experience. Laura recognized that the product of one process may serve as the input to another, illustrating a meaning of the rock cycle as an endless chain of processes and products.

Concluding discussion

Using the interactive diagram and probing questions, Laura developed her systems thinking about the rock cycle, showing evidence of the three elements described by Kali et al. (2003). Our analysis shows how specific orchestrations during the exploration supported Laura's constructions and reorganizations of her meanings about the relationships between the materials and processes of the rock cycle (Table 2). To elaborate, questions reduced visual complexity by focusing the student on one specific process at a time. Targeted questioning helped scaffold her exploration by starting with generic questions about her noticings and individual recipes before moving onto questions that asked her to generalize relationships between processes and input materials.

Table 2

Orchestration of Rock Cycle Systems Thinking

Systems Thinking	Supportive Orchestrations
Understanding the various materials and the processes producing them.	● Questions that led the student to identify variables in the simulation, e.g., *What two things do you control in this simulation?* ● Questions about the distinction between rocks and non-rocks, e.g., *Which two of the five ingredients aren't considered to be types of rocks?*
Understanding causal relationships among specific processes and their input and output products.	● Sequenced questions that led the student through each process, e.g., *What process turns [each material] into Sediment? Sediment is formed when any type of rock…* ● Questions about noticing, e.g., *What do you notice? What patterns do you see?* ● Questions about identifying all the materials that work or do not work with each process and explaining why, e.g., *Does it work for all materials? Why/Why not?* ● Student trials of ingredient/process combinations.
Understand the rock cycle system as a whole.	● Asking the student to reason about one possible path a rock might take through the rock cycle in a hypothetical environment (no diagram or process labels visible), e.g., *What processes do you think this specific rock experiences during its life?*

Table 2 thus helps us understand how to orchestrate students' development of systems thinking about the rock cycle within a technological environment. We are currently analyzing how other students' reasoning progressed through the Cooking Rocks exploration and examining patterns between different students. Because the findings of this study were a result of an interview between one student and a researcher, we also need to examine further how a teacher can provide similar guided questioning in a whole class setting.

Students' Constructed Explanations for How Artificial Intelligence Generates Recommendations in YouTube

Victoria Delaney, Stanford University, vdoch@stanford.edu
Parth Sarin, Stanford University, psarin@stanford.edu
Victor R. Lee, Stanford University, vrlee@stanford.edu

Abstract: This study examines high school students' dynamically-formed intuitive conceptions of one type of frequently encountered artificial intelligence (AI) technology: the recommendation system used in YouTube. Drawing from videorecorded interviews, we sought to understand how 18 students assembled explanations about how the platform's design used AI to provide users with video suggestions. Our findings have implications for how students construct knowledge of AI-systems by their own means, and yields implications for designers of curricular resources seeking to build from students' prior knowledge.

Introduction

The motivation for the present study is twofold. On the one hand, as new technologies appear and become more commonplace, this paper follows conceptual research that asks about the intuitions that youth have about how novel technologies work. The second motivation is that we wish to inform design of new learning experiences about specific classes of technologies. Currently, calls are being made to build artificial intelligence (AI) and machine learning (ML) learning experiences for school-aged students (Touretzky et al., 2019). While preparing students to pursue future work in these areas can be one motivation, public understanding of how AI works at a conversational level is also important for an informed citizenry and to reduce the risk for documented harms to groups that are frequently marginalized and harmed by technologies.

Based on collection and analysis of interviews with high school-aged students in the United States, we present three "assemblies" of knowledge resources that students drew upon in explaining the presence of AI in YouTube's recommender system. We ask: what explanations do students construct about how artificial intelligence generates recommendations? Recent work has looked at how children understand the operations of voice assistant technology (Beneteau et al., 2020) or the extent to which teens understand algorithmic bias (Lee et al., 2022). It is a research area we hope learning scientists will continue to contribute to now and in the future.

Theoretical framework

This work operates under the "knowledge in pieces" (KiP) framework (diSessa, 1988) by which student knowledge and reasoning can be understood productively as involving a complex system with many knowledge resources that are differentially accessed. KiP offers an overall orientation for how broadly and precisely knowledge should be described. However, on that foundation, various approaches have been used to recognize and refer to specific knowledge elements of importance. Theorized "collections" are one known type of knowledge element, and within "collections," "coordination classes" are a way of modeling "concepts" as they rely upon perceptual extractions and inferential networks of interconnected knowledge elements.

For this study, which explores what "collections" of knowledge elements are involved in explaining a contemporary technology, we draw from Sherin et al.'s (2012) "mode-node" framework. While maintaining the KiP commitment to modeling knowledge as a complex system, the mode-node framework is intentionally neutral about what is the precise form of those knowledge elements. Modes are functionally-grouped activations of nodes. Diverse knowledge elements are all considered "nodes" and could include remembered slogans and factoids, specific remembered episodes, and other knowledge resources in the extant literature. Given that we are focusing on contemporary technologies used in everyday life, students are likely to have varied specific experiences they recall, things they have heard, and general intuitions about how things should work in the artificial digital world. At the same time, when pressed to explain certain phenomena or observable behaviors, we expect that students are able to actively generate explanations. In this paper, we focus on those explanations and refer to them as "assemblies" to reiterate that they are constituted of sub-elements (nodes) in the moment.

Methods

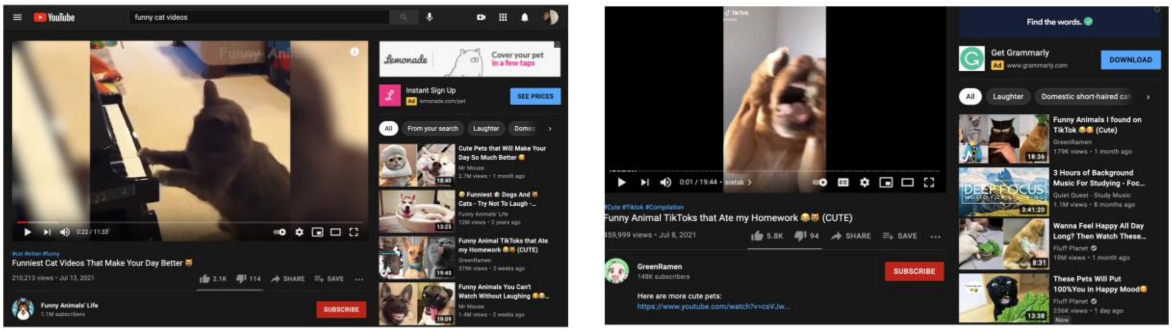
Participants and procedure

The participants in this study are 18 high school-aged students from a range of local high schools between 14 and 18 years old. 11 identified as female, 6 as male, and 1 as gender non-binary. Most (16) attended public schools, with 1 student from a patriarchal school and another from a private school. Only 2 students had taken AI-related coursework, which was achieved through after-school enrichment programs. A few students encountered AI concepts and ideas through their caregivers' career. Four researchers conducted 45-minute interviews with participants on the Zoom videoconferencing platform from January through March of 2022.

The interviewer asked each student if and how artificial intelligence was involved in three contemporary AI-based scenarios: iPhone's Siri voice assistant, YouTube's video recommendation system, and a hypothetical AI-based college recruitment technology. In this paper, we unpack students' ideas from the second scenario.

The interviewer displayed a visual prompt of the AI-based technology to students and asked them to state what they noticed aloud. Figure 1 shows an example of the visual prompt shown to students for YouTube's recommendation algorithm. Then the interviewer followed a semi-structured protocol with the goal of determining how students believed artificial intelligence operated within YouTube's recommendation algorithm. The interviewer followed up with clarification questions until they gained a complete understanding of the student's theory, or until the student said, "I don't know."

Figure 1
Visual prompts shown to students from YouTube.



Data analysis

This study follows a knowledge analysis tradition (diSessa, Sherin, & Levin, 2016) and is of the "microanalytic regime". After data were transcribed, students' assemblies about YouTube were identified and agreed upon. To be counted as an assembly, students' utterances needed to contain a causal explanation about how AI operated within the system, however primitive or incomplete. Some students constructed a single assembly, some students constructed multiple assemblies within the same response to the interviewer, and one student did not construct any assemblies at all. In total, we identified 37 distinct assemblies. Next, we analyzed and coded the data to unearth and categorize assemblies. Working first as individuals, we examined each student's explanation carefully, then identified the causal mechanism in each. Then, the research team held several joint review sessions where we systematically discussed and agreed upon groups of student assemblies. We discuss several patterns of explanations that appeared across students in the findings.

Findings

The *profile assembly* appeared in 14 of 18 responses. In this assembly, YouTube attends solely to the user and constructs a profile of that person's interests and habits. Then, it makes recommendations based on what content fits with that "type" of user. Mokund explained how the algorithm can do this using one's "watch history":

> "Maybe if you're really into, let's say, pencil videos like "how to build a pencil" … based on their watch history, they might have other suggestions that may not be as related to the video they're currently watching." (*Mokund's interview*)

Mokund suggests that the algorithm can parse a user's watch history and group videos by topic. He does not explain how YouTube does this, but it seems that recommendation algorithm needs to intuit that the video "how to build a pencil" falls into the category of "pencil videos." Once the videos have been grouped into categories, Mokund notes that YouTube can deduce what types of videos the user is "really into." Once again, he does not say how it does this. Finally, YouTube searches through existing data for other videos that fit into that category.

Other students described profiles as facts that YouTube's algorithm believes about the user:

> "Maybe … they think you have a pet. And since you're looking at a cat video, maybe they think you have a cat. So, they want to recommend some of their products." (*Jennalin's interview)*

When Jennalin describes the user's profile, she does not explicitly mention watch history or the patterns of user behavior. Rather, YouTube has a collection of beliefs about the user (e.g., "they think that you have a pet"). Like Mokund, Jennalin understands a profile to be dynamic and contain data that the algorithm uses to make recommendations. Yet, Jennalin does not articulate a theory about how those beliefs were formed.

Finally, McKenna described a profiling pattern based on intentional user differences:

> "It's branching out to more content. So, it's something in the viewer's comfort zone. But it's something different that could get them to look at different content and different creators." (*McKenna's interview*)

In McKenna's interpretation, the algorithm is aware of a user's profile ("comfort zone"), but it makes intentionally different recommendations to encourage the user to diversify. McKenna seems to think that the algorithm will generally recommend similar videos because users tend to stay within their comfort zone; so, videos that are only slightly different are likely to be successful recommendations.

Other students intuited that YouTube provides recommendations from attributes of video content or search. We labeled explanations like this as *attribute assemblies*. Students suggested that YouTube provides recommendations by comparing the keywords, content, or author of the current video to the keywords, content, or author of a potential video to recommend, absent of the users' search history. 10 out of 18 students described an attribute assembly. For instance, Wilhelm describes the impact of keywords in the user's current search:

> "Because of that input in the search bar, funny cat videos, that might prompt YouTube to search for videos that are related to cats, or just animals. Because, it also has that word funny. You can see the title of that first video is "cute pets that will make your day so much better." Maybe it's not directly related to cats, but it could be related to funny. And so, I think that they're searching for the keywords in the search bar, and then like finding videos that may relate based on the title." (*Wilhelm's interview*)

Wilhelm's description reveals several aspects of knowledge coming together to form an attribute assembly. First, he notices and connects terms in the search bar to content within videos. Then, he realizes that recommended videos on the screen contain content and keywords other than cats, such as "animals" and "cute pets," and he updates his theory to include words similar to "cats" and to "funny." Wilhelm demonstrates knowledge that multiple attributes (e.g., nouns or adjectives) are used by YouTube to assess similarity. Finally, his last utterance reveals a belief about how similarity comparisons are conducted: that keywords during search are matched or similar to ("relate[d] to") words in titles of recommended videos.

Other students built attribute assemblies from metadata. Erma noticed the content author:

> "If they know, for example, you like this creator, if it was from the same period, they could know that it's more likely that you like multiple videos from one creator than others." (*Erma's interview*)

Erma credits the YouTube algorithm to "knowing" that users enjoy videos from the same author, and explains that "it's more likely that you like multiple videos from one creator than others." To Erma, the aim of YouTube's algorithm is to identify similarity based on video authorship, then provide recommendations.

Finally, some students identified that YouTube's algorithm works by referencing the preferences and user histories of like-minded others. Only 4 of 18 students constructed theories about YouTube based upon others, which we labeled as *social proof.* Akshay proposed that YouTube provides recommendations by creating "lists" (e.g., rankings) of similar content between users:

> "Because [other] users that searched up funny cat videos, they might have clicked on one of those... you might have clicked on something that came up in the [recommendation] list, so

> they've just made like a recommended list of videos that you could watch after you've finished." (*Akshay's interview*)

Akshay's assembly draws upon social proof by highlighting how intersections in users' interests can be used to create lists of recommended videos. He suggests that users who view similar content likely have conducted similar searches. Then, he shows knowledge that what videos users click on informs their next searches. Akshay infers a structure used by YouTube ("something else that came up in the list"), suggesting that search histories are organized into lists and that recommendations are presented according to what each user's list contains.

Other students, like Annabeth, articulated the goal of providing novel content through social proof:

> "I think the technology wants to give them fresh videos, because if they see that people are searching it up, they would want to get eyes on something else and not the same [videos]." (*Annabeth's interview*)

Annabeth suggests leverages user communities to recommend videos whose content is intentionally different than what the user may be watching currently. The algorithm's goal is to examine what content users within the community are watching, and then to recommend different videos, because users desire novelty.

Discussion

Our findings illustrate how students who use AI-reliant tools make inferences about their functionality. We observed that visual aspects of the user interface cued various pieces of knowledge about AI for students at different times and in different, sometimes inconsistent, ways. For example, of the students who noticed the video view count, some related it to aspects of social proof ("popular videos") whereas others related it to content novelty ("new videos"). This finding suggests that while students are able to notice various features of digital technology, it is less apparent how the feature relates to the innerworkings of an algorithm.

Our study has implications for curriculum designers who seek to construct learning experiences based on students' prior knowledge of AI-based systems. We found that students do possess informal knowledge about artificial intelligence from their daily encounters, but there are some areas where instruction could build upon students' intuitive understandings. We hope that this study will serve as a first step toward developing a more nuanced model of how students make sense of AI-systems.

Adults as Users and Facilitators in Family Interaction with Multimedia Exhibits

Alisa Maksimova, Center for Advanced Internet Studies (CAIS), alisa.maksimova@cais-research.de

Abstract: The study is concerned with adults' and children's participation at multimedia museum exhibits. I examine how adults deal with their role as both facilitators for children and as users of interactive exhibits. To reveal which situated resources adults rely on to assess a child's interaction with an exhibit and to construct their own stance, video excerpts of visitors exploring a museum exhibit are analysed using videography. I demonstrate that adults treat repetition and unfinished action as indicators of children's trouble in interacting with the exhibit. The exhibit's material, spatial, and multimedia features, such as voiceover or shared display create opportunities for relevant feedback and subsequent action.

Introduction

Museums present diverse opportunities for self-guided, free-choice learning (Falk et al., 2006). Various hands-on activities and interactive multimedia installations are a crucial tool to convey educational content and construct meaningful and entertaining museum experiences for children and adults.

Interactive objects that visitors encounter often are unusual, and scripts they have to follow unclear (Laursen, 2013; Scott et al., 2013). This can pose a problem for family groups, where adults simultaneously aim to facilitate children's learning and themselves are faced with the necessity to examine and comprehend interactive exhibits. In this study, I elaborate how families interact with interactive exhibits in a museum of science and technology. I take the perspective of interactional analysis and use videography to study how adults deal with their dual role as facilitators in supporting children in exploring the interactive exhibit and as users of the exhibit. Two specific questions are considered: Which situated resources adults employ as feedback to assess a child's interaction with the exhibit? How do adults construct their own stance in the interaction?

Theoretical background

Family visitors have complex, mixed preferences and agendas. Multiple studies have analysed communication in family groups in museums and explored the ways to support their collaborative learning. Researchers argue that exhibits that promote collaboration between family visitors and allow them to build upon each other's interpretations lead to improved learning (Gutwill & Allen, 2010). Iterative design process has been implemented to study family groups engagement and develop principles for museum interactives encouraging rich parent-child sensemaking (Beheshti et al., 2018). Research of how families provide social scaffolds to each other and how social and material scaffolding are related in their interaction with exhibits shows that both communication and material features of the museum environment are important (Dornfeld Tissenbaum, 2018). Family members' modes of participation in the interaction ("roles", "stances", "contributions") have also been under examination (Shine & Acosta, 2000; Dietmeier & Devane, 2020). Family interaction is dynamic, participants take on different roles and are able to switch between them. Both children and adults lead interaction, however, their participation is qualitatively different (Dooley & Welch, 2014). The question remains how these adaptive practices are accomplished by visitors and how they are connected to the specific material informal learning environments.

As research shows, it is common for museum visitors to spend much time and effort on trying to work out the way to interact with a hands-on exhibit instead of engaging with its content (Hornecker, 2008). On the one hand, interactive objects often prescribe a strict sequence of actions which users have to follow to get the desired effect (Heath & vom Lehn, 2008), on the other hand, there also is evidence that visitors invent new scenarios (Laursen, 2013). Ambiguity of the script may lead to problems in interaction, leaving visitors confused and unwilling to engage with exhibits (Scott et al., 2013). Research has also focused on the ways to design for productive collaboration in open-ended and exploratory informal learning environments, where participants' tasks are not aligned (Tissenbaum et al., 2017).

In this study, I follow the idea that museum visit should be viewed as an embodied, situated social experience (Shaby & Vedder-Weiss, 2021; Heath & vom Lehn, 2008; Christidou & Diamantopoulou, 2016). Ecology of participation is formed around museum objects, with many modes and levels of engagement. Embeddedness of social interaction in the physical environment and multimodality of interaction are reflected in the concepts of embodied participation and embodied interpretation (Steier et al., 2015).

Methods

The data was collected in 2015 in a museum of science and technology in Moscow, Russia. In total, over 10 hours of video were recorded. A camera fixed on a tripod was placed in several museum halls so as not to bother visitors, but at the same time be visible to them.

Videography (Knoblauch, 2012) captures the multimodal orchestration of interaction and is able to overcome some limitations of methods that rely on participants' self-reports. The video fragments were transcribed using conversation analysis notation system. Transcripts graphically present action as it unfolds in the fragment. To note when and what happens, and which actions are responses to what, multiple iterations of rewatching the recording and updating the transcript are needed. Sound and visible transformations of the exhibit, as well as visitors' talk and actions were transcribed. For the sake of readability and brevity, transcripts are not included in the paper. One limitation of the study is that our recordings do not allow elaborate analysis of talk, as the museum was quite noisy. There was little opportunity to record sound near the exhibit and not to be too intrusive. Some of the audible utterances are included in the analysis.

In this paper, I will discuss two video fragments of visitor interaction with the same multimedia exhibit. Both cases involve a family engaging with the exhibit called "Rocket Launch", located in the hall devoted to space exploration. The exhibit has several parts, including a launch pad and a large screen, and is supplemented with a voiceover. A script for operating the exhibit goes as follows. After turning on the voiceover, the user heads to the box with the plastic details. The image on the screen changes: the metal door opens with a loud noise, and the visitor sees a launching pad with a silhouette of a rocket on the ground. The rocket must be assembled on the screen from plastic parts which attach due to magnets. If the rocket is not assembled on time, one can press the Continue button on the dashboard and get extra time. When it is ready, one presses Start. Rocket then takes off: the background image changes so that the assembled rocket looks like it is ascending. At a certain "altitude", "stages" of the rocket detach. Voiceover narration is intended to provide instructions and immerse the visitor in being present in a control center. In what follows I describe how social interaction unfolds in two similar cases: at the beginning stage of visitors' exploring the "Rocket Launch" interactive exhibit.

Analysis

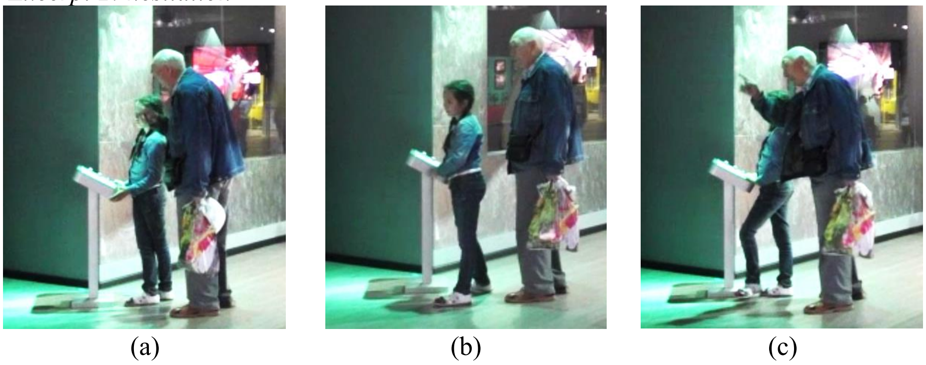
Excerpt 1. A woman and a boy approach the exhibit. After the boy turns on the exhibit, they go forward together and look inside the box. The boy stays near the screen, while the woman takes two steps back, taking the position of an observer. As the door on the screen opens, the boy moves a step back too. In his case, though, he is not withdrawing from the exhibit, but taking a visibly temporary position (his weight on one foot) which allows him to see the screen better (Figure 1a). The boy moves closer to the screen, picks up a detail and attaches it. As he holds the second detail, something catches his attention and he turns away from the screen. The woman uses his head turn as an opportunity. Gesturing toward the screen from a distance, she tells him he is holding the detail wrong and gives a hint ("look how it's drawn", Figure 1b). Seeing that he does not follow the hint, she comes to the screen and shows him where the magnets are (Figure 1c). She stays a few steps behind the boy, occupying a position that allows her to remain an observer with but also to rapidly intervene (Figure 1d).

Figure 1
Excerpt 1: giving instructions

(a) (b) (c) (d)

Excerpt 2. In the second excerpt, a girl and a man start by standing by the dashboard. They spend some time listening to the opening voiceover speech. Throughout the video fragment, the man almost does not change his body position. However, during the speaker's instructions he briefly points at the screen and immediately lowers his hand (Figure 2a), drawing the girl's attention to something. The girl then starts moving towards the screen, but as seen in the still, she does not let go of the dashboard. She does not make any further steps and after a hesitation returns to the initial position (Figure 2b). Her return leads to another hand gesture by the man, this time more pronounced and prolonged, as he points at the screen and tells her something (Figure 2c).

Figure 2
Excerpt 2: hesitation



(a) (b) (c)

The girl eventually comes to the screen and attempts to attach the first part. The attempt is unsuccessful, the rocket part does not stay in place. The girl holds the detail close to her chest and looks at the screen (Figure 3a). Then puts it back in the box, turns around and with her head oriented toward the dashboard returns there. The moment she starts to move away from the screen, the man takes a step back (Figure 3b), although he never moved closer to the dashboard. His step back is unnecessary - there is enough space for the girl anyway. His gesture works as production of certain role distribution in interaction, re-establishing the girl's leading role.

Figure 3
Excerpt 2: attempt and return

(a) (b)

Results

What details of the situation did adults orient to in order to assess a child's strategy of exhibit exploration? They are available to the analytic through pinpointing what preceded an adult's change of participation stance: what happened before an adult's pointing gesture, instruction, correcting or hinting utterance, etc. In excerpt 1, *repetition* of the same actions caused increasing adult's intervention: the woman comes closer to the screen to show the correct way to place parts after the boy does not change the way he tries to attach them. *Unfinished action* also serves as an indicator of troubles in interaction, as is evident in excerpt 2. At first, the girl hesitates to go to the screen: she starts moving and abruptly stops. Following it the man encourages the girl by gesturing toward the screen and talking to her. Likewise, when the girl holds the detail and looks at the screen without resuming to attaching it (Figure 3a), it is a part of constructing a "failed attempt". She returns to the initial place at the dashboard right after this. However, the girl's actions this time do not result in man's intervention. Instead, he takes a step back from the dashboard, allowing the girl to manipulate it (Figure 3b). Although he sees that she experiences trouble in figuring out how to assemble the rocket, he also sees that she does not look at him, but is headed straight to the dashboard. Her *gaze direction* thus does not open the supporting position for him. Children make their understanding intelligible. Performance of "not-understanding" tells the co-present adults that they can, or should, engage more actively.

Spatial organisation of interaction at the exhibit was a crucial resource for adult visitors to construct their stance. In excerpt 2 by not moving from the spot near the dashboard the man publicly establishes his role as not directly engaged. He actively makes room for the girl when she returns, allowing her to hold the leading role and explore the exhibit on her own. By contrast, the woman in excerpt 1 gradually occupies a more "authoritative" place, as she moves from a spectators' spot to instructor's spot right behind the boy. Her intermediary position halfway to the screen creates opportunity for more active engagement.

Finally, affordances of the exhibit contribute to feedback and action construction opportunities for adults. "Rocket Launch" has a stage-like area at the screen, so that it creates a *shared display*. While children are preoccupied with manipulating the exhibit, adults are able to observe the screen and a child's actions at the same time. By having the same objects in front of them as children have, they are able to quickly intervene. Moreover, the exhibit's voiceover sets up a particular *temporal order*, synchronises the action for all participants. The material, spatial, and temporal organisation of an exhibit enables certain modes of participation and creates opportunities to monitor children's actions. These findings are consistent with previous research which showed that shared space of tabletop exhibits offers opportunities for spontaneous collaboration even when participants have divergent tasks (Tissenbaum et al., 2017), and that exhibits' material scaffolds complement families' social scaffolds by enabling joint activity of visitors (Dornfeld Tissenbaum, 2018).

Conclusion

This study elucidates how adults deal with their dual role as facilitators for children exploring interactives and as novice users of the same exhibits. I demonstrate that adults treat repetition and unfinished action as indicators of children's trouble in interacting with the exhibit. Gaze, gestures, and body position serve important roles in coordinating the actions. Children's gaze direction tells adults if they are confused. Gestures help orient participants and give instructions. Body position, specifically the place occupied by a child or an adult, provides opportunities for participation and forms publicly available "roles" of spectators, active explorers, or instructors. The exhibit's material, spatial, and multimedia features, such as voiceover or shared display create opportunities for feedback and subsequent action. Thus, specific affordances of interactive exhibits are important if we want adults to have a clearer understanding of whether they need to engage in interaction and how they can do it.

Abstract: Socio-ecological histories of places are political, contested, and intimately linked with ways of knowing and being in the world. Thinking within and across time scales is necessary to understand the complexity of socio-ecological systems more deeply and to account for these layered and intersecting scales as a part of ethical decision making with and for places. In this paper, we describe our work as an interdisciplinary team of geoscientists, ecologists, fisheries biologists, and learning scientists to understand how STEM educators can use the Learning in Places Socio-ecological Histories of Places Framework, to support justice-centered, field-based learning. Our initial findings show that the framework supported STEM faculty in 1) situating humans as a part of the natural world, 2) making visible Indigenous peoples' time as central to disciplinary learning, and 3) thinking about ethical decision making as a central practice in disciplinary STEM work with students and communities.

Introduction

Socio-ecological histories of places are political, contested, and intimately linked with ways of knowing and being in the world in everyday as well as disciplinary contexts. Histories span across land, waters, plants, animals, and human communities over time, yet undergraduate science education in the U.S. is often taught in ways that render the powered and historical intersections of social and ecological systems invisible to learners and researchers (Learning in Places Collaborative, 2021). Thinking within and across many time scales is necessary to understand the complexity of socio-ecological systems more deeply and to account for these layered and intersecting scales as a part of ethical decision making with and for places– a practice that is critical to enacting just and equitable STEM research with places and communities. The Histories of Places framework involves thinking across six time scales to support learners in understanding how decisions lead to ethical, just, and sustainable futures and possibilities for humans as a part of the more-than-human world (see Figure 1). Providing a framework for thinking across multiple time scales supports learners and educators across contexts (i.e. K12, undergraduate, and professional) in being able to think about past, present, and future impacts to our lands and waters when engaging in field-based learning and research.

Environmental science research and learning rarely address colonialism in their fields of study, and often reproduce colonial structures and practices by engaging in ahistorical, universalizing, and discovery-focused field-based investigations that invisibilize the heterogeneity and complexity of ecological process that occur across peoples, lands, and waters at multiple scales (Liboiron, 2021). Supporting educators and learners in perspective taking and reasoning through contested histories of places are equity practices that allow for multiple and diverse stories to be told, honored, and incorporated into environmental and STEM professional learning and practice (McGrath & Jebb, 2015). Providing a framework for STEM researchers and faculty to engage in powered and historical analyses around the social, historical, and ecological dimensions of the places they study is required for enacting more just decisions in the future (Learning in Places Collaborative, 2021; Liboiron, 2021). Further, a failure to incorporate these histories reduces opportunities for STEM professionals to understand the complexities of social and ecological systems central to 21st century challenges, such as the environmental injustices that arise from the intersection of ecological crises and systemic racism.

The work we describe in this paper describes Learning in Places (LiP), a four-year, participatory design research study funded by the National Science Foundation. Learning in Places seeks to co-design (with classroom educators, families, and community-based organizations) learning engagements that support science learners and educators with equitable, culturally-based, socio-ecological systems learning and sustainable, ethical decision-making using field-based science education across settings and in partnership with families and communities. In this work we come together as an interdisciplinary team of geoscientists, ecologists, fisheries biologists, and learning scientists to understand how undergraduate STEM educators can use the Learning in Places Socio-ecological Histories of Places Framework, associated tools, and practices to support justice-centered, field-based learning in their own contexts that include undergraduate courses, projects, and multigenerational citizen-science efforts. **Research questions that guided this analysis are: (a) How do two STEM faculty across disciplines**

take up and use the Histories of Places framework in their own research and teaching?, and (b) How can attending to Histories of Places create more just and equitable framings of disciplinary learning across classroom, field, and community contexts?

Theoretical framing

STEM fields are increasingly recognizing the need to address social theories and context in the study of natural systems (Schell, et al, 2020; Hildebrandt, et al, 2018; Liboiron, 2020). We draw heavily from work in social design experiments (Gutiérrez & Jurow, 2016) and participatory design research (Bang & Vossoughi, 2016) to co-construct meanings and applications of Histories of Places across disciplines and contexts in partnership with STEM faculty in ways that integrate core principles of Learning in Places into their fields of study. These principles include positioning humans as a part of (rather than apart from) natural systems (Learning in Places, 2021), broadening what counts as STEM knowledge to include cultural and community ways of knowing, and making visible racialized and powered human decisions and actions that have shaped socio-ecological landscapes over time. Participatory design research requires a fundamental examination and critique of structural sources of inequity, and collective dreaming of alternative, more just forms of partnering. In the work, we intentionally engaged in co-design with STEM faculty to support the development of co-designers as historical actors (Gutiérrez & Jurow, 2016), and designers of their discipline's present and future orientations towards justice in higher education as well as community contexts. This involves not only a sense of one's own identity in broader cultural and systemic contexts, but also a historicized understanding of how certain practices--in particular, practices that perpetuate inequality--came to be and are sustained over time within STEM fields. We use this as a lens through which to examine the case studies presented below.

Design

In the Learning in Places project, we have designed a set of *educator frameworks* that make visible core dimensions of practice for just and equitable field-based science education. In this paper, we focus on one of those frameworks, called *Socio-ecological Histories of Places* (Learning in Places Collaborative, 2021). When scientists study complex systems phenomena in places, they need to understand those places across different scales of time and space. For example, when engaging in restoration, scientists need to first understand the history of a place and the various historical decisions that have been made to shape the land and waters of a place. They need to think across timescales–from geologic time to nation-state time to global time to the future–to understand how natural processes intersect with human decisions and the effects those might have on the future health of a place for all of its inhabitants (cf. Santos-Martin et al, 2019). The socio-ecological histories of places framework (see Figure 1) provides a pathway for supporting more expansive framings of disciplinary learning, teaching, and doing to account for the temporal and spatial variation of natural phenomena at scale, with a focus on centering humans and human decision making as a natural and emergent part of ecological systems.

Figure 1: Histories of Places visual graphic

Geologic Time includes the histories of lands, oceans, and other water processes.

Plant, Animal, & Soil Time includes the histories of plants, animals, and soils and their relationships to lands and waters.

Indigenous Peoples' Time recognizes First Peoples' histories, presents, and sovereignties in places and across time.

Nation-State Time refers to global shifts in political and economic structures that often include human movements across continents, powered shifts in technology, language, culture, and human relationships with the natural world.

Global Time includes how our local places are connected to, impact, or are impacted by other places across the earth and interact with other time scales.

Living Ethical Responsibilities and Possibilities Time includes the possible stories for places in the future.

Socio-Ecological Histories of Places diagram, Learning in Places Collaborative 2021

Methods and analysis

This study takes place in one public university in the Pacific Northwest. We use a case study method to understand how two STEM faculty members, who are co-authored on this proposal, understood, applied, and adapted the Histories of Places framework to their own teaching and research (Yin, 2017). For each faculty case study, we have collected multiple sources of evidence that included collaborative discussions about the nature and use of Histories of Places in their work during monthly faculty meetings (18 hours total), artifacts of their adoption of the histories of places framing for their work across contexts (including multigenerational citizen science programs, and STEM course design), and recordings of academic and community talks and workshops in which each faculty member describes their work the six socio-ecological timescales.

Initial findings

We found that the Histories of Places framework was taken up across multiple faculty members that participated in a small, interdisciplinary co-design group aimed at developing just and equitable models of science learning across STEM fields. Below we highlight two examples of how this framework was used by a geoscientist in an undergraduate GIS course, and a fisheries biologist in a university-partnered citizen science program.

Case Study 1: Visualizing socio-ecological Histories of Places with geospatial mapping tools

In co-design conversations geoscientists, Luis, shared that "most environmental issues or problems have a spatial and temporal dimension. When we teach undergraduates about these issues, we need to make sure they have an understanding of the complexity that this entails. There are many tools we can use today to help students visualize and interpret the interconnections between multiple socio-temporal dimensions to gain insights about where and why socio-ecological issues arise. These are usually contentions spaces, where people compete for resources and geopolitical control, but this is all mediated by particular cultural and socioeconomic conditions between people and places. Geospatial technologies such as geographic information systems (GIS) can help assess complex socio-ecological systems to address global environmental challenges and can help students visualize the scale of powered decision making over time."

In this case study, this faculty member shared how he used multiple layers in ArcMap to engage his undergraduate students in thinking about the multiple, historically-situated, and politically-contested socio-ecological histories of the areas around our University. These mapping layers moved from *hydrogeologic time* to *plant, animal and soil time* by showing how glacial formations shaped our region in ways that supported the emergence of unique ecosystems. He then positioned humans as a part of (rather than apart from) nature through these emergent systems by layering *Indigenous peoples' time* onto the map, noting that "we have a map of the ancestral territories of this area, and we can have a clear image of the human footprint even before Europeans arrived." In moving towards *nation-state time*, Luis shared that, "we know that these landscapes are contested and shaped by socio-ecologic and geopolitical factors, and here we have a layer of land that is currently under the jurisdiction of Indigenous peoples in the area." In moving between Indigenous peoples' and nation-state layers, students could clearly see the immense scale of land loss for Indigenous peoples locally as well as nationally. These visualizations supported students in understanding the patterns and lasting impacts of colonialism on peoples, lands, and waters in ways that oriented their independent GIS work towards proposing pathways for more just and equitable futures in relation to land-based decision making.

Case Study 2: Histories of Places through Stories and Study of Kokanee Salmon

In our second case study, a fisheries biologist, Greg, shared how the Histories of Places framework enabled him to "draw connections between biological systems and their historical and socio-ecological context" for Kokanee salmon. Greg noted that "there is a complicated history between what settlers have done to the landscape and what historically has been." Greg shared how he used the Histories of Places Framework across multiple contexts, including his work with tribal research partners, his undergraduate courses, a STEM field camp for marginalized youth, and a citizen science salmon monitoring program in order to tell the "many stories that can emerge from the study of Kokanee." In a talk with local community members about the future of Kokanee salmon, Greg shared that, "the story of Kokanee begins in the ice ages… much biology was built after the glacier receded and left behind freshwater lakes…Native Americans and Kokanee have lived here together since the retreat of the glacier over 10,000 ago. Historical records and stories show the origins of this relationship over time…. Just over 100 years ago the small streams were loaded with Kokanee salmon, which were thought to have gone extinct by the middle of the 20th century… but in 2021 we found middle-run Kokanee in a local stream. We found that these salmon that are historically important and culturally important are still with us, which brings up ethical responsibilities and possibilities for how to [sustain these populations] into the future."

In this excerpt, Greg makes visible the significance of Indigenous knowledge systems and relations to Kokanee in the region, and the impact of settler colonialism and resource extraction on both ecological and human communities over time, with an emphasis on ethical decision making for re-making more just relations with tribal members and Kokanee now and in the future. Greg recognized how colonial practices work to invisibilize these layered histories and how conservation work requires us to make them visible and present as a part of our decision making practices. In talking with local community members, Greg reflected, "If you think about kokanee and their cultural history of their evolution in lake systems… all of that is still here, but it's easier to overlook because our views are limited by our day-to-day interactions and it can be hard to see this history [because of powered decision making about the land and waters in our area].” In moving between timescales, Greg noted that “Native Americans and salmon have been here together since the departure of the glaciers, and Kokanee have and continue to be very important to Native Americans living in and around [our local lakes]. Greg shared how historic records and stories were foundational to understanding the biology and significance of Kokanee over time. In this talk, Greg shared a portion of the origin story for the Snoqualmie tribe, but juxtaposed this historical account with a contemporary one, stating that “Kokanee continue to be an important cultural component for the Snoqualmie tribe today and in the future” as is represented by the two quotes below. In this way, Greg, uses the Histories of Places Framework to uphold Indigenous presence in present and future awareness.

> “There’s a little story about how the Snoqualmie came to settle in Lake Sammamish, Lake Washington. To find that red fish and that red fish was only in two lakes, I think … Then they got a taste of that red fish, and they settle there.” -Ed Davis, Snoqualmie community elder (1888-1987)
>
> “Gathering on days like this, on this beautiful evening, is one small step in honoring the kokanee and caring for the communities connected by this little red fish. The Snoqualmie Tribe and these kokanee have been here since time immemorial.” - Snoqualmie Tribal Council Member Jolene Williams. 10/12/22

Our initial findings show that the Histories of Places framework supported STEM faculty in 1) situating humans as a part of the natural world, 2) making visible Indigenous peoples’ time and cultural knowledges as central to disciplinary learning past, present and future, and 3) thinking about ethical decision making as a central practice in disciplinary STEM work with students and communities.

Conclusion & implications

Shifting the dynamics of power and historicity in moment-to-moment interaction is central to creating educational equity and forms of education that support culturally thriving communities. We have a paucity of work that traces the learning pathways of STEM faculty learning more justice-centered practices, particularly as it relates to Indigenous peoples and histories. This study marks a new dimension of how place-based science education addresses the complicated and layered social histories of places as central to equitable learning within and about STEM fields.

Abstract: This linguistic anthropological case study examines one episode of play involving refugee-background teenagers participating in an informal STEM learning experience. This empirical case shows how the disciplinary practices of cosmic ray detector building were productively interwoven with spontaneous play directed by participating youth. The analysis reveals the need for a greater focus on play, which designers and researchers may initially dismiss as "off-task," but may in fact be an important component of disciplinary practice. Furthermore, we call for attention to play as a potentially important feature of designing and researching culturally sustaining pedagogies (CSPs) with and for diverse learners in informal STEM learning contexts.

Introduction

In this paper, we examine one scenario of extended play among five teenage boys making jewelry out of tinfoil whilst they are constructing a cosmic ray detector in an afterschool program for refugee-background youth. This spontaneous play had no direct content-based relationship to the disciplinary work students were engaged in. However, we argue that this moment of extended play encouraged students to interact with each other in relationally productive ways. And, we argue that by playing along with the students, instructors legitimized a form of youth-directed play to create a learning context that supported the participation of culturally and linguistically diverse refugee-background teens.

Literature review

Play has long been examined in educational settings for its social dynamics and for the role it has in learning (Goodwin, 1999). Research on play has also addressed impacts on learners' ability to work with peers, problem-solving skills, and use of prior knowledge to support learning (e.g., Taylor & Boyer, 2020). While these studies have addressed play-based learning among elementary school learners, fewer studies have examined the concept amongst older learners. Furthermore, the existing scholarship examines the experiences of learners in designed play opportunities (e.g., the "Physics Playground," Ba et al., 2021) as well as spontaneously while "tinkering" in a makerspace (McLean & Roswell, 2021). However, within STEM education, less attention has been given to play that researchers deem "off-task" or unrelated to prescribed disciplinary practices. In parallel to research on play, scholarship on creating more equitable informal STEM learning environments has explored the ways in which programs are culturally or linguistically sustaining for youth participants, ways in which programs fail to offer sustainment for students of color, and ways in which youth push back against hegemonic practices that leak from formal contexts into informal ones, to instead claim informal learning spaces as their own and to reshape the values and practices of those spaces (Calabrese-Barton et al., 2022). The CSP movement focuses on humanizing, decolonizing, socially just, and sustaining pedagogies that re-center the values, practices, and lifeways of marginalized students, thereby reversing course on the processes that lead to their marginalization (Paris & Alim, 2017). However, spontaneous play has not been specifically conceptualized within CSPs. Thus, we examine spontaneous play as a practice and suggest how such play might be conceptualized in the design of CSPs in STEM.

Theoretical framework: Identity pathways

As noted above, foundational research on play has focused on both its social functions and its role in structuring conceptual change or disciplinary knowledge development. We take the theoretical position that learning and social identification are inextricable (Wortham, 2006). Thus, in any moment of play, participants enact social roles (local identities, however momentary or enduring they may be) and orient themselves through language and embodied action to particular objects (e.g., components of a cosmic ray detector, or any other materials or tools in the physical space). In so doing, learners engage in identity work that crafts local personae that both reflect and construct their participation in the learning context. When designers endeavor to craft CSPs that create equity for traditionally marginalized students in STEM, we argue that they are attempting to design learning environments that afford students opportunities to engage in STEM-related identity work as part of a local process of becoming. In such processes of becoming, engaging in or refraining from what might traditionally be labeled "off-task" conversations about dating and other social activities can interweave with students' physics learning experiences and inform how students develop expertise in the disciplinary work of physics lab exercises (Braden, 2022). To explore and begin to understand how another commonly disregarded practice, play, may be related to designing CSPs with a diverse group of teenagers we ask: How does the students' jewelry-related play interweave with their detector building activities?

Methods

Context

This analysis comes from year two of a three-year ethnography studying the STEM identity development of teens in an afterschool program that specifically serves refugee-background youth. The program involves twice weekly sessions during the school-year, and a 1-week intensive summer experience in which students build and learn to analyze data from cosmic ray detectors and create digital stories about cosmic rays and detector building. The program also hosts twice yearly family and community events in which students share what they are learning with others. The research is guided by a linguistic anthropological framing with the goal of tracing students' pathways of STEM-identity development over time. Instructional design is informed by culturally sustaining pedagogies (Paris & Alim, 2017) and specifically focuses on relationship-building, power-sharing, student agency, and student-driven inquiry. The jewelry-making episode analyzed in this paper occurred during a detector building session at the end of year two during the summer session. Students were involved in wrapping the scintillator (produces light when struck by a cosmic ray) and light guide (directs the light towards a photomultiplier tube) to create a light tight seal around these components. The wrapping involves delicately cutting, folding, and smoothing multiple pieces of aluminum foil cut to size and taped down with electrical tape, followed by affixing pre-cut thin black plastic sheets and sealing the edges with electrical tape. To complete the detector, students then attached a photomultiplier tube to the light guide so that the light produced from the scintillator as a result of being struck by cosmic rays can be converted into a measurable electrical signal.

Participants

The five students represented in this analysis have the following national and linguistic backgrounds (all names are pseudonyms): Ali (Iraq; Arabic), Fabien (Congo; Swahili), Raphael (Mexico; Spanish), Habte (Ethiopia; Amharic) and Raj (Nepal; Nepali). Three of the students moved to the U.S when they were young through refugee channels, while Habte (refugee parents) and Raphael (unrecognized refugee status) were born in the U.S. Of the 5 boys, Fabien often seemed disengaged and disconnected socially from his peers and program staff. We noticed a shift in Fabien's engagement in the moment analyzed in this paper. The adults present in the data include the instructor, Ricardo (US - Puerto Rico; Spanish), who recently left a physics PhD program, Jordan, a PhD physicist (US; English), and program support staff (US; English).

Data collection

Audio and video recordings capturing naturalistic conversations, field notes describing communicative practices and episodes of interest related to how students discursively performed or resisted performing expertise in cosmic ray physics, and photos of students engaging in program activities were recorded in every program session by members of the research team who acted as participant-observers.

Data analysis

In this paper, we analyze one 25min jewelry-making episode which occurred during a detector-building session. The episode was initially identified in the broader corpus as an instance that might reveal success in delivering a culturally sustaining science learning experience. Specifically, we identified instances where students engaged in joint activity and conversation that transcended social lines around which the students sometimes organized (e.g., shared national origin, race, or language), and episodes in which students behaved playfully (e.g., laughter, smiling). The episode was transcribed for talk and embodied action using a linguistic anthropological approach (Wortham & Reyes, 2020), with modifications to enable us to examine the simultaneous activity of nine participants. The transcript was then viewed simultaneously with the video and coded in two rounds. The first round of coding traced and categorized the topics of talk and embodied action that students engaged in over the course of the episode (e.g., detector work, jewelry play, shooting play, conversation about psychics, etc.). The second round of coding focused on tagging moments of shift between play and detector work, which allowed us to see student-led changes in orientation, as well as to identify how the adults, the "physics experts," oriented to the students' play and detector work. During this phase, still images were made from the video to capture shifts in activity and joint attention to the jewelry and detector. Images were rendered into line drawings using Adobe Photoshop for inclusion in this paper.

Findings: How play interweaves with detector building

We found that all students who participated in the jewelry play alternated between constructing and commenting on the jewelry and wrapping the scintillator with foil. The jewelry play episode begins when Ricardo slides a piece of foil from the bottom of the detector and Raj gently slides the foil away from Ricardo and picks it up. Raj holds up the foil strip and looks at Raphael as if he is going to place the foil on him, but Raphael is not looking and leans forward to smooth the foil on the detector with the proper tool, a popsicle stick. Raj then puts the long strip of foil around his own neck and attaches the two loose ends together, carefully adjusting the strip to widen it slightly onto his shoulders. Fabien and Raphael pretend to shoot each other with popsicle sticks. Ali comments to Raj, "that's clean," which is slang for cool new attire. Ali and Raj are smiling and laughing, Habte looks on with a broad smile, briefly gesturing up at the necklace and continuing to smile and laugh. Fabien and Raphael continue alternating between smoothing the foil on the detector and play-shooting at each other with popsicle sticks, sometimes making gunshot noises. Habte then gestures to Raj and says, "diamond test it, bro, that's glass," and Raphael turns to Raj to examine the necklace. Raphael places the edge of the popsicle stick on the necklace and makes a sound "dee, dee, dee, dee," (simulating a beeping sound). An electronic diamond tester often beeps as it is reading the stone to indicate whether or not the gem is a diamond. The boys laugh hard. Ali and Ricardo are then folding the corners of foil around the scintillator. As the episode continues, the boys alternate back and forth between the jewelry play and work on the detector as depicted in Figure 1.

Figure 1

Alternating between detector work and play. The images span 4 min and are ordered chronologically from a-d.

(a) 18:04 - Fabien smooths foil with a popsicle stick as Ricardo unrolls it on top of the scintillator. Ali, Raj & Habte look on. Raphael and Raj are wearing their aluminum foil necklaces. Talk centers around Ricardo's back pain and posture.

(b) 18:46 - Habte reaches over the detector to pretend to diamond test Raphael's pendant on his necklace using a popsicle stick, Raj looks on and smiles. Fabien begins crafting a bracelet out of foil as he watches the diamond test. Ali and Ricardo look at the base of the scintillator.

(c) 20:39 - Fabien and Habte work together to tape down foil using electrical tape. Raj and Ali look on, Raphael touches his necklace looking away for a moment.

(d) 21:03 - Raphael picks up an audio recorder and pops out the USB plug to diamond-test Fabien's ring. Habte, Ali, and Raj watch smiling along with a staff person. Ricardo holds out a piece of tape.

The sequence of activity in Figure 1 shows how play was interwoven with detector construction. For example, Fabien's attention alternates between detector work in (a) and (c), and jewelry making and diamond testing in (b) and (d). Eventually, Raphael, Habte, and Fabien all construct tinfoil jewelry. As scraps of tinfoil are produced from cutting the sheets that they are using to wrap the scintillator and light guide, the boys smooth and wrap the foil on the detector and use the extra bits to make their necklaces and rings. Over the course of approximately 25 minutes, the boys transition back and forth between the jewelry play (including rounds of diamond testing), the work on the detector, and additional conversations that might be deemed "off-topic" in a more formal learning setting such as the difference between a psychic and a side-kick, and how to manage back pain.

Rather than taking away from the experience of detector building, we argue that this moment of extended play allowed the boys to construct practices that they found enjoyable while working on a scientific project. Two of the five students (Ali and Raj) had previously expressed interest in cosmic ray physics and coding. They frequently participated in science conversations with physicists in the program. Ali, Raj, and Habte had also been involved in constructing a detector prior to this one. For Raphael and Fabien, this was their first time participating in detector construction. Interweaving play with detector construction work created a joyful and engaging space for this racially and linguistically diverse group of students where they crossed social lines that were previously present in the afterschool program. Prior to the summer session, we had seen Raj and Ali work together, Habte and Fabien work together with other students from African countries, and Raphael usually worked with another Latinx student who was not present. By engaging in play surrounding jewelry making, students co-created a local version of youth culture that interleaved with their work on the scientific project of cosmic ray detector building. Crucially, rather than shutting down this play, the instructors and staff in the program celebrated the jewelry making by taking photos (Jordan & a staff person) and by validating the play with joint laughter, smiling, and engaging in talk around topics other than detector-making (Ricardo). The students and instructors were nonetheless focused on detector construction and worked steadily to complete the detector with playfulness along the way.

Conclusion & discussion

In offering this analysis, we begin to theorize moments of play as the construction and reproduction of youth culture. When these moments transcend the cultural and linguistic subgroups of the afterschool program, we argue that they reveal important relational work that is part of building an equitable informal STEM learning space. In informal contexts, designers and instructors should have freedom to (re)define the role of play in their programs and to develop strategies to support spontaneous play. Researchers may begin to see play as a sign-post of youth culture in the making in their learning contexts. And, rather than dismissing or shutting down this play as a distraction or unimportant component of the learning context, researchers might instead look to these moments to identify ways to further build spaces for youth culture to thrive as a means of creating inclusion. Such revision may require reimagining what counts as a "disciplinary practice." More research is needed on the playful practices of teenagers in order to further build the knowledge base on how to design CSPs in STEM.

Abstract: In K-12 science education research and design, narratives are commonly employed to contextualize content and foster engagement. This literature review analyzes 104 empirical studies, identifying three primary narrative types: authentic, realistic fiction, and science fiction/fantasy. Students are often positioned as problem investigators or professionals in story plots. The narrative types are correlated with nine science learning outcomes, revealing their use and student positioning in K-12 science learning environments. Future research will focus on evaluating the effectiveness of narratives in enhancing science learning and exploring supporting technologies and mediation.

Introduction and background

Sociocultural theories emphasize the importance of embedding learning in meaningful tasks (CTGV, 1997). By creating narrative flow and mimicking complex scenarios, using stories in learning environments can contextualize learning objectives and promote learners' immersion and involvement (Barab et al., 2007). Given the role of storytelling in art, communication, social life, and sensemaking across cultures, it is an appealing tool for educators and designers to use in creating engaging and effective science learning environments (Mawasi, 2020). However, many types of narratives exist, ranging from simple one-time animating scenarios to expansive immersive learning environments. Further, narratives can be embedded in different instructional models such as problem-based, project-based, or game-based learning environments (Hmelo-Silver, 2004). To explore what kinds of stories researchers have designed and their effectiveness, we initiated a systematic scoping literature review on the role of narrative in science education. Based on this review, the present paper focuses on the kinds of stories researchers design and how different story types affect science learning, with the following research questions:

- What types of stories has the field used in K-12 science learning environments?
- How are learners positioned within these stories?
- How are different types of learning outcomes related to types of narratives?

In this paper, we use "narrative" and "story" interchangeably. Both fiction and non-fiction narratives are pervasive in human life and integral to cognition (Dickey, 2011). They represent information in terms of sequences of related events, often with cause-and-effect relationships (Prince, 2003). Humans have used stories to construct, communicate, and learn (Mott et al., 1999). Therefore, when narratives are embedded in learning, they leverage learners' inherent cognitive competencies to situate them into the context formed by the narrative (Wells, 1986). However, given the wide use of narratives in science education, it is not clear if there are important differences in what kinds of stories are told, how students are positioned in those stories in K-12 science education, and whether different kinds of stories promote different learning outcomes. We build on Mawasi et al's (2020) review to examine narrative in both digital and non-digital environments from a learning sciences perspective.

Method

To conduct this literature review, our team followed practices outlined by Alexander (2020). We iterated on search terms and selected databases. We ultimately used the search terms:

- ("narrative-centered" OR "story-centered" OR "scenario-centered" OR "problem-centered" OR "narrative-based" OR "story-based" OR "scenario-based" OR "problem-based") AND (STEM OR science OR engineering) AND (learn OR learning OR education) AND (classroom OR school OR class) AND (method OR study OR studies OR methods OR methodology)

We searched four databases using specified terms: Web of Science, ERIC, selected ACM conferences, and the ISLS proceedings repository. Ultimately, we prioritized studies that met each of four inclusion criteria, namely that the articles had to include: (1) narrative-related instruction, including scenarios, stories, and problems, with the specific narrative explained in the article; (2) empirical data about student performance in the environments; (3) studies based in a science discipline; and (4) K-12 school contexts. An initial search yielded 4,273 hits, and after two review rounds, 109 articles remained as valid studies. Excluding five articles with narratives only for assessment, 104 articles were analyzed.

Employing an inductive approach akin to thematic analysis (Braun & Clarke, 2006), we examined scenarios in each article, assigning initial codes to narrative features and developing groupings. Themes were identified and described preliminarily. Our systematic review aimed to characterize existing narrative types in studies, focusing on how stories support learners considering their age, curricular standards, and learning outcomes. To assess the effects of narrative learning environments, we examined each dependent variable for positive, negative, or neutral (i.e., no effect). Utilizing a vote count approach, we included qualitative and quantitative studies, deeming an effect positive if statistically significant or qualitatively improved.

Findings

Types of narrative

Inductive coding identified three narrative types concerning reality: (1) authentic scenarios, (2) realistic fiction scenarios, and (3) science fiction and fantasy scenarios. *Authentic narratives*, found in 31 of 104 studies, involve real-world events, people, or phenomena, making science learning personally relevant and plausible. In some studies, natural phenomena were described, such as the mechanisms for how vaccinations work (Yang et al., 2021). Other studies focused on narratives that requested students to investigate social issues (Sterling, 2007) or environmental issues (Evrim & Dadli, 2020). In another example, Drymiotou et al. (2021) used STEM-related career-based scenarios to situate students within personally relevant contexts.

Realistic fiction, following realistic logic, the objects in the stories exist in the real world, and the characters behave as real people would (Chavez, 2022). As the most frequent narrative type in 55 of 104 articles, realistic fictions mimic real-world situations, allowing researchers to incorporate scientific concepts into the narrative more easily. Fifteen of the 55 studies positioned the realistic fiction narratives as requests from stakeholders (Cerezo, 2004). Still others positioned their realistic stories as mysteries to be solved. For example, Sabourin et al. (2013) put students in a game-based learning environment called Crystal Island to investigate a mysterious disease. Often used in problem-based learning environments, these narratives can be presented as requests from stakeholders or mysteries requiring investigation.

The remaining 18 studies employed non-realistic stories, including *science fiction* and *fantasy*. Science fictions are tales of potential future science and fantasy with supernatural elements (California Department of Education, 2021). Examples include Alien Rescue, a technology-enhanced STEM astronomy curriculum that employs PBL (Liu et al., 2002). Some other studies utilize widely known fantasy stories, including *Harry Potter* (Beaton, 2004), *Cinderella* (Talaue et al., 2015), and *Frankenstein* (Mawasi et al., 2022). These narratives offer complex systems for exploring science concepts without real-world constraints.

Student roles

We examined whether the 104 reviewed studies positioned learners as characters in the narratives. 65 studies involved students as active participants, adopting *professional roles* or acting as *problem investigators*, while in 39 studies, students had *no role*, learning from a third-person perspective.

In 29 studies, students assumed *professional roles*, designing projects for stakeholders. Such curricula often involved writing, drawing, or hands-on exercises. For example, in a study by Lee and Bae (2008), students were requested by the city board to propose and present solutions to two problems involving the construction of a high school and vocational issues in Hawaii. Adopting professional roles provides simulated experience, allowing students to apply knowledge and develop skills like communication and collaboration. In 36 studies, students were positioned as *problem investigators* of a mystery (e.g., Sabourin et al., 2013), phenomenon (e.g., Cheng et al., 2017), or object (e.g., Sterling, 2007). For example, students investigated car accidents using Newtonian Kinematics and Friction (Kapur & Kinzer, 2007). The position of problem investigator may enable experience narrative transportation by drawing students into the story as agentic participants in the narrative flow.

Finally, in 39 studies, narratives served as instructional materials providing context and problem triggers *without* assigning student roles. This could be because the stories were based on or imitate real-world events that had already occurred; students could not change what happened (Batlolona et al., 2019). Some studies provided multiple scenarios around disciplinary ideas. For example, Evrim and Dadli (2020) arranged five independent scenarios about the ecosystem and related concepts. These stories were authentic or realistic fiction, allowing students to investigate and analyze situations from a third-person perspective.

Types of learning outcomes

Our final research question addressed science learning outcomes associated with narrative use. We identified nine themes characterizing the outcomes: (1) content learning; (2) inquiry skills; (3) other cognitive, higher-order thinking, and ethics skills; (4) collaboration and interaction; (5) argumentation; (6) motivation, engagement, and participation; (7) self-efficacy and confidence; (8) interests and attitude; and (9) self-regulation. Using a "vote count" approach, we examined learning outcomes in both quantitative and qualitative studies. For each type of narrative, we identified the types of outcomes measured and then the number of positive effects. We analyzed the relationship between learning outcomes and narrative types, noting that multiple outcomes were examined in many studies, totaling more than the 104 studies reviewed.

Various assessment tools were employed to measure learning outcomes including qualitative, quantitative, and mixed-method approaches. *Content learning*; *inquiry skills*; and *other cognitive*, *higher-order thinking*, *and ethics skills* were primarily assessed through formative and summative assessments, while *collaboration and interaction*, and *argumentation* skills were often measured using surveys and questionnaires. *Motivation*, *engagement*, *and participation*; *self-efficacy and confidence; interests and attitude;* and *self-regulation* were typically reported through questionnaires and interviews. Realistic fiction was the most studied narrative type for promoting disciplinary learning, such as content knowledge. For instance, Georgiou and Kyza (2021) used a mystery to foster collaborative problem-solving and achieve high conceptual learning gains. Realistic fiction was also used to facilitate learning and to support practice of inquiry collaboration, and self-regulation and thinking skills. Content knowledge was the most frequently measured outcome across all narrative categories, with inquiry skills also frequently assessed in realistic fiction studies.

Vote count results show predominantly positive outcomes, particularly for content learning (93%). Inquiry skills and argumentation also demonstrated uniformly positive results. Measures of inquiry skills include problem solving, scientific inquiry, investigation, and data collection. Other cognitive and higher-order thinking skills, which include reflective thinking, critical thinking, and creative thinking, had lower proportions of positive effects, but there were also a relatively small number of studies in which those were measured. These were lowest in authentic scenarios and highest in realistic fiction. A small number of studies measured collaboration, and these were generally positive across narrative types. Argumentation was only measured in realistic fiction with all positive results. Affective and strategic measures were generally positive, with the exception of interest in science fiction and fantasy narratives, where only 3 out of 6 studies showed positive effects.

Discussion and implications

This review aids in building our understanding of how narratives have been used in K-12 science classroom research and their associated learning outcomes. Our findings suggest that many types of narratives have been effective, but that it is productive to consider the desired learning goals as well as how disciplinary knowledge can be embedded in narrative-centered inquiry before making decisions about narrative type and student positioning. For educators, this often may require making choices about what narratives and positions will be most engaging to students in ways that increase participation as compared to a non-narrative-centered discussion of the topic. Learning designers should engage in in-depth research or co-design with target students, teachers, and communities to develop relevant content and storylines with a deep attention to the relevant science ideas and how they can best be situated in a learning progression as well as a narrative. Further research is needed to understand the what alignments between different narrative types, problem types, tasks, and pedagogical approaches result in which kinds of learning gains in narrative-centered learning environments.

Worldmaking in COVID-19:
Youth Restructuring Reality via Anime Roleplay

Abstract: This paper examines youth co-creation of anime-focused roleplay practices in an online program during the COVID-19 multi-pandemic. These roleplay practices reimagined and repositioned the online learning environment as a disruptive, multimedia space of new possibilities for youth direction of expertise and imagination. We argue that youth roleplay can be a justice-oriented, participatory learning practice, with potential to disrupt informal learning environment design and support a regenerative shift toward new ways to learn and engage.

Introduction and significance of youth worldmaking

The COVID-19 pandemic forced millions of U.S. students into virtual life: school, extracurriculars, and peer socialization structures were digitally transformed. At the same time, decades of local and national labor, health care, and housing injustices put Black and low-income communities under greater economic stress and at greater risk of COVID-19 infection and complication. Situated within these unprecedented-yet-historicized contexts, youth created structures of support to connect, imagine, and create together. As our after school makerspace program went online in the 2020-21 school year of COVID-19 quarantine, we observed youth spontaneously begin discussing and roleplaying anime as lenses and languages for reimagining and restructuring relations to one another, to their work, and to the world. They laughed and joked within favorite anime/manga roles, cultivating shared narratives and ways of being/speaking to reposition reality as more playfully malleable. They layered on top of this repositioning their own desires, hopes, fears, worries, and ways of being to create a new world of expanded possibility. We refer to this as ***worldmaking***; a practice wherein youth restructure and reposition themselves in relation to each other and the world around them. This was an act of reimagining and reorganizing the world towards more playful possibilities, leveraging specific ways of being to reimagine learning in pandemic context.

Worldmaking

We situate our study in the idea of worldmaking (or worldbuilding) as a social process by which people collectively imagine in order to co-construct. We define the worldmaking we witnessed in our community as a reimagining and repositioning of the online learning environment into a disruptive site for new possibilities. Worldmaking is about seeking something further than systemic collapse of traditional power structures. As youth "require more than resistance," they engage in inventing the future towards new sociopolitical narratives (Hassler-Forest, 2016, p 174). In centering youth imagination and co-construction, we honor youth-expressed desires to expand the possible. As worldmaking includes reimagining and reorganizing the present as well as multiple possible futures, this necessarily involves identity development (Holland & Lave, 2009, p 2). In our online makerspace program context, then, we recognize broader forms of learning that comprise all interactions that youth participated in together as they sought to make shared sense of the complex and unjust world around them in the midst of a multi-pandemic. Such a youth-centering focus on community practices involves paying attention to the subtleties of youth interactions and repertoires of practice as imbued with "radical political potential" (Hassler-Forest, 2016, p 17). But rather than centrally organized argumentation, such practices get shared among youth in more untraditional and joyful ways. In this way, youth find ways to engage together in worldmaking with "multitudinous energy," using learning spaces as sites for "looser, more playful form(s)" of disruption that embrace alinearity (Hassler-Forest, 2016, p 20).

Anime-mediated practices to reimagine reality

In the context of a multi-pandemic of health suffering exacerbated by racial and economic injustice, we are interested in how youth used our online afterschool program as a type of digital-imaginary reality to accomplish this regaining of control over their reality by inventing new forms of collective control (Hassler-Forest, 2016, p 174). We aim to highlight how the emergent youth roleplay was a way to reimagine and reorganize our digital space into the site of new potentialities youth needed in the 2020-2021 remote school year. Following Stornaiuolo and Thomas (2017), we position this study to "emphasize and amplify youth efforts to be heard and to affect change in order to disrupt deficit discourses" (p 338). Anime roleplay and related digital self-representations and restructurings were speculative practices developed from youth knowledge and culture, where "friendship itself frequently became a resource on which to draw in the moment of creation of a new game." (Potter & Cowan, 2020, p 260)

Framework: Worldmaking via collective, imaginative digital practice

In the in-between and undefined landscapes of online reality (McDougall & Potter, 2019), youth find access to sites of social/emotional and sociopolitical freedom to be and become in radical ways that align with efforts towards social transformation. In digital media spaces, knowledge and expertise can be developed outside of the constricting confines of sexist, racist, and classist power hierarchies (McDougall & Potter, 2019; Parry et al., 2020). The "productively disruptive" spaces of youth digital practice require peer collaboration to negotiate and map out progress (Parry et al., 2020, p 409), lending themselves towards "flatter structures" of social transformation and new creation (Cannon, 2018, p 8). This imaginative remixing also connects worldbuilding to identity work as a part of a collective learning-and-development process. By looking at youth-produced digital media as identity artifacts and assemblages, we can witness youth efforts to become as they seek to change the world around them.

Context, methodology, & methods

The data for this paper was generated in a community of youth who attended a local community-based makerspace, the Green Club (GC), housed in an afterschool center in Great Lakes City, a medium-sized city in the U.S. Midwest. GC is a community-centered makerspace, meaning that youth who participate in this program design, prototype, and build projects that are meaningful to the community. In the 2020-21 school year, this program was taken online in response to youth and parent requests and co-design conversations. The lead researcher of this program and the last author has a decades-long partnership with this organization, while the first two authors have been working with the youth in this program for 9 and 3 year(s) respectively. The third author is a volunteer and former member of GC.

Using critical participatory ethnography with six participating BIPOC youth (ages 12-14), data include recorded Zoom sessions, Zoom chat logs, interviews, focus groups, informal dialogue with youth and parents, and 2020-2021 youth-produced artifacts. Data also included participant-observation and co-viewing (multiple sessions involved peer debates about what character traits fit program adults, with three authors following youth recommendations to watch particular anime).

Data analysis included youth artifact co-analysis using youth artifacts and multiple rounds of researcher analytic memos, shared across co-authors. We co-analyzed data with participants using critical inquiry/grounded theory, in a constant comparative, continuities/contradictions approach (Charmaz, 2017). We developed a set of emergent open codes, focused on forms and focus of roleplay. We generated analytic memos for each Zoom session that involved roleplay, using critical feedback from participating youth to guide iterative analysis. These memos helped us organize open codes into relevant categories and generate insights on youth worldmaking practices of roleplay. Then in axial coding, we referred to our conceptual frameworks to establish relationships between forms/focus of roleplay and purposes as described by youth. Meanings were debated until coauthors came to a consensus interpretation of themes of youth engagement in digital practices as part of our afterschool program.

Findings

Youth co-created and leveraged anime in multiple ways to reimagine and reposition their learning environment as a disruptive, multimedia space of new possibilities. Here, we describe roleplay as an anime-mediated digital practice youth engaged in towards this reconfiguration. For more, see our forthcoming paper (Greenberg et al., 2023).

Anime roleplay as worldmaking

Youth collectively, and unprompted by adults, engaged new acting repertoires to create and be/become in ways that supported them to navigate through COVID-19 extreme isolation and uncertainty. We saw this support youth to assert a coconstructed sense of stability through an imagined alternative reality, shared within trusted peer relationships of silliness/goofiness and joyful resistance to traditional interaction modes. We highlight two dimensions of this roleplay: renaming and teasing/play-fighting. We highlight these to bring attention to how roleplay shaped youth's engagements with one another and how this ultimately created the conditions for youth's relationship building. Over time, such roleplay practices reimagined our maker program as a multimedia playground for remaking reality as more playful and malleable. Youth layered their own desires, hopes, fears/worries, and ways of being/speaking/thinking on top of their work, creating a new world of expanded possibility.

Renaming practices: Role of the characters

Roleplay was a reimagined way to be with friends despite social isolation, but also a way to embody and enact identity work in active and peer-encouraged ways. Youth changed their names continually throughout the program. They enacted new identities-in-practice by taking on alter-egos, personas either directly reflective of favorite anime/manga characters or hybridized with their own identities and names. When arriving to our digital sessions, many of them had already signed into their Zoom programs with these alternative names and had already changed their Zoom backgrounds to feature images of their chosen characters. They would take characters names from their favorite animes, create nicknames as character-referring aliases, and combine their own name and character names to visibly announce their desired hybrid identities, such as "Finn Midoriya." These practices solidified both how the youth related to each other in the virtual space and also helped understand each other.

Teasing and play-fighting in character

Teasing and play-fighting in character, as we see in the example, occurred almost every session we met during the 2020-21 school year. Roleplay often took on rough-housing playfulness, surrounded by laughter, one-upping practices of improvisation, and debate-style arguments weighing evidence presented by peers. Importantly, in an interview after the year ended, Lulu mentioned that Bakugo shares similarities to her personality of good-natured teasing but also short fused impatience (the character is overconfident and aggressive, though his beliefs in his own abilities drive him to work hard and support others). Lulu channeled him often through changing her name, using his sayings in chat and in maker projects, and changing her background to his image. This shows that what was important to the youth was who the characters are- the relationships can be rewritten as the youth see fit.

Anime-lensed digital production as worldmaking

Reorganizing our online program through an anime-centered lens helped youth remake our learning community. This allowed for a shared language and shared origin stories to serve as a foundational background of solidarity and social/emotional safety, contextualizing their ways of hanging out and chatting with each other as they engaged in digital practices. We witnessed youth leverage this shared background to enhance their practice engagement. For more information about our second finding, see our forthcoming paper (Greenberg et al., 2023).

Discussion

As our community went online, we witnessed youth engage in practices to co-create and reimagine existing relationships, structures and resources. As adult facilitators, we sought to recognize, support, and begin more explicitly planning around such practices, to incrementally leverage them towards enhancing engagement in our digital space. As we did so, we noticed how central anime roleplay was becoming to youths' daily engagement repertoires in our Zoom sessions, leading to new possibilities to direct expertise and imagination. Their collaborative efforts supported a regenerative shift toward new ways to be and become together, including new forms of identity development and new relationalities to scaffold collective maker practices. We consider broader implications of these findings, for youth learning and development and for program design in a multi-pandemic informed future.

First, youth in this study demonstrated how anime-mediated practices opened up new possibilities for being and becoming together in the context of digital making, with digital production technologies as tools of identity play and tools of storytime with friends. This was a joyful resistance against the felt personal constraints and social isolation of youths' lived realities outside the maker program. In the context of a global multi-pandemic, we know that engagement in digital practice often served as a conduit for access to social/emotional support (e.g., online art and coding communities, anime affinity websites, and friend networks). In our disciplinary learning space, we saw how dynamic and fluid processes of sharing and co-constructing knowledge were integral to productive digital practice (McDougall & Potter, 2019). Supporting youth-defined imaginative and collective uses of digital tools can support youth wellbeing in learning spaces. We seek here to call attention to the "fluid non-linear affordances of digital media that favor collaboration and plurality" and how such dynamic fluidity allows for imaginative remixing or repositioning of reality in collectively beneficial ways (Cannon, 2018, p 8).

Second, in engaging anime-mediated digital production practices, youth helped us to reconsider the design and purposes of a maker learning environment. Our positionings as youth accomplices helped us facilitate youth disruption and restructuring towards collective reimagining of our learning environment. As part of this, youth disrupted our own assumptions about learning outcomes, pushing for expanded "sociomaterial practice" in making (Friesem, 2020, p 263). We were invited to reevaluate our own understandings and values (our own epistemic and axiological perspectives) of what counted as learning and participation in a maker program.

This can serve as a wakeup call to reconsider structures of hierarchical engagement in informal learning spaces. Unique patterns of youth-agentic discourse develop in different learning spaces, especially where youth feel empowered to express themselves and support each other. What discursive patterns develop in these spaces are important to notice in service to learning how to better facilitate and leverage them towards expanded opportunities for learning and development that acknowledge youth lives, ideas, and dreams as valuable forms of knowledge and practice. By prioritizing collective youth imagination, we could support youth-directed positionings and identities. This opened up ways to digitally embrace and facilitate who youth were and wanted to be and become, while offering a space of social and emotional support in a time of fear and uncertainty.

Conclusions

We studied how youth brought specific forms of knowledge and ways of being to reimagine what an online space could become and how this helped youth remake the world towards new possibilities. During the COVID-19 pandemic, youth had to process rapid, extreme changes in many aspects of life. Embracing anime roleplay online allowed youth support and recognition for using new tools towards identity exploration and shared meaning-making in a time of heightened uncertainty about life and the world. It also supported youth in leading imaginative structural reorganization. All of this contributed to enhancing their shared learning and their reimaginings of what community practice could look and produce. Youth maker work became acts of reimagining and reorganizing the world they saw around them, when they decided that that world was simply not enough.

Material Anchors for Young Children's Spatial Planning: Contextualizing Path-Program Relationships

Deborah Silvis, State University of New York at Cortland, deborah.silvis@usu.edu
Jody Clarke-Midura, Utah State University, jody.clarke@usu.edu

Abstract: Planning a path from an origin to a destination is a common task for studying children's spatial thinking and a foundational part of many early programming environments. This paper examines children's means of abstraction between the grid space and the program domain through an exploration of the strategies they used to plan a robot's routes in 2-D space. Qualitative analysis focused on ways children used materials to aid in spatial planning and programming, advancing previous work on material anchors for concepts (Hutchins, 2005). Through an elaboration of several path planning strategies, we illustrate how children varied in their use of materials in space to represent a path-program relationship. We argue that these strategies represent multiple ways of contextualizing and abstracting in a programming task, with implications for design of equitable CT assessments in early childhood.

Introduction

The material world is implicated in how we conceptualize spatial activities. For example, Hutchins (2005) theorized how a concept of "queuing" is informed by encountering the physical arrangement of bodies forming a line towards some destination; people learn to get in a queue by relating the conceptual space of the queue with its material referent. This complex interplay of conceptual notions and material setting presents questions about the role of concrete objects in dynamic spatial concepts, such as forming a line or following a path. Planning a path from an origin to a destination is a common task for studying children's spatial thinking and a foundational idea in programming environments frequently used in early childhood. For children who are still acquiring directional language like left and right, planning the steps of a route can be challenging. In addition, the symbolic system of navigational arrow codes can be confusing for children who are in the process of associating a wide variety of symbol systems with meanings and material structures (Clarke-Midura et al., 2019; Silvis et al., 2020). Verbalizing or visually representing instructions for another agent to move in sequential steps makes the task even more complex, as the child must engage in perspective taking and reconcile sometimes conflicting spatial orientations (Clarke-Midura et al., 2021; Flood et al., 2022). This paper presents research on children's materially-based strategies for path planning on a two-dimensional (2D) grid with a tangible agent (i.e., a robot) and manipulable directional arrow codes (see Figure 1).

The tasks were intentionally designed to observe children's thinking through their interactions with the materials. As children planned and programmed instructions for the agent, they manipulated arrows in different ways and demonstrated a range of strategies for conceptualizing a path-program relationship. For young children, planning routes involves tacking back and forth between a path and programming materials to anchor abstractions of space across physical and conceptual domains. Our findings highlight the critical role of material context in task design and implicate abstraction in spatial planning.

Contextualizing path planning

The relationship between material and ideational tools mediating human knowledge is an important pillar for situated theories of cognition, child development, language, and mathematical thinking. Hutchins (2005) referred to the "association of conceptual structure with material structure" as "a general and ancient human cognitive phenomenon" (p. 1555). Hutchins used the cultural practice of queuing to theorize how people learn to encode spatial relations to form concepts. He suggested that "in order to see a line as a queue, one must project conceptual structure onto the line" (p. 1559). Not all lines are queues, and not all queues are straight; in order to have a concept for a queue, one must turn line-like structures into a meaningful type of line, one that sequences bodies as they progress towards some location. What Hutchins called "material anchors" are the physical, material, (in our case) tangible objects used in bodily interactions with the physical world as part of the process of conceptual development. A question that Hutchins asked was "*Where* does queueing happen?" Does queueing happen in the conceptual space where the queue-concept takes shape and stabilizes, or in the world where the queuing body takes a place in line? At stake in this question is the role of concrete objects in forming spatial concepts.

This example was instructive for us as we examined the literature on children's development of route planning and spatial thinking. For example, Rogoff (1991) investigated 4- and 5-year-old children's development of route planning through guided participation in a task where children and parents planned a series of imaginary errands on gridded maps representing their neighborhoods and grocery stores. She found that it may be particularly difficult for young children to engage in abstract thinking about future events or anticipated spatial movements when these activities do not have "concrete, present referents" (p. 361). Sophisticated planning strategies involved marking map destinations with colors and symbols to facilitate planning the optimal route that *children themselves* could conceivably follow if they ran errands or navigated the grocery aisles. Similarly, in Hutchins' example, the queue represents a conceptual-material space that the queue-conceptualizer will use. Our tasks were different in that the planner was designing a route *for another agent*.

Providing instructions for another agent involves spatial perspective taking (Clarke-Midura et al., 2021) and draws on Papert's (1980) notion of "body syntonicity," or the ways children use a sense of body and self to learn abstract concepts like codes (Flood et al., 2022) or states of matter (Danish & Enyedy, 2020). Our work draws on the paradigm of LOGOs turtle geometry and tangible computing (Papert, 1980). The tasks described below situate abstract spatial movements in Cartesian space within a "program space" (Silvis et al., 2020). Children must make a series of associations between the abstract codes representing directional movement in the program space and the concrete physical path where movements happen on a grid. It is this relationship between physical space and abstract symbols that prompted us to consider a version of Hutchins' question: Where does the path happen? We use this theoretical question as a point of departure for asking: *How did materials help children represent their conceptual understanding of a path-program relationship in CT tasks?*

Study design and context

This analysis is part of a broader study in which we used Evidence Centered Design (ECD; Oliveri et al., 2019) to iteratively develop a CT assessment for kindergarten-age children that measures their ability to engage in CT practices (e.g., write or enact sequences of code, debug buggy programs). Materials include 2D 6x6 grids (Figure 1) that provided storyboards to situate the tasks, a small wooden agent/robot, and wooden tiles depicting four individual arrows: rotate right on a point (R), rotate left on a point (L), move forward one square (F), and move backward one square (B). Children were instructed to line up or sequence the directional codes in a row *underneath* the grid ("left to right like reading a book"). Despite this instruction and gentle reminders in-task, children developed a range of different strategies for sequencing arrows to build programs.

Participants, data, and analysis

We conducted qualitative analytic coding of video-recordings of children (N=272), ages 4-8, across five semi-rural elementary schools in the United States, as they engaged in CT assessment tasks (average length = 15 min). Assessments were standardized and administered one-on-one by members of the research team.

Figure 1
Materials used in CT tasks.

(1) box of 4 types of arrow codes
(2) storyboard grids
(3) wooden robot agent
(4) administration items/scripts
(5) observational record sheet
(6) pre-set programs

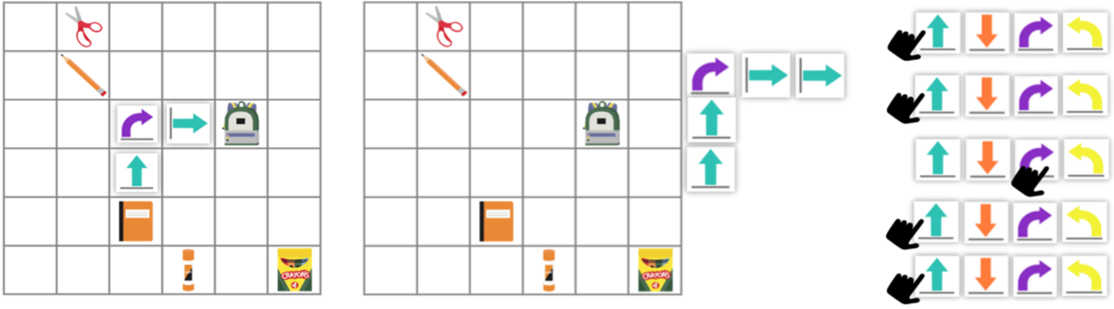
Prior to the current analysis, we conducted a round of coding, where we established a preliminary analytic code system for children's programming strategies, including how they used materials during tasks, how they used movement and gesture while coding, and how they verbalized program planning. Starting with this *a priori* code system, two research assistants coded the majority of the assessment events (83 hours of video). First, they open-coded a subset of the video, adding to the *a priori* codes and reducing redundant codes. The research team met weekly to establish agreement for strategies that were unclear or were hard to determine from the video record. We reached saturation with descriptive codes after coding approximately 50 assessments. Then both research assistants coded approximately 100 students, to refine the strategy code definitions. One theme that cut across categories involved *children's path planning*: how children were using materials, their bodies, and spatial language to plan the robot's routes during tasks. We focus on several forms of path planning selected because they represent both common and uncommon material-based strategies and because they speak to our larger theoretical question about the "where" of path planning.

Findings

Some children placed the arrows on each grid square. Others assembled the arrows in the shape of the path off the grid. Some stacked arrows in a tower vertically, while others placed arrows in random, nonlinear positions on the table. Children also interpreted path planning creatively, sequencing instructions that sent the robot "elsewhere" to a destination image on the grid, even when the task did not specify a destination. We illustrate three of these strategies: *mapping symbols onto spaces*; *path-shaping off-grid*; and *remotely planning a path*.

Figure 2

The Notebook Task, Robot travels from notebook to land on backpack. (Left) mapping symbols onto space; (Middle) path-shaping off-grid; (Right) remote path planning



Mapping symbols onto space

Program and path planning involves conceptually mapping a correspondence between the symbolic meanings of the directional codes and the material movements of the agent in physical space. For many children, mapping this correspondence meant placing codes directly on the map or grid-space. Children using the grid as a programming space allocated one code per grid square, creating a path-shaped program on the grid. This strategy was frequent in the Notebook Task (Figure 2), where children were asked to write a program for the robot to travel from the notebook to the backpack. The correct path was FFRFF. Because the rotation code just reorients the agent, children placing codes on the grid often undercounted their codes, producing FRF.

Path-shaping off-grid

Some children sequenced their codes spatially in the *path shape*, or what we call off-grid "path-shaping" with codes. As with programming on-grid, the Notebook Task served as a useful task to make off-grid path-shaping observable (see Figure 2). Children who performed path-shaping off-grid relocated the program from the grid space to an adjacent area on the table for path planning. This new context off-grid lacked the grid lines that had scaffolded reasoning about path-program-movement correspondence for on-grid programmers. However, the programs children assembled on the table in the shape of the path continued to resemble the grid.

Remotely planning a path

On-grid and off-grid path planning strategies described above represented alternatives to linear program sequencing. Less often, children declined to use the directional arrows to *build* programs altogether and took another approach to path planning. One radically different approach was to select one of each of the directional codes (even those not needed for a given task), place them on the table, and press them like buttons on a remote control to execute each code. Using this strategy to perform the Notebook Task, required tapping FORWARD twice, then ROTATE RIGHT, then another two FORWARD taps (Figure 2). Tangible sequencing that we had designed our assessment tasks to simulate, was instead associated with a different computational context (e.g., TV remotes, video game controllers), where remote controllers operate the machine. Remote paths did not take shape on the grid, nor did they materialize on the table in a path-shaped program. Rather, children planned paths in a remote space, where each movement was invisible, rather than a durable, manipulable sequence of codes.

Material anchors for CT assessment design

Path planning in tasks where an agent moves around a gridded space involves mapping a correspondence between at least two domains: the domain of the grid (path) and the domain of the arrow symbols (program). Children's use of the arrows indicated how they were understanding the relationship between these two domains. Their material strategies demonstrated how they abstracted from the immediate physical grid to the directional codes (mapping symbols onto space), from the grid-space to the program-space (path-shaping off-grid), and from directional codes to imagined movements (remote path planning). This series of abstractions allowed children—at different moments, in different items, and selectively employing different strategies—to traverse task contexts and bridge path-program concepts in ways that are important for emerging CT.

While we would not claim children were making huge leaps in abstraction characteristic of programmers who treat algorithms or problems as decontextualized objects (Hazzan, 2003), our CT tasks and materials elicited modest context-shifts that allowed children to move freely between levels of abstraction. Decontextualizing and recontextualizing problems is a critical part of abstraction and central to CT (Flood et al., 2022). Rather than progressive levels of abstraction—whereby children perform increasingly sophisticated forms of path planning from the grid, to the table, to the remote control— we prefer to see children's diverse strategies in terms of *varying degrees of material anchoring* (Hutchins, 2005). The various shapes their solutions took was another reminder for us, as designers, that an abstract, linear logic of programming is not inherent to computing, it is but one way of thinking computationally (Turkle & Papert, 1990). Even in a relatively constrained system of four directional arrow codes, children demonstrated a range of concrete strategies for approaching programming. Our findings are making us question the underlying rationale for prompting children to write linear algorithms for complex, dynamic paths. Particularly for preliterate children for whom "left to right like in a book," already involves abstract, arbitrary conventions, we want to incorporate multiple ways of using materials in our task models so that our assessments are accessible and equitable.

Abstract: This work reviews and analyzes how elementary teachers connect their professional development (PD) experiences to the science lessons they plan and implement in their classrooms. We present the SRL framework–Surface, Recognize, Leverage–as an axiological tool that supports teachers to value students' experiences and ideas, and therefore, make space for student-driven science inquiry about the world in which they live. Hence, teachers are actively working to "expand what constitutes science" and promote collaborative sensemaking across multiple ways of knowing and being.

Introduction

The consensus report, *Science and Engineering in Preschool through Elementary Grades: The Brilliance of Children and the Strengths of Educators* (NASEM, 2021), emphasizes "expanding what constitutes science" as one way to approach equitable science teaching and learning. This includes inviting and building on "learners' and families' diverse sensemaking and cultural and linguistic resources" and "accounting for heterogeneous understandings of the natural and designed world" (p. 24). The literature on teacher responsiveness (Kang, 2022), noticing (Sherin et al., 2011), and culturally sustaining pedagogy (Alim & Paris, 2017) provides insights into how to organize professional development (PD) to nurture teachers' learning about students' equitable sensemaking. Yet, there are few studies that document PD designs and facilitation that enhance elementary teachers' responsiveness to promote equity in science (Kang, 2022). We report on the final year of a four-year, ongoing PD effort with 14 elementary teachers, most of whom teach large populations of multilingual learners. The PD has consistently emphasized: 1) a centrality of representations in eliciting and being responsive to students' thinking and 2) "making space" for students' heterogeneous sensemaking (Bell et al., 2021; Haverly, et al., 2018). Here, we report on an emergent framework—*Surface, Recognize, Leverage* (SRL)—co-developed *with* teacher-participants. We asked: how does the SRL framework function as an axiological tool to expand what constitutes science toward teaching in more equitable and responsive ways?

Conceptual framework

The teacher responsiveness literature emphasizes: 1) *attending* to student ideas; 2) *interpreting* the meaning of students' ideas; and 3) *responding* appropriately (Jacobs et al., 2010; Jessup, 2018), or A-I-R. Our SRL framework is a parallel one, created with teachers using language, mediational means, and definitions they were comfortable supporting within our PD community: *surfacing* is a form of eliciting or attending to students' ideas; *recognizing* is a form of interpreting students' ideas; and *leveraging* students' ideas for the group's collective sensemaking is a form of responding. Louie et al. (2021) critique the AIR framework because it overlooks the ideological framings of students, the discipline, and interactions. They argue that the practice of *framing* provides opportunities to understand the sociopolitical nature of AIR. For instance, framing (shifting AIR to FAIR) allows participants "to understand what kind of task they are engaged in, what kinds of knowledge are relevant or valuable, and what sort of behavior they or others are expected or entitled to engage in" (p. 97). Culture, power, and injustice are inevitably implicated in AIR practices, even if they appear neutral (Kang, 2022; Louie et al., 2021). *Anti-deficit noticing with the FAIR framework* became an interpretive lens to help us understand how SRL worked as a practical tool to shift teachers' perspectives about what is valuable in science learning; but it is an incomplete way to explain the robustness and nuances of teachers' learning.

During the last two years, a responsive goal of our PD project focused on how teachers can "make space" (Bell et al., 2021; Haverly et al., 2018) for students to bring their personal experiences into the classroom for science learning. Our work engaged teachers, in community, to reflect about how they validated and supported students' multiple ways of knowing and being for sensemaking. PD conversations called attention to institutional constraints (e.g., 30 minutes a week for science) and sometimes foregrounded hierarchical language used to define student identities (e.g., low, high, EL). Among these tensions, SRL emerged as a co-constructed tool of shared language about what teachers were doing when they made space for students' experiences. We developed SRL as a tool together using sticky notes, chart paper, videos of practice, and focused conversations to engage in critical reflection about how students' science engagement and teachers' responses to their engagement. Bang and colleagues (2016) explain this approach to design as *axiological innovations* which are "theories, practices, and structures of values, ethics, and aesthetics that shape current and possible meaning, meaning-making, positioning, and relations" (p. 29). We acknowledge that the language of SRL is not necessarily 'new' in teaching and learning practices. Yet, we view it as an *axiological tool*—recursively co-constructed through PD sessions, teacher practice, and reflection—with which the PD community defined shared values and commitments to expand ideas about what science is.

Methods

This is a multi-year, design-based research project (Barab & Squire, 2004). For four years, we worked with over 20 elementary teachers across 12 schools in a large metropolitan southeastern U.S. community. The data analyzed here is from the current cohort of 14 teachers: five teachers from year 1, seven teachers from year 3, two teachers from year 4. Each year began with a 5-day summer workshop. Throughout the year, we conducted two classroom observations of science lessons per teacher, followed by a post-observation interview about each lesson. We held four video clubs (Danish et al., 2021) throughout each school year wherein teachers shared student artifacts from science lessons through gallery walks and engaged in social viewings of video excerpts of their classroom activities. Every activity was video recorded (Hall, 2000). We present data from Year 4 (22-23). All names here are pseudonyms. After several planning sessions using digital media and concept maps to coordinate our stances, practices, and goals, SRL emerged (in name, theory, and practice) as an *intentionally incomplete* framework for engaging with teacher sensemaking about science learning. We conducted iterative video analysis (Derry et al., 2010) which included reviewing AI-generated transcripts, time-indexing and content-logging video, analytic memos, and collective viewings for refining our understanding (c.f., Engle et al., 2007) about the co-constructed meaning of the SRL framework.

Findings & discussion

"Making space" as a framing tool

To review, "making space" worked as a framing component of classroom practice wherein teachers made moves to engage in "equitable sensemaking—collaboratively constructing knowledge with students' diverse epistemic resources" (Bell et al., 2021). The following assumptions surfaced repetitively in teachers' discourse about making space: 1) students' "ideas are valid" because of background experience and knowledge; 2) students need opportunities for "ownership of their learning/knowledge"; 3) students can recognize and leverage each other's thinking with representations; and 4) representations "help students notice changes in their own thinking." In short, the teachers came to the SRL framework with *shared assumptions about the importance of children's scientific thinking*. Teachers' relatively sophisticated noticing practices, framed through "making space," may have made it more likely that the SRL framework became a meaningful axiological tool to name what they value. Next, we provide evidence that SRL functioned as an axiological tool by identifying three values that repeatedly surfaced across our PD activities, previously mentioned.

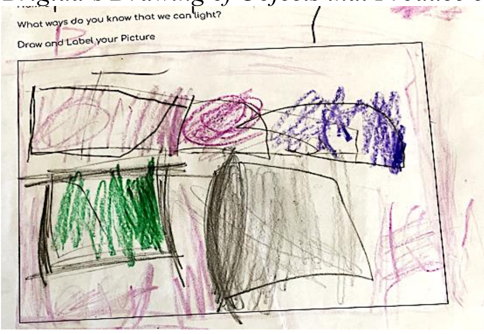
Value #1: Children as capable sensemakers

While teachers knew how to make space for children's sensemaking, the SRL framework helped them refine their practices to support changes in student thinking (*recognizing*), and to build on and use students' ideas as resources (*leveraging*). Teachers became adept at recognizing their students' brilliance even if children's ideas were not expressed in canonical ways. For example, while discussing Brigida's work from a lesson where students identified classroom objects that produced or reflected light, first-grade teacher, Katie reflected:

> I asked her, 'What is this?' She says, 'That.' She points at our smart board [as something that produces light.] 'And then these things [Katie points to top of drawing]? What are those?' And she goes, 'Oh those!' [Katie points to lights above]. *I was impressed with her picture*. (Figure 1)

Brigida, whom Katie described as a student "figuring out English more than other students," redrew her picture on a chart hung on the classroom whiteboard, and Katie also placed her idea on a summary chart. This example illustrates how SRL functioned as an axiological tool: 1) Katie was knowledgeable enough about the child's drawing to recreate and help our group interpret the scientific thinking in the drawing. She valued the scribbles as meaningful; 2) Brigida's drawing was "impressive" even though it may not have been considered artistic or representational in a normative sense; 3) Brigida's ideas were *surfaced* through drawing (versus written English), gesturing, and talk, *recognized* as important by including it on the class's chart, and included on the summary chart for *leveraging* in subsequent lessons.

Figure 1
Brigida's Drawing of Objects that Produce or Reflect Light



Value #2: Teacher risk-taking toward student risk-taking

Risk-taking was a value that worked for the teachers on multiple levels. Not only did teachers use SRL to describe their own risk-taking, they explained how students took risks in their learning, too. In a post-observation interview, Soren, a kindergarten teacher, used the SRL framework to explain how making space allowed her to *surface* student ideas, then take risks to *recognize* and *leverage* what they contribute by "accept[ing] what [students] are saying, and then figur[ing] out what [the teacher] can do…to acknowledge how great it is or how it connects." Soren also described her own participation in the research project as doing activities out of her "comfort zone," then by extension, she offered a rhetorical question: "I've loved that I took that risk…the amount of growth I've had…if that's beneficial for me, why would I not make that available for my students?" Specifically, then, Soren described how she took a risk during a phenomenon-centered lesson involving a melting snowman. When asked what a snowman was made of, the kindergarten students offered potentially risky ideas ("salt and water together will make a snowman," and "soap and water will make a snowman"). Then, rather than shut them down, Soren "wrote all these ideas down" and made a (risky) pivot to follow student inquiry and experiment with these ideas in the classroom the next day. For her, this "was a totally different change from the plan." Soren embraced what the representation of the melting snowman surfaced, wrote down student ideas to recognize their contributions, and leveraged their ideas for scientific inquiry. From these instances, SRL coupled with ideas about making space provided us with a shared language and framing to acknowledge and critically reflect on the value in risk-taking for teaching and learning.

Value #3: Collective knowing for teaching and learning

SRL facilitated reflection on the value of students collectively building knowledge. Reflecting on a video where Katie made space for students to build on each other's ideas about what produces light, Soren commented: "At the beginning [in Summer PD] I felt like leveraging was, like this *ultimate* thing, right? But it doesn't have to be. It can be as simple as what *you're* doing. You're taking what they said and leveraging it. You've recognized it, you're leveraging it to help them take the next step up." Soren doubled down in later reflection:

> More so than ever is if a child is saying something that at first seems incorrect…I asked for someone to build on their thinking…in the hopes that someone will add to it, take it and go with it in the right direction. So I think the building piece…is a really important part of any classroom…If you don't know what to do with what a child has just said, maybe the kids do…Even in kindergarten, they will do something pretty amazing.

In reflecting on Katie's video, Soren saw how SRL enabled collective knowledge building, and in reflecting on her own practice she articulated how recognizing students' ideas and inviting others to build on and leverage them supports a "group thing"—collective knowing.

Ongoing tension: Reproduction of hierarchies while recognizing students' brilliance

So much of teachers' learning through our PD demonstrates anti-deficit noticing (Louie et al., 2021) but, unsurprisingly, there are tensions. One such tension is the continued use of institutional ways labeling children as "high kids" or "low kids" (Horn, 2007). Teachers often identified children in this way at the same time they delighted in children's thinking and reasoning. For example, Katie discussed Brigida (above) as "one of my lower ELs" and "on my other end" compared with a boy who is "technically an EL, but he's like a three or something. He's high." These are tensions to confront as we continue to refine the intentionally incomplete SRL framework.

Significance & implications

The NASEM's (2021) *Brilliance and Strengths* consensus report recommends that elementary teachers, who have few opportunities for sustained professional learning in science, are supported in "developing the ability to recognize and value their learners' conceptual, linguistic, and cultural resources" (p. 248). The report also "urges that research be conducted to understand and support how learning science…can contribute to equity" (p. 250). We use SRL as an axiological tool for this purpose. Drawing on Louie and colleagues' (2021) anti-deficit noticing framework, we noticed how knowledge hierarchies are so easily reproduced, even when the framing of the PD ("making space") centers the value of all students' ideas. Even with a nearly ideal professional learning arrangement—teachers committed to strengths-based perspectives in long-term, job-embedded, collaborative PD—there is still work to be done.

Making Sense of Modes in Collective Embodied Science Activities

Selena Steinberg, Mengxi Zhou, Morgan Vickery, Nitasha Mathayas, Joshua Danish

Abstract: In this paper, we explore how students navigate collective mixed-reality embodied science activities in two contexts. We analyzed students' interactions using a mediated discourse analysis approach by creating bubble maps that captured modal density: the modal complexity (frequency and number of modes) and modal intensity (how much attention participants give to each mode) during embodied modeling and how these maps highlighted participants' engagement with science. We found that the content of the models shaped the modes that were relevant for participation and how the modelers interacted with each other.

Introduction and framing

In education, there has been increasing interest in understanding the role of bodies and movement in learning. We are particularly interested in supporting students' learning through *collective* embodied science modeling, or activities where students coordinate their actions in order to create an embodied model and to learn about complex science phenomena (Danish et al., 2020). In our work, students participate in these activities in mixed-reality environments; as they move around the classroom, they see themselves and their classmates projected as avatars on a screen. To an outside observer, these modeling sessions often seem messy and chaotic. They require that students move around and collaborate in a physical space, while also paying attention to how their actions influence the projected model. It is important to understand how students make sense of these activities in order to support their noticing of and engagement with target science ideas.

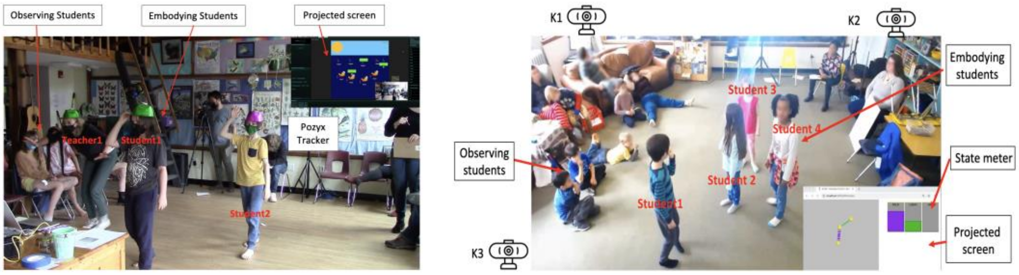
We explore these activities through the lens of mediated discourse analysis (MDA; Scollon, 2001). MDA is a framework that considers what actions are happening in a given site of engagement, and how discourse contributes to those actions. In MDA, the unit of analysis is a mediated action, or the things that people are able to do in a moment using available cultural tools. Central to this focus on mediated actions are modes, or systems of mediated action that "are part of the action that the individuals perform with others, the environment, and objects within" (Norris, 2016, p. 142). Wohlwend (2021) offers a modal categorization scheme, in which modes can be considered embodied (e.g.. gaze, speech, movement), environmental (e.g. color, layout, proxemics), or designed (e.g. image, music, shape). She argues that researchers may overlook meanings that children create because they are focused on fixed speech or print, rather than on actions in lived spaces. Mixed-reality embodied play activities are modally complex; they require students to coordinate multiple modes to be successful. In this paper, we explore how mapping the modal density of modelers' interactions, that is their modal intensity (how foregrounded or backgrounded a mode is for each modeler) and their modal complexity (how intertwined modes are with other modes), can inform our understanding of students' actions during embodied activities. We ask: how do students and teachers navigate modally complex multi-reality embodied play activities, and how does this impact what they notice and their participation in scientific modeling? We explore this question across two contexts where students engaged in embodied science activities: 5th and 6th grade students (ages 10-12) embodying energy transfer in aquatic ecosystems, and 1st and 2nd grade students (ages 6-8) embodying solid, liquid, and gas particles. In putting these contexts next to each other, we do not intend to compare them directly, but to explore the value of modal density for understanding modelers' participation across contexts.

Methods

Participants and data sources

Data for this analysis comes from two iterations of our projects on embodied science modeling: Science through Technology Enhanced Play (STEP) and Generalized Embodied Modeling: Science through Technology Enhanced Play (GEM-STEP). In these projects, students embody various agents (e.g. energy, particles, fish, worms, bees) in order to model complex systems. As they act as these agents, their movement is tracked and projected on a screen (Figure 1). Students generally model in small groups, while other students watch and make observations.

Figure 1
Students embodying energy in GEM-STEP (left) and students embodying particles in STEP (right)



Context 1: 5th and 6th graders embodying energy transfer in aquatic ecosystems
The first modeling activity occurred in the GEM-STEP environment, a platform that supports students to move between cycles of embodied and computational modeling (Danish et al., 2022). This iteration of the project took place in a 5th-6th grade mixed age classroom in a private school in the Midwestern United States. The students engaged in six one-hour long class sessions to learn about energy transfer within aquatic and garden ecosystems. The lessons were taught primarily by the research team, although the two classroom teachers were present and helped to facilitate, participating in the activities alongside students, and providing feedback on the lessons throughout the implementation. Data sources that were collected included video of the classroom implementation, screen recordings of GEM-STEP, and pre and post tests and interviews for each student. Because MDA relies on multimodal data, we focused on classroom video and screen recordings.

Context 2: 1st and 2nd graders embodying solid, liquid, and gas particles
The second modeling activity occurred in the STEP environment, a predecessor of the GEM-STEP that leverages students' embodied play as learning resources to understand scientific phenomena. Students' movement was tracked by three kinect cameras (labeled as k in Figure 1) and simulated as water particles on the screen. The present analysis focuses on an implementation of the particle curriculum in which 22 first and second-grade students from the Midwest participated in seven thirty-minute class sessions to learn about the behavior of particles in three states of matter (Danish et al., 2020). Three researchers, one classroom teacher, and student observers watched the embodied modeling and offered in-time feedback and questions. Previous analyses have shown that students made significant learning gains from the pre/post tests (Tu et al., 2021) and that the collective embodied modeling activities developed their mechanistic reasoning (Zhou et al., 2022). This current analysis uses multimodal interaction analysis to investigate how students' multimodal resources played out in their coordination and emergent scientific understanding.

Analysis

We engaged in multimodal interaction analysis (Norris, 2004) to understand how the modelers navigated the complex mix of modes and meanings as they engaged in a round of embodied activity. To begin, we selected one clip from each context that contained complex interactions between multiple modelers because we wondered about how modal density could shed light on the modelers' collaboration. In context 1, two students and one teacher embodied energy in an aquatic ecosystem in a 130-second-long round. The model included the sun, five algae, and five fish, which students could bring energy between. We selected this clip because we were struck by the sharp contrast between the way that the teacher used the mode of gesture, as she acted out energy, and the students' lack of engagement with acting, even though it was encouraged by researchers. In context 2, four students each represented a particle and explored how their speed controlled different states of matter in a 190-second-long round. We selected this clip because we were interested in how students worked together as they planned, tested, and refined an idea.

Next, we made bubble maps of modal density for each modeler (Norris, 2006; Wohlwend, 2021). To do so, we segmented each clip into ten second segments, and coded each segment for the modes that were present and absent for each modeler (frequency of modes). Next, we assigned values for which modes were foregrounded and backgrounded (attention), that is, which modes required conscious attention, based upon discussion among the authors. In this process, we included embodied modes (gaze, speech, movement, posture, gesture, haptic) due to our interest in modelers' embodiment, as well as proxemics (proximity to others) because we were interested in the modelers' collaboration with each other. We noticed that gaze was present and foregrounded for the majority of both clips, and so we split gaze into gaze towards the screen, gaze towards other modelers, and gaze towards the community (including observing students and teachers) in order to better understand this mode. Speech referred to anytime the focal modeler spoke, movement to their movement through the space, posture to a modeler standing still, gesture to hand movements that conveyed meaning, haptic to moments when touching something (like the hats) and/or other modelers was relevant, and proxemics when modelers seemed aware of or navigated around other modelers in the space. After creating these bubble maps, we explored the implications of a particularly foregrounded or backgrounded mode for participation. In context 1, we noticed that movement was foregrounded and frequent for all the modelers, so we tracked how each modeler's movements corresponded to their engagement with the science model. In context 2, gaze was heavily foregrounded but in different ways across students, and movement was foregrounded for everyone except for student 4, which was surprising in a modeling activity about speed. Thus, we rewatched this clip iteratively to understand how those modes informed students' coordination.

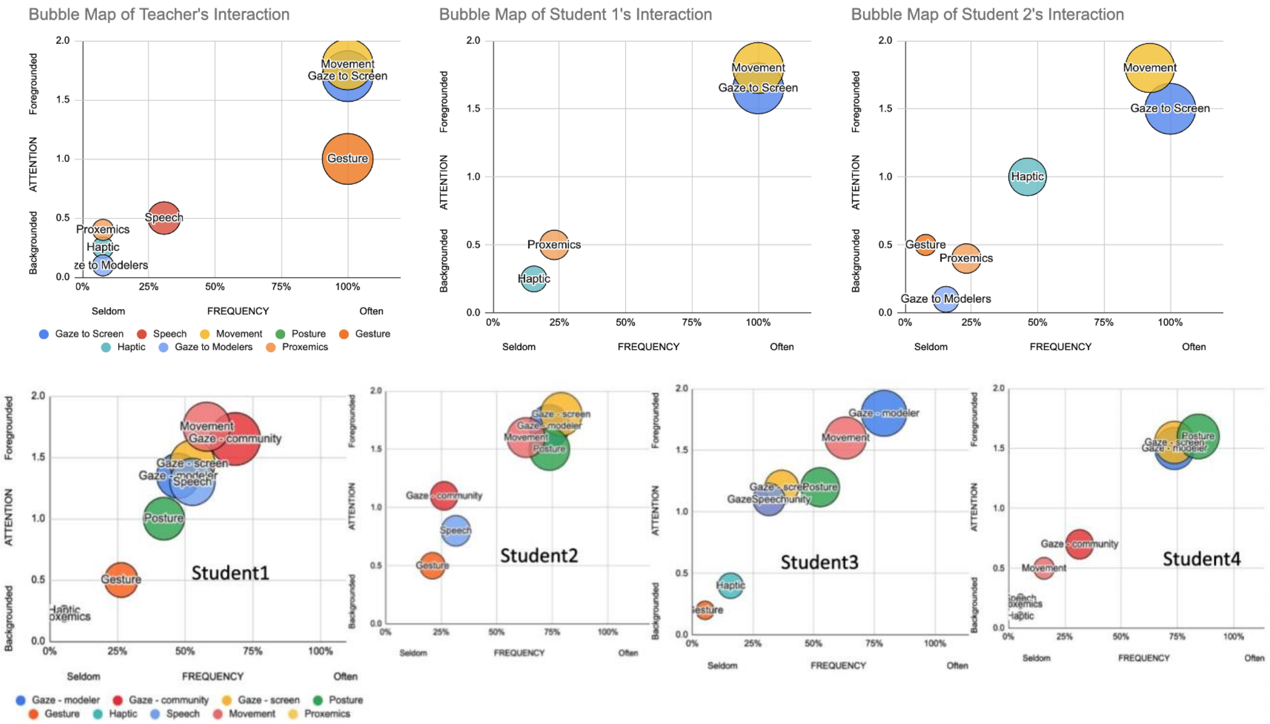
Findings and discussion

Context 1- 5th and 6th graders embodying energy transfer

The bubble maps for each modeler demonstrated that both movement and gaze to the screen were modes that occurred often and that modelers explicitly attended to as they made meaning (Figure 2). The modelers' actions were characterized by an intense, constant gaze towards the screen: they rarely looked at each other, yet only had a few close calls in terms of bumping into each other. There were distinct differences between the teacher and the students' modal interactions. The teacher used speech to coordinate with students: "talk to me people, who do I need to save?". She also engaged playfully through her hand gestures, a mode that drew negative attention from observers: "you look ridiculous". Instead, students seemed more focused on modeling through movement. Even though movement was frequent and foregrounded for everyone, they attended to the model through movement in different ways. The teacher often traveled far distances, ensuring that the fish and algae furthest away from the sun received energy, while the students attended to the fish and algae closest to them. However, they all seemed aware of which agent needed energy, as indicated by a red or orange energy bar, and only brought energy to an agent with a green bar once. All of the modelers were in nearly constant motion as they moved between the sun, algae, and fish. They attended to all of the agents, engaging in what looked like parallel play.

Figure 2

Bubble maps of modelers' modal interactions during a modeling round in Context 1 (top) and Context 2 (bottom)



Context 2- 1st and 2nd graders embodying particles

While gaze and movement were also foregrounded for the modelers in this context, they varied in where their attention was directed most often (Figure 2). Student 1 predominantly focused on the community, student 2 on the screen, student 3 on other modelers, and student 4 on both the screen and other modelers. Rewatching this clip iteratively as a team, we noticed that each student's bubble map related to their roles in the cycle of initiating/planning a goal, enacting/refining the plan, and starting a new plan. Student 1 initiated the modeling plan and addressed questions about the goal from the community, thus directing his gaze there. He assigned each student to move at still, slow, and fast speeds to correspond to the three states (solid, liquid, and gas). Student 2 was initially assigned to be a still particle and complied (as seen by foregrounded posture in the bubble map). Student 4 joined the modeling late and was not assigned a speed. As a result, she was often still and movement was backgrounded. Thus, students collaborated in this context; each students' modal density highlights their role (or lack of role) in the model.

Implications

The bubble maps helped us to attend to how each design necessitated and benefited from different modes. In particles, students needed to collaborate with each other to be successful: as such, their gaze was divided between other modelers, the screen, and the community. In energy transfer, students gazed almost entirely at the screen to make sure the algae and fish did not die, perhaps limiting collaboration. Using bubble maps to attend to these differences in gaze helped us to understand how the content areas and model designs facilitated different modes, leading to different ways of collaborating and engaging. Attending to different modes also seemed to afford different opportunities for engagement and learning. For example, proxemics were backgrounded for all of the particle modelers: students attended to speed and its relationship to the macrostates and had not yet determined that distance to each other mattered. In energy transfer, modelers' intense gaze to the screen enabled their movements to hold meaning– they moved intentionally between agents as they embodied an energy cycle. While we focused on the foregrounded modes in analysis, the backgrounded modes point to actions that may be important but are beneath notice, or to which participants are centralized or excluded from activity. Differences in bubble maps across participants also may indicate differences in experience, like the teacher's gestures during energy transfer or student 4's lack of movement in particles. Future research can explore how to design embodied activities that support specific kinds of modes and engagement.

Acknowledgments

We would like to thank all of the students and teachers who participated in this work over the years. We also appreciate the support of Dr. Karen Wohlwend and of our lab groups at IU and Vanderbilt for their efforts and contributions. We would also like to thank both the OpenPTrack and Inquirium teams for helping develop the amazing STEP software. This work was supported by the following grants from the National Science Foundation: 1908632 and 1908791.

The Influence of Informal Transdisciplinary STEAM Programming on Adolescent Cultural Learning Pathways

Abby Rhinehart, Philip Bell
rhinehah@uw.edu, pbell@uw.edu
University of Washington Seattle

Abstract: We lack adequate longitudinal accounts of learning and becoming across settings and pursuits, especially with respect to how out-of-school learning experiences might productively shape extended life pathways and civic engagement. This ethnographic longitudinal study examines how transdisciplinary, out-of-school STEAM programs in Ireland and the U.S. contribute to adolescent cultural learning pathways, with an emphasis on how young people come to transform their worlds. We found these out-of-school programs helped youth deepen their engagement with STEAM practices and gave youth material, ideational, and relational resources, all of which youth used to pursue their imagined futures in other settings (e.g., school, work). This research informs our understanding of the variegated cultural learning pathways traversed by adolescent youth (Bell et al., 2012; Nasir et al., 2020) across developmental timescales after their participation in STEAM program experiences.

The longitudinal study of STEAM learning

In this paper, we apply the framework of a cultural learning pathway to the longitudinal cases of three adolescents to better understand how out-of-school STEAM learning experiences can help young people fight for their desired futures for themselves and their communities (Arada et al., 2023; Sequentials Volume 2, Issue 1: Learning to Engage, 2021). Our focal research question was: How does participation in transdisciplinary programs shape adolescents' subsequent participation in other learning settings?

Conceptual framework

To approach this question, we leverage the conceptual framework of cultural learning pathways, incorporating research on youth civic engagement and transdisciplinary learning. We see learning as developing repertoires of cultural practices within communities (Gutiérrez & Rogoff, 2003; Lave & Wenger, 1991). As they learn, young people reorganize possible futures for themselves and their communities as they imagine themselves and the world as if it were otherwise (Gutiérrez & Jurow, 2016; hooks, 1994; Uttamchandani, 2020). At the same time, youth are constrained by the histories, structures, and powered relations within which they act (Holland and Lave, 2019).

Therefore, we take up the framework of cultural learning pathways to analyze individual learning and identity shifts over extended periods of space and time. Cultural learning pathways consist of personally consequential activities and sensemaking over time and across settings; they are shaped by cultures, social practices, and values (Bell et al., 2012). For example, Ma et al. (2020) use the learning pathways framework to illustrate the interplay between one young person's peer relationships and his statistical reasoning about national LGBTQ+ presence. Through analyses such as these, researchers and practitioners can better understand how to design learning environments that help youth from historically marginalized communities navigate their learning pathways and advocate for their desired future selves and worlds.

This project studies transdisciplinary programs, specifically those that blend practices from traditional science, technology, engineering, and/or mathematics fields (STEM) with practices from the arts. We define transdisciplinarity as a co-equal blending of disciplines, in which epistemic practices from different historically constructed disciplines are interwoven, hacked, or repurposed, creating new integrations of knowledge and new practices, such as defining a problem space or exploring materiality (Bevan et al., 2019; Mejias et al., 2021). We take up transdisciplinary learning as a strategy to support culturally sustaining education, countering colonially constructed disciplinary divisions (Bang & Medin, 2010; Simpson, 2017).

Methods

To better understand how transdisciplinary learning can shape youth cultural learning pathways, we conducted longitudinal ethnographic case-studies of three participants in four transdisciplinary programs for adolescents.

Transdisciplinary out-of-school STEAM program designs

This study draws on case studies from participants in four STEAM programs that were part of an NSF-funded research-practice partnership: (1) Science Gallery Dublin's OPEN MIND Studio, a week-long program of workshops and activities in Ireland; (2) ListoAmerica Clubhouse, which focuses on creative use of technology in the United States; (3) YR Media, a youth journalism and digital media program in the United States; and (4) WAC Arts' digital music production program in the United Kingdom, though no case studies from WAC Arts are featured in this paper. These programs share intertwined design elements (also described in Hurley et. al., 2022), which we hypothesize shape participant learning.

1. **Investigating and developing solutions to personally and locally consequential problems.** All programs in our study support learners to leverage their interest, knowledge, and experiences to investigate problems that they and/or their communities find consequential, such as the interplay between AI and privacy. Youth engage in ethical deliberation around these problems and collectively envision solutions. Programs and facilitators give youth social and material support for individual and/or collective action, e.g., brokering opportunities to join existing social movements.
2. **Building a collaborative community of learners.** Programs in this study desettle traditional hierarchical structures in learning settings. Facilitators use icebreakers to build community. More experienced youth often take on mentor roles, while adults act as near-peers.
3. **Sequencing practices to support transdisciplinary investigations.** In all programs, youth engage in transdisciplinary learning and practices. Disciplinary practices are used as steppingstones to support eventual engagement in transdisciplinary learning. For example, at Science Gallery Dublin, youth began with the engineering practice of building circuits, which ultimately prepared them for the transdisciplinary design challenge of storytelling via electronic dioramas.

Longitudinal study of cultural learning pathways and case selection

As part of our research-practice partnership, we employed cross-setting research techniques—ethnographic interviews, participant artifacts, autoethnographic data sources, and participant observation when possible—to build case studies of the cultural learning pathways of adolescent youth (Yin, 2008). Interviews were conducted annually over the course of three years with 37 youth from the four study sites described above.

Participants ranged in age from 11 to 22 at the start of the study and had been involved in the focal program for as little as one week to as many as nine years. This report shares data from three annual interviews with youth, begun in 2019 or 2020 and running through 2023. We conducted theory-driven purposeful sampling based on the cultural learning pathways of youth, selecting cases in which young people made direct claims about connections between the STEAM programs and subsequent learning in relation to their activist identities.

Three cases of out-of-school STEAM and cultural learning pathways

The following section offers three case studies, followed by our findings about this data set when considered as a whole. These case studies represent a range of cultural learning pathways, practices, and STEAM programs.

Grace, Science Gallery Dublin, and environmental activism

Grace (she/her) attended Science Gallery Dublin's week-long OPEN MIND Studio during her transition year (10th grade equivalent). When she attended, the art-science program was focused on human uses and disposal of plastics. Youth formed small groups to propose technology- and art-informed actions to help combat this environmental issue, then presented their ideas to peers and facilitators, who offered suggestions and feedback.

The next school year, Grace joined her school's environmental club, the Green Committee. The school's new principal solicited this club for ideas for environmental actions to take in the school. In her first interview, Grace recounted, "Because I knew all the stuff that I learned in this course [at Science Gallery Dublin], I felt like it was a lot more easy to engage with her," indicating that she felt the program had given her epistemic resources, such as the practice of defining the problem space, that supported her in this environmental activism.

Nuri, ListoAmerica Clubhouse, and social justice activism

Nuri (they/them) was a Latinx student who had been a member of ListoAmerica Clubhouse for six years when they were first interviewed at age 17. Nuri's high school had a large Latinx population, but Nuri said they felt a lack of Latinx visibility in school activities, interactions with faculty, and advanced classes. As a result, Nuri helped launch a high school club called Teens for Justice (pseudonym), which focused on raising awareness about racial and economic inequality and advocating for an ethnic studies graduation requirement.

In their interview, Nuri described how they had asked ListoAmerica Clubhouse facilitators for support with Teens for Justice. In response, ListoAmerica Clubhouse offered everybody in the club licenses to the Adobe

Creative Cloud software. Mentors at the nonprofit also offered graphic design lessons to Teens for Justice club members, which the club used for its advocacy work over social media.

In high school, Nuri had been a member of the Science Olympiad with future plans to be an engineer. By the time of their second interview, Nuri was attending a college with two robotics clubs–one club that built battling robots and another club that built food-delivery robots. Nuri chose to join the latter club specifically because they saw potential social good in the project — delivering food to people with limited mobility. This indicates that they continued to engage with transdisciplinary practices to solve community and civic problems even after leaving ListoAmerica Clubhouse.

Ben, YR Media, and building a just music production community

Ben (he/him) was 20 years old at the time of his first interview, and was passionate about music, especially playing the saxophone and digital beat making. He had joined YR Media specifically because of that interest in music, which he said he deepened in the program by creating and editing a music video series. In his second interview, Ben described a new endeavor: a new studio and production company, called The Town Sound (pseudonym). Ben found his business partner through DJ shows he did with members of his YR Media social network. Ben said he wanted The Town Sound to reimagine the relationship between audio production studio and artists, describing it as “almost like a label, but not exactly like a label, because we don't really want to have ownership over people. We just want to partner with people,” rather than own the rights to artists’ music.

Ben said his work at YR Media had been key to starting The Town Sound. He related, “What was really helpful was learning about all the other technological stuff that could assist me outside of music or within music” like graphic design of a concert poster or music video editing. This experience helped Ben communicate with people in these related fields, such as describing his preferred website design for The Town Sound.

Findings

With this project, we sought to better understand how participation in focal programs shapes adolescents’ subsequent participation in other learning settings. These findings are tied to youth engagement in programs with particular design elements, specifically that they engage youth in investigating and developing solutions to personally and locally consequential problems, build a collaborative community of learners, and sequence practices to support transdisciplinary investigations.

Cross-case thematic analysis resulted in the following interpretations and findings. Each case illustrates all three findings, but for the sake of brevity, we only give one example for each finding.

Finding 1: Youth deepened their engagement with STEAM practices

Youth continued to deploy and refine epistemic practices learned in STEAM program spaces within other pursuits over time. For example, Grace drew on her experience with the STEAM practice of defining the problem space at Science Gallery Dublin when she discussed possible new activities for the Green Schools Committee with her principal (Bevan et al., 2019). Participation in all programs in this study helped young people deepen and expand their engagement with transdisciplinary STEAM practices (Bevan et al., 2019).

Finding 2: Youth combined STEM / STEAM practices with community changemaking

The design of these programs helped youth see their practice-linked STEM or STEAM identities as connected to community changemaking. ListoAmerica Clubhouse encourages youth to use the organization’s resources to solve community challenges, such as building a teen mental health app. Participating in this model may have helped Nuri to imagine ListoAmerica Clubhouse as a possible resource for Teens for Justice, particularly as the teen activist group sought to engage in the STEAM practice of audiencing (Bevan et al., 2019). Nuri’s use of STEAM practices to pursue imagined futures is further illustrated when they said they chose the meal delivery robotics club because they saw it as having a social purpose.

Finding 3: Youth gained material, social, and ideational resources to shape desired future communities and relations

Throughout these cases, young people used the resources they gained in out-of-school STEAM programs to make changes in other settings. For example, Ben began The Town Sound with a musician he met through his YR Media social network, an instance of a social resource affecting his learning pathway. Additionally, at YR Media, participants collaboratively decide on products. Mentors are also paid for their work, affording them a level of dignity not offered at many jobs for teens. We argue that being a part of this community offered ideational resources to Ben about how an organization like The Town Sound might operate with a flatter structure.

Discussion and conclusions

With this longitudinal ethnography, we hope to better understand how out-of-school transdisciplinary programs can be designed to help youth advocate for their desired future selves and communities. By proposing solutions to issues that are meaningful to themselves and their relations, as part of a community of learners engaged in transdisciplinary practices, these three youth STEAM identities become enmeshed with community-engaged activist identities. Cultural learning pathways are not linear trajectories; they meander and shift, as people manage different priorities, struggle to find available time, fight for recognition and resources, and engage in ongoing identity work. By better understanding how these programs can foster youth dignity and how youth can be connected into ongoing systems and communities of support, we hope to continue efforts to build transformative learning experiences for youth both in and out of school.

“These Two Worlds are Antithetical": Epistemic Tensions in Integrating Computational Thinking in K12 Humanities and Arts

Rafi Santo, Telos Learning, rafi@teloslearning.net
Anne Drew Hu, Michigan State University, annedrew@msu.edu
David Phelps, Telos Learning, david@teloslearning.net
Secil Caskurlu, Florida State University, scaskurlu@fsu.edu
Aman Yadav, Michigan State University, ayadav@msu.edu

Abstract: While advocates for interdisciplinary learning have voiced risks of separating out disciplinary learning into discrete silos, studies of contact between heterogeneous disciplinary perspectives in both pedagogical and real world professional settings point to other risks that educators may need to consider. As such, designing for interdisciplinary learning does not simply require addressing functional problems such as teacher professional learning and time in the school day, but rather implicates complex epistemological navigations that must be taken into account. This manuscript explores potential epistemic tensions between Computational Thinking (CT) and humanities and arts disciplines based on a Delphi study with experts from three humanities disciplines—language arts, social studies, and arts. We analyzed how experts talked about epistemic tensions between CT and their disciplines and how they saw possible resolutions for those tensions. Our analysis found 5 epistemic tensions: contextual reductionism, procedural reductionism, epistemic chauvinism, threats to epistemic identities, and epistemic convergence.

Introduction

There have been recent calls for the field of the Learning Sciences to attend to learning processes in contexts that cross disciplinary boundaries (Herrenkohl & Polman, 2018), such as cross-disciplinary collaborations (Edwards, 2005), interdisciplinary learning ecologies (Damşa et al., 2020) and classroom curriculum that promotes epistemic heterogeneity (Pierson, Brady, Clark & Sengupta, 2022). Simultaneously, there have been increasing efforts to overcome the way the typical school day is organized around the norm of disciplinarity by designing learning environments that directly integrate disciplines together (e.g. Finch, Moreno & Shapiro, 2021), or that help learners make connections and appreciate distinctions between disciplines (Stevens, Wineburg, Herrenkohl, & Bell, 2005). These directions of scholarship have generated important questions for the field such as how learners draw across epistemic practices as they navigate complex problems, and how learning environments can be better designed to support learners' development of meta-epistemic fluency (Damşa et al., 2022; Stevens et al., 2005).

Yet, these questions cannot be fully answered without adequately attending to the tensions that emerge when heterogenous epistemic disciplines come into contact—tensions that can lead to missed opportunities and/or harms in the learning process. For example, in K12 classroom settings, such as the life sciences, teachers and students using epistemic approaches that map onto 'settled' Westernized practices (such as classifying nature into taxonomies) have actively silenced students who use epistemic perspectives that draw on non-Westernized approaches (such as viewing nature in terms of ecological relationships) (Warren, Shirin, Rosebery, Bang, & Taylor, 2020). In another example, in the context of the professional setting of public policy, data-driven cost-benefit analysis has dominated humanistic epistemologies, resulting in an elevation of values of efficiency over those of equality in policy construction (Berman, 2022). As such, considering differences across, and tensions between, epistemologies is critical for scholars and designers of interdisciplinary learning if they wish to effectively prepare students to not just address societal challenges, but avoid reinforcing them through a lack of meta-epistemic fluency.

Unfortunately, the phenomenon of epistemic tensions is understudied, and there is little guidance for educators on how to recognize epistemic tensions, and to support learners in productively navigating them. Utilizing the context of pedagogical integration of computational thinking (CT) practices (Grover & Pea, 2013) within the context of K12 language arts, social studies, and arts instruction, this manuscript presents findings from an empirical study of expert perspectives that surfaced epistemic tensions between CT and humanities disciplines, and potential avenues for resolution of these tensions. Identifying the epistemic tensions within the context of CT integration in K12 humanities disciplines is particularly timely given growing nation-wide efforts to implement comprehensive computing education under the banner of Computer Science for All (Vogel, Santo, & Ching, 2016), which is often inclusive of efforts to integrate CT directly into the humanities (Neumann & Dion, 2021)

Methodology

Our study aims to address two research questions. RQ1: Within the context of interdisciplinary pedagogy, what potential tensions exist between epistemologies of K12 humanities disciplines—social studies, language arts, and arts—and those associated with computational thinking? RQ2: What possibilities exist for resolution of these epistemic tensions within interdisciplinary pedagogical contexts? In order to address these questions, we conducted a Delphi study (Linstone & Turoff, 1975) to utilize expert consultation as a means to gather judgments on the intersection of CT and K12 humanities disciplines, assess and compare across expert perspectives that are not currently documented in extant literature, and generate new ideas (Franklin & Hart, 2006).

We collected qualitative data from each of the 43 participating delphi experts who ranged in institutional role (10 classroom teachers, 10 instructional specialists, and 23 education researchers), focal discipline (Arts=13, Social Studies=14, and Language arts=16), and pre-existing expertise in computational thinking (21 with, and 22 without). Study data included ~26 hours of video recordings and transcribed audio of whole group and small group discussions across six delphi focus group sessions (two for each of the three focal disciplines), and 312 written annotations of varying length by experts sharing their perspectives on the potential intersection of computational thinking and their focal discipline.

We analyzed data using a coding scheme aligned with the conceptual framework of Expansive Learning (Engeström, 1987), whereby contradictions experienced within and between activity systems, in this case epistemic tensions (RQ1), become focal points for advancing beyond the current limitations of existing systems and generate previously unconsidered solutions, in this case, resolutions to said tensions (RQ2) (Engeström & Sannino, 2016).

Findings

In considering possible relationships between epistemologies of computational thinking and those associated with K12 disciplines of social studies, language arts, and arts within integrated learning, participants in our study repeatedly surfaced five epistemic tensions (Table 1), as well as three potential resolutions (Table 2).

Table 1
Epistemic tensions expressed by delphi study experts related to integration of computational thinking into humanities and arts disciplines

Tension	Definition
Contextual Reductionism	Losses of nuance, particularity, and ambiguity around, for example, historical events or pieces of literature that could result from CT’s valuation of abstraction, quantification, modeling, pattern recognition, and prediction practices.
Procedural Reductionism	Problematic reduction of complex epistemic practices into sets of tractable steps. This tension was often expressed in relation to what was seen as inappropriate application of algorithmic logics to knowledge production.
Epistemic Chauvinism	Elevation of CT epistemologies at the expense of those related to a focal discipline in ways that devalue existing ways of knowing within a discipline. For example, some experts raised concerns that interdisciplinary approaches under discussion would end up foregrounding computational tools in ways that would supersede ways of knowing connected to their focal disciplinary values.
Threats to Epistemic Identities	Concerns that cultural and historical identities associated with humanities and arts epistemologies—their epistemological ‘ways of being’, so to speak—could be under threat during integration of computational thinking epistemologies. Some arts experts, for example, expressed concern about alienating ‘art kids’ who identify less with epistemologies that center logic and deductive reasoning.
Epistemic Convergence	Concerns that overlaps and similarities in epistemologies associated with CT and those of a focal discipline could lead to superficial semantic shifts and “reskinning” of existing practices, rather than substantive extensions into authentic interdisciplinary learning.

Table 2

Possible resolutions to epistemic tensions expressed by delphi study experts related to integration of computational thinking into humanities and arts disciplines

Resolution	Definition
Educator meta-epistemic assessment of CT applicability	Suggestions that educators actively reflect on the specific pedagogical context and associated epistemic learning goals of their core discipline in order to determine benefits and tensions of integrating CT practices into said context (e.g. a particular unit of study, particular students). In this process, educators would actively define ways in which CT might be grounded in their core disciplinary epistemology, and how to avoid integration approaches likely to result in epistemic tensions.
Student exploration of epistemic affordances and limitations of CT	Suggestions that educators highlight epistemic affordances and limitations present in integrations of CT and their core disciplinary epistemology within interdisciplinary learning settings, centering contradictions as a site of inquiry and student learning about deployment of varied epistemic practices.
Embracing epistemic pluralism	Suggestions that educators actively highlight the value of differences between CT and core disciplinary epistemologies for students, instead of shying away from them. For example, a social studies educator could use abstraction to look at patterns across historical events alongside epistemic practices of historical analysis that examine the nuance between those situations. Experts viewed combining these two perspectives as a way to new opportunities for learning.

Conclusion

As the Learning Sciences field turns its attention to designing and studying contexts that span disciplinary boundaries, fundamental questions need to be addressed such as: what kinds of epistemic tensions emerge when multiple disciplines are brought together? Further, what harms might these tensions cause? Further still, how can educators effectively design and implement interdisciplinary learning environments that support learners to productively navigate these tensions?

We see it as critical to actively attend to these issues as the field of computing education considers further work bringing its ways of knowing and doing into humanities and arts disciplines in K12 contexts. Our analysis works to put into conversation contemporary trends occurring within the computing education community that see interdisciplinary integration as a key site of implementation in K12 (Neumann & Dion, 2021; Weintrop et al., 2016) with the voices and perspectives of those that have expertise within disciplines that might be sites of integration.

More than any specific tension in and of itself, the study's findings demonstrate that the dynamics implicit in integrating computational thinking into K12 humanities and arts pedagogies are not merely limited to implementation challenges such as availability of instructional time, technology, and teacher capacity, but rather also operate on the fundamental level of epistemic commitments, identities, cultures and histories of the disciplines in question. This space of epistemic interaction between CT and existing disciplines is one that, ideally, would be attended to *prior* to addressing more "classic" implementation challenges in classrooms and schools in order to ensure that various harms are avoided, and opportunities for interdisciplinary enhancement are centered.

While this study is limited in that it did not directly examine epistemic tensions *in situ* within interdisciplinary learning environments, we see the expert perspectives surfaced here as advancing broader scholarship on interdisciplinary learning. Especially given possible risks, consulting experts and exploring tensions that can arise during contact between disciplines provides important starting points for both future scholarship and intentional design of impactful interdisciplinary learning.

Narrative Construction Game as Consent Knowledge Assessment

Caleb Probst, University of Wisconsin-Madison, cwprobst@wisc.edu

Abstract: Sexual assault rates on American college campuses remain high, despite students' ability to accurately describe consent policies. Therefore, conceptual change in consent knowledge is needed, specifically for concrete knowledge to become more complex. In this case study, I examined how constructing a narrative through a card game revealed concrete consent knowledge in 21 undergraduates. I argue if colleges devoted more time to consent education, narrative construction could show if student understanding becomes more complex.

Introduction

There is a disturbingly high prevalence of sexual violation on American college campuses (Cantor et al., 2015) despite recent consent education efforts. Programs tend to focus on teaching a concrete understanding of consent—*only yes means yes*. While this is important, it is insufficient for developing the expertise necessary to produce any noticeable decrease in campus sexual assault rates (Cantor et al., 2019). Campus hook-up narratives held by undergraduates show their current understanding of sexual consent; reducing campus sexual violence will require students to change their conceptual understanding. In this paper, I describe *The Hook Up Game*, a card game for constructing consent narratives, and the ways that playing it revealed the consent knowledge of 21 students at a large university in the Midwestern United States. Through analyzing the results of this case study, I argue the efficacy of narrative construction through gameplay to assess conceptual understanding of consent. Furthermore, such gameplay can theoretically assess conceptual change of sexual consent in students over time.

Conceptual change in consent knowledge

Conceptual change research has traditionally addressed learning in physical science disciplines, where experts largely agree on explanations of the natural world. More recently, research of conceptual change in history has shown what it looks like for novices to begin thinking more like experts in areas where multiple perspectives are inherent. Rodríguez-Moneo and Lopez (2017) argue that conceptual change in history involves learners progressing along two different continua: shifting from concrete to complex knowledge, and shifting from seeing only isolated events to seeing them situated within systems. Conceptual understanding is embedded in a learner's narratives, and conceptual change is evidenced by shifts within them (Lopez et al., 2015). While this assumes an individual cognitivist perspective, the cognition necessary for successfully engaging in a complex social activity occurs within "the interactions among people, tools, and task" (Hutchins, 1993, pp. 36-37). When young people cognize sexual consent, they do so in a distributed manner, using tools like socially constructed narratives and the perspectives of others.

The model of conceptual change in history, through a distributed lens, provides a framework for studying conceptual change in sexual consent. Conceptual change in any discipline involves transitioning from novice toward expert understanding. While it may be odd to use *expert* in relation to sexual consent, my purpose is to examine consent learning as disciplinary learning. Experts view novel problems in ways that are quite different from novices (Chi et al., 1981). Consent novices concretely interpret sexual encounters: Was everyone sober, and did everyone say *yes*? This simple conception fails to account for the complexities of campus culture. Learners who develop consent expertise, however, understand both the nuances of a specific encounter and the ways the encounter exists within complex systems. They see the sexism and heteronormativity in the typical sexual script: man initiates, woman coyly refuses, man persuades, woman agrees (Hust et al., 2017). If they follow it, they do so critically aware of the differences in refusal and token resistance. Further, consent experts appreciate the differences in hooking up while binge drinking at a party and doing so after a glass of wine on a date. However, a novice would say any alcohol negates a *yes*. This is not to minimize the role alcohol plays in sexual assault, rather to suggest telling students to fully abstain from either sex or alcohol does little to deepen understanding.

Methods

I worked as a consent educator for a decade, facilitating in-depth discussions with nearly 10,000 young people. These conservations influenced my design of *The Hook Up Game* and interpretation of how students played it.

Description of the Hook Up Game

The Hook Up Game is a collaborative social game where players co-construct a story of an intimate or sexual encounter between two characters. In addition to my consent education experience, constructionism (Papert, 1980) and the theory of transformational play (Barab et al., 2010) informed the design. Players use four types of cards to construct their narrative: character, setting, action, and dialogue. As shown in Figure 1, the story emerges through the order in which people play the action and dialogue cards. Character backstories and settings provide additional context. Players can “tinker” with their construction (Flannery et al., 2013) by adding, eliminating, changing, and reordering these cards, resulting in dynamic relationships between the players, their knowledge, and the narrative context. Players also have a *Woah there!* card to use if the story becomes non-consensual.

Figure 1
Layout of game play

Participants

I recruited 21 participants for this case study by demonstrating the game in undergraduate classes at a large university in the Midwestern United States and asking for volunteers. Convenience sampling is appropriate for this study, as consent learning is relevant to all undergraduates. These efforts yielded three play groups, each with seven players. The participants in each group were over age 18. Table 1 shows the composition of each group.

Table 1
Demographic composition of gameplay groups

Group	Player pseudonym, gender	Academic standing
1	Alice, Beth, Cindy are cis-women; Devon is a trans-man; Elliot, Freddy, Gil are cis-men	Juniors
2	Heather, Isa, Jo, Kelly, Lauren, Megan, Nora are cis-women	Sophomores
3	Oscar, Pete, Quinton, Raj, Sam, Tom are cis-men; Uma is a cis-woman	Sophomores

Data collection

I reserved a room on campus with couches and a coffee table for playing the game, and I provided snacks to create the atmosphere of a game night. Each play group met for roughly one hour, playing the game for 20:00 minutes and discussing their experiences for the remaining time. I facilitated these discussions as semi-structured group interviews. I video recorded each session to capture the conversations and the cards played. I made jottings throughout each session. I told participants ahead of and at the start of the session that the game included explicit descriptions of sexual activity and possible references to sexual violation, and they could stop at any time.

Data analysis

This case study examined one question: How might narrative construction through a card game assess undergraduates’ conceptual knowledge of sexual consent? By examining the potential of this game to reveal participants’ consent knowledge, I aim to suggest possibilities for narrative construction games generally. To do this, I analyzed the sessions at two levels by writing and coding two sets of field notes after watching the videos multiple times. At the first level, I analyzed the constructed narrative, and at the second, how players discussed it.

I coded the first set of notes inductively (i.e., identified themes that emerged), resulting in 27 codes. I then collapsed them into five codes (Table 2). I coded the second set of notes deductively, looking for examples of concrete or complex consent knowledge and examples of group agreement or disagreement. This coding scheme (Table 3) came from the conceptual change framework described earlier.

Table 2
Narrative codes

Code	Description	Example
Performance of gender; social power	Typical sexual script; behaviors expected in a social situation	Giving a woman alcohol at a party
Female character initiation/aggression	Counternarrative to the typical sexual script	Female asking male partner for sex
Aggression/violation; manipulation/coercion	Physical or verbal tactic to extract sex from partner	"Why do you think you're here?"
Affirmative consent; explicit boundary	Verbal communication of desires or boundaries	"Just hands, ok?"
Mutuality; assumed consent or boundary	Non-verbal communication of desires or boundaries	Freely kissing back; pushing away

Table 3
Consent knowledge codes

Code	Description	Example
Concrete	Knowledge that closely aligns with formal consent education	Any alcohol negates consent
Complex	Knowledge of the complexities of social systems and relationships	Awareness of sexism's impact
Agree	Multiple members shared an interpretation	
Disagree	At least one member disagreed	

Results

Group 1 created a hook-up between a non-binary pansexual character named Mars and a cis-gender lesbian named Erin. The narrative did not contain any elements of the typical sexual script. The power dynamics constantly shifted, with Mars and Erin taking turns instigating greater sexual intimacy. There were numerous examples of mutuality, where kissing or touching by one character was reciprocated by the other. There was one sexually aggressive action where Mars tore Erin's underwear, prompting Erin to explicitly state a desire to "keep our underwear on." Erin later disregarded her own boundary by explicitly asking Mars to have sex, and Mars responded with assumed consent by "putting a condom on their partner."

While little in the story was obviously problematic, the group seemed unsure if it was consensual. Beth said the ending "took a weird turn," alluding to Erin's decision to rescind her own boundary. Elliot thought the characters were "off all night," referring to multiple shifts in instigation. Everyone agreed the characters should have more explicitly discussed boundaries. This reflects concretely understanding consent as always being verbal. However, they demonstrated emerging expertise at a few points. Gil, Freddy, and Beth discussed the power that setting can wield, suggesting Erin had additional power by being in her own apartment. Elliot and Beth explained reciprocating actions can show consent, prompting Devon to say these can be misinterpreted when people do not know each other well. Beth agreed, adding people also misinterpret what it means to go home with someone.

Group 2 created a hook-up between a fraternity member named Trevor, and a first-year student named Mariana. It was not consensual. Mariana did not want to have intercourse but was open to oral sex. She explicitly expressed this boundary several times, saying things like "What if I just go down on you?" and "I don't want to go all the way." Each time, however, Trevor responded with manipulation, trying to extract a *yes*. This closely follows the typical sexual script. He then got Mariana drunk, and she vomited. When Trevor asked explicitly for sex at this point, Mariana said yes and put a condom on Trevor.

In discussing this story filled with sexual violation, the group agreed it was not consensual. However, Jo said it "wasn't really rape." Several members said they needed to use their *Woah there!* cards more often, but Lauren lamented "we just treat this like it's normal." The group showed concrete knowledge of consent by pointing out that Mariana was too drunk to meaningfully say *yes*. They held Mariana responsible for drinking, though with more complex knowledge they would have situated this individual action within the broader systems at play during a fraternity party. There were hints of emerging expertise when players acknowledged that the story was "complicated," suggesting they knew their current conceptualization of consent was insufficient for understanding the story completely.

Group 3 created the most consensual hook-up. Callie and Jake were on a first date in a restaurant. Over a glass of wine, Jake said he was "hoping to get lucky." Thwarting the typical sexual script, Callie responded by removing her own underwear. They mutually kissed each other a few times, Callie said she did not think she should drive home, so they headed to the bathroom. Jake explicitly asked Callie if she wanted to have sex, and she replied, "yes please!" During sex, Callie said it was painful, so Jake offered to perform oral sex on her instead.

Most professional sexual assault advocates would identify this story as completely consensual, as would many feminist scholars. Callie's removing her underwear at the table was a bold assertion that she was as interested in having sex as Jake. When she said the sex was painful, he immediately stopped. Instead of making her feel bad for delaying his pleasure, he prioritized hers. However, because of their concrete knowledge, the group did not see consent. They said the verbal communication was insufficient. Raj called Callie's *yes please!* "hazy," and Sam agreed, noting the wine. They thought when Callie said she should not drive, it meant intoxication. While there was little evidence the characters were too drunk to consent, four participants thought Callie would feel violated and think her interactions with Jake were "a drunk mistake."

Discussion

The sexual narratives constructed through this gameplay became objects to think with. Students used their consent knowledge to interpret the sexual encounter. Unsurprisingly, these interpretations showed the undergraduates held mostly concrete knowledge of consent. Groups 2 and 3 showed the most concrete knowledge, possibly because they completed their consent education online due to the Covid-19 pandemic. While the members of Group 1 also had a largely concrete understanding, they showed more ability to recognize the complex systems in which an individual hook-up occurs. This could be due to an in-person consent education, an additional year of in-person college, or—most likely—a combination of these and many others. Research has shown that concrete knowledge has not reduced sexual violation. Though it has also shown that long-term, multimodal education can deepen students' consent knowledge (Ortiz & Shafer, 2018). If the purpose of consent education is to reduce sexual harm, then colleges—and high schools—need to devote far more time to it, and educators need a way to meaningfully assess consent learning. Narrative construction through gameplay can provide one way for such assessment.

Limitations

This study is limited in the following ways. First, the small sample size does not represent the knowledge of all undergraduates. Next, I constructed the interpretations alone, without the benefit of other's lived experiences. Further, this iteration of *The Hook Up Game* did not allow for bystander intervention, something included in most consent education. The next version will enable the introduction of additional characters, providing the option for bystander intervention and adding to the elements of consent knowledge that the game can assess. Finally, more research, conducted in a variety of settings, is needed to understand the full assessment potential of these games.

Changing Task, Changing Talk: An Analysis of Whole Class Discussions of Literary Texts

Allison H. Hall, University of Illinois at Chicago, ahall33@uic.edu
Candice Burkett, University of Indianapolis, burkettc@uindy.edu
Susan R. Goldman, University of Illinois at Chicago, sgoldman@uic.edu

Abstract: This work examines two lessons implemented one year apart by the same 11th grade English teacher. The lessons occurred at the same time of year and were around the analysis of the same passage from a novel. However, the task structure and the way the teacher mediated the discussion differed. The findings detail the consequences of these differences for students' engaging with each other in building literary interpretations and arguments. Implications for the design and implementation of literary tasks and discussion are considered.

Introduction

Design-based research (DBR) is a hallmark of the learning sciences. The reflection phase is particularly important for understanding what worked for whom and implications for redesign. This paper examines how redesign impacted classroom discussion of literary works in a first as compared to second design iteration. The design encompasses the text choice, the task and its structure, the activities in which students engage, and the teacher's instructional moves during implementation. Laboratory research has shown that task structure, texts, and activities impact student's literary interpretive reasoning (McCarthy & Goldman, 2015). These studies have not looked at the mediating role of teachers' instructional moves. Classroom-based studies also indicate that the task and its structure impact the intellectual work and discourse that students engage in during classroom discussions (Jackson et al., 2013; Kang et al., 2016). These studies did not explore the reflection phase of DBR and the resulting redesign of tasks, texts, and activities across DBR cycles. This paper examines two iterations of a DBR cycle in an 11th grade English classroom focused on literary interpretation to explore how the redesign following iteration one impacted students' engagement with literature and each other during whole class discussions.

The design work was informed by the nature of literary reading and interpretation. Literary texts portray the human condition through messages beyond the literal words (Langer, 2011). "Going beyond" the literal includes constructing interpretations that incorporate literary knowledge with personal, real-life experiences (Goldman et al., 2015; Lee et al., 2016). Interpretations can be particularly difficult for literary novices and thus require support from teachers (Levine & Horton, 2013). Lee and Goldman (2015) discuss factors that contribute to complexity in designing a learning environment to support students' development of requisite skills to engage deeply with literature. Teachers must understand the text and challenges that it might present students, as well as the demands of the task they ask students to engage in. The given task can vary in its level of cognitive demand from literal questions to questions about how the author uses the language and structure of text to convey meaning (Hillocks & Ludlow, 1985). As literary texts allow readers to explore the personal, cultural, and social aspects of human experience, individual readers can be expected to vary in their interpretations. Literary reading values this multiplicity and variety of perspectives on text. One way that teachers can support students in literary reading and interpretation is by creating opportunities for social interaction and exchanges of ideas around readings of the texts. These forms of argumentation encourage deeper exploration of author's use of language as well as connections to the everyday worlds of students (VanDerHeide et al., 2023; Lee & Goldman, 2015). Instructional moves during classroom discussions can support students sharing ideas and perspectives on text and make student ideas the center of classroom discussions (Howe et al., 2019; Nystrand et al., 2003).

The study reported here compares students' interpretive reasoning about literary works in the context of classroom discourse across two design iterations implemented by the same teacher, Ms. Edwards. Reflection on the first iteration (Year 1) led to changes in the task and teacher instructional moves for the second (Year 2).

Method

As part of a larger multi-year project focused on literary reading as multi-text evidence-based argumentation, Ms. Edwards designed and implemented a year-long curriculum focused on gender and power as manifest in several short texts and two novels. She taught 11th grade English in a large urban high school serving a diverse student population (47.9% Black, 43.1% Hispanic, 3.8% White, 1.9% Asian, and 3.3% mixed race; 87% free and reduced lunch). The teacher is White and was in her second year of teaching at that school when she joined the project.

The present paper draws on classroom observation video from two successive iterations of the year-long curriculum when students were reading *A Thousand Splendid Suns*, a novel by Khaled Hosseini that traces the stories of two women in Afghanistan. The two observations that constitute the primary data for this study were selected because the focus and content of the instruction was the same across iterations. The focus was on a passage that depicted the relationship between a husband and wife (Babi and Mammy). However, the task and set-up (instructions) for the task were different as were the teacher's moves during the class discussion.

In the first iteration (Year 1), the teacher gave the students the passage and asked them to "perform a close reading," annotating for power and agency. Students worked for about six minutes individually and then shared what they had noticed in the passage during a whole class discussion. In the second iteration (Year 2), the teacher put the passage up on a screen and told students to write four sentences in response to the question "Does this passage confirm or challenge your thinking about Babi's power?", reminding them that in a previous discussion they had decided Babi was powerless. She emphasized the importance of backing up their claims: "What evidence is showing you that it either confirms that he is weak or challenges that he is weak?" Students wrote responses individually for about four minutes and then discussed the passage as a whole class.

Data sources for this study are field notes and video and audio recordings of the two classroom observations. Each video was segmented into Interactional Units (IUs) independently by two coders. An interactional unit was a set of utterances that were "interactionally related and connected" (Smith, 2008, p. 81). The two coders agreed on the boundaries for the majority of IUs. Disagreements were resolved through discussion. Each interactional unit was analyzed for teacher moves and students' disciplinary practices, including the types and substance of the claims, the resources they used to make sense of the text, and the ways their contributions related to those of other students (e.g., building on others, challenging or disagreeing with others).

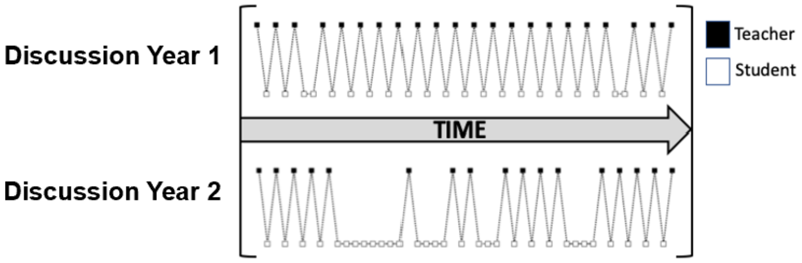
Findings

Our analyses of the discourse revealed differences across the two iterations in the teacher-student turn-taking interactions and students' disciplinary practices during whole class discussions. These differences can be traced to differences in the set up for the discussion as well as the teacher's instructional moves during the discussion.

The Year 1 discussion (~12 minutes) included 45 talking turns—22 by the teacher and 23 by students. Figure 1 depicts the distribution of talking turns in both discussions. The distribution of turns in Year 1 was almost entirely back and forth teacher-student. However, the Year 2 discussion (~12.5 minutes) was different, with 48 talking turns—17 by the teacher and 31 by students. Although the teacher did intervene in the second discussion, unlike the first discussion, we see chains of student-to-student talk moves that did not involve the teacher.

Figure 1

Distribution of Teacher and Student Talking Turns Over the Two Class Discussions



The Year 1 discussion was set up as a share out of annotations focused on agency and power from a close reading of the passage, and students did just that: They shared their annotations, all students agreeing Mammy had power (Babi was weak) until the teacher played "devil's advocate" to prompt them for alternative viewpoints. In contrast, the Year 2 discussion posed a question that had multiple viewpoints, and students provided those in their responses. Of eleven students, six claimed Babi was weak, three claimed he was strong, and two said he was both weak and strong. This represents a difference from the first discussion in the variation among student claims.

The Year 1 discussion began with the teacher asking students to share what they said in their annotations of the passage for power and agency. The first student asserted that Mammy had power. Several more students supported this idea and elaborated on Mammy's motivations. The teacher then asked the students to raise their hands if they thought Mammy was in power. Most students raised their hands, indicating that they agreed with the first student's statement. The teacher then stated: "I want to play devil's advocate for a minute and push us a little bit on this. What if I were to tell you that I don't agree?" Only after the teacher raised the possibility of a different interpretation of the text did students begin to argue about Mammy being in power. One student shared his thoughts "…he (Babi) wants to leave, but then like, she wants to stay so he actually goes by her agreement even though he is the male figure…I think he's more, like, devoted to his family's feelings than what he wants."

This interpretation uses Babi's actions in the text to counter the interpretation that Babi is weak and Mammy is in power. The teacher picked up this claim and directed students to compare Babi to the other male figures from the book, guiding them towards thinking about the multiple forms that power can take in different characters and situations. Towards the end of the discussion, she asked students to take another look at the passage: "See if you can pull some kind of reading that makes this kind of power structure less clear." The pattern and content of teacher talk moves, although it built on the initial student's interpretation, directed the students to what she wanted them to discuss (i.e., the complexity of power relations among the characters) rather than inviting students to respond to the initial claim. The teacher's moves likely reflect her realization during the lesson that the task set up ("annotate for power and agency") did not lend itself to literary argumentation and multiple viewpoints regarding power relationships. This realization may have triggered teacher moves intended to direct students to specific comparisons to surface this complexity. However, the directed teacher prompts also likely inhibited student-to-student talk moves and the free flow of ideas because students were looking to the teacher for direction.

After reflecting on the Year 1 implementation, the teacher re-designed the task and its structure for Year 2. She set it up as an argument from the beginning by directly posing multiple viewpoints in the central question: "Does this passage confirm or challenge your thinking?" Multiple students' hands shot up after she initiated the discussion with this question. The first three students who contributed to the conversation stated that they thought Babi was weak because he did whatever Mammy wanted. Without prompting from the teacher, a fourth student spoke up and said, "I disagree with all of them because they are lookin' at it the Afghanistan way, …cause some men, they don't wanna make a scene or wanna react to it cause they feel like that's not being manly. Cause like my momma when she at her house, you know, and my daddy just sit there like he doesn't want to say nothing because it would be a conflict…what I'm trying to say is like he got power, but he probably don't wanna use it on her, like what's the point of doing it?" The next student jumped into the conversation and said he also disagreed that Babi was weak. "Basically, just like [student] said …she might tell him to stop talking and shut up, and he might stop talking… [but] I feel like it doesn't change because I still feel like he's the smart one, he's the calm, like the brain of the household." Following these two contrasting viewpoints, another student stated, "I agree with both sides. Sometimes he is kinda weak, but sometimes he is strong…" The idea that someone can be both weak and strong represents the complex nature of the characters and of power relations both in the text and in the world, an understanding students came to by discussing and arguing varying viewpoints with each other. The Year 2 set up obviated the need for the teacher direction in the Year 1 discussion. The Year 2 task set up and the teacher's initial talk move were sufficient to support students arguing with one another, arguments that were grounded in the literary elements of the book.

Discussion

These two discussions demonstrate turn-taking structure and substantive differences that we claim are in large part the result of the redesign of the Year 2 task setup and teacher instructional moves. In Year 1, students mostly responded to the teacher with similar claims and rarely spoke to or referenced each other's ideas. In contrast, the Year 2 discussion consisted of varied claims and students directly disagreeing (and agreeing) with each other's ideas. The teacher staged the task as part of an ongoing discussion of power relations and character development over time, prompting students to decide whether new textual evidence "confirmed or challenged" their previous ideas. This problematization set the task up as an argument for which there could be multiple points of view. The design of the Year 1 discussion did not explicitly open space for multiple points of view and resulted in more summarizing annotated ideas than exploring multiple perspectives. In addition, the teacher stepped in and directly guided the Year 1 discussion, whereas in Year 2, she positioned herself out of the picture and let students build on and counter each other's ideas in a rich literary discussion.

These two discussions involved the same teacher, passage, and point of time in the year's curriculum, but the redesigned elements – the task set up and the teacher's mediation – made a profound difference in students' disciplinary reasoning during the discussions. Of course, we cannot rule out differences in the Year 1 and Year 2 students as contributing to the observed differences. However, the demographics of the classrooms across the two years suggest that such differences were minor compared to the differences in task structure and teacher mediation.

The present findings have implications for efforts to support teachers in engaging in instruction that provides opportunities for students to engage in literary argumentation and reasoning as well as in disciplinary argumentation in other disciplines. Teacher professional development often focuses on better lesson planning and designing of curriculum and instruction. It less often focuses on student learning that occurs when these designs are implemented. Professional learning activities that enable teachers to reflect on instruction, often facilitated by video records of instruction, indicate that such reflection leads teachers to greater awareness of their own instructional practices and how they are impacting student learning (e.g., Hall & Goldman, 2022; van Es & Sherin, 2010). Other efforts open up the classroom to teacher/research co-instruction through Learning Labs (Kavanagh et al., 2022; Kazemi et al., 2018). During Learning Labs, instruction is put on hold momentarily for reflection on what is happening. Reflection both after and during instruction leads to greater teacher awareness of the relationship between what teachers are doing and what students are doing. Increased teacher awareness is a powerful lever for change not only in designing instruction but in how teachers interact with students during instruction to support them in the intellectual work of the discipline, productive disciplinary discourse, and deeper learning.

Imagining Generatively Together: Exploring Strategies for Deepening Problematizing in Design Thinking Towards Justice-Oriented Futures

Sakinah S. J. Alhadad, Griffith University, s.alhadad@griffith.edu.au

Stephen Santa-Ramirez, University at Buffalo, srsantar@buffalo.edu

Abstract: The remarkable capacity of the human mind to travel through time and space enables us to think about our futures often. However, when analyzing complex problems towards justice-oriented futures, our methodological toolbox still has limitations. We draw from the processes of design thinking as a way to address wicked problems entangled in higher education injustices and inequities. In design thinking, the 'problem' phase is arguably one of the most challenging, yet critical phases. If a problem is ill-defined, then ideation of any possible future is constrained. We explore two innovative strategies to generate deeper problematizing for design thinking with multidisciplinary university students: an anti-goal strategy and the '7-problems-with-problems' strategy. In this preliminary analysis, we discuss the potential implications of the two strategies on design principles to support generative processes of problematizing for justice-oriented futures.

Introduction

'Design thinking' (DT) has been purported to be an effective approach to creative problem-solving, particularly for addressing *wicked*, or complex, real-world, problems. DT as a methodology has a multitude of approaches rooted in design theory (see Johansson-Sköldberg et al., 2013). Despite the common critique of its lack of conceptual clarity (Panke, 2019) and theoretical grounding (Micheli et al., 2018), DT has been increasingly adopted as the approach to support society-focused, human-centered, equity and justice-oriented, sustainable problem-solving (e.g., Wolcott et al., 2021), including as a key method of solving complex real-world problems in curricula of multiple disciplines (McLaughlin et al., 2022). Thus, we sought to explicitly problematize the methodology of DT, particularly that of one of the most influential DT approaches, the Stanford d.school method (Hasso Plattner Institute of Design at Stanford, 2020). The d.school method puts participants into contexts that support them to think and work like a designer across a series of phases. Each of these phases (i.e., empathy, problem definition, ideation, prototyping) encompasses a complex set of design cognition, each of which iteratively affects the efficacy of the next phase and, ultimately, the proposed 'solution(s)'. Empirical research on design cognition focusing on phases of DT (e.g., prototyping: Jobst & Meinel, 2014; empathizing, Svilha & Kachelmeier, 2022) elucidate nuance in emergent design cognition, supporting informed design-making for researchers and practitioners alike when using DT, such as *whether* design thinking as an approach does indeed support the intended outcomes, and importantly, *how* designers might optimize their collaborative approach toward creative, future-oriented problem-solving as intended through DT.

In this paper, we focus on the *problem definition* phase in DT. The problem definition phase follows the empathy phase, where designers use knowledge from empathizing to generate the identification of the problem(s) they are trying to solve. This stage is a critical step in the design process; inappropriately defined or misidentification of problems will lead to unviable solutions (Abdulla et al., 2020), or even the perpetuation of systemic injustice or tokenism (Ortiz Guzman, 2021). Thus, we investigated possible approaches to support design cognition for problem definition in DT with university students and staff collaboratively working towards possible justice-oriented future(s) of higher education. In two participatory workshops, we explored two innovative strategies to generate deeper problematizing in design thinking: an anti-goal strategy (van Lamsweerde et al., 2003) and the '7-problems-with-problems' strategy (Ortiz Guzman, 2021).

Methodology

Overarching methodology and methods

This paper is part of a larger study addressing epistemic diversity and equity when learning how to learn in college (Alhadad et al., 2021; GU ethics 2020/600). The broader research study brought together 20 university students across various disciplines (e.g., information technology, psychology, environmental science) and year levels (2nd-year undergraduate to masters' levels) to unpacked research from 'the science of learning' with the view to re-design research translations for students whilst centering equity. This program officially lasted eight weeks, however, it continued informally for another year and a half. This broader research was underpinned by participatory design research (PDR; Bang & Vossoughi, 2016) and social design-based experiments (SDBE; Gutiérrez & Jurow, 2016), centering students as the community of focus for equity-based futures in knowledge participation at the university. The use of PDR and SDBE as the overarching methodology allowed us to strongly anchor the program with deep roots of justice-making, disrupting power, and with strong attunement to our diverse identities, historicities, and positionalities as we collaborate to enact change. DT was employed as an analytical method within the broader research to support an equity-focused critique of the science of learning research translations. As part of this broader program, we conducted optional participatory workshops intended to support students to deepen their application of the design thinking processes in a defined topic (e.g., disability, future-focused curriculum, etc.). Two of the participatory workshop sessions focused solely on imagining justice-oriented futures of higher education, which the current paper will focus on. To activate thinking about social and epistemic justice in higher education, we began both sessions by discussing a current issue covered in the media (e.g., the presence/ absence of Indigenous ways of knowing in schools, current issues impacting critical race theory socio-politically). The sessions were conducted eight months apart. Each workshop ran for two hours, with most of the students overlapping across the two sessions (student $n_{session1}=10$; $n_{session2}=8$). One staff member participated in the first session (anti-goal strategy), while four staff participated in the second session (7-problems-with-problems strategy).

The two strategies: The anti-goal strategy and the 7-problems-with-problems strategy

The *anti-goal strategy* (AG) instructs participants to consider the worst possible outcomes or scenarios that can be imagined or experienced in relation to the design aims. Initially a strategy used in engineering (van Lamsweerde et al., 2003), the AG strategy has shown potential to support students' insights as they work to strategize ways forwards for their everyday wellbeing (Dresser et al., 2021). An AG can be thought of as the antithesis or negation of what is considered the desired goal. Its utility is suggested to support the generation of desired goals by focusing on things they might dislike or want to avoid the most. In the case of justice-oriented higher education futures, as in this study, this means that participants in the first workshop collaboratively generated problematic goals that cause or lead to injustices or inequity, thereby creating a list of behaviours, practices, or activities that would reliably achieve the anti-goal of ensuring injustice in higher education. The second strategy, the *7-problems-with-problems strategy* (7PwP), was created by Ortiz Guzman (2021) through a series of industry-wide workshops and extensively critiqued the problem with problems for equity-focused design work by supporting participants to *understand* what these problems might be before going into problem identification and definition collaboratively. Some examples of the problems with problems identified are that the problem articulated is "just a symptom but treated as a root cause" (P4) or is "described at the level of individuals, absent institutional, systemic, or ideological factors that are also at play" (P5). In the second workshop, participants were briefly familiarized with the 7PwP statements before collaboratively generating problems of injustice and inequity in higher education.

Evaluating the problem statements

To evaluate each problem statement, collaboratively generated across the two workshops, we used the 7PwP rubric developed by Ortiz Guzman (2021). This rubric provided seven criteria to evaluate how these problem statements can better address social injustice (Table 1). Each statement was scored against each criterion, from 1 to 3, where a score of one means "Needs work", two means "Getting there", and three means "Close to the goal". Statements from both workshops were combined in the same spreadsheet, and their order was randomized, so the researcher doing the scoring could not identify the strategy used to generate each statement.

Table 1
Scoring criteria using the Seven Problems with Problems

Code	Definition
P1	Is your problem stated as the absence of a solution you wish to implement?
P2	Is your problem statement missing specific references to people?
P3	Does your problem implicitly or explicitly blame those experiencing the problem as having caused or being responsible for it?
P4	Does your problem treat a symptom as a root cause (unintentionally)?
P5	Does your problem focus on the problem at the individual or interpersonal level and miss the institutional, systemic, or ideological aspects?
P6	Does your problem statement forget to acknowledge the historical context of the issue?
P7	Are you trying to solve the problem for everyone or trying to solve all the problems at once?

Data analysis

To compare the difference between the distribution of the scoring of each criterion, for the AG and 7PwP tasks, we conducted a multinomial test. We tested the equality of the distributions considering the frequency of scoring of the AG task as our null hypothesis. We conducted Bayesian analysis, using the statistical software JASP (2022), with default priors. The strength of evidence for the null (H_0) or alternative (H_1) hypothesis was measured using Bayes Factors (B_{01}). A high value for B_{01} suggests stronger evidence for H_0 (here that there was no change between the distribution of scores from the two workshops), and a small value suggests stronger evidence for H_1.

Findings

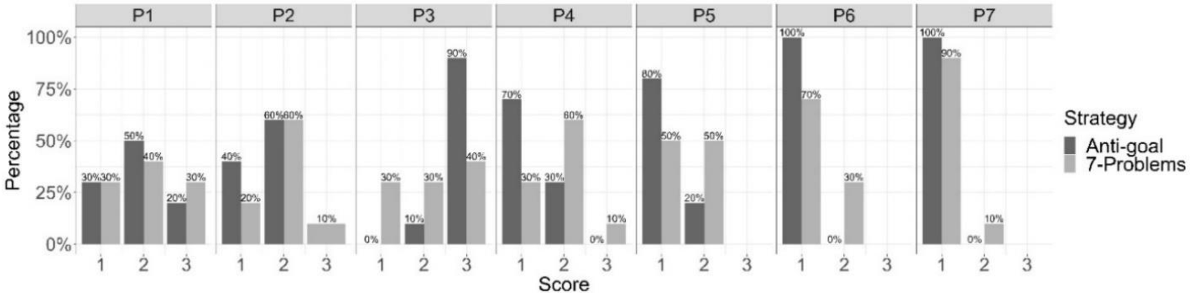
The results from the multinomial test show that there is moderate evidence that the distribution of the scores for the 7PwP has similar distributions to the scores of the AG strategy for P1(B_{01}=4.2), while there is very strong evidence that both have different distributions for all other criteria (B_{01}< 1/30). Overall, the problem generated in both strategies needed to be improved for criteria P5 to P7 (Figure 2). The 7PwP have slightly better performance overall, with a higher percentage of statements being classified as "Getting there" (2) or "Close to the goal" (3), in most criteria, except P3, where it is outperformed by the AG task. As an example, a statement that was scored for P4 (symptoms or root cause) as "needs work" is "unpaid internships as a requirement in the degree is the actual worst and so unfair in many ways" compared with a "close to the goal" statement scored example was "learning about our histories are sometimes truncated/ only get to learn part of an erased or amended history". The statement with the highest score (18, summed scores across the seven criteria) was from the 7PwP session:

> How we assign value to students as an entity in society: racism, and all other forms of prejudice as intersecting and disproportionately imposed in this. e.g., students as activists (climate strike, Black Lives Matter) - a form of surveillance, and assigning values, and expectations to those. (sic) And for some students are deemed problematic, but not others (e.g., racialized super surveillance) this happens to White allies as well as they 'take sides'. An attack on anything that might challenge the status quo.

The quote above was scored as "Close to the goal" (3), for P1 to P4, and as "Getting there" (2), for P5 to P7. In contrast, the statement with the lowest score (7) was from the AG: "introducing these issues early on in academic careers and not simply at the end of an undergrad class or something to opt-in." This statement is not a problem but a solution (P1) and also failed to address the other problems with problems, thereby scoring as "Needs work" (1) for all criteria.

Figure 2

Distribution of scores for each criterion, for the AG (46 problem statements) and the 7PwP (35 problem statements) tasks.



Discussion

Both the AG and the 7PwP strategies as a nuanced method to generate deeper problem statements in DT showed promise, while also indicating limitations as conducted in this study. Even though we used the 7PwP as *scoring criteria*, the 7PwP *task* did not produce deeper problem statements overall. Both the use of the AG and 7PwP strategies provided practical directions to generate problem identification, as well as further developing the articulation of the problem statement. We found that even though both strategies required improvement with the articulation of the problem statement in addressing the 7PwP criteria, the use of the 7PwP strategy slightly improved the depth, complexity, and quality of the problem statements, in particular, not treating the symptom as the root cause (P4). However, the AG strategy was more effective in avoiding attributing people experiencing the problems as being responsible for them (P3; 90% of AG statements, compared to 40% of 7PwP statements). This might be because of the nature of the AG strategy, which encouraged the focus on issues participants wanted to avoid or deny, which inherently meant overt consideration of the people impacted. The counter effect to this was that the AG strategy failed to generate problem statements that identified root causes, but rather were of symptoms.

Within two hours, the AG strategy was able to elicit a brainstorming style of problem definition. However, given the extent to which the AG generated inappropriate or misidentified problems, this strategy limits the depth and quality of problem definitions. This lack of depth was also observed in the 7PwP session, albeit less severe, suggesting that with more time, participants may further refine the problem statements in ways that address the 7PwP rubric more closely to the ideal statement. Thus, we suggest that following a brainstorming phase, there is a need to prioritize and expand the problem statements through deeper discussion and reflection. Combining elements of these two strategies may support the generation of more equity-focused problem statements that are less problematic for design thinking. Further, we observed that the problem statements generated in the AG session tended to exclude staff perspectives, unlike those in the 7PwP session. This suggests that an important design consideration is to ensure a diverse representation of the community involved in the context of the wicked problem so that the problems articulated include the multiple vantage points of people most proximate to the entangled problem. This is particularly important as we observed that if we only worked off the very student-centric AG statements, some of the proposed solutions might create additional burdens for other people in the same complex system of higher education (e.g., disability staff, academics), thus inadvertently creating or perpetuating further inequity and injustice. Whilst the two strategies used in this study continue to highlight the challenge of supporting people and communities in problematizing for speculative justice-oriented futures in their contexts, they offer some ways to deepen the process of justice-focused design thinking that much further.

Building Teachers' Digital Competence Through a Self-Reflection Process

Anastasia Economou, Joint Research Centre, European Commission, anastasia.economou@ec.europa.eu

Abstract: Teachers' digital competence is a key element of the digital transition and transformation of education for quality teaching and learning. Education systems are seeking meaningful and effective professional development to support teachers build their digital competence. We propose a self-reflection process for teachers' professional learning and an online tool to facilitate this process. The SELFIEforTEACHERS tool uses the DigCompEdu framework as the conceptual reference for educators' digital competence. Personalised feedback generated by the tool can help teachers design their professional learning paths, while anonymous aggregated data can support plan professional development programmes. We implemented a pilot study to test the tool validity and reliability and collect preliminary data on its use. We are currently conducting a qualitative study to explore how the tool can be used effectively for the self-reflection process. This paper presents the conceptual approach of the project, while empirical results will be shared in future papers.

Introduction

Digital transition and transformation of education for quality teaching and learning has been a high priority in national and regional strategies. The COVID-19 health crisis revealed what research had already shown: not all schools and teachers are ready to use digital technologies to provide quality online and remote learning (OECD, 2021). According to the Teaching and Learning International Survey (TALIS) in 2018, only 43% of the participating teachers felt well or very well prepared in the 'use of ICT for teaching' (OECD, 2019). The teaching profession requires educators equipped with the necessary competences to respond to rapidly changing demands for teaching and learning. Thus, there has been an increasing need to find ways to support teachers' professional development to harness benefits and opportunities, as well as deal with challenges that digital technologies present to education.

To provide meaningful and effective professional development, learner-centered pedagogical approaches are emerging. Boeskens et al. (2020) use the term 'professional learning' to distinguish more active and contextualised forms of learning, with emphasis to the teachers' active role and own agency as reflective professionals. Reflection is perceived as a "personal process that can deepen one's understanding of self and can lead to significant discoveries or insights" (Desjarlais & Smith, 2011). It can trigger self-assessing one's capacity in order to improve it. Important aspects of successful self-assessment incorporate the measurement against a model, which can provide a benchmark for identification of further development priorities, as well as acting upon the results (Hillman, 1994). In our case, we used the European framework for the Digital Competence of Educators (DigCompEdu) as the conceptual reference for educators' digital competence (Redecker, 2017).

In this short paper, we present a comprehensive approach for building teachers' digital competence, encompassing self-reflection as a learning process and an online tool to facilitate this process. We will share empirical results of the proposed approach in future papers.

Conceptual approach

In the recent European Commission Education Action Plan 2021-2027 (DEAP), digital competence is considered a core skill for all educators that should be embedded in all areas of teacher professional development (European Commission, 2020). The launch of an online self-assessment tool for teachers based on the DigCompEdu has been foreseen in one of the actions.

Taking into consideration the DEAP, the research team endorsed two posits: first, that self-reflection as a process can support teachers' professional learning; second, that DigCompEdu framework can serve as the conceptual framework to benchmark educators' digital competence. The goal is to address the need for effective professional development to foster digitally competent primary and secondary teachers across Europe, by developing an up-to-date, valid and reliable online tool for teachers, based on DigCompEdu. The tool is an integral part of a comprehensive professional learning process based on self-reflection.

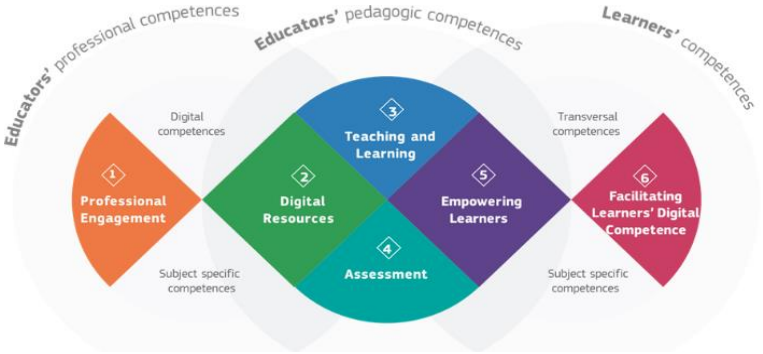
To achieve our goal we: analysed existing self-assessment tools based on conceptual frameworks; explored self-reflection as a learning process for teachers' professional learning; performed a content analysis of DigCompEdu in relation to up-to-date pedagogical trends literature; adapted DigCompEdu content to primary and secondary teachers' professional practices; designed and developed an online tool to guide teachers' self-reflection, providing personalised feedback with suggestions how to level up; suggested a process to support teachers' designing their professional learning; ran a pilot study to test the tool validity and reliability; are investigating how the tool can be effectively used at both process level and outcomes level; will analyse aggregated data to measure the tool impact; and will explore the adaptation of the tool to other education contexts.

DigCompEdu

Digital competence is one of the eight key competences for lifelong learning and is approached as a combination of knowledge, skills and attitudes, for "confident, critical and responsible use of, and engagement with, digital technologies for learning, at work, and for participation in society" (European Council, 2018, p. C189/9). To describe educator-specific digital competences, the DigCompEdu framework has been developed. It is the result of work at the European Commission, which brought together experts from across Europe to reach a common understanding and provide a comprehensive model for describing educator-specific digital competences (Redecker, 2017). DigCompEdu has been widely used by educational systems, researchers and education stakeholders to support national frameworks and strategies, assessment tools, education and training programmes, and educational resources.

DigCompEdu describes 22 educator-specific digital competences in six areas, with emphasis on the pedagogical competence of using digital technologies to enhance teaching and learning. It involves educators' digital competence in their professional context and their competence to facilitate the development of their learners' digital competence (see Figure 1). The framework proposes a progression model with six stages through which an educator's digital competence typically develops for each of the competences.

Figure 1
The DigCompEdu framework (Redecker, 2017; CC license)



Several self-assessment tools have been developed to help measure teachers' competence. For example, the MENTEP TET-SAT (1), a tool developed as part of a policy experimentation project and the CheckIn tool (2), an experimental tool based on the DigCompEdu framework, used, adopted or adapted in various research projects, as in work with teachers in Germany (Ghomi & Redecker, 2019), Portugal (Lucas et al., 2021), Morocco (Benali et al., 2018), Switzerland (Cattaneo, 2021), and Southeastern Europe (Petrovic, 2021). SELFIEforTEACHERS advances beyond the CheckIn tool, enriching its content with current trends and validating its internal and external validity with a pilot study.

The self-reflection tool and process

To design and develop the self-reflection tool the research team performed a content analysis of DigCompEdu to adapt it specifically for primary and secondary education teachers in Europe. The framework 22 competences were studied and deconstructed through their descriptors and activity examples provided. They were then transformed into statements with examples relevant to teacher practice to facilitate their understanding of the framework and guide their self-reflection (Economou, 2023). The tool comprises 32 self-reflection items (corresponding to the framework competences, parts thereof, or emphasising aspects of teachers' digital competence based on emerging educational needs) (see Figure 2). Each item provides an introductory statement describing what the corresponding competence is and six proficiency level statements - based on the DigCompEdu progression model - from which teachers can choose the one that best captures their competence level. The tool also generates a personal report for each teacher with results and feedback with suggestions on how to level up.

- 6.6 Problem solving

Through guiding self-reflection statements, teachers identify strengths and gaps in their digital competence. Upon completing the session, they are prompted to take action for further development. As critical self-reflection can lead to engaging in strategies for continuing personal, professional and career development (setting goals for example) (Cheng et al., 2015), teachers are encouraged to design their own professional learning paths to further develop their digital competence.

SELFIEforTEACHERS aims to involve teachers in self-reflection at three stages: reflect on their professional practice and self-assess their digital competence guided by the tool items; reflect on their results and the tool feedback to plan their professional learning paths; and reflect on the whole process and their progress.

The self-reflection learning process suggests a spiral of six steps: (1) Complete a self-reflection session; (2) Analyse the personal feedback report; (3) Design professional learning path; (4) Implement the learning path (e.g. participate in a training course, join a community practice); (5) Apply new competences in professional practice; and (6) Repeat the self-reflection to monitor progress.

Tool validation

To validate the tool we implemented a pre-pilot with 795 teachers in two countries (Italy and Portugal) during December 2020 and January 2021, and a pilot study with 3218 teachers in five countries (Estonia, Italy, Lithuania, Portugal and Ireland) in April 2021. Psychometric statistics verified the competence areas and progression levels as proposed by the DigCompEdu framework, and the validity and reliability of the 32 items for each of the areas. A follow-up study, using quantitative and qualitative methodologies, explored user perceptions about the tool and the self-reflection experience.

The pilot study confirmed that the SELFIEforTEACHERS tool is valid and reliable for primary and secondary teachers to self-assess their digital competence. Factor analysis confirmed a good fit for the suggested six-factor model of teachers' digital competence. Confirmatory Factor Analysis (CFA) did not suggest any changes to the dimensionality (factor structure) of this construct; all items had good - or at least satisfactory - factor loadings. Correlation analysis did not reveal significant overlap between any two items in the self-reflection tool and none of the item pairs correlated highly with each other.

The follow-up study analysis confirmed that a large majority of participants were satisfied with the self-reflection experience, the online tool user-experience, the items, the help texts and the feedback report. Analysis of qualitative data showed that participants found the tool relevant to their job and professional development and felt motivated to proceed with planning professional learning based on the tool feedback report.

Discussion and future directions

The study proposes a comprehensive approach to support building teachers' digital competence. It entails an online tool and a self-reflection process to empower teachers' active engagement and agency in assuming a central role in their professional learning, by capturing their current digital competence and initiating and designing their learning pathways. They are empowered to take ownership of their professional learning and development and act as reflective practitioners, identifying their own training needs and mapping out their learning pathways in a context of autonomous lifelong learning (European Commission, 2007). At the same time, it provides policy makers, teacher educators and trainers, and school leaders with a tool for teacher professional development programmes as well as anonymised aggregated data to support policy planning.

The online tool developed is valid and reliable. At the current stage of the study, we are investigating how the tool can be effectively used. Through a network of experts across Europe we explore in various *use cases* how the tool can help different stakeholders support building teachers' digital competence. We are also designing twelve cases studies in six countries to investigate the factors that can play a role during the tool use, and how participating teachers' digital competence might change. We will then analyse the aggregated data to investigate what impact the tool may have on teachers' digital competence.

Through the whole process, we also expect to identify contextual factors, such as systemic, institutional, cultural and personal, that might have an influence on the tool use and how, contributing to research on teachers' digital competence in relation to personal and contextual factors. Based on the study results, we will explore the adaptation of the tool to other education sectors and different contexts (e.g., specific teacher groups based on subject matter, regions, and roles).

Toward A More Comprehensive Definition of Collaboration: Scholarly Literature vs. Practitioners

Abstract: Collaboration is a core component of collaborative learning. However, the definition of collaboration still lacks consensus and differs across disciplines. Therefore, this study aims to provide a comprehensive definition of collaboration that is generalizable across different contexts. We gathered the definitions of collaboration from 52 scholarly articles and 22 focus group interviews with 87 practitioners. We found some alignments and gaps between scholarly articles and practitioners regarding the collaboration definition. The study underscores the need for bridging gaps in defining collaboration between research and practice to provide a complete picture of collaboration in collaborative learning environments. A comprehensive definition of collaboration creates opportunities for the development of transferrable assessments, rubrics, instructional supports, and technology.

Introduction

Collaborative learning is a commonly used instructional approach across various domains of work. Research has found that collaborative learning has the potential to improve learners' conceptual understanding, motivation to learn, and metacognitive skills (e.g., Hatami, 2015). Regardless of the potential positive impact of collaborative learning, many scholars have agreed that the core component of collaboration still lacks a coherent definition. Thomson et al. (2009) argued that this coherence issue is due to the varied definitions of collaboration across disciplines. Patel et al. (2012) echoed such a concern that "for a concept so widely used in everyday language, there is a surprising lack of a clear understanding of what it is to collaborate, and of how best to support and improve collaborative working" (p. 1). Bedwell et al. (2012) contended that, etymologically, collaboration is a vague and elusive concept. It stems from the Latin word *collabore* referring to "to labor with or together" (Lewis & Short, 1879, p. 365), which can be interpreted in many ways across disciplines. Sundaramurthy and Lewis (2003) added that many collaboration definitions do not include a description of what the process of collaboration looks like. Therefore, when different definitions of collaboration are translated into classrooms and workspaces to build professional skills and support learners, educators and practitioners do not operate from the same conception of collaboration and therefore demonstrate varied implementation approaches.

The lack of a common collaboration definition may be due to the gaps between scholarly literature on collaboration and how practitioners define and implement collaboration. Identifying these gaps is crucial to bridging discrepancies and ambiguities. It may also aid in moving toward a more comprehensive definition of collaboration that is applicable across disciplines. Therefore, this study aims to investigate such gaps by conducting a systematic literature review of scholarly articles and interviewing individuals across different fields to gather data on how they define and operationalize collaboration. The following research questions guided this study: (1) How does scholarly literature define collaboration?, (2) How do practitioners define collaboration?, and (3) What are the intersections and gaps between scholarly literature and practitioners' definitions of collaboration?

Methods

This study employed a grounded theory approach to develop an in-depth and comprehensive understanding of collaboration definitions across different disciplines (Strauss & Corbin, 1998). We conducted a systematic literature review and a series of focus group interviews to gather data on how scholarly literature and practitioners define collaboration (1). For the systematic review, we started with a keyword search in the ERIC database using the term "collaboration" from any papers published in any journals and any disciplines (e.g., humanities and social science, medicine and health, and STEM) (Gough & Thomas, 2012). This search resulted in a total of 6400 publications. We then used random and theoretical sampling approaches to collect any definition of collaboration from the papers. We adhered to two exclusion criteria: papers that 1) cited others' definitions of collaboration, and 2) restricted access to full papers. We collected and qualitatively coded the data. We reviewed 52 papers and we did not find any new categories until reaching theoretical saturation.

We also recruited 87 participants (22 groups with three to four members each) for the focus group interviews. The participants represented a wide range of ages, races, and occupations. The focus group participants were students and professional practitioners that use collaboration in their educational and professional interactions. The mean age was 32 (*SD*=10). Participants identified racial groups included 43% Asian/Pacific Islander, 17% Hispanic/Latinx, 37% White, and less than 1% Black/African American and other. Participants' occupations varied and included fields such as academia (e.g., students, teachers, researchers), corporate (e.g., business analysts, attorneys), and technical fields (e.g., engineers). The participants engaged in an hour of collaborative activity and were subsequently interviewed for approximately 15-20 minutes. Focus groups were recorded and transcribed verbatim.

We used open and in-vivo coding processes (Creswell & Poth, 2018) to analyze the definitions of collaboration from scholarly literature and transcriptions of focus group interviews. Three researchers were involved in the qualitative coding process and modifications and generation of the initial and final coding scheme. Table 1 presents the modified coding scheme consisting of elements of collaboration that were used to define collaboration.

Table 1

Elements of Collaboration Definition (Note: % = percent of papers and focus groups for each element)

Element	Sub-element	Description	% Papers	% Groups
Input	Joint/group effort	More than two individuals jointly working.	81%	91%
	Complementary expertise	Everyone brings their expertise to ensure efficiency (e.g., knowledge and experience).	21%	77%
	Task/problem solving skill complexity	The tasks or problems faced require multiple skills, knowledge, or experiences.	4%	18%
Process	Knowledge/ resources sharing	The process of information exchanges.	23%	0%
	Workload decomposition	The process of decomposing tasks and workload for efficiency.	0%	23%
	Conflict negotiation and resolution	The process of exploring and resolving differences.	8%	45%
	Shared decision-making	The process of collective conclusions or solutions for problems.	19%	14%
	Layered decision-making	The process of evaluating the conclusion, including monitoring and regulating the shared knowledge and/or outcomes.	6%	0%
Norms	Shared goals	Belief in achieving or solving one or multiple common goals.	63%	68%
	Reciprocal engagement	Everyone actively contributes to all processes and interacts with each other.	19%	14%
	Responsible and accountable	The degree to which members can justify any roles/actions/decisions they are assigned to.	13%	14%
	Mutual trust and respect	Everyone believes in each other's strengths.	21%	9%
	Non-hierarchical (shared power)	Involving a shared power and authority, or everyone is considered equal.	17%	5%
	Voluntary participation	Everyone has the willingness to contribute/participate.	6%	14%
Output	Quality outcomes	The end goal is to produce better or different solutions/outputs than working alone or gain new knowledge and skills.	6%	45%

Findings

How does scholarly literature define collaboration?

Based on the findings of the systematic literature review shown in Table 1, we found that most papers included *joint/group effort* and *shared goals* within the elements of Inputs and Norms when they defined collaboration.

This is not surprising since a common definition of collaboration is working together toward a common group goal. In addition to this definition, many papers proposed more extended definitions of collaboration to include Processes and Outputs as elements of collaboration. For example, Friend and Cook (1992) defined collaboration as:

> …a style for direct interaction between at least two co-equal parties voluntarily engaged in shared decision making as they work toward a common goal… [and has characteristics of] voluntary, individuals who collaborate share a common goal, requires parity among participants; includes shared responsibility for decisions; share accountability for outcomes among individuals; includes sharing resources; emergent characteristics. (p. 5)

Although this definition is robust, it omits various sub-elements from Norms, Processes, and Outputs, such as *mutual trust and respect*, *conflict negotiation*, and *quality outcomes*, that other papers included in their definitions of collaboration. For example, Scoular et al. (2020) defined collaboration as involving "perseverance, contributing to team knowledge, valuing contributions of others and resolving differences… a division of labor with participants who are engaged in active discourse that results in a compilation of their efforts" (p. 2). Still, this definition does not cover sub-elements other scholars consider necessary when defining collaboration.

We also found that very few papers (*n*=3) included sub-elements *quality outcomes* of collaboration and *layered decision-making* as elements of collaboration. In summary, there was no clear consensus on how to define collaboration. Each paper provided a different definition of collaboration with emphases made to different sub-elements, as shown in Table 1.

How do practitioners define collaboration?

Based on the findings of the focus group interview analysis shown in Table 1, we found that when defining collaboration, most groups emphasized three sub-elements: *joint/group effort*, *complementary expertise*, and *shared goals.* These sub-elements are seen in Groups 5 and 15's definitions: "two or more people who are working together towards a common objective" and "help(ing) each other to get a better advantage, especially understanding the different group members' strengths and weaknesses and how can you, like, supplement each other…. [to] accomplishing the same goal." Furthermore, we found that some groups emphasized *task/problem solving skill complexity* and *workload decomposition* as sub-elements. For instance, Groups 3 and 2 stated that collaboration should include tasks that require collective efforts and a process of "many people try[ing] to reach the goal altogether, dividing on the task, and make the load easier for each member of the group." In addition to *workload decomposition*, participants mentioned *conflict negotiation and resolution* as important for collaboration. Unlike the scholarly literature, many groups mentioned Output when defining collaboration. Specifically, they identified *quality outcomes* as being a collaboration product.

Although, the focus group participants defined collaboration using all the elements of collaboration, we found that many sub-elements were not mentioned. For instance, none of the groups described *knowledge and resource sharing* or *layered decision-making* as sub-elements to Process. Additionally, very few of the groups touched on some of the sub-elements to Norms, like *mutual trust* and *non-hierarchical (shared power)*.

What are the intersections and gaps between scholarly literature and practitioners' definitions of collaboration?

Based on the intersections of various definitions of collaboration, Figure 1 shows the concept of collaboration bringing together elements of Input, Process, Norms and Output. We brought ideas from research papers and focus group practitioners together to construct a description of collaboration: *A complex process through which a group of individuals interdependently and constructively explore ideas to search for solutions and construct new knowledge. As individuals work interdependently, they create a socio-cognitive space where goals, ideas, beliefs, and plans are collectively generated and shared among the members in the group. The socio-cognitive space includes the sharing of tools and promotes learning that extends one's own limited vision to create high quality products.*

Figure 1
Integrated concept of collaboration.

Discussion and Significance

Our findings show that while there are intersections of how research and practitioners define and operationalize the concept of collaboration, they also show that there are gaps between research and practice. Research literature and focus group participants generally agreed on the Inputs and Norms of collaboration and varied on Process and Outputs of collaboration. Research literature emphasized *sharing knowledge and resources* while focus group participants emphasized *conflict negotiation and resolution* and *quality outcomes*. Perhaps practitioners are more interested in a functional production of artifacts while researchers may be more interested in gaining new knowledge and making intellectual contributions to their fields. Our study helped us put together a definition of collaboration that incorporates multiple elements of collaboration that can be used across disciplines and in various settings, like in online collaboration and face-to-face collaboration. Having a comprehensive definition of collaboration creates opportunities for the development of transferrable assessments, rubrics, instructional supports, and technology. Future work would require an expanded analysis of additional practitioners, until saturation is reached more broadly.

“So, They Said Harder Math, Right?”
Youth Pedagogical Development in Youth Teacher Debrief Sessions

Eli Tucker-Raymond, Xi Yu, Juan Gutierrez, Ashley Houston-King, Katherine K. Frankel,
Cliff Freeman, Maria C. Olivares
etuckerr@bu.edu
Boston University

Abstract: This study explores how young people, aged 14-22, employed as facilitators of math learning for younger children in an out-of-school time organization, talk with each other about their experiences as they participate in a routine known as “debriefs.” Debriefs occur between facilitation sessions and allow opportunities for youth to discuss mathematical ideas and understand their roles as facilitators. They also provide space for youth to begin planning the next facilitation. Through interaction analysis of one typical debrief session, we offer implications for understanding how debriefs contribute to the unique ways that young people develop their pedagogical approaches—a process we call “youth pedagogical development.”

Introduction

This study takes seriously the idea that young people can be effective intellectual leaders in formal and informal STEM learning contexts, among others. As facilitators of STEM learning, young people learn to teach and develop positive identities as leaders and as STEM doers. We call these processes of identity development and learning that occur while youth are engaged in disciplinary teaching *youth pedagogical development* (Yu et al., 2023). In this case, we analyze how young people reflect on their facilitation of mathematics learning for other young people during debriefs, and how debriefing contributes to youth pedagogical development. The near-peer teaching program we discuss in this paper, The Young People’s Project (YPP), is a grandchild of the organizing practices of the Student Non-Violent Coordinating Committee (SNCC) (Moses et al., 1989). In SNCC practices, organizing is carried out in collaboration with, and eventually led by, the hands, hearts, and minds of the people who will be most impacted by the goals of that organizing. It is grassroots and collaborative. Leadership is decentralized. Likewise, the debriefs we describe below are learning and organizing tools rooted in the freedom movement in 1960s Mississippi and elsewhere.

Literature review

Taking various forms, teacher reflection practices are often studied in teacher education as ways to improve teachers’ pedagogy (e.g., Liu & Ball, 2019). An important component to engaging in reflection is for teachers to be able to identify and make connections between events and pedagogical principles, and notice contexts in which events occurred (e.g., van Es & Sherin, 2021). In preservice settings, opportunities for collaborative reflection have been shown to be crucial to preservice teachers’ development and self-perceptions as facilitators and future classroom teachers (Jao et al., 2020)..Our study explores reflection among multiple youth who all taught together, as opposed to groups of people debriefing one person’s pedagogy as is the case in many schoolteacher reflection sessions. We pay particular attention to how youth at YPP take up their own configuration of semi-structured verbal debriefs regarding their teaching of mathematics to elementary school-aged children. We orient to the exploration of young people’s engagement in debriefs through an emerging framework, detailed below, that we call *youth pedagogical development* (Yu et al., 2023).

Theoretical framework: Youth pedagogical development

Youth Pedagogical Development (YPD) helps explain how youth learn to teach as they engage with disciplinary ideas and attune to pedagogical strategies that support learning and engagement for others. Youth’s engagement also transforms the ways in which they come to identify as teachers, learners, and doers of, within, and across academic disciplines (Tucker-Raymond et al., 2016). We conceptualize development as the socially, culturally, and historically situated processes through which individuals learn together in joint activity and, in so doing, transform those processes (Vygotsky, 1978). To further theorize YPD, we highlight its interrelated components—identity; learning and doing; teaching; and disciplinary ideas, literacies, and practices. At the core of YPD are identities. Identities are situated within specific social practices and developed over time as part of social interaction with others (Nasir & Cooks, 2009). Oftentimes, young people employed as facilitators in informal environments are not experts in whatever it is they are supposed to teach. In YPD, teaching and learning are explicitly interrelated processes in which there is a short period of time between the time when young people learn about and engage with disciplinary ideas, practice what they are going to teach, and then teach others. Therefore, new youth teachers, leaning on more experienced ones, learn alongside the children they are supposed to be "teaching." This component of YPD disrupts normative distinctions between "teacher" and "learner." Finally, in YPD, disciplinary ideas, literacies, and practices, are thought of more expansively than in schools. For instance, the mathematics in this study is solely taught and learned through games. Pedagogical goals are concerned with *familiarizing* learners with ideas and helping them feel comfortable exploring them. It is important to note that YPD will look different in different youth teaching contexts because the relationships between the commitments, practices, and engagements of each unique organization and the youth teacher participants will be different.

Research question

How does participation in a YPP debrief session contribute to youth educators' pedagogical development?

Methodology

The data in this paper come from a multi-year study of youth teaching in three organizations, including YPP. YPP employs predominately students of color from local high schools and colleges to serve as Math Literacy Workers (MLWs) and College Math Literacy Workers (CMLWs), respectively (collectively, C/MLWs). The C/MLWs work together to design mathematics workshops for elementary- and middle-school aged students in local public schools and camps during the academic year and summer. After outreach workshops for younger students, the C/MLWs engage in a reflective practice called a "debrief." The C/MLWs in this paper were part of a smaller group at YPP that visited a summer camp for children ages 4-13 run by a community organization. These C/MLWs provided an hour or so of programming two times a week. The group included two CMLWs, both of whom had been MLWs, and eight MLWs, all of whom were in their first year at YPP. These C/MLWs were tasked with introducing a game to the campers called Flagway™. Flagway (see typp.org) is a timed, competitive game in which participants categorize numbers based on characteristics of their prime factorizations and then run a physical course based on their answers. Activities leading up to the final Flagway game are meant to break down into parts the mathematics ideas needed for the final game.

Data for the larger project were collected through participant observation and interviews during Summer 2021 and Spring and Summer 2022, for a total of roughly 200 hours across sites. We identified 31 instances where our data sources from YPP mentioned "debrief" or "reflection." For this paper, we focus on illustrative examples from one, approximately 15-minute-long debrief. This debrief occurred after the third visit to the summer camp. We engaged in an interaction analysis protocol as a team of seven (Jordan & Henderson, 1995). We created themes based on our noticings and discussions while listening to the audio file and reading the transcript of the debrief. Our ongoing analysis had clued us in to how debriefs reflect the four tenets of YPD (i.e., identity, teaching, learning, doing). Therefore, in our deductive coding, we highlighted moments in the transcript that demonstrated one or more of these tenets. We then wrote analytic memos for each of the themes that emerged as most prominent. Two of these themes are presented here due to limited space. Each member of the team checked and edited the analytic memos.

Findings

During the last 15-20minutes of their summer workday, the C/MLWs typically debriefed that day's workshop in some detail. The debriefing process at YPP served as both reflection of the day's teachings in meeting the learning goals as well as planning for the next outreach lesson. Debriefs were not only opportunities to think about what worked with participants, but also to debate ideas, including mathematics, for themselves. At the debrief that is the focus of this paper, the C/MLW team sat together in a room while one CMLW acted as notetaker on a chalkboard. As the MLWs shared pluses, minuses, and deltas (i.e., changes to make), the CMLW wrote their responses on the chalkboard. As was typical, CMLWs led the conversation, facilitated MLW contributions, and then made contributions based on their own observations of the outreach activities. Next, we share illustrations of young people learning to teach at YPP during one debrief. We focus on two themes: 1) learning and teaching mathematics ideas as interdependent processes, and 2) learning to decenter the self in favor of collective responsibility. The excerpt begins with conversation among a few MLWs while Adri (CMLW) is at the front of the room getting organized to facilitate the debrief.

1 Nate: They wanted, like, something harder.
…
3 Garvey: Do multiplication then!
4 [Laughing from elsewhere.]
5 Nate: Yeah, no, we did multiplication. They wanted something, like, more than that.
…
9 Garvey: Do some factor tree races. That's… if we struggle with that, 9th graders struggle…

10 Nate: They're actually smart like… some of the kids are just smart
…
14 Adri: So, they said harder math right?
15 Nate: We could do, like, factor tree races 'cuz, like, aren't we supposed to teach them Flagway?
…
21 Adri: They wanted… they wanted multiplication.
22 Josiah: Yeah.
23 Nate: I mean, factor tree races are basically multiplication.
24 Cesar: It is. But it's also division, too.
25 Nate: But like that's the same…

In the beginning of the conversation two MLWs, Nate and Garvey, discussed different possibilities for mathematics activities they could use with the workshop participants the next time they went to that site for outreach. This time, they had played games related to finding and sorting prime and composite numbers. The conversation beganresponsively, when one MLW noted that the participants "wanted something harder." They then engaged in a brainstorming of how "harder math" might be embodied in different activities. As they debated which mathematical activities might be "harder," they also recognized themselves as learners, "if we struggle with that." That is, the debriefing offered them an opportunity to reflect on their own mathematical learning by juxtaposing it with that of the younger participants, all while recognizing the students in asset-based ways ("they're actually smart").

In [14], Adri responded to the talk among the MLWs. As Nate and Garvey were talking, she overheard some of what they were saying and used it to direct the conversation. She then affirmed that factor tree racing was a good activity because it was next in the sequence of ideas in which they were engaging participants to learn Flagway. As the experienced CMLW, she had a sense of the larger scope and sequence of activities, rationalizing the choice as serving the larger pedagogical purpose, not just making it harder. Nate and Cesar in [23] and [24] discussed whether factoring is multiplication or division, if multiplication and division are the "same thing," and whether that suffices to meet the needs of the students they were serving who requested "harder math" [14]. Being positioned as teachers pushed them as learners to grapple with relationships between mathematical patterns in multiplication, division, and factoring. In the following excerpt from the debrief conversation, two CMLWs in the group, Adri and Dion, emphasize learning to decenter the self in favor of collective responsibility.

35 Adri: Anything else? I think the transitioning inside [the community center] to outside [in the adjacent park] didn't work very well. Everybody wanted to go back inside. [MLWs: Yeah.] It was hot outside, everybody wanted to go back inside.
36 Dion: That's another thing. CMLWs, MLWs, it's hot outside, we know it's hot outside. Kids don't want to be out there just as much as you don't. So, there should be no reason you're like, "Oh, it's hot outside, I can't participate, I don't want to participate." We're all on the same page on that one.
37 Adri: Transitions. Oh yeah. I'm thinking if we're trying to do—first of all, like to begin with, once y'all see the kids immediately you should be like gathering them to, to be in like a circle or something so that whoever's facilitating can start, right? So, like we saw all the kids coming out and going into the playground, you should have immediately directed them…even if it's not your activity, but we're all supposed to be circling up and so therefore it just makes it run smoother for whoever's facilitating, for everyone to be on the same page and everyone to get into the circle. And you can do that through modeling.
38 Dion: And then knowing what's being facilitated. All of us should know how to facilitate the activities.

Adri and Dion solicited ideas from MLWs regarding what they felt was significant about their time in the workshop and were now making their own suggestions about what they felt was important. As MLWs were learning to attune to critical self-reflection, the CMLWs called their explicit attention to identities-in-practice, identities that were collective as well as personal. Until they started facilitating workshops at YPP, most of the MLWs had been only students in learning settings. In outreach they were asked to take responsibility for the learning of others. It was their job. Dion signaled this shift in [36]. It was a shift in identities–who they were to be and to whom they were responsible (each other and the workshop children). Before the workshop they had created the lesson plan and assigned each other sections of the workshop so that leadership roles were distributed. Different people would lead the ice breaker, main activity, and the closing with the younger students. However, once in the workshop, Adri also drew their attention in [37] to how they could influence how the workshop went even if they were not leading a section. In [38] Dion emphasized collective responsibility again when he said that "all of us should know how to facilitate the activities." In part, this collective responsibility meant recognizing that what one might be feeling as an individual (e.g., "hot") is an experience that many other people are having. It also means not prioritizing oneself over group goals. In both of his statements, his use of "we" and "us" signaled his own and other C/MLWs' membership in that group. In doing so, he modeled his own responsibility to the collective in the debrief (Brewley, 2012).

Discussion

We highlighted two themes in this paper: 1) learning and teaching mathematics ideas as interdependent processes, and 2) learning to decenter the self in favor of collective responsibility. Through these two themes, we show how YPD is distinct from models of learning and development related to learning to teach in schools. Debriefs like the one analyzed here offer opportunities for youth to reflect on and plan for the ways they organize others to learn mathematics. Here, we emphasize the organizing aspect of YPP as distinct from traditional models of teaching. Within a typical school system, teachers organize students to do the learning. At YPP, young people organize themselves and others as both learners and as teachers. When participants are learners *and* teachers, authority is distributed, and identities are fluid. With multiple people to learn from and alongside, MLWs can find their own style of leadership and organizing without the high stakes of being solely responsible for workshop activities or children's learning. The collective offers a safety net for trying out roles and identities. C/MLWs are responsible for one another's success. Commitments like distributed authority and collective responsibility are orientations toward teaching drawn from the organizing practices of SNCC (Moses et al., 1989). Ultimately, YPP does not develop individual teachers. YPP develops practices of teaching and learning (e.g., debriefs) as key aspects of YPD.

Conclusion

Youth's identities as learners and teachers, their investment in their pedagogical improvement, and their commitment to understanding mathematics ideas are integral parts of YPP debriefs. These and other aspects of debriefs not highlighted here due to space constraints help us to characterize how young people learn to teach, what we call YPD, by connecting their development to organizational commitments and practices. Debrief sessions like the one described here offer opportunities for C/MLWs to socialize one another into YPP's commitments and practices. Distinct from teacher pipeline programs, YPP's main purpose is to help young people to organize themselves around mathematics, much in the same way SNCC helped people in Mississippi organize around voting rights. An implication for understanding identities and learning as part of YPD at YPP is not just that youth teachers are individuals becoming STEM doers and teachers, but that they are doing so for collective empowerment and movement building.

Abstract: Understanding abstract concepts in mathematics has continuously presented as a challenge, but the use of directed and spontaneous gestures has shown to support learning and ground higher-order thought. Within embodied learning, gesture has been investigated as part of a multimodal assemblage with speech and movement, centering the body in interaction with the environment. We present a case study of one dyad’s undertaking of a robotic arm activity, targeting learning outcomes in matrix algebra, robotics, and spatial thinking. Through a body syntonicity lens and drawing on video and pre- and post-assessment data, we evaluate learning gains and investigate the multimodal processes contributing to them. We found gesture, speech, and body movement grounded understanding of vector and matrix operations, spatial reasoning, and robotics, as anchored by the physical robotic arm, with implications for the design of learning environments that employ directed gestures.

Introduction

Within the growing literature on embodied learning in mathematics, gesture has been investigated as part of a multimodal assemblage with speech and movement (e.g., Alibali & Nathan, 2012), centering the role of the body in interaction with the environment. The use of directed and spontaneous gestures has shown to support learning and has been especially useful for grounding abstract concepts, which have continually presented as a challenge (e.g., Pier et al., 2019). Though extant work has focused on children’s use of gesture and its implications for mathematics learning (e.g., Abdu et al., 2021), few studies have explored students’ use of gesture as part of their sense-making process toward understanding of specific domain knowledge in mathematics within higher education. Engaging the body along with and beyond the use of gesture and speech, in interaction with physical artifacts, is another aspect of existing research that has been left underexplored, yet holds the potential to reveal much about students’ learning processes in mathematics (Robutti et al., 2022).

This paper is a case study of one dyad’s undertaking of a robotic arm activity targeting learning outcomes in matrix algebra, robotics, and spatial thinking. We designed the activity to assess participants' growing understanding of vector and matrix operations, spatial reasoning, and robotics, as they manipulated the robotic arm and calculated its end coordinates. This exploratory pilot study adopts a constructionist learning theory lens of body syntonicity and takes on a mixed methods approach to address the following research questions: *To what extent did the robotic arm activity inform student learning gains in mathematics? How did gesture, speech, and the body contribute to these learning gains across dimensions (i.e., vector and matrix operations, spatial reasoning, robotics)?* Two out of the four participating groups who observed the largest learning gains from pre- to post- test engaged gesture and the body in their sense-making. We selected one of the groups to theorize the processes that contributed to the observed learning gains, with implications for the design of learning environments that employ directed use of gesture.

Background

Within the literature on embodied learning in mathematics, extant work has considered the role of multimodal dialogue of small groups for learning mathematics (Abdu et al., 2021), the role of teachers’ gestural use in improving math understanding (e.g., Nathan et al., 2017) and increasing learners’ visual engagement (Farsani et al., 2021), and the design of technology-integrated tools to support embodied interactions in math learning (Abrahamson, 2009). With mathematical ideas inherently metaphorical (Lakoff & Núñez, 2000), gesture has been found to be especially helpful for grounding abstract concepts calling for higher-order thinking. For instance, Pier and colleagues (2019) investigated undergraduate students’ multimodal use of gesture and speech in mathematical reasoning, finding that the use of dynamic gestures (i.e., gestures “that depict and transform mathematical objects," p.3) correlated with the construction of valid mathematical proofs. Gesture has also been found to support problem solving reliant on spatial reasoning skills in particular (e.g., Chu & Kita, 2011).

To understand students' use of gesture in an embodied learning task in matrix algebra, we drew on constructionist learning theory (Papert, 1980), which puts forth the notion of "objects-to-think-with," that is objects in the physical or digital world that help ground mental models and help advance understanding of abstract ideas as learners interact with these objects. Papert further puts forth the notion of body syntonic learning, or a form of embodied learning, aligned with constructionism, where learners draw on their experience as a person with a body to imagine themselves in place of or in relation to the object they are interacting with. Learning thus emerges as a result of these processes of interaction between the learner and the physical object. Adopting a body syntonic lens supported our investigation of students' gestural use in interaction with the robotic arm and motivated our analysis of the ways in which specific gestures and speech grounded abstract concepts across the four dimensions previously discussed.

Methods

Set in the context of a graduate elective class at a 4-year minority-serving public institution in Southern California, this paper zooms in on a hands-on activity, which contextualizes a matrix math application within robotics. Before the activity, students assembled a robotic arm kit at home and viewed a pre-recorded 90-min lecture, introducing them to foundational concepts in matrix algebra and robot kinematics (e.g., degrees of freedom; vector and frame notation; matrix operations). For the activity, we positioned the arm in front of a grid and students selected how to rotate each of the three middle servos, marking the position of the end effector (i.e., the position of the arm's claw) and determining its coordinates. Students then created a diagram to visualize the servos' rotations and calculated the coordinates of the end effector, with facilitators available on Zoom and on site for guidance.

Participants were PhD or MS students in Education, Informatics, Engineering, or Computer Science and formed 2 dyads and 2 triads (Latinx = 3, Asian = 2, Multiracial = 2, and White = 3). We selected one of the dyads as an instrumental case study (Stake, 1995) to understand how students negotiate understanding of servo rotation, the z-axis, and their abstract mathematical representations. We selected this dyad because of their engagement in episodes of independent problem-solving and the high density of gestural content related to the discussed mathematical content. One student in the dyad, Miguel, had taken a linear algebra course as an undergraduate, while the other student in the dyad, Alex, had not (all names are pseudonyms).

We drew on pre- and post- assessment data to evaluate student learning gains, conducted before and after completion of the activity. The assessment consisted of 13 items, covering (a) vector operations, (b) spatial reasoning, (c) matrix operations, and (d) robotics fundamentals, which we evaluated on a 0–3-point scale. The first and third author established IRR with 20% of the assessment data (n=52 items, α=.97), before proceeding to code the rest of the data. We conducted paired-sample t-tests to evaluate the significance of the learning gains, and calculated effect sizes. After an initial pass of the focal dyad's video data from a 360-degree camera (a total of 1.5 hours), we selected 7 short clips with low facilitator involvement and high-density of pertinent gestural content for more in-depth analysis. In our iterative analysis of these segments, we identified and grouped student gestures, developing coding rules around them, and qualitatively analyzing representative moments.

Findings

Assessing learning gains and effect sizes

On average, participants increased their total scores on all four components, with our focal dyad observing learning gains well-above average for most categories (see Table 1).

Table 1
Average learning gains and effect sizes

	Max score	Range at pre-test	Range at post-test	Learning gains (avg)	Learning gains (focal dyad)	Cohen's *d*
Total score	30	1-16	4-21	4.11*	7	0.79
Vector operations	9	1-7	1-6	0.33	0	0.38
Spatial reasoning	9	0-6	0-7	1.78	2	0.65
Matrix operations	6	0-3	0-4	0.44	1.5	0.29
Robotics	6	0-1	0-5	1.56*	3.5	0.86

* $p < .05$

Hand gesture and talk ground concepts in spatial reasoning and vector operations

Purposeful use of hand gestures grounded the dyad's developing understanding of key concepts in spatial reasoning and vector operations (e.g., concept of a plane, vector components). The *drawing-in-space* gesture was a one or two-handed gesture aimed at the physical representation of an abstract construct through "drawing" and bounding the construct in space. For instance, Miguel used the drawing-in-space gesture to situate the Cartesian plane in the physical space through two cutting hand motions, one from top to bottom to represent the y-axis and one from left to right to represent the x-axis (see Figure 1). He named the vector components in the x- and y-direction concurrently, capturing the expanse of the Cartesian plane as constituted at the intersection of the two axes, *"That perfectly straight line is* n_y*. And that perfectly horizontal is* n_x*."* Alex followed what Miguel was doing, interrupting his notetaking to observe his gestures. The hand gestures Miguel performed were key in establishing common ground with Alex about the properties of the physical space. Miguel naming the vector components further signaled an understanding of a vector as being able to be broken into its respective components, in the horizontal x-direction and the vertical y-direction, and the importance of doing so in this context for calculating the end coordinates. Altogether, the drawing-in-space gesture established common referents for the dyad moving forward in a way that could be replicated when necessary, and established a sense of direction, needed when discussing servo rotation and the axis of rotation.

Figure 1

Miguel (left) using a drawing-in-space gesture to represent the x-axis, with a start in (a) and end in (b)

(a) (b)

Another type of hand gesture, *rotational gesture,* most directly informed understanding of servo rotation, what it looks and feels like, drawing on one's spatial reasoning to envision the rotation – and its specifics, such as the axis of rotation – in space. For instance, following the drawing-in-space gestures from above, Miguel modeled the rotation of the first servo by bringing his hands together at an angle and turning them counterclockwise, noting that the rotation is completed around the first angle, *"So this is rotated on* θ_1 *[froomph]."* Difficult to describe it in words, Miguel used utterances (i.e., "froomph") to signify when the gesture was completed. This rotational gesture closely followed the drawing-in-space gesture, so Miguel's right hand was still in the direction of the x-axis while his left hand was in the direction of the y-axis. Though the axis of rotation was not brought up until later, through the specific choice of how to orient one's hands and the direction and angle of rotation, Miguel represented the z-axis as the axis of rotation (see Figure 2). As it was not discussed explicitly, we termed this representation of the z-axis, "the invisible z-axis". Essential to understanding the servo rotation and its properties, the z-axis emerged as an inherent albeit not explicit component of rotational gestures, whose understanding, we theorize, contributed to the development of one's spatial reasoning competencies.

Figure 2

Miguel enacting a rotational gesture to represent a servo's rotation, with a start in (a) and end in (b)

(a) (b)

Body movement and utterances highlight nuances in robotic arm movement

Extending the traditional hand gestures, *augmented gestures* incorporated sound or shifts in body movement to emphasize the size of angle of rotation or the change in frame. For example, Miguel overlaid rotational gestures with sound, which increased in volume with the greater angle of rotation. He explained to Alex, *"The second part – this one - is rotated – [FROOMPH] in comparison."* To underscore the magnitude of the angle of rotation for the second servo, in relation to the angle of rotation for the first servo, Miguel augmented the rotational hand gesture with sound where varying volume levels correlated with the angle's magnitude. In the activity, it was especially important to understand servo rotation as a relative rotation with respect to a specific frame and we found that shifts in full body movement helped articulate the change in frame. To trace the movement of the first, second, and third servo, Miguel used rotational gestures, augmented with shifts in head and body movement and extending the gestures in space to capture the change in frame. When modeling the rotation of the second servo, we observed Miguel turn his body in the direction specified by the new frame (see Figure 3b) and yet again, when modeling the rotation of the third servo, with respect to another, new frame (see Figure 3c). Involvement of full body movement enhanced and grounded understanding of what is meant by a change in frame, otherwise difficult to grasp through hand gesture alone.

Figure 3

Miguel modeling the shift in frame for the first (a), second (b), and third servo rotation (c)

Discussion and implications

Drawing on constructionism and body syntonicity, in this paper, we presented an application of matrix algebra within robotics and investigated how gesture, speech, and the body contribute to learning gains in the case of the focal dyad. Though we observed statistically significant learning gains in total scores, the small sample size could have produced larger effect sizes, which is a limitation of the study. Qualitative analysis of the focal dyad's interactions with the robotic arm showed that gesture and the body complemented speech by providing a visualization of what is otherwise abstract and difficult to articulate through language alone (e.g., z-axis, servo rotation). Collectively, this study contributes to the literature on learners' unprompted use of gesture and the body to ground understanding in a specific domain (matrix algebra in context), as anchored in the physical "object-to-think-with". The paper has implications for the design of learning environments that use directed gestures to support specific learning outcomes as learners negotiate more challenging and abstract concepts in mathematics.

Abstract: Prosodic features of speech, such as pitch and loudness, are important aspects of the social dimensions of learning. In particular, these features are likely related to sustained disciplinary uncertainty in collaborative STEM learning contexts. We present a case conducting an exploratory, descriptive analysis of sustained uncertainty in groupwork in a secondary mathematics lesson integrating computational and qualitative methods with audiovisual data. Results of computational audio feature extraction of loudness and pitch, combined with a transcript, were used to identify potential patterns between laughter and uncertainty.

Introduction

Qualitative research in the learning sciences has long relied on audio data as an important data source. This research has recognized the role that non-lexical features of utterances, such as intonation, pitch, and loudness in informing qualitative interpretations. However, the methods for capturing them in the transcript (see Hepburn & Boldin, 2013 for a range of examples) are time-consuming and typically useful for micro-analyses of single events. Computational tools such as voice activity detection (VAD) can be useful for quantifying features of audio data that transcript-based representations do not easily attend to but are often used for goals around prediction or automation (Slyman et al., 2021). This project seeks to explore potential uses of computational tools such as VAD for descriptive purposes within a qualitative methodological paradigm. In this paper, we present an in-the-weeds example exploring sustained uncertainty in collaborative student problem-solving in mathematics.

Background

Sustained uncertainty in problem solving in STEM

Exploration, inquiry, and modeling — important interdisciplinary processes that support student learning (NRC, 2012; NGA & CCSSO, 2010) — provide opportunities to make sense of disciplinary questions or problems. Productive engagement in these processes likely involves sustained uncertainty negotiated over time (Rosenberg et al., 2022; Watkins et al., 2018). However, uncertainty is often risky, devalued, and discouraged in schools, especially in science and mathematics classrooms (Archer et al., 2017). Previous research exploring disciplinary uncertainty from an interactional perspective has highlighted its complex and contextually-situated nature. For example, Watkins et al. (2018) identified a student repeatedly bringing up an idea until it evolved into a question that others picked up. Similarly, explicit expression of uncertainty may be a poor indicator of epistemic stance. For example, “I don’t know” might signal uncertainty in knowledge, but also “I don’t want to talk about this anymore,” or simply, “I am disengaged.” (Tsui, 1991). Attending to the prosodic features of speech could help tease apart nuances in these uses that are not apparent in the lexical (e.g., words used) features of speech alone.

Prosodic features related to uncertainty

The features of discourse relevant to communicating uncertainty have been examined both qualitatively and using computational methods. In both cases, it is common to look at the linguistic and semantic features of discourse. Qualitatively, these analyses have emphasized the social and rhetorical functions of uncertainty, such as how various linguistic features communicate epistemic stance to readers (e.g., Hyland, 2005); and how scientists’ discussions about different claims about data include a gradual softening of assertions (i.e., decreasing the certainty of claims) until they come into alignment with one another (Lynch, 1985). Computationally, these analyses have been used to detect when questions are asked (e.g., Hirsh, 2019) or what intonation speakers use (Hübscher et al., 2017). In addition to identifying questions, there are other linguistic features of semantic uncertainty, including adjectives/adverbs such as “probable, likely, unsure, perhaps”; auxiliaries such as “may, might, can, would, should”; conjunctions such as “if, whether”; and specific verbs and related nouns, such as "propose/proposal; question; investigate; consider;" etc. (Szarvas et al., 2012). These features have been used to detect uncertainty in speech automatically using probabilistic models (e.g., Jean et al., 2016).

Other studies have examined paralinguistic features such as intonation, as well as descriptive features of audio data such as the number and duration of turns. For example, Berger and colleagues (Berger & Calabrese, 1975) showed a correlational link between the amount of verbal communication in an interaction and the degree of uncertainty in the talk: as amount of talk increases, uncertainty decreases. Intonation is also an important marker for differentiating between uses of different types of question words (tag questions, wh- questions, inverted questions, and repetition questions) between speakers of different languages (e.g., Farais, 2013).

Methods

In this paper, we present an in-the-weeds example of how we are "layering on" automatically-detected non-lexical features of audio data in order to increase depth/complexity of descriptive qualitative analysis. We use a methodological approach integrating computational and qualitative techniques within a qualitative methodological paradigm focused on rich description. To do so, we use a single illustrative case or data episode, which allows us to deeply explore the potential features and characteristics of sustained uncertainty. We position this approach in contrast to prediction-oriented computational work, aiming to leverage large data to identify relationships among variables. Our goals and aim are to layer complementary perspectives about a common data episode to develop a descriptive account that incorporates a multiplicity of analytical perspectives spanning both computational and qualitative findings. Additionally, this analytical process involves placing these perspectives in conversation with one another to re-interpret findings with the addition and revision of layers of analyses, similar to the iterative hypothesis generation and testing used in qualitative analysis of video (Engle et al., 2007). This integration is guided towards a goal of rich multi-faceted description, rather than convergence on a single or simple characterization or label.

We selected an approximately 20-minute segment of video/audio of groupwork from a high school mathematics classroom, focusing on a single group. This data comes from a larger study, including video/audio recorded classroom lessons in high school mathematics from 10 teachers. The segment comes from a lesson on solving trigonometric equations as part of a math course for grade 10 and 11 students. This course and teacher, Mrs. Perry, was selected because the teacher used significant amounts of groupwork and previous research has documented that Mrs. Perry's teaching practice is responsive to student thinking (Dyer & Sherin, 2016).

The specific lesson and segment were selected to include a 4-minute episode of collaborative mathematical exploration among the teacher and students identified from previous qualitative analysis (Dyer et al., 2021). This analysis identified shifts in epistemic agency and authority among the participants, as well as sustained disciplinary exploration over several minutes. We selected this larger episode because we expected that exploration would involve frequent instances of disciplinary uncertainty and/or other forms of uncertainty that were not immediately resolved. The larger segment corresponded to the beginning and end of the first portion of groupwork in the lesson and thus included portions with the teacher present and not present. We hypothesized this would provide variation in the interactional patterns and structures of the group interactions over time.

To analyze the episode computationally, we use prosodic feature extraction audio analytics techniques from *openSMILE*, an open-source audio processing program (Eyben et al., 2010) in conjunction with a time-coded transcript of the episode. For prosodic feature extraction, we focused on pitch and loudness as two features we hypothesized would be related to uncertainty based on prior work. Both outputs are provided at the frame level, and thus, we created aggregate measures and displays for each turn of talk as a unit of analysis. These include the maximum value, minimum value, mean value, and smoothed line graph of values over time.

Findings

To facilitate the interpretation of our results, we first provide a short summary of the episode. The episode comes from a small group of four students working together on a task that asked students to solve the equation $-15=20\cos(30x)$. Across the episode, the students consider graphical and equation-based approaches to find different solutions. The first approximately 13.5 minutes of the episode involved the students discussing and working with one another, followed by the teacher visiting the group for around 12.2 minutes, and concluding with less than one minute of the group talking before the class transitions to whole-class student presentations (not included in the episode).

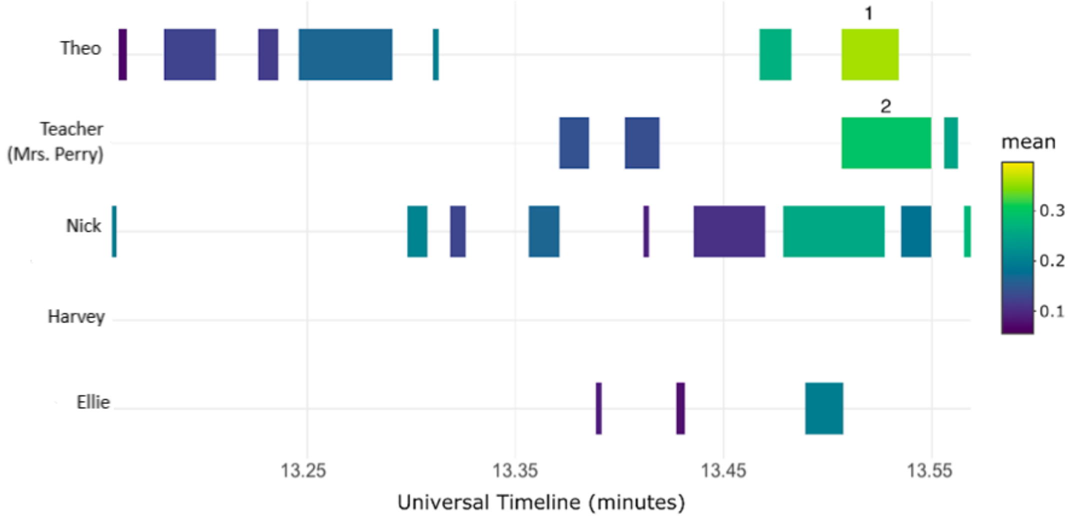
Case: Examining anomalous moments of loudness

We present here a case example that emerged from our explorations of the loudness of turns during the focal episode. Figure 1 shows the mean normalized loudness of speech by segment, with each row representing an individual speaker. Note the most yellow-appearing segment, located in the top-right of the graph and annotated with the number "1.". We can see that this utterance from Theo's had the highest average loudness. It also had the highest maximum loudness. The other speakers' turns during this time were also louder than the turns preceding it.

In examining the transcript, during segment 1, Theo said, "I know *((LAUGHTER))*! I still don't understand, though." During segment 2, the teacher said, "*((LAUGHTER)) And you still didn't get it ((LAUGHTER))*!"–the segment with the second-highest mean loudness. Examining the frame-by-frame measures of loudness within each turn shows that the loudest portions of each segment were not when the individuals were laughing. Instead, although laughter occurred *during* the segments with the highest mean loudness, the laughter was not registered as the loudest part of the segment.

Figure 1

The Mean Loudness Per Utterance During the Period of Sustained Uncertainty



These patterns suggest two things. First, laughter may accompany (or indirectly be the cause of) louder utterances. Perhaps students became louder when they laughed because their laughter represented an expression of relief or a breaking of tension caused by uncertainty. The words they spoke may have been louder in order to match the tension-breaking tone of the laughter. Alternatively, perhaps these segments were not exceptionally louder than average but were instead louder than the unusually quiet turns that preceded them—turns that were quiet because they were tentative or embarrassed about whatever it was that they were *still* not understanding (Theo).

Discussion and future work

We have presented an analytic case of leveraging computational tools in service of qualitative methods. Specifically, we used prosodic feature extraction (loudness) to initiate grounded hypotheses for future exploration. Rather than serving as an endpoint for prediction, the computational analysis instead functioned as an early pattern-detection tool. In our ongoing analytic work, we are expanding our analysis beyond the 20-min segment described to explore hypotheses generated within the segment. For example, how often does loudness correlate with laughter? How do moments of laughter (and/or loudness) reflect uncertainty, or other epistemic markers?

This example provides an initial demonstration for how prosodic features are helpful as accompaniments to intensive qualitative analysis—and not a replacement for such methods. Specifically, we found that the prosodic features of pitch and loudness are most helpful in a descriptive, rather than a highly inferential, manner. For example, the transcript allowed our team to identify the association between segments of high average loudness and laughter. Similarly, examining the pitch within segments led our team to interpret the role of laughter as a co-occurrence with loud speech rather than the primary driver of high average loudness.

Our future work will continue to leverage additional computational tools, such as automatic speech recognition, as an additional layer and visualize select components from that output (e.g., use of hedging words; use of question words) in conjunction with prosodic features such as loudness. Another feature under development is a way of representing the absence of speech, including pauses within turns, using voice activity detection (VAD) algorithms. Though unconventional and atypical, we encourage other researchers to creatively and critically leverage these tools for computational tools such as VAD for descriptive purposes within a qualitative methodological paradigm, rather than only for automated prediction.

The Debate Between Inquiry Learning and Direct Instruction: What Should Count as Evidence?

Abstract: In the ongoing debate regarding whether direct instruction or inquiry learning is superior, there exists a lack of clarity—even confusion—regarding the core features of each type of instruction. This paper argues that scholars advocating direct instruction have frequently misconceived core features of inquiry learning. The consequence of this is that many studies purporting to support direct instruction over inquiry learning fail to do so. We present three arguments for this claim, focusing on three essential features of inquiry learning environments: epistemic agency, community interaction, and complexity of inquiry learning environments. We call for and sketch a new approach to conducting research on the relative affordances of core features of these two approaches to instruction.

Introduction

For over five decades, educators have debated the efficacy of learning through inquiry and other constructivist forms of instruction versus learning through direct instruction (e.g., Furtak et al., 2012; Hmelo-Silver et al., 2007; Kapur, 2016; Kirschner et al., 2006; Shulman & Keislar, 1966; Tobias & Duffy, 2009; Zhang et al., 2021). Although a series of reviews in the 2010s by psychologists (Alfieri et al., 2011) and educators (Furtak et al., 2012; Kapur, 2016; Minner et al., 2010) argued for modest positive effects for guided forms of inquiry over direct instruction or traditional forms of instruction, subsequent reviews have argued for the greater efficacy of direct instruction over learning through inquiry (Stockard et al., 2018; Zhang et al., 2021). Empirical studies continue to argue for the relative advantages of direct instruction (e.g., Martella et al., 2020; Yaghmour & Obaidat, 2022).

In this debate, there is widespread agreement on one point: Direct instruction (i.e., telling students the answers they are expected to learn, typically followed by practicing use of what they were told) promotes more learning than pure discovery learning (i.e., learning environments in which students try to invent answers with little or no guidance). This point is conceded by most proponents of inquiry learning (e.g., Furtak et al., 2012; Hmelo-Silver et al., 2007). Proponents of inquiry learning argue instead that, in contrast to pure discovery learning, guided discovery or guided inquiry—in which students are given scaffolds to support their discovery processes—are superior to direct instruction (e.g., Hmelo-Silver et al., 2007). However, proponents of direct instruction continue to argue that direct instruction is superior to both guided and unguided forms of inquiry (e.g., Zhang et al., 2021). We will focus our discussion on the debate between direct instruction and *guided* inquiry.

Although many learning scientists strongly endorse instructional approaches grounded in inquiry (see chapters throughout Duncan & Chinn, 2021), some also endorse instruction more aligned with direct instruction, such as direct explanations of inquiry skills in history (Van Boxtel et al., 2021). Although the pages of *The Journal of the Learning Sciences* and *International Journal of Computer-Supported Collaborative Learning* seldom investigate learning environments grounded in direct instruction, the pages of many other journals include many papers investigating predominantly direct-instruction methods such as learning from worked examples and explicit strategy instruction.
