Conference Organizers and Committees

Conference Organizers:

James D. Slotta, *OISE, University of Toronto, Canada*
Elizabeth Charles, *Dawson College, Canada*
Thérèse Laferrière, *Université Laval, Canada*
Alain Breuleux, *McGill University, Canada*
Rob Cassidy, *Dawson College, Canada*
Joel Wiebe, *OISE, University of Toronto, Canada*
Preeti Raman, *Toronto Metropolitan University, Canada*
Bojana Krsmanovic, *Concordia University, Canada*
Stephanie Beck, *McGill University, Canada*

Doctoral Consortium Co-Chairs:

Erica Halverson, *University of Wisconsin—Madison, USA*
Xueqi Feng, *Southern University of Science and Technology, China*
Daniel Bodemer, *University of Duisburg-Essen, Germany*

Early Career Workshop Co-Chairs:

Julia Eberle, *Ruhr University Bochum, Germany*
Carol Chan, *University of Hong Kong, Hong Kong*
Clark Chinn, *Rutgers University, USA*

Mid-Career Workshop Co-Chairs:

Heisawn Jeong, *Hallym University, South Korea*
Kris Lund, *University of Lyon, France*
Doug Clark, *University of Calgary, Canada*

Interactive Tools and Demos Co-Chairs:

Dimitra Tsovaltzi, *DFKI GmbH/Saarland University, Germany*
Alwyn Vwen Yen Lee, *National Institute of Education, Nanyang Technological University, Singapore*
Lina Markauskaite, *The University of Sydney, Australia*
LuEttaMae (Lu) Lawrence, *Utah State University, USA*

Workshops and Tutorials Co-Chairs:

Mike Tissenbaum, *University of Illinois at Urbana Champaign's College of Education, USA*
Annelies Raes, *KU Leuven, Belgium*
Hiroki Oura, *Tokyo Institute of Technology, Japan*

Technology Support Committee:

Joel Wiebe, *OISE, University of Toronto, Canada*
James D. Slotta, *OISE, University of Toronto, Canada*
Bojana Krsmanovic, *Concordia University/SALTISE, Canada*
Meagan O'Hara, *OISE, University of Toronto, Canada*
Thomas Hillman, *University of Gothenburg, Sweden*
Renato Carvalho, OISE, *University of Toronto, Canada*

Registration and Sponsorship Co-chairs:
Preeti Raman, *Toronto Metropolitan University, ON., Canada*
Naxin Zhao, *OISE, University of Toronto, ON., Canada*

Conference Platform Committee:
Jun Oshima, *Shizuoka University, Japan*
Arnon Hershkovitz, *Tel Aviv University, Israel*
Oskar Lindwall, *University of Gothenburg, Sweden*
Yotam Hod, *University of Haifa, Israel*

Social Media Communications Co-Chairs:
Jenny Olsen, *University of San Diego, CA., USA*
Aditi Kothiyal, *IIT Gandhinagar, India*
Sueli Bonafim, *Dawson College, QC., Canada*
Tatiana Becerra, *McGill University, QC., Canada*

Volunteer Committee:
Anuli Ndubuisi, *OISE, University of Toronto, ON., Canada*
Zian (Kelly) Zhang, *OISE, University of Toronto, ON., Canada*
Bojana Krsmanovic, *Concordia University/SALTISE, QC., Canada*

Accessibility & Inclusion Advisory Committee:
Jrène Rahm, *Université de Montréal, QC., Canada*
Jennifer Vadeboncoeur, *University of British Columbia, BC., Canada*
Catherine Fichten, *Dawson College & McGill University, Montreal, QC., Canada*

Advisory Board:
Susan Goldman, *University of Illinois at Chicago, USA*
Oskar Lindwall, *University of Gothenburg, Sweden*
Ulrich Hoppe, *University of Duisburg-Essen, Germany*
Frank Fischer, Ludwig Maximilian University of Munich, *Germany*
Astrid Wichmann, *Ruhr University Bochum, Germany*
Joshua Danish, *University of Indiana*
Preeti Raman, *Toronto Metropolitan University, Canada*
Alain Breuleux, *McGill University*
Thérèse Laferriere, *University of Laval, Quebec, Canada*

Preface

This volume contains the proceedings of the Third Annual Meeting of the International Society of the Learning Sciences (ISLS 2023) under the theme "Building Knowledge and Sustaining our Community." The resilience and high cohesion of the ISLS community have prevailed after the turbulent pandemic years. In 2023, our community gathered again at Concordia University in Montréal, Canada. Long-standing members and newcomers came together in beautiful downtown Montréal to share new research, engage in lively discussions, expand their network, and taste the famous *poutine*.

Though this is the 17th time our community has come together for an annual meeting, it is only the third year that we have held an Annual Meeting of the International Society of the Learning Sciences (ISLS) where the International Conference on Computer-Supported Collaborative Learning (CSCL) and the International Conference of the Learning Sciences (ICLS) where held together. At ISLS 2023, in addition to the habitual categories, we again invited submissions in the Technology Innovation category and created two new ones: *Innovative Symposia* (which included, for example, hybrid participation and pre-conference activities) and *Practice-Oriented Papers*. The program also distinguished between empirical, theoretical, and methodological contributions for all submission categories.

The ICLS Proceedings feature long papers, short papers, posters, and symposia, all subject to rigorous double-anonymized peer review. We received an unprecedented 791 submissions, an increase of 8% compared to ICLS 2022. The submissions covered a broad range of ICLS research, design, and technological innovation. In total, 32.5% (105 out of 323) long paper submissions and 34.3% (93 out of 271) short paper submissions were accepted in the category in which they were submitted. In addition, several submissions were accepted into a different category (short papers or posters). As a result, the ICLS Proceedings features 105 long papers, 196 short papers, eight technology innovation papers, 21 practice-based papers, 244 posters, and 19 symposia.

We have had submissions from 44 countries in all continents. Unfortunately, almost 80% of those came from the US and Canada, and only about 7% came from low- and middle-income countries, which hold 70% of the world's population. Interestingly, the overall acceptance rate for South America (48%) is higher than that of the US (44%) and Western Europe (32%). Even though the number of US submissions is more than 20 times higher and covers more categories, these percentages suggest that the quality of the papers from low- and middle-income countries is high and that a larger participation of scholars from these countries would enormously enrich our community.

The program chairs would like to thank the 684 reviewers and 164 senior reviewers who carried out 2334 reviews and 791 meta-reviews. Collectively, we wrote 818,000 words--more than the Bible (788,000 words)! We would also like to thank the numerous people who have spent countless hours ensuring that the program is of high quality and the fantastic ISLS 2023 local organizing team.

ICLS 2023 reflected our collective pursuit to understand learning in its multifaceted contexts and to develop equitable and innovative learning environments. The conference's presentations and discussions underscored the importance of integrating diverse learning contexts to address the challenges and opportunities in a world undergoing intense transformation, diving into complex tapestries of learning processes, technologies, designs, and practices. Our eclectic community is exploring themes and methods that go all the way from machine learning to thick ethnographies, and is becoming, each year, more attuned to different epistemologies, worldviews, and ways of learning. The contributions in 2023 reflect this diversity, exploring topics such as learning in the disciplines (science, mathematics, history, civics, maker education, computer science, and others), equity and justice, artificial intelligence in education, embodied cognition, multimodal learning analytics, teacher learning, and informal learning environments.

ICLS 2023 should not just be a platform for academic discourse but also a catalyst for transformative action. Hopefully, the discussions and collaborations initiated in Montréal will resonate beyond the conference, inspiring new research and practice in the Learning Sciences. We hope that insights from these proceedings will empower participants to cultivate learning environments that are more inclusive, justice-oriented, innovative, and rigorous, enabling learners to realize what Paulo Freire considered to be the ontological vocation of every human: *changing the world.*

Saudações Freireanas,

Paulo Blikstein, Karen Brennan, Rita Kizito & Jan Van Aalst
Conference Chairs, ICLS 2023

Metacognitive Calibration: A Methodological Expansion and Empirical Application

Samuel Tobler, Manu Kapur
samuel.tobler@gess.ethz.ch, manukapur@ethz.ch
Professorship for Learning Sciences and Higher Education, ETH Zurich, Switzerland

Abstract: The ability to judge performance accurately is essential for successful learning. However, statistics or measures to do so are frequently limited to binary judgments and not scalable. Moreover, they primarily assess only one dimension of the metacognitive calibration accuracy. In this methodological paper, we develop and discuss a new set of statistics to determine the calibration accuracy and the direction of miscalibration. Together, they indicate the extent of confidence accuracy and whether learners are overconfident or underconfident in their judgments. These statistics are scalable to non-binary judgment data. We then illustrated them in an empirical study with 34 doctoral students' performance judgment data which were assessed when answering domain-specific conceptual questions. Results from traditional measures were calculated, serving as a reference for the new measures' reliability. In addition, we developed an *R*-package implementing and visualizing the latter. The theoretical and practical implications are discussed.

Introduction

The concept of *metacognitive calibration* describes the idea of a learner's ability to correctly judge their task performance (Keren, 1991). In other words, learners that are able to judge their correct performance as correct and incorrect performance as wrong display a high metacognitive calibration. Since the seminal literature review by Lin and Zabrucky (1998), the importance of metacognitive calibration became a highly acknowledged concept in the field of educational psychology and the learning sciences. Metacognitive miscalibration through overconfidence regarding the own performance appeared to negatively influence learning by reducing cognitive processing efforts (Lin & Zabrucky, 1998). Inadequate underconfidence, on the other hand, might negatively impact self-confidence, which is essential for successful learning as through the affected intrinsic motivation (i.e., through perceived competence). Similarly, it might influence potential ability-grounded failure attribution (Bandura, 1986; Dweck, 1975; Ryan & Deci, 2000). As such, empirical studies provided evidence for the predictive power of anxiety and reduced self-confidence (i.e., underconfidence) on lower test performance (Barrows et al., 2013). Furthermore, failure-driven problem-solving (e.g., Productive Failure; Kapur, 2014), in contrast to success-driven problem-solving, was shown to partly increase students' metacognitive calibration, potentially due to greater opportunities for self-evaluation (Sinha & Kapur, 2021a). In other words, the failure to successfully solve a problem might be beneficial to increase calibration accuracy, next to all other alleged positive effects of initial struggle as effective preparation for future learning (Sinha & Kapur, 2021b). In conclusion, high accuracy in the judgment of performance appears to constitute often a beneficial prerequisite for knowledge acquisition in any domain. The inability to accurately assess the own metacognitive calibration might hinder learning.

Whereas one major field of research is concerned with the analysis of metacognitive calibration in different situations, as presented above, another research branch aims to explore various possibilities of enhancing learners' calibration accuracy to ultimately facilitate learning. For instance, Xia and colleagues (2019) could show that students' reflections on their own performance contributed to a more accurate metacognitive calibration. In contrast, the calibration assessment after repeated judgments of learning revealed enhanced underconfidence, indicating that students who are continually asked to judge their performance might become less confident about their responses over time (Koriat et al., 2002). Yet, providing feedback on the actual performance might play an important role in an individual's performance judgment improvement, as empirical evidence suggested (Callender et al., 2016). Similarly, delayed conceptual summarizing (Thiede & Anderson, 2003) or strategy training for assessing calibration (Nietfeld & Schraw, 2002) supported students' calibration accuracy. Hence, next to the suggested significance of metacognitive calibration for learning, there is substantial empirical evidence on how to promote calibration accuracy.

However, to profit from theoretical and empirical work that investigated various ways of improving metacognitive calibration accuracy to positively affect learning, it is irrevocable to have a well-substantiated statistic to estimate this accuracy.

Theoretical background

In a recent explorative calibration accuracy comparison study, Schraw and colleagues (2014) evaluated the most commonly used statistics (e.g., *d'*, *gamma*, *G*-index). They found that the appropriate metrics of choice depend on the research question. One measure alone was shown to only be rarely sufficient to establish an estimation of calibration accuracy (Schraw et al., 2014). A particular reason for this conclusion is, however, inherent to the different measures themselves. Whereas *d'* measures the standardized difference between correctly judging the correct answer and wrongly judging a wrong answer as correct, this measure alone mainly indicates whether learners are rather over- or underconfident, hence the direction of the miscalibration. Additionally, the standardization of this measure does not allow for a direct comparison of calculated indices from different studies, as the results will depend on the measured variance in the specific sample population. The *G*-index, in contrast, looks at the proportion of correct judgments to incorrect judgments. Thereby, this index determines the accuracy of individuals but does not make any statement regarding the direction of the miscalibration. In other words, a low accuracy result does not indicate whether participants are rather underconfident or overconfident, despite the essential difference between these two concepts regarding learning. Lastly, *gamma* follows a similar approach to the *G*-index by subtracting the product of the wrong judgments from the product of the correct judgments, over the sum of both products. Whereas the weighting of over- and underconfidence is different from the *G*-index, also in this case, it remains impossible to determine the direction of the miscalibration. Overall, and in agreement with the suggestion from Schraw and colleagues, it appears that no measure drastically outperforms the others but that they are rather covering different aspects of the concept of calibration accuracy.

A further limitation of some of these statistics for performance judgment assessment is their restriction to dichotomous data sets. Calibration estimations can then only be determined if the judgments are assessed in a yes-or-no format (i.e., “Are you sure about your response?” with answer options “yes” and “no”). However, in practice, an individual’s judgment of their own answers might not always be so straightforward, and more fine-grained answering options could yield more accurate approximations of the calibrations. One way to increase the sensitivity of calibration analyses is by asking a similar question but assessing responses on a 4-point Likert scale (yes / rather yes / rather no / no). Having four items to choose from still forces the participant to decide but allows them to indicate uncertainties. Nonetheless, the currently available statistics for examining calibration accuracy do often fail to come up for the need for greater sensitivity. Thus, the generally used statistics might answer specific research questions very well but not coherently report accuracy and the miscalibration direction. Also, they are often limited to binary data sets, thus restricting their application in empirical studies.

In this paper, we propose a novel set of statistical measures for assessing calibration accuracy and the direction of a miscalibration. Moreover, we demonstrate the applicability of these statistics for binary data as well as data assessed in 4-point Likert scales, thereby taking into account the non-binary nature of actual performance judgments. Thus, we aim to advance the methodological standards of determining and interpreting metacognitive calibration. Lastly, we present and apply an *R*-software package to easily calculate and plot the calibration accuracy and miscalibration direction on empirical data from a study with 34 doctoral students to illustrate the suggested methodological advancements and compare the results with conventional measures for reliability.

Methodological expansion of calibration accuracy and miscalibration

As previous research showed, scholars mostly focused on binary confidence judgment data (Schraw et al., 2014). Thereby, students’ judgments are evaluated based on whether they correspond to the actual performance. These different combinations of performance and judgment can be visualized in a 2×2 matrix (Table 1, left). However, if working with non-binary data, this matrix must be expanded, for example, to a 2×4 matrix in the case of a 4-point Likert scale-based performance judgment (Table 1, right). Consequently, new statistics are needed.

A starting point for establishing new statistics comes from defining a robust measure for a binary system, which then can be scaled up, for instance, to a 4-point scale system. Of primary importance are thereby measures for overconfidence (1–sensitivity; Feuerman & Miller, 2008) and underconfidence (1–specificity; Feuerman & Miller, 2008). Simply put, the overconfidence ratings indicate the frequency with which a learner wrongly judges their answer as correct when they are wrong, thus being overconfident in their abilities. Likewise, underconfidence describes the frequency of correct answers that are wrongly judged wrong, thus indicating a learner’s lack of recognizing their abilities (Table 2). The accuracy of one’s metacognitive calibration depends on these two measures. High underconfidence and high overconfidence, as well as a combination of these two, must be reflected in such a value. Additionally, the frequency of their actual occurrence must be considered as well. If this is neglected, a participant with all judgments and performance correct beside one obtains the same calibration accuracy score as a participant with all judgments wrong. Thus, the values for under- and overconfidence must be considered in relation to their actual frequency. The resulting formula for the calibration accuracy is shown in Table 2.

Table 1
Performance-evaluation matrices for dichotomous and 4-point-based confidence judgments

Confidence Judgment	*Performance* Correct	Incorrect
Yes	a (true positive)	b (false positive)
No	c (false negative)	d (true negative)

Confidence Judgment	*Performance* Correct	Incorrect
Yes	a	b
Rather Yes	c	d
Rather No	e	f
No	g	h

Note. Letters a to d (left) and a to h (right) indicate the variables needed for the formulas used for the calculations displayed in Table 2. *Performance* specifies whether a specific problem was solved correctly or not. *Confidence judgment* indicates students' judgments of their own answers' correctness, either collected in dichotomous format (yes / no) or on a 4-point Likert scale (yes / rather yes / rather no / no).

Like the limitations of the statistics *gamma* and *G*-index, this new calibration accuracy measure does not make any statement regarding the direction of the miscalibration. However, it is possible to apply the same theoretical and mathematical reasoning to determine whether any calibration inaccuracy is due to over- or underconfidence. By relatively subtracting the false positive (b) from the false negatives (c), one obtains a similar statistic to *d'* that allows investigating the miscalibration direction (Table 2). Additionally, this miscalibration value is not based on standardization, as is the case for *d'*, but yields relative and comparable miscalibration estimates. Combining these newly established statistics (i.e., calibration accuracy and miscalibration), we can assess the accuracy of a performance judgment and the cause of any inaccuracy.

Table 2
Calibration calculation formulas for dichotomous confidence judgments

Statistic	Formula	Explanation of the formula
Overconfidence O	$O = b/(b + d)$	This value explains how often a student wrongly answers a question while wrongly believing to have answered it correctly.
Underconfidence U	$U = c/(a + c)$	This value explains how often a student correctly answers a question while wrongly believing to have answered it wrongly.
Calibration accuracy C	$C = 1 - \left(\frac{1}{a+b+c+d}\right) \cdot \left(\frac{b^2}{b+d} + \frac{c^2}{c+d}\right)$	The metacognitive calibration accuracy value is based on the relative occurrence of a students' over- and underconfidence judgment. 1 indicates perfect calibration, and 0 indicates full miscalibration.
Miscalibration M	$M = \frac{1}{a+b+c+d} \cdot (b - c)$	The miscalibration value explains the cause of any metacognitive calibration inaccuracy. $M = 1$ indicates full overconfidence, and $M = -1$ indicates full underconfidence.

Note. The variables a to d correspond to the participant-specific count values established as described in Table 1. If the nominator of any fraction is equal to 0, this specific fraction must be set to 0. For instance, if a student never judges an incorrect answer as correct (b), the overconfidence value must be set to 0. In this case, the calibration and miscalibration values remain dependent only on the underconfidence statistic.

Generally, there are two major advantages of using these statistics instead of a combination of the commonly used ones. First, the obtained measures are mathematically based on the same underlying construct and are, thus, directly comparable within and across studies. And second, both are directly scalable to any dimension of interest. Being able to estimate calibration for not only binary response judgments but those of a higher level might deepen the understanding of learners' actual calibrations. As such, we derived the formulas for performance judgments of a 4-point Likert scale (Table 3). The exact calculations to obtain the formulas in Tables 2 and 3 can be found in the supplementary materials on OSF (see methods).

Table 3
Calibration calculation formulas for 4-point-based confidence judgments

Statistic	Formula	Explanation of the formula
Overconfidence *O*	$O = \frac{xb+yd}{x(b+h)+y(d+f)}$	This value explains the weighted ratio of how often a student wrongly overestimates their performance in case the given answer is incorrect.
Underconfidence *U*	$U = \frac{xg+ye}{x(a+g)+y(c+e)}$	This value explains the weighted ratio of how often a student wrongly underestimates their performance in case the given answer is correct.
Calibration accuracy *C*	$C = 1 - \frac{1}{\text{tot}'} \cdot \left(\frac{(xb+yd)^2}{x(b+h)+y(d+f)} + \frac{(xg+ye)^2}{x(a+g)+y(c+e)}\right)$ with $\frac{1}{\text{tot}'} = \frac{1}{x(a+b+g+h)+y(c+d+e+f)}$	The calibration accuracy describes the inversed relative sum of the weighted overconfidence and underconfidence values. *C* = 1 indicates perfect calibration, and *C* = 0 indicates full miscalibration.
Miscalibration *M*	$M = \frac{1}{\text{tot}'} \cdot (x(b-g) + y(d-e))$	The miscalibration score describes the relative difference between the weighted incorrect answers (overconfident – underconfident). *M* = 1 indicates full overconfidence, and *M* = –1 shows full underconfidence.

Note. The variables *a* to *h* correspond to the participant-specific count values established as described in Table 1. If the numerator of any fraction is equal to 0, this specific fraction must be set to 0. For instance, if a student never judges an incorrect answer as correct (*b*) or as rather correct (*d*), the overconfidence value must be set to 0, and the calibration and miscalibration values remain dependent only from the underconfidence statistic. The factors *x* and *y* indicate the relative weighting of the individual values from the performance-evaluation matrix to come up for the different judgment certainty levels (*x* for "yes" and "no"; *y* for "rather yes" and "rather no"). The generalized formulas are described in the supplementary materials on OSF (see methods).

Weighting confidence ratings

Suppose working with a non-dichotomous performance-judgment matrix, as in those cases in which the response confidence was assessed with 4-point Likert scales. The weighting of the individual confidence judgments then gains importance. Not differently weighting the answers would reduce them again to a binary measure. Thus, introducing the weighting factors *x* and *y* could overcome the shortcoming of presently available measures that categorize judgments in a binary manner (Table 3).

Founding the weighting ratio ($w = x/y$) in theoretical elaborations, we propose one specific solution for this problem: attributing a three times higher weight to those ratings with greater confidence ($w = 3$). The rationale for doing so is motivated by the literature on and common practice of interpreting Likert-based data as interval data despite its ordinal nature (Wu & Leung, 2017). To understand why ordinal-scaled Likert data can be treated as interval scales in some instances, Boone's and Boone's (2012) distinguishment between Likert-type and Likert scale data comes into play. Whereas the first describes situations in which single items are compared, the latter is based on multiple items that describe together one characteristic. Thus, when having multiple items that constitute one composite characteristic, there is evidence in favor of analyzing them on an interval scale (e.g., Boone & Boone, 2012; Sullivan & Artino Jr, 2013).

Having concluded that interpreting Likert scales on interval data might be appropriate in specific situations, we need to assign values to the individual judgment options. On a 4-point Likert scale from "no" to "yes," the interval is set around the value 0 ("neither yes nor no"), whereby 0 is not a selectable option, aiming to enforce students' decisions. Looking at the two intermediate values ("rather no" and "rather yes"), it appears that they are mathematically twice as much represented on any interval scale than the border values ("yes" and "no"). In other words, if a student selects the option "rather yes," this answer implies that the student's decision of performance judgment was either in the interval of (0; "rather yes"] or ["rather yes"; "yes"). In contrast, a student's answer of "yes" suggests that the student's decision was only in the interval of ("rather yes"; "yes"]. Expanding this train of thought, we find the numerical decision interval of (0, 1.5) for the answer "rather yes" (at the interval value of 1) and [1.5,2] for the answer "yes" (at the interval value of 2). The absolute decision interval of the answer "rather yes" is thus three times as large as the interval of the answer "yes." Consequently, we can only mathematically account for this double representation if the weighting is set to 3 (see endnotes 1 & 2).

Empirical application

Methods

All data sets and annotated *R*-scripts used for the present analysis are openly available in an OSF online repository (https://osf.io/6pdjt/). The various functions of the novel *R*-package for the metacognitive calibration analysis can be directly installed as *R*-package (https://github.com/samueltobler/mcc).

Participants

The participants of the application study were 34 doctoral students in natural sciences at a highly-ranked European university. The participants were, in average, 27.1 years old (*SD* = 2.3), whereby 41% indicated to be female, 59% male, and 0% non-binary. Participation in the study was voluntary, and three vouchers from a local grocery store were raffled among all participants. The university's ethics commission approved all studies before their conductance.

Materials

The test materials consisted of nine multiple-choice questions that covered a fundamental concept of the participants' study field and were published as part of a validated concept inventory (α = 0.69; 95% CI: 0.54-0.84) (Tobler et al., 2023). The students' self-reported performance judgment was assessed for each question by asking them, "How confident are you with your response?" on a 4-point Likert scale with the descriptors *very unconfident, rather unconfident*, *rather confident*, *very confident*.

Metacognitive calibration R-package

The for this purpose developed *R*-package directly calculates metacognitive calibration accuracy *C* values and the miscalibration *M* estimations for data sets with performance results and performance judgments on a 4-point Likert scale. The calculations are based on the proposed formulas in Table 2. Moreover, conventional measures, including *d'*, *gamma*, and *G*-index are functionally integrated to directly compare the different statistics. Eventually, the package allows plotting the results for more informative analyses of the data set. The extensively annotated *R*-package can be directly installed in the *R* software environment from GitHub (see link above).

Procedure and analysis

The participants were recruited through university-internal mailing lists and asked to complete the online test alone and without further resources. There was no time limit for taking the test. However, we excluded participants who showed statistical duration outliers (*n* = 3) and those who were faster in finishing the test than it would take to read the individual questions (*n* = 4). The final sample size consisted of 27 participants (Age: *M* = 27.2, *SD* = 2.3; 30% female, 70% male, 0% non-binary).

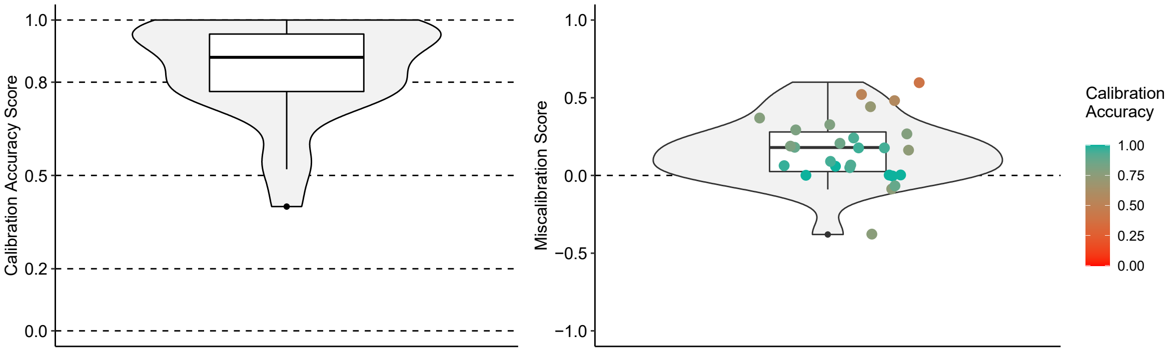
The test results were descriptively analyzed. The metacognitive calibration accuracy and miscalibration values were analyzed and plotted using the hereby introduced metacognitive calibration *R*-package. Additionally, we compared the results from the newly proposed calibration accuracy statistics with the results that would have been obtained by applying the commonly used calibration accuracy measures (i.e., *d'*, *gamma*, and *G*-index). Moreover, we investigated the correlation between calibration scores and actual performance. All analyses were conducted in the *R* software environment (R version 4.2.1; R Core Team, 2022). A list of all *R*-packages used for the analysis can be found in the supplementary materials on OSF.

Results

The normalized performance score analysis indicated that the participant understood the tested concept relatively well ($M = 0.72$, $SD = 0.21$, $min = 0.11$, $max = 1.00$). Furthermore, the results from the empirical application of the novel statistics revealed that most doctoral students answered the performance judgments with relatively high accuracy ($M = 0.84$, $SD = 0.16$; Figure 1, left). The miscalibration scores further indicated that most of the students, if demonstrating some calibration inaccuracy, were somewhat overconfident regarding their performance ($M = 0.16$, $SD = 0.22$). This finding is in line with the color-coded miscalibration scores demonstrating that those students with lower calibration accuracy rather were over- or underconfident but not both (Figure 1, right).

Figure 1

Metacognitive calibration and miscalibration values; Note. The dots in both sub-figures indicate the individual participants. The miscalibration scores (Figure 1, right) are color-coded according to the individual calibration accuracy. Green indicates perfect accuracy; red indicates complete inaccuracy.



Looking at the Pearson's correlation values determined for each comparison of newly proposed and priorly discussed measures, the results showed significant correlations between the new statistics and the *G*-index, but fewer between the new ones and *d'* or *gamma* (Table 4). Additionally, the correlation of *gamma* or *d'* accuracy values with the 4-point calibration accuracy and miscalibration scores were weaker compared to the binary values of the new measures. These results indicate that the 4-point-based calculations contain more information that the other measures cannot capture, explaining more variance and, thus, revealing more precise estimates. Lastly, we found no significant correlation between performance and calibration accuracy C ($r(25) = 0.26$, $p < .18$). Instead, the calibration results obtained by using the *G*-index statistics on the artificially binarized data set revealed a significant correlation with performance ($r(25) = 0.57$, $p < .01$). No significant correlations were found between performance score and *d'* ($r(25) = -0.01$, $p = .97$) or *gamma* ($r(25) = -0.37$, $p = .06$). However, a performance score-dependent visual breakdown of calibration accuracy and miscalibration descriptively indicates greater variability in accuracy and miscalibration with lower performance (Figure S1 in the supplementary materials).

Table 4

Statistic comparisons with empirical data

Measure	*M*	*SD*	1	2	3	4	5	6
1. Calibration accuracy *C* (4-point)	0.84	0.16	–					
2. Miscalibration *M* (4-point)	0.16	0.21	-0.64^{***}	–				
3. Calibration accuracy *C* (binary)	0.84	0.13	0.86^{***}	-0.62^{***}	–			
4. Miscalibration *M* (binary)	0.21	0.17	-0.56^{**}	0.89^{***}	-0.73^{***}	–		
5. *d'*	0.00	1.46	0.41^{*}	–0.19	0.43^{*}	-0.30^{*}	–	
6. *Gamma*	0.48	0.33	0.34	–0.29	0.46^{*}	–0.34	0.18	–
7. *G-index*	0.14	0.75	0.72^{***}	-0.42^{*}	0.89^{***}	-0.65^{***}	0.47^{*}	0.29

Note. The performance judgment ratings have been transformed to binary values to calculate the various statistics (*d'*, *gamma*, *G-index*). The newly proposed statistics have been evaluated with both the binary-transformed and the original 4-point Likert scale data. Statistically significant correlations are marked with an asterisk sign ($^{*}\ p < .05$; $^{**}\ p < .01$; $^{***}\ p < .001$). $N = 27$.

General discussion and conclusion

The significance of being metacognitively well calibrated and, thus, able to accurately judge the performance has been repeatedly shown to positively affect learning (Lin & Zabrucky, 1998). Moreover, prior work has documented and compared various statistical approaches to accurately estimate a learner's metacognitive calibration (Schraw et al., 2014). By comparing different statistics, they investigated which of them might show the best suitable measure for accuracy. Regrettably, they did not find a one-size-fits-all statistic to measure the latter but concluded that the appropriate measure must be chosen based on the research question. Furthermore, some of these measures can only be applied to dichotomous data but are not directly scalable to judgment data assessed on higher order Likert scales, for instance.

We developed a methodology that compensates for these two shortcomings. Our novel approach is grounded in two complementary statistics that are based on the relative occurrence of false positive and false negative performance judgments. These two statistics, the calibration accuracy and the direction of any miscalibration, yield a direct estimate of an individual's metacognitive calibration. Furthermore, they explain any deviation from a perfect calibration in terms of underconfidence or overconfidence. Additionally, these two statistics are directly scalable from binary judgment inputs to 4-point Likert scale ratings, and generalizable beyond that as well. Thus, it appears that the newly developed methodology to estimate metacognitive calibration accuracy might overcome the major limitations of commonly used statistics. Also, it presents easily applicable measures that might be valuable for researchers in and outside the field of the learning sciences when working with calibration measurements. Nonetheless, triangulating the results with other metrics such as d' or G-index, recommended by Benjamin and Diaz (2008) or Schraw (1995), might provide supplementary validity of the calculated accuracy estimates.

Moreover, we empirically tested the new measures to demonstrate their performance. Statistical comparisons with the established measures revealed significant correlations in most cases, indicating that the new statistics assess a similar construct to conventional measures but explain more variance. Lastly, we developed a freely available and directly implementable R-package to apply the proposed formulas as well as more conventional ones to calculate calibration accuracy and visualize the results for facilitated interpretation.

Limitations and future directions

One limitation of the current approach is that the ordinal nature of Likert-scale data is ignored and interpreted as interval data. However, treating the data as ordinal data would not allow determining a calibration score, which emphasizes the different extent of judgment certainty. Instead, it would lead again to a dichotomous data set. Furthermore, assessing calibration accuracy over multiple items was shown to approximately resemble an interval scale (Boone & Boone, 2012). Nonetheless, the technical advancements as present in online conducted studies (Evans & Mathur, 2005) would allow collecting performance judgment data directly on true interval scales. Yet, the herein presented statistics could easily be expanded for higher degree matrices.

Future work could focus on applying these statistics in classrooms where most participants are novice learners and not experts in the field. Whereas students at the end of their educational career (i.e., post-graduate students) might have learned well over the years to accurately judge their own capabilities, learners at lower educational levels might struggle more to do so. Thus, using these measures to continuously investigate the students' metacognitive calibration accuracy and the impact of success or failure on it might reveal more detailed insights regarding the development of calibration accuracy throughout their education. Similarly, future studies could emphasize assessing calibration accuracy with the proposed measures when testing new educational interventions to investigate their impact on this trait.

Endnotes

(1) Intervals are described according to the general notation standards for mathematical intervals. Round brackets indicate that all values until but without the start- or endpoint are included, and square brackets indicate that all values until and with the start- or endpoint are included. Mathematically expressed, this means $(0,1] = \{x \mid 0 < x \leq 1\}$.

(2) A weighting of $w = 2$ might appear more logical at first glance. To explain why this might be less exact, let's reconsider the interval of [-2; 2] on a 4-point Likert scale. This interval would then result in the values of [-2; -1; 1; 2] for ["no"; "rather no"; "rather yes"; "yes"]. Like before, we have three 0.5 interval steps for the answer "rather yes" (0, 1.5), but only one for the answer "yes" [1.5, 2]. Suppose we now set the weight of "yes" answers to be double as high as that for "rather yes" answers. In that case, the relative weight of the different answers with respect to their abundance on the interval scale corresponds to $1 \cdot 1.5$ for the "rather yes" answer and $2 \cdot 0.5$ for the "yes" answer. Thus, the "rather yes" answer option still weighs more than the "yes" option $((1 \cdot 1.5)/(2 \cdot 0.5) = 1.5 \neq 1)$. Only if we set the weight to $w = 3$, we get an equal ratio (i.e., 1) for the weighting of "yes" and "rather yes" answers.

“When We’re in Spaces Among People of Colour, Your Ideas Just Flow”: Politicized Trust and Educational Intimacy in Activist Spaces

Joe Curnow, University of Manitoba, joe.curnow@umanitoba.ca

Abstract: This paper examines how relationships of educational intimacy and politicized trust were constructed in an activist community. Bridging theories of politicization and activist becoming with emerging research on the significance of relationships for identity development and solidarity, this paper brings micro-interactional data of how relationships are constructed and why they matter. Tracing a group debrief by members of colour within the Fossil Free UofT activist group allows us to see how humour constructed intimacy alongside intense disclosure and collectivized grievance construction. This contributes to work in the learning sciences to demonstrate the political contexts and consequences of learning and provides tools for activists to organize learning ecologies for educational intimacy and politicized trust.

On relationships and learning

The question of how relationships shape learning has animated many of us in the learning sciences over the last decades, and particularly in recent years as attention in our field has shifted to attend more closely to the political and ethical dimensions of learning. Recent research has examined how relations of educational intimacy (Uttamchandani, 2021) and politicized trust (McKinney de Royston & Vakil, 2019) have made specific forms of learning possible, and this work, alongside other interventions toward understanding relationships and politicization is vital in understanding how other possible futures are imagined and enacted through the joint work of community members. This paper theorizes political transformation through a sociocultural lens, arguing that politicization is a learning process, one that unfolds not in the minds of individual participants, but rather as co-constituting processes of development involving the political concepts, practices, epistemologies, and identities of learners as they transform through their engagement in building new possible futures (Curnow, et al., 2020).

These theoretical and analytical questions align closely with questions emerging from social movements, where the need to understand how, when, and why some relationships support learning and collective action to change social systems toward more just futures (and why some do not). This question was a persistent undercurrent in the work of FossilFree UofT, a campus-based climate activist group. In their campaign to push the University of Toronto to divest the endowment funds from the 200 fossil fuel companies with the largest reserves, many of the young people engaged in this work dramatically shifted their political orientations. So often, young activists in the campaign wondered why some people “wouldn’t learn” and why, by contrast, other spaces felt so nurturing of their political engagement and growth as climate justice activists.

In this paper, I take up those questions, asking how relationships of educational intimacy enabled politicization. I use one particularly rich interaction as the basis of analysis, looking at video of an impromptu debrief of people of colour after a tense meeting. In this debrief, we can hear explicit talk about the value of relationships of trust and shared experience, and also see the ongoing unfolding of educational intimacy. Building from Uttamchandani (2021) and Vakil & McKinney de Royston (2019), I argue that the relationships of intimacy and politicized trust enabled participants in the debrief to become politicized, and that the politicization process further entrenched and reinforced their relationships.

To make this argument, I begin with a brief overview of recent research on relationships, politics, and learning from sociocultural perspectives. I then provide more detail on the context of Fossil Free UofT before describing the participatory action research project we undertook, the data collection, and the methods of analysis. I then pivot to an analysis of the debrief, highlighting the sensemaking happening in real time, and identifying how the relationships of politicized trust and intimacy make that learning possible.

Literature: Relationships, politics, and learning in the learning sciences

Research that interrogates learning as a sociocultural and interactional accomplishment is foundational to the learning sciences. Within that broad framing, we can look more specifically at work that attends to the affordances for learning that relationships enable. There has been work investigating how friendship shapes learning processes and outcomes among students (Takeuchi, 2016; Jackson, et al.; 2020; Vakil & McKinney de Royston, 2019), among social movement organizers (Curnow, et al., 2021; Teeters & Jurow, 2018; Uttamchandani, 2021; Vea, 2018), between teachers and students (Boaler, 2008; McKinney de Royston, et al., 2017), between research collaborators (Vakil, et al., 2016), and among researchers (Jackson, et al., 2020). All of this work recognizes that learning is social, and that who learners are surrounded with matters for what they learn, how they learn, and how they feel about learning. This work also identifies that a focus on relationality is a political act within a system of racial capitalism, but the political interventions they highlight are diverse. In this section I highlight the important contributions that have been made in this area to situate my work and to celebrate the web of relationships my analysis is entwined in. Through the process, I orient readers to the invitations and directions that emerge when these papers are read alongside each other.

For McKinney de Royston, Vakil, Nasir, Ross, Givens, and Holman (2017), a focus on politicized care means that interactional dynamics of support for Black boys from teachers, and in particular Black men, shapes the terrain of learning through kinship networks that extend beyond the classroom and are rooted in shared experiences of racialization. The use of "politicized trust", then, signals a shared experience within racialized relations, and the ways adults hold space for young people to be valued. This is political in that it works against normative anti-Black discourses that devalue and dehumanize Black children and centres their brilliance. Also working from the idea of politicized trust, Vakil & McKinney de Royston look at the ways politicized trust is enacted in STEM classrooms, examining how students come to understand and respect each other and enact solidarities (or not). Their use of the concept centres on the idea that relationships between students must be premised on good faith and solidarity when people are working across difference. When examining an explicit conversation about race in a classroom, they note how the conversation devolves in the absence of shared experience, politics, and identities, and how the absence forecloses opportunities for learning (predominantly for the White boy student). The trust that is politicized is premised on a shared understanding of the nature of racialization and racial injustice and a willingness to learn alongside each other in service to racial justice. This is a theoretical stance against work that takes up colour-blind approaches to learning and relationships (ie. Boaler 2008) and insists that learning relations must grapple with the lived experience and dominant social relations of white supremacy rather than elide them.

Teeters & Jurow (2018) look at how community promotoras build relationships of trust, commitment, and reliability that also extend beyond the bounds of their official work. Through creating spaces for shared stories which built convivencia, a sense of communalism, they built relationships that allowed them to surface experiences of domestic violence and create educative spaces for women to share their experiences, decreasing their sense of isolation, and building networks of support when women took legal action against their abusers. These relationships were consequential and political, embodying care and facilitating safety through listening and building programs from needs revealed to them in confidence—led by and for Latina im/migrant women.

For Vea's investigations of animal rights activists (2020), friendships are both a learning target and process for enabling learning. For these activists, being friends, building relationships of care and intimacy, and making activism fun and social creates incentive structures that attract people to vegan activism and keep people in. These relationships are instrumentalized in service to the political goals, and drive identity development as animal rights activists. Here the relationships are politicized in that they incentivize and sustain political engagement, fostering a sense of community and empowerment in contradistinction to meat eaters which keeps people involved in the fight for their shared vision.

Finally, in his work with LGBTQ2S+ youth, Uttamchandani draws our attention to the way relationships make political work possible. He argues that educational intimacy focuses on noticing the spaces that are created and how they prefigure relations of care, focusing on the discursive patterns of support created through joking, ribbing, gentle correction, and practiced facilitation strategies that were gender affirming and fluid. While Uttamchandani did not set out to theorize politicization, we can see ways that the youth in Chroma prefigured a queer social space that was affirming in the face of cis/het normativity/queerphobia in their schools and communities—which was and is a political act. This kind of work that draws attention to the mechanisms of spaces that stand outside the mainstream and in tension with mainstream politics and practices is exactly the type of work I take up as well, looking to see how the people made marginal through hegemonic masculinities, trans- and queer-phobia, and white supremacy, etc. make their own spaces and how those spaces then re-make them.

Across this emerging work, the attention to learning as collective, as always political and in service to political projects of liberation is vital—this learning is consequential (Jurow & Shea, 2015). These relationships are framed as political interventions in the context where learning itself is political, and where learners are engaged in counter-hegemonic action to build space for themselves in opposition to systems that devalue their existence. They show us that trust, in many forms, including felt trust and empowerment, politicized trust, and confianza and solidarity, make it possible for people to learn and work together to contest inequitable relations.

Conceptual framework: Politicization

I orient here to theories of learning as becoming (Lave, 1996). Situated learning and legitimate peripheral participation (Lave & Wenger, 1991) describe processes through which new members become centrally recognized and enmeshed participants within communities of practice. Full participation unfolds not only by learning skills or discourses, but more holistically by developing the ability to participate in the full practices of the community. Alongside this growth, new members come to identify with and be recognized as members of the community.

Politicization is a process of becoming; one where transformation toward collective action in the shared repertoires of social movements is critically important, and where ideas about what futures are possible (Gutierrez & Jurow, 2016) shift and expand based on the shared ideas, identities, practices (Curnow, et al., 2020). Politicization is a multidimensional shift in the political concepts/cognition, the practices, the epistemologies/ways of knowing and being, and the identities of learners (Curnow, et al., 2020). In our conceptual framework, these pillars cannot be disarticulated from each other, they continually reinscribe the development of each other as participants become increasingly politicized. This work builds on popular education (Horton & Freire, 1990; Arnold, et al., 1991) theory and practice and theorizations of sociopolitical development (Watts & Guesseous, 2006; Kwon, 2014) that attend to how people's understandings of their worlds shift toward systemic political analysis and drives them toward collective action to remake their worlds in more just and equitable ways. Politicization is a highly consequential learning process, and is a process of making and remaking ones' self, community, and larger social relations.

Within the framework of politicization, though, many questions remain about the when, the why, and the how of politicizing processes. Why do some members of a community of practice become more radical in their politics while others do not? What are the mechanisms that support politicization in learning ecologies? These questions animate social movement organizers whose aim is to expand the base of people engaging in politicized practices, and for whom political education work is a core focus. For this reason, I bring together the emerging work on relationships, to examine in micro-interactional detail how the relational practices of a subset of youth organizers within the Fossil Free UofT demonstrated the politicization of members while creating space for further politicization. In analyzing the relational construction of educational intimacy and politicized trust as it unfolds, we gain tools for understanding how space was held to enable politicization.

Context: Fossil free UofT

Fossil fuel divestment was the most common student campaign to address the climate crisis. The campaign works with students on campuses to their leadership bodies to divest their endowments from the 200 fossil fuel companies with the largest reserves of fossil fuels (Fossil Free, 2015). It is a kit-based campaign, coordinated by 350.org. At the University of Toronto, the fossil fuel divestment campaign was coordinated by undergraduate and graduate students. From October 2014 through May 2016, Fossil Free UofT met weekly to coordinate the divestment campaign. Between 15 and 35 people attended regular meetings. The group tended to be majority white, with roughly even numbers of men and women attending, and no openly identified (at the time) non-binary or trans students participating. Racial and ethnic make-up shifted over the course of the campaign, but the group remained predominantly white, even as Indigenous, Black, Latino, South Asian, and East Asian students became increasingly involved, in terms of numbers and leadership in the group.

This paper is based on a participatory action research project that examines how student activists learned about race, colonialism, and patriarchy through their involvement in environmental activist campaigns. We situate our work within militant ethnography. This approach anchors researchers within the social movements we are part of and argues it is inadequate for researchers to merely observe political contestation, but that researchers must be engaged in shared struggle (Scheper-Hughes, 1995). We enacted our commitments to relational accountability through a participatory action research campaign (Maguire, 1987) that resulted in the co-creation of the Rad Lab. This writing is a product of the RadLab analysis. The ideas that alternative spaces shaped their political development came out of those very spaces, and through the articulation of the shifts we were seeing. RadLab members were involved in bringing these ideas into the world, and as they have moved on from the project, I continue documenting findings and reaching out for feedback from the team (thus, when I use "we" I am talking about the collective work at the time (as part of FFUofT) or the collective analysis (we the RadLab), and when I use "I" I speak to my analysis here that draws from the collective work but isn't collaboratively written.

Methods

We started from the broad question: how do participants in the fossil fuel divestment campaign become politicized around racial justice, feminism, anticolonialism, and other radical politics? In the process, we worked collectively to theorize from below and articulate what we meant by politicization (Curnow, et al., 2020), and then to figure out when we became politicized, and when others who took up more radical politics became politicized, what enabled that? What could we recreate in other organizing spaces that would be useful to help develop critical consciousness, radical repertoires, a counter hegemonic worldview, and shared identity? From that question, we narrowed our scope to the impact that "alternative spaces" had in enabling the learning that we were interested in.

To answer these questions, video was collected with the University of Toronto (UofT) fossil fuel divestment campaign. Video was collected at meetings, actions, some caucus spaces, and debriefs over the two-year campaign, resulting in over 15,000 minutes of video. Videos last from 60-240 minutes and were captured from one to four angles and stacked so streams are visible and coded simultaneously.

After video was collected, it was content-logged and pre-coded using codes based on the research question (including race, gender, and colonialism). The first substantial analytic pass of coding was conducted by the RadLab members, including five women participants from the group, one white, one South Asian, two East Asian, one Indigenous, and one Black man. We watched segments of videos from across the year together and coded "interesting" segments, asking the broad question of how race matters in our group, discussing every instance someone raised and making extensive notes. After conducting "interesting" coding on three segments from the beginning, middle, and end of the year, we reviewed the "interestings" and consolidated them into codes that were most present in the video we reviewed and in our experiences of the group. From this collaborative data analysis, we established early coding domains which were applied to the video and other data.

In coding for moments where racialization, colonialism, and gender were discussed directly, I generated a condensed transcript of relevant talk from the content logs and transcripts. I then iteratively coded that looking for what enabled that talk. In this coding, specific instances that were particularly meaningful, where I could see learning reflected and unfolding simultaneously became examples of particular interest. In these instances, I found that the mechanics of educational intimacy were significantly different. I coded for humour, intimacy, and disclosure, as well as something harder to count, but which was deeply felt when watching the video; the significance of trust, the network of support, and the assumptions of shared experience/shared values/shared goals. These were identified through interactional practices, in tone, facial expressions, gesture and use of space, and in the context of the talk.

Findings

One example of learning is shared here, where politicization simultaneously unfolded and is demonstrated as an accomplishment as Black members and members of colour from the group expressed and constructed politicized trust, built consequential relationships where grievances were collectivized, enacted educational intimacy, and through the process sustained their ability to participate through rich relations of solidarity. I focus on a selection of talk by activists of colour where teasing, laughter, and intense disclosure and grievance construction are woven together. This choreography of levity and intensity created the conditions for politicization and reflected the ongoing learning of the community. This moment came during Winter Term in the second year of the campaign. At this point in time, the political dynamics in the group were growing increasingly polarized, as one set of group members became increasingly committed to working through bureaucratic structures toward a technocratic approach to addressing climate change, while another group became increasingly politicized around ideas of climate justice, where addressing colonialism, racism, and capitalism were central to their aims. As part of this polarization, the uneven racialized, gendered, and classed dynamics of who spoke in meetings, for how long, and to whom became problematized, as white men spoke an overwhelming majority of the time, creating a space that members of colour and white women described as problematic after it became clear how endemic the problem was. In the meeting, the Women's Caucus presented their concerns about womens' experiences in the campaigns and the ways their voices rarely broke through, and when they did, how they were not affirmed (Curnow, et al., 2020). In the large group discussion of the problems raised, people of colour bridged the gendered experience in Fossil Free UofT with the racialized experience, noting that people of colour were systematically marginalized and "underappreciated". The response from the members of Fossil Free UofT was mixed; some were grateful to learn the critiques, while others reacted angrily. The meeting included yelling, tears, and storming out.

An impromptu debrief happened after the meeting, as members of colour gathered in the back of the room to affirm the contributions several of the members of colour had made in the meeting, where their racialized positions and experiences were discussed explicitly, which almost never happened in the large group contexts. The debrief conversation lasted for over an hour, as at first a small group, and gradually almost all the members of colour in the group joined the huddle in the back of the room. There was other activity in the room and hallway, as several members (who had been unhappy about the content and process of the gendered grievances) gathered in the front corner of the room to discuss strategy that they said had not been adequately discussed in the meeting because of the fight over the Women's Caucus. Others gathered in the hallway around someone crying. What unfolds here is a snapshot of the broader trajectory of politicization and the relationships that fostered that politicization, but it is emblematic, and demonstrates sensemaking as it unfolds, the ways that consequential relationships were constructed, and how those relationships made transformational learning possible.

Constructing politicized trust

In a small circle of five people of colour, Cricket tells Dawood what he appreciated about Dawood's powerful interventions in the meeting while Jade nods enthusiastically, with Jade adding "No, I totally know, it's amazing." Over the course of the debrief, participants shared experiences and went into more detail about the kinds of discrimination that they had experienced on campus and had only hinted at in the large group meeting. As they talked, they were all affirmed, with Amil snapping, Jade nodding vigorously, and lots of verbal continuers, like "yeah", "mmmhhmmmmm", etc.

Standing around in the corner in a tight circle, as others moved in and out of the room, and as others dealt with the aftermath of the conflict-riddled meeting in the hall as well, the immediate processing was an extension of the sensemaking that was happening in the meeting, as people took up arguments that had been initiated in the meeting. The circle discussed the content of the meeting in serious and in mocking ways, noting the problematic nature of demands that women get permission to meet outside of the large group space. They discuss shared experiences of struggling to be heard in the group and the racialized experiences of being shut down that impact their participation in the group, especially when the White men were acting aggressive. Referring to one of the sticking points in the meeting where one of the men accused the women's caucus of not speaking up in meetings or raising their concerns in the moment, Jade took up this line of reasoning:

> Jade: Also, y'know sometimes, it's not that we don't want space to say it — sometimes we have nothing to say, because we're like internalizing all the thought (Wiggling fingers near head). And it takes a while for some people to like think of something to say from the brain and the (Gestures from head to heart space). Like some people just, like, whip it out (Snaps). Where for me it takes like 15 minutes, to like think of something. So yeah, different for everyone.
> Amil: (Snapping for Jade as affirmation) How much of that is being in spaces where your ideas are being shot down. It's like a mechanism to preserve…
> Jade: (Nodding) A lot, yeah.
> Amil: This is like something I find surprising. When we're like in spaces among people of colour, pretty sure for women (Gesturing widely around to this group of people), your ideas just flow, right?
> Tresanne: Yeah (Laughs)
> Amil: … but when you're in the space, how are you going to judge me…
> Jade: Yeah
> Amil: Cuz I've been in spaces where people shut down your ideas (Whipping gesture) and then you're like, OK. You shouldn't say anything.

There is consequential sensemaking happening across this exchange, all read through the relationships of politicized trust that are assumed in the circle. First, we can see Jade critiquing both the demand that women (and by her own extension, other people of colour) respond to men's requirements for how they participate in the space. She takes up the assumption that participants must think quickly and respond verbally for their feedback to count. This links up with two of the ongoing critiques that had circulated in the Women's Caucus and the People of Colour Caucus: the logic of being quick on your feet as a classed, gendered, and racialized performance, and the idea that the only valid criticism was explicit and verbal, which effectively ignored the embodied feedback, the withdrawal, and the refusals that were more common among women and people of colour in the group. Jade is bringing those arguments into the space, linking them to this context and problematizing the ideas yet again. Amil takes these up and extends to another idea that the People of Colour Caucus had discussed widely at this point in the campaign — their experiences of being shut down and the overall experience of being minoritized on UofT's campus. The political analyses are being rearticulated and collectivized again here, using the space of community to validate their experience, and to share these political critiques with Cricket and Jennifer, who were newer to the campaign and had been less involved in other alternative spaces. While these were pedagogical expressions, which I believe Amil intended to shape how others read the field, they also seem to be seeking validation and building solidarity among others who were likely to have experienced similar (though distinct given the expressions of anti-Blackness at UofT and in the world) things. His frank discussion of the strategic moves he makes to protect himself from racist responses was an invitation and a starting point for solidarity. It was a practice of invitation that made space for politicization and deepened politicized trust through vulnerability and shared marginalization. We see the significance of that relationship when he says, "When we're like in spaces among people of colour, pretty sure for women (gesturing widely around to this group of people) ... your ideas just flow, right?" Naming the dynamics of this small group, he notes the significance of politicized trust in relationships among people of colour, showing how they were flowing, as they riffed on each other's ideas in response to the problematic meeting, and noting that the relationships of support allowed them all to do that work without fear of being shut down. The ongoing construction of politicized trust enabled space to collectivize grievances, similar to what Teeters and Jurow found and what McKinney de Royston, et al. described. The relations of trust rooted in shared experience iteratively politicized members and reinforced feelings of belonging and shared identity within the People of Colour Caucus.

Consequential relationships

Relationships made the space possible; the intimacy that was created was expressed in the context of friendship, trust, and shared experience. This was made explicit as Dawood spoke. He was a newer member who was almost always silent at meetings, and who hadn't participated in many of the activities outside of large group meetings.

> Dawood: I feel so much more connected and appreciated in the group just by communicating myself. I don't even need a response from everyone.
> Jade: (Nods enthusiastically) Yeah, I know.
> Dawood: Just communicating it makes me feel more comfortable.
> Jade: Exactly
> Dawood: This is probably the first time you noticed me talking.

In this space, the validation from sharing their stories seemed impactful, further entrenching the shared identities, politicized trust, and the sense of accountability to one another, and the kinds of communalism that Teeters and Jurow note in their work. In this exchange the interactions feel transformed from that of the meeting. Where the meeting had been tense and the members of colours' gestures seemed fearful and quieter, this space looked different, filled with big gestures, smoother movements, and constant affirmative continuers, verbal and physical. The comfort that was built through articulating a different politics and a non-dominant experience that was shared clearly built the foundations for sustained engagement in what was otherwise a hard environment.

Fostering educational intimacy

Another dynamic in this impromptu debrief was the warmth and affirmation, the laughter and teasing, and the moving between very heavy conversation and joking. In this short example, we can see all of these at play, echoing Uttamchandani's findings around the construction of educational intimacy.

> Tresanne: But I think this is a really nice — yeah, this is a meeting I'll remember forever.
> Jade: (Nods vigorously) Yeah, I'll die remembering it
> Amil: What?!! (laughs)
> Jade: I mean on my deathbed. (All the participants are laughing about the different meanings.)
> Amil: (Laughing hard, looking at the faces everyone else was making in response to Jade's slip) Everyone's reaction!
> Jade: (Buries her head in arm) Sorry! I know, really dramatic.
> Amil: We, um… Yep. Yeah yeah. This is a sidebar, it's like, sorta like, learning to be people of colour, while dealing with all these historical oppressions while being in solidarity with Indigenous people. In a system of weird complicity
> Tresanne: Yeaaah
> Jade: Yeah, yeah.

In this exchange the sense of familiarity and friendship comes through strongly, as Amil teases Jade, everyone laughs, but in a way that is inclusive and builds relationship, rather than making fun or isolating. The moment in the video is so warm, and it's hard to demonstrate that feeling of intimacy through a transcript. Given the context of a very hostile and harmful meeting, the fact that this space emerged which was community-affirming, pleasant, and joy-filled was a meaningful and powerful thing. Centring relationships among members of colour was an active intervention to build belonging, to carve out a shared identity within this broader space. And then we see the fluid move back into one of the more challenging political questions that Amil had been dealing with, navigating white supremacy and settler colonialism as a Black person. This moment may seem like a non-sequitur, but it could only have emerged out of this shared space of racialized community, where politicized trust was being actively enacted and where shared practices of affirmation existed alongside educational intimacy and joking, as a place where the shared experience of members of colour was assumed and appreciated. In the context of those relationships, this broader political struggle around identity and accountability could be voiced and affirmed.

Redeeming and incentivizing participation

In this informal debrief, as people stand around in their coats, then take their coats off to stay longer, there's teasing, there's laughter, there are these very quick moves between intensity and levity, with learning and community. Across the room, during the entire exchange, three White men had gathered across the room to strategize around the governing council and seemed to act like there had not just been a big drama, or to acknowledge that other people were still out in the hall crying. When the White men walked past the debrief and said goodbye awkwardly, there was a collective exhale in the circle. One of them whispered "that's fucked," a shared acknowledgement of the trauma. Nothing else was said for a beat, and then they turned to levity, talking about setting up a potluck and discussing the Canadian Minister of Environment. The relief, the community, the relationship, and the space to just…be… is palpable in this small community where shared experience is understood and cherished. This is the kind of emotional intimacy that Uttamchandani points our attention to, except in this context it is hard won through conflict and micro and macro aggressions within the group rather than in a supportive learning community. In this way, educational intimacy was a tool for redeeming an otherwise hostile space and for incentivizing friendship, to echo Vea's findings, which kept participants active in this movement space. This debrief was the real time construction of community that was otherwise missing, and they carved out space for politicization through relations of intimacy that sustained their participation in the campaign.

Discussion

This relatively short instance of politicizing and politicized talk among activists of colour is highly generative for understanding both the what of politicization — that is, how it unfolds in real time as participants make sense of the testimonies of their comrades, the conflicts of the campaigns, and the shifting political commitments in the group — and the ways that relationships among the participants of colour held space for that learning through constructing educational intimacy rooted in expressions of politicized trust.

Looking to the learning sciences literature on sociocultural processes of learning and relationship, this study draws several pieces into focus. First, this analysis brings more texture into Uttamchandani's ideas of educational intimacy, we can see in living colour the ways that the participants here moved in and out of joking turns, and how teasing created space for difficult articulations of marginalization and made space for fun that sustained participation. While Uttamchandani's discourse analysis paints beautiful scenes of LGBTQ young people building spaces of educational intimacy, this work offers additional analysis into the interactional accomplishments that create that space (the gestures, the proximity, the facial expressions) and how the interactional practices related to the talk/learning/politicization. Second, speaking to McKinney de Royston and Vakil's theorization of politicized trust, this work brings another site of learning to bear, showing how shared experience is articulated and used to build that relationship, and how that trust becomes actively politicized. Trust, in this space, goes from being more than an assumed shared experience to being an articulated shared experience and an affirmed experience, moving people from lingering questions about whether they were the problem (so to speak) and into a politicized understanding of white supremacy and how it worked in the group and beyond the group. Finally, for studies of politicization or sociopolitical development, we can see how relationships facilitated the process of becoming more radical, how relationships served as an accelerant, throwing lighter fluid on the hot takes and making them collective/shared, important, and valid. This is important for the field, because while relationships make all learning possible, the kinds of counter-hegemonic transformations that we document across our work with the RadLab are often hard, both because they go against normative descriptions of how and why the world works as it does, and because it relies on naming difficult experiences of minoritization. Thus, having a community that welcomes that, holds space for it, and can sustain participation in that work is critical for staying in that learning and transforming it into collective action.

Conclusion

For participants in Fossil Free UofT, and particularly for the people of colour whose sensemaking we trace, relationships were consequential. The intimacy they constructed through their joint sense making, shared experiences, and emergent politicization opened possibilities for growth and created avenues for politicized participants to practice leadership and scaffold a pedagogical space for others to become politicized within. For organizers and designers, these moments of refuge show how important alternative spaces can be for minoritized participants to build community, to heal, to build political analysis, to laugh and to breathe. Designing intentional space can be a strategy for sustaining engagement in hegemonic spaces and forging politicized trust and educational intimacy that travels across spaces of participation.

For social movement scholars of learning, this work points us, again, to the significance of relationship, not as a fluffy or simply nice-to-have additive, but as an essential, prefigurative political process that enables and produces sense-making in ongoing ways. For theorists of learning, relationship needs to be at the core of what we examine to understand when, why, and how people learn, as well as whose learning is fostered or constrained through relationships that reinforce or contest hegemonic participation. This analysis brings texture to the conversation and expands the scope of political learning. Where others in the field have theorized politicized trust, educational intimacy, and other related concepts, the case explored here shows us again how important these relations are and what they make possible. In examining the interrelatedness of joy and grievance construction, we can see new avenues for future analytic work, to examine the choreography of learners and facilitators in making sense of tense conflict situations and finding levity within them that is rooted in shared experience and politicized trust.

Investigating the Role of Kindergarten Children's Constructed Models as Tools for Modeling-Based Inquiry

Loucas T. Louca, European University Cyprus, L.Louca@euc.ac.cy

Abstract: A growing body of evidence highlights the added value of Modeling-based Learning (MbL) in science when incorporated into kindergarten science education. This descriptive case study seeks to add to the literature by describing the ways two groups of kindergarten children engaged in MbL. The study focuses on the ways that these children used their constructed models as tools for investigations and knowledge development. Findings across the two cases suggest that participating children productively engaged in authentic MbL activities, while they (a) were able to use their own models as tools for further investigations of and knowledge development; and (b) have modeling resources for using their own constructed models as theoretical structures that can be applied in a (new) phenomenon to explain new (parts of the) phenomena. Implications of these findings suggest the dynamic nature of the kindergarten children's models and children's understanding of their models' functions.

Introduction

Extensive research has influentially advocated Modeling-based Learning (MbL) as a productive means for teaching and learning science (e.g., Louca, Zacharia & Constantinou, 2011; Louca & Zacharia 2015; Clement, 2008; Halloun, 2016; Jackson et al, 2008; Khan, 2007; Schwarz et al., 2009; Windschitl et al, 2008; Justi & Gilbert, 2016). NGSS (2013) defines modeling as a practice involving the construction, evaluation, revision, and use of models aiming at predicting and explaining physical phenomena (Louca & Zacharia, 2012). In this respect, models and modeling are considered integral parts of science learning, primarily because they provide the means for students to represent, describe, examine, and explain phenomena (e.g., Justi & Gilbert, 2016). Externalized in various ways, a student-generated model becomes a tool enabling students to understand how a phenomenon takes place and use it to make predictions related to this phenomenon (Schwarz et al., 2009).

Modeling-based Learning (MbL) takes place within the process of constructing models. During MbL the emphasis is placed on the modeling journey and the modeling processes rather than simply focusing on the model as the end product. Thus, MbL directs science learning beyond acquiring science facts, engaging learners in figuring out the mechanism that underlies science facts and phenomena (e.g., NRC, 2012; Krist et al, 2019).

Theoretical framework

The study I report here concerns the application of MbL with kindergarten children. Research suggests that children as young as kindergarten have sophisticated ways of thinking about the natural world around them, which is translated in the K-12 Science Education Framework as the effort to engage them in the development of explanations about natural phenomena (NRC, 2012). Towards this direction, the NRC (2012) framework includes the practices of students developing and using models, and students constructing explanations for natural phenomena. The construction of models may use a wide range of different types of modeling tools, such as everyday language, drawings, diagrams, gestures, dramatic play, 3D structures, computer simulations, and mathematical equations (Giere, 1990; Schwarz et al., 2009; Windschit et al, 2008; NASEM, 2022; NRC, 2012). The development of a model requires the use of representations of the elements included in the phenomenon at task, and, the corresponding underlying mechanism which entails how these elements work and interact with each other (NRC, 2012) resulting in the natural phenomenon.

Despite its added value, the research community has yet to have a clear, detailed picture of MbL in kindergarten science education, related to the fact that it is not clear how effective implementation of MbL in these ages look, posing considerable challenges to e.g., teachers and curriculum designers (e.g., Tobin et al., 2017). At the same time, modeling-based reasoning and practices tend to be considerably underemphasized in school-based science teaching and learning, mostly in the younger grades (Forbes et al., 2015; Schwarz et al., 2009; Windschitl et al., 2008). All these raise questions related to the modeling practices and processes that kindergarten children use when engaged in MbL.

In a very recent report about science and engineering in preschool through elementary grades, NASEM (2022) suggests that developing and using models and constructing explanations about natural phenomena should be part of learning in Science in early grades. The report suggests that models can be viewed as artifacts through which young learners can externalize their ideas about natural phenomena, which could be one main way of allowing children to communicate their thinking in science. NASEM (2022) also points to the fact that preschool children have been observed exhibiting substantial representational proficiencies within the context of MbL. I contend that these proficiencies are related to what Louca (2020) call "modeling recourses" from a variety of areas such as free play (during which they manipulate objects), storytelling (during which they describe things happening in particular order), drawing during which they make, recognize and interpret representational choices and intentions (e.g., DeLoache, 2004). There is also evidence that suggests that children may work with a range of representation types (with of course some support), along with abilities to comparatively discuss the advantages and disadvantages of different representations of the same phenomenon (NASEM, 2022).

In a series of studies, Author and colleagues have contributed to the literature about how kindergarten children engage in MbL. Louca & Zacharia (2015) compared the ways young modelers worked within the modeling process as highlighted by the literature (e.g., Louca, Zacharia & Constantinou, 2011; Louca & Zacharia, 2012; Mendonca & Justi, 2014). They reported that kindergarten modelers follow similar practices but in a different manner. For example, revising their constructed models occurs within the context of investigation and construction phases, suggesting that the model revision phase of the MbL might not be independent. In line with Stratford, Krajcik, and Soloway's (1998) work, the Louca & Zacharia (2015) also highlighted that the constructing-a-model phase is quite complex. The development of a model includes processes such as decomposing the phenomenon under study into smaller parts, identifying elements to be included in the model, and synthesizing (which involves inductive reasoning and requires that children mentally bring the model's elements together). This is also in line with what Krist et al (2019) proposed: during MbL learners may need to move between different scalar levels of the observed phenomenon in order to productively describe the mechanism underlying the phenomenon.

While research in kindergarten MbL has slowly gained some momentum, there are aspects of models (such as the nature of models, the existence of multiple models, the purpose of models, the process of testing models, and the process of changing models (Upmeier zu Belzen and Krüger, 2010)) that have not been studied yet with these ages. While prior research has highlighted differences and similarities in which kindergarten and older children engage in MbL, it is reasonable to seek to investigate the ways that kindergarten children may use models as tools for further investigation and learning, which is related to their understanding of the nature, the role and the purpose of models they construct through MbL.

Purpose

This is a descriptive case study (Yin, 2017) seeking to provide detailed accounts of the ways two groups of kindergarten children engaged in MbL, focusing on the ways that these groups of children use their own constructed models as tools for further learning in the context of MbL. In the first case, students developed models of a simple ecosystem (food chain), and then, they used their models to collect data to develop the concepts of ecosystem balance and the ecosystem web. Children in the second group (case 2) developed models of heat transfer between a stone ice cube and water, and then by using their models, they developed the concept of thermodynamic equilibrium, which led to a new revised model to include the idea of thermodynamic equilibrium.

With an emphasis on the representation of the mechanism of the natural phenomena, in this study, I analyze evidence from these two case studies to describe the process of model development for these phenomena for these groups of children and then, describe the ways that kindergarten children may use their own constructed models as tools that support further learning through using their models for new science investigations. Evidence from the two case studies at hand seeks to add to a growing body of research that children as early as kindergarten are able to engage in MbL. I also use this evidence to argue that (a) children are able to productively use their own models as tools for further investigations of the phenomenon, which can lead to the development of new concepts; (b) kindergarten children have modeling resources (Louca, 2020) that can activate and use in order to consider and use their own constructed models as theoretical structures that can be applied in a (new) phenomenon to explain new (parts of the) phenomenon (Upmeier zu Belzen & Krüger, 2010); and (c) highlight the dynamic nature of the children's models and children's understanding of their models and their functions within the context of children modeling discourse.

Design and procedures

Following a descriptive case study approach (Yin, 2017), this study involved two groups of kindergarten students (age range: 5-6) in Cyprus taught by 2 different teachers (19 and 21 children respectively). Both teachers participated in the same professional development (PD) program for MbL in kindergarten science organized by the author over a school year. The cases selected for this study were the teachers' final teaching unit of MbL in science for the school year, taught in April-June, after a year of developing, applying, and reflecting on MbL units of kindergarten science. Along with the author and the rest of the teachers participating in the PD program, the two teachers developed their units from scratch in a series of online, bi-weekly, 90-minute reflective meetings, and data-driven (video, and photos of children's work) reflections.

For this study, all lessons (about 40-minute duration) in each case study were videotaped and transcribed for analysis. Children's work was also collected for analysis. To facilitate the analyses, for this study I adopted the approach of drawing-based modeling in which students use annotated drawings to represent their model (Fretz et al, 2002), resulting in a children-constructed model that is accompanied by children's descriptions of their models. Thus, I analyzed student-developed models (artifact analysis) along with their presentation and discussion (discourse analysis), seeking to provide rich, detailed descriptions of the characteristics of these models.

Transcripts of student conversations served as the primary source of data. For the analysis of children modeling conversations, I used two complementary approaches for analyzing student conversations. The first analysis of children's conversations in science (e.g., Ball, 1993; Gallas, 1995) builds on the long-standing interest of the science education research community in classroom discourse (e.g., Kurth et al., 2002; van Zee et al., 2001). This analysis uses transcribed children's conversations as a gateway to children's reasoning and learning experiences (Edwards & Mercer, 1995). I used discourse to develop detailed accounts of the context and the content of the modeling conversation describing the student contributions toward MbL, which I describe in the findings section. To support this analysis, I also coded the same discourse data using Russ et al's (2008) coding scheme for mechanistic reasoning in students' discourse. Given that the main purpose of the MbL is to develop accounts describing the process of how a phenomenon takes place, the heart of MbL is the development of the mechanism underlying the phenomenon. In this study, this process was captured by analyzing discourse data by Russ et al's (2008) coding scheme of 7 components of mechanistic reasoning (see Tables 1 and 2 for details).

To support the discourse analyses above, I also analyzed student-constructed models using artifact analysis adopted from Louca, Zacharia, Michael & Constantinou (2011). Codes included the ways that children represented different elements in their models: physical objects, entities, processes, and interactions.

Findings

In this section, I present an overview of each of the two case studies and then turn into a discussion about common emerging themes. The descriptions of the findings below seek to cover the complete unit as it was enacted by the teacher and the children, seeking to give a detailed picture of how the children reached their final model and then use that as a tool for further learning.

Case study 1: A food chain in a simple ecosystem

The first lesson started with children in a whole classroom setting, discussing ways of organizing a number of different organisms to "live in a house". Children ended up with three different categories (plants and trees, insects and mammals). Then the teacher presented another grouping that she came up with, which included one organism from each category, asking children whether this was a possible categorization. Following a discussion about this, the children suggested revising their grouping to include 5 groups, based on the dietary relationships of the organisms involved (organisms that would not eat each other but prefer to eat organisms from other groups were put by the children in the same group). I consider this as the children's model 1 which, based on the artifact analysis, included physical objects (the organisms), physical entities (the organisms' dietary habits), and physical interactions (organisms eating other organisms). Figure 1 provides examples of children's constructed models.

The teacher started lesson 2 by asking children to explicitly represent on a single paper the relationships of the organisms from the different 5 groups. Each child developed their own model (model 2). In a discussion about the subsequent evaluation of those models, the children identified a variety of different representation approaches used in different models by different children. Some models included the organisms (physical objects) on a continuous, straight line connecting them (which I consider to be a form of representation of physical interaction), while others connected organisms with arrows showing the pray->predator relationship, and others putting numbers to show the linear relationship between the organisms. Children used those different ideas to collectively develop a revised representation (model 3).

In lesson 3, the teacher asked children to compare their model 3 with a model she provided in the form of a food pyramid with the same organisms. The children agreed that the two representations had some differences. In the food pyramid, as we moved to a higher level, children suggested, the number of organisms decreased, whereas in the food chain only one organism from each category was represented. However, children were unsure about the significance of the latter representation rule in the food pyramid. From a research perspective, this is related to a more detailed/advanced representation of the physical process in the phenomenon (Louca, Zacharia, & Constantinou, 2011).

In lesson 4, the teacher asked the children to develop their own food pyramid (model 4), from the food chain that they developed during lesson 2 (model 3). During this process, a number of children noticed that the organism on the top of the pyramid was not eaten by any other organism and brought that observation into the discussion. This was the first instance in this unit, that their own models became a tool to think and reflect about the phenomenon represented, providing children with opportunities to think about the phenomenon more deeply, identifying issues absent from their models but deemed important parts of the phenomenon. While discussing this observation in a whole class setting, children suggested that while this could be true, any organism may die from natural causes. Thus, they suggested that this could also be the case for the rest of the organisms. A child suggested that dead fruits, leaves, and vegetables could be eaten by organisms living on the ground such as worms. Thus, they collaboratively decided to include worms at the bottom of their food pyramids, although they were unsure how to convey the information about the role of the worms.

In lesson 5, the teacher proposed to represent their food pyramid using dramatic play (model 5). To do so, the children agreed that each of them will undertake the role of one organism. They spend considerable time discussing the rules of their dramatic play that included physical objects, physical entities, and physical processes involved in the phenomenon. They agreed that the play will include only 1 fox, 3 chickens, a lot of grass (10 children), and 5 worms (physical objects). They talked about different organisms' behaviors and relationships: the fox eats chickens, chickens eat worms, and worms eat dead organisms in the soil (physical interactions). They also discussed physical objects' behaviors such as the plants do not move, the worms move very slowly, the chickens move a bit faster, and the fox being the fastest one (physical entities). They also developed a rule to simulate what happens to one that has been eaten (sit still on the floor) (physical process): when touched by another organism of the same species, the organism could re-enter the game, simulating the birth of new individuals (physical process).

Figure 1

Examples of models from case study 1; (a) Model 1: Grouping (Group model), (b) Model 2: Diagram (Individual model), (c) Model 3: Diagram (Individual model), (d) Model 4: Drawing (Individual model), and (e) Model 5: Dramatic play (Group model)

(a) (b) (c) (d) (e)

In lesson 6, children tried their dramatic play model (model 5). The teacher suggested trying this out with different numbers of individual organisms at the beginning just to see what would happen. They run this with various number combinations as decided by the children. The results were puzzling for the children, because, e.g., a large number of foxes resulted in at some point no chickens alive, and a large number of chickens resulted in no worms alive. The latter also resulted in a round with a decreased number of worms at the beginning of the dramatic play. In a subsequent discussion about the results that children collected, they focused on the results which were different from the results of their initially agreed numbers. Based on the data collected from the various iterations of their model, children suggested the idea of "optimal" numbers of the organizations in their model, which in turn contributed to the development of the conceptual idea of a "balanced ecosystem" and its characteristic of "sustainability" facilitated by the teacher. In that discussion, the children also discussed the results of round 4. Although they suggested that the initial numbers were different (the amount of initial grass was 2 vs. 10), the results between the initial numbers and the final numbers for each round were not that different. During that discussion, children suggested adding a rule that they had not thought of before related to the notion of organisms starving to death if no food was available. Taken all together, children ended up describing that there is an "optimal" number of organisms within a particular ecosystem, which results in steady numbers of organizations overall during the time that the dramatic play is in action. There were not sure how this number would be different in other ecosystems, but they were able to relate this idea with the representation in the food pyramid, in which they previously identified that as we moved to a higher level, the number of organisms decreased. Although not explicitly addressed, children seem to imply that different types of model representations convey different information about the phenomenon, with each model having its own advantages and limitations.

Table 1 presents the coding of the children's modeling discourse based on Russ et al (2008), as I described above, suggesting that over time, children's modeling discourse became more "mechanistic" by including more components of mechanistic reasoning, which resulted in more advanced mechanistic models, and probably facilitated in part for the development of the concept of a sustainable balanced ecosystem.

Table 1
Discourse analysis based on Russ et al's (2008) scheme from case study 1

	Model 1	Model 2	Model 3	Model 4	Model 5
description of the target phenomenon	yes	yes	yes	yes	yes
identification of the set-up conditions	yes	yes	yes	yes	yes
identification of physical or conceptual entities	yes	yes	yes	yes	yes
identification of the entities' activities		some	yes	some	yes
identification of the entities' properties	yes	yes	yes	some	yes
identification of the entities' organization	some	yes	yes	yes	yes
Chaining (what happens prior and after)					yes

Case study 2: Water freezing (heat transfer)

Prior to this unit, this group of children investigated the phenomenon of an ice cube melting (8 weeks in total) developing and revising a total of 6 models in their effort to represent the mechanism underlying the phenomenon.

The teacher started the unit on water freezing by bringing in the classroom ice cubes made of stone and wondered what would happen to the water if she added one cold stone ice cube. In a whole-class setting, the children designed an investigation of measuring the temperature of the water with the stone ice cube every 2 minutes and creating a record of their measurement. The investigation took place in 5 groups. In a subsequent whole-class discussion, the teacher facilitated a process during which children transferred their data to graphs. I consider the children's representation of the data collected as their model 1 (Figure 2 presents examples of children's constructed models), which was a mathematical representation of the data in a graph. Based on the artifact analysis it only included physical entities (records of the temperature). From the data collected, the children noticed that at the beginning, the water temperature increased for a number of measurements until one point, at which it remained unchanged for the following measurements. After a short discussion, the children agreed that these data indicated that the water become colder until one point that the ice cube and the water reached the same temperature, at which point the water temperature stayed the same. Although not explicitly addressed by the children, this implied that the stone ice cube was becoming hotter.

In the next lesson, the teacher reminded the children of their representation (model 1) and asked them how this happened. Looking for a possible explanation, the children suggested using the final model they developed in their previous MbL unit, representing the mechanism of melting. That model consisted of a set of rules for a dramatic play model, in which each child laying on the floor represented a water molecule and showed over time how they moved away from each other (during melting) starting from the outside of the ice cube, as per their observations. Without discussing the rules for this model, children asked their teacher to "play out" this model to explain how cooling happened. This model included physical objects (water/ice molecules), physical processes (movement of the molecules), physical entities (velocity of the molecule movement), and physical interactions between the different molecules. During the application and the subsequent evaluation of their model 2, the children realized that the model could not explain what was going on in the phenomenon currently under study (how the water gets colder because of the ice), due to the fact that their model explains how an ice-cube made of "water melts" (pieces of ice getting detached from the ice cube and become water) and had no information about the change of the temperature, and what was causing this change. Thus, this model could not provide an explanation as to how the phenomenon of heat transfer takes place. In a sense, children realized that although this model was explaining a similar phenomenon (ice melting), it failed to explain the temperature change under study. Although children did not talk about the reason for that failure, this failure was due to what Krist et al (2019) refer to as the two models at hand requiring different scalar level explanations: the ice-melting model stopped at a lower scalar level, lacking information about how the ice-melting (molecules moving) was related to the process of heat transfer that caused the ice melting.

In lesson 3, the teacher gave the children a piece of paper to draw what they thought happened in the water with the stone ice cube. Children developed a third model that in most of the cases showed that the stone ice cube was giving (physical process) "coldness" to the water (physical entity) when the two physical objects (water and stone ice cube) were in touch in the water (physical interactions). Through their models, almost all of the children started talking about the idea of thermal equilibrium. For instance, one child suggested that the ice cube was giving "coldness" to the water, and the warm water was giving "warmth" to the ice cube until they [their temperature] became equal. A second child suggested that the ice cube gave half of its "coldness" to the water until its temperatures become equal. While most of their models 3 included (as in the case of model 2) physical objects, physical entities, physical processes, and physical interactions (and thus the artifact analysis coded similarly these 2 models), children's models 3 were in a higher scalar level compared to model 2, explaining how the phenomenon of heat transfer took place.

Figure 2

Examples of models from case study 2; (a) Model 1: Diagram (Group models), (b) Model 2: Dramatic play (Group models), (c) Model 3: Drawing (Individual model), (d) Model 4: Dramatic play (Group model), and (e) Model 5: Dramatic play (Group model)

(a) (b) (c) (d) (e)

In lesson 4, the teacher reminded the children of their previous models. During a discussion for evaluating model 3, children focused on the idea of "giving and taking", and the idea of the thermal equilibrium at the end of this process. During this discussion, the teacher proposed to develop a new dramatic play model like a two-player game, that would consist of a number of rules that would result in the phenomenon under study. Children discussed the rules of the game: two players, one representing the stone ice cube and the other the water. Both players had several plastic cubes. The children decided that the ice cube should have blue plastic cubes (representing "coldness") and the warm water should have grey plastic cubes (representing "warmth"). At each iteration of the dramatic play model (model 4), each child should give the other one plastic cube of his/her own color and get a cube from the other color from the other child. Children played the game twice with different players, only to notice that the model was not representing what they have observed in the phenomenon: at the end of the dramatic play, the cold entity became warm, and the warm entity became cold. Their model did not end in thermal equilibrium. The dynamic nature of their model enabled children to observe how it simulates the phenomenon and whether the simulation fit their observations of the phenomenon under study.

In lesson 5, the teacher reminded children about the difficulties they had with their model 4 and asked them to think about the phenomenon of warming water in a kettle, as well as the opposite phenomenon of a glass of water colling off in a refrigerator (children have studied both phenomena in the previous unit, without, however, discussing the idea of heat transfer). She then asked children to represent this change in each of the phenomena using a number of plastic cubes. Children proposed having a series of representations of instances for each phenomenon, with the cold water heating having first 1 plastic cube (representing the heat gained), then 2, then 3, and then 4, and the other way around in the warm water case that cools off. Based on this, the teacher reminded them of their model 4 and asked them to think about revising it accordingly. A child proposed having different colors of plastic cubes, based on the examples they considered at the beginning of the lesson. This suggestion took into consideration the number of plastic cubes that each body should have based on their temperature, and highlighted the fact that both bodies should have the same types of plastic cubes. After a long discussion, the children agreed that for model 5 the two bodies should have similar colored plastic cubes, and the warm water had more plastic cubes than the ice cube. They also agreed that both bodies should give cubes to each other, but the warm should give more plastic cubes (2) since it had more plastic cubes than the cold one (1). They also agreed that the game should stop at the point at which the two bodies had the same number of cubes. Children played the game (model 6) several times, changing the number of starting plastic cubes. Taken all together, the dynamic nature of children's model 4 helped them realize that it did not provide a representation of the mechanism of the phenomenon. They then developed a 5th model, that would include the idea of thermodynamics equilibrium (although this was in a crude form requiring refinement). This model is probably a very different solution from what the children first thought in model 4 (exchange of warmth and coldness), and simply the evaluation of the model they constructed leaded students to think about this possible idea. Similar to case 1, the development of the concept of thermodynamics equilibrium in case 2 took place during the process of model development, evaluation, and revision. At the same time, in both cases, the concepts started to develop based on data collected through their models, allowing student-constructed models to function as simulations of the phenomena at hand.

Table 2 presents the coding of the children's modeling discourse of case 2 based on Russ et al (2008). The findings suggest that over time, children's modeling discourse became more "mechanistic" by including more components of mechanistic reasoning, which resulted in more advanced mechanistic models, and probably facilitated in part the developmet of the concept of thermodynamics equilibrium.

Table 2
Discourse analysis based on Russ et al's (2008) scheme from case 2

	Model 1	Model 2	Model 3	Model 4	Model 5
description of the target phenomenon	yes	yes	yes	yes	yes
identification of the set-up conditions	yes	yes	yes	yes	yes
identification of physical or conceptual entities		some	yes	yes	yes
identification of the entities' activities			yes	yes	yes
identification of the entities' properties			some	yes	yes
identification of the entities' organization				yes	yes
Chaining (what happens prior and after)					yes

Discussion and significance of the study

In an effort to contribute towards a more clear, more detailed picture of MbL in kindergarten science education, in this study, I have investigated how two groups of children were engaged in the process of MbL. Evidence from the study adds to a growing body of research that children as early as kindergarten are able to engage in MbL (Louca & Zacharia, 2019; accepted) in a number of productive ways similar (but also different) to the ways that older children work within MbL. Most of my focus in this study was on mechanistic reasoning as evident from the modeling discourse and the children-constructed models (Russ et al, 2008; Krist et al, 2019). While the literature suggests a number of other MbL aspects (NASEM, 2022; NGSS, 2013), evidence from this study may suggest that directing MbL toward the discussion of the mechanism underlying the phenomenon may provide a productive way of engaging kindergarten learners in developing concepts related to physical phenomena.

At the same time, evidence from this study suggests that children used the models they created (and utilized them to collect simulated data from the phenomenon) in a way that led to the development of new concepts (the idea of a balanced ecosystem and ecosystem sustainability in the first case, and the idea of thermodynamic equilibrium in the second case). In both cases, children-constructed models were used by children as tools for further phenomenon investigation and learning. Interestingly, this use of their own models as theoretical structures that enable them to dive into additional investigations related to the phenomenon at hand was not explicitly taught by the teachers, but rather, was a process that was used spontaneously by the children (with of course the support of the teacher). Thus, I contend that kindergarten children may be seen as having a repertoire for modeling resources (e.g., Louca, 2020) that can evoke and use in order not only to develop and reflect on representations of the phenomena with different modeling tools but also to consider and use their own constructed models as theoretical structures that can be applied in a (new) phenomenon to explain new (parts of the) phenomenon. This has been also discussed in the literature (Upmeier zu Belzen & Krüger, 2010) as an essential part of children's modeling competencies, agreeing with NASEM (2022) report pointing to the fact that kindergarten children have been observed exhibiting substantial representational proficiencies.

Taken all together, these findings possibly suggest a potential dynamic nature of the children's models when used as references in children modeling conversations. Working with their own models, children seem to view them in such a way that they feel comfortable using them as theoretical structures that need to be in agreement with the data collected from the phenomenon and provide plausible as well as possible descriptions of the mechanism underlying the phenomenon under study but also making it possible to use them as leverage for "theoretical thinking" (thinking about theories of the mechanism underlying the phenomenon, assumptions, ideas underlying their models). Additionally, the findings suggest that different types of models may afford different learning opportunities, in addition to supporting children in developing abilities and knowledge to choose which modeling medium would fit better their model plans. Of course, these findings create possible new directions for further investigation in MbL such as the role of the teachers, anchoring activities, and the scaffolding needed to provide kindergarten learners in order to be able to engage in MbL in science in the ways I described in this study.

Supports and Barriers to the Spread of Learning Sciences Innovations: A Comparative Actor Network Analysis

Kay E. Ramey, University of Iowa, kay-ramey@uiowa.edu
Jaakko A. Hilppö, University of Helsinki, jaakko.hilppo@helsinki.fi
Reed Stevens, Northwestern University, reed-stevens@northwestern.edu

Abstract: This study compares the adoption and spread of a learning sciences innovation, a project-based, interest-driven STEAM learning program, in two culturally distinct contexts: a large school district in the southeastern United States and the public schools in Helsinki, Finland. Using Actor Network analysis, we show how and what actors needed to be mobilized for the program to get in, get rooted, and spread (or not) in these two contexts. Our findings have implications for understanding both how to spread and sustain learning sciences innovations and similarities and differences between the Finnish and American school systems.

Introduction

In the learning sciences, many of us share the goal of designing innovative learning environments and helping them succeed in the world. However, too many innovations ultimately fail to be sustainable or scalable because of a lack of attention to or understanding of broader organizational capacity (Penuel, et al., 2011) or needed infrastructure (Penuel et al, 2019). To address this problem, we must better understand the supports and barriers to sustainability and scale-up for the types of innovations produced by our community (Penuel, et al., 2011).

This study addresses this gap by comparing the adoption and spread of one educational innovation in two culturally and organizationally distinct contexts: a large, county-level, school district in the southeast United States and the public schools in Helsinki, Finland. This innovation, FUSE Studios (Stevens et al., 2016), is a project-based, interest-driven STEAM (science, technology, engineering, arts, and mathematics) learning environment. We provide a comparative analysis of the adoption and spread of FUSE in these two settings to identify commonalities in the processes involved in scaling the innovation across these two distinct systems.

Outside of the learning sciences, the scaling of educational innovations has long been an important research topic (e.g., Orlich, 1979) and has proliferated in recent years, fueled by globalization. Within scaling discussions, Finland's education system and its success are highlighted (Hargreaves, Halasz, & Pont, 2008; Hargreaves, et al., 2010; Sahlberg, 2010). Comparative research shows differences between the U.S. and Finnish education systems, along dimensions likely to impact innovation adoption. For example, since the 1980s, as part of the *global education reform movement* (GERM), the U.S. has focused education policy and reform efforts on: (1) standardization; (2) core subjects; (3) low-risk routes to learning goals; (4) transferring educational innovations between contexts; and (5) high-stakes accountability (Sahlberg, 2010). However, these elements of GERM have not been adopted as extensively in Finland (Sahlberg, 2010). The differences between these two education systems suggest value in a comparative, cross-national analysis of the adoption and spread of an educational innovation.

We have grounded our investigation in research arguing that adaptability to local contexts influences an innovation's ability to scale (Coburn, 2003). Fostering scaling by designing for adaptability (Stevens et al., 2018) and focusing on the enactment of core design principles—integrity instead of fidelity—can ensure and even enhance an innovation's impact (Cobb et al., 2003; LeMahieu, 2011; Stevens et al., 2018) by allowing actors like teachers and administrators to adapt innovations to local needs. Conceiving of scale as adaptation also emphasizes the work of local actors, in contrast to the passive metaphor of diffusion of innovations (Rogers, 2003).

Within the growing body of work on adapting innovations, international comparisons are rare, especially comparisons focusing on the process of adaptation in practice. A notable exception is research on the spread of the 5th Dimension afterschool program to several locations across the U.S. and internationally (Cole & Distributed Literacy Consortium, 2006; Cole, 2016; Lalueza, Sánchez-Busqués, & García-Romero, 2019). This work demonstrated how, as the program spread, promising implementations failed, and unlikely ones succeeded, as much through the involvement of unexpected actors as through intentional, coordinated effort. While this work provides insight into the longitudinal processes of scaling, it is largely based on *ex post facto* designs. What is missing are analyses of the processes of adaptation as they happen (Nespor, 2002; Fenwick, 2011).

Analytic framework

To address this gap, we used Actor Network Theory (ANT) (Callon, 1986; Latour, 1987; Latour, 2005). We chose this approach, because distributed perspectives on thinking and learning, like ANT, are well-suited to analyzing 'smaller' processes of implementation (Penuel & Spillane, 2014). This is because ANT treats organizations as dynamic networks of human and non-human actors that come into and out of association with each other, tracing associations between actors over time, and identifying moments of translation within networks (Latour, 2005). Because such translations are the building blocks of innovation, this approach is well-suited to analyzing change.

In our analysis, we drew on ANT's general analytic approach and specific ANT constructs. For example, we attended to *moments of translation* (Callon, 1986)—the processes of change through which networks assembled and extended themselves to adapt to local conditions (Fenwick & Edwards 2010). We explain how our innovation got in and got rooted, in terms of *interessement*—how allies or actors in the network were recruited and locked into place (Callon, 1986). We discuss how actors established themselves as *obligatory passage points* (Callon, 1986) in representing an idea, intermediary or problem and related entities in particular ways and invited other entities to detach themselves from their existing networks and connect to this new representation (Fenwick & Edwards, 2010). We discuss *enrolment*—the process whereby entities to be included in the network became engaged in new identities and behaviors (Fenwick & Edwards 2010)—and the *mobilisation of allies* (Callon, 1986)—"the moment...when the network becomes sufficiently durable that its translations are extended to other locations and domains" (Fenwick & Edwards 2010, p. 14) by representatives of the network (Callon, 1986). Finally, we distinguish between *intermediaries*—who move representations or information without transformation—and *mediators*—who transform the representations and information that move within networks (Latour, 2005). We applied these ANT concepts to answer two research questions: (1) How did FUSE get in, get rooted, and spread in these two contexts?; (2) How did the adoption and spread process differ in these contexts?

Method

Research context

Our focal innovation, FUSE Studios (Stevens et al., 2016), is a project-based STEAM learning environment. It represents a significant departure from the standard package (Becker, 1995) of school in both Finland and the U.S., because it is designed around youth interests and choice. Students choose STEAM challenges from over 30 options on the FUSE website. Each challenge has a trailer video to invite interest, and challenges level up like video games (Stevens, Satwicz, & McCarthy, 2008). Students choose when they are ready to upload evidence of level completion to advance to the next level. Students choose when to start and stop a challenge and whether to work alone or with others. While challenges have specific instructions and parameters, students have leeway in both approach and final product. Students complete challenges with a suite of digital and tangible tools. Finally, students' primary instructional resources are the FUSE website and other students, rather than the teacher, who plays a 'facilitator' role. In 2012, FUSE started as a middle school afterschool program in a large, racially and socioeconomically diverse, suburban school district in the Midwestern U.S. Subsequently, FUSE spread within that district, getting integrated into the school day, first at STEM elementary schools, then at all elementary schools. FUSE has subsequently spread beyond the district, to over 250 sites across the U.S. and seven in Helsinki.

Here, we compare two cases of district-level spread: Marvel County Public Schools (a pseudonym) and Helsinki Public Schools. We selected the Helsinki schools as a critical case (Patton, 1990) for comparison to their U.S. counterparts because of documented differences between the two countries' education systems. Marvel County represents a typical case (Patton, 1990) of within-district spread relative to other U.S. districts and a comparable case to the Helsinki Public Schools in size and structure. For example, both Marvel County and Helsinki have a population of roughly 600,000 served by one large, centralized school district. There are, however, important differences between the two contexts. Most notably, Marvel County is racially and socioeconomically diverse, while Helsinki is relatively homogeneous. School funding is also structured differently. Marvel County schools depend not only on local tax dollars but also on a mix of Federal Title I funds (available to U.S. schools enrolling at least 40 percent low-income students) and private industry grants, whereas Helsinki Public Schools are reliant solely on government funding. However, because these differences are reflective of broader, country-level differences, we believe they support rather than detract from the argument for comparing these two cases.

Data collection and analysis

In both districts, data were collected by researchers who had engaged previously in a year-long, ethnographic study of classroom culture and student experiences in the original U.S. district implementing FUSE. Research in Marvel County was conducted by the first and third authors, who are American-born researchers, fluent in English, and research in Helsinki was conducted by the second author, who is a native Finn, fluent in Finnish. Data collection began in mid-2017 with observations and video-recording of the professional development (PD) workshops for new FUSE facilitators. During the 2017-18 and 2018-19 school years, we conducted retrospective interviews with new and returning facilitators, school principals, and district-level administrators involved in implementation. We conducted onsite observations of FUSE classrooms at implementing schools (documented using video-recordings and field notes). These data were supplemented with observations and audio-recordings of administration meetings regarding FUSE (Helsinki) events where FUSE was showcased (Helsinki) and interviews with students about their experiences (Marvel County).

Consistent with our ANT frame, we used our field notes and transcripts from interviews, meetings, and classroom observations to identify relevant actors and their roles in the network at various time points. At each point, we were able to create a representation of the networks in Marvel County and Helsinki, which included relevant humans and nonhumans involved in implementation and how they were brought into *association* with each another. We then compared across time points to see changes over time. We supplemented this series of comparative snapshots by coding interviews and observation data for explicit mentions or observations of translation in the network (e.g., recruitment or attrition of new actors) and reasons for these changes. The result was a dynamic understanding of the composition of each implementing network and how and why it changed over time. We segmented network activity into three phases defined by their corresponding network goals: *getting in, getting rooted*, and *spread* (Stevens et al., 2018). We then compared the two districts.

Results

Getting in

FUSE came to Marvel County through the district's STEAM Integrator/Magnet Coordinating Teacher, Carol (all names are pseudonyms) and the Project Director of Magnet Schools, Natasha. They encountered the program at the National Art Association Conference in Chicago, in March 2016, where they attended a presentation given by the FUSE Art Director and Program Director. The district, which was otherwise under-resourced, had received a grant to create several STEAM magnet schools. So, Carol and Natasha were seeking STEAM programming (an interessement for FUSE). According to Carol, the primary actors that made FUSE appealing were STEAM and equity. Discussing equity, she said, 'A lot of people talk about STEM in underrepresented groups, but [FUSE] does it so well and naturally and capitalizes on that human curiosity that we all have.' The district piloted FUSE at Elementary School A during the 2016-17 school year as the core curriculum for a required, weekly technology class for grades four through six, run by the technology teacher, Jessica. This school was not a STEAM magnet school but one where Carol said, 'The then principal had a vision. She was going to move ahead as if she was a STEAM magnet.' This school paid for FUSE using Title I funds.

Getting into Marvel County was supported by the enrolment of a local aerospace and defense technology company, Stark Industries. Stark Industries was enrolled in the network after the principal expressed a need to have someone show her teachers how to do FUSE. Their interessement to join the network was a desire to have spaces for community outreach (mentorship) and to encourage a pipeline into the local STEM workforce for diverse students. Stark engineers volunteered to visit the FUSE studio two Fridays a month as mentors. For FUSE to get into Marvel County, it also had to be adaptable to local needs. For example, for Jessica to run FUSE as the core curriculum in her technology class, the administration required that she align FUSE challenges with ISTE (International Society for Technology in Education) standards. To fit FUSE within the school schedule and accommodate all fourth- through sixth-grade students, Jessica and her administration further translated FUSE by: (1) making it 40 minutes per week instead of 90 minutes; (2) assigning desktop computers to students, rather than letting students choose different computers each day; (3) adding non-FUSE activities, like building mazes in Minecraft; and (4) adding a 'Wall of Failure' displaying failed 3D-prints to destigmatize failure.

FUSE's entre into Helsinki also began with a conference. At this trans-Nordic conference, in Oslo, Norway, the third author (the principal investigator (PI) of FUSE) presented on FUSE in an invited keynote. This sparked an attending education professor (Liisa) from the University of Helsinki to invite the PI to give a talk on FUSE at the University of Helsinki in Spring 2015. While in Helsinki, the third author was brought by Liisa to School 1, an elementary school widely known as a local leader in testing educational innovations. During this visit, the school principal, Sanna, the FUSE PI, and Liisa discussed bringing FUSE to the school.

At this time, the Finnish schools were adopting a new national core curriculum, which emphasized multidisciplinarity and 'transversive' ('21st century') skills. Along with the district's upcoming strategy for "digitalization," this built interessement for FUSE. District leadership approved the implementation of FUSE in Fall 2016 in negotiations between district leadership, Sanna, and the FUSE PI. These negotiations brought in School 2, a comprehensive school, because district leadership wanted a second context for implementation. The principal of School 2, Jaana, reflected on this, saying, "Well of course the fact that [Liisa] was so impressed by [FUSE], so naturally it kinda increased my trust that this was a worthwhile thing...and then from what I knew about it, it seemed that many of the things in the then-new curriculum were there. And then of course it was especially a good thing for us…as part of our school's emphasis on design and design learning."

In Helsinki, as in Marvel County, FUSE had to be adaptable or translatable to the local context. For example, prior to implementation, the FUSE PI, Schools 1 & 2, the Helsinki leadership, and Liisa agreed all the materials, except for the instructional videos, would be translated to Finnish. However, in Helsinki, FUSE resisted proposed adaptations too divergent from its core design. For example, School 1 suggested running FUSE on available iPads instead of laptops. However, using iPads would have lowered integrity of implementation, as only a few challenges were accessible on iPads. So, the FUSE team pushed back, and School 1 agreed to obtain laptops.

In comparing the getting in phase in these two districts, we see similarities in what types of actors were mobilised and how. As actors, both districts displayed interessement for FUSE. In Marvel County, there was the need for equity-oriented STEAM programming for newly-funded STEAM magnet schools, and in Helsinki, there was the push for digitalization in primary education, a new national curriculum that emphasized multidisciplinarity, and a school with a history of being an early adopter of innovations. The path FUSE took to get into each district was also similar. In both cases, it came in through a professional conference and subsequent conversations between FUSE team members and district administrators. In both cases, external actors (Stark Industries and Liisa) were enrolled and served as intermediaries and lent credibility to the evolving actor networks. Finally, in both cases, FUSE needed to be adaptable to local conditions.

However, there were also important differences in the mobilized actors and their respective functions. In Helsinki, key non-human actors included “digitalization”, the new national curriculum emphasizing ‘transversal competences’ (skills related to well-being, interaction, multidisciplinary, creativity, society, ethics, the environment, global citizenship, and culture), while in Marvel County, non-human actors included equity, STEM/STEAM, the magnet schools grant, ISTE standards, and Title I funds. In Helsinki, the human actors were the FUSE PI, the University of Helsinki professor, and a school principal; only later were district-level administrators involved. In contrast, in Marvel County, the initial human actors were the two district-level administrators and the FUSE art and program directors, who were later joined by a school principal, a technology teacher, and mentors from Stark Industries. These actors also played different roles. For example, while Stark Industries and the University of Helsinki professor both supported implementation, the former contributed mentors, thus serving as a mediator, by altering the students’ and teachers’ experiences of FUSE, while the latter contributed credibility, thus serving as an intermediary but not significantly altering the form of implementation. Finally, while adaptability was important in both cases, specific adaptations to local context differed.

Getting rooted

As implementation progressed, new actors were enrolled or created, and associations between existing actors were strengthened. For example, prior to year two, Carol and Natasha pursued funding for six additional STEAM magnet schools to run FUSE. Three were funded by Stark Industries, and at one, Stark Industries engineers served as mentors. The other three were funded by a new actor, grants offered through FUSE provided by two other STEM industry partners. The second new actor was the two-day professional development (PD) workshop offered to all new and returning FUSE facilitators and administrators. Jessica, Carol, Natasha and several new implementing teachers and building administrators attended this PD in Chicago. When we asked Jessica whether the PD had been helpful, she said, *‘Oh, absolutely. Well, you know you kind of jump into it and you figure things out as you go, but it did really help validate my feelings as to what I was doing, that I was doing it correctly.’* During PD, Jessica, Carol, and Natasha helped new facilitators understand FUSE and lent credibility to the program. However, during the PD, some new facilitators and administrators expressed some ambivalence about their enrolment in the FUSE network. For example, some did not attend the PD, positioning FUSE as less of a priority than other initiatives. Others pushed back on elements of FUSE, like the lack of formal assessment. However, many attendees reflected on the PD’s importance in shaping their understanding of FUSE and implementation. For example, the Middle School A principal said, “I’m so glad I did that [went to the training], because I think as a principal, you’ll never understand FUSE if you don’t do it, and I think that’s why we have a full class of it, instead of just a couple of sections in a couple of days in science, because I felt it, saw it, loved it.”

Another set of actors that needed to be recruited to facilitate rooting were physical spaces, materials, and technology. Physical spaces were important, because many of the tools and materials needed to run FUSE were relatively immobile (e.g., 3D printers, vinyl cutters). Several new, year two schools delayed the start of FUSE by several months, because they did not have physical spaces set up for the program. Once the physical spaces were complete, however, they contributed to the rooting of FUSE. These spaces, alternately referred to as ‘FUSE Studios’ or ‘STEAM Labs’ were outfitted not only with computers, flexible seating, and STEAM-themed bulletin boards, but also with FUSE-branded banners, carpets, and bulletin boards. They represented both an additional investment in FUSE and a physical home for it at each school. Consequently, they aided FUSE in establishing itself as something of an obligatory passage point for STEAM learning. The need to install multiple software programs on the computers for FUSE also delayed implementation. However, unlike the physical spaces, which ultimately aided rooting, software problems continued to provide obstacles at many schools. Jessica reflected on software installation, saying that even though her building had a technology person right across the hall, she had to get ‘put on a list somewhere’ and the technology person ‘gets very, very busy. So it's hard to get her to come in and do 24 computers.’ She and another facilitator in Marvel County never got the software for the popular Game Designer challenge installed correctly. So, students did not have access to that challenge.

Finally, the physical kit materials for FUSE challenges proved important actors in rooting. While initial delivery of kits to Marvel County wasn’t problematic, once the kits were in use, teachers had to manage the materials to prevent loss, damage, or disorganization. Many teachers described this as burdensome. Consequently, some turned materials management over to students, but others denied students access to certain kits.

Despite these setbacks, the network sustained itself, and teachers’ and administrators’ initial impressions of it were positive. In interviews during Fall 2017 and Winter 2018, they mentioned observing emerging student skills like problem solving, persistence, collaboration, and self-directed learning. For example, Jessica said of her students, ‘They're more willing to take on problems. They're more willing to try and figure it out on their own. They're more willing to fail.’ Teachers also said students demonstrated increased confidence, new interests, and engagement in FUSE. For example, Jessica said, ‘I hear so many of them say it's their favorite activity.’ The Middle School B principal echoed these same sentiments and added, ‘I noticed...it was absolutely student led, not teacher led, which is amazing. Kids that I wouldn't normally see work together are working together. They want to help each other, and they congratulate each other.’ These positive impressions played an important role in rooting, as seeing the value in the program seemed to make stakeholders more willing to work to sustain it.

In Helsinki, as implementations progressed, new actors were also enrolled and created. Teacher training brought in teachers, who in turn, brought new spaces and students, as they set up and started their FUSE studios. FUSE also made its way into schedules, and School 2 created a new elective course. To set up the studios, the IT administration, laptops, software, charging stations, kit materials, and 3D printers were enrolled in the network. To facilitate set up, the IT administration also created an installation package of the various FUSE software.

However, not all the requisite actors had been recruited. Although district leadership had agreed on the implementations, they had not provided all necessary materials to schools. School 1 waited three months for their laptops, in part, because of the digitalization program that had helped FUSE get into Helsinki. The program outlined a plan to both upgrade and increase the use of IT in education. The district’s contracted supplier could not keep up with the demand, and when new computers were distributed, non-FUSE schools, with out-of-date devices or a low computer to student ratio, were prioritized. Additionally, the district decided to break down the standard FUSE materials package and purchase some equipment themselves, to cut costs and help with maintenance. This delayed the delivery of 3D printers and vinyl cutters. Local adaptations to the kit materials were also needed. For example, two challenges required electrical plugs and charge converters to work in the Finnish power grid, and pen lasers had to be swapped out to follow Finnish safety regulations. Managing materials, especially replacing broken materials, locally, also proved troublesome for teachers and meant some challenges were not available for considerable time periods. To address this problem, both schools assigned specific teachers to manage materials. Thus, while partly committed, as an assemblage of actors, the district maintained a degree of ambivalence in its connection to FUSE. Despite these setbacks, the network sustained itself. As in Marvel County, early teacher feedback was positive and helped keep the teachers, students and principals engaged with FUSE. For example, one teacher said, ‘The FUSE elective has been very motivating. The students have been enthusiastic about the challenges, have helped each other and learned to problem solve’.

Comparing across the cases, both human and non-human actors played significant roles in rooting. For example, FUSE PD significantly mediated rooting in both cases. New actors were recruited via the PD, however, recruiting these new actors surfaced ambivalence that needed to be managed. In Marvel County, Jessica, Carol, and Natasha played an intermediary role similar to Liisa’s and helped to enroll ambivalent actors by lending credibility to the program. However, Jessica and Carol also served as mediators, shaping implementation. Physical and technological infrastructure also mediated rooting in both cases, especially in establishing FUSE as an obligatory passage point for STEAM learning in Marvel County. However, to mediate rooting, these actors needed to be recruited into the network. Until recruitment occurred, they impeded rooting. In both cases, teachers’ and administrators’ first-hand experiences of FUSE helped stabilize the extending network. Finally, to further stabilize the network, new actors were created: material managers. However, while in Helsinki, these managers were always teachers, in some Marvel County schools, these were students.

One difference between the cases was that grant funding served as an intermediary in Marvel County but not in Helsinki. Stark Industries, in its capacity as a funder (as opposed to a provider of mentors/expertise), functioned as an intermediary, similar to Liisa in Helsinki, providing support for the program without altering it significantly, although the type of support differed. Another difference was in the needs and processes of setting up the physical and technical infrastructure for FUSE. For example, in Marvel County, obtaining computers was not difficult, once funding was in place. However, physical spaces needed to be created, which took time. In contrast, in Helsinki, physical spaces and funding were already in place, but the logistics of centralized distribution and the priority placed on equitable distribution across the whole Helsinki district led to delays in schools getting technology and highlighted the district's ambivalence toward FUSE, relative to other priorities. Finally, while digitalization served as an interessement for FUSE in Helsinki as STEAM did in Marvel County, FUSE did not establish itself as an obligatory passage point for digitalization in Helsinki as it did for STEAM in Marvel County.

Spread

In year three, the network of FUSE in Marvel County expanded, adding five non-magnet schools, for a total of 12 elementary, middle, and high schools. One actor that supported this was grant funding. However, funding also placed limitations on FUSE's ability to spread, because only schools able to procure grants could run it. The physical FUSE studios also played an important role in spread. Once these studios were set up, they were used as showcase spaces for visitors. For example, Wanda, the FUSE facilitator at Elementary School B, described her school showcasing their new FUSE studio, saying, "[W]hen we had our grand opening we invited a lot of district members. We had the chief of police. We had the mayor, the superintendent. [Carol] was here...Oh my gosh, it was amazing. It was, we had about 25-30 people." These visits and showcases helped increase awareness of and support for FUSE from district officials and local stakeholders, which helped it spread to additional schools. Carol also played a significant role in spreading and sustaining FUSE. She championed the program, applied for grant funding, supported teachers, and created opportunities for teacher collaboration. All teachers reported finding this helpful. Finally, spread was facilitated by the same adaptability that helped FUSE get into Elementary School A. Although FUSE came into the district as a fairly top-down initiative, each school was free to translate it to fit their needs. For example, at High School A, the interessement for FUSE was a need to redesign the ninth-grade career and technology education (CTE) pathways course. FUSE became the core component of that class.

There were also actors that inhibited spread. One, already discussed, was money. Two others were computers and standardized tests. Marvel County had recently switched to computer-based standardized testing. Because the district had limited funds for computers, the computers used for FUSE were also required for testing. Consequently, FUSE was significantly disrupted from March through May each year, while tests were occurring.

In Helsinki, in Fall 2016, building and district leaders and researchers from the University of Helsinki, including Liisa, visited the FUSE team at Northwestern University and toured Chicagoland schools implementing FUSE. The visit significantly impacted how FUSE spread in Helsinki. After the visit, the district's representative called FUSE 'the missing link' between the district's digitalization and STEM goals and the schools' current practices. He suggested to the district leadership that FUSE should be spread to five other Helsinki schools. The leadership agreed, and in a meeting of the district's Innovative Schools network, five new elementary schools expressed interest in implementing FUSE. However, word of FUSE had already found its way to some of the schools before this. In Fall 2016, School 1 showcased FUSE to other teachers in their local area as part of a professional development workshop. The principal of School 3, Eeva, recalled this, saying, 'But way before that [the network meeting], when I had been to [School1] and seen [FUSE] for the first time, I had then thought that how could we get this, like what would be my channels that I could pull so that we could get our own FUSE.'

As enrolment of new actors continued, complexity increased. New teachers, rooms, students, and equipment became part of the network, and the district showcased FUSE as a frontier innovation in educational events in Helsinki. However, again, there were significant delays in mobilizing infrastructure. New, FUSE-dedicated laptops and charging stations arrived three months late. This was due to both the digitalization program and centralization in the district's IT support, spurred by the discovery of embezzlement. This centralization meant that IT support was slow in responding to equipment orders. Furthermore, the FUSE software package created previously by IT support could not be used, because the new system required a different installation method.

This complexity eventually impacted the network's size and composition. Because of the delays, School 5 never started FUSE and School 4 implemented FUSE only as one part of its IT elective. Teachers, who were initially enticed by FUSE, told us, by the time the laptops had arrived, they had needed to plan their year without FUSE, and they had largely forgotten the PD. This ambivalence drove remaining teachers to organize themselves in a new way. To share FUSE experiences and information, they began regular meetings organized by a teacher from School 2, who had been appointed to the district's STEAM coordination team as a FUSE expert teacher.

We see similarities in the actors responsible for spreading FUSE in both cases. For example, technological infrastructure was key mediator that both supported and impeded spread. However, how technology mediated spread and the new actors it enrolled were different. Showcase spaces or events were important actors in both Marvel County and Helsinki, recruiting additional human actors. Specific humans also played important roles in both cases in advocating for the program or connecting other actors. However, these humans occupied different institutionalized roles and supported the network differently. Finally, the adaptability of FUSE to new contexts with particular interessements supported both within and between school spread in both cases.

Discussion

In answer to our question, 'How did FUSE get in, get rooted, and spread in these two contexts?', we found that in both cases, getting in was determined by how well FUSE aligned with local ideas and initiatives. It was also aided by the individual advocacy and support of actors like Liisa and Sanna (in Helsinki) and Carol and Stark Industries mentors (in Marvel County). Getting rooted was facilitated by the recruitment of additional teachers and administrators, through PD and these actors' positive firsthand experiences of FUSE. It was also impacted by the recruitment (or lack thereof) of non-human actors, including physical spaces, computers, challenge materials, and funding. Rooting was also aided by the program's ability to be translated to local needs and constraints. Finally, spread was facilitated by adaptability; non-human actors like physical showcase spaces, money, and technological infrastructure; and human actors serving as advocates, recruiting external actors to the network.

In answer to our second research question, there were important differences between the actors and processes of translation in the two cases. First, the interessement for FUSE was different. In Marvel County, it was a need for equity-oriented STEAM programming aligned with technology standards and the goals of the CTE pathways course. In Helsinki, it was the digitalization initiative and the new national curriculum. Second, in Marvel County, Stark Industries served as both a mediator (providing mentors) and intermediary (providing funding). In Helsinki, Liisa provided external support for implementation but only as an intermediary (advocate for the program). Third, while physical and technological infrastructure played an important role in both cases, they mediated implementation differently. Physical spaces played a more significant role in initially impeding and ultimately supporting implementation in Marvel County than in Helsinki. Conversely, computers and kit materials provided a more significant impediment to implementation in Helsinki. In Helsinki, technology problems were mostly with obtaining the computers and materials, while in Marvel County the problems were with their use and functionality. Finally, while adaptability was important in both contexts, in Marvel County, FUSE was adapted for use across multiple grade levels, and implementations varied widely based on specific local interessements. The Helsinki adaptations were more homogeneous; four of the five schools implemented FUSE as a grade 5-6 elective class, and only one incorporated FUSE into grade 5-6 science.

These differences in the processes and outcomes of translation reflect larger economic and cultural-historical differences between the two contexts. For example, Marvel County schools were reliant on external grant funding, reflective of the capitalist economic system in the U.S. and the inequitable way in which public educational resources are distributed. In contrast, in Helsinki, public funding for programming and materials was assured, but it depended on centralized distribution systems that moved slowly and had to balance multiple demands. The way in which equity was conceptualized and mobilized differently in the two countries was also reflective of cultural differences. In Marvel County, a diverse and majority low-income student population spurred an interest in programming that equitably engaged diverse students. In Helsinki, equity focused more on ensuring equitable distribution of technology across schools. Finally, in Finland, a country with a long and rich tradition of craft education, the interessement for FUSE was integrating digitalization into this craft tradition, whereas, in the U.S., where there has long been a push for technology in schools, the interessement was hands-on STEAM.

Our analysis has implications for understanding the spread of educational innovations broadly and specifically for innovations like FUSE. For example, as a STEAM program, FUSE is heavily dependent on technology, physical materials, and dedicated physical spaces. Therefore, the actors needed to implement it successfully were different from those for a traditional text-based curriculum (and may better reflect the future of educational innovations). FUSE activities also make connections to the work of industry professionals. This bent invited in Stark Industries, and it poses the question of the comparative advantages and disadvantages of external industry partners becoming more prominent actors in the spread of future educational innovations.

Altogether, our results underscore the importance of conceptualizing spread as an active, in vivo process in which enrolled actors—including the innovation itself and the adopting educational system—need to be seen as complex entities nested in and constituted by already existing and changing networks. In line with work on the spread of the Fifth Dimension (Cole et al., 2016), our analysis indicates that the spread of FUSE resulted from active efforts by various actors, both expected and unexpected. However, by following implementation processes as they happened, we demonstrated that some actors' roles changed over time, and some actors worked for and against the spread of FUSE. Ambivalence was created by the spread process and needed to be managed as part of it (cf. Fenwick, 2011). What this highlights for future spread studies is the need to remain open and responsive to changing circumstances. While the specifics of every future spread process will be endemic to and emblematic of the innovation and the adopting system(s) in question, what can be learned from our study is that existing network ties will need attention and maintenance while the innovation spreads. In this sense, our comparative case study offers a prototypical narrative (Nissen, 2015) that embodies the concreteness of lived practices and espoused theoretical perspectives in ways that can help researchers and designers see innovations in a new light.

Representations of Computational Thinking in Policy Documents in an Educational Context: The Cases of Denmark, Finland, and Norway

Abstract: Nordic countries have recently introduced computational thinking (CT) into school curricula. In this paper, we address the question: "Which key understandings of computational thinking are presented in Danish, Finnish, and Norwegian policy documents for primary and lower secondary education?" This study analyzes and compares the policy documents by using a combination of social network analysis (SNA) to obtain an overview of the whole dataset, and qualitative analysis to elaborate on some specific elements in the policy documents. Importantly, we find that: (1) all three policy documents focus on interpreting CT as both a problem-solving process and related to programming processes, and (2) how CT is written up in the policy documents reflects the line of thought concerning the extent to which CT is an integrated part of the course subjects in education.

Introduction

In recent years, digital transformation has become an indispensable part of society and is expected to be fostered in schools to better prepare students for their future lives. Along with digital transformation, the concept of computational thinking (CT) has become a frequently mentioned concept (Lenke & Tenberge, 2022). The term CT can be considered a relatively novel concept (Merino-Armero et al., 2022). CT was first introduced by Papert (1980), who claimed that when a child is given a computer, their learning processes and intellectual structures are strengthened. According to Wing (2006), who is often credited with reigniting interest in CT education, CT is defined as solving problems, understanding human behavior, and devising programs with the help of the core concepts of computer science. Since then, CT has been defined differently by various scholars. For example, Barr and Stephenson (2011) understood CT as a problem-solving skill that involves certain training, such as perseverance and confidence while facing a specific problem, whereas Zhang and Nouri (2019) captured CT as a 21st-century skill that future generations should develop.

CT is a concept that is both widely discussed and difficult to define (Psycharis, 2018; Tedre et al., 2021), and there is no one agreed-upon definition of CT (Shute et al., 2017). Therefore, researchers generally focus on the basic components of CT (Juškevičienė, 2020). Many countries include CT in their education policies and curricula (Hsu et al., 2019; Merino-Armero et al., 2022; Swaid, 2015). Scandinavian countries include and apply CT in their curricula in different ways (Bocconi et al., 2018). For example, in 2016, Finland, one of the first European Union countries to do so, integrated programming and CT into the "National Core Curriculum for Basic Education 2014" as a skill that should be taught to students starting from the first year of school (1st grade) (Finnish National Board of Education [FNBE], 2014). Similarly, Norway integrated CT and programming into the curriculum in mathematics, natural sciences, and arts and crafts, effective autumn of 2020. In Denmark, CT is integrated into the curriculum at the primary and secondary levels (K-9) (Bocconi et al., 2018). Furthermore, in Denmark CT was a key part of a three-year pilot program with technology comprehension that took place in 46 schools in the years 2018–2021 (Ministry of Children and Education, 2022). Despite the integration into several curricula, understanding the meaning of CT remains challenging for teachers, teacher educators, and researchers (Lee et al. 2020). Thus, we address the following research question: Which key understandings of computational thinking are presented in Danish, Finnish, and Norwegian policy documents for primary and lower secondary education?

Computational thinking in STEAM education

Science, technology, engineering, and mathematics (STEM) education has become renowned in educational studies, since it is an interdisciplinary approach (Liliawati et al., 2018; Tan et al., 2021) aimed at contributing to the improvement of students' skills such as problem-solving, creative thinking, questioning, and critical thinking (Psycharis, 2018). In STEAM, the art discipline is integrated into STEM disciplines to increase efficiency in STEM education (Tan et al., 2021) and add an aesthetic and authentic dimension to STEM (Bequette & Bequette, 2012). There is a close relationship between STEAM disciplines and CT. STEAM disciplines also aim to provide individuals with skills such as problem-solving, debugging, and sharing their ideas with others (Juškevičienė, 2020). Several researchers have emphasized the need to train students to acquire CT skills and use them (Barr & Stephenson, 2011; Park & Park, 2018). Moreover, researchers argue that CT should be taught by integrating it with an interdisciplinary approach, such as STEAM (Psycharis, 2018). Through STEAM education, students are expected to learn certain concepts in a meaningful way and to use these concepts to solve problems (Park & Park, 2018). Through STEAM education, students are exposed to many problem-solving activities that contribute to the development of students' CT (Charlton & Luckin, 2012). Beyond using technology, CT occurs while solving complex problems (McClelland & Grata, 2018). Thus, CT is an integral part of STEAM (Dolgopolovas & Dagienė, 2021).

Studies related to CT and policy documents

CT has been recognized as an important issue in policy and curriculum documents in various countries and has been recognized as a key competence (Voogt et al., 2015) and included in several transnational policy initiatives (McGarr et al., 2021). Robertson (2005) highlighted the demand for schools to respond to the global knowledge economy. Hsu et al. (2019) examined CT educational policy, concluding that CT involves diverse terminology, and its current status is diversified across the globe. The authors further highlighted four development trends that arise: collaboration and partnerships across sectors and nations, arguments presenting a broad perspective and citing common themes, a redefinition of digital competence, and an accentuation of expanding access and interest. Hsu et al. (2019) found that although a term that refers to "computational thinking" is used in policy documents and curricula, it is not used by others or is used rarely when compared to other terms. For example, in the Nordic context, "algorithmic thinking" is the CT term used in Finland and Norway (Hsu et al., 2019).

Methods and case design

This study adopted social network analysis (SNA) (Scott, 2000) as a research approach. Prior to conducting the data analysis, two steps were taken. First, all three countries participated in the data analysis, which ensured contextual understanding. Thus, we were conscious of the challenges inherent in comparative interpretation (Phillips & Ochs, 2004). Second, to increase the validity of the process, a minimum of two researchers analyzed each policy document from the respective country.

Methods for collecting data

Relevant policy documents from Finland, Denmark, and Norway were accessed through government repositories. In Finland, strategic education aims are described in national-level curriculum materials and government programs. The national-level curriculum is revised, on average, every 10 years. Consequently, two documents from Finland were included in this study. One of these documents is the National Core Curriculum for Basic Education 2014 and the other is the current Government Programme 2015. The Finnish documents were accessed through two archives; National Core Curriculum for Basic Education 2014 was accessed from the "Finnish National Agency for Education" website https://www.oph.fi/en and "Government Programme 2015" website https://vnk.fi/en/government-programme.The Danish documents were obtained through searches in two governmental databases: the Danish Ministry of Higher Education and Science at ufm.dk and the Ministry of Children and Education at buvm.dk. The Norwegian documents were accessed through two repositories: the government.no and the Directorate for Education and Training websites. Only documents related to education were extracted, and the included documents focused on compulsory education and primary and lower secondary education.

Screening policy documents with a set of predefined CT keywords

The relevant policy documents were screened using a set of predefined CT keywords. Shute et al. (2017) defined CT as consisting of the following components: *decomposition*, which is about the process of breaking a complex problem into manageable smaller pieces; *abstraction*, which is about the ability to extract the essentials of a complex problem; designing logical *algorithms* and ordering them to solve the problem; *debugging*, which is about the process of finding and resolving errors; refining the process by performing *iterations* to achieve the ideal result; and *generalization*, which is about the ability to transfer CT skills to other problems and situations.

Taking Shute et al. (2017) as our point of departure as well as the source of country-specific CT terms, we used the following CT terms to screen the policy documents: digitalization, algorithmic, problem-solving, programming, automation, identifying patterns, computational thinking, computer science, modeling, coding, and technological comprehension.

Methods for analyzing the data

SNA was used to analyze the most relevant policy documents in teacher education in Finland, Norway, and Denmark. Scott (2000) defined SNA as a set of techniques and operations that analyze the relational aspects of a network by utilizing algorithms and computational techniques. Since SNA makes it possible to analyze and compare a considerable set of data by evaluating the social relationships in a network by conceptualizing individuals or groups as nodes and their connections as ties and by scrutinizing these connections as mathematical or visual patterns, it was considered a suitable method (Scott, 2000). We applied SNA measurement degree centrality to calculate which policy documents had the highest frequency of CT keywords and, as a result, identified the most central policy documents regarding the use of CT keywords. Degree centrality is defined as the number of ties attached to a node (Scott, 2000). In our case, this means the number of times the CT keywords appear in the policy documents. Gephi, a software program for conducting SNA analysis (Gephi, 2022), was used to create and visualize the sociograms of the different countries (Norway, Denmark, and Finland) (Figures 1, 2, and 3) and their policy documents and the use of CT keywords in them. A sociogram is a visualization of SNA analysis, which consists of nodes representing actors and lines to show ties or relations (Hanneman & Riddle, 2005). SNA provided us with useful information about the most relevant policy documents and CT keywords connected to them; the analysis did not reveal information about the qualitative content in the documents. To address this limitation, we also take on a qualitative perspective by analyzing the qualitative data extracts illustrating the use of CT keywords in the policy documents.

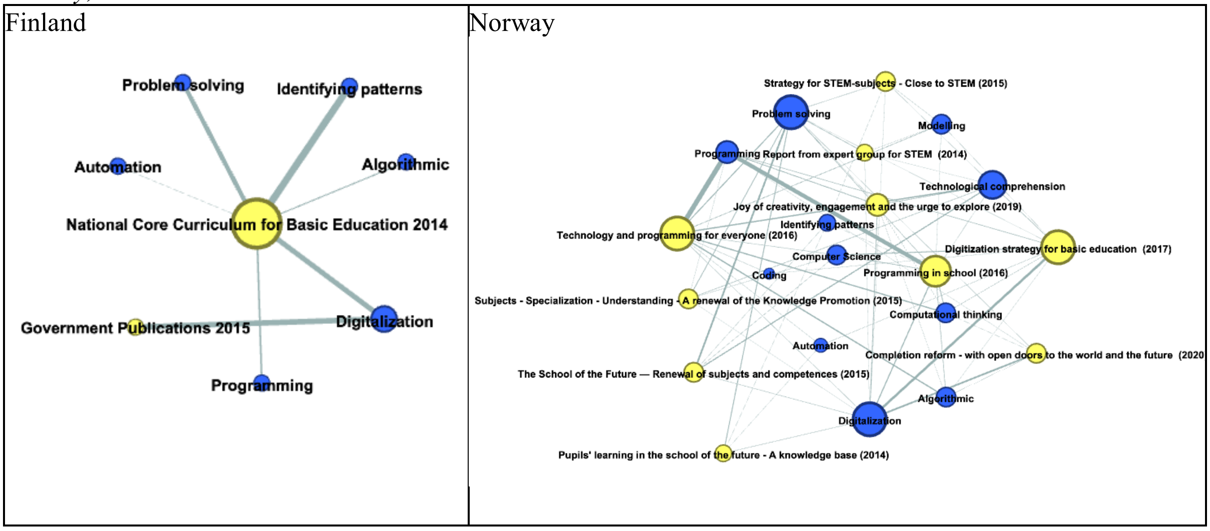
Results

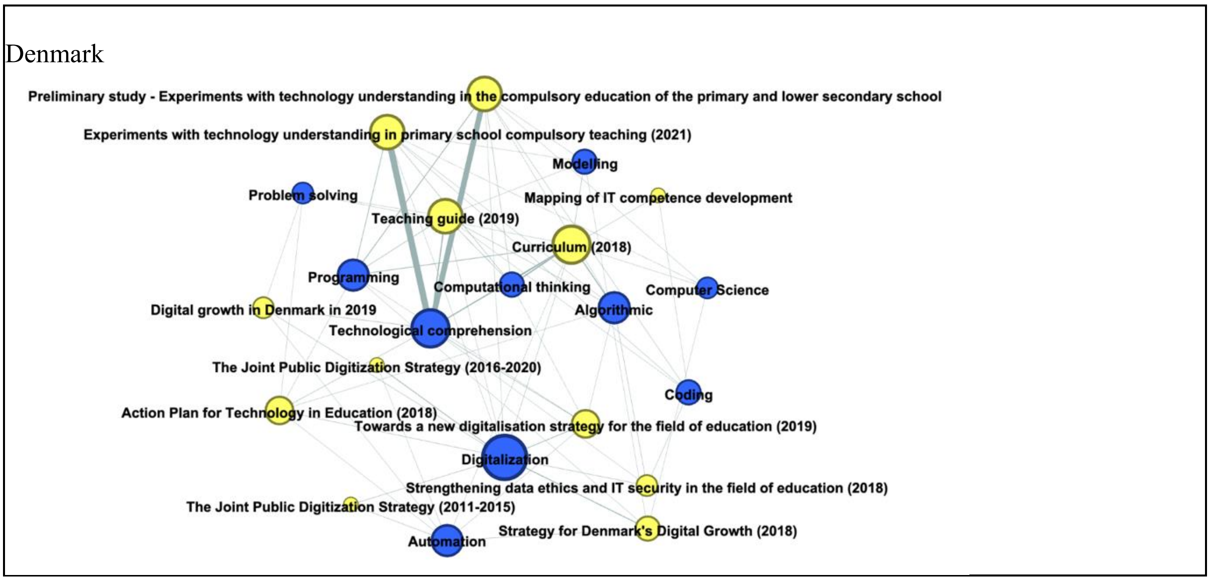
Social network analysis of policy documents in Finland, Norway, and Denmark

Below, in Figure 1, we present three sociograms that visualize the SNA results, reflecting Finland, Norway, and Denmark. The yellow nodes visualize the policy documents, and the blue nodes visualize the CT keywords. The SNA centrality degree measurement was computed for both the policy documents (yellow nodes) and the respective CT keywords (blue nodes). As such, the larger size of a node reflects a larger degree of centrality. A thicker tie indicates a higher frequency of the use of the CT keyword in the policy document, as the size of the ties also provides information on degree centrality. Figure 1 presents a visualization and comparison of the policy documents.

Figure 1

An overview of the policy documents (yellow nodes) and the related CT keywords (blue nodes) in Finland, Norway, and Denmark.





Denmark

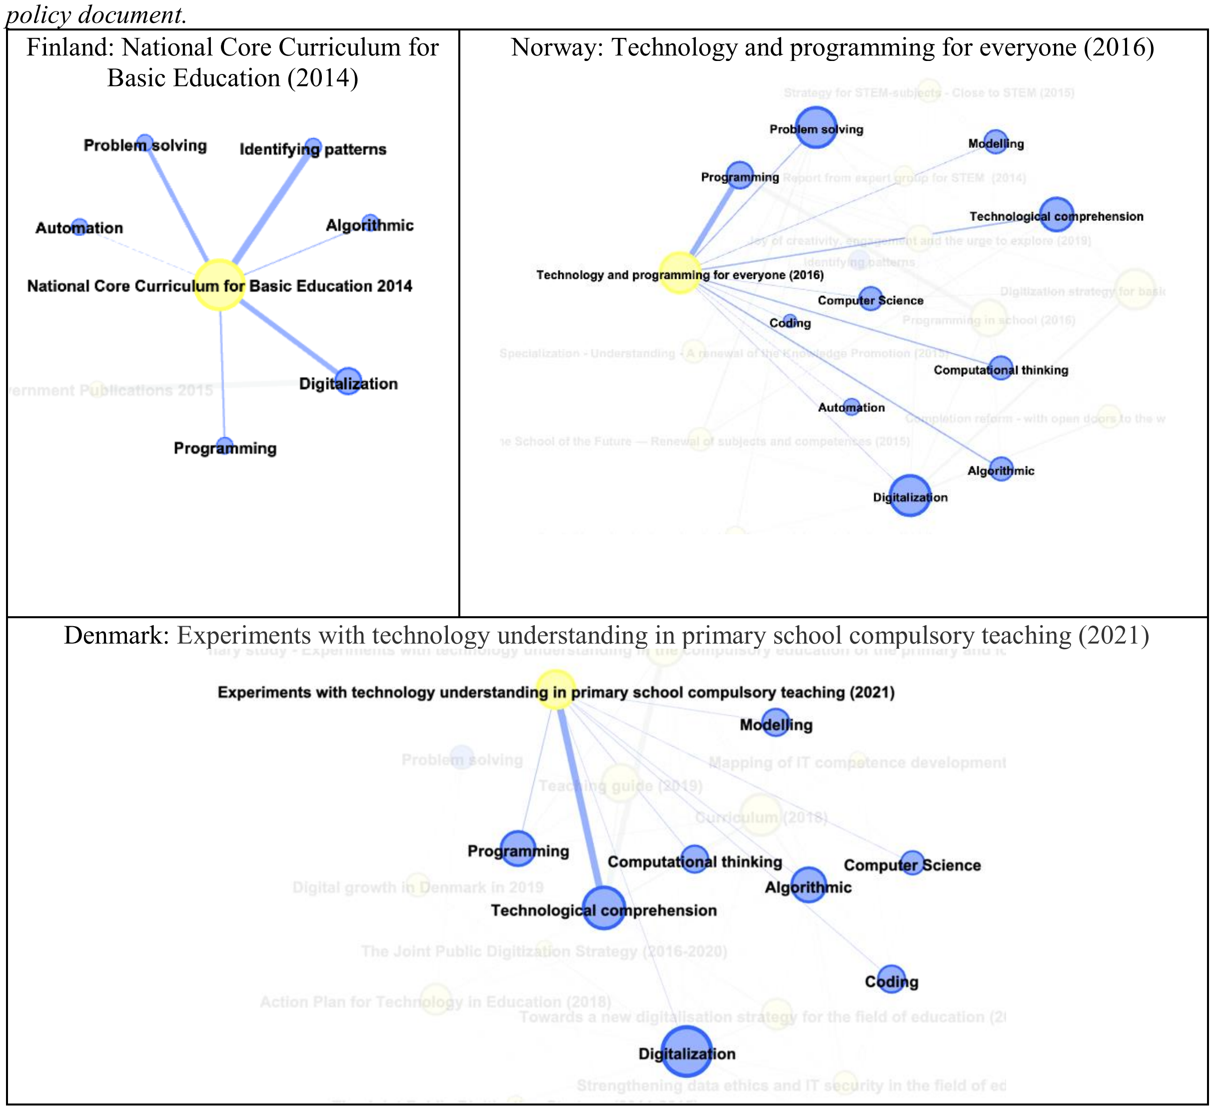
Analyzing the policy documents: In Finland, the sociogram shows that there are mainly two policy documents, with the "National Core Curriculum for Basic Education 2014" being the most relevant document from a CT perspective, as reflected by the size of its yellow node being the largest. The positioning of the node in the center of the sociogram reveals that this document often refers to and uses several CT keywords. However, in Norway and Denmark, the landscape is quite different, where there are multiple policy documents that relate to CT in different ways. In Norwegian policy documents, the most central policy document using CT keywords is "Technology and programming for everyone." However, the policy documents "Digitalization strategy for basic education (2017)," "Programming in school" (2016), and "Joy of creativity and the urge to explore" are central according to the degree of centrality (reflected in the size of the node). The most central policy document in Denmark is "Experiments with technology understanding in primary school compulsory teaching (2021)," since it has the largest degree of centrality (reflected in the largest yellow node). However, as the nodes visualize with their size, "Curriculum (2018)," "Preliminary study – Experiments with technology understanding in the compulsory education of the primary and lower secondary school," and "Teaching guide" are also among the top 5 most relevant policy documents using key CT words.

Analyzing the use of CT keywords in relation to the policy documents: In the Finnish sociogram, we found that the CT keywords *digitalization* and *automation* are the ones with the highest degree of centrality (reflected in the blue nodes with the largest size), which means that these keywords are most used in the policy document in connection to CT. By contrast, it is interesting to observe that *computational thinking* and *algorithmic thinking* as explicit keywords are not present in the policy document at all. In the Norwegian sociogram, the top three most used CT keywords across the policy documents are *problem-solving*, *digitalization*, and *technological comprehension*. The CT keywords *programming* and *computational thinking* are also central. In the Danish sociogram, the two most prominent keywords in the policy documents are *technology comprehension* and *digitalization*, whereas *identifying patterns* does not appear at all. To summarize, most keywords appear in policy documents across all three countries, with *digitalization* standing out as a prominent keyword in all three countries, setting an important context for the integration of CT in education. However, the sociogram also reveals significant differences: For instance, while *problem-solving* is a predominant keyword in the sociogram for Norway, it is far less central for the other two countries. Similarly, *computational thinking* as a keyword is markedly present in the Norwegian and Danish sociograms but does not appear at all in the Finnish case. Thus, the sociograms expose how the different countries apply different CT keywords in their policy documents, entailing different implementations and approaches to CT.

Exploring the understanding of the CT keywords in the policy documents

Based on the SNA analysis visualized in Figure 1, we selected the most central policy document in each country that had the largest degree of centrality. This document was used as a starting point for the qualitative analysis. Figure 2 below present an overview of the selected policy document from each country and the CT keywords that are connected to that policy document, as reflected in the sociograms in Figure 2. Furthermore, the two most relevant CT keywords from each policy document were selected. To contextualize the CT keywords, qualitative data extracts are presented together with their interpretations.

Figure 2
Sociograms reflecting the selected policy document from each country and the CT keywords connected to that policy document.



Finland: National Core Curriculum for Basic Education (2014)

Norway: Technology and programming for everyone (2016)

Denmark: Experiments with technology understanding in primary school compulsory teaching (2021)

A comparison of the sociograms in Figure 2 revealed a common denominator in the policy documents: CT keyword *programming* is among the top 3 most used CT keywords in the documents, which is reflected in the size of the nodes. The CT keyword *problem-solving* is also the most central node in the selected policy document in Finland and Norway, whereas it is not apparent at all in the Danish policy document. Although *digitalization* is a prevalent keyword in all the policy documents, it does not reveal much about how CT is understood and will therefore not be further discussed. However, a notable difference in the sociograms is in Denmark's policy document, in which *technological comprehension* stands out as a central node, which we further explored.

In the Finnish policy document, National Core Curriculum for Basic Education (2014), programming is mentioned as being integrated into the subjects: "As part of the studies of various subjects, programming is practiced." The document further expands this notion: "Students develop an understanding of in how the decisions taken by people have an effect on the path technology progress while working on programming." Programming is considered the way that "ordinary relationships are defined and objects are placed, classified and compared by the learners. By taking different perspectives, they practice analyzing mathematical situations. The learners become acquainted with the core features of programming by formulating and testing step-by-step instructions." We can also conclude that the policy document defines the reason for the relevance by stating that "the learners get the chance to have and share their practices with digital media and programming activities fitting their ages and the rationale being to inspire the learner to come up with as computer programs in graphic programming medium." In the policy document, problem-solving is described as "the guidance for the learners to develop their algorithmic thinking and skills in applying mathematics and programming in problem-solving," and it is explained as a process of "guidance for the learners to develop their reasoning and problem-solving skills." It is further expanded as the way "the learners are mentored to use information on their own and in interaction with others in terms of problem-solving, argumentation, reasoning, drawing of conclusions and invention." Together, these statements underscore the relationship between problem-solving and programming.

In the Norwegian document "Technology and programming for everyone" (2016), *programming* is defined as "breaking a given problem into a set of commands and then having a computer execute those commands." The document underlines that the rationale behind programming is for students to take control of technology and "gain insight into and experience with basic technological principles and digital technology - including programming." Programming can be viewed as both a problem-solving process and a technical process when using a computer to perform tasks. Problem-solving is highlighted as part of a key competence in digital technology, and an integral part of computational thinking: "Solving a problem by specifying a precise sequence of commands is called computational thinking or algorithmic problem-solving, and such a precise sequence of commands is called an algorithm." The notion of problem-solving as an integral part of CT is further elaborated as "transforming a general problem into a form that can be solved using programming." Programming in the Norwegian policy document is understood as the technical programming process when using a computer to perform tasks, whereas problem-solving is understood in relation to CT and programming.

The Danish policy document "Experiments with technology understanding in primary school compulsory teaching" (2021) is an assessment of the three-year pilot program in the years 2018–2021. Technological comprehension is mentioned as "an educative and creative subject in the school consisting of four competence areas: (1) digital empowerment, (2) digital design and design processes, (3) computational thinking, and (4) technological knowledge and skills." Thus, in Denmark, CT occurs in the context of this subject. The subject is displayed in two general approaches: one that is "creative and constructive (focus on design and skills), and the other that is critical and analytical (focus on empowerment and thinking). The overarching purpose of the subject is described in the document as enabling students to become "active, critical and democratic citizens in a digitalized society," again displaying the two general approaches. CT is explicitly employed as a key concept in the document. It is characterized as being about "analysis, modeling, and the structuring of data and data processes." Thus, CT is understood as a predominantly *analytical* competence, and not a creative and constructive one. Accordingly, CT does not include programming, coding, debugging, etc. in the Danish case. Although it is not part of CT, programming is nonetheless included in the subject of technological comprehension as part of "technological knowledge and skills." Here, it is linked to the creative approach, as programming "makes it possible for students to influence what they want to create" and "means the freedom to determine in which direction the students want to work."

Discussion

Our comparison of the policy documents from the three Nordic countries and their relations to CT keywords (Figures 1 and 2) revealed two main findings: (1) All three policy documents have a focus on interpreting CT as both a problem-solving process and related to programming processes. (2) How CT is written up in the policy documents reflects the line of thought concerning the extent to which CT is an integrated part of the course subjects in education.

CT as both problem-solving and a programming process. One common denominator from the analysis of the sociograms in Figures 1 and 2 is that CT is portrayed in all three policy documents as both a problem-solving process and a programming process. However, by focusing on the qualitative data extracts from the policy document in Denmark, we observed that the picture is more nuanced. Programming is not part of CT in the Danish context, as CT and programming are viewed as two separate competences, both elements of the overarching subject of *technological comprehension*. Lee et al. (2020) stressed that although programming and coding may be considered part of CT, it would be incorrect to restrict CT to computer science, since it is present in a broad range of professional fields. Thus, the separation of CT and programming in Danish policy documents seems to take one step further, emphasizing the difference between the general, predominantly analytical thinking processes of CT and the creative and constructive skills of programming. Similarly, although there are no instances of *problem-solving* in the Danish policy documents, this CT keyword is part of the overarching subject *technological comprehension* and thus related to, but nevertheless separated from, CT. In Norway and Finland, the policy documents reveal that problem-solving and programming can be considered related.

CT as an integrated part of learning subjects. How CT is presented in the policy documents reflects the reasoning of the policy documents concerning the extent to which CT is an integrated part of the course subjects in education. In Norway, CT is viewed as fully integrated in the subjects of math, science, music, and arts and crafts. In Denmark, CT is part of the wider subject of "Technology comprehension", which in the pilot program was taught both as a separate subject and as an integrated part of the subjects Danish, math, visual arts, natural sciences/technology, craft and design, physics/chemistry and social studies. In Finland, CT is fully integrated into subjects. The analysis of the qualitative text extracts from the policy documents in Norway and Finland showed that they both mentioned CT as a keyword. In the Norwegian policy document (Figure 2), CT is mentioned in connection with programming as part of specific course subjects, which is similar in Finland. However, Denmark differs, as it has an explicit focus on CT (supported by the visible node in Figure 2). Denmark has its own subject, *technological comprehension*, which focuses on CT. This supports the finding that CT in the Nordic countries is an integrated part of learning subjects: (a) In Norway, CT is viewed as fully integrated into the subjects of math, science, music, and arts and crafts; (b) Finland has fully integrated CT into subjects; and (c) Denmark considers CT as part of the wider subject "Technology comprehension".

Conclusion and implications

In this study, we explored key understandings of CT as presented in Finnish, Norwegian, and Danish policy documents for primary and secondary education. By conducting an SNA analysis of selected policy documents retrieved using CT keywords, we found that the understanding of CT is two-fold in these countries: 1) CT as both a problem-solving and programming process, and 2) CT as an integrated part of learning subjects. Integrating CT and programming as part of learning subjects enforces new demands on teachers in classrooms, as many of them have only some or no experience with CT and, especially, programming from their own schooling or teacher education. Some of the skills needed have previously been associated with computer science, and often these skills have been left to teachers of computer science to teach. However, the new changes imply a new focus on teachers' competencies, and we urge teacher educators to strengthen continuing professional development programs, enhance the focus on CT in teacher education, and facilitate support for communities of CT practice involving teachers, teacher educators, and researchers.

Preparing Collaborative Future Learning with Representational-Competency Supports

Jihyun Rho, University of Wisconsin – Madison, jrho6@wisc.edu
Martina A. Rau, University of Wisconsin – Madison, marau@wisc.edu
Barry D. Van Veen, University of Wisconsin – Madison, bvanveen@wisc.edu

Abstract: Collaboration in many STEM domains centers around the collaborative construction and interpretation of visuals. Thus, to become effective practitioners in the STEM disciplines, students need representational competencies: the ability to appropriately use and understand visuals that depict scientific concepts. Although visuals are often used in collaborative contexts, prior research on representational-competency supports has mostly focused on individual learning. To address this limitation, we conducted an experiment with 134 undergraduates who worked collaboratively in 56 small student groups as part of an engineering class. Students were randomly assigned to work with different types of representational-competency supports. The main outcome measure of interest were students' learning gains from a subsequent, novel collaborative learning activity. We found that representational-competency supports can prepare student groups to efficiently learn from novel instructional materials.

Introduction

Many professional practices in STEM domains are collaborative in nature. Indeed, STEM instruction is moving toward active learning, where students are encouraged to collaborate during learning (Freeman et al., 2014). Such collaborative practices often center around joint interpretation and construction of visual representations (Johri et al., 2013) because visual representations can help establish a common ground and make divergent views apparent (Nathan et al., 2013). Hence, collaborative STEM instruction often uses visual representations.

However, research on learning with visual representations shows that students may have difficulties interpreting visual representations (Ainsworth, 2006; Rau, 2017). Students need *representational competencies:* the ability to understand how visual representations depict relevant scientific concepts and use those visuals appropriately (diSessa, 2004; Kozma & Russell, 2005). Indeed, previous research on representational-competency supports found that supporting students' competencies enhanced students' content knowledge both in individual and collaborative learning settings (Berthold et al., 2009; Kellman & Massey, 2013).

However, prior research on the effectiveness of representational-competency supports has two limitations. First, prior research has examined only short-term effects of representational-competency supports. For example, Rau et al. (2017) tested whether adding support for representational competencies to instructional activities enhances students' learning from those activities. It is unclear whether representational-competency supports also enhance students' learning from future instructional activities where students encounter novel visuals they have not seen before. A second limitation is that prior research has mostly focused on individual learning settings even though, as mentioned, visuals are commonly used collaboratively (Rho et al., 2022). To our knowledge, only one study systematically tested the effects of representational-competency supports in a collaborative setting, but focusing on short-term effects on chemistry learning (Rau et al., 2017). In sum, it is unclear whether representational-competency supports enhance *future collaborative learning*. The goal of this paper is to address these limitations by investigating whether representational-competency supports enhance students' collaborative learning from future instructional activities.

Additionally, previous research suggests that spatial skills may affect students' learning with visual representations (Stieff et al., 2020). Visual representations typically depict visuospatial concepts. Students draw on spatial skills when mentally generating, retaining, and manipulating information depicted in visual representations. Students with low spatial skills have fewer cognitive resources to store and process such visuospatial information (Hegarty & Waller, 2005), making them more likely to struggle when learning with visual representations (Kozhevnikov et al., 2007). Hence, a further goal of this paper is to investigate whether representational-competency supports differentially affect students with different levels of spatial skills.

Literature review

Representation competencies

Instruction in STEM domains commonly uses visuals because they can help students understand content knowledge by making abstract concepts accessible (Ainsworth, 2006). However, previous research also showed that such visuals can impede students' learning if students lack representational competencies. Specifically, students need two types of competencies; sense-making competencies and perceptual fluency (Rau, 2017).

First, sense-making competencies refer to explicit, analytical knowledge that allows students to explain how representational features map to concepts (Bodemer & Faust, 2006) and to connect multiple representations depicting the same concepts (Chang et al., 2021). Since students acquire sense-making competencies by verbally explaining how representational features map to concepts, instructional supports for these competencies ask students to explain relationships between representational features and concepts (Joo et al., 2021). Students should receive support to focus on explaining structurally relevant relationships between the representations instead of surface similarities (Ainsworth, 2006). Second, perceptual fluency refers to implicit, automatic knowledge that allows students to efficiently extract meaning from representations and to quickly translate across representations (Kellman & Massey, 2013). Students acquire perceptual fluency via nonverbal and inductive processes (Koedinger et al., 2012). Consequently, instructional supports for these competencies expose students to a variety of representations while asking them to quickly identify relevant information (Kellman & Massey, 2013).

So far, research has established that these representational-competency supports enhance students' acquisition of content knowledge in individual learning settings (e.g., Rau et al., 2017). However, previous research has focused less on the effectiveness of representational-competency supports in *collaborative* learning settings. Thus, this study investigates whether representational-competency supports help students' acquisition of content knowledge in a collaborative learning setting.

Role of representation competencies in collaborative learning

Collaborative instruction in STEM often uses visual representations because they can provide common ground for students' discussions (Nathan et al., 2011). Effective collaboration builds on representational competencies. First, collaboration involves sense making of visual representations. When students collaborate, they often verbally share their thoughts about visuals and critically discuss different interpretations of the visual (Kozma & Russell, 2005). Sense-making competencies enable students to verbally explain how visuals show information about problems (Johri et al., 2013). Therefore, sense-making competencies may enhance collaborative learning. Indeed, previous research on sense-making competencies found that providing adaptive collaboration scripts as a supportive tool for sense-making competencies improved students' benefit from a collaborative learning session (Rau et al., 2017). Second, collaboration involves perceptual fluency. When collaborating, students often refer to visual representations (Singer, 2017). This requires students to be perceptually fluent at extracting information from the visuals while also following along with the conversation. Indeed, previous research found that supporting perceptual fluency can enhance collaborative learning (Rau & Patel, 2018).

Thus far, the few studies that examined effects of representational-competency supports on collaborative learning have focused on students' immediate learning outcomes from instruction that contained the supports. However, students may not always have access to representational-competency supports. It remains unknown whether representational-competency supports enhance students' future learning from later instruction when students no longer have access to representational-competency supports. To address this question, this paper investigates whether representational-competency supports prepare students for *future* collaborative learning.

Preparation for future learning (PFL)

Students build on prior knowledge when learning novel concepts (Singley & Anderson, 1985). Building on this finding, research on preparation for future learning (PFL) examines how instruction can support students to adapt prior knowledge or skills in ways that support their learning of novel concepts (Schwartz et al., 2005). While some research has used the PFL framework to guide specific types of instructional designs, we adopt it as a research framework for investigating whether a given type of instructional design is beneficial beyond its duration (as suggested, for instance, by Schwartz et al., 2005). Although prior research shows that representational-competency supports can enhance students' ability to solve problems they have not encountered before (e.g., using a traditional transfer paradigm; Cromley et al., 2013), little research has investigated whether representational-competency supports prepare students' future learning from novel instructional materials they have not encountered before. To our knowledge, only one study showed that support for sense-making competencies and perceptual fluency enhanced students' future learning from novel instructional materials (Rho et al., 2022). However, this study focused on learning in an individual context, even though, as argued above, students often learn with visual representations in collaborate contexts. Thus, it is unknown whether representational-competency supports prepare students for future collaborative learning.

Collaborative learning may naturally promote discussion among students, which helps students to understand novel visuals in instructional materials (Strickland et al., 2010). Consequently, students may not need extra support for representational competencies in future collaborative learning. However, when students work with novel instructional materials they have never encountered before, students may have difficulties because they may not know which visual features they should focus on. Representational-competency supports might alleviate these difficulties, as documented in the context of individual learning (Rau et al., 2017). Furthermore, as argued above, representational-competency supports enhance students' ability to engage in productive collaborative practices with visual representations. Such enhanced collaborative practices may, in turn, result in higher learning outcomes. Therefore, in this study, we investigated the effect of representational-competency supports on future *collaborative* learning.

Spatial skills

Because many concepts in STEM domains are visuospatial, instruction frequently uses visual representations to illustrate concepts (Ainsworth, 2006). To understand concepts depicted in visual representations, students draw on spatial skills that allow students to mentally retain, retrieve, and transform the given visuals (Kozhevnikov et al., 2007; Uttal et al., 2013). Cognitive research on spatial skills explains individual differences in spatial skills in terms of differences in the amount of working memory consumed to store and manipulate visuospatial information (Hegarty & Waller, 2005; Stieff et al., 2020). By definition, low-spatial-skill students require more working memory resources to store and manipulate visuospatial information compared to high-spatial-skill students. Thus, low-spatial-skill students may lose such spatial information while mentally manipulating the given visuals, requiring them to revisit the visuals to find and extract visuospatial information again (Hegarty & Waller, 2005). As a result, low-spatial-skill students are more likely to experience cognitive overload, which can impede their learning (Höffler, 2010). By equipping students with the skills to extract information from visual representations, representational-competency supports might be especially effective for students with low spatial skills.

However, our prior research found that the effectiveness of representational-competency supports depended on students' spatial skills (Rho et al., 2022). While all students benefited from support for perceptual fluency, support for sense-making competencies was effective only for students with high spatial skills. In contrast, support for sense-making competencies was ineffective for students with low spatial skills did not. Our findings suggest that low-spatial-skill students were overwhelmed when working with supports for sense-making competencies. This is, of course, an undesirable finding because it disadvantages students who are known to experience difficulties in STEM domains. However, considering that collaborative learning might give low-spatial-skill students opportunities to discuss their difficulties and receive help from peers, it is possible that the impact of spatial skills on students' benefit from representational-competency supports differs in a collaborative learning setting. Therefore, we tested whether students' level of spatial skills moderates the effect of supports.

Research questions

Our review of prior research reveals a gap in our understanding of how representational-competency supports affect students' learning from future instructional activities, especially in collaborative learning contexts. Therefore, we investigate the following research questions (RQ):

RQ1. Do representational-competency supports prepare students for future collaborative learning with a novel visual representation?

Further, given that spatial skills may affect students' learning with visual representations, we investigate:

RQ2. Do spatial skills moderate the effect of representational-competency supports on future learning?

Lastly, because little research explored representational-competency supports in a collaborative learning setting, we investigate:

RQ3. How do students experience collaboratively working on representational-competency supports?

Methods

Participants

We conducted the experiment as part of an active learning electrical engineering course at a university in the Midwestern U.S. All 184 students who were enrolled in the course participated in the experiment. The course involved twice 75-minute course meetings per week. Our experiment took place in the first three weeks of the course. Students worked collaboratively in groups of two or three. Student groups were formed prior to the intervention and remained intact for the duration of the experiment.

Representational-competency supports

Representational-competency supports were implemented in an educational technology for electrical engineering undergraduates: Signals Tutor. Signals Tutor offers activities where students learn about sinusoids by manipulating interactive time-domain and phasor graphs. Signals Tutor provides three types of activities, which differ in terms of whether and which types of representational competencies they support.

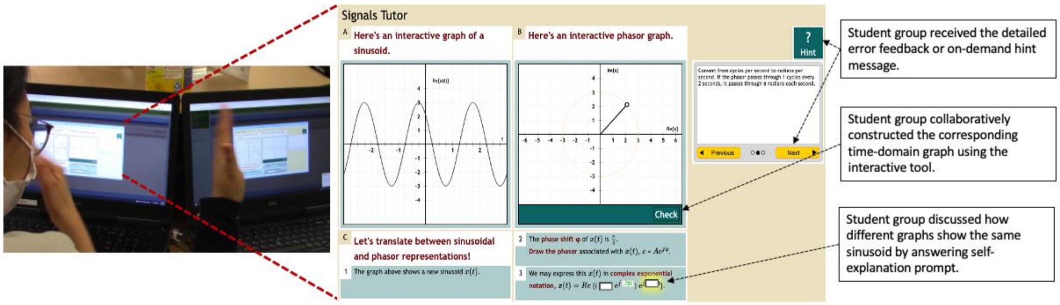
Regular activities

Regular activities do not support specific representational competencies. Following the design of regular instructional activities, they ask students to use time-domain or phasor graphs to answer questions about sinusoids. Regular activities provide detailed feedback and on-demand hints related to the concepts covered in the activities.

Sense activities

Sense activities support sense-making competencies. Prior to working on sense activities, student groups see a brief video instructing them to actively participate in a discussion and come to an agreement before submitting their answers. As shown in Figure 1, students receive step-by-step guidance to build a phasor graph that represents the sinusoid given in a time-domain graph (or vice versa). Then, sense activities ask student groups to verbally explain how specific features of a phasor graph can be translated into a time-domain graph. For example, in Figure 1, the student group is prompted to reflect on how the phase shift shown in the given time-domain graph can be translated to the vector's rotation in the phasor graph. Similar to regular activities, sense activities provide detailed feedback and on-demand hints to guide students.

Figure 1
Example of student group collaboratively working on a sense activity



Here's an interactive graph of a sinusoid.

Here's an interactive phasor graph.

Convert from cycles per second to radians per second. If the phasor passes through 1 cycles every 2 seconds, it passes through π radians each second.

Let's translate between sinusoidal and phasor representations!

1 The graph above shows a new sinusoid $x(t)$.

2 The phase shift φ of $x(t)$ is $\frac{\pi}{4}$. Draw the phasor associated with $x(t)$, $c = Ae^{j\varphi}$.

3 We may express this $x(t)$ in complex exponential notation, $x(t) = Re\{(\square e^{j\,.785})\, e^{j\square}\}$.

Student group received the detailed error feedback or on-demand hint message.

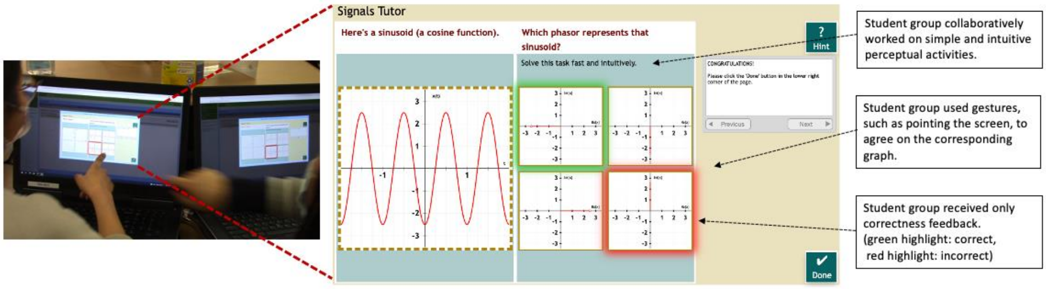
Student group collaboratively constructed the corresponding time-domain graph using the interactive tool.

Student group discussed how different graphs show the same sinusoid by answering self-explanation prompt.

Perceptual activities

Perceptual activities support perceptual fluency. Prior to working on these activities, student groups see a brief video instructing them on perceptual learning. They are instructed to solve the activities quickly and intuitively. Further, the video asks students to collaborate using nonverbal communication, such as pointing gestures, because verbal communication interferes with perceptual learning processes (Schooler et al., 1997). As shown in Figure 2, perceptual activities ask student groups to find one out of four time-domain graphs which represent the same sinusoid depicted in the given phasor graph (or vice versa). The four choice options are designed to direct students' attention to important visual features. Perceptual activities only provide correctness feedback so that students focus on perceptual processing (Kellman & Massey, 2013).

Figure 2
Student group collaboratively working on a perceptual activity



Here's a sinusoid (a cosine function).

Which phasor represents that sinusoid?

Solve this task fast and intuitively.

CONGRATULATIONS!

Please click the 'Done' button in the lower right corner of the page.

Student group collaboratively worked on simple and intuitive perceptual activities.

Student group used gestures, such as pointing the screen, to agree on the corresponding graph.

Student group received only correctness feedback.

red highlight: incorrect)

Experimental design

Student groups were randomly assigned to one of four conditions resulting from a 2 (sense activities: yes/no) x 2 (perceptual activities: yes/no) experimental design. To control for time on task across conditions, we ensured that all conditions solved the same number of problem-solving steps.

The sequence of instructional activities was organized as follows across five Signals Tutor units. Unit 1 was identical across conditions because it introduced to time-domain and phasor graphs. Unit 2 covered time-domain graphs and their corresponding equations. Because time-domain graphs were the only type of visual used in this unit, Unit 2 did not provide sense activities. However, Unit 2 provided perceptual activities where students practiced quick translation between equations and visuals. Units 3 and 4 involved both time-domain and phasor graphs. Thus, each group received representational-competency supports according to the assigned condition.

Finally, Unit 5 provided regular activities on a novel concept, phasor addition, which is depicted in a novel visual, a vector addition graph. Working on activities about phasor addition required student groups to apply concepts and representational competencies they practiced in previous Units 2-4.

Measures and analyses

To investigate the effect of representational-competency supports on students' future collaborative learning (RQ1), we assessed learning gains with pretests and posttests for each unit (except for the introductory Unit 1). The tests for Units 2-4 served as an implementation check. Our main outcome of interest were the tests for Unit 5, which assessed students' learning from future instruction that did not offer representational-competency supports. Students solved all tests individually. We computed learning gains through accuracy and efficiency scores. Accuracy scores were computed as the percentage of correct answers. Efficiency scores were computed to take account how long it took students to achieve correct answer, following as: efficiency = (z-score of accuracy – z-score of duration) / $\sqrt{2}$, (Van Gog & Paas, 2008). We used statistical analyses to compare students' learning gains scores (i.e., efficiency and accuracy scores) across four conditions. To investigate the moderation effect of spatial skills (RQ2), we assessed spatial skills with the Vandenberg & Kuse mental rotation test (Peters et al., 1995), which is prevalent measure of spatial skills in engineering education. We used statistical analyses to see students' level of spatial skills moderate the effect of representations-competency supports across conditions. To investigate how students experience collaborative work on representational-competency support activities (RQ3), we qualitatively examined interview responses for themes that emerged across dyads.

Procedure

On the first course meeting day, students were briefly informed about the study and instructed to collaborate on problems in Signals Tutor. In the following course meeting days, students completed the instructional activities according to their experimental condition, with Unit 2 being assigned in class in the second course meeting day, Unit 3 in the third meeting day, Unit 4 as homework, and Unit 5 in the fourth meeting day. Students worked collaboratively on Units 2, 3, and 5. We also conducted a semi-structured interview asking students to reflect on their collaboration experiences with peers in Unit 2, 3, and 5. We randomly chose one student from each condition. The interviewers asked questions about what was difficult and what was helpful and, how a group collaborated.

Results

Student groups were excluded from analysis if one of the group members absent from any test, failed to complete the instructional activities, or dropped the course. As a result, a total of N = 134 students and 56 small groups were included in the data set (control: n = 37;15 groups, sense: n = 39; 16 groups, perceptual: n = 30; 12 groups, and sense-perceptual: n = 28; 13 groups). We report p. η2 as a measure of effect size, p. $\eta^2 \geq 01$ being a small effect, p. $\eta^2 \geq .06$ being a medium effect, and p. $\eta^2 \geq .14$ being a large effect (Cohen, 1992). Table 1 shows the mean and standard deviation of efficiency scores for Units 2, 3 and 5, on which students collaboratively.

Table 1
Means and standard deviations (in parentheses) of efficiency scores for each unit

Unit	Test	Control	Sense	Perceptual	Sense-Perceptual
2	Pre	-0.197 (0.874)	0.106 (0.807)	-0.093 (0.761)	-0.559 (0.938)
	Post	0.231 (1.097)	0.426 (0.989)	0.514 (0.692)	0.320 (0.802)

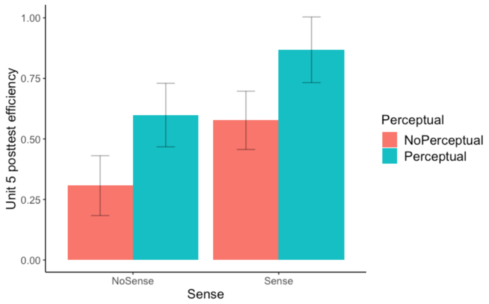
Effects on future collaborative learning

Following Cress (2008), we tested if adjustments were necessary for that fact that students were grouped together during learning with Signals Tutor. We calculated intraclass correlations (ICCs), which provided an estimate of how much clustering occurred due to factors such as group, TA, professors or sections. The ICCs score for our primary outcome variable, Unit 5 posttest scores, were very low (ICCs < .10). Therefore, adjustments for non-independence were not required. We investigated whether representational-competency supports prepare students future collaborative learning (RQ1) by conducting an ANCOVA with Unit 5 posttest as dependent measure, sense and perceptual factors as independent variables, and Unit 5 pretest and spatial skill as covariates. For the accuracy measure, we found no significant effects. For the efficiency measure, as shown in Figure 4a, we found that student groups working on perceptual activities showed significantly more efficient performance on the posttest than groups which did not work on perceptual activities, $F(1, 133) = 3.941$, $p = .049$, p. $\eta^2 = .030$. Similarly, student groups working on sense activities showed marginally more efficient performance on posttest than groups which did not, $F(1, 133) = 3.239$, $p = .074$, p. $\eta^2 = .024$.

To test whether students' level of spatial skills moderate the effect of representational-competency supports (RQ2), we tested for aptitude-treatment interactions of spatial skills with the sense and perceptual factors by adding these effects to the ANCOVA model described above. To be consistent with previous research on aptitude-treatment interaction, we did not categorize spatial skills into separate group, but instead modeled how sense and perceptual factors interacted with continuous variable of spatial skills. In Unit 5, we found no significant interaction between sense or perceptual factors and spatial skills ($p > .10$).

Figure 3

Student groups that worked on both sense and perceptual activities showed the higher efficiency on posttest.



Collaboration experiences

To understand how students experience collaboratively working on representational-competency supports activities in Signals Tutor, we examined students' collaborative experiences. We found that three themes emerged: confidence, comfort, and helpfulness.

First, with respect to *helpfulness*, students commented that they were able to cement their understanding through verbally explaining the concepts to her partner during collaboration. Similarly, another student commented that collaboration was helpful because they were able to explain each other about the confusing points during Unit 2: "we spoke out our thoughts and it was helpful because the parts I missed or got confused was the part he knew how to solve."

Second, regarding *confidence*, all students reported that collaborative working increase their confidence: "Collaboration gives me confidence, because when you think you know how to do the problem and you get the same answer as your partner, it shows that two brains are better than one." Collaborative working also released self-doubt: "Sometimes there's self-doubt, especially when answering a complicated question and having someone else agree with you makes you feel more confidence and feel like you understand the material better."

Lastly, regarding *comfort*, students reported that they become comfortable about working with their partners in Unit 5: "Yes, we got more comfortable with each other now, like, we are not strangers anymore so that helped." Students were able to find each one's strengths based on previous collaboration experiences in Units 2 and 3: "From the past experiences, we got to know each other.", which leads to more comfortable collaborative work on Unit 5: "We now kind of know who's explaining what, so I think that it got easier [in Unit 5]."

Discussion

This study investigated whether representational-competency supports enhance students' future collaborative learning (RQ1). Specifically, we provided sense and perceptual activities to student groups and tested whether these activities have an effect on students' learning of a novel concept with a novel visual in Unit 5. We found that student groups who worked on sense or perceptual activities showed higher learning efficiency in Unit 5 than student groups who did not receive these activities. These results extend previous findings about the effectiveness of representational-competency supports to collaborative learning. Further, our findings expand prior research by showing that representational-competency supports are an effective intervention to prepare students for their future learning.

Our finding that perceptual activities alone were effective stands in contrast to the prior research on representational-competency supports in individual learning contexts, which showed that students benefit from perceptual activities when they were combined with sense activities (Rho et al., 2022). While prior research found perceptual activities to be effective only when they were preceded by sense activities first, student groups in the present study benefited from perceptual activities even if they had not previously received sense activities. A possible explanation for these divergent findings is that student groups in the present study learned in an active learning format, which encourages students to engage in co-construction of explanations and inferences (Freeman et al., 2014). The active learning format may have supported students in making sense of visual representations so that additional sense activities were no longer necessary to enable students' learning from the perceptual activities. Indeed, our interviews revealed that students who worked on perceptual activities had an active discussion, which supports our interpretation.

Further, we investigated whether spatial skills moderate the effect of representational-competency supports (RQ2). We found no evidence that spatial skills affected students' benefit from sense activities or perceptual activities; in other words, all students benefitted equally. This finding differs from our unfortunate previous finding (Rho et al., 2022), where sense activities were effective for high-spatial-skill students in preparing for future learning. It is possible that collaboration alleviated the moderation effects of spatial skills. As mentioned, the active learning setting of our encouraged students to help one another, which might have particularly benefitted students with low spatial skills. Our findings related to students' experiences of collaborative learning with representational-competency supports activities (RQ3) supports this interpretation. We found that students received *help* from each other while having an active discussion. Through such discussion, students felt *confidence* and *comfort* about collaboratively working on activities. As a result, students created a supportive environment where low-spatial-skill students can ask for and receive timely help from their peers. Further, high-spatial-skill students were able to enhance their understanding by providing an elaborated explanation to their peers.

Our findings should be interpreted considering the following limitations. First, we conducted our experiment as part of an electrical engineering course. While the naturalistic context of a real classroom enhances the external validity of the experiment, it might have reduced its internal validity. For instance, students might have received help other than our intervention in an unknown way, for example from teaching assistants. Thus, future research should replicate our findings in a more controlled environment. Second, we did not test whether collaborative work on representational-competency activities is more effective than individual work on activities for preparing for future learning. Future research could address this limitation by comparing individual to collaborative learning from representational-competency supports.

To conclude, our research is, to the best of our knowledge, the first to demonstrate that representational-competency supports in collaborative learning are effective for preparing future learning with novel visuals. This finding provides new evidence that fills the existing research gap between representational-competency supports and preparation for future learning. Our findings also provide practical contributions to instructional design in collaborative learning. Considering many STEM instruction activities moving toward collaborative learning, our study demonstrated that collaborative work occurring in a supportive environment has potential to evenly distribute the effect of representational-competency support, especially for preparing future learning.

Abstract: This study explores how middle school students build and share knowledge about viral transmission through scientific modeling. We built a framework for modeling based on the literature with a focus on the epistemic dimensions of the practice. In the framework, we identified five epistemic considerations related to modeling: 1) representation, 2) mechanism, 3) communication, 4) justification, and 5) limitation. We use these considerations to inform our analysis of how middle school students discuss and participate in knowledge construction around viral transmission through modeling. Our results indicate (a) students use several modeling considerations from the Framework for Modeling Principles and Performances to build and share knowledge about viral transmission, and (b) through the modeling experience, students came to appreciate the multi-dimensional nature of viral transmission and pandemics. The findings indicate that middle school students can engage with modeling as part of socio-scientific issues, such as pandemics, in sophisticated ways.

Introduction

The COVID-19 pandemic has highlighted a long-standing call for classrooms to be spaces where learners develop knowledge and practices for informed decision-making. Specifically, science educators saw the need for students to engage in learning experiences around public health issues, including the transmission of disease and methods for preventing epidemics. Unfortunately, the science education community was not well prepared to support student learning concerning viral outbreaks because of the complex, multidimensional nature of pandemics. As the pandemic spread across the globe and impacted the lives of students and their communities, there were limited curricular materials from which educators could draw and many teachers felt ill-prepared to design learning experiences that could address students' emerging questions (Trygstad, Smith & Craven, 2021). Pandemics, such as COVID-19, fit into a broader class of issues referred to as socio-scientific issues (SSI). SSI are complex social issues conceptually connected to science, such as climate change, antibiotic resistance, and pandemics (Friedrichsen et al., 2020). SSI positions learners to explore these complex issues through disciplinary practices such as modeling as a means of developing more sophisticated understandings of complex phenomena (Zangori et al., 2017).

Modeling as a pedagogical tool has long been included in classroom instruction (for a review, see Louca & Zacharia, 2012); however, since the dissemination and implementation of *Next Generation Science Standards* (NRC, 2012), modeling has gained much attention as a science and engineering practice. With this renewed popularity as a target for learning and an instructional approach, some research warns that the practice can be reduced to procedural routines, such as copying pictures, that do little to encourage productive disciplinary engagement and therefore does not leverage the epistemic potential of modeling (Ke & Schwarz, 2020). This essentialized method of modeling comes from an implicit trust that simply *doing* science practices will render scientific understanding. Unquestioned routines that mechanically focus on student attainment of pre-determined components or ideas are a pitfall of science teaching and learning that can be most evident in some modeling activities (e.g., making a cell model from candy with a list of required organelles). Berland and colleagues (2016) suggest that one way to mitigate this pitfall is to highlight the epistemic considerations of the practice and create learning environments where students actively construct and evaluate ideas. In response to this recommendation along with the broader modeling literature, we developed a Framework for Modeling Principles and Performances with the purpose of highlighting the epistemic considerations of modeling.

When used meaningfully, modeling is a powerful practice that can help learners visualize and make sense of their ideas and externalize them in a way that makes visible how their ideas fit into a broader context (Berland et al., 2016; Ke et al., 2021; Schwarz et al., 2009; Schwarz et al., 2022). Because of its value as a learning tool, many researchers have investigated how a modeling experience can be made meaningful to learners. For example, several researchers have explored the importance of providing a model as a physical representation of an abstract phenomenon (Winsberg, 2001), a tool to facilitate scientific discourse (Penner, 2000), and provide insight into systems' mechanisms (Zangori et al., 2017). We build on our prior research that models are made more meaningful when learners are active epistemic agents and engaged with phenomena that are relevant to their lives, such as the climate crisis (Zangori et al., 2017). Given the significance of the COVID pandemic for students and society more generally and the relatively limited knowledge base that we as a research community have about learner understandings of viral disease processes particularly in the context of use of this knowledge in disciplinary practice (Ke et al., 2021), we focus on student modeling practices associated with the transmission and spread of respiratory viruses like COVID. This proceedings paper describes our development of a Framework for Modeling Principles and Performances which informed our analysis of how middle school students discussed and participated in knowledge construction around viral transmission through modeling. The following research question guided our analysis: How do middle school students use modeling to build and share knowledge about viral transmission?

Framework

We built a framework based on the modeling literature (Berland et al., 2016; Forbes et al., 2015; Pluta et al., 2011; Schwarz & White, 2005; Schwarz et al., 2009) with a focus on the epistemic dimensions of the practice. In the framework, we identified five epistemic considerations related to modeling: 1) representation, 2) mechanism, 3) communication, 4) justification, and 5) limitation. For each consideration, we highlighted two dimensions: principles and performances. By principle, we refer to epistemic ideas about the nature of scientific models that students can use to guide their modeling work. For example, in the case of representation as a modeling consideration, principles that learners should understand include that models should represent key features of a phenomenon or system; models are not intended to replicate reality; model can take multiple representational forms; and the degree of detail included in a model will depend on the model type and the nature of the detail itself. By performance, we refer to modeling tasks students should be able to accomplish when they model for certain epistemic goals. For example, again using the case of representation as a consideration, a performance that learners should be able to engage with is the construction of models that represent key features of a phenomenon or system. The framework also suggests that students should be able to move flexibly between different representational forms as they use models. We further describe what each dimension entails in Table 1.

While this framework was influenced by prior work on modeling, it differs from other modeling frameworks or rubrics and contributes to the field in two major ways. First, the framework focuses on both epistemic knowledge (i.e., modeling principles) and practice (i.e., modeling performance) with the assumption that they are both important for students' learning and experiences with modeling. We contend that meaningful modeling practices involves students using modeling principles as epistemic criteria to guide their modeling performances. In turn, engaging in modeling performances gives students opportunities to reflect on the experience and revise their understanding about modeling principles accordingly. Second, existing frameworks for modeling account for ideas consistent with the first four considerations included in our work (representation, mechanism, communication, and justification)—we offer limitation as a new consideration for modeling practice. The limitation consideration addresses a critical research gap in the modeling literature, that is, how students evaluate not only individual models, but multiple models as well. We argue that it is essential for students to recognize the merits and limitations of different models, and how a combination of different models may better represent, explain, and predict the underlying phenomena or system.

Table 1
A Framework for Modeling Practice

Modeling Consideration	Modeling Principle	Modeling Performance
Representation	• Models represent key features (e.g., conditions, components, processes) of system/phenomenon/issue • Models don't replicate reality • There are multiple representational forms of models • The particular details necessary for a model depend on its purpose	• Construct and use models to identify/represent/simplify key features of system/phenomenon/issue in their models • Move flexibly between different representational forms of models
Mechanism (about how/why)	• Models are used to explain system/phenomenon/issue	• Construct and use models to explain system/phenomena/issue

	- Models can be used to make predictions (based on the mechanism)	- Construct and use models to predict system behaviors/scientific phenomena/issue dynamics
Communication	- Models are communication tools for conveying understanding/knowledge - Models are communication tools for supporting arguments.	- Construct and use models to communicate understanding
Justification	- Models should align with relevant evidence - Models are revised based on new evidence obtained.	- Construct/Revise/Evaluate models based on evidence - Select among models based on their evidentiary support
Limitation	- Different models have different merits and limitations - Multiple models combined could better represent/explain/predict system/phenomena/issue	- Recognize the merits and limitations of single models - Compare and evaluate the merits and limitations of multiple models

Method

Context and participants

This study was conducted as part of an afternoon outreach program for middle school (grades 6-8) students in the summer of 2022. During a three-hour session, researchers facilitated a series of curricular events designed to activate and investigate students' prior knowledge of COVID-19 and promote engagement with modeling viral transmission. These learning activities are the first iteration of a multi-year project in which researchers will investigate how middle school learners coordinate different types of models to make sense of multidimensional and profoundly complex phenomena, such as pandemics.

The afternoon began with a modified version of a susceptible-infectious-recovered (SIR) model to encourage students to think about viral transmission at the level of a population (modified from Gaff et al., 2011). The SIR model was presented as a game which is essentially a simulation. The goal for students working with the simulation was to track how numbers of infected individuals within a population change over time. The simulation featured two processes: transmission, the process through which susceptible individuals become infectious ones, and recovery, the process through which infectious individuals become immune. Following engagement with the SIR model, we facilitated a conversation about respiratory droplets and their role in the transmission of viral infections between individuals. Students then completed four different stations where they participated in activities to inform their thinking about social distancing, how germs spread via objects, how masks are designed, and how particle size relates to the spread of viruses through different types of masks. In the social distancing and the particle size station, students completed an investigation answering driving questions: a) How does distance affect transmission, and b) are all materials effective barriers against transmission. The other two stations were a demonstration and an observation lab using microscopes to investigate the differences between the materials masks are made of. Following the activity stations, students worked in groups to construct a model, on whiteboards, based on the following prompt: *draw a model to explain how and why you may (or may not) get infected by a COVID-19 positive person in an indoor space, such as in a classroom, on a school bus, or in a restaurant.* The intent of the model creation exercise was to encourage students think about and share their knowledge of the mechanism through which respiratory viruses spread. As a final step, students were asked to reflect on the SIR model as it was given to them and the transmission model that they created and to critique both models.

The outreach served 14 students in 6th – 8th grades (ages 11 – 13 year old). Six of the 14 students identified as people of color. All names in used in this paper are pseudonyms. The students were divided into five learning groups designated by a color (i.e., yellow, purple, green, red, and blue groups). Students completed the SIR model, the activity stations, and the transmission model in their learning groups.

Data collection and analysis

The data for this study included videotaped recordings of the learning groups as they completed the modeling activities. A researcher facilitated activities within each group and employed a group interview protocol after the

SIR model, each station, constructing the transmission model, and discussing the critiques of the models. The researchers facilitated the interviews to allow learners to build on their group members' responses in order to capture a more authentic experience. Students were asked a series of questions that encouraged them to explain their models, what evidence they used to construct them, how they knew their models were correct, and to identify the limitations of their models. For the purpose of this paper, we focus primarily on the groups' creation and critique of their transmission models.

Through constant comparison (Glaser, 1965), the transcripts from the videotaped recordings were categorized based on modeling considerations from the Framework for Modeling Principles and Performances (see Table 1). These considerations were then further divided into themes that captured the nature of the students' modeling experience. For example, in the modeling consideration representation, students negotiated representation in terms of details, relationship to reality, and accuracy. These were each used as themes to inform how the learners built and shared knowledge about viral transmission.

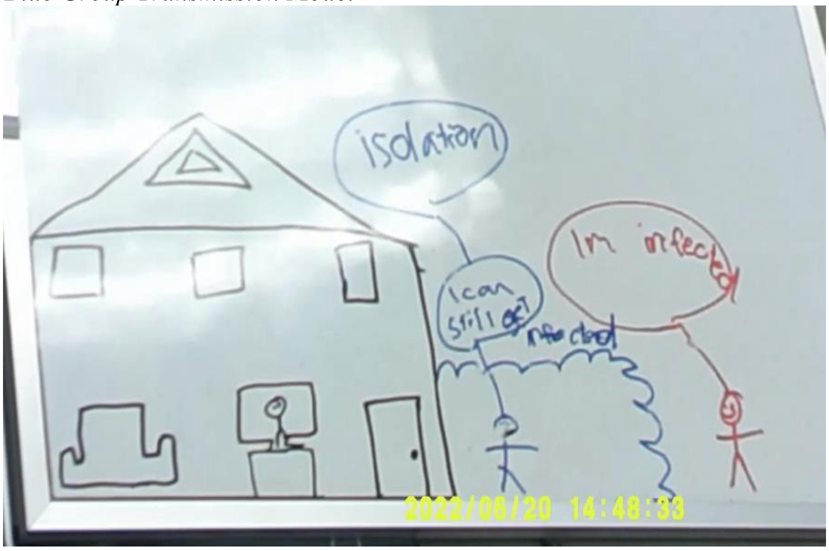
Results

Our results indicate two main findings: (a) students use several modeling considerations from the Framework for Modeling Principles and Performances to build and share knowledge about viral transmission, and (b) through the total learning experience, students came to appreciate the multi-dimensional nature of viral transmission and pandemics. Of the modeling considerations, representation was the most frequently discussed or demonstrated followed by limitation and justification. The other considerations (mechanism and communication) were reflected in some of the students modeling work. For example, Georgia, a student from the green group declared that "the messages will be different" when considering different models. However, this focus on communication was not as prominent as other considerations. Therefore, for the purpose of this presentation, we focus our analysis on how the groups worked with representation, limitation, and justification in their modeling experiences.

Modeling consideration: Representation

All of the modeling principles within the consideration representation (presented in Table 1) were evident in the video that captured group participation and/or the models they created, and the most common theme observed related to the first principle: how students represented key features of viral transmission in their models. Although students varied in how they approached representing the key features of their transmission model, they each generated a strategy (not provided to them) to distinguish the key features of the system. In all but one of the models, the students identified COVID-19 positive person using a different color, usually red. In most models, the susceptible person was represented in blue, while the background context was typically black or a neutral color; see Figure 1 as an example.

Figure 1
Blue Group Transmission Model



The need to provide a context to show viral transmission presented a challenge for the learning groups. Here we are classifying contextual details as background information that was not necessary for representing the key features of viral transmission. For some of the groups, the context of their model was as important as what might be considered the key features of transmission. In these cases, groups devoted a lot of time to negotiating contextual details like where transmission might be taking place and specifics associated with these places. For example, the yellow group immediately decided on a COVID-19 positive person sneezing as a means of infecting a susceptible person; however, there was extended discussion about what context they would represent in their model. The below excerpt captures a brief part of their conversation.

Yandy: Somebody sneezes, and it goes through the mask.
Gabriel-Yosuf: No, the kid's not wearing a mask.
Yasir: No, the kid's not wearing a mask, and he has huge snot particles.
Yandy: You can see it through a microscope.
Yolanda: It's on a school bus.
Gabriel-Yosuf: It's the chef. Okay, whoa, whoa, whoa, whoa, he's sneezing all over the food. Then they eat the food, and the people get COVID. Let's do that.
Yolanda: Yeah, okay. Let's just draw two pictures.

Ultimately, the yellow group drew two representations of the transmission of COVID-19 from one person to another through a sneeze in two different contexts, a restaurant and on a school bus.

While constructing these two representations, the group members further debated which illustrations to include to capture the key features and contextual details in their model. For instance, Yolanda critiqued the restaurant representation and suggested a simplified version; "make the chef delivering your food and sneezing because it's easier to understand," indicating a desire for models to be simplified representations. This is further supported by an interaction between the yellow group and their facilitator about their decisions representing COVID-19 in their models.

Yolanda: Maybe it shows that that’s not what COVID looks like at all. It looks like it is extremely small, and it doesn’t have color.
Yasir: You can’t see it.
Facilitator: Okay. It’s extremely small. It doesn’t have color. Probably can’t see it.
Gabriel-Yosuf: It probably does have a color
Yolanda: It's grey.
Gabriel-Yosuf: Right, but grey is a color.
Facilitator: So, can I ask you all about a decision? You said you can’t see COVID. Why did you draw all of the dots?
Yasir: As a representation to show
Yolanda: To show where it is going

This interaction highlights the yellow group’s understanding that representation is separate from reality but serves a visual purpose.

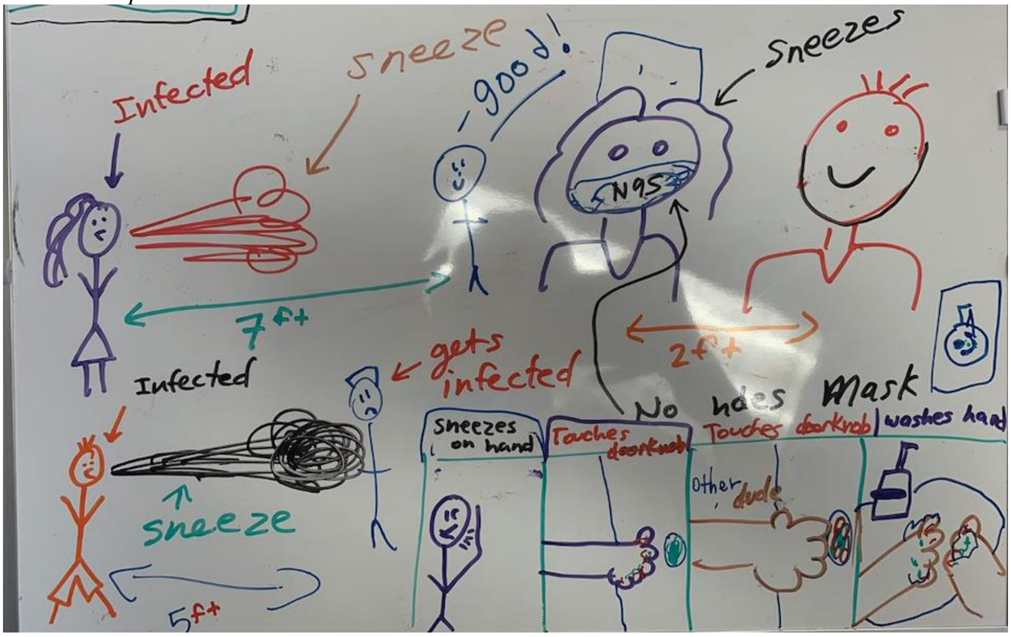
Additionally, upon reflection, the yellow group pointed out that their model was good because it fulfilled their representational goals. Yandy said, "They [models] do their purpose by showing the spreading of germs." He placed the value of their model on its ability to show the spread of COVID-19. So even though they spent time negotiating contextual details which were not essential for the representation (like the fact that the infected individual was a chef) of their models, when pressed to reflect on the purpose of their model they were able to recognize and discuss mechanistic aspects of the model. Along with the attention to distinguishing key features, this implies that the learners value the context of the model; but they see the purpose of the model is to represent a simplified version of COVID-19 transmission, not to deliver a broader narrative for which contextual details may have been more significant.

Modeling consideration: Limitation

Students mentioned the limitations of their transmission models throughout the entire experience. At times, they expressed dissatisfaction with their model's inability to fully explain all aspects of viral transmission. Groups tended to initiate model creation with a single figure or representation, but as they considered dimensions of transmission not accounted for in this initial representation, they would start adding scenes to account for additional aspects transmission. In some cases, the additional representation did not necessarily expand a model's account of transmission mechanisms. For example, the yellow group started their model by drawing a possible transmission scenario in the context of a restaurant (with an infected chef spreading respiratory droplets to customers). Some group members were dissatisfied that this initial attempt only showed transmission in one context so they added a new scenario showing how a virus might spread to multiple individuals in a school bus.

In contrast, the green group added to their representation as a way of expanding the mechanistic explanations accounted for in their model. Figure 2 presents the final model from the green group. The group started with scenes on the left with the intention of showing how respiratory droplets spread through sneezes and highlighted the significance of distance as a factor influencing transmission. They were concerned that this initial representation did not show enough so they next added the figures to show the importance of mask wearing (Figure 2, top right). Next, the conversation shifted to the potential for viruses to spread on objects, and in response, the group added a final scene (Figure 2, bottom right) that showed how viruses might spread on objects and the importance of hand washing. When asked by the facilitator what the model did not show, Georgia responded, "it's hard to tell why some masks are good, and others aren't." If space on the white board remained, it seems likely that the group would have added another scene to account for variation in mask quality. This pattern, which was observed in other groups as well, reveals that the students could recognize model limitations and sought strategies for expanding what their models could explain. In some cases (e.g., the yellow group), the changes to the models added contexts but did not necessarily expand the ability of the models to account for transmission mechanisms. In other cases (e.g., the green group), the changes broadened the explanatory power of the models. In all cases, the learners remained focused on specific examples (spreading viruses in a restaurant, on a bus, at different distances, with/without a mask, etc.) and responded to perceived model limitations by adding new examples. An alternative strategy could have been to consider aspects of transmission in more abstracted ways that could apply across specific examples, but the students did not appear able to take that step, at least not with the scaffolds provided.

Figure 2
Green Group Transmission Model



Modeling consideration: Justification

Students discussed the justifications that supported their models primarily by pulling evidence directly from that day's activities. When asked how they knew what they were modeling was true, they responded with particular reference to the station activities. They reflected on the fact that the stations showed the complex nature of viral transmission, such as not all masks offering adequate protection from the virus. When asked why the green group labeled the mask as "N95," Grace responded, "because, in the microscope, it had no holes." She later described how the "gaiter masks" are ineffective because she saw large holes under the microscope, which would not offer protection to a susceptible person. In the microscope station, students looked at an N95 mask, a surgical mask, a homemade double layered cotton mask, and a neck gaiter. Grace was referring to the porous, loose weave of the neck gaiter she observed under the microscope. Additionally, in the blue group, Bill said he used what he learned from the "6 feet apart" station which showcased the inverse relationship between spread of respiratory droplets and distance, to build his model showing isolation (Figure 1).

Evidence emerged that the students also justified their models based on personal experience. For example, Grace from the Green Group referenced her own experiences wearing a mask to protect herself and the people around her as a justification for including masks in her group's model. The attention to protecting others through wearing a mask, which was not discussed in the stations, indicates that Grace is bringing personal experience to her understanding of viral transmission. In a separate conversation, Yolonda similarly responded that the yellow group's model was good because it showed possible scenarios from real life, "Yes, people can sneeze on your food, and people can get sick from riding the bus." At another point in the modeling experiences, Yolanda expressed dissatisfaction with the SIR model by saying, "if there's a pandemic, you're most likely not just going to be walking around without anything on"—a reference to her own experience wearing masks in public places throughout the COVID pandemic. In the case of the SIR model, the students used a fixed simulation, and the fact that this simulation did not account for evidence from Yolonda's experience was a source of her critique for the model.

Conclusion

This research shows that, with a limited, short intervention, middle school students can effectively use models to better understand viral transmission. Moreover, both their transmission models and their discussions of the models include a variety of critical components that support the development of scientific literacy. In each group, we saw evidence that students engaged in informed decision-making through collaboratively creating, reflecting on, and critiquing the models.

The learning activities and interview questions prompted students' engagement with the representation, limitation, and justification dimensions of modeling. At the same time, these designed experiences were less effective at eliciting communication and mechanism dimensions of modeling. The activities that students participated in around the modeling exercises provided students with opportunities to gather evidence of (a) the best types of materials to use as a mask, (b) why social distancing is an important strategy for limiting transmission, and (c) how germs spread through objects. The limited attention on the part of student groups to other modeling considerations, namely mechanisms and communication, may have resulted from the design decisions our team made in creating the overall set of learning activities.

Notably, the findings suggest that middle school students can engage with modeling as part of socio-scientific issues, such as pandemics, in sophisticated ways, which is consistent with explorations of young learners modeling competencies in the context of strictly scientific phenomena (Duschl, Schweingruber, & Shouse, 2007; Louca & Zacharia, 2012; Zangori & Forbes, 2016). These young learners articulated scientifically appropriate criteria for modeling as the practice is ambitiously outlined in the *Next Generation Science Standards* (NRC, 2012). Students authentically engaged in building their transmission models and, as a result, navigated between complex decisions of what to include and for what purpose (i.e., superficial details, context, and simplified illustrations, as seen in the representation section). For example, although the yellow group included multiple contexts representing the same type of transmission, they ultimately decided that their model was appropriate because it showed the spread of germs. Additionally, all the groups identified limitations of their transmission and SIR models to conclude that COVID-19 is too complex to be singularly represented. Their dissatisfaction with what one model could accomplish shows an understanding of the pandemic that can be useful for supporting scientific literacy, most importantly in this case, informed decision-making for a healthy lifestyle.

Understanding how middle school students engage in modeling viral transmission may guide future researchers in clarifying how young learners use modeling to make sense of other complex SSI. Educators may also leverage the modeling considerations to encourage the types of learning environments that allow for all five considerations to flourish for meaningful epistemic engagement.

Cultivating Generative Emotion in Science Classrooms

Abstract: This paper addresses two shifts in science education: (1) a move away from a focus on content and toward a focus on practice to engage students in inquiry and (2) calls for learning to be justice-oriented and dignity-affirming. We propose that attending to generative *feeling* can cultivate *emotional configurations* (interrelationships between feeling, sensemaking, and practice; Vea, 2020) that help students make progress on investigations that are personally meaningful to them. Using data from a 6th grade STEM classroom, we illustrate how attending to generative feeling opens up the questions students can ask and answer, the stances they can take, and the interpretations of data that are recognized as legitimate in their classroom. Thus, attending to feeling enables investigations that respect the dignity of students and the dignity of the more-than-human participants in their investigations.

Objectives and significance

This paper addresses two shifts in science education. First, science education has moved away from a focus on content alone and toward a focus on *practice* in order to engage students in inquiry (Duschl et al., 2007; National Research Council, 2012). Second, science education researchers have called for learning to be *justice-oriented* and *dignity-affirming* (e.g., Espinoza et al., 2020; Warren et al., 2020)—a shift that could empower students to ask and answer personally meaningful questions. We argue that, when integrated, these two shifts could support genuine and generative inquiry through the development of classroom knowledge and practices related to students' concerns and interests. With such goals, it can be challenging for teachers to recognize students' potential contributions and amplify them. First, a shift toward forms of practice modeled on disciplinary science (e.g., NGSS practices; NGSS Lead States, 2013) has, in some cases, led to students' rote participation rather than empowering them to generate their own knowledge and practices as a community (Berland et al., 2016; Manz & Suárez, 2018). Second, teachers have traditionally been encouraged to amplify student contributions with explicit connections to specific disciplinary ideas and phenomena (e.g., in "storylines;" Reiser et al., 2021). This approach filters students' contributions in a way that could feel manageable for teachers, but oppressive for students. On the other hand, a perspective that centers students' contributions could be overwhelming for teachers (and also students), because attempting to incorporate any and all student contributions could threaten the coherence of students' investigations. This paper asks: How can teachers invite and cultivate students' ideas, practices, and connections in order to support classroom investigations? How can students shift this discourse?

We propose that one solution is attending to generative *feeling* (embodied intensities) in order to cultivate *emotional configurations* (interrelationships between feeling, sensemaking, and practice; Vea, 2020) that help students make progress on investigations that are personally meaningful to them. Using data from a 6th grade STEM classroom, we illustrate how attending to generative feeling opens up the questions students can ask and answer, the stances they can take, and the interpretations of data that are recognized as legitimate in their classroom. In this setting, we argue that attending to feeling enables investigations that respect the dignity of students as well as the dignity of the more-than-human participants in their investigations (in our case, guppies).

Our findings offer theoretical and pedagogical contributions. First, while *emotional configurations* has previously been used as a descriptive framework, we demonstrate how this tool could be used to design for justice-oriented and dignity-affirming classroom science learning. Second, while emotional configurations have previously been used to analyze emotions within small groups in science classrooms (Lanouette, 2022; Pierson et al., in revision), we use this framework to analyze emotion within a classroom as an emergent *social* field. Third, by focusing on generative feeling as a lens, we suggest an approach that teachers could use as a means for determining when and how to amplify their students' expressed emotion to support classroom investigations.

Conceptual framework

We argue that attending to feeling can be responsive to calls for justice and dignity (Boler, 1999; Shalaby, 2017), as well as calls for authentic science practice (Jaber & Hammer, 2016; Zembylas & Papmichael, 2017). To understand emotion in 6th grade STEM classrooms, we draw on Vea's (2020) emotional configurations framework. Rather than separating emotion from practice, Vea argues that emotion is an inextricable dimension of learning as a sociocultural activity. This perspective shifts the analytic focus from *affect* (a heuristic used to describe "ambiguous felt intensity as a mode or moment in the process of emotion;" Vea, 2020, p. 326) to *emotion* (the coordination of feeling with social meaning and practice). To understand the nature of emotion in learning, Vea offers the analytic construct of *emotional configurations*: the situated and reciprocal interrelationships between feeling (embodied intensities), sensemaking, and practice. This framework was developed in the context of activism; in our application to classroom science learning, we draw on science education literature to understand sensemaking (recognizing and resolving inconsistencies or gaps in knowledge; Odden & Russ, 2018) and practice (developing procedures and measures to build knowledge; Lehrer & Schauble, 2015).

We conceptualize dignity-affirming and justice-oriented science learning as valuing participants' "intrinsic worth" (Espinoza & Vossoughi, 2014, p. 290), enabling students to feel that their "whole person" is invited into learning (Calabrese Barton et al., 2021, p. 1231). In addition, in our data, a sense of justice and dignity includes more-than-human participants (Tzou et al., 2021)—in this case, the guppies that the students studied to understand ecosystems. As Calabrese Barton and colleagues (2021) explain, justice-oriented and dignity-affirming science learning requires making space for students to be "disruptive." Rather than framing students as "troublemakers" in moments of disruption, instructors can instead frame disruptive moments as opportunities for transformation (Shalaby, 2017). Our data include examples of such generative disruption—for instance, one student critiqued classroom practices that put guppies at risk based on her commitment to caring for the guppies.

Method

This study was conducted in a public middle school in a suburban school district in the southeastern US in Ms. S's classroom. Ms. S is a STEM teacher who was in her 26th year of teaching at the start of the study. We analyze data from two of Ms. S's 9-week sixth grade classes (13-25 students per class). Q1 refers to the first implementation of the unit (August-October); Q2 is the second (October-December). According to the state report card, 18% of the school's students qualify for free or reduced lunch. The students in the school are culturally and linguistically diverse: 55% of students identify as White, 34% as Hispanic or Latino, 7% as Black or African American, and 4% as Asian. 8% are classified as English Learners. Students participated in a unit that foregrounded modeling that was co-designed and co-taught by Ms. S (teacher, author 4) and Ms. P (researcher, author 1). The unit was framed by two design challenges: students designed a biosphere, a closed-system physical model that included plants, snails, and guppies; and they programmed a computational model that represented a larger ecosystem of plants, snails, guppies, and guppies' competitors and predators. Throughout the unit, the students gathered information and re-represented the guppies' environment with increasing complexity.

We analyzed whole-class data during two implementations of the 9-week unit. Two cameras positioned on opposite sides of the classroom captured classroom discourse. We began by creating content logs and rough transcripts of classroom videos (Erickson & Schultz, 1997). In our analysis, we focused on identifying feelings that shaped the trajectory of classroom investigations. We used Discourse Analysis (Gee, 2014; Norris & Jones, 2005) to closely analyze the multimodal expression and interplay of feeling, sensemaking, and practice. We conceptualized emotional configurations as sustained and shared sensitivities to phenomena during the class's investigations, where (a) students expressed embodied intensities (feelings), (b) students worked collaboratively to build knowledge (sensemaking), and (c) students developed shared ways of participating in the investigation (practice). We then traced these emotional configurations back to their roots in classroom interactions, as well as forward to their ending points (when students' goals for their investigations were achieved, frustrated, altered, or otherwise exhausted). For evidence of feeling, we attended to the following forms of expressed emotion (Boler, 1999): (a) physiological, for example, a gasp or laughter; (b) cognitive/conceptual, for example, describing a feeling of connection with the guppy, including hope or concern; and (c) moral/evaluative, for example, making decisions about guppies or models based on feelings of connection. For evidence of sensemaking, we attended to moments where students iteratively noticed inconsistencies or gaps in their knowledge and generated explanations to reconcile these issues (Odden & Russ, 2018). For evidence of practice, we attended to the ways that students used procedures, measures, and materials in service of the shared investigation (Lehrer & Schauble, 2015). Then, after identifying these components of emotional configurations, we traced their interplay. Specifically, we analyzed transcripts to determine whether and how feeling influenced sensemaking (new questions or understandings) and practices (new ways of seeing and interpreting the biosphere jars), as well as whether and how sensemaking and practice sustained or evoked feeling within small groups or across the classroom (for instance, observing the jar evoking feelings of care or concern for the guppies).

Findings

Below, we illustrate how Ms. S attended to feeling in order to cultivate generative emotional configurations that supported justice-oriented and dignity-affirming science learning. This analysis shows how one student, Dolores, shifted the classroom's discourse about the biosphere jars through her persistent representation of feeling to critique classroom practice on a day when guppies were discovered to have died—a shift that influenced the design of the unit and Ms. S's teaching in subsequent implementations of the unit.

Dolores's critique of classroom practice:

Although no guppies had died in the pilot implementation of the unit (during the previous school year), in Q1 several of the guppies did die, soon after being placed in the biosphere jars. The classroom discussion illustrates tensions that arose between students' feelings and the pursuit of the classroom investigation. In the end, Ms. S's classroom culture did enable the group to navigate these tensions, but the episode also pointed to the need to adjust the framing of the unit in ways that would tap more deeply into students' feelings as epistemic guides.

Ms. S began the class session with a focal question, "What is happening in our [biosphere] jars?" Dolores's group was one of the groups whose fish had died, and one of her group mates, Reid, normally a quiet student, spoke first, saying "Nothing, because ours are all dead." Dolores's subsequent participation in the class discussion carried this theme forward. She was habitually a more vocal contributor to class discussions than Reid, and she was quite active in this session as well. During our focal episode, she accounted for 35 of the 73 student turns of talk. Much of the classroom interactions on this day followed the Initiation-Response-Evaluation ("IRE") pattern (Mehan, 1979; 1980); and several additional exchanges involved a slightly more open "IRX" form, in which Ms. S replaced the Evaluation turn with a request for additional responses to the Initiation prompt. Dolores participated in 13 of the 15 IRE sequences in this episode and 3 of the 5 IRX sequences.

The IRE format is effective in eliciting expected answers to teacher questions (Mehan, 1980), and many of Ms. S's questions aimed to confirm students' memories of key facts in the Carbon Cycle and in plant and animal respiration. This agenda appeared to bother Dolores, who seemed increasingly impatient with a discussion of general knowledge that neglected the specific events of the fish's deaths. Dolores responded by participating in ways that increasingly subverted the IRE interaction pattern. The first came in an exchange about plant respiration:

Ms. S: They take in something. What do they take in?
Dolores: Carbon Dioxide
Reid: Oxygen?
Ms. S: They take in which one?
Reid: [Oxygen]
Dolores: [Carbon Di]oxide ((pause. raises hand)) Carbon Dioxide
Ms. S: Mm- Carbon Dioxide (.) What do they release? ((Hand gesture))
Dolores: Oxygen
Reid: Ohh! ((realizing his prior error))
Dolores: ((softly)) But then we just stressed out the fish; that's why they're all dead.
Ms. S: Right.

In her second-to-last turn, Dolores responded rapidly with the correct answer (Oxygen). Then, before Ms. S could close the IRE sequence with her ratifying "Right," Dolores quickly interjected a novel idea ("But then we just stressed out the fish; that's why they're all dead"). This turn introduced a conjecture about the *cause* of the fish's deaths (stress), and, in using the pronoun "we," it implicated the classroom group as *culpable* for their deaths. Further, caught by Dolores's quick interjection, Ms. S's "Right" (unintentionally) endorsed Dolores's statement. Ms. S then moved on to ask about animal respiration:

Ms. S: What do WE, what do WE take in?
Dolores: Oxygen
Ms. S: Oxygen, ok
Dolores: ((gesture over shoulder at fish tank)) but [inaudible] in there.
Ms. S: What do the fish take in?
Dolores: Nothing, because they're dead.

As before, Dolores worked within the form of the IRE pattern to introduce ideas that interrupted Ms. S's press for general knowledge with a focus on the fish. In saying "Nothing, because they're dead" Dolores also returned to Reid's first comment. Dolores's answer further reframed Ms. S's "the fish" (in general) to refer to the particular fish who had died in the jars. Ms. S attempted to move on, resetting and asking the question again:

Ms. S: What do the fish take in?
STUDENT: Oxygen
Dolores: Stress

Ms. S: Oxygen
Dolores: And stress

At one level, Dolores's responses here returned to the theme of "stress" that she initiated in the first exchange. At another, participating in the IRE pattern also led her to develop her argument. Whereas she earlier introduced the idea of stress as a cause of death, here the parallel with "oxygen" positioned stress as a material factor that the fish "take in" from a hostile environment.

Next, Ms. S steered the conversation to the reasons that some fish had survived while others had died. Dolores raised her hand, and Ms. S called on her:

> Um. Maybe they weren't as stressed out. Or they like – they got used to the hot tank quicker. Or the other ones, they still were confused and weren't um. Because you had them in that big tank and you put them into a smaller ecosystem, so they weren't sure and they didn't know what to do.

Dolores advanced further sensemaking about the fish, connecting the concept that the classroom group was culpable for their death with the idea that their environment was hostile. To this, she added the concept that the *size* of the jars was a problem, and that fish in an environment with very limited space wouldn't "know what to do." This raised a theme that she had been concerned about on Day 12 of the unit. (On first seeing the jars they would be using for biospheres on that day, Dolores had asked, "Isn't it kind of bad for a fish to live in a jar since it's not much space?")

Then, Ms. S described how she had introduced the guppies to the classroom tank, acknowledging that she didn't take the usual step of giving them some time floating in their bags before releasing them. The discussion then returned to the question of why some fish died.

Dolores: I think it was because maybe they got STRESSED OUT - like the ecosystem was too small. Or the fish let out these things, and it caused them to like [dysfunction] with sand [inaudible] got in whenever they breathe — the gills
Ms. S: There are lots… there are lots of things for us … to consider, lots of things for us to consider.
Dolores: Because I feel like whenever you imagine like a project, you imagine fish would be in a big tank. And not in like little jars, because fish can get stressed out really easily if they don't know what to do, or they don't ... not sure what to eat, so they don't eat, they don't know they can't really… function right. So then everything just goes off and they just die because of the stress.
Ms. S: Okay.
Dolores: Everything just starts to shut down within them…
Ms. S: Um, stress can be a factor.

In this exchange, Dolores linked the fish's experience of stress to the emerging theme of environmental factors that could be harmful to the fish. Stress now served as a bridge connecting the interior states of the fish (e.g., "they don't know what to do"), the external conditions (e.g., "the ecosystem was too small" and "sand…going wherever they breathe"), and the fish's health (e.g., "they can't really function right" and "everything just goes off") leading them to die "because of the stress." Dolores generated a conjecture in the form of a causal web of factors and symptoms, which could in fact serve as a guide for monitoring the health of the remaining fish. Moreover, Dolores's passionate articulation of her conjecture showed how empathy and connection with the fish's plight animated her reasoning. For her part, Ms. S made a large amount of space in the classroom discussion for Dolores to develop her thinking, first by responding in a tolerant way to Dolores's disruptions of IRE sequences, and then by inviting her to voice her thinking in a more extended way in these final contributions. She acknowledged that Dolores's evocative explanation has been compelling in her last line: "stress can be a factor."

The significance of this episode was twofold. On one hand, it showed how one student, Dolores, experienced emotions and ethical concerns that made her feel out of sync with the classroom and the way that the investigation was being conducted. On another, it demonstrated how, by insisting upon the relevance and importance of her emotional response, Dolores was able to articulate her sense-making grounded in that emotion and bring this to light within the constraints of the classroom's existing discourse practices.

While Dolores's contributions did not shape the direction of the class's investigations immediately, Ms. S did make room for her to articulate her perspective. Thus, the tension between her emotional response and the classroom's perspective was resolved in a way that validated and re-integrated her and her ideas. Moreover, this episode had an impact on the design and facilitation strategies for the unit in future quarters, guiding refinements that invited emotion and tapped into the epistemic potential of connecting feeling, sensemaking, and practices.

Adapting teaching based on dolores's critique: Inviting and incorporating feelings

In response to the episode above, in subsequent quarters, Ms. S adjusted her stance toward inviting and incorporating students' feelings as important resources for class investigations. Below, we show how she built upon her existing practices for fostering supportive relations among the humans in the room to make additional space for students to develop connections with the non-human living beings in the investigation as well as to express and act on feelings of care and concern for their survival, health, and well-being.

In Q2, Ms. S did several new things that invited students to engage with the ideas of the unit in ways that foregrounded feeling. After showing a video about the Biosphere 2 project, she gave students time and specific prompts that asked them to make connections between human needs and the situation of being sealed up in a closed system as part of a scientific investigation. For instance, Ms. S asked the class whether they would be willing to be a member of the team sealed into Biosphere 2. Students' responses showed that they were beginning to visualize what this would mean. They expressed hesitation for a variety of reasons, including a desire to be paid, to bring particular belongings (a blanket, their bed), or to bring their family as a whole. Later discussion opened up questions about whether they could bring a change of clothes, and how one might wash clothes within a closed ecosystem. This question in particular appeared to create visceral reactions—disgust about not being able to expel waste water, concerns about its being too hot inside, and claustrophobia about being shut in. Here, students were practicing perspective-taking for other humans; the following conversations invited students to take the perspective of more-than-human beings.

Ms. S then introduced a recurring theme of "planning well" for the biosphere jars:

Ms. S: Why do you want to plan well?
Ana: Because you want your guppies to live.
Ms. S: Ye-es!
Abby: And your snails!
Ms. S: And our snails, and whatever else we put in there!

Even in this first contact with the idea, the importance of planning well was framed in slightly different ways than it had been in Q1. In Q1, this was the opening exchange:

Ms. S: Someone tell me about planning well. Why is that important? (.5 sec) David?
David: You don't want everything in your ecosystem to die on the first week ((smiling))
Ms. S: No-ho we don't, we don't. Because it IS a contest, it's a contest.

The framing of the class's parallel biosphere jar investigations as a *contest* (to see which group's jar would do best) was not a persistent one, even in Q1, but it was a framing that foregrounded feelings of pride and competition in the students, as opposed to feelings of connection to the fish and other living organisms, which were more consistently highlighted beginning in Q2.

In Q2, after discussing "planning well," Ms. S moved to another key question that she asked multiple times in the days before the class created and closed off their biosphere jars.

Ms. S: Now, I want you to be honest with me, ok? Closing that lid, does it make anyone go "ooh" ((gasping)) –
Hillary: No. No.
Ms. S: -- those fish are going to die? Or whatever's in there.
Abby: They won't get oxygen, because there's no holes in the lid!
Ana: [inaudible] ((gesturing))
Ms. S: That's what, that's what's scary, ok?
Student: They'll jump out
Hillary: They'll be fine.
Ms. S: But why will they be fine?
Hillary: Because there- (.) Because fish need water, and water is in there.
Abby: But they also need (inaudible)
Ms. S: What? ((pointing to Abby))
Abby: They need plants.

Hillary: Well ((gesturing)) then well, we'll PUT plants in there!

Above, a range of levels of concern was revealed, from Abby's experience that fish can die even when cared for to Hillary's confidence that the class could provide for the guppies' needs.

Later in the unit, on Day 7, after the Plant Investigation, Ms. S returned to the question of whether students were concerned:

Ms. S: And you're going to be ready to design your...
Student: Yay!
Ms. S: ...little ecosystems? ...that we're going to ((screwtop gesture)) CLOSE OFF? Is that scary to [anyone? That]
Students: [Yes]
Abby: [Yes!]
Ms. S: we're going to close that jar?
Ana: I feel like the guppies are going to DIE because ((inaudible))
Abby: ...they're all going to die, and it's going to be our FAULT.

Here, the group expressed not only greater concern ("the guppies are going to die"), but also accountability ("it's going to be our fault"). The discussion continued, as students imagined possible problems that could arise. Andrea asked "How are we going to clean it?" which launched a discussion of algae, the possibility of an "algae explosion," and Ana's personal experience with her turtle's tank if it was not cleaned for a few days. Finally, Lucy asked:

Lucy: Will the guppies try and eat the plants?
Ms. S: M-m! That's a good question
Abby: We need to KNOW this stuff!

Along with others in the class, Lucy has shifted to imagine the dynamic behavior and emergent needs of the living beings in the jars. This line of thought emphasized the responsibility of students, as scientists, to imagine what *could* occur (e.g., the guppies might "try and eat the plants" that sustain them), to do research to prepare for such contingencies ("we need to know this stuff"), and to be on the watch for what was actually happening in the jars.

Again, there was a subtle difference between how Ms. S responded to and encouraged these "what if" reflections about the ecosystems processes in the biosphere jars in Q2, compared with how she responded to similar ideas in Q1. In Q1, after the class began to process the idea that the fish and plants might each make important contributions to the other's survival, Madison had asked a question:

Madison: The ideal thought is that the water will be turned into ... what [the fish] needs. But what if the system that usually like makes it do that…the plant…dies? So, then what if our fish dies?
Ms. S: Ah-h. Well that, would answer some questions for us, right? Now we would probably have to test many times before we could say, ok this is definitely what is going on.

Ms. S's response here was consistent with a line of thought that she had pursued earlier that day, positioning the students as scientists and researchers who should think about designing experiments to control variables of interest and offer opportunities for repeated measures to verify findings (which anticipated the upcoming Plant Investigation).

Yet, in light of the experience of guppy deaths later in that quarter, Ms. S made a shift in how she positioned the biosphere investigation as connecting with scientific practices in her future facilitation. Specifically, in Q2 and following, Ms. S framed the investigation of the ecosystem as a whole (including the fish) as an engineering design challenge. The notion of a controlled experiment *did* persist as the focus of the unit's Plant Investigation, but Ms. P and Ms. S were careful to distinguish this kind of controlled-variable testing to identify what the plant needed for survival from the Biosphere Jar inquiry into ecosystem dynamics that depended on the survival and well-being of the fish. On Day 7 of Q2, they made this contrast explicit:

Ms. P: So, with the plants, we were totally cool with saying, "Let's give some plants some water, and let's give some plants no water." Why would we feel not so good about saying, "Let's have a guppy that we feed and a guppy that has no food?" Why would we feel worse about that?

Student: Because guppies actually [move around?]
Lucy: We think that guppies are like... (1 sec). Even though plants are living, too, we don't think of plants with personality. We think of guppies as things that live, and eat, and stuff. So they need [inaudible]. We have this instinct that makes us want them to live.
Ms. P: We do, and so how does that make testing what guppies need different for us? Like, how does that make our GOALS different when we test plants versus when we test for animals? Yeah?
Lucy: We want to make sure that like the guppies have enough dirt, and enough, like everything, and that like [inaudible] they have enough air, and....
Ms. P: Yeah, so with our plants we were kinda trying to see what works, but also what DOESN'T work. And we wanted to be sure about what DOESN'T work, right? With guppies, we don't really want to roll the dice in that way, right?

Ms. P reframed the Biosphere Jar investigation as having a different kind of goal from the Plant Investigation. In Q2 and following, Ms. S and Ms. P cast this investigation as an *engineering design challenge*, whose scientific focus was on the ecosystem level. Such investigations depend on establishing and maintaining a thriving biological system whose network of behaviors and interactions can then be studied. This enterprise opens up an avenue by which students' feelings of connection to the organisms involved and their sense of justice and dignity for these more-than-human beings can be intertwined with their sensemaking and practice.

Discussion and implications

In the analysis above, we illustrate how Ms. S heard and responded to Dolores's generative feeling as a critique of classroom practice, shifting her teaching in the subsequent quarter to invite and acknowledge students' feelings as part of classroom practice. We argue that attending to feeling in this way contributed to justice-oriented and dignity-affirming science learning and respected the feelings of both the students and the more-than-human participants in their investigations (the guppies).

In Q1, the research and teaching team experienced two forms of "disruption" to the intended unit plan. First, the death of guppies was a new experience in this unit—guppies did not die during the pilot implementation of the unit. In this way, tragedy occurring to the more-than-human participants created an opportunity for the classroom to reconsider and critique classroom sensemaking and practice. When Ms. P and Ms. S responded to this disruption by drawing on existing classroom resources grounded in disciplinary sensemaking and practice (asking questions, for example, about the variables that changed from quarter to quarter), Dolores instead took up the opportunity to critique this approach, building from her feelings of care and concern for the guppies. Disciplinary sensemaking and practice had failed to protect the guppies from harm, and Dolores's commitment to caring for the guppies offered a new resource for moving forward with the investigation in a way that honored the guppies' lives and respected their wellbeing. The way that Dolores shared her care and concern was disruptive to the intended lesson. However, rather than framing this disruption as a problem, Ms. S made space for Dolores to share her feelings and engaged with Dolores's concerns. Ms. S and Ms. P continued to listen to this critique as they redesigned the unit to more carefully establish a foundation of connection and care with the guppies in Q2, which served as a starting point for generative sensemaking throughout the unit.

These episodes offer an example of how teachers might attend to and amplify generative feeling in science classrooms. Creating space for students to share their feelings, even if their contributions may be disruptive to the planned lesson, can open new trajectories for sensemaking and practice while also recognizing emotional resources that are not always welcomed in science classrooms. Yet, encouraging students to express all feelings could be overwhelming to students and teachers; we offer *generative feeling* as a lens to help teachers consider when and how to encourage and amplify student feelings in class discussions. In our case, Dolores's feelings of connection and concern were generative, because they led to the classroom exploring new questions and practices for studying guppies that impacted Author 4's teaching not only in Q1, but also in subsequent quarters. The foundation of care that was established in later quarters led students to new questions about the guppies and their ecosystems (see Authors, in revision, for more detail about these later cases).

This approach is a theoretical contribution because it applies the emotional configurations framework in a new way. Rather than using the framework retrospectively to recognize the interplay of feeling, sensemaking, and practice, we argue that considering how feeling could shape sensemaking and practice could help teachers make pedagogical decisions about how to facilitate classroom discussions. Moreover, this application of the framework demonstrates how emotional configurations can operate at a classroom scale, taking up one student's concern to influence how content and practice is discussed in her classroom and with future students, and at the same time, affirming the dignity of students and of the more-than-human participants in their investigations.

Braiding Feeling, Sensemaking, and Practice in Science Investigations

Ashlyn E. Pierson, The Ohio State University, pierson.199@osu.edu

Sarah J. Lee, Vanderbilt University, sarah.lee@vanderbilt.edu

Abstract: Attending to emotion can expand the range of resources valued for science learning and offer insights about how students develop investigations and science practices. However, research that characterizes emotion as an integral part of science learning is relatively nascent (Jaber & Hammer, 2016; Lanoutte, 2022). In response, we explore dynamic relationships between feeling, sensemaking, and practice in a 6th grade STEM classroom, guided by Vea's (2020) framework of *emotional configurations*. Following from critical perspectives on western science that emphasize connectedness rather than objectivity (e.g., Fox Keller, 1985; Kimmerer, 2013), we illustrate how students' feelings, their sensemaking about biology and ecology concepts, and their practices of observation were intertwined in generative and mutually-reinforcing ways.

Objectives and significance

Attending to emotion in science classrooms can be a means to critique and expand typical images of science, which position science as culturally-neutral, objective, and value-free (Bang et al., 2012). Attending to emotion in this way takes students' feelings and their role in investigations seriously. Yet, education research that attends to emotion as a part of science, rather than as ancillary to disciplinary engagement, is relatively nascent (e.g., Lanouette, 2022; Jaber & Hammer, 2016). As a result, the role of emotion in learning is undertheorized (Boler, 1999). This is particularly problematic for our understanding of science learning, because, as critical scholars have noted, feeling is intertwined with sensemaking and practice (Vea, 2020), and feeling can generatively drive and even shape scientific investigations (Barad, 2007; Fox Keller, 1985; Haraway, 2016; Kimmerer, 2013).

We draw on Vea's (2020) emotional configurations framework to illustrate the dynamic interplay of feeling, sensemaking, and practice in 6th grade STEM investigations, focusing on classrooms' participation in a 9-week unit about biology and ecology. From our analysis, we argue that feeling is a critical part of learning in these classrooms. We illustrate that feeling is not only important to individuals and the classroom community inherently (Boler, 1999), but also that it plays key roles in constituting classroom investigations. Feeling shapes students' stances toward the organisms and systems they study, and it shapes the direction of their collective investigations. Reciprocally, novel sensemaking and practices provoke new feelings and depth of feeling.

In this paper, we focus on aspects of feeling and practice that have not yet been explored in research about emotion in science classrooms: feelings of *connectedness* and the practice of *observation*—both of which have been the focus of critiques of western images of science (e.g., Fox Keller, 1985; Kimmerer, 2013). In addition, whereas previous research has explored emotional configurations within student dyads (Lanouette, 2022), we trace emotional configurations across student groups to illustrate how feeling, sensemaking, and practice interact to shape multiple groups' investigations.

Theoretical framework and literature review

From physiological, psychological, and philosophical perspectives, emotion has historically been seen as an individual and interior affair. Classically, perspectives that view emotion as individual and interior have also positioned emotion as separable from scientific practice, which has been portrayed as objective and value-free (Bang et al., 2012). In response, in critiques of western science, scholars have argued that emotion is embodied, situated, and collaboratively constructed (e.g., Boler, 1999; Greene, 1988; Jagger, 1989) and have illustrated the fundamental roles of emotion in shaping disciplinary work (e.g., Barad, 2007; Fox Keller, 1983; 1985; Kimmerer, 2013). Applying such critiques to education, Boler (1999) argues that our educational systems and institutions have restricted expression of feeling as a form of social control (for example, through gendered ideas about who is allowed to express feelings in classrooms or by promoting skills such as "emotional intelligence").

While recent research has begun to attend to the role of emotion in learning, most studies characterize emotion as a "psychological construct distinct from the substance of learning" (Vea, 2020, p. 313; see also Pintrich, 2003; Ryan & Deci, 2000). In science education specifically, emotion, while intrinsic to scientific work, has been framed as a distinct instructional goal in its own right—for example, helping students "feel like a scientist" (Jaber & Hammer, 2016; see also Davidson et al., 2020; Jaber, 2021; Jaber et al., 2021; Radoff et al., 2019; Watkins et al., 2018). Rather than separating emotion from practice, Vea (2020) argues that emotion is an inextricable dimension of learning as a sociocultural activity. This social perspective shifts the analytic focus from *affect* (a heuristic used to describe "ambiguous felt intensity as a mode or moment in the process of emotion;" Vea, 2020, p. 326) to *emotion* (the coordination of feeling with social meaning and practices). To understand the nature of emotion in learning, Vea (2020) offers the analytic construct of *emotional configurations*: the situated and reciprocal interrelationships between feeling (embodied intensities; Vea, 2020, p. 315), sensemaking, and practice. In the context of science classrooms, we define sensemaking as recognizing and resolving inconsistencies or gaps in knowledge (Odden & Russ, 2018) and practice as developing procedures and measures to build knowledge (Lehrer & Schauble, 2015). We also build on Lanouette's (2022) application of the emotional configurations framework in her analysis of two pairs of elementary students engaging in ecology. Drawing on indigenous epistemologies that emphasize the importance of place in learning, Lanouette focused on how students' sampling practices were shaped by feelings related to specific places in the schoolyard. Following from this work, we look to critiques of western science to identify additional emotional resources that may often be overlooked in science classrooms. Inspired by these critiques, we focus on feelings of *connectedness* that were intertwined with sensemaking and with *observation* practices. However, we do not anticipate students' values or practices would reproduce these professional values or practices; such an assumption would be a disservice to both professional and classroom contexts, which each address different goals.

In professional science, scholars from multiple backgrounds and perspectives have emphasized *connectedness* to critique western practices, which are often positioned as unemotional and objective (Bang et al., 2012). For instance, reflecting on her own practice as a scientist, Kimmerer (2013) offers a critique of the ideology of mainstream western science—a critique that motivates her own approach as a biologist, which she conceptualizes as "braiding" traditional disciplinary practices and perspectives with indigenous ways of knowing. One of the many transformative effects of this braiding is a radical reconfiguration of the relationality between scientists and nature. In particular, Kimmerer critiques the dualistic stance of objectivity, in which separations between knower and known, observer and observed, and scientist and nature underwrite the extractive perspective of traditional science (e.g., industrial forestry practices that maximize short term yield of lumber but damage complex ecosystems). In contrast, Kimmerer advocates a transformed relation that integrates science and scientists with the world being understood. From this perspective, science becomes a "conversation" with phenomena that involves "listening and translating the knowledge of other beings" (p. 158). Such conversations offer insights that were not initially apparent from the perspective of western science (e.g., how harvesting sweetgrass promotes its growth; how pecan trees communicate). While Kimmerer draws on her own experience bringing indigenous epistemologies into her disciplinary science practice, others have described ways that scientists have implicitly or explicitly challenged western science by drawing on practices or epistemologies that have historically been considered external to science. For instance, scientists and critics drawing on feminist perspectives (among other critical stances, e.g., post-humanism, eco-feminism, and materialism) have traced standard notions of objectivity and dualism in observation and other scientific practices as a grounding for objectification and power relations (Fox Keller, 1985) that endorse overly limited epistemologies as natural to STEM disciplines (Turkle & Papert, 1992); encourage essentialism (Haraway, 1988); undermine relations of kinship with the more-than-human (Haraway, 2016); and neglect the entanglement of ethical, epistemological, and ontological dimensions of science (Barad, 2007). In classroom settings, we argue that feelings like connectedness can be generative drivers of investigations as well, including in practices such as observation.

Historically, *observation* has been described as "neutral" and "passive" (in contrast with an "active" experiment; Daston, 2011). Pushing back against more recent characterizations of the practice of observation as objective, Goodwin (1994) explained that observation is socially structured, using the term "professional vision" to describe a socially organized way of seeing and understanding phenomena, which influences what is worth observing and what actions should occur in response. Moreover, Hall and colleagues (e.g., Hall & Jurow, 2015) showed that what is "seen" by a professional community is driven by that group's values (a component of feeling or emotion; Boler, 1999). Yet, in classrooms, students are often encouraged to use disciplinary scaffolding (Barth-Cohen & Braden, 2021; Eberbach & Crowley, 2009; Smith & Reiser, 2005), which can them from drawing on their resources to develop their own observational practices (Manz et al., 2020; p. 1159). We argue that encouraging students to draw on resources considered external to science (such as feelings of care and connectedness) could support students' engagement with the full spectrum of practices involved in observation (e.g., asking questions, hypothesizing, developing explanations; Marin & Bang, 2018).

In our findings below, we illustrate that connectedness was a generative force in students' investigations that shaped (and was shaped by) students' sensemaking and practice (specifically, feelings of connection-with-others, including the teacher, peers, and the "object of study;" Jaber & Hammer, p. 193—in this case, guppies). Extending previous research, we consider the reciprocal and generative relationship between feeling, sensemaking, and practice not only for individual students or dyads, but also across student groups, and we illustrate how these strands are *braided* together in classroom investigations. “Braiding,” as a metaphor, builds on Kimmerer’s (2013) personal account of constructing an approach to draw on both indigenous epistemologies and disciplinary science to explore and understand natural phenomena. While students in our data do not draw on indigenous epistemologies, they do critique and are supported to transform their classroom’s understanding of science by bringing their feelings (of care, concern and connectedness) into the realm of scientific investigations as driving factors that organize their observational work.

Method

This study was conducted in a public middle school in a suburban school district in the southeastern US in collaboration with a STEM teacher, Ms. S, in her 26th year of teaching at the start of the study. We analyze data from one of Ms. S’s 9-week sixth grade classes (25 students, August-October 2019). According to the state report card, 18% of the school’s students qualify for free or reduced lunch. The students in the school are culturally and linguistically diverse: 55% of students identify as White, 34% as Hispanic or Latino, 7% as Black or African American, and 4% as Asian. 8% are classified as English Learners. Students participated in a unit that foregrounded modeling that was co-designed and co-taught by Ms. S and the first author, Ashlyn. The unit was framed by two design challenges: students designed a biosphere, a closed-system physical model that included plants, snails, and guppies; and they programmed a computational model that represented a larger ecosystem of plants, snails, guppies, and guppies’ competitors and predators. Throughout the unit, the students gathered information and re-represented the guppies’ environment with increasing complexity.

We analyzed whole-class data during the 9-week unit. Two cameras positioned on opposite sides of the classroom captured classroom discourse. We began by creating content logs and rough transcripts of classroom videos (Erickson & Schultz, 1997). In our analysis, we focused on identifying feelings that shaped the trajectory of classroom investigations. We used Discourse Analysis (Gee, 2014; Norris & Jones, 2005) to closely analyze the multimodal expression and interplay of feeling, sensemaking, and practice. We conceptualized emotional configurations as sustained and shared sensitivities to phenomena during the class’s investigations, where (a) students expressed embodied intensities (feelings), (b) students worked collaboratively to build knowledge (sensemaking), and (c) students developed shared ways of participating in the investigation (practice). We then traced these emotional configurations back to their roots in classroom interactions, as well as forward to their ending points (when students’ goals for their investigations were achieved, frustrated, altered, or otherwise exhausted). For evidence of feeling, we attended to the following forms of expressed emotion (Boler, 1999): (a) physiological, for example, a gasp or laughter; (b) cognitive/conceptual, for example, describing a feeling of connection with the guppy, including hope or concern; and (c) moral/evaluative, for example, making decisions about guppies or models based on feelings of connection. For evidence of sensemaking, we attended to moments where students iteratively noticed inconsistencies or gaps in their knowledge and generated explanations to reconcile these issues (Odden & Russ, 2018). For evidence of practice, we attended to the ways that students used procedures, measures, and materials in service of the shared investigation (Lehrer & Schauble, 2015). Then, after identifying these components of emotional configurations, we traced their interplay. Specifically, we analyzed transcripts to determine whether and how feeling influenced sensemaking (new questions or understandings) and practices (new ways of seeing and interpreting the biosphere jars), as well as whether and how sensemaking and practice sustained or evoked feeling within small groups or across the classroom (for instance, observing the jar evoking feelings of care or concern for the guppies).

Findings

Below, we illustrate how the classroom approach of braiding feeling, sensemaking, and practice emerged and persisted, generating emotional configurations that helped to shape the students’ investigations. First, we describe the appearance of baby guppies in one of the jars. Then, we describe a 26-minute episode focusing on students in one group, Genesis, Hannah, Amy, and Pepper, whose feeling (hope, excitement) about the baby guppies shaped observations and interpretations of their own jar. This event led the focal group to ask new questions, fostering the development of a “professional vision” (Goodwin, 1994) about what was happening with their guppy and to broader scientific and social conversations about reproduction across species relevant to these 6th grade students.

When students arrived in class on Day 15, they were surprised and excited to find baby guppies in Bob, Denise, Princess, and Margaret’s jar. Students crowded around the jar with the babies, gasping, squealing, and expressing excitement about this change. After this interaction, Genesis ran back to his own jar to look for babies. As he leaned in to look at his own jar, he asked Hannah, “wait, did ours have babies?” While they did not find babies, Hannah reminded Genesis that the group thought their female guppy was pregnant, saying “did you not know that? That’s the only reason why we chose it.” These baby guppies indicated to students that birth was a real *possibility* in the jars and attuned students to potential indicators of baby guppies in observations of other jars.

Genesis began to observe and interpret his jar in terms of guppy reproduction. He suggested that their guppy had laid eggs in the jar, though Hannah disagreed:

Genesis: Ours laid eggs, we see little red eggs in there
Hannah: Those aren't eggs
Genesis: No they are eggs
Hannah: ((exasperated)) No they're not.

More than five minutes later, Genesis was still focused on the question of whether babies could appear in his jar. He listened as Ms. S talked to the group with baby guppies in their jar:

Ms. S: Okay, make some observations, that's really interesting, so what about, um, what do they look like, you can keep that observation but what do those babies look like? Do you think that they were an egg first and then a baby or do you think they just came out as a baby?
Genesis: Wait they can come out as a baby? She said do they lay eggs or just come out as a baby.

After hearing Ms. S's question, Genesis considered that the fish might "come out as a baby" rather than as eggs, shifting what was important to look for and notice in his jar. Throughout the class session, Genesis's hope and excitement about the possibility of baby guppies drove how he observed his jar.

On Day 21, Bob, Denise, Princess, and Margaret showed connection to the baby guppies, checking on them at the beginning of each class period and framing the guppies as part of their family (Denise: "I'm a grandma!). Genesis, Hannah, Amy, and Pepper hoped to similarly see baby guppies appear in their own jar. While walking into class on Day 21, Pepper asked her group from across the room, "are our guppies dead? Do we have babies?" When they leaned in to look at their jar, hope for baby guppies shaped how they saw the jar. Amy and Genesis initially focused on "eggs," which led to a discussion of guppy reproduction in the context of observations of their jar:

Genesis: What's happened?
Amy: Where's the - where's the clear eggs?
Genesis: Oh wait! Are those brown things kinds of eggs? Look at all those eggs down in the sand.
Hannah: Eggs don't um - fish don't lay eggs
Hannah: So those are either poop or
Genesis: No wait- no fish lay eggs, but guppies don't. Guppies are like- wait, what if guppies are genetically modified fish?
Amy: Guppies - guppies have live birth
Pepper: Wait I have a question. So, supposedly, they're not pregnant, they have a baby like instantly?

Above, the students looked for eggs in the jar, which required them to decide what might be an "egg" versus "poop." How they saw the "brown things" in the jar was shaped by the reminder that guppies don't lay eggs; thus, their vision of the jar was shaped by their concern, excitement, and specific interest (feeling) as well as their developing understanding of guppies' life cycles (sensemaking). As Pepper wondered if this meant the guppies "have a baby like instantly," Genesis raised a new concern about the jar:

Genesis: What is that thing like sticking out of the female. There's something like sticking out of the female.
Pepper: It's poop
Genesis: No, that's not poop.
Genesis: It doesn't come from the same place.
Pepper: ((whispers to Amy)) Oh, she's on her period. Wait, can fish have periods?
Amy: I don't know
Pepper: ((whispers to Hannah)) Can fish have like, you know, periods?
Amy: Yeah they do
Hannah: They can?
Pepper: I did not know that, I did not know that, I actually, I did, but I didn't like know until like a month ago, like I s—((twirling hair)) Me and my mom were talking about it

and I was like, "I want a girl dog" and she was like "no, it's too much to take care of" and she told me and I was like "really?" And she's like "yeah"
Genesis: There's something pooping out and it's not poop, I can tell. I think, I think - it looks like blood, or it might be part of the fish

Genesis noticed something "sticking out of the female" that was "not poop" – "it doesn't come from the same place." This observation led Pepper to a new question about guppy reproduction – "can fish have periods?" She raised the question with Amy and Hannah, considering evidence from a conversation with her mom about how other animals (dogs) might have periods. This conversation occurred in whispers, and the girls did not include Genesis. Yet, Genesis's continued close observation fit with their theory ("it looks like blood").

This line of investigation reciprocally impacted feeling in the group—it bonded the girls, who had an "inside joke," yet made Genesis feel excluded. He asked Ms. S:

Genesis: Why are they all laughing?
Ms. S: ((wave away gesture)) It's cause they're girls. Alright
Amy: Chill, Pepper, it's not even that funny
…
Genesis: I don't understand. Is there like some inside joke?
Amy: No
Hannah: Yes, it's an inside joke
Pepper: It's a girl joke

Later, Genesis guessed why the girls were laughing:

Genesis: I just remembered something my mom told me
Hannah: No
Pepper: It's an inside joke - I think Genesis knows
Genesis: Why are you laughing at that, that's so gross
Pepper: It's not gross
Pepper: I don't get how that's gross.

After Genesis figured out the "inside joke," he asked, "why are you laughing at that? That's so gross." Pepper pushed back on this characterization of periods as "gross," saying "it's not gross, I don't get how that's gross," braiding students' lived experiences and social issues with their observations of the guppies.

When Ms. S came over to check on the group, Pepper asked Ms. S whether the guppy was pregnant. Ms. S guided the students to look for indicators (a black spot at the back of a female guppy's abdomen could indicate pregnancy). She also raised a new concern for the students – that the male guppy could try to eat the baby guppies:

Pepper: Guys isn't our - isn't our guppy pregnant?
…
Ms. S: Does it have a black sort of spot toward the back of its abdomen? ((pointing at jar))
Pepper: Yes
Ms. S: Usually they have a black spot
Amy: Yeah, right there ((pointing at guppy in jar))
Ms. S: Okay. Now this one may be trying to eat the babies
Amy, Pepper: ((Lean back, surprised/scared faces))
Ms. S: He seems pretty aggressive
Pepper: ((glancing back and forth between Ms. S and the jar)) ohh
Amy: ((laughs))
Ms. S: They do that sometimes
Pepper: What if he already ate a couple?
Ms. S: Could have been
Ms. S: It's happened before. You notice how
Pepper: He's like following her
Ms. S: It's happened
Pepper: ((to the male guppy)) I'm gonna kick you if you do

Ms. S helped Amy and Pepper "see" pregnancy in the jar by looking closely at the female guppy's abdomen, pointing at the jar – a gesture that Amy repeated when she also saw the black spot on the female guppy. Then, she described a new indicator – that the aggressive male guppy could be a sign about babies, as well as a threat to the babies' safety. That is, on one hand, the male guppy's attention could indicate a birth was imminent, but it also could indicate a threat to the newborns, because male guppies, in the past, had tried to eat babies. For the students, this raised another concern for the safety of both the female guppy and the babies, which served as a press for closer observation and once again raised the stakes for the students – making sense of events in their jar could be critical to the guppies' wellbeing. They responded by speaking directly to the male guppy as they watched him for signs of aggression ("I'm gonna kick you").

The question about the blood on the female fish was still unresolved, and it was raised again by Pepper:

Pepper: (to Amy) Wait, how is that possible?
Amy: I don't know
Pepper: (to group) Wait, if she's on her… then how is she pregnant?
Amy: Oh
Genesis: I'm not going to ask question about the blood in the water
Amy: It happens to some girls still
Pepper: I know - it depends like when you start

Pepper and Amy decided it was possible for the fish to be "on her [period]" and still be pregnant – resolving a question that emerged in the process of sensemaking about the groups' observations – but also resurfacing the Genesis's earlier characterization of periods as "gross" that was still unresolved:

Genesis: I have older teenage sisters
Amy: So you know what it is?
Genesis: Yes, I know what it is
Pepper: You find it nasty?
Genesis: ((nods))
Pepper: In my opinion it's not nasty
Genesis: In my opinion it's …
Pepper: You know, probably your mom instead of having her period she had you. That's all what I'm gonna say.
Genesis: ((hides head in shirt))
Pepper: ((covers mouth and laughs))
Genesis: I don't like that
Pepper: No but it's true. Instead of having that she had you, and she probably didn't like that, instead. You should think about that.

Pepper again challenged Genesis's earlier implication that periods are "gross," arguing that periods are "not nasty" because they are a normal part of (human) reproduction and life cycles – connecting Genesis himself to periods ("your mom instead of having her period she had you"). In this way, feeling (in terms of the biosphere jar and in terms of students' social dynamics) continued to be interwoven with students' sensemaking about their jar and their observation of their jar.

Throughout the rest of the class session, the students closely watched their jar – both out of concern for the female guppy and in hope that they might "see her have babies." They raised new questions in an attempt to make sense of their conflicting interpretations of their observations (potential pregnancy, or potential period):

Hannah: Maybe she lost -
Pepper: ((gasps))
Amy: ((hands out, palms up))
Ms. S: Maybe
Genesis: No cause there's a guppy like- it's like that big inside of her. So I think it's too big.
Pepper: They can have miscarriages?

Above, students' observations (e.g., the male guppy following the female), questions (e.g., can a guppy have a period and be pregnant?) and feelings (e.g., concern, hope) guided their observations of the jar. Until the end of class, the students continued to ask questions as they closely watched the female guppy. While the female guppy did not give birth during this class session, attending to the biosphere jar through the lens of the *possibility* of this event led students to engage in in-depth explorations of guppies' life cycles and comparisons to other species (primarily humans) and to events and experiences that were meaningful and familiar to them.

Discussion and conclusions

Our findings demonstrate that attending to emotional configurations in science classrooms can support new understandings of science learning and new forms of participation in these spaces. Existing research in science education shows that emotion is intrinsic to epistemic activity (e.g., Jaber & Hammer, 2016) and can guide students' investigations (e.g., Lanouette, 2022). Our findings build on this work by illustrating the reciprocal relationships between feeling, sensemaking, and practice.

In the episode above, students' feelings, sensemaking, and practice shaped their relationship to their peers and the biosphere jar project, as well as to the trajectory of the classroom's investigation. Bob, Denise, Princess, and Margaret's jar alerted the other students to the *possibility* of reproduction in their own biosphere jars. This possibility fostered an emotional configuration that led students, like Genesis, Hannah, Amy, and Pepper, to more closely examine and actively observe their own jars, looking for new evidence or indicators that could help them make sense of their questions and observations. They exerted effort to make sense of indicators in their jars (sensemaking, practice) because of their own concerns for their guppies' lives and wellbeing (feeling). For this group, questions about guppies' reproduction were intertwined with sensemaking about experiences related to human reproduction (periods, miscarriages) that led to uncomfortable, yet meaningful, conversations in which Pepper pushed back against stigmatizing periods as "gross" or "nasty." In the interactions through which the group regulated and negotiated Genesis's response, at issue was not only his relationship to and participation in the social group of the table, but also his ability to effectively participate in and contribute to the observational work that the group was doing. These conversations unfolded in the context of close observation of their jar, motivated by hope and excitement, but also by concern, for their guppy and its potential babies, in relation to the observations and experiences of other groups with newborn guppies. In this way, feeling and sensemaking were intertwined and shaped students' observations and investigations across the classroom community.

This study adds to the growing body of literature that demonstrates the importance of attending to feeling in order to understand learning (e.g., Jaber & Hammer, 2016; Lanouette, 2022). Specifically, we show that if researchers overlook feeling, they could be missing a driver of students' investigations, especially in classrooms in which students have significant epistemic authority to shape the questions they ask and explore and the practices they develop in response. Just as critical perspectives of images of professional science emphasize the importance of feeling in disciplinary work (e.g., Fox Keller, 1985; Kimmerer, 2013), we propose that feelings like connectedness can play an important role in supporting students' sensemaking by guiding the content they focus on and their practices and by guiding the methods they develop to explore this content. Moreover, we argue that connectedness is important at multiple levels; for the classrooms we have studied, learning was consequential because of connections to guppies, peers, their teacher and to social issues.

Furthermore, we echo the arguments of scholars who propose that attending to feeling is essential for equitable teaching and learning (e.g., Boler, 1999; Shalaby, 2017). While this work has normatively characterized feeling as a separate from learning (through equally important), we follow Vea (2020) and critical scholars of professional science (e.g., Fox Keller, 1985; Kimmerer, 2013) in characterizing feeling as inextricably intertwined, or braided, with the disciplinary work of sensemaking and practice. Acknowledging the epistemic role of feeling can help both researchers and educators transform what it means to participate in science learning, re-interpret students' feelings as essential to inquiry, and thus invite students to bring a wider range of resources to classroom science learning. Moreover, this frame explicitly welcomes non-dominant images of science that have traditionally been excluded from western science learning (Bang et al., 2012; Warren et al., 2020). For instance, this lens enables us to attend to mediating factors for the practice of observation beyond disciplinary knowledge (e.g., social, imaginative, and motivational factors). There is still much to learn about attending to feeling in science classrooms. Even so, these findings demonstrate the transformative potential of emotional configurations as a lens for designing curriculum and for analyzing science learning.

Abstract: Learners' current motivation according to the conceptualization of Rheinberg and colleagues is crucial for taking up and pursuing learning activities. Yet, there is still little research regarding the necessary level of factors affecting current motivation itself. This study was designed to start filling this research gap by examining the relative contributions of person-related factors on students' current motivation to learn with a digitally-supported learning environment, focusing on experiments in chemistry education. The study's sample consisted of 155 second graders. Multiple linear regression and necessary condition analysis (NCA) were used to investigate possible factors that predict students' current motivation to learn (i.e., interest and challenge). Results indicate that students' self-perceived experimentation competence and self-determination positively influence interest, while self-determination alone predicts challenge. However, NCA results reveal all variables as necessary conditions, that set restrictions for the maximum level of interest and challenge. Practical and research related implications are discussed.

Introduction

At the beginning of a learning phase, learners' current motivation plays a major role in taking up and pursuing learning activities (Keller, 2008; Thoman et al., 2017; Vollmeyer & Rheinberg, 2013). Current motivation to learn results from an interplay between characteristics of learners (e.g., topic-related interest or motive to achieve) and characteristics of a specific learning situation (e.g., the difficulty of the task at hand). A large body of research has already proven, that especially during self-directed learning situations, the current or initial motivation to learn has a high impact on learning behavior and is closely linked to task performance and learning success (e.g., Barron & Hulleman, 2015; Rheinberg et al., 2001; Scholer et al., 2018; Schwinger et al., 2009; Thoman et al., 2017; Vollmeyer & Rheinberg, 2006). However, there is less research on the factors that in turn influence current motivation itself, in particular on their necessary extent (Liebendörfer & Schukaljow, 2020; Paulino et al., 2016; Scholer et al., 2018). Thus, the purpose of the present study is to investigate potential influences on the level of second graders' current motivation during learning (interest and challenge) when working through a self-directed, digitally-enriched learning environment within chemistry education, the so called EXBOX-Digital. The EXBOX-Digital consists of three main components: 1) a web-based training (WBT) presented on a tablet PC, 2) three small-scale hands-on experiments, and 3) sequential digital support during experimentation. Three person-related aspects were included as possible factors of influence on current motivation: First, students' level of self-determination (i.e., the overall level of intrinsic motivation) to learn in chemistry classes is investigated as a basic and rather time-stable personality variable that is assumed to influence current motivation (Thomas & Müller, 2015). Second, the students' self-perceived experimentation competence is included, because similar to effects of self-efficacy expectations, students' feelings of competence represent an important component for describing interest-driven action (Krapp, 2002). Finally, students' perceived usefulness of tablets for learning is included as an indicator of their attitude towards a characteristic of the learning situation, i.e., the tablet as digital learning medium used in this study (Davis, 1989; Vogelsang et al., 2017). The first aim of this study is to investigate via regression analysis, to what extent those three factors predict students' current motivation to learn with a digitally-enriched learning environment within chemistry education. In addition, the present study uses a relatively new statistical approach called necessary condition analysis (NCA), to investigate the extent to which the above-mentioned factors prove to be necessary (but not sufficient) conditions for current learning motivation (Dul, 2016).

Theoretical background

In the following, the concept of current motivation to learn is introduced as well as the three potential influences: students' level of self-determination to learn in chemistry classes, self-perceived experimentation competence, as well as students' attitude towards the learning medium, i.e., perceived usefulness of a tablet for learning purposes.

Current motivation to learn

Motivation of learners is proven to be essential for learning processes and academic success. However, the nature of motivation is multifactorial and rather complex. The concept of motivation in general describes the intention to actively engage in a learning activity, but it can vary in amount and kind of motivation. Pintrich and Schunk (2002) argue that motivation is a "(…) process whereby goal-directed activity is instigated and sustained" (p. 5). The concept of current motivation as it is described by Rheinberg, Vollmeyer and colleagues (e.g., Rheinberg et al., 2000; Vollmeyer & Rheinberg, 2013) includes different aspects of activity-related (or intrinsic) motivation in the sense of self-determined behavior, interest or the will to achieve anticipated goals (Rheinberg et al., 2000; Rheinberg & Engeser, 2018) and is of high relevance for task processing in learning situations. It captures a current motivational state that is a product of the learners' rather enduring personality traits (trait variables) and the specifics of the learning situation at hand (state variables; Scheffer & Heckhausen, 2018; Vollmeyer & Rheinberg, 2013). Person characteristics include rather stable motives, interests and self-efficacy beliefs, while situational characteristics are defined by the specific circumstances of the learning situation, like task difficulty, its structure or subject matter. Rheinberg and Vollmeyer (2013; see also Freund et al., 2011) describe four components of current motivation: 1) situational interest in the specific task content (how much learners are interested in the content at hand), 2) anticipated challenge (learners' perception of to what extent the task at hand requires competence; competence-related opportunity to test one's proficiency), 3) anxiety (how anxious are learners to fail the task), and 4) probability of success (extent of probability to succeed in the task). Current motivation influences, for example, learning performance, learning success and persistence during learning (Barron & Hulleman, 2015; Rheinberg et al., 2001; Scholer et al., 2018; Schwinger et al., 2009; Thoman et al., 2017; Vollmeyer & Rheinberg, 2006). In particular situational interest and anticipated challenge are related to learning performance in understanding-oriented and self-directed learning environments that require a certain amount of effort beyond routine, e.g., the use of (meta-)cognitive strategies (Freund et al., 2011, Rheinberg, et al., 2001).

Possible factors influencing students' current motivation to learn

While it is empirically confirmed that the various aspects of current motivation have a high impact on learning, there is less empirical research on the level of possible factors of influence on current motivation itself. In the following, three factors are described in more detail, that might affect current motivation when learning with the EXBOX-Digital and, thus, are part of the following empirical investigation: students' level of self-determination during chemistry learning in school, self-perceived experimentation competence, and perceived usefulness of the tablet as digital learning device.

Level of self-determination during chemistry learning (SDI)

Self-determination theory (Deci & Ryan, 2002; Ryan & Deci, 2000, 2018) has differentiated between two main facets of motivation: intrinsic motivation (or activity-related motivation; Rheinberg & Engeser, 2018) and extrinsic motivation. According to Deci and Ryan (2002; Ryan & Deci, 2000, 2018) intrinsic motivation refers to self-determined interest- or joy-based engagement in an activity, while extrinsic motivation refers to rather outcome-oriented motivation. Intrinsic motivation in particular is of relevance for instruction, as it fosters sustainable learning. However, within the framework of self-determination theory, motivation is not considered as a dichotomous variable, but extrinsic motivation is divided into four subdomains according to the increase in self-determination (Ryan & Deci, 2018). All types of motivation can be located on a continuum, from extrinsic to intrinsic motivation with a gradually increasing proportion of self-determination (Müller & Palekčić 2005; Thomas & Müller, 2015).

Based on these assumptions, a possible influence on current motivation in learning with the EXBOX-Digital might be the students' level of self-determination in school-related chemistry learning, which expresses the degree of the students' intrinsic motivation. It can be considered as an overarching trait variable and is assessed in this study via students' self-determination index (SDI; Levesque et al., 2004; Müller & Palekčić, 2005; Thomas & Müller, 2015). The SDI is calculated using a formula composed of individual components of motivational profiles and based on self-determination theory (Ryan & Deci, 2000, 2018; Deci & Ryan, 2002).

Self-perceived experimentation competence

Self-perceived competence is a major factor of influence of intrinsic motivation and according to self-determination theory one of the motivation-related basic needs of learners (Deci & Ryan, 2002; Ryan & Deci, 2000, 2018). It can be seen as closely related to self-efficacy expectancy, which is an important component in promoting overall motivation and interest-driven actions (Barron & Hulleman, 2015) and can be seen as a necessary but not sufficient condition of interest development (Krapp, 2002). Self-efficacy describes the beliefs of persons in their own ability to perform a specific task and has a positive influence on learning performance and motivation (Bandura, 1997).

Since the EXBOX-Digital includes a practical part with real hands-on experiments after the web-based training, self-perceived experimentation competence can be considered important for the successful completion of the EXBOX-Digital intervention. Preparing, conducting and observing experiments can be seen as essential components of experimentation competence (Busker et al., 2010; Meinhardt et al., 2018). Although all of the EXBOX-Digital experiments are designed to be easy to understand and can be performed by all students using the digital sequential learning aids, it is still important to examine the influence of how the students perceive their own experimentation competence.

Attitude towards the learning medium: Perceived usefulness of a tablet

The tablet plays a major role in learning with the EXBOX-Digital, both in the WBT and for accessing the digital sequential learning aids during experimentation. The third factor investigated is therefore the students' attitude towards the learning medium, i.e. the perceived usefulness of a tablet for learning purposes. This factor is derived from the attitude variable "perceived usefulness" of the Technology Acceptance Model (TAM; Davis, 1989; Venkatesh et al., 2003) that is often used to classify possible factors for a person's intention to use digital technology.

The extent to which a tablet is perceived as helpful for learning is relevant to students' current motivation to learn with the EXBOX-Digital, given its prominence in the lesson. Ngai and colleagues (2007) found that perceived usefulness is a dominant factor affecting the use of a web-based learning program. Therefore, it is interesting to investigate how strong the influence of the perceived usefulness of a tablet for learning purposes might be on current motivation.

Research questions

Taken all the above described issues into account, this study seeks to explore the following research questions: (1) *To what extent do self-perceived experimentation competence, self-determination in chemistry learning, and perceived usefulness of the tablet for learning purposes influence current motivation (interest and challenge) when learning with a digitally-supported learning environment, focusing on experiments in chemistry education?* (2) *To what extent are self-perceived experimentation competence, self-determination in chemistry learning, and perceived usefulness of the tablet for learning purposes necessary conditions for current motivation (interest and challenge) when learning with a digitally-supported learning environment, focusing on experiments in chemistry education?*

Method

In the following, sample, learning material and instruments will be described. Finally, data analysis methods are explained in more detail.

Sample

158 Austrian students with a mean age of 13.38 years (*SD* = 0.73), attending lower secondary school, participated in the study. The participants consisted of 82 males, 74 females and one non-binary person (plus one missing value). Three students were excluded from the calculations as outliers, leaving a sample size of *n* = 155 participants.

Learning material

STEM education aims to provide with an understanding of scientific concepts, scientific thinking, and problem solving (Brown et al. 2016), and experiments are an essential component of STEM education. In this study, students learned about redox reaction in two chemistry lessons using the EXBOX-Digital. The three components of the EXBOX-Digital adapt to the individual learning pace and provide support when needed: 1) An adaptive web-based training (WBT) was designed for the respective lesson, which teaches basic subject knowledge via tablet PC. The students' comprehension is checked by some quizzes and, if necessary, supplementary learning modules are presented to bring all students up to the same level of knowledge. 2) When the WBT is successfully completed, three real hands-on experiments follow. These are designed as small-scale experiments, and students individually work on them. 3) While working on these experiments, students can independently receive scaffolded digital assistance in the form of images, videos, or augmented reality (AR), which can be accessed via tablet PC through QR codes provided on a separate document for individual use. This concept allows learners to work according to their individual competences and at their own pace.

Instruments

Data collection took place within the winter semester 2019/20 and in the summer term 2020 at Austrian secondary schools. The following measurement means were used:

Current motivation to learn: As dependent variable, we assessed students' current motivation to learn, i.e. current *interest* and anticipated *challenge*, based on Rheinberg et al. (2001). Since the students already had experience with another version of the EXBOX-Digital, the learners already knew what to expect. Five items assessed interest (example item: "The tasks seem very interesting to me."; α = .85), and four items assessed challenge (example item: "These tasks are a real challenge for me.", α = .77). Each item could be answered on a seven-point Likert-scale ("agree" to "disagree").

Level of self-determination in learning chemistry (SDI): Furthermore, the level of self-determination in learning chemistry was added to the analysis. This was calculated using the SDI questionnaire, that includes 13 items related to intrinsic motivation, identified regulation, introjected regulation and external regulation (e.g., "Mostly I learn chemistry because I enjoy it", Levesque et al., 2004; Thomas & Müller, 2015) with the following formula: SDI = (2 x intrinsic motivation) + identified regulation – introjected regulation – (2 x external regulation). Values between -12 and 12 can be assumed: If the SDI is negative, the person is more externally determined; if the SDI is positive, the person is rather self-determined (cf. Levesque et al., 2004; Müller & Palekčić, 2005; Thomas & Müller, 2015). A four-point Likert-scale was used, with answers ranging from "not true" to "completely true".

Self-perceived experimentation competence (SEC): As first independent variable, the self-perceived experimentation competence of the students in chemistry was surveyed. For this purpose, a scale with 15 items was developed based on Busker et al. (2010) and Meinhardt et al. (2018), assessing students' self-perceived competence in setup, execution, and observation of experiments (e.g., "I have manual skills to set up experiments independently,"). All items could be answered on a five-point Likert-scale ("strongly disagree" to "strongly agree"). A mean value was calculated across all domains (α = .88).

Perceived usefulness of a tablet for learning purposes (PU): Finally, the perceived usefulness of a tablet PC for learning was assessed. Two items measured students' perceived usefulness of the tablet for school-related learning purposes (α = 0.69; e.g., "The tablet allows me to complete tasks faster."). The items were created based on the paper of Vogelsang et al. (2017) and could be answered on a five-point Likert-scale from "strongly disagree" to "strongly agree".

Data analysis

For answering RQ1, SPSS version 27 was used to analyze descriptive data and to conduct regression analysis in order to find determinants that (on average) contribute to current motivation, to predict current motivation based on the independent variables. It is of further interest (RQ2) to analyze to what extent the independent variables are actually necessary for a certain amount of current motivation (even if the presence of the variable cannot guarantee the occurrence of motivation, i.e., it is not sufficient). A relatively new approach to the educational sciences is used to address this issue and to complement regression analysis: necessary condition analysis (NCA; cf. Dul, 2016; see also Garg, 2020; Garg & Sarkar, 2020; Lee & Borgonovi, 2022; Tynan, 2020). To compute NCA, we used the statistical software R version 4.2.1 with a package entitled NCA. The logic behind NCA is explained by Dul (2016) as follows: A necessary condition is a critical factor of an outcome (like a constraint or bottleneck). If a necessary condition is missing, there will be no outcome, and this cannot be compensated by other determinants. To prevent failure of a specific outcome, each single necessary condition must be in place. However, when the necessary condition is in place success is not guaranteed: the condition is necessary but not sufficient. Three statistical values are of importance in NCA: accuracy of the ceiling line (must be above 95%; NCA reveals areas that indicate the presence of a necessary condition by determining a ceiling line on top of the data in a XY-scatter plot. This boundary separates the zone with observations from the empty zone without observations in the left upper corner by drawing a straight ceiling line. Its accuracy is described by the number of observations that are on or below the ceiling line divided by the total number of observations, multiplied by 100%), effect size (common d-value standards to detect the impact of the necessary condition) and statistical significance (common p-value standards, calculated by permutation test). Further, a bottleneck table reveals which level of each condition is necessary for which level of interest and challenge.

Results

Within the next section, descriptive data and results of regression analysis and NCA are presented.

Descriptive data

Table 1 shows mean values and standard deviations for each scale.

Table 1
Means and standard deviations of each scale

	M	*SD*
Interest^{+}	4.60	1.38
Challenge^{+}	4.85	1.46
Self-determination index (SDI)$^{++}$	2.19	2.93
Self-perceived experimentation competence (SEC)$^{+++}$	3.71	0.63
Perceived usefulness of tablet (PU)$^{+++}$	4.05	0.85

Notes: $^{+}$Likert-scale 1 to 7; $^{++}$Scale -12 to 12; $^{+++}$Likert-scale 1 to 5

On research question 1

According to regression analyses, the predictors explained a significant amount of the variance in interest ($R^2_{corr} = .30$; $p = .000$) and challenge ($R^2_{corr} = .09$; $p = .002$). SDI ($\beta = .39$) and SEC ($\beta = .25$) significantly predict interest (see also Table 2). For challenge, SDI ($\beta = .24$) is a significant positive predictor (see also Table 3).

Table 2
Beta-values, t-values and p-values of possible predictors of interest

	β	*t*	*p*
Self-determination index (SDI)	.39	5.20	.000***
Self-perceived experimentation competence (SEC)	.25	3.18	.002**
Perceived usefulness of tablet (PU)	.14	1.89	.062

Table 3
Beta-values, t-values and p-values of possible predictors of challenge

	β	*t*	*p*
Self-determination index (SDI)	.24	2.80	.006*
Self-perceived experimentation competence (SEC)	.12	1.33	.184
Perceived usefulness of tablet (PU)	.10	1.16	.247

On research question 2

For both interest and challenge, all three variables turn out to be significant necessary conditions according to NCA. All variables show medium effect sizes for interest (PU: $d = 0.24$; $p < .01$; SEC: $d = 0.21$, $p < .00$ and SDI: $d = 0.17$, $p < 0.01$) and challenge (PU: $d = 0.21$, $p = .02$; SEC: $d = 0.14$, $p = .03$; SDI: $d = 0.13$, $p = .04$). CR-FDH ceiling line accuracy for all scales is above the critical value of 95%.

The bottleneck table indicates the required level of the necessary conditions for specific levels of interest (Table 4) and challenge (Table 5). Guideline is the range of conditions and outcome: 0% is the smallest observed value and 100% is the largest observed value. Table 4 reveals, that from the value of 50 % of interest level (3.50 points on interest scale) and up, all variables can be identified as necessary conditions (SEC: 17.5 % / 2.30 points on SEC scale; SDI: 8.6 % / -6.29 points; PU: 13.2 % / 1.53 points). Table 5 reveals that all three variables are indicated as necessary conditions for a 40% challenge level (2.80 points on challenge scale) and up (SEC: 8.0% / 2.0 points on SEC scale; SDI: 9.3% / -6.18 points; PU: 2.5% / 1.1 points).

Table 4

Bottleneck analysis for interest (in %)

Level of interest	SEC***	SDI**	PU**
0	nn	nn	nn

Discussion

This paper contributes to existing knowledge about what factors influence learners' current motivation, namely interest and challenge. It is one of the first studies to examine in detail the levels of possible influences (i.e. self-determination during chemistry learning, self-perceived experimentation competence, and perceived usefulness of tablets for learning) necessary for students' motivation to learn with a digitally-supported learning environment in chemistry education.

Results from regression analysis indicate that level of self-determination and self-perceived experimentation competence have an average positive influence on learners' current interest at the beginning of the learning process. With regard to current challenge, regression analysis reveals an average positive influence of self-determination. In addition, necessary condition analysis contributes to these findings by revealing all predictors as individual necessary conditions for current interest and challenge, with different effect sizes. NCA further reveals restrictions for the maximum level in interest and challenge based on the extent of the necessary conditions: The absence of self-perceived experimentation competence, self-determination and perceived usefulness of the tablet constrains high levels of current motivation, while their presence enables motivation. Thus, all three variables are required for currently motivated students; however, they might still be insufficient on their own because other variables also need to be present when learning with a digitally-supported learning environment in chemistry education (e.g., prior knowledge or self-regulation competences; Song et al., 2016). These results provide further evidence to the assumption that person-related factors are of high relevance for current motivation (Freund et al., 2011; Scheffer & Heckhausen, 2018; Vollmeyer & Rheinberg, 2013).

Limitations of our study include the fact that our data is limited to a specific domain (chemistry) and specific task type (experiments and digital learning). Investigation within another subject or other tasks would be of advantage. Further research could also include other possible influencing variables, (e.g. the influence of prior knowledge; social and emotional aspects; qualitative approaches and situational factors such as task-difficulty).

It would also be of interest, to analyze what level of interest and challenge is conducive to learning in this learning environment, e.g. using post-test scores. Finally, the NCA values are point estimates, so no confidence intervals, can be calculated so far, for example.

In conclusion, taking measures to promote the self-determined motivation of the students in learning chemistry could enhance students' current motivation to learn in the digitally-supported learning environment. However, bottleneck analyses reveal that even students with a relatively low level of self-determined motivation (represented by low negative scores on the SDI) can show a relatively high current learning motivation. Thus, it is not only a purely intrinsic level of motivation that is necessary to be currently motivated to learn with the EXBOX-Digital (in line with the assumptions about rather autonomous forms of extrinsic motivation that are relevant for learning in school; Ryan & Deci, 2000). Furthermore, it can be motivating to provide students with manageable experimentation tasks to foster their self-perceived experimentation competence (preparatory exercises or competence-based feedback can be helpful here; Nguyen et al., 2019; Wollenschläger et al., 2011). Finally, demonstrating the usefulness and handling of the tablet PC for learning purposes could help to avoid unfavorable attitudes and increase current motivation (whereby the values in the present sample are already quite high on average). The effect sizes show that these implications can be seen as more relevant to interest (emphasizing the voluntary nature of the activity) than to challenge (challenging one's ability).

Abstract: With the rise in post-truth discourse, there is growing urgency to develop an informed understanding of the evolving nature of scientific knowledge through the teaching of epistemic practices (EPs) (i.e., practices scientists use to establish knowledge). Researchers recommend creating *epistemically authentic* environments to help meet this objective. However, creating such an environment requires teachers to make fundamental shifts in the way science is taught. Specifically, it requires highlighting the ambiguity inherent within the application of EPs and creating evaluation measures that communicate the socially negotiated nature of science. We have limited models examining how this goal can be accomplished inside formal classrooms. In this study, we examine how a teacher created an *epistemically authentic* environment using a curriculum designed to promote EPs. Our results show that the teacher was successful in creating this environment by distributing instructional authority, crowdsourcing parameters to evaluate EPs, and normalizing making wrong predictions.

Introduction

Increase in post-truth discourse has resulted in citizens questioning the validity of science and scientific methods (Hobbs, 2017; Peters, 2017). Citizens' skepticism about the nature of scientific knowledge is particularly relevant among topics such as climate change, evolution, and vaccination, where the information evolves based on emerging evidence (Chinn et al., 2021; Hobbs, 2017). Researchers recommend the integration of epistemic practices (EPs) into K-12 science classrooms to help with this reasoning gap among the public (Barzilai & Chinn, 2020; Muis et al., 2016). EPs are domain-specific processes that scientists use–such as peer review, systematic experimental design, and collecting ample evidence–to negotiate, debate, and establish knowledge across fields such as science and mathematics (Barzilai & Chinn, 2020; Sandoval et al., 2016). A deeper understanding of EPs is likely to help students understand the nature of scientific knowledge, as a construct that changes over time and one which is socially negotiated among scientists instead of as an absolute and static construct (Sandoval, 2016; Ford, 2008). However, current high school instructional structures lack an explicit focus on EPs as a primary goal of instruction (Chinn et al., 2021). Additionally, most instructional models inside schools lack the messiness of scientific information found in the real world where multiple claims are made with evidence that appears convincing (Sandoval, 2016; Ford, 2008).

Researchers recommend creating *epistemically authentic* environments inside classrooms to teach EPs (Chinn et al., 2021; Muis et al., 2016). These are classrooms designed to intentionally narrow the gap between environments found inside and outside classrooms - by engaging students with information that vary in claims, authorship, quality, and reliability of methods used. The premise is that engaging students in the ambiguity involved in the processes of *how to know* instead of processes of *what to know* - through these environments - will promote students' understanding of the nature of scientific knowledge. However, creating such environments requires a significant shift in how disciplines such as science are taught in schools. For example, from a content perspective, it requires selecting portions of science curricula that can communicate the epistemological underpinnings of scientific knowledge as fluid and changing rather than binary and static (Muis et al., 2016). With respect to pedagogy, this requires teachers to create an inquiry environment where students negotiate EPs as being good or bad, mirroring the real-world practice of peer review and the socially negotiated nature of knowledge (Chinn et al., 2021). Additionally, this environment also requires assessments that evaluate the EPs students use and additional supports that help students through negative emotional experiences that may be triggered by navigating ambiguity inside classrooms that usually direct them toward the right answer (Muis et al., 2016). In sum, this requires creating a classroom climate where ambiguity inherent in using EPs is emphasized and evaluated as opposed to a climate that focuses on content-driven instruction (Muis et al, 2016). However, important components of *epistemically authentic* environments, such as pedagogical choice, evaluation structures, and instructional supports, continue to be under-examined (Chinn et al., 2021; Muis et al., 2016). This limits our scope to understand the nuances teachers navigate to create such environments and consequently, limits the field in providing teachers with the support they need to teach EPs effectively.

Over the last couple of years, our work based on design-based research has focused on promoting EPs in science classrooms to address post-truth issues. In our previous analysis, we found that the teaching of EPs is difficult for science teachers to integrate into their existing curriculum (Cottone et al., 2022). So, in our third year of this research, we designed a curriculum unit on epidemics where the primary objective was for students to engage with EPs to understand the nature of scientific knowledge, using an agent-based simulation. In this paper, we investigate the ways in which one teacher created an *epistemically authentic* environment using this curriculum. We ask the following research questions: (1) In what ways did the teacher create an *epistemically authentic* environment? and (2) What strategies did the teacher use to promote an understanding of EPs?

Theoretical framework

There are different conceptual recommendations for creating *epistemically authentic* environments (Chinn et al., 2021; Muis et al., 2016). In this paper, we use the **PACES** framework (Muis et al., 2016) to conceptualize *epistemically authentic* environments. This framework provides a way to analyze multiple salient elements of a learning environment required to create a climate focused on EPs inside classrooms. The framework details five facets of a learning environment that should be intentionally designed to teach EPs. We use these facets to analyze the classroom environment created by the teacher. They are: 1) **P**edagogy: studies show that the use of social constructivist pedagogies, where the nature of inquiry is emergent and there are opportunities for students to engage in the knowledge building process actively - is more likely to engage students with EPs (Stroupe, 2014). Here the focus of the inquiry is on engaging students with epistemological underpinnings of scientific knowledge. Additionally, honing in on opportunities that highlight the ambiguity or paradox inherent within the use of EPs is likely to promote an informed understanding of scientific knowledge (Chinn et al., 2021), 2) **A**uthority: this examines the degree to which the instructional authority is distributed inside a classroom. In an optimally designed *epistemically authentic* environment, the source and justification of knowledge from an expert (e.g., teacher) are decentralized. Teachers will create opportunities for students to actively engage and lead the knowledge building processes by legitimizing the criteria and negotiations students engage in to establish knowledge inside the classroom (Miller et al., 2018). Some emerging literature references this as epistemic agency (Miller et al., 2018; Stroupe, 2014), for clarity we choose to reference this as authority, 3) **C**urriculum: refers to any instructional content, and resources used to achieve the educational objective of promoting students' understanding of EPs. Refutational texts, content that explicitly focuses on scientific methods (e.g., the iterative process of experimentation, systematic planning of experiments, socially negotiating consensus), and prompts that elicit conversations about the tentative nature of knowledge are recommended as more conducive to creating an *epistemically authentic* environment (Muis et al., 2016), 4) **E**valuation: refers to ways in which students understanding of EPs is measured. Complex, less structured, or more challenging tasks that elicit mental processes (e.g., knowledge elaboration, integration of new knowledge into prior knowledge, and critical thinking) are more aligned with the goals of promoting EPs. As opposed to tasks that are simple, overly structured, and require content recall and match processes, and 5) **S**upport is any scaffolding that teachers provide to facilitate the change process in students, such as explicit modeling of critical thinking or resolution strategies opportunities for students to discuss their beliefs or acknowledgment of the negative emotional experiences that students may face during epistemic change (Muis et al., 2016).

A well-designed *epistemically authentic* environment will result in the explicit talk about EPs that lends itself to establishing an informed understanding of scientific knowledge. In such an environment, students are most likely to engage in the EPs scientists use to establish reliable and valid knowledge. This will include, designing controlled experiments, running multiple trials, testing for multiple hypotheses, and socially negotiating the criteria to evaluate EPs. We use this framework to code for interactions that occurred inside the classroom to make inferences about the degree to which the epi*stemically authentic* environment the teacher created was successful in promoting an informed understanding of scientific knowledge.

Methodology

Context

This study is part of a larger NSF-funded project that aims at designing professional development (PD) supports to promote EPs in high school science classrooms (Cottone et al., 2020). This study explores the implementation of an epidemic curriculum designed to teach EPs. Students use an agent-based simulation to design and run experiments to propose the most ideal mitigation factor to control the pandemic. This issue was chosen because it allowed teachers to draw from their recent experiences of navigating COVID-19 and the publicly contested nature of facts about the pandemic. This is a curriculum that consists of eight lessons designed for 45 minutes each. Students engaged with *"The Epidemic Unit"* while working in groups of 2-5 as they played the role of scientists trying to control an outbreak by running experiments and gathering data to find which mitigation strategies (e.g., masking, vaccination, lockdown, and surface cleaning) they would recommend as the most effective for controlling the spread of the disease. Students start by coming up with class criteria for evaluating scientific evidence and experimental designs. In the following lessons, they collect data and engage in productive disagreements about the validity of methods used across groups to come up with recommendations. In this paper, we examine the last two out of the eight lessons. These two lessons were selected because of the rich discussion we observed unfolding regarding EPs during the implementation. In the first lesson, students were asked to provide feedback on the experimental designs proposed by their peers to investigate the mitigation strategies and revise their respective designs based on the critique received. In the second lesson, students executed their experimental designs and presented their findings. The lessons were implemented in a public school in the Northeast U.S.

Participants

We used a case study methodology which requires researchers to purposefully select information-rich cases, to gain an in-depth understanding of relevant and critical issues under investigation (Yin, 2017). Therefore, we investigated one of the teachers who participated in the PD, Nafisa, and her class implementation of the curriculum. She identified herself as African American and was in her 22nd year of teaching, with previous experience teaching biology, and environmental science, all at the high school level. She taught the unit across two weeks with a section that had 25 students in her environmental class. Students in this class identified as 54% Latino/a, 24% Black, 12% Asian, 7% White, and 4% other.

Data source and analysis

We analyzed three data sources: Videos of the two classroom implementations which included whole-class instruction and small group discussion among students (90 mins), teachers' post-implementation interviews (90 mins), and classroom observation notes. The observation notes included descriptions of the classroom conditions, teachers' instructional practices, and the activities and interactions among students taking place. The semi-structured post-implementation interview was conducted to probe the teacher's specific practices, beliefs, and understanding of implementing the new curricula, as well as the teacher's experience of preparing the class and participating in the project. These two data sources were primarily used to answer the first research question on the nature of the *epistemically authentic* environment the teacher created in the classroom.

Data analysis was qualitative in nature, informed by constant comparative method (Glaser, 2008). There were three interacting phases of data analysis: a) applied open coding to classroom implementation videos, b) used a priori codes informed by **PACES** framework to code for interactions that spoke to **P**edagogy, **A**uthority, **E**valuation, and **S**upport constructs during whole class interaction. The **C**urriculum was conceptualized as the two lessons from the larger *"The Epidemic Unit"*. This included the agent-based simulation students used to design and run their experiments and teacher and student-facing worksheets. The other constructs (**P**edagogy, **A**uthority, **E**valuation, and **S**upport) were coded from teachers' implementation of this lesson (refer to Table 1) and c) thematic analysis and triangulating data. The first phases of data analysis focused on developing a coding scheme. The coding scheme was initially informed by the **PACES**, and later by emergent themes from the data. The coding scheme was debated and iteratively revised until a consensus was reached between the two authors. We each coded a sample of data using the final coding scheme and identified areas of disagreement and refined the coding process over time. Refer to Table 1 for the coding manual used and the excerpt of instructional episodes coded.

Table 1
Coding scheme and examples of instructional episodes that were coded for the lesson where students were asked to provide feedback to the experimental designs proposed by their peers

Codes	Description of Codes	Examples of Instructional Episodes
Pedagogy	Opportunities where the teacher explicitly highlights the ambiguity in *ways of knowing*, presents varying interpretations, and highlights the importance of the justification process through valid evidence, and/or highlights the iterative	The teacher highlighted the ambiguity that the public felt on the dissemination of COVID-19 vaccine information when explaining the iterative nature of scientific knowledge, "So how many people remember that conversation initially? Like if you got COVID-19 and you took the vaccine, you won't get COVID-19 […]. Then there were some people

	process of how knowledge is established in science.	like me like, I'm not taking that, how sure are you of the data?"
Authority	Moments where the teacher reinforces the legitimacy of students' role as active decision-makers by positioning them as scientists capable of driving the decision-making process in class, and by encouraging students to set their own aims for investigation.	The teacher encouraged students to select the critique they want to work on just as scientists do when engaging with feedback received from peers, "I mean you are two brilliant scientists who received feedback from fellow scientists, you don't have to ask me which to pay attention to, decide which feedback is most useful in strengthening your experiment."
Evaluation	Instances when students are exposed to the assessment criteria, and the teachers explicitly link those criteria to facets of knowledge and knowing.	The teacher highlighted that the way to evaluate students' work is to refer to the list of scientific practices students negotiated as good EPs at the beginning of the unit. "Be explicit about the evidence in terms of the data, this is what you set as a class as good way to do science. [...] We need some facts. We need to know that you're just not saying this mitigation factor works because this is what you want. Instead, show some proof that this might work. Okay?"
Support	Teachers help students through negative emotional experiences of being wrong by normalizing those experiences.	The teacher signaled it is okay to get data that negate their initial predictions, positioning this as a practice scientists do in the real world by saying, "All scientists have a plan, okay? And sometimes their plan changes. So, I want you to take that into consideration.? So, you don't have to prove your hypothesis is right, focus on the evidence you see."

Result

In this section, we present the analysis of PACES categories and our coding of how an *epistemically authentic* learning environment was created in Nafisa's classroom. We aim to provide illustrations of the main themes that emerged and how these themes connected to the teacher's attempt to provide an informed understanding of the nature of scientific knowledge.

Pedagogy: Navigating ambiguity with EPs and historical narratives

In implementing the curriculum, Nafisa honed in on opportunities to highlight the ambiguity and uncertainty inherent within the EPs used by scientists to investigate emerging processes and establish scientific knowledge. She used students' lived experiences with COVID-19 to explicitly focus on the ambiguity that resulted among the public, from not understanding the iterative nature of scientific knowledge. For example, she mentioned in her post-implementation interview, "So, I asked the students about the vaccine and how scientists, you know, came up with a vaccine and they first said it won't give you COVID but then people who got the vaccine started getting sick, so were the scientists lying?"

Nafisa navigated these ambiguities by asking students to reflect on the nature of evidence (e.g., did they have a control group? how many times did they run the experiment? Did they test multiple hypotheses?) when confronted with conflicting results or claims when running their respective experiments. For example, the observation notes highlighted that when two groups designed their investigation on a common mitigation strategy (e.g., masking) but found that their experiments resulted in opposing claims of the effectiveness of the strategy. Nafisa asked the two groups to examine their EPs, she noted,

> You need to make sure that your process in which you're carrying out your plan is one that will not be biased toward what you think is right, as you carry out the processes you'll be able to get enough evidence to either prove your hypothesis correct or find something that needs to change [..] Did both of you use the same control design - I see that you (Group A) tested masking with a vaccine and (Group B) tested with social distancing. Now, look closer did you both run the same number of trials [..] "

In the above example, Nafisa draws students' attention to the iterative nature of scientific knowledge by mentioning that the goal of EPs is to improve our understanding of a concept or product as new or opposing evidence emerges. She references EPs as 'processes' and points out that these are in place to ensure scientists do not advance knowledge that they are biased to thinking is right, it is in place to avoid confirmation bias.

Nafisa also used examples of incidents in the history of science, where the knowledge changed over time as the field progressed to gather more evidence and began to think about the problem differently. When setting the context for students to critique each other's EPs, she used the example of how vaccination for chickenpox was developed and linked it to the development of vaccination for COVID -19.

> Before you were born, the only way to get over chicken pox was to get it. It took time for scientists to test and retest until they figured from the people who had the disease the antibodies required to fight it and create a vaccine from it. Same with COVID [..] They are still figuring it out. But that's okay! because in science, nothing is necessarily a hundred percent because there are new developments.

In the above examples, Nafisa used historical narratives to communicate that scientific knowledge is never absolute. It changes in the face of new evidence. She communicates that EPs make the processes reliable for a certain period and that they are in place to ensure that biased perspectives or one person's agenda are not used to establish knowledge. She tackled ambiguity by using examples that normalized the iterative nature of scientific knowledge and by redirecting students' attention to critically examine the EPs used by scientists to make the claims.

Authority: Providing student choice while retaining invisible authority on EPs

Nafisa created opportunities for students to actively engage and lead the knowledge building processes by legitimizing the criteria and negotiations students engaged in to evaluate EPs inside the classroom. She ceded her authority as the bearer of the 'correct' knowledge, by verbally using sentences that positioned students as scientists and thereby communicating their capacity to actively drive the decision-making process within their small groups. For example, when a group of students asked which mitigation factor they should investigate, Nafisa responded, "You can choose any two mitigation factors of your choice, but you need to tell me why! And how will you investigate it? You are scientists so tell me how these factors will help you generate multiple hypotheses?" In this quote, Nafisa emphasizes that they have the agency to investigate the mitigation factor of their choice. She instead redirects their attention to justify the rationale behind the choices they make and to focus on explaining why they made certain decisions around EPs such as running a certain number of trials, and the nature of the control group. By doing so she dissolves her authority as the figure whose criteria need to be met.

Interestingly, while she ceded most of the authority on decisions made about the selection of mitigation factors, the trials to run, and the control group to be selected. She retained authority on the broader criteria of the EPs that should be met to design a good scientific experiment. For example, when setting the context for experimental design, she mentioned that every group should meet the criteria of EPs they negotiated earlier as a class as good practices such as having two hypotheses, running multiple trials, and recording their methods. She noted, "Remember, you have two different hypotheses and that means for each hypothesis you're going to have two different plans [...] but remember, this is your plan and we're going to carry out your plan. And you can always change." In this quote, Nafisa reiterates that students have the choice to design and change the experiments they saw fit while emphasizing that these choices should be negotiated within the broader EPs that were socially negotiated as the best practices to follow in class. Similarly, in another video of classroom implementation, she communicated that while students are being asked to critique their peer's designs, she has already graded their designs but made these invisible because she does not want to influence students' opinions about their peer's designs. She said,

> [M]any times scientists receive feedback from their colleagues throughout the process because they have to eliminate bias, okay? So it's not what you think or what you feel, but based on data [...] I didn't put a grade because I don't want to influence your critique of your classmate's design.

The above examples show that the teacher ceded authority in terms of choice in designing individual experiments but retained an invisible authority on whether the broad parameters of EPs that the class had negotiated as good practices were being retained or violated. She justified the maintaining of invisible authority as a way to communicate that while science is subjective (e.g., it is shaped by scientists' choice of the question to pursue, and methods to study) this negotiation occurs within a larger realm of what scientists have established as good EPs or measures to study processes, in her post-interview. She positioned EPs as the authority to defer to instead of her as the teacher or the more knowledgeable one in the classroom.

Curriculum: Focusing on ways of knowing instead of what to know

Nafisa created an *epistemically authentic* environment using a curriculum that explicitly focused on EPs. The learning objective of the unit was on understanding *ways of knowing* scientists use, by engaging with EPs rather than finding the one correct mitigation strategy that could resolve the epidemic students were investigating. The teacher noted in her post-implementation interview that the primary focus of the curriculum remained on the process of evaluating good scientific experiments from bad ones.

> Unlike the lab experiments we run, where students usually just follow a manual imitating scientific practices. I see students actually engaging with scientific practices in this unit because we are not focusing on the content, but on the skill of how scientific knowledge is established […] like changing and tweaking their predictions and using the class criteria of good practices to evaluate their decisions.

In the above excerpt, Nafisa points out this curriculum stood apart from other traditionally used practice-based curricula such as lab experiments because students weren't following a prescribed standard of instructions for emulating EPs. Instead, students were actively making predictions and revising them based on the evidence they collected from the simulation. Additionally, Nafisa pointed out that not having access to which of the mitigation factors was most effective in tackling the pandemic that students were investigating, helped keep the focus of instruction on the EPs. In her post-implementation interview she noted,

> I didn't know the answer myself. The curriculum did not tell me if vaccination or masking or distancing was the most effective. So, I guess there wasn't an answer I could accidentally nudge students towards. When students asked me questions, I would ask them to find their answers in the methods they were using.

The above excerpt indicates that the explicit focus of the curriculum on EPs allowed Nafisa to retain her students' attention on EPs and the nature of scientific knowledge. Not having a predetermined right answer ordained by the curriculum helped Nafisa retain the focus on EPs instead of scaffolding students to design experiments to get the predetermined right answer.

Evaluation: Using socially negotiated criteria for assessing EPs

Nafisa crowdsourced the criteria for evaluating EPs from her students and she used this class criteria recurrently for students to evaluate their own designs and critique their peers' designs. She had students at the beginning of the unit brainstorm and negotiate a list of EPs they considered to be parameters of a well-designed scientific experiment. This included parameters such as reporting the number of trials as an attempt to communicate all evidence collected, designing experiments that tested multiple hypotheses to prevent confirmation bias, etc., These were displayed on the google slides throughout the lessons - especially during the time when students were asked to critique others designs and revise their own. In one of the videos of classroom implementation, when the students asked Nafisa to check their experimental designs to see if they are doing them right, she pointed to the slide that had the class criteria on good scientific experiments and told the students that "The answer does not lie with me. Check if your design meets the criteria you set as a class, [...] look at the critique you got from your peers. Go talk to them and ask if it looks okay to them."

On another occasion, she prefaced the need for students to collect and record the evidence they were referring to make the arguments about the effectiveness of their chosen mitigation strategy. She guided students to take screenshots of their trials from the simulation and record them on their final poster so that other scientists can make sure that they are not making up data to prove their hypothesis correct. The teacher told the whole class, "Remember, you cannot convince people without even running an experiment because [...] We need some facts. We need to know that you're just not saying this is what I want to do, but you have some proof that this might work." Nafisa's implementation of the curriculum used evaluative strategies that were socially negotiated within the class, which dissolved any impression that the right answer lay with the teacher. This allowed an environment where students were more deeply engaged with EPs than attempting to find the answer that the teacher thought was right. She also connected this practice of referencing a socially negotiated list of practices to evaluate EPs to the real-world practice of peer review used by scientists. She mentioned that scientists critique other scientists on the EPs used to establish knowledge. When setting the context for peer critique she gave the following instruction.

> So, what you have at your tables, are your list of good scientific practices. You may use them to help you determine if they are carrying out good scientific practices [...] because scientists

> always give each other advice, right? Scientists do not work alone. So other scientists in class are going to see your plan and give you some advice or suggestions. They will critique to improve your design. They use the criteria we all agreed on are good practices in this class.

In the above examples, Nafisa communicates that the criteria of evaluation are the EPs that students used to design their experiment, and the parameter for evaluating if these EPs are 'good' or 'bad' is by repeatedly referring to criteria the class had negotiated as signs of a good experiment. She communicates to students that the process of peer review is in place to prevent biases and that scientists do not work in isolation. This communicates the socially negotiated nature of scientific knowledge. That scientific knowledge is generated within a larger culture, the norms of which are upheld by the scientists through the process of constantly critiquing emerging research by evaluating the EPs used by other scientists.

Support: Normalizing making wrong predictions

Nafisa helped students navigate negative emotional experiences of being wrong or being lost while engaging with ambiguities by normalizing these experiences. She used real-world examples of scientists changing their claims based on new evidence and reiterated that the process of proving predictions wrong is a way of ensuring EPs are not violated by scientists. For example, where students appeared frustrated on getting their predictions about their chosen mitigation strategy, masking, wrong. The teacher told the group,

> All scientists have a plan, okay? And sometimes their plan changes. So, I want you to take that into consideration. [J]ust to give you an idea, initially, when the vaccine was introduced? How many people do you think they tested it on before introducing it, and how many times did they run those tests?

On another occasion, when setting the context for students to provide feedback on each other's findings. She mentioned that the focus should not be on if the group's prediction came true, it should be on how they investigated their mitigation factors and made sense of the data. She reiterated that it is okay if the group's findings demonstrated that their data proved their respective hypothesis wrong.

> So what you're going to do today is we are actually going to give each other feedback. We're gonna be honest because it's always a good practice to notice if you or others as scientists did not get something correct, it's how you do good science.

In the above examples, Nafisa creates an environment for students to feel okay with being *wrong* about their predictions or hypotheses. She normalized the process of making the *wrong* predictions with personal narratives that normalized the idea that scientists change their claims based on evidence they see, which eased students' frustration of finding and reporting data that did not align with their hypothesis.

Discussion

This paper contributes to the recent calls to investigate curricula that teach EPs in formal classrooms, specifically the supports that result in the creation of *epistemically authentic* environments in science classrooms (Chinn et al., 2021; 2020; Muis et al., 2016). Our findings affirm assumptions that attending to multiple salient features of an environment such as curriculum, assessment, and evaluation concurrently and intentionally directing them to emulate EPs scientists do in the real world is an effective way to create an *epistemically authentic* environment. We found that a curriculum that explicitly focused on EPs where students actively engaged in a scientific investigation where outcomes were emergent and not predetermined facilitated the creation of an *epistemically authentic* environment. The epidemic unit Nafisa used did not focus on students' ability to find the right mitigation factor. There was not one right answer the teacher could guide students to, therefore the focus of instruction remained on the EPs scientists use to establish knowledge (e.g., designing systematically controlled experiments, socially negotiating the validity of claims through peer review, and revising predictions based on evidence). Our findings provide empirical evidence to advance the existing hypothesis that engaging students in curricula where teachers explicitly highlight ambiguity and engage students with paradoxical perspectives of the ways in which scientific knowledge is established (Chinn et al., 2020; Muis et al., 2016) - is an effective way to engage students with EPs in science classrooms.

Our findings suggest the importance of attending to distributed instructional authority in the classroom when creating an epistemically authentic learning environment. Our findings align with previous research (Author et al., 2020; Stroupe, 2014) that indicates providing students with authority to negotiate the knowledge building process that occurs in classrooms can successfully afford students to engage with EPs. Nafisa consistently redirected questions about the "correctness" of students' experimental design to the class criteria of good EPs the students had negotiated early on in class. She used the socially negotiated EPs as the evaluation criteria to consult - she did so by ceding authority to students to provide critiques and recommendations to each other's designs but by retaining an invisible authority on the border parameters of EPs. Our findings also reveal that instructional supports are necessary to address students' emotional reactions when engaging with e*pistemically authentic* environments. Previous research recommended teachers to explicitly model resolution strategies or provide real-world examples that normalize the negative emotions students may associate with getting their predictions wrong (Muis et al., 2015). In our study, Nafisa provided emotional support in the form of linking the ambiguity students experienced to lived experiences with COVID-19. She repeatedly emphasized how scientists conduct experiments to find the truth and not necessarily to prove their predictions right, students in the class felt comfortable reporting their methods even when they nullified their predictions. Previous research has shown that students struggle to engage with this complexity of normalizing "wrong predictions" (Cottone et al., 2022). This indicates that emotional support can help students grapple with the tension they may experience when pursuing directional goals (i.e., goals that promote more inquiry) instead of accuracy goals (i.e., goals of finding the right answer) when creating an *epistemically authentic* environment. Future research will examine how this environment resulted in improving students' epistemic performance in class.

Teachers' Engagement with Analysis Outputs of Large-Scale Identity Productions as a Move Towards Culturally-Informed Curriculum Development

Raquel Coelho, Stanford University, rcoelho@stanford.edu
Alden McCollum, New York University, amccollum@nyu.edu

Abstract: We previously demonstrated that insights into students' socially shared knowledge and identity expressions could be gained through analysis of large-scale identity artifacts - productions shared by students with the world via social media platforms or more hybrid spaces such as writing or audiovisual competitions. Here, we take a step further and explore how engagement with these artifacts could inform teachers' design work in culturally-informed ways. We now address this question in context. We designed a workshop for in-service public school teachers focused on helping them engage in planning that is centered on students' everyday lives by drawing on the analysis outputs from our previous work, including an outline of top topics students wrote about in essays submitted to a national writing competition in a Global South country and a subset of those students' essays. Our findings suggest such analysis outputs can play a number of roles in teachers' culturally-informed planning.

Introduction

It is well established within educational research that teachers need to build instruction that draws on students' cultural resources developed in their out-of-school experiences for their potential to improve teaching and learning for both children and adults, and for those from both dominant and non-dominant backgrounds (Gay, 2002; Gutiérrez & Rogoff, 2003; Moll et al., 1992; Ladson-Billings, 1995). By not recruiting students' cultural resources, educators miss crucial opportunities to support student learning and might, even if inadvertently, reinforce a deficit framing of marginalized students, their families, and their communities (Gutiérrez, Morales, & Martinez, 2009). Over the last three decades, two pedagogical frameworks – Funds of Knowledge (FoK; Moll et al., 1992) and more recently, Funds of Identity (FoI; Esteban-Guitart & Moll, 2014) – have been highly influential in providing guidance for teachers to capture students' cultural resources and capitalize on these in their instruction. The Funds of Knowledge approach focuses on the collective bodies of knowledge and skills that students develop through their participation in the practices and lived experiences of their families – their *funds of knowledge;* whereas Funds of Identity, which builds on the FoK approach, focuses on "whatever and whoever" (Moll, 2016, p. 48) students perceive as meaningful to self-definition, self-expression, and self-understanding, and that can include their funds of knowledge (Esteban-Guitart, 2012; Esteban-Guitart & Moll, 2014).

While FoK researchers' original approach called for teachers to visit students' families and engage in interviews and ethnographic work (Moll et al., 1992), many other methods have since been proposed for teachers to learn about their students' funds of knowledge, including, for example, having students discuss local issues (Zipin, 2009; Zipin et al., 2012); giving students opportunities to share personal experiences during classroom instruction (e.g., Barton & Tan, 2009; González & Moll, 2002); calling on students to apply their cultural knowledge (e.g., Maher et al., 2001); sharing meaningful artifacts in the classroom (e.g., Hughes & Greenhough, 2006), etc. FoI researchers have proposed complementary methods to learn about students' funds of identity/funds of knowledge, especially through the use of *identity artifacts*: student productions that constitute visions, expressions, or understandings of self (Esteban-Guitart, 2012; Esteban-Guitart & Moll, 2014). Among the techniques and procedures used by FoI researchers to help teachers learn about students were, for example, graphical representations about people, institutions, activities, and hobbies that are most important or significant to students, as well as photographs of participants that would alow teachers to learn about students' routines and ways of life (Esteban-Guitart, 2012). As happened with FoK, a number of different strategies have been proposed to teachers to recognize students' funds of identity. These include, for example, personal diaries (Esteban-Guitart, 2012), poems (Subero et al., 2015), photos (Marsh & Zhulamanova, 2017), maps (Moulton, 2018), meaningful artifacts from students' life experiences (Zipin, 2013), and/or identity drawings (Ordóñez et al., 2021).

In previous work (Coelho & McCollum, 2021), we proposed a new type of artifact that could aid teachers in crafting a repertoire of knowledge about their students: the outputs of automated analysis (via structural topic modeling) of student-produced essays. We frame this as part of a discussion of how teachers might make use of the outputs of automated analysis of large-scale identity productions that are shared by students with the world, be it through social media platforms or through productions that circulate in more hybrid spaces, such as, for instance, the competition essays we consider. While FoK and FoI methods have their merits and present excellent options when feasible, teachers need as many strategies as possible as some are time consuming (e.g., visiting families), and as students will not always be willing to volunteer information about themselves and their families or communities to teachers (Moje et al., 2004). Further, we argue that the use of the same strategy over and over may not always be productive for teachers, may be tedious for students, or may not work well for all teachers across the curriculum. As such, we believe that teachers' toolkits should be continually expanded to include complementary strategies.

We see great potential in the automated analysis of large-scale community-produced identity productions to elucidate patterns about students that lie outside the realm of unaided human perception and which no feasible amount of manual analysis could bring to light. By analyzing a large corpus of student essays submitted to a national writing competition in a Global South country using machine learning techniques, we have previously demonstrated that insights into students' socially shared knowledge and identity expressions could be gained through analysis outputs in the form of a collection of topics and a smaller corpus of associated essays (Author & Author, 2021). In the current study, we were interested in addressing the following question: What role do the analysis outputs of community-produced identity artifacts play in setting teachers up for designing culturally-informed learning experiences? Stated differently, how were teachers triggered by these analysis outputs? Ultimately, we are interested in understanding and answering a larger question: How and why might reviewing essays (and the topics thereof) written by students who are not a teacher's own students but who may navigate similar spaces, and who may share similar experiences, practices, and communities, support a teacher's design work in culturally-informed ways?

To address these questions in context, we designed a workshop for in-service public school teachers focused on helping teachers engage in planning centered on students' everyday lives. In the first three weeks of the workshop, teachers engaged with the analysis outputs in the form of tables that outlined top topics students chose for their essays (29 topics total), as well as a subset of students' essays (10 essays per topic; 290 essays total).

Method

Research context and participants

The context of this study was a three-week, nine-hour unit that was part of a seven-week, 21-hour workshop for in-service public school teachers from different disciplines, held online over Zoom, due to limitations on in-person field research during the Covid-19 pandemic.

Eleven public school teachers from different school districts, school sizes, and disciplines (two language arts teachers, six science teachers, one history teacher, and three math teachers) from a state in a Global South country were selected to participate in the study. After receiving ethical approval from the Institutional Review Board, we approached the state's Department of Education requesting their permission to allow teachers from different school districts to participate in the study. We asked the Department of Education to select teachers who they believed are especially committed to working with disadvantaged students under the assumption that, given teachers' dispositions and experience, they would be more likely to join the study as well as to make contributions to the design of the workshop, as this was one of the goals for a concurrent study seeking to study the environment designed to support teachers' work toward culturally-informed curricula with an eye toward progressive refinement.

After receiving recommendations from the principals of 15 schools recognized for excellence (the Department of Education interpretation of our selection criteria), the State Department of Education compiled and sent to us a list of 26 potential candidates. All 26 were invited via email for an interview prior to the beginning of the workshop. Of those, 16 accepted the invitation and were interviewed. The goal of the interview was to learn more about the teachers' backgrounds as well as their teaching philosophies and practices so as to inform the selection of a diverse pool of teachers and thereby capture a broader range of experiences and perspectives.

The final 12 teachers selected had anywhere from 6 to 35 years of teaching experience and included six women and six men. With the exception of one teacher, who taught grades 6, 8, and 9, most teachers taught high school students at the time of the study, with some of them also teaching in one or more grades from 6-9. Teachers averaged 33 students in their classrooms. About six teachers lived in the capital of the state or in the capital metropolitan area. The other five lived in small sized cities in the countryside of the state. The majority taught in urban schools, with those living in smaller cities reported having a greater average number of students living in rural areas. All teachers were asked to sign an informed consent before the beginning of the study. Given the time intensiveness of the interview and workshop, each teacher was compensated $10 per hour for all activities completed as part of the study as a means of incentivizing them to remain in the study over time. All but one teacher completed the entire workshop series, dropping before the beginning of the first workshop meeting.

The workshop was focused on using the analysis of large-scale identity artifacts to help teachers engage in planning that is centered on students' everyday lives. More concretely, the workshop was developed to help teachers in state in of a Global South country (from hereon, State X) redesign an existing curricular unit and adapt/complement it so that it incorporates some aspect(s) of students' out-of-school experiences. The workshop was divided into two units. In the first unit of the workshop, which is the focus of this study, one core activity was designed to support teachers to achieve the above mentioned goal: a) having teachers engage with and learn from outputs of automated textual analysis applied to a large corpus of essays (17,936 total) written by students from State X who participated in the Portuguese Language Olympics (PLO) between 2012 and 2019. More specifically, teachers were given access to the analysis outputs in the form of tables that outlined top topics students chose for their essays (29 topics total, e.g.: "Violence against Women, Children, and LGBTQ people," and "Water: Scarcity, Drought, and Misuse"), as well as a subset of students' essays (10 essays per topic; 290 essays total).

As far as the ethics of using this data in this way are concerned, it is important to note that teachers and students sign agreements to transfer ownership of the data to the institution that organizes the Portuguese Language Olympics, agreeing to have their essays published on a range of outlets. To further address the issue of privacy and data management, all essays used in our study were anonymized, including references to schools and students. Additionally, teachers who participated in the study were asked not to share the data outside of the study. It is also important to note that, despite the data being produced for a different initial purpose, the Portuguese Language Olympics' mission is to make students' voices heard, and we believe that our study supports this goal while protecting the privacy of the students; repurposing this data to support teachers in designing curricula and lesson plans ultimately benefits, even if indirectly, the students who produced the essays.

Timeline, units and activities for the first unit are presented in Table 1. The first unit consisted of three meetings of 90 minutes each, distributed across three weeks. Teachers also had 90 minutes of asynchronous work per week.

Table 1
Workshop timeline and activities

Week	Event	Content/Activities
1	Meeting 1	Introduction to the workshop; Community building activities.
1	Homework 1 (asynchronous)	Teachers were asked to read and select topics they considered most relevant to their own students. They then selected and read a collection of essays associated with those topics. After that, they were asked to summarize the situations and experiences described in those essays. Next, teachers reflected on questions such as: What comes to your mind when reading about these topics and associated essays? Why? Do you think about your own students when reading about these materials? Why or why not?
2	Meeting 2	In small groups, teachers were asked to discuss what stood out to them about topics and essays, any relevance to their students, and any connections between situations described in the essays and their students. As a group, we discussed the importance of learning goals, setting up the stage for Homework 2.
2	Homework 2	Teachers were asked to describe their learning goals for their curriculum unit.
3	Meeting 3	In small groups, teachers were first asked to think about how to improve Homework 2. Then, teachers gave feedback to each other on their planned curriculum goals.
3	Homework 3	Teachers were asked to revise their learning goals based on the peer feedback received during Meeting 3.

Data sources & approach to data analysis

The data used in this study consisted of the following: 1) transcriptions of three 90-minute video recordings (recorded via Zoom's integrated recording feature) and 2) 11 teacher workbooks/reflective diaries, in which teachers documented their reflections about their own students based on their reading of topics and essays.

To answer the study's research question, the first author first mapped all instances where teachers talked during the two meetings in addition to each teacher's individual workbook. This process was done for all 11 teachers, so the unit of analysis consisted of two documents for each teacher (22 documents total), one containing a set of excerpts from the meetings and another one composed of the teacher's workbook. The data were then uploaded into NVivo, a qualitative analysis software package that allows for coding and analysis of documents. Next, the first author coded each teacher's documents individually and, as she progressed with the analysis, constantly looked for patterns in the data. After deciding on categories to label the patterns found in the data, the author shared an analytical journal with the second author and three other researchers, containing raw data passages and preliminary analytical findings. The second author and external researchers were asked to comment on the first author's interpretations. Categories were revised based on their feedback and the final phase of analysis resulted in three learning processes that teachers used to learn about their students through engaging with the analysis of community-produced artifacts, namely.

Findings and discussion

A crucial aspect of implementing culturally-informed instruction is the need for teachers to build knowledge on their students' cultural resources– including students' funds of knowledge and/or funds of identity – and attend to those resources in the classroom. Teachers who participated in this study were invited to engage with topics and associated essays produced by students whose macro-communities (state, country, area) overlapped with those of the teachers' own students. Analysis of the data suggests that topics and essays played a number of roles in teachers' planning. While the topics and essays served multiple functions for every individual teacher, in the analysis we present here, we group teachers based on which of the following three functions was most prominent for each of them: a) topics and essays as a basis for analogical mapping; b) topics and essays as tools for brainstorming and ideation; and c) topics and essays as a platform for dialogue with students' voices. Below, we trace illustrative examples of how each of these functions were apparent in different teachers' participation in the workshop.

Topics and essays as a basis for analogical mapping

For four teachers (two math, one history, and one language arts teacher), topics and essays functioned as a basis for analogical mapping (Gentner, 1989). The issues and situations students described reminded teachers of some prior experience stored in memory, sometimes changing the way they thought about one or both situations. These teachers mapped elements of the topics and essays to the substantive nature of the lived experience between a child and their place, and further mapped this onto their own students' situations. For example, Ricardo, a history teacher, selected to read essays in which students shared their concerns about their most immediate social reality (the daily life of their neighborhood or city) and about the greater reality of their state and country (issues related to health, education, violence, etc.). He provides a number of examples of how topics and essays could function as a basis for analogical learning. During a brainstorming group activity, Ricardo shared the following:

> *I selected texts that are very connected to certain aspects of the country's reality, which if we stop to think about it, citizens in general should have access to education, basic sanitation, or safety in relation to crime. In my homework for this week, I highlighted one thing, let's put it that way…what I realized is that they (my students) know what's going on around them, they have a certain awareness of the absence of public power in several areas – that the school and the health center are both falling apart, that the little square in the neighborhood, which could serve as a leisure space, is all destroyed, plundered, taken over by crime, etc. …and they worry about it, they feel this insecurity in their daily lives….**a very interesting text that talked about this issue … if we stop to think about the basic right of freedom of movement, the right to come and go ... it seems to me that the text was from (city), from a student from (city), and he talks about how this right is denied to him, because if you leave your house, you can be the target of an assault, a violent action, whatever**…* (Meeting 2, First Activity: Group discussion of topics and essays; connections to students' lived experiences)

In this segment, Ricardo focuses on a specific essay that caught his attention, in which a student claimed that a high crime rate in his neighborhood is a denial of his basic right to freedom of movement. Ricardo draws an analogical connection between this essay's author and his own students and the ways they have basic rights denied to them. Later in the same activity, Ricardo discusses how he applied this analogical insight in his 12th-grade classroom during a lesson on the military dictatorship in 1960s in the country in which Institutional Act #5 (AI-5) was brought up:

> *… we got into how the AI-5 suspended the right to habeas corpus, which is the mechanism that in practice protects the citizen's right to come and go, and I started to discuss with them… what*

> *is this right to come and go…in what situations is your right to come and go denied? Why is the habeas corpus an important legal mechanism? And I was saying that it prevents illegal arrests, for example…a given authority, when it takes away your right to come and go, what does that mean? It arrests you, puts you in jail, right? The authority has to substantiate the reasons why it is arresting you, which law you violated….so habeas corpus exists because of that and it is such an important mechanism, that I don't know if you (teachers) know...any citizen can ask a judge, it doesn't have to be a lawyer…so I made this relationship, because I said, the text I read about this issue of* ***being able to walk freely*** *around (city) caught my attention…* (Meeting 2, First Activity: Group discussion of topics and essays; connections to students' lived experiences)

In a different brainstorming activity, Ricardo makes explicit the connections between the situation described by the essay's author and concepts from his discipline, such as dictatorship and democracy. Using the essay as a starting point, Ricardo shares that he wants students to understand several big ideas around democracy and dictatorship through helping students reflect on their own rights. In the following excerpt, for example, he connects a situation described in an essay that was previously brought up in the workshop with concepts of his discipline in articulating goals for students. Specifically, he wants to help students understand that governments can violate citizens' rights both by omission (in a democracy, as evidenced by the student's essay) and by abuse of power (in dictatorial regimes).

> *… my students will understand that a simple basic right of a democracy, such as peacefully gathering to demand from public authorities the resolution of a certain problem, or to complain about rights being violated, becomes a crime against the state that must be suppressed. This is in the context of dictatorship.* (Meeting 3, Second Activity: Feedback in groups on teachers' curricular unit goals)

Ricardo plans to invite students to investigate and reflect on whether their basic rights are being denied; to help students understand what a democracy is and how it works; and to give students the tools to change their realities.

> *I circled back to this topic a lot, so that students would have something lasting, which would be the functioning of a democracy itself. Even if later on … they forget those details, for example, what happened during the military dictatorship, the redemocratization process, … they have the ideas of … how a democracy works at a basic level.* (Meeting 3, Second Activity: Feedback in groups on teachers' curricular unit goals)

Ricardo's engagement with topics and essays illustrates how these can function as a source of new learning through analogical thinking. It also evidences how these can support the design of learning experiences that are inextricably linked to students' lives, just as identity artifacts produced by students during classroom instruction would under funds of identity approach (Esteban-Guittart & Moll, 2014). Through a series of analogical reasoning moves departing from one single essay, historical events in Ricardo's planning become inextricably linked to his students' daily lives.

Topics and essays as a tool for brainstorming and ideation

For three teachers (one math, one biology, and one geography teacher) topics and essays served primarily as a tool for brainstorming. It was not a specific topic or essay that called these teachers' attention and motivated their decisions; instead, brainstorming exercises played a bigger role in their planning, including exercises that prompted teachers to explore possible connections between topics or situations described in essays and the curriculum, working in both directions (that is, from essays to curriculum and vice versa). Bruno (a math teacher) exemplifies the use of topics and essays as a brainstorming and ideation tool.

In developing his plan for a curricular unit about percentages, Bruno's first idea was to work with percentages in the context of public investment and economic development, but he later shifted his plan toward focusing on percentages in the context of daily purchases. His first mention of working with percentages in the context of economic development is developed dialogically with colleagues:

> Bruno: Shall we brainstorm one with percentages?
> Rita: Let's do it.

Paula: That's cool too. I like the idea of working with probability too – I think it's a very good topic, but let's go with percentages …
Bruno: Yeah, because percentages…we would be able to use it with any of the topics (from the essays) that we choose.
Paula: I think so too.
…
Bruno: I could teach percentages in the context of … Ok, so, I think percentages cover a lot of these topics. We can cite more than one here.
Paula: Many.
Rita: Public investments.
Bruno: Public investments.
Rita: Economic development.
Rita: Economic development.
(Meeting 2, Second Activity: Brainstorming connections between disciplinary learning and students' lived experiences in groups)

In the above exchange, Bruno invites the two other teachers in his group to generate ideas collaboratively, and they welcome his invitation. Four classic guidelines in brainstorming research (e.g., Osborn, 1963) can be observed in the group exercise. The first of them is *freewheeling*; Bruno seems comfortable sharing his ideas, no matter how wild they are. He starts with curriculum content in mind (percentages) and moves freely through many more ideas, such as public investment and economic development. Here, we are seeing the second classic guideline for brainstorming: *quantity*, which encodes the notion that, the more ideas there are, the higher are the chances of arriving at good ideas. In this case, these ideas come from the topics that Bruno was presented with, highlighting once again the potential for this type of engagement with outputs to support teachers in designing instruction that engages with issues that students seem to care about.

In a later brainstorming activity, Bruno discusses his decision to change his plan while working and reflecting on his curricular unit, bringing it – even if not intentionally – closer to what students actually experience in their daily lives:

> *Do you understand? My initial idea was to work with a percentage of profit and loss. I proposed the topic of public investments, economic development, economy of the region. Even thinking about a somewhat political side, of city hall policy, of the city, economy of the region and of the city, even thinking about a public policy even with this profit and loss. Then I started writing it down and saw that I was proposing something that had nothing to do with politics anymore, you know? I've already put it into percentages in general, including, for example, you arrive at a store and make an analysis of whether that purchase you are going to make is worth buying in cash or dividing it ten times. Then I started framing the situation in that sense, you know?* (Meeting 3, First Activity: Brainstorming connections to students' lived experiences in groups)

Bruno's decision to change his plan is supported by another teacher at the end of the group activity, who explains back to him what he is doing, which is actually getting closer to students' experiences. The following segment illustrates two other guidelines for brainstorming: *combination and improvement* by other participants and *criticism being deferred* to until after the group activity.

> *Bruno, I think you should ask this question more about the students' daily life, this percentage, just like you did, in the second case. So, putting it this way, the student will make a purchase, he has X discount, you say "is it feasible to pay in cash, in installments, the increase." I think it makes more sense for the student. Even for the student's understanding from what he has, from his daily practice, because sometimes he will think, "Why do I have to learn percentages? Where am I going to apply this here?" And it is present all the time in his life.* (Meeting 3, First Activity: Brainstorming connections to students' lived experiences in groups)

These passages show how a teacher draws on topics (analysis outputs) to bring his plan closer to his students' lives, strengthening the evidence that engaging with analysis outputs can support instruction connected to students' lived experiences.

Topics and essays as a medium for dialogue with students' voices

Finally, for four of the 11 teachers, topics and essays served mainly as a platform through which they entered a conversation with students' voices and built knowledge around, among other things, the importance of inviting students' worlds into the classroom, their own role in their students' lives, and the school's role in dealing with social issues through making space in the classroom for students to discuss topics that are relevant to them and to society as a whole, but which are usually not considered part of the official curriculum and are often treated as taboo topics. Here, analysis outputs served as the medium for *a knowledge building dialogue* (Wells, 2000), allowing teachers to construct new knowledge and understanding through information from these sources that went beyond teachers' past experiences. Ferrnando, a biology teacher, exemplifies how analysis outputs served as a platform through which he could reflect on the importance of making connections to students' lived experiences. When asked whether he thinks about his own students when reading these artifacts, he shared the following in his workbook:

> *Yes, it feels like these essays were written by my own students. I saw a similar experience when I did a survey about their experiences and practices in the beginning of the school year. The diversity of ways of seeing things highlights how students see the world. Often these students do not verbalize it (because they do not have the opportunity to do so) in the classroom*. (Homework 1, Answer to "Do you think (or not) about your own students when reading these materials?)

That the analysis outputs ignite reflection in Fernando becomes even more evident when Fernando is asked what comes to his mind when reading selected topics and essays:

> *Reading students' essays on such diverse topics highlights how students approach the same topic in so many different ways, and have so many different views about the same issue. This exercise can open up possibilities for approaches not thought of before by the teacher.* (Homework 1, Answer to "What comes to your mind when reading these materials?)

Similarly, when asked to reflect on his main takeaways from the exercise, Fernando articulated that reading students' essays and thereby learning about students' ideas on a given topic can help teachers design instruction that is closer to – and thereby more relevant to – students' experiences.

> *It is important to read students' conceptions about certain topics before preparing lessons on that topic. Based on students' ideas and conceptualizations, it is possible to approach certain themes in a way that brings them closer to the students.* (Homework 1, Answer to "What are your main takeaways from this exercise?)

Fernando's reflections highlight the potential that this sort of engagement with students' voices through topics and essays may have in bringing teachers closer to adopting culturally-informed teaching practices and/or philosophies.

Conclusion

In this paper, we have discussed how having teachers engage with analysis outputs of large-scale identity productions can support teachers' design work in culturally-informed ways. Our findings suggest that such an approach has great potential to complement teachers' toolkits and enkindle culturally-informed curriculum design. Through engaging with texts, teachers in our study recruited three separate but intertwined learning mechanisms to build new knowledge: analogical mapping, brainstorming, and dialogue. To capitalize on this potential, future research should use these insights to inform the design of learning experiences for teachers that incorporate the analysis of large-scale identity artifacts as part of supporting design work toward culturally-informed instruction.

The particular forms that such large-scale artifacts might take is still an open field. In the current project, we rely on automated analysis of a corpus of student writing to produce the artifacts that then get taken up in teachers' learning. We believe that such automated analysis is quite powerful, and can be useful in overcoming barriers that teachers might confront in attempting to assimilate all the details of thousands of student productions in the absence of such automated approaches. That said, automated analysis is not the only potentially fruitful way to arrive at such artifacts, and future work can further explore the possibilities here. Additionally, future work can explore varied combinations of methodologies, types of large-scale identity productions, types of analysis outputs, and teacher populations so as to see how globally applicable these findings are and where they might need to be further tailored. In our own future work, we plan to delve into the details of how teachers *use* learning like that explicated here to design learning experiences in culturally-informed ways.

Perspective Taking Interventions and Socioscientific Issues: The Case for Cautious Optimism

Eric A. Kirk, University of North Carolina at Chapel Hill, eric.kirk@unc.edu

Abstract: Perspective taking has been identified as a key skill in navigating the contentious socioscientific issues that threaten society. There has recently been a surge in interest in understanding how best to support perspective taking in science classrooms. This paper advocates for an optimistic, but cautious approach to the design and evaluation of perspective taking interventions. Although there is reason to be enthusiastic about the future of these interventions, there are also pitfalls associated with perspective taking in contexts like socioscientific issues. This paper concludes with recommendations to help address those concerns.

Introduction

The world is facing grand challenges like climate change, the COVID-19 pandemic, and environmental degradation. These issues (i.e., socioscientific issues) have profound social implications and adequately addressing these issues requires the understanding and application of scientific knowledge (Sadler, 2004; Zeidler, 2014). Because of the complex nature of these issues, straightforward solutions are rare if not non-existent, as they implicate a wide variety of people and institutions (i.e., stakeholders), often with competing interests (Sadler, 2004; Zeidler, 2014). Simple solutions that appear optimal may, in fact, present grave consequences for others implicated in the issue. For example, whereas moving away from coal is an important step in addressing climate change, it also necessarily involves taking away the livelihood of entire communities. Advocating for the divestment in fossil fuels without considering and constructing a means of addressing the economic strife it will create is myopic at best, cruel at worst. As a result, these issues are inherently moral and often politically fraught. Addressing socioscientific issues necessarily requires engagement with the ethical considerations when designing just solutions (Sadler & Zeidler, 2004; Zeidler, 2014).

Science education is well positioned to address these issues. Science learning experiences can be structured to create a supportive environment for students to engage with these issues and develop the skills needed to apply scientific knowledge to improve the lives of others (Sadler, 2009). However, traditional science instruction can miss the social context that is critically important to understand when navigating socioscientific issues. If the knowledge is to be applied, it is not enough to simply use these issues to generate superficial interest in the science content: students must actively engage in the sociocultural practices of science and civic discourse that are required to navigate these issues beyond classroom walls (Sadler, 2009; 2011). Thus, the dual goals of socioscientific issues-based education should be to help students learn about the issue and prepare them to engage in civic discourse that leads to solutions that improve society (Sadler, 2009; 2011; Zeidler, 2014).

Perspective taking is thought to be a crucial skill in these contexts. Recent studies suggest that perspective taking may be a prerequisite to higher-order reasoning about socioscientific issues (Romine et al., 2017; 2020). Perspective taking has also been explored as a way of promoting empathy for disagreeing others (Herman et al., 2020, 2021), something that feels to be in increasingly short supply in the current sociopolitical context. Perhaps unsurprisingly, there has been a recent movement to more deliberately explore how perspective taking occurs in socioscientific issues-based contexts, and how it may be supported during instruction (e.g., Herman et al., 2020, 2021; Kahn & Zeidler, 2016, 2019; Newton & Zeidler, 2020). Doing so will not be without challenges, however. Herman and colleagues (2020) have noted the need for more a rigorous approach to understanding how students engage in perspective taking in authentic contexts, acknowledging the limitations of self-report measures and fictitious contexts that are often used in research and instruction.

The purpose of this conceptual paper is to argue that perspective taking interventions should be subject to a high level of scrutiny due to the high stakes, contentious nature of these issues. I begin by discussing the role of perspective taking in reasoning about socioscientific issues. Next, I discuss promising examples of perspective taking interventions in the context of contentious social issues. I then qualify this optimism, identifying several potential challenges that may hinder the success of these interventions in socioscientific issues-based contexts. In doing so, I advocate for particular attention to be paid to the accuracy of inferences made by students, and the pragmatic consequences of those inferences. I conclude this paper with recommendations for future directions, focusing on how we might design and evaluate perspective taking interventions in educational contexts.

Literature selection

Although I argue that the studies presented in this paper raise concerns worthy of our attention, this paper should not be taken as a systematic review. The purpose of this search was not to provide a comprehensive overview of perspective taking research. Instead, I present select studies outside the field of science education that illustrate challenges associated with perspective taking that may be of interest to the science education community. Articles were identified through database searches and bibliography mining. During this process, I paid close attention to studies and lines of research that illustrate challenges associated with perspective taking in contexts like those covered in socioscientific issues-based instruction. Articles that fit these criteria were evaluated closely, with articles whose methods were either unclear or lack in rigor being excluded.

Socioscientific reasoning and perspective taking

Sadler and colleagues (Sadler et al., 2007) have identified socioscientific reasoning as a key construct that underlies engagement with these issues in the real world. This construct is comprised of four key competencies:

- understanding and appreciating the inherent *complexity* of the issue that must be considered when designing solutions,
- engaging in apt *perspective taking*: identifying and considering the positions, interests, and concerns of stakeholders who are implicated,
- recognizing the need for ongoing *inquiry*, noting where more information is needed and re-evaluating positions as new knowledge is constructed,
- and exhibiting *skepticism* towards new information, evaluating it for potential biases and the overall quality of the arguments supporting the knowledge claims made by the authors.

Kirk & Sadler (2023) argue that for perspective taking to be aligned with the goals of socioscientific issues-based education (i.e., promoting civic discourse and solution finding), it must honor the experiences of potentially disagreeing others, establish genuine understanding, and orient students towards finding common ground and ethical solutions. Perspective taking is positioned both as a practice for learning about the issue in question as well as a skill to develop for navigating these issues beyond the classroom. In the classroom, when students learn about the experiences of various stakeholders from their perspectives, it helps them understand the challenges of finding a solution (Sadler et al., 2007; Sadler & Zeidler, 2005). Outside of the classroom, simulating other perspectives can be used to anticipate counterarguments and craft rebuttals when engaged in civic discourse, argumentation, and advocacy (Sadler & Donnelly, 2006), as well as promote the moral and emotional sensitivity needed to engage in productive dialogue around the issue (Fowler et al., 2009; Zeidler, 2014).

Kahn & Zeidler (2017; 2019) argue that apt perspective taking involves not only identifying where one stands on an issue, but also the reasons behind that stance. By their definition, it is entirely possible to predict where an individual stands on an issue without meaningfully engaging in perspective taking. For example, one could rightfully predict the position an individual would hold on fossil fuel divestment based solely on the information that they live in a coal-mining town, and geopolitical stereotypes. However, in doing so one omits the visceral experience of managing the anxieties that come with financial hardship, and uncertainty about what that decision means for the future of themselves, their family, and their neighbors. Perspective taking in the context of socioscientific issues necessarily involves engaging with the cognitive and affective experiences of others (Kahn & Zeidler, 2019). Doing so contextualizes the positions of others they may disagree with. Supporting students in grounding their perceptions of others in the legitimate concerns of stakeholders through perspective taking invites the understanding needed to make compassionate decisions.

Although perspective taking interventions should result in accurate inferences about the positions stakeholders are likely to take on an issue, this information is not sufficient to evaluate the quality of an intervention. Perspective taking interventions should also be evaluated based on how closely insights from student perspective taking aligns with the experienced reality of a target-other (i.e., the reasons behind the position). Additionally, researchers should attend to whether an intervention results in behaviors that support the pragmatic goal of preparing students to positively transform society (Zeidler, 2014).

Perspective taking interventions: The case for optimism

Because perspective taking interventions have not received much attention to the science education community until recently, Kahn and Zeidler (2016) have noted the need to attend to research on these interventions beyond science education contexts. Indeed, there is a growing body of empirical evidence that demonstrates the value of perspective taking interventions in the context of pressing social issues (e.g., Shachnai et al., 2022; Todd et al., 2011; Tompkins et al., 2015). For example, Shachnai and colleagues (2022) found that engaging in perspective taking through pretend play may help address gender disparities in science fields by supporting young girls' persistence in difficult science tasks. Children were assigned to one of three groups, a control group, a group where they were exposed to descriptions of a gender-matched science role-model, and a condition where they were asked to pretend they were the scientist they had just learned about. The children then participated in a challenging science game. Persistence was measured based on how many trials of the game children were willing to participate in before expressing the desire to "do something else." Although boys persisted longer in the game, girls in the pretend-play condition persisted significantly longer than girls in the other two conditions. Perspective taking, not simply learning about role models, helped young girls persist in a field that continues to grapple with representation issues. The findings presented in this study demonstrate that meaningful behavioral change can be obtained as the result of perspective taking.

Perspective taking can also help increase empathy for others in the context of potentially divisive social issues. For instance, Tompkins and colleagues (2015) explored how perspective taking interventions can be used to shape beliefs about outgroups. Specifically, they set out to study whether perspective taking interventions can be leveraged to reduce prejudice against transgender persons. Participants in the perspective taking condition watched a 15-minute documentary of a transgender child before being asked to imagine that they were themselves transgender and craft a letter coming out to their parents. In the comparison condition, participants were educated on the diagnostic criteria for gender-identity disorder followed by an interview with an expert in gender identity disorder in an intervention that lasted 15 minutes. Following this, comparison-group participants were asked to write down all the information they could recall about gender identity disorder. Individuals in the perspective taking condition demonstrated a significant decrease in their levels of genderism and transphobia, whereas those in the education condition increased in this measure. Individuals in the perspective taking condition also reported being significantly more willing to have transgender persons in their close social network following the intervention, whereas those in the education condition exhibited no change. Decreases in prejudice and willingness to include outgroup members in one's social network are indeed desirable outcomes that are aligned with the goal of promoting civic discourse around contentious issues.

Perspective taking has also been explored as a way of disrupting implicit racism. Todd and colleagues (2011) asked participants to clearly visualize the experience, thoughts, and feelings of a Black man experiencing discriminatory treatment while watching a short video or participating in a short writing task. These participants demonstrated a reduction in measures of implicit racism in comparison to control groups and groups who were asked to evaluate the situation objectively. These differences were observed through a diverse array of instruments, including computer-based measures (e.g., Implicit Attitudes Test), self-reports (e.g., feeling thermometers), behavioral measures (e.g., seating distance), and the subjective experience of Black experimenters in interaction with participants. These findings suggest that not only did the perspective taking intervention result in measurable shifts, but also that those shifts translate to positive, real-world behaviors that can be felt by others.

Interventions that positively shape the ways people persist in difficult tasks and orient towards outgroup members are desirable and present promise for supporting outcomes aligned with the goals of socioscientific issues-based instruction. It is particularly promising that the interventions presented in the preceding papers echo some of the recommendations made by scholars advocating for perspective taking in science classrooms (e.g., Kahn & Zeidler, 2016; Newton & Zeidler, 2020). Taken together, these papers suggest that perspective taking presents unique benefits that may not be felt through approaches which emphasize objectivity (Todd et al., 2011) and knowledge alone (Shachnai et al., 2022; Tomkins et al., 2015).

Challenges in contentious contexts: The case for caution

Despite the promising findings outlined in the previous section, it should be noted that these results may not readily translate to other contexts that are, perhaps, more analogous to the socioscientific issues that are commonly addressed in science classrooms. Whereas the studies above certainly involved participants engaging with politicized social issues through perspective taking, they did so outside of a competitive context. Participants were not engaged in debate with the individuals they were assuming the perspective of. These contexts present different environmental cues that have the potential to shape the ways perspective taking occurs and the associated outcomes. The often competitive, politicized, and moral dimensions of socioscientific issues are important for students to directly engage with during instruction (Zeidler, 2014). Thus, it is important to consider how perspective taking interventions behave in these contexts specifically.

Accuracy matters

Apt perspective taking involves being able to accurately infer the content of another person's psychological experience (i.e., empathic accuracy; Ickes, 1993; Myers & Hodges, 2008). It is important to note that empathic accuracy should be differentiated from empathic concern, a construct that has been better explored in the context of science education (e.g., Herman et al., 2020, 2021). Although empathic concern may motivate an individual to help others (indeed a positive outcome), empirical studies suggest that these two constructs are uncorrelated (Myers & Hodges, 2008). Just because an individual demonstrates concern for the wellbeing of another does not mean they are generating accurate inferences about the thoughts and feelings of that person.

Despite empathic accuracy research suggesting we are far from expert mind-readers, Myers and Hodges (2008) argue that in most situations, our reliance on stereotypes and heuristics leads to accurate-enough inferences. There are times when this approach results in problematic outcomes, however. Perspective taking that is grounded in inaccurate representations of the target-other can have damaging repercussions. For example, Lees and Cikara (2020) demonstrated that in competitive political disagreements, people tend to hold overly negative, inaccurate judgements of the perceptions and motivations of outgroups. It is important to note that participants in this study were not necessarily failing to predict the attitudes held by outgroup members. Rather, they were over-estimating the extent to which the outgroup harbored negative feelings towards the participants' ingroup, and over-estimating the motivation of the outgroup to engage in obstructive behavior. These misconceptions can further the divides that make conflicts intractable. As such, ensuring that perspective taking interventions are grounded in accurate knowledge should be of paramount importance. Failing to do so can lead to results that are antithetical to the mission of preparing students to engage in discourse that supports the design of equitable solutions to problems facing society.

Accuracy: Necessary but not sufficient

Even if perspective taking is grounded in accurate representations and yields accurate predictions, it may not lead to desirable outcomes (Epley & Caruso, 2008; Epley et al., 2006). In a study of how participants engage in resource allocation tasks, Epley and colleagues (2006) found that asking participants to adopt the perspectives of others exacerbated selfish behavior in competitive contexts. It is worth noting that one experiment in this study leverages a dilemma where individuals are asked to determine how to manage harvests in a stressed fishery. Wildlife and water management issues are examples of typical socioscientific issues taught in environmental science contexts (e.g., Newton & Zeidler, 2020), suggesting a degree of ecological validity despite its laboratory context. Although participants demonstrated a decrease in egocentric framing when evaluating fairness, participants in competitive contexts ended up taking *more* resources when given the opportunity than their non-perspective taking counterparts. Despite participants articulating an understanding of fairness, their behaviors were incongruent with sustainability goals. These results were then replicated using different contexts through four other studies.

Epley and colleagues (2006) attribute this to *reactive egoism* whereby perspective taking leads people to infer self-serving motives of competitors, driving self-serving behaviors regardless of fairness. Reactive egoism is diminished in cooperative contexts, but these findings point out the dangers of treating perspective taking as a goal in itself. Although participants did indeed engage in perspective taking, the repercussions of doing so actively worsened outcomes. Many socioscientific issues are experienced as zero-sum games rife with politicization and partisanship. Perspective taking in these contexts may occur with fidelity, but at the expense of positive outcomes. As such, evaluations of perspective taking interventions should consider whether those interventions result in pragmatic actions that impact society in desirable ways, not simply whether participants can predict and articulate the position of others.

Future directions: Evaluating perspective taking within the classroom

Currently, there is a dearth of instruments designed to measure perspective taking in educational contexts to the extent discussed above. As noted by Herman and colleagues (2020), self-report measures and assessments that rely on students taking the perspective of invented characters omit critically important facets of the perspective taking experience. How well these assessments speak to students' ability to engage with the perspectives of real-world stakeholders is unclear. Invented characters are themselves abstractions, devoid of the depth that makes perspective taking such a challenging yet impactful experience. They reflect the biases and assumptions of the creators, not necessarily the populations they aim to represent. If we wish to understand how well students' inferences reflect the nuanced concerns and experiences of real-world people, we should strive to co-construct perspective taking assessments with actual stakeholders. Likewise, we should pay particular attention to whether these predictions translate into behaviors conducive to civic discourse and solution finding.

Addressing the concerns outlined above certainly poses a genuine measurement challenge, but not one that is insurmountable. For example, the methods used to assess empathic accuracy developed by Ickes and colleagues (Ickes, 2001; Ickes et al., 1990) holds promise for educational research. This approach compares the actual thoughts and feelings of a target person with the inferences about those thoughts and feelings made by the perspective-taker. To do so, a target person is videotaped in an interaction. The target person then watches the videotape, pausing the tape when they remember having a particular thought or feeling and recording that experience. The perspective-taker then watches the video. The tape is paused at each point where the target other recorded their experience and the perspective-taker is asked to infer what the target other is thinking (Ickes et al., 1990; Myers & Hodges, 2008).

Although this method has been shown to be both reliable and valid (Ickes et al., 1990; Myers & Hodges, 2008), these methods are highly labor-intensive, require careful planning and multiple, trained coders to successfully implement, and require direct collaboration with stakeholders whose perspectives one wishes to foreground. Likewise, this laboratory-based approach can rightfully be critiqued for being removed from the sociocultural context these perspective taking experiences are situated within. Thankfully, this is not a new problem for educational research. It is not uncommon for design studies to involve both laboratory and naturalistic components, placing these findings in conversation with one another to refine both the product and theory (Brown, 1992; McKinny & Reeves, 2018).

The approach detailed by Ickes and colleagues (Ickes, 2001; Ickes et al., 1990) is well suited to inform design studies. Socioscientific issues-based research and instruction often incorporates partnerships with stakeholders (e.g., Newton & Zeidler, 2020). Because much of the infrastructure and rapport already exists, the additional work required of stakeholders to craft these assessments is relatively small compared to situations where these partnerships may not already exist. Additionally, this approach also grounds evaluations of these interventions in the real-world thoughts and feelings of stakeholders, rather than fictitious, abstract characters that emerged from the researchers' own biases and assumptions. The act of interviewing and co-constructing the instrument can itself yield valuable data that can inform curricular design decisions. Researchers will have an instrument that was co-created with real stakeholders that can help ensure curriculum honors their experiences and attitudes. Stakeholders are given agency over their story, and how that story is used for research.

Observational studies of students engaged in learning experiences can be used in tandem with the laboratory-based studies outlined above to explore how students approach the solution-finding process. Particular attention should be paid to student discourse as students engage in authentic culminating activities. Are students using deficit framing and stereotypes when discussing the perspectives of others? Or are they demonstrating empathic concern, exploring the genuine concerns of disagreeing others, and appreciating the reasoning that led to those positions? Similarly, do students adopt a "scorched earth" or "zero sum" approach to solution-finding whereby they attempt to maximize immediate returns for those who share their position? Or do students attempt to understand the needs of other stakeholders, working to find a solution that satisfies the needs of many while minimizing collateral damage? These findings could be placed in conversation with laboratory-generated data using methods like those detailed by Ickes and colleagues (Ickes, 2001; Ickes et al., 1990) and the resource allocation games used by Epley and colleagues (2006). Doing so can refine our understanding of how, when, and why the phenomena observed in the lab are likely to replicate in the real world.

Conclusion

Given its central role in socioscientific reasoning, the current calls to better understand how perspective taking can be supported in socioscientific issues-based learning experiences are well-justified. Perspective taking interventions present promising opportunities to enrich our students understanding of the world as well as prepare them to rise to the challenge of addressing pressing issues that face society. However, due to the nature of the issues at hand, perspective taking interventions may not result in the outcomes they intend to support; in some contexts, these interventions may actively go against those outcomes. Special attention must be paid to the accuracy of knowledge recruited by students when engaging in perspective taking, as well as whether perspective taking results in behavioral outcomes aligned with the pragmatic goals of socioscientific issues-based instruction.

Investigating the Efficacy of an Ontological Framework for Teaching Natural Selection Using Agent-Based Simulations

Abstract: Integrating agent-based models (ABMs) has been a popular approach for teaching emergent science concepts. However, students continue to find it difficult to explain the emergent process of natural selection. In this study, we employ an ontological framework–the Pattern, Agents, Interactions, Relations, and Causality (PAIR-C)–to guide the design of the ABM simulation module. This study examines the effects of the PAIR-C ABM module versus the Regular ABM module on fostering students' understanding of natural selection. Drawing on pre-posttest data, we found that students in the Intervention group had a better causal understanding when explaining natural selection than the Control group. This paper sheds light on applying an innovative framework to designing effective agent-based simulation modules to teach emergent science concepts.

Introduction

The learning of natural selection has been a challenging concept for learners to grasp. Not only naïve learners, but even advanced learners at the postsecondary level also often hold robust misconceptions in explaining the process of natural selection (Bishop & Anderson, 1990; Gregory, 2009). To address this challenge, many researchers and practitioners have used agent-based models (ABMs) or simulations to teach evolution and natural selection over the past decade (Dickes & Sengupta, 2013; Wagh & Wilensky, 2018).

ABMs are computer simulations used to study individual agents' interactions and how they give rise to unpredictable aggregate patterns (Wilensky & Rand, 2015). A substantial number of studies have explored various approaches toward integrating ABMs into learning evolutionary concepts and natural selection. For instance, researchers have taken a hybrid approach of using multiple external representations (aka. MERs-complemented approach) to complement ABMs in explaining emergent phenomena (Basu et al., 2015; Chi et al., 2012b). Although students' conceptual understanding of natural selection can be positively improved by participating in the MERs-complemented approach, the degree to which learning is improved remains limited. Students continue to have inadequate understanding and robust misconceptions, especially when explaining the causal mechanisms for the process of natural selection (Chi et al., 2012a; Su et al., 2021; Peel, 2019).

Researchers (Chi et al., 2012a; 2012b) thereby propose that developing a correct understanding of natural selection (e.g., how an outcome, such as "darker moths" or "long-neck giraffes", becomes common) requires being able to explain how and why agent-level behaviors could give rise to pattern-level outcomes, referred to as the inter-level causal relationships. Moreover, it is important to distinguish inter-level causal relationships from agent-aggregate complementary relationships or input-consequence relationships. Understanding the agent-aggregate complementary and the input-consequence relationships can be less challenging because neither of them considers all the interactions between agents nor emphasizes the nonlinear, dynamic causal relationship between agent-level interactions and pattern-level outcomes. This paper posits that using ABMs without explaining inter-level causal relationships is not likely to result in a deeper understanding of the emergent process of natural selection.

Building on early works, authors recently proposed an ontological framework - the Pattern, Agents, Interactions, Relations, and Causality (PAIR-C) framework - to explain the root causes for misconceptions and support instructions on inter-level causal relationships (under review). Therefore, this paper aims to show the efficacy of integrating the PAIR-C framework into teaching the emergent process of natural selection using the MERs-complemented ABM approach. Specifically, it compares the effect of the PAIR-C ABM module with a Regular ABM module on facilitating students' deeper understanding of inter-level causal relationships when explaining the emergent process of natural selection. The paper focuses on addressing one major research question: What are the effects of the PAIR-C ABM module versus the Regular ABM module on fostering students' understanding of natural selection?

Theoretical framework

The PAIR-c framework

The PAIR-C framework identifies five dimensions to describe a science process: **P**attern, **A**gents, **I**nteractions, **R**elations among the interactions, and the **C**ausal relationship between the agents and the pattern (Chi et al., under review). A Pattern describes the overall changes by a process that is often visible and meaningful, Agents are elements that participate in the process which produces the pattern, Interactions refer to how the agents of the process interact, Relations compare some agents' interactions with other agents' interactions, Causality refers to the causal relationship between the agents and the pattern.

PAIR-C also deduces seven features from the Relations and Causality dimensions (first column, Table 1). Among them, there are four *Interaction features* (Feature 1-4, Table 1) identified from the **R**elations dimension. These four *Interaction features* are often perceptible and can provide learners with visual cues to recognize an emergent process (Features 1-4, Table 1). To further illustrate this point, we use the emergent process of ants foraging for food as an example. When ants search for food, they all walk around, emit, and follow pheromones (Feature 1: have the same set of actions). They can follow or stop following any other ant (Feature 2: bi-directional interactions with random others). At any moment, ants can follow other ants without any specific order (Feature 3: occurs simultaneously). Whether an ant follows another is independent of whether another ant follows yet another ant (Feature 4: independent).

In addition to the four *Interaction features*, three other *Inter-level features* (Feature 5-7, Table 1) are identified from the **C**ausality dimension. These *Inter-level features* also cluster multiple attributes as implications of the same feature. For instance, feature 5 specifies some critical attributes of a converging pattern. One is that the initial pattern has no resemblance to the final pattern (e.g., the initial pattern of ants foraging for food is a random distribution of ants. It does not resemble the final pattern of ants forming a single line). Feature 6 clarifies the method to compute the resulting Pattern by adding positive and negative numbers or by averaging out the magnitudes and directions within each unit of time (e.g., the single-line pattern of ants is computed by averaging all the ants' distances and directions - towards and away from the line - at each unit of time; it is the proportion of ants staying on a single line increasing over time, not the absolute number of ants on the single line increasing in each time). Moreover, some of the attributes that describe inter-level causal relationships (i.e., "i. decentralized", "ii. equivalent status", "iii. unintentional", "iv. not teleological", "v. no direct effect", and "non-matching") are classified as implication features for the **C**ausality dimension (see Feature 7a and 7b).

Overall, the PAIR-C framework provides a clear guideline for qualitatively describing and quantitatively computing the causal mechanisms for emergent processes. It is hypothesized that by grasping these PAIR-C features, students can correctly describe and explain inter-level causal relationships for emergent processes.

Table 1

The Seven PAIR-C Features for Describing and Explaining Emergent Processes

Interaction Features	Dimension IV: **R**elations among the agents' interactions
Feature 1	Same set of interactions
Feature 2	Random, bidirectional interactions
Feature 3	Occur simultaneously
Feature 4	Occur independently
Inter-level Features	Dimension V: **C**ausal relationship between the Agents-pattern
Feature 5	Converging change a. The initial pattern has no resemblance to the final pattern b. The changing pattern reflects the interactions of *all* the agents' interactions
Feature 6	Collective summing a. Adding positive & negative numbers within time b. Net effect: Adding magnitudes & directions within each time unit, then comparing across time units (e.g., proportion change)
Feature 7a	All agents are responsible for the pattern i. Decentralized, distributed control ii. Equivalent status iii. Local goal: Unintentional iv. Not teleological/not purposeful v. No direct effect
Feature 7b	No alignment (non-matching) between the agents and the pattern

Using PAIR-c to evaluate ABM integration efforts

In this section, we use the PAIR-C framework as an analytical lens for evaluating previous ABM integration efforts. We also analyze what PAIR-C features were present or absent in previous studies and consider how including/not including such features might affect students' learning outcomes.

In Dickes & Sengupta (2013), after interacting with a Birds & Moths ABM simulation, all students could provide agent-aggregate complementary explanations in which they explained aggregate-level outcomes using the agent perspective. For example, in reasoning the aggregate-level outcome of darker moths becoming more common, students state "the dark moth population will go up because they will have babies because they're not eaten." (p.932, Dickes & Sengupta, 2013). However, this causal statement was not necessarily correct even though it explains an aggregate-level outcome (i.e., dark moth population goes up) in terms of agent-level behaviors (i.e., dark moths have babies, dark moths are not being eaten). Similar statements could be found in students' utterances sampled in other studies (Dickes et al., 2016; Wagh & Wilensky, 2018). According to the PAIR-C framework, these agent-aggregate complementary explanations tend to focus on a subgroup of species (i.e., the dark moths) without considering all interactions between all species at the agent level (i.e., the dark moths, the light moths, and the birds who prey on moths). The causal statement seemed to distinguish dark moths' behaviors from other moths as they have special abilities to have babies and avoid being eaten. Moreover, these statements tend to attribute the aggregate-level outcome as static rather than explain how the agent-level behaviors give rise to the aggregate-level outcome by considering all the interactions among the agents. Therefore, agent-aggregate complementary explanations do not necessarily subsume a correct understanding of inter-level causal relationships. Compared to these student explanations, a more sophisticated causal explanation should state "the dark moth population will go up because in most generations dark-colored moths survive from being spotted by birds and those survived can reproduce, compared to light-colored moths who have lower survival and reproduction rates (due to industrial pollution, trees became darker with soot and thereby dark-colored moths could blend in the environment more easily than the light-colored moths). Over many generations, dark-colored moths will become more common." Since previous studies already used models with multiple breeds of agents governed by the predator-prey relationship (e.g., both birds and moths are shown in the ABM simulations), explicit instruction on the *Relations among the agents' interactions* (i.e., having the *same set* of interactions: all moths can reproduce with each other and can be eaten by birds, see Table 1 Feature 1) should be available to students.

Existing efforts also reveal that researchers often used ABMs to teach the simple idea of "interactions or relations between agents" rather than using ABMs to teach "Relations among the agents' interactions". For example, Basu et al. (2015) used a Saguaran ecosystem model to teach students about the relations between agents (e.g., "Doves eat seeds of the cacti", "Rats eat pods of the ironwood trees", "Hawks prey on rats", "Hawks prey on doves", etc.) without mentioning the relations among the interactions, such as whether one interaction can occur at the same time (*i.e. simultaneously*) as another interaction (missing Feature 3 from Table 1). Their study showed that understanding the interactions between agents did not help students reason in causal chains unless they were scaffolded to notice the *simultaneous and bidirectional* nature of interactions. When asked, "Knowing that hawks eat rats and rats eat pods, what would happen if hawks were removed from the ecosystem?", all students in their study initially stated that "If there were no hawks to eat the rats, rats would increase. So, pods would decrease and disappear soon." What was missing in students' responses was the ability to reason further about the consequences of the lack of pods on the population level of rats (missing Feature 2 from Table 1). To remedy this issue, Basu et al. (2015) later introduced an external representation tool (i.e., the causal map) as a complementary approach to scaffold students' understanding of the bidirectional nature of the food chain causal relationships. By visualizing the bidirectional interactions between pods and rats, hawks and rats using the causal mapping tool, students showed significant improvement in their causal understanding of the Saguaran ecosystem.

Recent efforts used multiple external representations (MERs) to illustrate PAIR-C features and complement the use of ABMs (Su et al., 2021). A pilot study modified ABMs by adding "links" as visual cues to represent agent interactions within the model and later generated enhanced visual representations in the form of videos, animations, and screenshots to show and prompt students about all four *Relations among the agent's interactions* features. However, results showed that there was no significant difference in pre-post test scores between the Control and the Intervention group. Although most of the PAIR-C features were illustrated throughout the simulation module in the pilot study, one limitation was that the PAIR-C instruction was not explicit in teaching ideas about inter-level causal relationships. Therefore, to facilitate students' deeper understanding of natural selection, there is a need to explicitly teach the *Inter-level features*, especially the "converging change" and "collective summing" causal mechanisms through the MERs-complemented ABM approach.

Methods

Participants and settings

The study took place at a Southwestern University in the United States. Participants were a diverse group of online students enrolled in a 7-week technology literacy course, majoring in Education (n = 29, 58%), Social Studies (n = 13, 26%), and Arts & Humanities (n = 8, 16%). Participants were predominantly juniors (52%), sophomores (22%), and seniors (16%). The gender distribution was 76% female students, 22% male students, and 2% non-binary. The average age of the participants was 27.4 years with a standard deviation of 8.91. Participants reported their ethnicity with the following proportions: 68% as White, 14% as Hispanic/Latino, 6% as Asian or Asian American, 6% as Black or African American, 2% as Native American, and 4% as Other. 86% of participants reported having taken 1-2 biology classes at high school, 12% had taken 3 or more biology classes at high school, and only 2% had taken no biology classes at high school. Only two participants reported having heard about and used NetLogo simulation before the study. This paper included a total of 50 participants: 26 in the Control group and 24 in the Intervention group.

Study design and procedure

The study adopted a pretest-posttest randomized block design (RBD). The blocking factor was the participants' scores on the pretest True or False (T/F) questions. The pre-posttest and the surveys were distributed via Qualtrics. This study designed two simulation modules: the Regular ABM Module used in the Control group and the PAIR-C ABM Module used in the Intervention group. To deliver the simulation modules in an online environment, we used NetLogo Web to show the simulation models and Qualtrics to present relevant instructional materials. Participants in both groups received tutorials on how to navigate the NetLogo Web and the Qualtrics-supported instructional page before starting the simulation modules.

Simulation modules

Both simulation modules were about the same length and used the same types of multiple external representations (MERs) including simulation models, explanatory texts, images, screenshots, and videos. We also used prompts to help students actively make connections between MERs by asking them to generate new inferences beyond observing or manipulating MERs. More importantly, students in both groups had the same sequence of activities which allow them to observe, explore, and investigate questions using interactive simulations and MERs. Table 2 presents a detailed comparison between the Regular ABM module and the PAIR-C ABM module and points out the main differences between them.

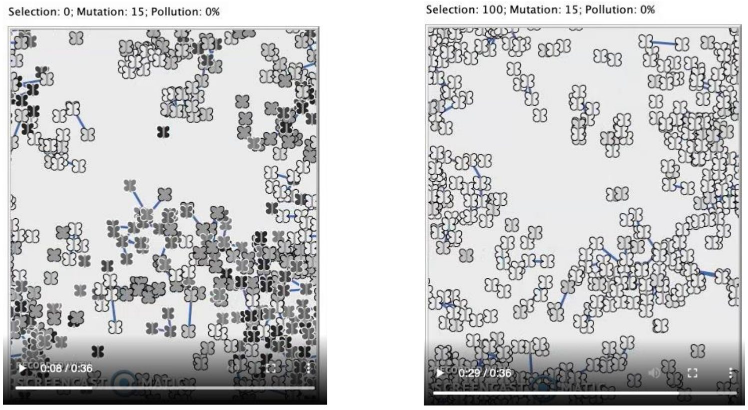
Table 2
Comparison of the Two ABM Simulation Modules

	Regular ABM Module (Control group)	PAIR-C ABM Module (Intervention group)
Overall Use of Multiple External Representations	Both modules use the same amount of MERs at the same location.	
Simulation models:	Both modules use the same interactive simulations - the Peppered Moths model and the Rock Pocket Mice model- and allowed learners to observe, explore, and investigate these simulations at their own pace.	
Explanatory texts:	Provide texts on the five Darwinian principles (such as genetic determination, adaptation, reproductive advantage), conventional definitions, and common misconceptions but withhold information on the emergent properties shown in the simulations.	Provide texts on the seven PAIR-C features and how to apply these features to explain the emergent properties of natural selection caused by mechanistic details of agent interactions (such as inheritance, predation, and reproduction).
Images, screenshots, videos:	All representations were generated from the agent-based models directly and did not contain external visual	Most of the representations were modified and provided visual cues (e.g., blue links were used to

	cues to represent different types of agent-level interactions.	represent mating interaction. See example in Figure 1)
Overall Use of Prompts	Both units use the same number of identical generic prompts that contain the same types of questions.	

Figure 1

Screenshots of the Simulation Video with Different Selection Pressure



Note. The screenshots were taken from the link-visible ABM video used in the PAIR-C intervention group. The video in the control group did not show any links.

Pre-posttest instrument

Understanding of Natural Selection was assessed by the pre-posttest instrument. The pretest and the posttest are identical despite the sequence. Most of the questions were revised from the AAAS conceptual inventory and past AP Biology Exams. The revised items were validated by a high-school biology teacher who was a collaborator with our team and previously taught the PAIR-C framework in his natural selection lessons. The test contained three sets of True or False (T/F) questions with five statements for each set. These fifteen T/F statements were designed in the format of two-tiered questions. The first tier simply asked students to decide whether a statement was True or False. The second tier asked students to explain the statement they picked as False. In our previous experience with T/F explanations, students tend to rephrase or copy the True statement without giving an explanation. Therefore, the pre-posttest in this study only asked students to explain the False questions to reduce the likelihood of guessing while remaining a relatively shorter test. For the True/False selection part of the question, if students correctly determined whether the statement was True or False, they were given a score of 1, otherwise a 0 point. For the open-ended part of the T/F items, we created scoring rubrics for each false item (on a scale of 0, 0.5, and 1).

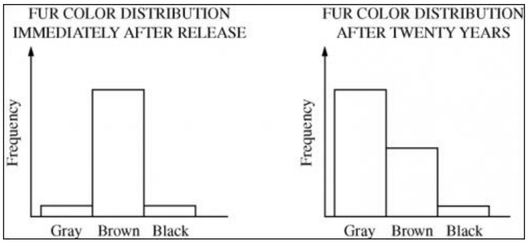
Seven out of the 15 T/F questions were labeled as Shallow which assessed basic understandings of Darwinian principles or knowledge of either agent-level or pattern-level understanding while eight out of the 15 T/F questions were Deep questions that assessed understanding of inter-level causal relationships. For example, the following T/F statement *"Changes you observed in the mice's fur color patterns from the start of the experiment to the end were wholly due to random factors"* was considered a shallow question. The reason was that it did not require an explanation or understanding of how the mice agents' interactions produce the pattern of fur color change, and 64% of the participants answered it correctly in the pretest. In contrast, another T/F statement *"The number of gray mice in the population increases slightly each year for 20 years, which adds up to the pattern of gray fur becoming more common in the population"* exemplified in Table 3 was considered a deep question because it requires a deeper understanding of the inter-level causal relationships. A correct causal explanation of this statement would imply that there was no alignment between the agents and the pattern as well as no continual increase in the number of agents for each generation. Only 20% of participants correctly determined this statement as a false statement in the initial pretest.

The test also contained two open-ended (OE) questions assessing students' understanding of the natural selection process in different contexts (to be referred to as context transfer items). These two context transfer questions were adapted based on Peel et al. (2019). Similarly, we also created scoring rubrics for each context transfer item to assess students' transfer performance on a scale of 0 to 5. For each open-ended item, more than 50% of student responses were scored by the first author and the third author for inter-rater reliability over three rounds (Kappa for the open-ended part of the T/F questions was an average of 0.843, $p < 0.001$, Kappa for OE context transfer questions was 0.925, $p < 0.001$, indicating strong scorer agreement). Table 3 provides examples of the pre-posttest items, the scoring rubrics, along with sample responses from students.

Table 3
Pre-posttest Items

True or False (T/F) Question

Q1. Decide True or False for each of the following statements that explains the change in the frequency distribution of fur color in the mouse population after 20 years, as shown in the figures below. Provide explanations for the false statements you identified.



A. The number of gray mice in the population increases slightly each year for 20 years, which adds up to the pattern of gray fur becoming more common in the population.

Rubric for explaining statement A:
This statement is False.

- ***Score 1*** *if the explanation mentions that the increase is not gradual or continuous by every generation OR refers to the "not align or non-matching" PAIR-C feature.*
- ***Score 0.5*** *if only refers to not enough data or information.*
- ***Score 0*** *if the answer only describes the bar chart.*

Sample responses for explaining statement A:

- S39: "One year there could be a surge of gray mice and one year there could be many dying instead. It is *not a continual increase*."
  Score 1
- S42: "While the grey mice population did increase significantly, *without more data we don't know* that it increased slightly for 20 years."
  Score 0.5
- S38: "The population of mice with grey fur dramatically increases."
  Score 0

Open-ended Context Transfer Question

Q4. How would biologists explain how a living mouse species with claws evolved from an ancestral mouse species that lacked claws?

Rubric:

- ***A score of "5"*** *should be given to responses that mention:*
  - *trait variation present before selection pressure*
  - *random mutations result in trait variations*
  - *mice survive and reproduce*
  - *influence of selective pressure or environment on survival and reproduction rate*
  - *changes occur over time or multiple generations*
- ***A score of "1-4"*** *should be given to responses that contain 1 to 4 key points mentioned above.*
- ***A score of "0"*** *should be given to responses that contain no key point.*

Sample response from S5:

"If one mouse was born with *a mutation in their DNA* which produced claws [score 1 for random mutations]/, once they reproduce there is a *good chance the mutated gene will present* in their offspring. [score 1 for trait variation]/ As the trait is passed down *through generations*, the population of the mutated mouse species would increase [score 1 for over time/generations]/. The claw likely provided a form of defense toward their predators, *making the mice without the claws an easier prey* [score 1 for the influence of selective pressure]. As those with claws *survived at a higher rate*, they also *reproduced at a higher rate* due to the overall lack of mouse without claws in the

population [score 1 for survive and reproduce]/.”
(A total of five points was given to S5’s response).

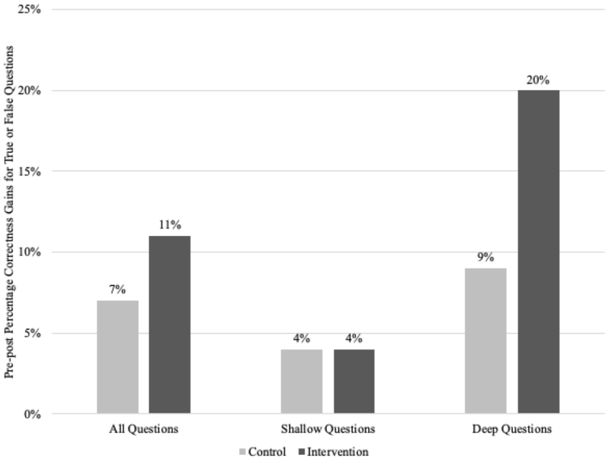
Results & discussion

Results show that student performance on the T/F items improved significantly from the pretest to the posttest for both groups. The control group (N =26) improved from a mean score of 8.94 (SD = 3.09) to a mean score of 10.89 (SD = 2.87), t =2.60, p = .016, with a medium effect size d = 0.51. The intervention group (N = 24) improved from a mean score of 9.31 (SD = 2.78) to a mean score of 12.73 (SD = 4.36), t =4.42, p < .001, with a high effect size d = 0.90. These results indicate that both the Regular ABM simulation modules and the PAIR-C ABM simulation modules used in this experiment could successfully improve students’ overall understanding of natural selection. To investigate group differences attributed to the different simulation module treatments, ANCOVA was conducted using pretest scores as covariates. The result shows that there was a marginally significant difference between the two groups in the overall understanding of natural selection (F = 2.94, p = .093, partial η^2 = .059). This difference is also reflected in the first two columns of Figure 2. As shown in the figure, the percentage of correctness gains was 7% for the control group whereas the percentage of gains was 11% for the intervention group. This result indicates that the intervention group who used the PAIR-C ABM simulation modules had a better performance on the overall understanding of natural selection compared to the control group who used the Regular ABM simulation modules.

Results also show that students improved significantly in answering deep questions from the pretest to the posttest for both groups. The control group improved from a mean score of 2.54 (SD = 2.16) to a mean score of 3.73 (SD = 2.52), t =2.08, p = .048, with a medium effect size d = 0.41. The intervention group improved from a mean score of 2.52 (SD = 2.15) to a mean score of 5.56 (SD = 3.95), t =3.90, p < .001, with a high effect size d = 0.80. These results indicate that both the Regular ABM simulation modules and the PAIR-C ABM simulation modules used in this experiment could successfully improve students’ deep understanding of natural selection. ANCOVA analyses show that there was a statistically significant difference between the two groups in answering the deep questions of natural selection (F = 4.16, p = .047, partial η^2 = .081). This difference is reflected in the last two columns of Figure 2. As shown in the figure, the percentage of correctness gains for answering deep questions was 9% for the control group whereas the percentage of correctness gains was 20% for the intervention group. These results indicate that the intervention group had a significantly better performance in answering deep questions of natural selection compared to the control group after the simulation modules. In other words, the PAIR-C ABM simulation modules were more effective in fostering students’ deeper understanding of natural selection compared to the Regular ABM simulation modules. In contrast, students’ performance did not differ between groups in answering shallow questions (F = .01, p = .934, partial η^2 = .000). This pattern is shown in the middle two columns of Figure 2.

Figure 2

Pre-post Percentage Correctness Gains for All, Shallow, and Deep T/F Questions



To see whether the PAIR-C ABM simulation module could further impact students’ abilities to explain the process of natural selection, analyses were conducted based on their responses to the two context transfer questions. Results show that there was no significant improvement in answering the two context transfer questions from the pretest to the posttest for both groups. The control group improved from a mean score of 1.73 (*SD* = 1.34) to a mean score of 1.77 (*SD* = 1.75), $t = 0.09$, $p = .928$, with a small effect size $d = 0.02$. The intervention group improved from a mean score of 2.04 (*SD* = 1.68) to a mean score of 2.38 (*SD* = 2.36), $t = 0.78$, $p = .445$, with a small effect size d = 0.16. For testing group differences in answering the post-test context transfer questions, ANCOVA was conducted. There was no statistically significant difference between the two groups ($F = 0.70$, $p = .409$, partial $\eta^2 = .015$). Similar results were also manifested in students' responses to the simulation prompt question.

The above findings suggested that the ABM simulation module integrated with the PAIR-C features could contribute to deeper learning of emergent process concepts, such as natural selection. Nevertheless, students in both groups were not able to demonstrate significant improvement in explaining the process of natural selection across different contexts. One reason could be that students did not receive enough instructions on how to use PAIR-C features or Darwinian Principles to elaborate on the process of natural selection in the simulation module. More explicit instructions should be provided to scaffold students learning.

Conclusion

In conclusion, this study shows the potential of using the PAIR-C framework in designing agent-based simulation modules for learning complex emergent phenomena. Using natural selection as the exemplary concept, the PAIR-C framework has its ecological validity as it underscores the importance of understanding the inter-level causal relationships for emergent science processes taught in school curricula. Moreover, our approach of integrating the PAIR-C framework using MERs-complemented ABM seems promising to be operationalized for science instruction broadly. We believe it can impact how science teachers produce curricula, create assessment rubrics, and use computer technologies to help students reach a deeper understanding of emergent causal mechanisms in science processes.

Abstract: 'Algorithms' is a core CS concept included in the K-12 CS standards, yet student challenges with understanding different aspects of algorithms are still not well documented, especially for younger students. This paper describes an approach to decompose the broad middle-school 'algorithms' standard into finer grained learning targets, develop formative assessment tasks aligned with the learning targets, and use the tasks to explore student understanding of, and challenges with, the various aspects of the standard. We present a number of student challenges revealed by our analysis of student responses to a set of standards-aligned formative assessment tasks and discuss how teachers and researchers interpreted student responses differently, even when using the same rubrics. Our study underscores the importance of carefully designed standards-aligned formative assessment tasks for monitoring student progress and demonstrates the need for teacher content knowledge to effectively use formative assessments during CS instruction.

Introduction

The demand for computer science (CS) learning opportunities in K-12 is rapidly increasing as it becomes clear to policy makers, educators, and parents that an understanding of computing is essential to success in a technology and automation-rich society. One of the most fundamental CS concepts is the algorithm, an ordered set of precise and clear instructions to solve a problem or generate a desired output. An algorithm is often a first step towards planning the logical flow of a computer program. Algorithmic thinking encompasses knowledge and skills specific not only to CS and programming but also to general problem-solving and computational thinking (ISTE, 2016).

The Computer Science Teachers Association (CSTA) K-12 CS Standards identify 'Algorithms and Programming' as a key CS concept across all grade bands and 'Algorithms' as one of its five sub-concepts (CSTA, 2017). Most state CS standards in the U.S. also include algorithms as a core CS concept (Guo & Ottenbreit-Leftwich, 2020). Algorithms are often introduced in K-12 through simple activities such as students writing instructions for making a peanut butter and jelly sandwich and teachers enacting the instructions. These lessons are appropriate for communicating the idea that computers will execute instructions as written (rather than as intended) but they do not touch upon other important ideas emphasized in the 'algorithms' standards such as representation, interpretation, comparison, testing and debugging of algorithms. In our review of several existing K-12 CS curricula, we have found that many of them do not include the full scope of concepts and practices covered by 'algorithms' standards. CS education research currently provides little guidance on how to unpack the broad 'algorithms' standards, making it difficult for educators to understand the full scope of the standards and the range of skills that comprise proficiency.

A thorough understanding of the algorithms standards is a necessary, though not sufficient, component of teachers' ability to develop and effectively use formative assessments on algorithms (Basu et al., 2022). In addition to content knowledge, a deep understanding of how K-12 students think about algorithms would allow teachers to identify and address student challenges and advance student understanding. Formative assessment tasks that intentionally target individual aspects of algorithms standards can reveal useful information about student understanding and specific challenges on each of those aspects (Basu et al., 2022). The ability to use such standards-aligned formative assessments to measure and support student progress on CS standards is articulated as part of the CS teacher standards (CSTA, 2020). However, there is currently limited literature on K-12 students' conceptualization of, and challenges with, the concept of 'algorithms', and many CS teachers report feeling underprepared to use formative assessments to monitor student learning (Gordon & Heck, 2019).

In this paper, we unpack a broad CSTA middle school 'algorithms' standard, 2-AP-10, "Use flowcharts and/or pseudocode to address complex problems as algorithms" into finer grained learning targets. We then discuss an approach to developing aligned formative assessment tasks (and rubrics) and describe how we used a set of tasks to explore student understanding of, and challenges with, the fine-grained learning targets underlying the standard. Finally, we compare our evaluation of student responses with how middle school CS teachers evaluated the same student responses using the same rubrics and how teachers' own understanding of algorithms informed their evaluation of student responses. By looking at both students' responses and teachers' interpretations, we are able to infer student understanding and challenges as well as explore how teacher knowledge mediates the impact of formative assessment. We are guided by the following research questions:

RQ1: How can formative assessment tasks be developed to examine student understanding on various aspects of the middle school algorithms standard?

RQ2: What can we infer about middle school students' understanding of and challenges with the concept of algorithms from students' responses to standards-aligned formative assessment tasks?

RQ3: How do teachers' interpretations of middle school students' understanding of algorithms compare to researchers' interpretations, when using the same assessment tasks and rubrics?

Theoretical perspectives

Relevant related work

Characterizing and assessing students' understanding of algorithms.

Recent research in CS education includes efforts to assess K-12 students' algorithmic thinking skills and have been situated within a computational thinking (CT) framework (e.g., Basu et al., 2021). These research studies have noted middle school students' challenges with devising algorithms to solve real-world problems (e.g., Wong & Jiang, 2018) and comparing algorithms when the comparison is based on multiple criteria (Basu et al., 2021).

However, there is still limited research on several aspects of the 'algorithms' concept. For example, the middle school standard for algorithms includes the practices of representing algorithms as flowcharts and pseudocode, testing algorithms with a wide variety of inputs, predicting algorithm behavior, and debugging algorithms, many of which are currently under-investigated. Assessments for algorithmic thinking are typically part of broader CT assessments and hence do not cover all aspects of the 'algorithms' concept. Some research on high school students' understanding of algorithms has revealed challenges with using flowcharts to create, call, and manage different sub-algorithms (Rahimi et al., 2018), as well as misconceptions related to the efficiency of algorithms, thinking that fewer lines of code and fewer variables characterize algorithm efficiency (Gal-Ezer & Zur, 2004).

Teachers' content knowledge and pedagogy related to algorithms

While information about how teachers conceptualize algorithms and perceive their own knowledge of algorithms is limited, there have been some studies that explore teachers' understanding of algorithmic thinking in the context of CT. Rich and colleagues found that elementary school teachers who are new to the field of CT associated the term 'algorithmic thinking' with the mathematical term *algorithm* that specifies steps for performing traditional arithmetic operations, and conceptualized algorithmic thinking as "following steps", and "discovering and explaining strategies" (Rich et al., 2019, p. 179). Research has also shown that appropriate professional development (PD) opportunities can expand teachers' knowledge of algorithmic thinking. For example, Yadav and colleagues (2018) analyzed and compared teacher responses before and after a year-long CT PD and found that teachers initially made generic comments about algorithms but were later able to identify and discuss specific characteristics of algorithms such as efficiency, abstraction, and generalization.

Given the fundamental role of algorithms in CS education, researchers have sought to understand how teachers teach algorithms. A common instructional task is having students construct an algorithm in the form of a flowchart or pseudocode to solve a given problem. A study by Vivian and Falkner (2019) found that teachers with high confidence in teaching a digital CS curriculum frequently used algorithmic language, made more connections to learning objectives on algorithms and programming, and were more likely to engage students in algorithm development and manipulation activities before programming. In our current study, several middle school teachers mentioned that their teaching of algorithms was limited to facilitating activities such as instructions for creating peanut butter and jelly sandwiches, because the CS curricula they used did not include specific lessons on algorithms. Teachers remarked that they formatively assessed their students' understanding of algorithms based on completion of project-based activities rather than the knowledge and skills students demonstrated on individual activities.

Evidence-centered design (ECD)

We employed ECD (Mislevy & Riconscente, 2006), a principled assessment design approach, to analyze and unpack the middle school 'algorithms' standard and develop aligned formative assessment tasks. ECD helps 1) define what to measure, 2) identify the evidence needed to measure these goals, and 3) design tasks to produce this desired evidence. The ECD process starts with analyzing the target domain (outlining the scope of the middle-school algorithms standard) and decomposing the standard into a set of finer-grained knowledge, skills, and abilities that students should possess. The ECD process results in a set of assessment tasks that elicit desired evidence on different aspects of the standard as well as aligned rubrics.

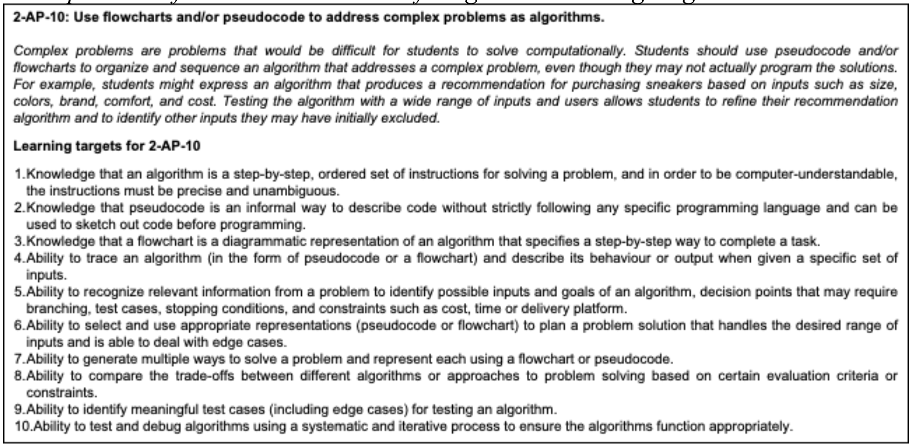
Methods and data sources

Designing standards-aligned formative assessments

We employed the ECD approach to define the scope of the 2-AP-10 standard by clarifying the knowledge and skills expected of this standard relative to elementary and high school 'algorithms' standards. We found that this middle-school standard transitions students from interpreting algorithms in upper-elementary grades to creating algorithms that solve complex problems and testing algorithms using a variety of inputs. The standard focuses on fluency with representations such as flowcharts and pseudocode that represent the steps to solve a problem pictorially or using plain language description. It includes the ability to identify relevant information from a problem description (e.g., inputs, goals and decision points) and translate it into an algorithm, as well as the practices of testing and debugging algorithms. Analyzing the scope of the 2-AP-10 standard helped us to decompose the broad standard into a set of ten fine-grained learning targets (LTs) on which we could individually examine student understanding (see Figure 1). Specific LTs enable teachers and curriculum developers to design targeted instruction and assessment opportunities to check student understanding and help students overcome specific learning gaps (Basu et al., 2022).

Figure 1

The CSTA Middle School 'Algorithms' standard and its description, followed by out decomposition of the standard into ten fine-grained learning targets.



2-AP-10: Use flowcharts and/or pseudocode to address complex problems as algorithms.

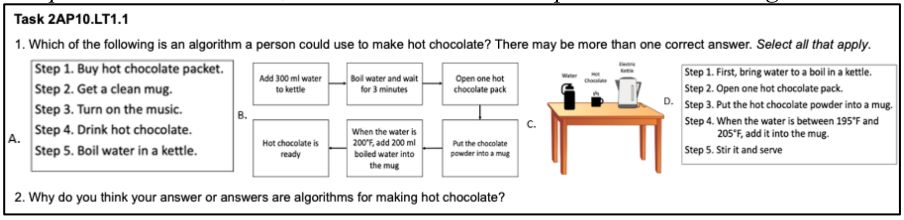
Complex problems are problems that would be difficult for students to solve computationally. Students should use pseudocode and/or flowcharts to organize and sequence an algorithm that addresses a complex problem, even though they may not actually program the solutions. For example, students might express an algorithm that produces a recommendation for purchasing sneakers based on inputs such as size, colors, brand, comfort, and cost. Testing the algorithm with a wide range of inputs and users allows students to refine their recommendation algorithm and to identify other inputs they may have initially excluded.

Learning targets for 2-AP-10

1. Knowledge that an algorithm is a step-by-step, ordered set of instructions for solving a problem, and in order to be computer-understandable, the instructions must be precise and unambiguous.
2. Knowledge that pseudocode is an informal way to describe code without strictly following any specific programming language and can be used to sketch out code before programming.
3. Knowledge that a flowchart is a diagrammatic representation of an algorithm that specifies a step-by-step way to complete a task.
4. Ability to trace an algorithm (in the form of pseudocode or a flowchart) and describe its behaviour or output when given a specific set of inputs.
5. Ability to recognize relevant information from a problem to identify possible inputs and goals of an algorithm, decision points that may require branching, test cases, stopping conditions, and constraints such as cost, time or delivery platform.
6. Ability to select and use appropriate representations (pseudocode or flowchart) to plan a problem solution that handles the desired range of inputs and is able to deal with edge cases.
7. Ability to generate multiple ways to solve a problem and represent each using a flowchart or pseudocode.
8. Ability to compare the trade-offs between different algorithms or approaches to problem solving based on certain evaluation criteria or constraints.
9. Ability to identify meaningful test cases (including edge cases) for testing an algorithm.
10. Ability to test and debug algorithms using a systematic and iterative process to ensure the algorithms function appropriately.

Figure 2

An Example 2-AP-10 Assessment Task Aligned with LT 1 "Knowledge that an algorithm is a step-by-step, ordered set of instructions for solving a problem, and in order to be computer-understandable, the instructions must be precise and unambiguous."



Task 2AP10.LT1.1

1. Which of the following is an algorithm a person could use to make hot chocolate? There may be more than one correct answer. *Select all that apply.*

A.
Step 1. Buy hot chocolate packet.
Step 2. Get a clean mug.
Step 3. Turn on the music.
Step 4. Drink hot chocolate.
Step 5. Boil water in a kettle.

B.

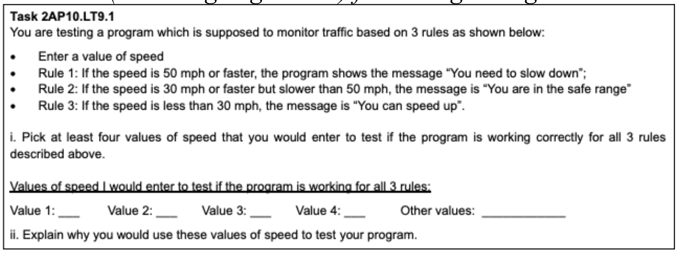
C.

D.
Step 1. First, bring water to a boil in a kettle.
Step 2. Open one hot chocolate pack.
Step 3. Put the hot chocolate powder into a mug.
Step 4. When the water is between 195°F and 205°F, add it into the mug.
Step 5. Stir it and serve

2. Why do you think your answer or answers are algorithms for making hot chocolate?

Next, we followed the ECD framework to develop a set of formative assessment tasks, each focused on eliciting evidence of student understanding on one LT (see Figures 2, 3 for examples). Task formats included multiple choice questions, short-answer prompts, and open-ended explanations. Tasks were short enough to be practical for in-class use to diagnose student understanding of the LTs. Each sub-task was accompanied by one of two rubric types (see Table 1). A RC rubric grouped student responses into Response Categories (RCs) such that each RC was indicative of a certain level of student understanding (a student can be in only one RC). An IC rubric listed a set of Indicated Challenges (ICs) that could be inferred from student responses (a student can have multiple ICs).

Figure 3
An Example 2-AP-10 Assessment Task Aligned with LT 9 'Ability to identify meaningful test cases (including edge cases) for testing an algorithm'.



Task 2AP10.LT9.1
You are testing a program which is supposed to monitor traffic based on 3 rules as shown below:

- Enter a value of speed
- Rule 1: If the speed is 50 mph or faster, the program shows the message "You need to slow down";
- Rule 2: If the speed is 30 mph or faster but slower than 50 mph, the message is "You are in the safe range"
- Rule 3: If the speed is less than 30 mph, the message is "You can speed up".

i. Pick at least four values of speed that you would enter to test if the program is working correctly for all 3 rules described above.

Values of speed I would enter to test if the program is working for all 3 rules:

Value 1: ___ Value 2: ___ Value 3: ___ Value 4: ___ Other values: ____________

ii. Explain why you would use these values of speed to test your program.

Table 1
Rubric for analyzing student responses to Task 2AP10.LT1.1 shown in Figure 2

Rubric for Part 1			Rubric for Part 2		
Student Response	**Possible inference about student understanding**	**Response Category**	**Student Response**	**Possible inference about student understanding**	**Indicated Challenge**
A only	Challenges with order and final goal: Student does not realize that the steps of an algorithm need to be in order/sequential and the last step should be the goal which is making hot chocolate.	RC1	Student does NOT indicate that their selected options contain instructions that are "clear" or "specific".	Student may have difficulty recognizing that an algorithm needs to include a set of clear or specific instructions.	IC1
C only	Challenge with representation: Student does not realize that an algorithm is a process or ordered set of steps to get to a goal state; a static diagram depicting objects is not an algorithm.	RC2	Student does NOT indicate that their selected options contain instructions that are ordered in a logical way.	Student may have difficulty recognizing that an algorithm includes instructions that are ordered in a logical sequence.	IC2
B and D	**Student understands what defines an algorithm and can recognize an algorithm in various forms.**	**RC3**	Student does NOT mention that the algorithm will fulfil the goal of making hot chocolate.	Student may have difficulty recognizing that the instructions in an algorithm need to fulfil the goal of the algorithm.	IC3
B only or D only	Student understands what defines an algorithm but can only recognize an algorithm in certain forms (i.e., flowchart/diagram process or procedure list).	RC4	Students states that the algorithm "makes sense" or that is how they would make hot chocolate.	Student may not recognize that their explanation should include characteristics of an algorithm instead of their personal opinion.	IC4
Any other response	Student may not understand what an algorithm is.	RC5	Student only restates the algorithm without explaining why it is an algorithm.	Student has difficulty understanding the concept of algorithms and/or articulating it.	IC5
			Student states something that is incorrect or not relevant	Student has difficulty understanding the concept of algorithms and/or articulating it.	IC6

Small-scale classroom study

We collaborated with eight middle school CS teachers from an urban school district in the Midwestern U.S. who used code.org's CS Discoveries (CSD) curriculum for their teaching. All teachers had participated in CSD PD offered by code.org prior to participating in our study. The teachers varied widely in terms of overall teaching experience (1-21 years), but they had all taught CS for less than three years. We provided teachers with professional learning in the form of educative resources on unpacking the 2AP10 standard and standards-aligned formative assessments for algorithms. Teachers participated in an hour-long, online, synchronous PD session on algorithms where we introduced them to the 2-AP-10 standard, corresponding state standards, our unpacking of the standard, and the aligned formative assessment tasks and rubrics that we had developed. Throughout the PD session, the teachers were engaged in short activities that provided us with important information about their understanding of and familiarity with the 'algorithms' standard. For example, teachers had to identify the LTs with which a given task was aligned. They were also asked to indicate which LTs they were already addressing during instruction and which they planned to address in the future. Teachers were divided into two groups where each group looked at two examples of student responses to an algorithm task (see Figure 3) and discussed how to evaluate the responses using the provided rubrics or by modifying the given rubrics. Teacher responses and discussions were recorded for future analyses. Teachers took a CS pedagogical content knowledge (PCK) survey before participating in the PD and at the end of the classroom study. We designed the survey to measure teachers' attitudes towards CS, knowledge of algorithms and programming concepts, and ability to interpret student work. For this paper, we analyzed teachers' pre-survey responses to two tasks that asked teachers to interpret and compare students' algorithms and predict possible student challenges.

Here we report on student data from formative assessments administered by two out of the eight CS teachers – Dina and Remi (pseudonyms) – who consented to sharing student work and their evaluation of student work. Dina and Remi administered a subset of the formative assessment tasks to their students, evaluated student responses, and shared both student responses and their evaluations with our research team. We collected student data for 36 students across grades 7 and 8. Most students had taken at least one other CS class in the previous school year, though classes were disrupted by school closures and remote instruction during the global pandemic. At the time of the study, students in both Dina and Remi's classes had completed CSD units 1 and 2 (Problem Solving, Web Development) and were working on CSD Unit 3 (Interactive Animations and Games). We gathered data on student responses to six algorithm tasks aligned with LTs 1, 6, 8, and 9, with each task yielding 15 to 36 student responses. Using the same task-specific rubrics we shared with teachers, we coded student responses to the tasks. For each open-ended prompt, at least two researchers coded student responses into RC or IC categories. Researchers met regularly to discuss discrepancies in their coding until they reached consensus. Memos were recorded throughout the discussion and used to refine the rubrics. We then compared our coding to that of the teachers. We conducted descriptive and thematic analyses (Saldaña, 2016) of our coding of student responses and the comparison findings to explore students' understanding of algorithms and the similarities and differences in how teachers and researchers coded students' responses.

Findings

Students' understanding of algorithms

We summarize our findings about middle school students' understanding of algorithms in terms of the LTs targeted by the tasks we analyzed. These findings have implications for CS instruction, curriculum design, and PD design.

LT1: Understanding what an algorithm is. Analysis of student responses to two tasks aligned with this LT revealed that most students understood what an algorithm is. For example, for task 2AP10.LT1.1 shown in Figure 2, 21 of 35 (60%) students who completed the task were able to identify both options B and D as algorithms for making hot chocolate, while 10 (29%) students identified only one of options B and D. However, only nine of the 31 students who selected options B and/or D could justify their selection(s) to any degree. Explanations often mentioned ordered steps, clear instructions, or achieving the goal of making hot chocolate, but rarely included all aspects (see Table 2).

LT6: Selecting flowcharts representing problem solutions. Students responded to one task asking them to select a flowchart that appropriately represents a delivery robot's actions. Ten of 15 (67%) students who worked on this task could represent the given text-based problem solution for the robot as a flowchart. Among the remaining five students, three struggled with using a decision box and selected a flowchart where the decision box did not have an arrow labeled 'NO' flowing out of it. Two students had difficulty understanding that the steps of an algorithm should appear in the same order regardless of the algorithm representation, whether text-based or pictorial as in a flowchart.

LT8: Interpreting and comparing algorithms. Students responded to two tasks involving comparison of algorithms. The first task involved comparing three simple algorithms for navigating a robot based on time and cost criteria. Most students (23 of 34 or 68%) correctly identified the algorithms that would reach the goal, the fastest algorithm and the cheapest algorithm. However, students found it challenging to compare algorithms based on multiple criteria. Only 37% students could compare the algorithms correctly when considering both speed and cost criteria simultaneously. This finding is similar to that observed by Basu and colleagues (2021) with students in grades 4-6 in Hong Kong. The second task involved comparing two relatively complex algorithms that included user input and compound conditionals. Only 20 of 36 (56%) students were able to correctly interpret the individual algorithms. Several students seemed to have difficulty following the logic of conditional statements in the algorithms. Twenty-two (61%) students were able to compare the algorithms and decide which one to use for solving a given problem. However, few of these students could justify their selection. Seven students gave a fully correct explanation, 2 students gave a partially correct explanation, and 13 students were not able to give any suitable explanation for their selection.

LT9: Selecting meaningful test cases to test algorithms. Student responses to Task 2AP10.LT9.1 (Figure 3) revealed that only 5 of 20 (25%) students could identify appropriate test cases (i.e., numbers in different ranges that would test all three program rules). Several (40%) students identified test cases that only tested one of three program rules, while others tested two of the rules. Only four of 20 (20%) students could justify their selection of test cases by describing how they were trying to test all three rules included in the program (see Table 3 for sample responses).

Table 2

Analysis of sample student responses to Task 2AP10.LT1.1 (Figure 2) using the rubric shown in Table 1.

Selection for part 1	Response to part 2	Possible inferences about student understanding
B, D *(RC3)*	They're both algorithms for making hot chocolate because they're in the correct order and they give the instructions in a stepwise, efficient order that can be easily read and followed through. *(no IC)*	Student can recognize algorithms and understands the characteristics that define an algorithm.
B, D *(RC3)*	I selected both of those answers because they're explaining the instructions clearly. *(IC2, IC3)*	Student can recognize algorithms but may not understand all the characteristics that define an algorithm.
D *(RC4)*	I think my answer is an algorithm for making hot chocolate because this would be how I make my hot chocolate. *(IC1, IC2, IC3, IC4)*	Student can only recognize algorithms written as a list of steps, may not be aware of characteristics of an algorithm, and is using their experiences to explain their choices.

Table 3

Sample student responses to Task 2AP10.LT9.1 shown in Figure 3

Value 1	Value 2	Value 3	Value 4	Other values	Explanation for choice of values to test	Possible inferences about student understanding
55 mph	50 mph	49 mph	30 mph	29 mph, 20 mph	I would use these speeds to see if the program gives each of the three messages only when it is supposed to.	Student is able to identify meaningful test cases to test all three rules (both values in the range and at the boundaries of the rules).
40 mph	30 mph	5 mph	0 mph	-	I would use these values of speed to make sure the program works as it should.	Student is able to identify some meaningful test cases but may not recognize that testing an algorithm requires testing all of its rules or conditions.
49 mph	48 mph	47 mph	46 mph	45 mph, 44 mph	I would use these speeds to see if I need to be exactly on 50 mph to slow down.	Student struggles to identify a full range of meaningful test cases and has challenges recognizing that they need to test the algorithm under different scenarios to make sure it works for all three rules.

Teacher interpretation of student work

Next, we compare our evaluation of student responses with teachers' interpretations of the same responses. Teachers used the same set of rubrics as the researchers, and though they were encouraged to modify the rubrics as needed, neither Dina nor Remi changed the rubric for any of the tasks. Teachers were consistent with researchers when evaluating the multiple-choice tasks, which allowed no room for subjectivity in terms of which rubric category each response corresponded to. For the open-ended tasks, such as selecting meaningful test cases and explaining selection of algorithms, there were several differences in teacher and researcher interpretations of the same student responses. For example, for Task 2AP10.LT1.1 Part 2 (Figure 2) where students explain why they think their selection is an algorithm, teacher and researcher categorization of student responses matched for only 25% of the responses. While researchers considered certain explanations to be inadequate evidence of student understanding of what constitutes an algorithm (e.g., "I chose these because you end up with the right result", "I think my answers are algorithms because they make sense"), teachers did not select any ICs and interpreted those responses to be indicative of a complete understanding of the 'algorithms' concept. When evaluating student explanations that compared two relatively complex algorithms (aligned to LT8), agreement between researchers and teachers was fairly high (agreement on 30 of 36 or 83% responses). In instances where there were disagreements, there was no clear pattern. Teachers appeared to focus only on student explanations and not on students' choice of algorithm when applying the rubric, leading to differences in overall interpretation of student understanding.

For Task 2AP10.LT9.1 (Figure 3), there was a 43% agreement between teacher and researcher evaluations of student responses to part i, where students identified a range of test cases, and a 67% agreement on part ii, where students explained their choice of test cases. Teachers consistently assigned student responses to a category that was indicative of greater student understanding. Though the rubric explicitly mentioned various acceptable values or value ranges for students to use as test cases so that they could test all the rules in the program, teachers could not identify student challenges when students picked distinct values that tested only one or two of the three rules (e.g., "45, 39, 25, 47") or when students picked non-numeric values (e.g., "45, 40, safe range, 40"). For the explanations, disagreements in evaluating student responses seemed to stem from teachers' preference for articulate, logical, and well written explanations, rather than explanations that articulated the need to test all three rules of the program.

Teachers' knowledge of algorithms. While some of these disagreements between teachers and researchers may have been caused by lack of clarity in the rubrics, our analysis of teacher engagement during the PD and teachers' PCK survey responses suggest that some of the disagreement may have also stemmed from teachers' lack of knowledge of the full scope of the 'algorithms' standard. During the PD, when asked about which LTs teachers already use in their instruction, most teachers identified LT1 and LT5, but no teacher selected LT9, indicating that testing algorithms and identifying test cases were not things they associated with 'algorithms.' Additionally, during a PD group activity where teachers practiced applying rubrics to evaluate example student responses to Task 2AP10.LT9.1, we found that teachers struggled to identify negative numbers as legitimate test cases. Also, consistent with what we found when teachers evaluated their students' work, teachers evaluated correct explanations to be inadequate during PD just because they were short and did not provide enough details about the program's behavior. Further, analysis of teachers' pre-PD PCK survey responses revealed teachers' challenges with interpreting and comparing algorithms. These algorithms included nested conditionals or nested loops and were more complex than those featured in students' formative assessment tasks. Most teachers, including Dina and Remi, had difficulty interpreting some of the individual algorithms which then translated to difficulty comparing the algorithms.

Discussion, limitations and conclusion

In response to the current demand for quality CS learning opportunities and useful CS pedagogy in K-12, we offer an approach to unpack a broad CS standard into fine-grained LTs, develop formative assessments aligned with the LTs, and use the assessments to reveal student understanding and challenges related to the standard. Both CS educators and curriculum developers can benefit from this approach by gaining a more complete understanding of CS standards and known student challenges. This approach allows teachers to focus on conceptual understanding of CS standards and formative assessment practices, which they can then leverage in any curriculum to improve CS instruction.

In this paper, we chose a fundamental CS concept, 'algorithms,' and demonstrated our approach by decomposing a middle school CS standard on algorithms into ten discrete LTs. We employed an ECD approach to design formative assessments that capture information about student understanding and challenges for each LT (RQ1). The assessments we developed allowed us to identify common student challenges related to aspects of the 'algorithms' concept, such as comparing, and testing algorithms (RQ2). This work aligns with and adds to a growing literature on middle school students' understanding of algorithms. These are, however, preliminary findings, and we acknowledge that generalizations from this study are limited by our small sample size. Another limitation of our study is that the requirements of our formative assessment tasks did not always align well with typical middle school CS classroom expectations. For example, many of our tasks required open-ended responses and/or explanations of selected responses – something many students were not accustomed to doing in CS class. In many CS classrooms, teachers do not always expect detailed written responses from students and when they do, they often provide students with clear rubrics. Hence, it is unclear whether some student responses to our formative assessment tasks are truly indicative of a lack of understanding or merely reflect students' understanding of classroom expectations.

This paper also adds to the limited literature on middle school teachers' understanding of algorithms and describes how teachers' understanding of CS standards may influence their interpretation of student work and their ability to identify student challenges. While our teacher sample was limited, all teachers in our sample agreed that they did not associate the concept of 'algorithms' with testing algorithms systematically and identifying test cases. Several teachers remarked that they did not introduce their students to algorithmic representations such as flowcharts because it was not covered in the middle school CS curricula they used. Upon examining the types of student responses for which teachers and researchers differed in their interpretation of student understanding of algorithms, despite using the same set of rubrics (RQ3), we concluded that some inconsistencies could be reduced by increasing the clarity of our rubrics, while others needed to be addressed through additional teacher training on the concept of 'algorithms.'

Our findings indicate that middle school CS teachers may benefit from additional PD on the 'algorithms' standard, in particular the concepts of algorithm representation, comparison, and testing and debugging. Merely designing principled formative assessments and rubrics that can elicit evidence of student understanding may not be sufficient to support teachers; teachers also need deep content knowledge to ensure they can use the formative assessments effectively. While it may seem unsurprising that teachers who lack content knowledge are not able to support their students adequately, empirical data to showcase these connections between teacher knowledge and student learning is important in a nascent field like CS education research, especially when many CS teachers claim to learn along with their students and be self-taught. We hope that with a more complete understanding of the 'algorithms' standard, teachers can move beyond just using the peanut butter and jelly sandwich activity to employing a range of activities and assessments that promote a more complete understanding of algorithms.

This work is part of a larger project to support middle school CS teachers with their understanding of five different 'algorithms and programming' standards and their ability to use formative assessment tools aligned with these standards. Next steps on this project will involve similar research using different standards and examining whether the findings in this paper hold with a larger sample of students and teachers.

Abstract: Grounded in the literature on STEM identities and ongoing endeavors for STEM education to be equitable, just, and humane, this project draws from Chicana/Latina plática and CRT methodological approaches to center the identities and experiences of nondominant learners in STEM. Through the ritual of a shared meal, researchers and study participants were involved in three pláticas to describe their personal backgrounds, STEM identities and experiences, as well as visions for their future. Following this communal experience, researchers and participants collaboratively made meanings of collected data and co-wrote counterstories. With participants and researchers engaged in telling, sharing, and writing stories that have been historically "unheard" and "unmentionable" in STEM fields, this work contributes to the recognition of the heterogeneity of students' identities, values, and agency.

Introduction

For historically underrepresented students, STEM education is often promoted and perceived as a gateway for upward economic mobility and social equality. Paradoxically, they endure profound systemic challenges. Structural issues of access and participation have remained significant, driven by the stratification of socioeconomic status, race and ethnicity, gender and sexuality, language background, disability designation, as well as national origins (NCSES, 2019; Philip & Azevedo, 2017). In addition, mainstream cultures, pedagogies, and spaces are often aligned with dominant values, interests, and experiences to favor Eurocentric, masculine perspectives, thereby discounting the identities of many nondominant groups (see Bang & Medin, 2010; Calabrese Barton & Tan, 2020). Finally, while colorblind and assimilationist policies and practices reproduce social inequality (Bonilla-Silva, 2013), social justice and culturally responsive approaches have been largely rendered irrelevant and as a result under-researched across STEM fields (see Morales-Doyle, 2017). In short, despite the progress made towards equitable opportunities, both in academic and professional realms (NCTM 2000; NRC, 2012), the double-bind faced by nondominant learners in STEM—whereby a high-status field explicitly recruits these students while continuing to marginalize them—remains prevalent.

The current study is situated in a broader university-based science and engineering outreach program–AirProject (a pseudonym). In this program, undergraduate and graduate students from various engineering departments learn to conduct project-based research on air quality topics and later on teach these content and skills to middle and high school students. Education research activities that accompany AirProject are mainly ethnographic, including participant observation, field notes, surveys, and focus-group interviews. The research team has shown how the design of AirProject affords learners ample opportunities to rotate among different roles and responsibilities where they see themselves being both an engineer and an educator (Tran et al., 2022). The current study is an extension of the AirProject's ethnographic research agenda; our team leveraged Chicana/Latina plática methodology and Critical Race Theories' tradition of counterstories to facilitate dialogues, reflection, and storytelling to center the experiences of nondominant students in STEM fields. We asked how do nondominant engineering students identify themselves in and outside of STEM fields? And how do nondominant engineering students articulate their experiences, re-imaginations, and possibilities for transformation in STEM fields?

Literature review and conceptual framing

This study has taken insights from the extant STEM identity, STEM equity, and decolonizing STEM education literature. As in other fields, STEM learning constitutes not only accruing and applying discipline-related knowledge but also concerns how learners engage in specific concepts and experiences drawing from their existing understandings of the world. The notion of STEM identities does not entail a set of fixed, stand-alone traits and instead suggests nuanced, multidimensional, and intersectional characteristics. In particular, scholars and practitioners have critiqued how the dominant approaches to STEM identity often applaud 1) certain traits—ones aligning to white, masculine perspectives—as encoded identification of learners' suitability for a future in STEM and 2) the ideas that STEM pursuits are for some but not others (see Collins, 2018; Rodriguez & Blaney, 2021). Failing to integrate how students of different backgrounds identify with STEM thus imposes ramifications for historically minoritized students who often have to compromise how they see their authentic selves in exchange for the development and identities that are deemed worthy in their disciplines.

Growing research on STEM identities draws from notions of learner agency (Lave & Wenger, 1991) and practice-linked identification (Nasir & Cook, 2009) to explain the dialectical, evolving relationship between STEM learner, identity, and learning across timescales (Polman & Miller, 2010) and social settings (Bell et al., 2017; Pinkard, 2019). In this vein, the *trajectories of identification* framework attends to how a learner's participation in STEM in the present is unfolded by differing experiences and interactions that they have had in the past and by visions of themselves being involved with STEM in the future (Polman & Miller, 2010). This approach unravels the interactions and mediations, both moment-to-moment and overtime, where learners co-construct their learning experiences by drawing and combining cultural identification—encompassing communities, languages, practices, and values—with disciplinary understandings. Examining STEM education and endeavors from identity perspectives counters dispositions of STEM education being objective, acultural, and apolitical. Specifically, scholars have investigated the structures and processes that support or inhibit student agency within the dominant norms, cultures, and practices (Greenberg, 2019; Nasir & Vakil, 2017). In this context, Vakil (2018) argued against discourses that assume female students and students of colors lack genuine interest in technology. The author highlighted that discipline interest and identity are not intrinsic, instead, derive from resources, materials, and ideas that students are introduced to throughout their learning and development.

Education research is pressed to break down its long-established conceptions of what counts as knowledge. Relatedly, Patel (2015) grappled with the role that education research—by upholding narrow notions of objectivity and generalizability—has played in compartmentalizing and stratifying knowledge to center white upper and middle class culture while purposely discounting other ways of thinking, knowing, and sense-making. From here, Patel urged education researchers to clarify ethical implications and responsibilities that their works, as part of a system that is built on inequity and injustice, have in regard to colonial legacies. Decolonizing STEM education efforts, as they concretize critical and historical perspectives of STEM education in relation to socio-political materialities, challenge pedagogies that fragment and compartmentalize learners as disembodied vessels of STEM knowledge. Such efforts lend arguments and evidence for how learners' bodies and emotions are themselves important socio-historical sites of learning, guiding their development, fluency, and change-making across and beyond their disciplines (Takeuchi & Dadkhahfard, 2019).

Methodology

On preceding ethnographic research and relationship-building activities. While the current study was primarily guided by the Chicana/Latina plática and counterstory methodological approach (detailed further below), much of its implementation was scaffolded by the preceding ethnographic research components and relationship-building activities. Tran was introduced to AirProject's students as the program's a research assistant in fall 2022. In the following seven months, Tran joined the class every other week to build rapport with students, as well as to observe and prepare observation notes. She often drew from these notes to report patterns of engagement and learning in meetings with the instructor and research teams. She also delivered a workshop to support students' communication with middle- and high school teachers who they would be collaborating with in the following spring. Furthermore, she accompanied two students on their multi-day trips to a partnered school, one that was located 5 hours from their campus. In Spring 2022, Palomar and McKoy joined the research team to co-design and co-facilitate three pláticas with Tran–in the form of shared meals–engaging eight students (including Aguirre-Marmolejo, Sheperd, Song and five other classmates) who self-identified as nondominant learners in STEM.

On plática. In Spanish, plática means "talk." In research settings, Chicana/Latina scholars perceive plática as a useful and powerful *research method* because its intimate and friendly conversational approach is congruent with the ways of learning and doing in their community's everyday contexts. That being said, following the work of authors who draw from both Chicana feminist epistemological orientation and plática methods, such as Gloria Anzaldúa, Emma Pérez, and Delgaldo Bernal, Fierros and Bernal (2016) contended that plática is more than a tool to support data collection; these authors conceptualized plática as a *research methodology*.

Our study was designed to follow the principles of the plática methodology (Fierros & Bernal, 2016), which fundamentally prioritize how participants can heal from oppressive realities through the process of theorizing their own experiences and envisioning their own futures. At the beginning of each plática, Tran led a cultural rapport passage where she presented her researcher positionality and began to cultivate an agreement for the group dialogue. She invited participants to embrace and respect vulnerability when sharing their experiences, and emphasized the options for them to pause and to prioritize their mental health. Besides, students were asked to arrive to plática with cultural artifacts that represented their identities in general and STEM identification in particular. With all researchers and participants engaging in sharing stories and cultural artifacts, the priority of the conversation was to create a comfortable and safe space for students to share. During the meeting, researchers and participants discussed background and interests, STEM identification and experiences, and perspectives on future careers and possibilities for transformation in STEM fields. Each plática ran between 60 to 90 minutes, were video- and audio recorded and later transcribed for analysis. After each plática, Tran, Palomar, and McKoy discussed impressions and takeaways; and students were asked to respond to a feedback survey.

On writing counterstories. In conversations pursuing the STEM pláticas, the three researchers often talked about the ethics of research practices, specifically noticing how researchers' choices in examining, analyzing, and presenting data will matter to the version of the "truth" that we construct. At the same time, we learned about emerging spaces that scholars from different traditions of story work have facilitated for alternative ways of meaning-making and presenting knowledge (Marin et al., 2020). From here, we took up the CRT approach of constructing counterstories. The narrative-driven and justice-oriented technique informed an analysis process that centers the complex and multifaceted natures of learner identities; unmasks how interlocking systems of power work to dominate and marginalize nondominant communities; disrupts the *majoritarian discourse* (1) that diminishes and erases the histories, presents, and futures of these communities; and finally, makes room for social movement, solidarity, resistance, and transformation (Solórzano & Yosso, 2002).

To prepare data that supported counterstory writing, Tran generated eight separate individual transcripts, each consisting of all quotes voiced by a specific participant. Together, the three researchers rearranged quotes into six categories, including: a) personal background and artifacts; b) STEM identification and learning pathways; c) marginalized experiences in STEM; d) experience with outreach; e) components that have affirmed students' persistence in STEM; and f) components that will determine transformation in their future STEM careers. We invited all participants to re-construct their own counterstories, and five (out of eight) participating students joined our team. The process of collective writing has been as follows: As Aguirre-Marmolejo expressed an interest in writing his own counterstory, he read through the plática transcript to retrace the places, events, and relationships critical to how he identifies personally, socially, and professionally. The writing process about self has encouraged him to embody the craft of storytellers to "go back and forth between the part and the whole" (Fox, 2015, p. 324) of his upbringings, to provide more details, and to emphasize the concerns (about self and community) that co-constituted his STEM learning experiences. The three researchers then met in person to read the draft that Aguirre-Marmolejo had shared with them and provided him with a written note for feedback and clarification. Meanwhile, other students (like Sheperd and Song) who preferred to work with the researchers to co-write counterstories—were asked to read through their individual transcript, identify details (pertaining both human and more-than-human relations) that are important for their stories, and articulate the directions they would like the story to go. The researchers then read the individual transcript as well as comments left by each participant. During this process, researchers and participants engaged in conversations to pick out moments corresponding closely to participant's understandings and experiences with STEM. The researchers built a narrative that weaved these moments together into a telling of self and STEM participation, all in relation to everyday cultural practices. Participants made edits and suggestions for changes, as they ascertained next iterations of the draft.

Findings

Our findings present various dimensions of identities that combine to show how nondominant learners see themselves in their disciplines and future careers. Through dialogues, collective meaning-making, and storytelling, participants and researchers brought together parts and pieces of memories–voiced during and following our pláticas—to make arguments for their belonging and their love for STEM. Here, we present three counterstories, animated with life events, relationships, embodiments, and emotions, all embraced by storytellers to theorize our own experiences of learning and being in STEM.

Story 1. Blessings from the cedar

> I have this little bottle filled with cedar that I keep in my car. Where I come from cedar is something gentle. We entomb it—burn it and say prayers because it is sacred. When I'm driving around and catch glimpses of it on my way to school and work, it is a reminder. I could palpably smell the Navajo reservation, where my parents grew up. I did not grow up on the reservation, though I lived in Arizona for eight years; in fact, it is a place that I had spent time in …longer than many other spaces. My dad has been in the Air Force ever since I can remember which means we did move around a lot, but the cedar still lingers—a connection to a place, a community, a home that will always matter to me regardless of where I am. And I think this, the connection to my dad, is a big reason why I chose a career in STEM. Growing up close to someone who worked on aircrafts taught me what it means to think like an engineer, and how to tinker and build things with curious and critical eyes. That curiosity traveled with me to new places, even when we moved across states and continents.

In eighth grade I was living in Japan, a small town, in the middle of nowhere. The boys and girls club was sponsoring a trip to go to space camp in America. I did not know about it at first, but my science teacher came up to me and said "hey, I heard about this thing. You should apply." The hesitance came flooding in—how was I going to a camp all the way in America? How could we afford it? Who would actually pay for me to go?—But still, my teacher encouraged me and I'm glad he did … because I actually got to go to space camp! I realize that moment with my teacher was the first time I felt valued in a STEM space. I felt seen. At the space camp in Alabama, we were surrounded by planes and models of spaceships. It was where I really started thinking that I, too, could help design and work on these things.

Since then I was pretty much set on a career in STEM. I have been working as an engineer and as of right now, I am a PhD student in Mechanical Engineering. However, thinking back, I have had to work to feel like I belong. Kind of unconsciously, I used to hyperfocus on getting myself ready for work—making sure I looked professional and presentable, making sure I looked like I fit in. I did not want to give anyone, especially in a career filled with folx who do not necessarily look like me, an excuse to undervalue or dismiss me. Maybe it is a mind game—that there is a certain way an engineer is supposed to look—and somehow we internalize that? What I know is that I have to keep fighting that game, because I do belong here—in STEM.

A moment that I have always kept close to my heart was from my first day as an undergrad. There was a big opening ceremony to welcome the freshmen in which the Dean told the story of a former student, explaining that this person came from the reservation. He was Navajo. He studied Mechanical Engineering and designed for NASA's most recent trip to Mars. Hearing that introduction, I sparkled. I was filled with so much energy, so much curiosity. I kept asking myself, "who is this person?" I knew I had to meet him. I have never met anyone, besides my dad, who identified that closely with my background and was doing the exact work that I wanted to do. As I am writing this story, I am now working at the same place with this person, at NASA Jet Propulsion Laboratory, and we are not only colleagues but also friends!

I am never going to forget my time in space camp. Just like I will never forget the sound of my dad's voice when he talked about working on aircrafts. Just like I will never forget my first day being an engineering student, which made such a staple in how I identify with my career. Like the cedar that still hangs over my car dashboard, I carry these stories as reminders of where I have been and how I can make an impact. I keep them close just like prayers for myself, my family, and my community, as through thick and thin, I see them standing with me.

Story 2. Will I ever fit in?

Dear Little Meiou,

Remember the smile on your face the day you learned about the microenvironment of the cell? Remember how your eyes lit up … it felt like your little head was drawing a thought bubble connecting everything your teacher was saying about the structure of the cell? You envisioned yourself as a scientist, wearing a lab coat, with a pipet in hand, moving the solution from one beaker to the other? While this was once a dream, it is now a reality.

Little Meiou, I will take you back to the start of our voyage.

A few years ago, your passion for science and research led you to another part of the globe. Wanting to leave behind what you have been told: "males are typically more motivated and talented in math and science," you left Beijing–your home–to go to the United States. Almost immediately though, the boundaries of being a woman in STEM and the overload of relocating to another country kicked in. You have been known as a chatty person at home; and yet in the new country you were surprised to find yourself quiet. You became nervous with the language barrier. It was not that you did not know what to say, but you were scared to speak and embarrassed by your English.

It took some time for you to realize studying in a foreign country does not only mean more opportunities: working with experienced and knowledgeable professors, fancy equipment, and frontier technologies. It also brought moments when you felt inferior to your peers who were native speakers. It also brought disappointment as you realized the unfamiliarity with the language, custom, and culture had prevented you from joining groups and laboratories. You started to think, was the way how STEM learning is set up in the United States ever prepared for a foreigner, like yourself, to thrive? You started to wonder, "will I ever fit in?" At times, you felt like you did not have either language or companion to process these struggles and hence there was not a space for healing. It was difficult, little Meiou, to be a Chinese woman in STEM, and even more difficult to be one at a predominantly white institution. You have found yourself always learning the unfamiliar, and there yet seems to be more that you need to take on. You did everything you could to go above and beyond: work hard, take initiatives, and be confident. Not only exceeding expectations you have also defied many limitations inscribed for women in STEM. Despite all challenges–you shine.

I wanted to tell you a little about your journey, our journey. While there are constant struggles, you are where you need to be. You are Meiou Song, a Chinese woman who loves science and teaching. You are pursuing a career in Mechanical Engineering, where you and your colleagues are dedicating time to develop low-cost diagnostic technologies to improve healthcare in developing countries. This path is bringing you so much love and joy. And, also! you have met and observed many women, who are from different backgrounds, in your classes and in your labs; they have become your academic sisters and mentors, all determined to support each other to participate and succeed in STEM. “What draws these great women to STEM in a world that prioritizes male scientists and engineers?” You continue to ask.

Your love for science and passion for teaching are the driving force behind your constant resistance. I wanted to let you know that you are following your heart, and that alone is one of the bravest acts you have done. As I write this letter to you, my younger self, my heart is filled with pure bliss, as it knows that I am, in fact, making Little Meiou's dream come true. My dear, stay passionate, curious, and joyful!

Spring 2022, Boulder, Colorado
Meiou

Story 3. The broken ouroboros

The ancient Greek symbol, ouroboros, is often used to refer to an eternal cyclic renewal, a *cycle of life, death, and rebirth*.

While I was born in Leon Guanajuato, Mexico, my conscience was born in East Los Angeles right by the abandoned Sears tower; that is where I have my first memories. In the early 2000s, East LA had a lot of culture that I found amazing. Mobile food stands that sold elotes, paletas, or pan; customized low-riders with hydraulics that made them jump; and lots of Mexican heritage events, all of which were made or hosted by my family and neighbors. I found a lot of comfort in this community because I had great exposure and opportunity to celebrate my roots and my culture. Unfortunately, East LA was not perfect. To be frank, it was more of a war zone at times. Gangs were idolized amongst the youth and occupied the area on every street. Their actions affected everyone. I have many memories of my elementary school getting tagged with graffiti and school maintenance men would paint over it, only for it to happen again and again. I also have memories of my mother tackling me down because there were gunshots fired outside our apartment building. But to me, I did not even know our home was in the “hood.” Maybe the “hood” never bothered me because I thought that this was how the world was for everyone.

As a kid, I really wanted to be an astronaut, like Neil Armstrong. My family, friends, and teachers knew that. Beautifully, they all showed great support, and everyone pretty much told me the same thing every time: “Osmar, you have to *work really hard* and *be very smart* to do that!” By the mid 2000s, my family moved to Albuquerque, a unique place famous for our Hatch Green Chile and *Breaking Bad*. The city hosted tours for the TV series’ hotspots while providing an assortment of green chili flavored snacks to tourists—some of whom thought that New Mexico was in Mexico. People paid money and were very excited to witness a setting for a show that epitomizes my city: addiction, crime, murder, and the recruitment of children for nefarious schemes. Here, my friends and I were young children looking for guidance. Lacking proper role models, wannabe gangsters were the only people that my friends looked up to and felt community with.

Fast forward to college, I spent my days and nights working three jobs while being a full-time engineering student. Meanwhile, some of those friends who did not have much direction ended up in jail, dealing drugs, getting addicted to drugs, or dead. All these people have been my friends since my elementary, middle, and high schools, and regardless of their choices, are some of the best friends I have ever had in my life.

I had a hard time facing this reality.

> Simultaneously, I graduated as a “rocket scientist race car engineer,” literally. Never allowing myself to mourn, I felt completely alone. At some point, I drove beyond burnout.
>
> A couple years ago, I moved to Boulder, Colorado to attend graduate school. While getting through my Master’s program, I slowed down and took care of my mental health. I have been reflecting on my new life–now–a better life, one that my friends would be happy for me to have. Thinking forward, I choose to be a broken ouroboros that stops the toxic traits that have been passed on against my community, generation by generation. This reflection has provided me clarity to pursue a career path as both an engineer and an educator. By helping and inspiring the next generations in different ways, I feel that *I am not alone* when I see others, who look like me and my friends, are thriving and achieving their own potential.

Discussion

Our group, comprising three learning sciences graduate students and three college STEM students, has come together to reflect on our experiences across different STEM environments and co-write our stories. We explain the interrelationship between our identities, learning, and the broader society that we grew up in. Below, we depict what characterizes these stories as counterstories. First, as we (Aguirre-Marmolejo, Sheperd, and Song) tell stories about our own intersectional experiences, we fight the master, “monovocal” (Solórzano & Yosso, 2002) narrative–one that maintains the homogeneity of all learners who identify differently from the normative student population in STEM fields. Aguirre-Marmolejo unpacked a constellation of identities, some tie to his Mexican culture and heritage. Other layers of the constellation were unveiled as he time-traveled to his childhood and adolescence to see a younger self surrounded by best friends, teachers, and family members and as he space-traveled to see various places that he has called home, some associated with gangsters and others called “the hood.” Song’s letter to her younger self echoed complex experiences that accompanied her journey in which she left her home country–China–for the U.S seeking to fulfill her dream to be a scientist. Sheperd’s story surfaced what it means to be a Navajo woman who, for various reasons, did not grow up near the majority of her family who live in the Navajo reservation, and her observation for not having many people of similar backgrounds in her career path. Concomitantly, intersectionality is not solely about issues of identity, and rather a prognostic instrument to interrogate how power is structured and maintained in both learning spaces and broader society (see Annamma & Booker, 2020). In this vein, these stories unmask how gendered, raced, and classed hierarchies have shaped writers’ lives and determined the pain that we endure being distant from our own culture and heritage. Our stories provided examples for how our “intelligence” and “fit” for STEM fields continue to be perceived and mediated in learning and working environments that are wrought with Eurocentric and American-centric ideologies, and how such structure recursively undergirds our own lived experiences under broader projects of pathologization and assimilation. We describe how we grappled with systemic constraints, be they social, linguistic, or political, across these spaces to articulate and assert our whole, complex identities as critical processes of STEM learning.

Our stories depict endurance and resistance. As we traveled to the past, present, and future to assemble our identities, we noticed moments of vulnerability, uncertainty, and lack of confidence, and at the same time, we were reminded of our own power and agency. For instance, while “Will I ever fit in?” is presented as a letter that Song wrote for her younger self, it was also dedicated to her inner child; this writing tended to the stress and worries that Song has been coping with by reminding her of her emotions, hopes, and dreams to make an impact in the world through researching and teaching science. Her letter raised awareness about some contentions that she experienced, being a female, international student in a STEM graduate program; at the same time, it is glistened with an adamant enthusiasm for exploring and strengthening new scientific ideas and practices–what she had repeatedly named during the plática as “bringing me joy.” In this vein, while toiling under constant pushbacks, our endeavors have been fueled by the strong belief and passion that writers have for STEM disciplines and for our own future selves. From contestation comes re-configuration. Realizing our power and agency entails a recognition that STEM participation, while contingent on social and historical circumstances, is neither static, predefined, nor deterministic (Bell, 2017; Polman 2012). The celebration of our STEM achievements neither equates with us losing sight in building solidarity with our communities nor essentializing STEM knowledge as all-knowing. Constructing a holistic and pluralistic view of STEM identities and participation, our group affirms that our persistence in STEM fields has extended beyond a process of enculturation into a specific academic or professional program. Rather, this process has been generative to how we strategize for our positions in our fields, as it is dialectically informed by our various lived experiences in which we concurrently navigated everyday contexts and practices, participated in STEM formal and informal learning curricula, and constructed new identities. STEM identification conjoins with how we build relationships and solidarity with other nondominant learners and colleagues as well as how we promote dialogues, visions, and practices synergetic to the values and ethics of our communities (see Phillip & Azevedo, 2017; Vossoughi & Vakil, 2018).

Our study is motivated by ongoing efforts that cultivate transdisciplinary approaches in STEM education (Takeuchi et al., 2020), moving away from traditional structures of subject-based education to frameworks that composite and integrate heterogeneous ways of knowing (Bang & Medin, 2010; Roseberry et al., 2016). Holding conversations in the format of “every-day talks” and reconstructing counterstories from memories, reflections, and dialogues that have been gathered throughout the length of our collaboration are decisions grounded in a persistence to center the multiple identities and multivoicedness of nondominant learners in STEM. The plática approach has made available a communal space where researchers and participants–all are students from historically marginalized communities–reclaim history and full narratives of our stories, workshop arguments to defend ourselves against deficit narratives, and experience healing. During the writing of counterstories, we experienced a re-location of roles, tasks, and expertise, where how we chose to collaborate with each other destabilized the binary of the researcher versus the researched. Importantly, we have engaged in and sustained the conversations with an understanding that relationships are being attended to and worked on by everyone in the room. Such collective composure has opened a space for *fugitive learning* (Patel, 2019) where we traversed across conventional boundaries of research practices and STEM education to recount unconventional nuances that have brought us to our academic and professional choices. Together, we build a vulnerable, affective space–which rarely exists in our current pathways–to relate STEM to who we are.

Endnotes

(1) “A majoritarian story is one that privileges Whites, men, the middle and/or upper class, and heterosexuals by naming these social locations as natural or normative points of reference.” (Solórzano & Yosso, 2002, p. 28)

Abstract: Making engages young people with the material world and reflection-in-action, creating promising science learning contexts. Emphasizing relational and social dimensions of making, we conducted a week-long workshop for middle schoolers who are current and aspiring pet companions. Supporting participants' inquiry into pets' senses and related behaviors, we asked them to work on maker projects meant to improve their pets' lives. Following a qualitative analysis of participants' positioning in relation to their pets, we present case studies of two female participants' positioning. We find that through the process of making, the two participants demonstrated an increased awareness of pets' biology and related behavior and their personal interests in pet care, while also differing in what aspects of human-pet relations they focused on. We conclude that through making, especially in contexts with a robust relational draw, youth become attentive to complex and otherwise difficult-to-notice transactions central to taking care of pets.

Introduction and background

We know that through making, youth sustain engagement with learning processes (Resnick & Rosenbaum, 2013; Washor & Mojkowski, 2010), understand the affordances of designed materials, and learn concepts (Martin, 2015; Bevan, 2015; Kostakis et al., 2015, Peppler & Glosson, 2013, among others). When youth make artifacts that solve their communities' problems, they feel more invested and persevere in finding solutions (Barton, et al., 2016; Holbert & Wilensky, 2019) and learn better (Hughes & Morrison, 2018). Further, through making, makers and educators question the power dynamics inherent in multi-stakeholder learning situations (DiGiacomo & Gutiérrez, 2016; Vossoughi et al., 2020). In light of the above strands of maker education research and research on youth's engineering and design processes in loosely or unstructured, informal settings (Parekh et al., 2023; Simpson et al., 2017) which illuminates the convoluted path of the decision-making, problem identification, and solution process, we see value in studying making as a trajectory. Emphasizing the importance of the complex processes through which youth negotiate ideas when designing for a close more-than-human (i.e., a pet companion), we extend the lines of inquiry in maker education into the domain of learning while making for those whose lives and needs humans can understand only through a commitment to care and relationality. To this effect, we draw from the following constructionist ideas.

Maker education in STEM values learning through building complexity from simpler parts, particularly in difficult-to-learn and complex contexts such as Agent-Based Models (Wilensky & Rand, 2015) and video games (Holbert & Wilensky, 2019). Learning artifacts such as interactive models and games exist at the intersection of cultural presence, embedded knowledge, and the possibility for personal identification. They are a part of youth's material environment and disciplinary domains, inviting the exploration of complex ideas. Objects-to-think-with are transitional objects that bridge the abstract and the concrete, the physical and the psychological (Turkle, 1990). We explore a new dimension in maker education research by examining youth's positioning in their recognition of relationality within their everyday pet-care and pet-related maker-project work at a summer workshop. We define relationality as connections to peoples, creatures, lands, and objects.

Relationality is mutually affecting and reinforcing (Bateson, 1972); in relationships with others, we "become with" them and are defined by the relationship within a shared ecosystem rather than being othered. A relational perspective on learning entails attention to the relationship between the learner and the world. Specifically, we study how learners understand themselves as a part of the ecosystem they share with their pets or will share with future pets. By adopting this perspective, we argue that in this specific learning context, many factors, such as understanding pets' behavior associated with sensory experiences, pets' and humans' interests, learners' existing relationships with pets, and the setting of the human home are simultaneously present and shape learning.

A relational perspective has deep roots in theories of learning. In a departure from the cognitive theories of learning concerning information processing and sensory data in the learners' brain (for example, Gardner, 1987), the many traditions of constructivist learning consider the learner a social being. The individual constructivist perspective is concerned with the internal construction of knowledge followed by testing the knowledge in the outside world (von Glasersfeld, 1995) in a continuously interacting and iterative three-part system (Biggs, 1993). A social constructivist perspective proposed that learners construct knowledge through interactions with the social world (Vygotsky, 1978; Wertsch, 1985). Situated learning theories emphasize the importance of learners' active participation in the context of learning, constructing meaning through their participation in activities within communities of practices (Lave & Wenger, 1991; Brown, Collins, & Duguid, 1989). For many who subscribe to these perspectives on learning, the separation between the individual learner and the world is clear – knowledge is constructed through learners' interactions with material, social, and semiotic elements in the outside world. When one takes on a fully relational perspective, the learner is seen as a part of the world, becoming increasingly aware of the complex ecosystem and its connections through interaction with it over time. However, it is challenging to support learners to consider themselves in relational ties, co-becoming with the world.

Our response to this challenge is two-pronged. First, we emphasize the importance of youth's relationships with animals that live in the same home and yet experience the world differently. By including pets in the workshop, we harvest a complex yet accessible setting that might foster a relational approach to learning. Second, we introduce to the learning environment an Augmented Reality (AR) tool to facilitate youth's understanding of the relational ties with pets through perspective-taking (Parekh et al., 2023), supporting a sense of what it means to be an animal in a shared ecological setting. To this end, we designed a summer workshop where youth learned about pets' sensory experiences and related behavior and worked on maker projects to enhance aspects of the pets' lives at home. Below, we describe our orientation to learning while making, especially in our case, where youth make things for use by more-than-humans.

We consider youth's maker projects meant for their more-than-human pets to be objects that bridge youth's understanding of humans' and more-than-human's experiences in the ecology of the human home. In an ecosystem where youth feel compelled to recognize the effect of their maker projects and ideas, we highlight youth's awareness of how the process and outcomes of knowledge production make a difference in being ethically accountable to ongoing relationships. We ask the following research question: *How do the social positioning of makers and making objects for more-than-human pets contribute to opportunities for ecological learning?*

Theoretical framework

Positioning refers to the ways individuals locate themselves and others in a social context and along a storyline (Harré, 2012; McVee, 2011). Broadly, positioning is based on the implicit understanding that rights, responsibilities, obligations, and duties to perform and react to meaningful actions, and actors in an interaction, are reserved for only certain individuals (Harré 2012, p. 4). Hence, it is vital to highlight practices that support and detract from individuals' location of themselves and others while performing discursive acts (Harré 2012). Storylines, metaphors for individuals' discursive interactions within different activity systems, are recreated in conversations and link the past, present, and future. Studying changing storylines helps us interpret changing interactions in episodes of activity as positioning moves to change existing storylines and give rise to new ones. Positions within storylines can be dynamic and open to interpretation, those who are not the key players in a situation are able to interpret positions in different ways. Importantly, initial positioning moves are often subconscious, and individuals resist others' reading of one's positioning (Harré 2012, p. 6).

Although positioning is discursive and dynamic, individuals cannot freely position themselves. Through reflexive positioning, individuals position themselves (Davies & Harré, 1990) to match their worldviews and how they live, act, and think. Hence, this is a way of indexing events with actors' points of view. Through interactive positioning, individuals position others, giving us an opportunity to study how the position of specific individuals can differ in different contexts, thereby limiting how those people can act, perform, and think. Finally, roles are a subset of positions and are scripted, static, formal, and ritualistic (Davies & Harré, 1990, p. 43), while positioning concerns individuals' taking up specific locations in dynamic, temporal ways (McVee, 2011).

Foucault (1979) argued that power is everywhere because it comes from everywhere, thus opposing the view of power as a function of privilege. As a privilege enjoyed only by certain members of a social group, the division of power would present a binary worldview of the oppressor and the oppressed, the ruler and the ruled, and the dominant and the subservient. The scholars mentioned above question such binary divisions and emphasize instead the multiplicity and connectedness of human experiences. Others studying human-nature interactions are similarly intrigued by replacing the perceived binary of human-non-human existence with an intricate, complex, interweaving human-nature coexistence conceptualized as natureculture (Fuentes, 2010; Haraway, 2008). Challenging notions of human exceptionalism and speciesism, natureculture emphasizes entanglements. We are interested in the entanglement of human learners with their canine and feline companions and the learners' relative positioning of and with regard to more-than-human companions at home. Our study takes place in a pet sciences-focused maker workshop. Specifically, after introducing the hidden world of pets' sensory perceptions to middle school-aged learners, we study the learners' positioning of themselves and their pets as they construct their understanding of their pets' lives while working on maker projects meant for the pets. Following Donna Haraway (2008), we believe our entangled relationships with domestic animals are especially revealing because the human-pet co-evolution redefines humans and their more-than-human companions. In the following section, we detail our study design details and analytical strategy.

Methods

Workshop details

In the Summer of 2022, we conducted a week-long summer workshop for middle-school-age youth in partnership with a university outreach program. The outreach program recruited middle school age learners through their partnership with local schools and from contacts with previous participating families. All participants traveled to the university campus for the workshop. We began with eleven participants, and other than one participant who suffered a COVID infection, all participants completed the workshop. We collected whole-group video recordings and small-group audio recordings for each of four groups of participants. We also conducted semi-structured interviews with each participant once during the workshop, on the fourth day, once immediately following the workshop, and finally a month later. The semi-structured interview included questions about participants' project work, their motivations for the projects, how the projects improve their pets' lives, how they think the pet might use the project and what they expect to learn from their observation of the pets, some changes that they would like to make to the project, and how working on the project has helped them think about pets at home. In the post-workshop interviews, we sought participants' responses to questions such as the following: On the days of the workshop, did you do anything differently with your pet? What were the activities you would say you did with your pet? What role did your pet play in your projects/project ideas/testing projects? What did you learn from working with your pet? What science topics did you learn at the workshop? How did you use science to learn about pets? How was this program similar or different from other science classes you have taken? What do you think it would be like to have a career as a scientist? What would you like, what would you dislike? How would you describe your identity as a scientist, an animal scientist, and a designer? We asked participants without a current pet at home to talk about a pet they knew.

The workshop plan was as follows: Day 1: Exploration of pets' senses through Augmented Reality filter applications and enhanced hearing applications, mapping of pets' activities at home and around; Day 2: Discussion of findings and experiences with pets, sharing pet stories about sensory experiences, identifying pets' experiences to understand better, planning investigations; Day 3: Best practices and examples of investigation of pets' senses, sharing outcomes of investigations conducted at home with pets; Day 4: Discussion of individual projects with peers and project work; Day 5: Presentation of learning to peers and families.

We analyzed data collected from two participants working at two different tables. We chose these two participants because of the following reasons. These two participants talked enough at the workshop, giving us enough data to analyze, maintained unique and contrasting relationships with the pets (one had pets at home, and the other hoped to be a pet companion in the future), and participated in the workshop in different ways as well. These factors help us inquire into different possibilities for learning.

Participants

Stella and Mabel (both pseudonyms) are female and twelve. Stella is of Hispanic descent, and Mabel is White. The two participants were seated at separate tables with two other participants and a teaching assistant. For this paper, we analyzed only Stella and Mabel's talk and not the other members of the group. We paid attention to participants' talk following moments of recognition of pets' sensory abilities, specifically, vision, smell, and hearing. We specifically planned to inquire into these senses at the workshop.

Data analysis

Our analysis is based on the following assumptions about positioning. First, an individuals' positioning in a situation is complex and shaped by multiple factors. Second, positioning is fluid and can be read differently. Third, just as individuals can position themselves, others can position them as well; these positionings might not align. Fourth, individuals with similar positioning in one context can position and be positioned differently in a new context because individuals respond to cultural resources differently.

We present our findings in the qualitative research tradition of a case study (Stake, 1995) meant to capture the complexity of the human experience. Each case- individual participant in the setting of the workshop (with activities, facilitators and peers) and the backdrop of the relationship between the participants and pets at home. We chose two workshop participants for our analysis because of the contrasting nature of their participation that would help us answer the research question, and the quality of the audio data we collected. We transcribed Stella and Mabel's talk throughout the workshop and during the interviews. We began our analysis by inductively coding for participants' positioning within the initial goal of identifying as many intelligible positionings as possible. Next, for each of these positionings, we categorized events in the group (For example, open sharing, answering workshop prompts, etc.), along with the specific details about Stella and Mabel's participation. For example, what are Mabel and Stella acting as, what they are doing, possible reasons for them acting in a certain way, the outcome of the interaction between these participants, how the participants relate to pets, projects, and ideas and materials for the project, etc. Parallelly, we coded for the participants' projected role through positioning including 9 inductive categories: pet expert, pet novice, pet knowledge seeker, pet-related problem solver, pet empathizer, pet advocate, pet companion, aspiring pet companion, advocate for pets and humans. Following this, we wrote analytical memos about the nuances of Stella and Mabel's positioning with respect to the roles they chose in specific moments and aspects of the interaction that spoke to the interaction between individual's positioning and assumed role. We were especially attentive to situations where Mabel and Stella appeared to position themselves in different ways and in different roles.

In a parallel round of predetermined deductive coding, we analyzed the participants' maker motivations in response to the general question, why does the participant work on the project? Codes included the following: investigating with the intent to find something out, entertaining and fun to make something, making something nice and attractive, because my friends are making something similar, problem-solving for pet, problem-solving for humans, wanting to use an attractive material, wanting to look busy. We wrote memos to clarify how the participants' positioning and assumed roles in specific moments related to their project motivations. Finally, we created a critical participant narrative account (VanMaanen, 1990; Polkinghorne, 2005) for each of the two participants with attention to their positioning at various moments at the workshop and its implications. We would like to draw attention to the importance of our analytical scheme. We do not compare each participant's general talk (off-topic talk, friendly banter) to their pet-related talk; hence, we do not know if Stella and Mabel's pet-related talk is unique to their positioning in the workshop. Rather, we say that they are different as learners, and in the backdrop of a particular kind of difference, i.e., their positioning and social interactions at the workshop, they took part in particular ways and achieved certain outcomes.

Findings

Below we detail Stella and Mabel's positionings at the workshop along the general storyline of the importance of pets and pet care to humans who desire the company of pets. Later, we summarize the importance of their positioning while making objects for their pets to opportunities for ecological learning.

Stella's positioning as an aspiring pet companion

On the first day of the workshop, Stella quietly declared that if she ever had a pet, it had to be a cat. She had known her friend's pet cat, Toasty, for years, and Toasty was Stella's frame of reference for understanding all cats. However, although Stella cherished memories of being Toasty's play companion, she knew that Toasty was not *her* pet. Among those at her table, when others shared stories of their pets, Stella's stories of Toasty always followed with questions. "Does your cat jump into the air like that?" "I think Toasty rubs his head on my calf when he needs pets. Do other cats do this as well?"

On the second day of the workshop, Stella continued to ask if her understanding of cats was accurate, but at the same time, after using the KittyVision filter tool to investigate how the world must appear to cats, she began sharing her observations. "Well, I see that they don't really see red, so (Toasty) must have jumped because it (a toy) was moving." At the same time, she began refining others' understanding of their pets when they shared stories. Daphne, the facilitator at her table, too, began supporting and appreciating Stella's observations. "That's a very good question!" Stella also started seeking details about Daphne's cat Willow. What does Willow like? Why does Willow like certain things? Would Willow like this or that? Was Willow a box or blanket-loving cat?

Stella was stumped when the workshop moved on to making artifacts for the pets on the third day. She was aware of her peers' relationships with pets at home, and how they were confident about their pets' reactions to their projects for them, so Stella wondered if she "knew how to love a pet." She knew it was impossible to care for a cat without knowing the animal closely. For example, Stella wondered how she could make specific aspects of a cat's life better. When another participant began working on a project, Stella closely observed him and asked how his cat might play with the toy, a catnip-stuffed felt food item, a catnip stuffy. Stella made a similar toy for Willow while discussing the cat's possible reaction to the toy with the facilitator. She hoped that Daphne would have the answers to her questions. She found out that Willow might cuddle the catnip stuffy and sniff it lying down in a cozy corner. Also, finding out Willow loved cozy nooks and boxes, Stella decided to venture into another project – a cardboard Shrek-style outhouse for Willow. She also sent home with Daphne several catnip stuffies and two outhouses, asking her to introduce these to Willow and observe the cat's behavior. Daphne's reports back provided Stella with a new awareness of the cats' preferences, sensory experiences, and specific information about Willow's play with her projects. Stella used this information to choose her final project's materials, colors, smells, and dimensions carefully. She designed these specifically for Willow and hoped the cat would like her projects.

Throughout the workshop, Stella positioned herself as a pet novice and aspiring pet companion. She actively sought knowledge of pets, sought to take on the perspective of cats, but not dogs, and tried to understand and solve problems faced by cats she knew. Although lacking confidence in her understanding of cats and acutely aware of existing relationships with pets as her peers' source of knowledge of pets, Stella sought to understand cats more than her peers. Once she thought of an explanation of cat behaviors or a potential solution to problems faced by and created by cats, she sought confirmation of the accuracy and relevance of her ideas from peers and the facilitator. To Stella, it was not enough to know of other cats to take care of a future feline pet; every cat is different and needs to be understood as a unique member of the species.

Mabel's positioning as a pet expert

Mabel began the workshop by declaring her love for her pets; she had three pets in her family. Her primary family unit had a dog, a hamster, and her grandparents were companions to a cat. Mabel enjoyed close relationships with all three but had a special attachment to the hamster, Puffpuff: "well, the dog is everyone's pet, but the hamster is mine. He lives in a cage in my room." From the beginning of the workshop, Mabel demonstrated deep care about the specific animals and refrained from collecting general trivia about the species. Mabel shared rich details of her pets' behaviors, especially her hamster. "Puffpuff isn't really picky about taste, kind of eats whatever. It's hard to know a favorite because it seems like they would eat, like, a lot of things they don't like. The others (the dog and the cat) don't eat everything."

On the second day of the workshop, after investigating the pets' visual experiences, Mabel began connecting details of her dog and hamster's behavior to their sensory experiences. In response to stories of pets shared in the group, Mabel asked clarifying questions about the pets' surroundings and considered alternate explanations for pets' behavior. For example, when discussing dogs' sniffing behavior, Mabel asked a peer, "Are they really intent on like staying there, and they, like, pull away from you so that they can sniff at it?" Mabel wanted to learn about the possible environmental elements that were causing the pets' behavior. Her questions implied that she was thinking about what the pets could be seeing, hearing, and smelling something different than the humans, causing them to behave peculiarly. She considered as many available details as she could gather. For details that were not shared but Mabel considered necessary, she asked probing questions.

On the third day, when the workshop progressed to making artifacts to improve the pets' lives, Mabel was motivated to solve specific problems in her pets' lives. For example, the dog needed help communicating its needs, the cat needed to play freely with its ball-like rattle toys without losing them underneath furniture, and the hamster, who liked soft materials, needed a cozy shelter inside its cage. Mabel quickly generated potential solutions to all these problems and made multiple projects for the pets. In addition to solving problems faced by the pets, Mabel hoped to find a few things about the pets' needs through their use of the projects. She was careful not to conclude she could predict *these* pets' behaviors from others' descriptions of their pets. For example, she expected Puffpuff to have preferences similar to but not precisely matching her friend's hamsters, who liked mattresses and pushed the mattress around inside the crate. Instead, Mabel relied on her friend's stories of their hamsters as a data point, collected more information about hamsters through research, and combined these with her knowledge of her hamster to predict what Puffpuff would be like. For example, she conjectured that her hamster, who liked to burrow, and dark but cozy corners, would probably like a sleeping bag. To this, Mabel added her own preference for swings and made a felt sleeping bag that could hang from the crate's ceiling. While sharing her plan, Mabel speculated, "There's a possibility that it could work. I don't know if it's gonna work with *her*."

On the final day of the workshop, the realization struck Mabel that the pets might need some training to get accustomed to the projects. She needed to show the cats the right way to play with the toy, train the dog to use the need detector to match his needs with a pattern to communicate the needs to the humans, and train and convince the hamster to use the sleeping bag enclosure. Mabel actively sought to understand the nuances of the pet's behavior and was careful not to harm the pets. However, simultaneously, she was motivated by the understanding that pets lived with humans and humans' preferred ways of caring for pets.

While Mabel described her projects' features in great detail, details concerning how the pets stood to gain from the projects were largely missing. Considering that when seeking knowledge of and describing the pets' behavior, Mabel sought depth and nuance, this omission is a critical contrast. Overall, Mabel positioned herself as a pet expert and a knowledge seeker. Her care for the pets was situated in the knowledge that she was responsible for their well-being, her curiosity about animals' senses and behavior, her love for the pets, as well as her and other humans' interests and preferences.

Stella and Mabel's positioning while making for pets

Both Stella and Mabel positioned themselves favorably in relation to pets at home and as learners at the workshop. Building on the tools and topics of the workshop facilitators, each girl spoke at length about their pets' unique sensory abilities - vision, smell, and hearing, and associated the pets' senses with everyday behaviors such as sniffing under rocks while out on walks (territorial action), rubbing their heads against human legs (transferring pheromones to claim human). Hence, both girls valued an understanding of pets, that pet behaviors meant specific things and sought to interpret pet behavior accurately.

In their conversations, while working on projects, Stella, for example, repeatedly asked her peers who had cats as pets if the boxes were big enough. "I heard that cats, in general, like boxes, but one of the boxes might be a bit small for bigger cats. I don't want the cat to feel stuffy inside" "I was thinking like a tube or like a box thing. I could put treats in it, open the bottom, just a tiny bit on it, once you open it, the cat could jump onto it and grab it, some of the treats that shot up. So, like, how big should the box be, I mean, how far will the cat jump?" While some of Stella's questions correlated to her not knowing a cat closely and hence, not knowing enough about cats, other questions pointed to her concern for the cat's well-being. She wanted the cat to find her project useful; the cat had to feel loved and cared for in the cat's preferred ways. Stella's positioning was of a human who desired the company of a cat, cared for cats, and valued in-depth and specific information about individual cats. Most importantly, Stella knew that cats could reject her company.

Mabel, on the other hand, having known several pets as close companions, asked different questions. While working on the projects, she repeatedly considered the training as a requirement for pets to be able to use her projects. "I think having him go inside the sleeping bag is going to be hard, but I am going to try. Like leave it (the sleeping bag) in her crate and leave the room, or leave it overnight in the crate and come back next morning." Later, she worried, "I just hope he does not eat it up; he is a big chewer." Mabel's idea of hanging the sleeping bag from the crate's ceiling may have helped with this problem, but Mabel did not consider this affordance. Instead, she used multiple felt fabric layers for the project to prevent the hamster from chewing it. Mabel recalled that the hamster "only chewed food and cardboard, not the crate and toys," and concluded that Puffpuff might not eat the project. She felt the need to train the hamster to use the sleeping bag but pointed to the difficulty of humans wanting to train an animal that slept all day and stayed up all night. Mabel's positioning was of a human who enjoyed the company of several pets, cared for each of the pets, and was confident in her skills as a pet carer and pet-related knowledge seeker. Like Stella, Mabel, too, sought in-depth knowledge of pets' behavior but reserved the final decision for herself. Mabel knew what was good for her pets; she was confident the pets would agree with Mabel's choices.

Stella and Mabel's work on the maker projects demonstrates that both girls were attentive to aspects of pet behavior and taking care of pets that are difficult to notice, indicating their attention to pets' and humans' unique interactions with social and material environments. Notably, the two participants noticed different aspects of the pets' behavior, and their noticings correlated with their positioning at the workshop. Stella positioned herself as a novice regarding knowledge and care of pets and repeatedly sought information and confirmation of her developing understanding. She considered the cat's and other humans' preferences above hers and wanted to avoid failure. On the other hand, Mabel positioned herself as a pet expert. She actively sought details clarifying pets' behavior. Still, while making the projects for her pets, she considered her attention to future training as more consequential to the pets appropriating her maker projects than further observations of their empirical preferences and responses.

Discussion

Against the backdrop of research in maker education and relationally and ecologically informed science learning, we set out to understand how the social positioning of makers and making objects for more-than-human companions contributed to learning opportunities at a pet sciences summer workshop. Analyzing two youth participants' actions and talk at the workshop as well as their reflections on it in interviews, we found that their positioning of themselves as pet companions and aspiring pet companions coincided with their noticing different aspects of their pet's lives and the affordances of maker projects. We conclude that making for more-than-human companions opens up new opportunities for science learning. Specifically, depending on individual positioning, youth in our study became aware of pets' unique sensory experiences and related behavior and its implications for their life with human companions. Based on our findings, we identify the following two directions to extend this line of research.

First, our findings reaffirm the importance of maker projects as transitional objects (Turkle, 1990), but we found Stella and Mabel's making to be unique because of how they needed to think while making these. Beyond the focus on detail and process-oriented thinking while making, the emphasis on the artifacts' functionality, the learners' design and process skills, content learned, and humans as the intended users is noteworthy in this research body. We highlight that Stella and Mabel's projects, as artifacts made especially for more-than-humans by their human companions, bridged the learner to the ecosystem through relational ties. Although Stella and Mabel are yet to position themselves as embedded in a unified natureculture, they are clearly aware of the pets' and their relational connections. As evident in their talk during the making process, the girls' attention to several aspects of the ecosystem, how these aspects affected them and the pets differently, and some of the resulting differences in their and the pets' experiences in the ecosystem, were critical departures from existing research on making and learning. We see this as a step forward in valuing making and maker projects as processes and artifacts that highlight what and how we become with others.

Second, broadly, we have thought of thinking and learning while designing and making as approaching scientific thinking through reflection. Schön (1983) compared reflective practitioners to scientists engaged in impromptu experimentation and careful examination of situations where the "situation talks back" (p. 131). When the boundaries between thinking and acting collapse, reflective practice becomes an ongoing, cyclical process. Despite the obvious importance of reflection in practice, scholars (van Maanen, 1999) have questioned what we leave unexplored by focusing solely on reflection. Parallelly, sensing the need for criticality, we ask, what do we fail to understand about learning in human-more-than-human relationships when considering reflection as the only way of thinking about the relationship? How should we think when just thinking about our actions and their consequences fall short? Our participants, for example, had to venture beyond thinking about pets as animals living with them to considering the animals' distinct species-based and personal needs. Only with this understand could the participants hope to make artifacts for their more-than-human companions, artifacts that might make life better for them. Feminist and new materialist scholars propose the metaphor of diffraction as a means of sense-making, understanding what constitutes experiences, and critically studying similarities and differences in situated and relational contexts, indicating the need for "marking a place where change occurs" (Haraway, 1997). We see promise in studying learning contexts that draw attention to expected patterns and deviation from patterns, where learners create something ontologically new rather than the repeated, objective mirroring of perceived reality (Barad, 2007). Such a critical examination of how different meanings are made and lived would indeed help us value ecologically and relationally-informed science learning for a multispecies coexistence. As we rely on different ways of knowing to know others, we can illuminate similarities and differences in epistemologies, and consider why they exist, and how they come to matter.

Abstract: Based on the widely recognized situated nature of identity and youth as social producers and products, this qualitative case study reports findings from a week-long informal pet-sciences workshop for middle schoolers who have existing relationships with pets or a strong interest in future pet companionship. Mindful of the structure-agency dialectic, we analyze youth's wayfaring and trajectories of identification as they learn about their pets at the workshop, accounting for how youth see themselves and their pets and are seen by others. In contrast to a commonly assumed analytic directionality seeing people as moving towards or away from STEM, we find that there were different ways for youth to meaningfully engage themselves in learning about their pets at the workshop. We conclude that attention to fluidity in youth's identifications can inform us, the adults in the community, of the need to affirm the many possible trajectories that youth may follow.

Introduction and background: Youth science identity

This paper details two young learners' science identity work in a pet sciences summer workshop. We examine science identity in a personal-historical and practice context (Holland & Lave, 2009). Particularly, we illuminate the entanglement of multiple contexts, practices, and feelings in shaping youth's science identity. We define identity as being recognized as a certain "kind of person" in a given context (e.g., Gee, 2001; Carlone & Johnson, 2007), in relation to individuals' performances in society. Understanding the performance of whom individuals are becoming, in tandem with whom they are obligated to be and what it means to be them, with attention to what settings demand and prohibit, is key to understanding identity in practice. Identity work is an agentic understanding and performance of oneself that individuals develop over time and across settings (Barton et al., 2013).

Valuing the notion of identity as changing and shaped across contexts and activities rather than static, we study identity with two motivations. First, objecting to the metaphor of a STEM pipeline which alludes to a few predetermined ways of engaging in science, we adopt the view that there are many ways of engaging in science. Second, we draw attention to the personal attributes of people engaged in learning science and science practice across many locations. Together, these help us understand learners' situated aspirations, motives, perceived benefits, and future hopes of continuing in science. We construct two case studies sampled from data collected at an out-of-school pet sciences summer workshop conducted at a university campus. Middle-school-aged youth participated in the workshop designed for current and aspiring pet-companions to learn about and explore canine and feline pets' sensory experiences and related behavior in and around human homes. We used simple phone applications to introduce participants to the pets' hidden senses, generally unnoticed and unperceivable by human beings. Later, we asked participants to identify problems their pets likely face at home and make an artifact or design an experience to address the problem. After participants planned, prototyped, and completed their projects, they tested the prototype with a pet, and presented their findings to the group, we interviewed them about their learnings and their interest in science and their science identity. We craft a theoretical framework to study identity in practice, fluid and interactive, and shaped by individuals, others, and activities, and ask one research question: *What insights into science learning as wayfaring informed by trajectories of identification can we gain from two teen boys' participation at a pet sciences workshop?*

Theoretical framework

Dorothy Holland and colleagues (1998) described identity as the ongoing and dynamic "imaginings of self in worlds of action" (p. 5). Identities, as social products, are means through which individuals "care about and care for what is going on around them," (p. 5) and find out ways of being— "persons taking form in the flow of historically, socially, culturally, and materially shaped lives." Lave (2012) asked how lives, persons, and practices are produced in ongoing everyday practice. Understanding youth's science identities requires an understanding of the structure-agency dialectic, the view that identities are in flux, forming and re-forming in relation to historically specific and structured contexts. Individuals shape their identities constrained and facilitated by the social context of activity. Individuals' agency functions within, through, and against social structural constraints (Varelas et al., 2015; Verhoeven et al., 2021). Understanding youth's ongoing relations within, across, and beyond contexts and how this contributes to their figuring of and identities in science requires recognition of what scholars have described as "intimate and social landscapes through time" (Holland et al., 1998, p. 285) and meshworking (Ingold, 2011; Rahm et al., 2022). This view of science identity as agentic and unfolding across time and contexts is relational and attends to learning and becoming as life-long emergence, paths of wayfaring, and the threading of ways through the inhabited world (Ingold, 2011). Therefore, what we know and who we are becoming, in addition to being in flux, is meshworked. Scholars studying youth's science identities agree. For example, scholars (Avraamidou, 2020; Carlone et al., 2015; Polman & Miller, 2010; Rahm et al., 2022) have advocated for plurality of science identities along complex trajectories within a web of meanings and practices, and other identities such as gender, ethnic, and language identities. Correspondingly, our framework moves beyond identifying factors influencing youth's science identity to understanding the meshwork and wayfaring as informed by the intersecting trajectories shaping their science identity work. We focus on the movement undertaken by the learners.

Research on science identities across time and space

Polman and Miller (2010) found that in the sheltered borderlands of a science outreach apprenticeship program, African American youth developed professional work and career aspirations through "trajectories of identification" (see also Lemke, 2000; Wortham, 2006). The program designed to utilize participants' cultural capital successfully engaged some youth, developing positive trajectories. Some participants were initially hesitant to engage, but later found reasons and ways to engage in the program, yet others found no reason to participate and did not develop positive STEM trajectories through the program. Gonsalves et al. (2013) studied how youth relied on immediately accessible and relatable cultural resources to position themselves as insiders in science while reimagining science as a readily accessible domain of exploration. Across time and space, participants remained determined to stay true to their school-aligned definitions of science and science identities, indicating the lack of connections between their discursive practices and the world of formal science learning. Wade-Jaimes and Schwartz (2019) demonstrated how African American girls tread complex, multilayered discourses only to be positioned outside of science. Rahm et al. (2022) studied young women of color's STEM pathways through the lens of personal histories and local practice. Highlighting movement and the multiple ways of becoming in science, they found multiple ways of becoming, including the girls' transnational identities, to be relevant to their STEM identities. Finally, Page-Reeves et al. (2022) described the transformed identities of Native American learners in predominantly White institutions of higher education. They found that the learners were motivated to repurpose STEM content knowledge and connect to their communities. They described learners as "wayfinding" through different institutional and cultural contexts, thereby gathering experiential wisdom.

Relationally and ecologically informed science learning

Our study concerns a unique kind of learning – about pets at home with whom human youth are known to have deeply cherished relationships (Parekh et al., in review). We know from science education research that in close association with nature, youth practice attentive, caring learning of science (Bang et al., 2007; Koda, 2013). Several empirical studies on youth-pet relationships (for example, Simeonsdotter Svensson, 2014; Zimmerman, 2012) support Donna Haraway's (2003) observation that human-pet relationships are about "significant others." Haraway noted— "Dogs matter. . . They are not just surrogates for theory; they are not just here to think with... They are here to live with" (p. 5). Haraway's conceptualization suggests that learning about pets involves more than learning about their biology and how their senses can be helpful to humans.

Human-pet relationships represent multispecies knots of reciprocal action, enmeshed in ecosystems and generally addressed as natureculture (Fuentes, 2010; Haraway, 2003). In our work, we are most directly concerned with natureculture in the human home; in this particular multispecies interface, humans and pets are both actors and acted on as they mutually shape the ecology. Specifically, we study youth's relational science identities as trajectories, enmeshed in places and activities, and as they learn science in a context that requires attention to relationality with pets at home. In doing so, we respond to recent calls for a science education attentive to ecosystems and the relationships within them (Hecht & Crowley, 2020).

Methods

Workshop details

In the summer of 2022, we organized a summer workshop for middle-school-age learners on a public university campus in the western United States. A science outreach program within the university recruited participants for the workshop through alliances with local school districts and a mailing list of previous participants in programs offered through the program. Eleven middle schoolers signed up for the workshop, and other than one participant who tested positive for COVID on the first day of the workshop, ten participated until the end.

The workshop plan was as follows: Day 1: Exploration of pets' senses through Augmented Reality filter applications and enhanced hearing applications, mapping of pets' activities at home and around; Day 2: Discussion of findings and experiences with pets, sharing pet stories about sensory experiences, identifying pets' experiences to understand better, planning investigations; Day 3: Best practices and examples of investigation of pets' senses, sharing outcomes of investigations conducted at home with pets; Day 4: Discussion of individual projects with peers and project work; Day 5: Presentation of learning to peers and families.

Data collected

We collected session video data for the workshop using one camera and audio-recorded conversations at each table. We had asked participants to partner with two other participants to work with throughout the workshop. On the fourth day of the workshop, we conducted brief, semi-structured interviews with each participant to record their inquiry into their pets' senses in relation to their projects. The participants responded to questions such as the following: Describe your project and your reason for working on this project. How does this project improve or solve a problem in your pet's life? What are some problems that you think your pet might have when using this project? What are some changes that you would like to make to the project? How has the workshop helped you think about pets at home? We conducted two rounds of interviews with each of the participants two and eight weeks after the workshop, respectively. The following are some questions we asked the participants: On the days of the workshop, did you do anything differently with your pet? What were the activities you would say you did with your pet? What role did your pet play in your projects/project ideas/testing projects? What did you learn from working with your pet? What science topics did you learn at the workshop? How did you use science to learn about pets? How was this program similar to or different than other science classes you have taken? What would it be like to have a career as a scientist? What would you like, what would you dislike? How would you describe your identity as a scientist, an animal scientist, and a designer? Eight participants completed the first interview, and seven completed the second interview.

Data analysis

We identified two participants whose talk we analyzed for this paper. Our choice of participants was dictated by the nature of their participation and the contrasting nature of their personal experiences and orientation. Both Mateo and Yan (both pseudonyms) identified as male and attended local middle schools. Mateo's family is of Hispanic origin and immigrated to the U.S. from Mexico, while Yan's family immigrated to the U.S. from East Asia. Both boys are fluent in their native tongue and English, participated in all workshop sessions, and interacted enough with their peers through talk for us to gather enough of their talk for the analysis. After the workshop and the interviews, we transcribed both participants' talk at the workshop in their small groups and during the post-workshop interviews. The talk recorded in the small groups was a mixture of responses to facilitator prompts and conversations with peers. At the interview, we asked them questions concerning their experience of learning at the workshop, how the workshop affected their pet-care practices, and how the workshop possibly affected if and how they can see themselves pursuing science as a career. In the second interview, we asked them questions about their science identities in relation to school and the workshop and asked them to scientifically analyze an incident involving a pet and a human companion. For this analysis, we focused on Mateo and Yan's talk on the first two days of the workshop and post-workshop interviews. The first two days of the workshop were structured to allow participants to share freely about their pets and themselves.

Our analytical strategy is based on the following theoretical assumptions about identity. First, as individuals, we exist in and navigate multiple worlds, each with its own rules and ways of figuring worlds. Second, positioning and locating ourselves and others, by choice and inadvertently, makes us appear as certain individuals. Third, degrees of freedom exist within each participation domain relevant to our study. At home, in school, and informal spaces, youth exercise agency to transform themselves in specific ways and decide if they want to blend in or stand out. Fourth, who youth have been in the past and across spaces and time shape who they are becoming. Mindful of these four assumptions, we analyzed Mateo and Yan's trajectories concerning pet-care practices and science learning. The following paragraphs detail our analytical strategy in detail.

After transcribing Mateo and Yan's talk at the sessions and the interviews, we had a general sense of the big areas of talk we wanted to explore through thorough analysis. For example, the boys' stories of their pets' life at home, the many ways in which they established themselves as trusted and beloved pet companions, and their descriptions of the attributes of projects and why these were desirable were promising categories of talk at the workshop. Noting the similar domains of participation for both participants (pet-care at home, school, talk about pets at the workshop, and personal interests), we set out to understand the finer aspects of their trajectories through pet-care at homes, pet-sciences work at the workshop, and science learning at school and other places. Specifically, we coded for (1) the activities they engaged in, (2) how they engaged in these, (3) how they spoke about these, and (4) their overall observations and comments about how they are able to position themselves in each of these domains. To analyze Mateo and Yan's identities in each of these domains, we coded for (1) the attributes they assigned to the activities in each of the domains, (2) how they saw themselves as they engaged in these, (3) how they thought others saw them, and (4) the alignments and conflict with any other identities these indicated. Simultaneously, we were attentive to how they spoke and when, and what the timing of their talk implied for the purpose. This gave us an understanding of their concerns, doubts, confidence, etc., and what these might indicate for their identities. Combining our analyses following these strands, we wrote analytical memos about the boys' figuring across domains of practice, along with the negotiation of identities and location of themselves and others.

In a parallel analytical strand, we analyzed the participants' talk for their descriptions of their pets and what they considered to be valuable about pet biology and pets' experiences at home. This constituted evidence of learning about pets. After identifying the aspects of the pets' lives they talked about, how, in their view, these aspects were connected, and how these mattered to pets' lives, we understood their attention to ecologically and relationally-informed science. Unifying the two strands of analysis, we created a critical narrative for each of the two participants with attention to their practice of an ecologically and relationally-informed science and their identities in each of the domains of participation, the relationality of their identities across these domains, and what this meant for their science identity. Finally, we created a critical participant narrative account (VanMaanen, 1990; Polkinghorne, 2005) for each of the two participants with attention to their practice of an ecologically and relationally-informed science and their identities in each of the domains of participation, the relationality of their identities across these domains, and what this meant for their science identity. We present our findings in the qualitative research tradition of a case study (Stake, 1995) meant to capture the complexity of the human experience.

Findings

We briefly describe Mateo and Yan's trajectories through their homes and the workshop as pet companions and as science learners through the workshop and school. Following this, we summarize our findings with attention to the insights we gain from studying Mateo and Yan's wayfaring and trajectories of identification.

Mateo and Pepe

Mateo is thirteen years old. He is close to his younger sister, and they are each companion to one of two dogs in their home. Mateo loves caring for the dogs, walks, and plays energetically with both dogs. Mateo, an amateur boxer and wrestler, also likes fixing and making things at home. When the vet suggested that his sister's dog lose weight, Mateo described the dog as "muscular and strong, not fat," but planned to make him exercise in the yard by chasing the dog and throwing sticks far away. At the workshop, Mateo's project ideas were meant to engage his dog, Pepe, in active and energetic play at home and in the yard. Taking into account Pepe's high level of energy and tenacity, Mateo's plans involved tying "strong knots with ropes" and securing poles in the yard, things he thought he was good at. Initially, Mateo wondered if he could make a harness and a leash that could be attached to a treadmill to help Pepe exercise when Mateo exercised. Or, Mateo could attach a thin, flexible rod to Pepe's harness with a treat dangling from it over Pepe's head so the dog could smell the treat and be motivated to walk long distances. This way, he could use his skills in making things and exercise and fitness to solve a problem in the dog's life.

When Mateo considered his final project idea, he decided to carefully install a multi-purpose entertainment system for Pepe in the yard. He built a sturdy but flexible tug-and-squeak toy that hung from a pole firmly planted in the yard. He also added a treat to the toy as a reward for Pepe. He was mindful of the dog's need to "vent excess energy," "stay out of trouble with the other dog," and wanted to "reward him for good behavior, but not by harming him." Pepe played with the installation for a long time, making Mateo deem his project successful. Pepe's interaction with the toy provided evidence that Mateo understood the dog's needs and preferences and what constituted a desirable playtime for the dog. However, despite Mateo's obvious understanding of Pepe's nature and needs and his ability to find suitable solutions to the problems the dog faced at home, he considered himself just "okay" as a learner. Expressing difficulty articulating his ideas with words, Mateo said that he could "never explain the details and outright say it because then they'll get confused."

Mateo considered learning facts about pets' senses and systematically investigating pets' lives to be scientific. In his words, at school, he learned facts, but at the workshop, he found out why and how these facts mattered. For example, he knew that the sense of smell was essential to dogs, but at the workshop, he learned why smell was crucial for dogs' behavior and how smells affected dogs, specifically how smell affected Pepe. Mateo valued such learning but considered it to be different from learning science at school which constituted "mixing liquids with chemicals and stuff, calculating stuff," "building things to see if they work," and "testing things repeatedly to see if they worked well." Per this school-aligned understanding of science, only some aspects of his pet care experience, i.e., learning how pet senses worked and experiments about pets' senses, were scientific. Mateo considered other aspects of his pet-care practice at home and at the workshop, such as understanding the nature of the problems Pepe faced, thinking of solutions to these problems, designing and creating toys for Pepe, and testing it repeatedly to check if they worked for Pepe, to be everyday pet care and not scientific. Further, Mateo felt that using science to solve pets' problems under challenging circumstances, such as concerning a sick or dying pet, would be too difficult. Overall, Mateo's experiences at home, school, and the workshop, the different domains of activity such as chores at home, pet-care, making, and school coincided with him feeling like a certain kind of learner. Along with his predominantly school-aligned perception of science, Mateo's awareness of his strengths and limitations had a bearing on his perception of himself as a science learner.

Yan and Bear

Yan is eleven years old, lives with his family, and is a proud companion to a cat, Bear. Yan described Bear as a former stray adopted by his family as a tiny kitten. Among all four humans at home, Bear preferred Yan's company. The cat, eighteen months old at the time of the workshop, napped on Yan's bed and refused to follow the instructions offered by Yan's father, who wanted to keep Bear off the furniture.

Yan practiced playing a musical instrument at home, read his favorite book series, studied hard, and stayed out of trouble with his younger sibling. As a science learner, details mattered to Yan. His stories of cats, including those about Bear's life in their home, were rich with observations of feline behavior. Yan closely observed cats and tried to identify problems in their lives with humans. For example, why did the cat like specific locations inside the house and not others? Why would the cat spend time with some members of the household at certain times of the day? Upon finding out about cats' senses at the workshop, Yan could make sense of some of the problems he had previously identified. Then, he methodically talked through some problems and their potential explanations with his peers.

Later, Yan worked on many projects at the workshop to find out about the cat. Through most of these projects, Yan investigated Bear's preference for catnip. Yan wondered if Bear liked the smell, the taste, or just the feeling and experience of being near catnip. So, he made fish-shaped dangling prey toys filled with synthetic stuffing and catnip and introduced these two to Bear. Once he saw that Bear was not interested in using the toy as prey, he made a collection of food item-shaped toys stuffed with catnip to understand the cats' preferences. Yan concluded that Bear definitely liked the toys stuffed with catnip but did not prefer the toy's shape and nature (prey toy versus a cuddly toy). Although Yan could not understand why Bear liked catnip, he concluded that the cat liked a certain kind of catnip toys.

In his descriptions of Bear, Yan's language was noteworthy. Rich in details of feline behavior, Yan consistently referred to Bear as "his" cat. In his stories, Bear always preferred Yan to other humans, and Yan, in turn, understood the cat the most and was duly rewarded with attention and cuddles. Through his description of cat behavior in relation to senses, Yan demonstrated his ability to solve all of Bear's and other cats' problems and narrated these problems and their solutions in exquisite detail. After the workshop, Yan shared that he aspired to be a scientist. Having spent many hours after school and during breaks at his father's laboratory, he was quite fascinated with lab coats, safety goggles, and intense scientific investigations. Yan knew a lot about the investigations in this laboratory and similarly imagined himself – "I do feel like I am pretty strong in that area." However, he could foresee some challenges as well. For example, what would happen if something went wrong? What if he got impatient when experiments took too long to yield the expected results? Overall, Yan was confident that taking care of a pet required him to use scientific knowledge and that he would like to be a scientist in the future.

Yan's experiences at home, his parent's lab, and the workshop, the different domains of activity such as pet-care, finding out about events and phenomena as a hobby, and making, coincided with him feeling like a certain kind of learner. Confident of his ability to learn science and having access to scientific practice through his parent, Yan looked forward to a career in science, expressing only slight concerns about his personal limitations.

Summary of findings

Mateo and Yan were both exceptional in their abilities as learners. Both learners saw the animals in relation to themselves and were attentive to the pets' interests while working on their projects. However, their trajectories, as evident in their talk, are distinct. We highlight three aspects of their trajectories that are important to ecologically and relationally informed science learning.

First, Mateo treated Pepe as an animal living with his family. He referred to Pepe and the family's other dog as individual animals who occasionally got into trouble with each other at home and to whose distinct needs he had to be attentive. Yan perceived Bear as *his* pet, who sometimes spent time with his sibling but was most loyal to him. Yan also showered the most attention on Bear within the family and cared for him the most. Mateo was attentive to Pepe's habits and interactions with the surroundings because these were important to the dog's wellbeing, while Yan was attentive to Bear's habits and life at home because he felt rewarded by the cat's affection. Mateo and Yan's different relationships with the pets illuminate different ways in which the boys were attentive to relationality within the ecosystem. Mateo's attention was directed at the relational aspects of Pepe's existence within the home ecosystem because he knew that such attention was vital to the dog's wellbeing. On the other hand, Yan's attention, although directed to the relational aspects of Bear's life at home, was meant to find out more about the cat and to make him feel good as a pet companion and a learner.

Second, despite Mateo's ability to be attentive to Pepe's unique canine needs and his ability to successfully investigate the dog's behavior and design projects for him, he felt only moderately successful as a science learner. He perceived himself to have a lack of communication skills, academic vocabulary, and fluency, and saw these as significant setbacks. Yan, too, was an expert investigator of Bear's experiences in a human home, but he saw a future for himself in science. Yan felt that his extensive communication skills and precision, along with his assertiveness and outgoing nature, would help him do well in science. Research on learners' discourse development in science classrooms (Lemke, 1990) shows that through their participation in social situations, learners become habitual in their use of certain discourses in use in these social situations. In a setting such as an out-of-school pet science workshop, science talk was a valued discourse that Yan could engage in; this, in turn, affected how Yan self-identified as a successful science learner. Unfortunately, Mateo's interpretation of the science talk at the workshop was informed by his experiences of science talk norms at school, and made him feel less successful as a science learner, despite the goals of ourselves as the program designers to disrupt those school norms. Relatedly, Mateo perceived a divide between school science and everyday science such as pet-care. In fact, Mateo held school science in high esteem, while workshop and everyday activities that required investigations, problem-identification, and solutions did not qualify for him as scientific, even though he valued them as pet care. Yan readily accepted everyday pet-care-related practices, investigations, and problems as scientific. It is possible that regular conversations between Yan and his parent included everyday science topics or the structure of scientific inquiry, and this helped him immediately identify the workshop as a place for learning science and himself as a science learner. Nevertheless, the divide, and lack thereof, between school and everyday science in Mateo and Yan's perception points to the importance of learners' ability to relate to science practice as having certain features, including certain benefits for themselves (e.g., Martin, 2019; Rahm et al., 2022; Sengupta-Irving, 2021).

Third, Mateo and Yan reflected differently on their future in science. Initially hesitant about identifying himself as a science learner and the workshop as a place for science learning, Mateo finally expressed that the workshop had made him feel that he could pursue science, especially animal science, and "building things, constructing things that solve problems." Still, in the absence of a clear sense of the path ahead, Mateo was doubtful of such a possibility. On the other hand, Yan thought he knew what lay ahead and was confident in his ability to pursue a career in science, but was afraid that he might not know how to deal with failures and mistakes. Mateo and Yan's confidence and doubts in their own strengths and the path ahead are evidence of their awareness of navigation - following a path others have laid out and traveled before (Page-Reeves et al., 2018). However, wayfaring in science, using contextual cues to agentively weave the fabric of one's own life in the traditional system of science education might be easier for only one of the two middle-school-age learners.

Discussion

We set out to examine two male middle-school-age workshop participants' science learning as wayfaring and trajectories of identification at a pet sciences workshop. Analyzing their talk at the workshop and during interviews, we found that their trajectories were unique. Both participants spent considerable time taking care of their pets at home, understood the science of pet-care, and were good science learners, but only one participant had appropriated a strong science identity. This learner was supported by his successful science talk and knowledge of science facts and processes, while the other was doubtful of his presence and future in science. Our dual focus on learners' trajectories and wayfaring, relational identities in movement across space and time, and relationally-informed science learning, draws attention to the following two points.

First, one of the two participants saw himself as an invested member of communities, a learner, and a pet companion. His attention to relationality, both as a learner and in his learning about pets, was noteworthy.

However, his understanding of relationality also posed challenges for him when, at times, he felt overwhelmed by emotions and the recognition of the challenges that lay ahead. The other participant was attentive to relationality, mostly as factors affecting his pet's life. He did not consider the relationality pertaining to his movement across the different domains of participation in his life and found wayfaring to be minimally relevant. In fact, as someone who saw himself and who others saw as a successful science learner who liked to learn alone, he sometimes doubted his ability to foresee mistakes and prevent them and considered failures as impediments that might lead him off-track. He saw his trajectory as passing through a few predetermined domains of activity that were fixed and predictable. Despite this relative inattention to his trajectory, his experiences in science learning were rewarding. This contrast in the two participants' trajectories through the workshop raises an important question: How might we help learners become aware of their relational trajectories as well as relational learning of science? This is a pressing question because institutions of learning often reward learners' "intelligible identities" (Günter et al., 2020) rather than attention to relationality and relational identities. Second, our findings indicate learners with already strong science identities established elsewhere felt more comfortable at the workshop, while those with an emerging or questioning science identity hesitated. We were unable to make all learners inquire into their participation and identities along trajectories to identify their strengths and weaknesses as science learners. Drawing attention to multiple practitioners across settings and communities might communicate to youth the many possible trajectories, thereby making them confident in their own trajectories and relational identities. Brayboy, 2004; Rahm et al., 2022, Gonsalves, 2020, Page-Reeves et al., 2019, make similar recommendations based on similar observations.

In relation to the above two points, questions of access and opportunities beyond the inclusion of learners become important. That students should have access and opportunities to participate in science discourses is widely acknowledged and endorsed (e.g., Barton & Tan, 2020; Martin, 2019). However, key aspects of the participation of students lacking a strong science identity remain challenging and warrant continued research. Knowing learners' sociocultural locations, identities, and choices emerging from these locations are vital to their recognizing their identities. This, however, requires a deep understanding of learners and their contexts, leading to altering the status quo. We see promise in drawing attention to learners' political struggles across settings, and promoting acts of justice (de Royston et al., 2017). The struggles are key sites of identity work, particularly in middle-school-age learners who are acutely aware of stereotypes (racial and ethnic, and gender stereotypes in our case) and negotiate what it means for themselves and others (Nasir et al., 2017).

The Promise of Sketching in Biological Problem Solving for Self-Directed Learning From Online Resources

Yael Rakocz, Iris Tabak
yarakocz@gmail.com, itabak@bgu.ac.il
Ben-Gurion University of the Negev

Abstract: This study brings together two research traditions. The first, investigates the ways in which learners' representational practices influence learning. The second, investigates the ways in which we can support learners in self-directed learning using online resources. We examined whether learner generated sketches that accompany self-study from a video and written text result in a better understanding of a novel biological mechanism than such study without sketching. We found a significant advantage to sketching. To reflect a real-world need for incidental learning, our study was couched in a scenario of running an online discussion group. Our findings suggest that fostering sketching as a habitual tool for sense-making is a promising way to prepare learners for the new realities of ubiquitous self-directed learning.

Introduction

The learning sciences have a rich history of investigating the ways in which learners' representational practices influence learning (e.g., Cooper et al., 2017; diSessa et al., 1991; Halverson, 2013; Kindfield, 1994; Medina & Suthers, 2013; Pierroux et al., 2022; Ramey & Uttal, 2017). Learner created representations serve multiple goals: they reify disciplinary practices, they make thinking visible, and they facilitate reasoning. We were especially interested in the ways in which sketching can facilitate reasoning and comprehension, because we are interested in understanding how to support learners who use online resources for self-directed informal learning—a form of learning that is becoming increasingly prevalent in the lives of both youths and adults (Esteban-Guitart et al., 2018). In this paper, we report on a study in which participants were asked to learn about a biological mechanism as part of a fictional scenario reflecting an everyday need for learning (running an online discussion group). The study compared understanding between those that learned with sketching and those that learned without sketching. Our study focused on learning through sketching in the life sciences, which has received less attention than design, engineering, and physical sciences. Thus, we both contribute to a broader understanding of learning through sketching and consider implications for supporting self-directed informal learning.

Literature review

Sketching as an external representation

Sketching, creating an external visual representation portraying any type of content (Quillin & Thomas, 2015), is a ubiquitous practice for artists, designers (Fish & Scrivener, 1990), architects, and engineers (Landay & Myers, 2001; Sangiorgi et al., 2012; Verstijnen et al., 1998; Zurita et al., 2007). By using lines as well as numbers and letters as symbols (e.g., H2O for water) sketches can depict structures, relationships, or processes (Haddawy et al., 2006; Zhang & Linn, 2011). Sketching can actively involve learners in the cognitive process of selecting, organizing, and integrating learned information (Ainsworth & Scheiter, 2021; Cooper et al., 2017; Schmeck, Mayer, Opfermann, Pfeiffer & Leutner, 2014), in other words, in creating a mental model (Mayer, 2009). According to Van Meter and Garner's (2005) generative theory of drawing construction, the sketch of a model might occur after the creation of a mental model or in parallel to the three cognitive processes listed above. Creating such external representations can facilitate comprehension and learning (Quillin & Thomas, 2015).

The process of drawing or using abstract graphic representations, as part of the development of a visual idea, is identified with content worlds such as design and engineering (Zhang & Linn, 2011). The necessity of using graphic representations arises from the need to construct or manipulate several objects without creating the product itself; thus, the verbal language and other tools used by the sketcher contribute to the development of visualization and self-expression abilities (Fish & Scrivener, 1990). Sangiorgi et al. (1990) and Kavakli et al. (2006) suggest that drawing in the early stages of visual design is an important part of the process because designers engage in a form of dialogue with their drawings that enable them to examine, critique and tweak their own and others' ideas.

The merits of sketching in problem-solving and knowledge construction

Spontaneous sketching of images that emerge in the designer's head during pencil-and-paper drawing is often observed during a creative design process. Designers sketch ideas in various ways, allowing themselves to look at a problem from different angles (Sangiorgi et al., 2012). One explanation for this phenomenon is that the drawing helps in translating creative thought discovery into dynamic visual ideas one can work with and return to during the work process; when eventually, a review of the visual image that comes to mind and a new structural and graphic interpretation for it will occur on the solution page (Forbus & Ainsworth, 2017; Verstijnen et al., 1998). Observing problem-solvers using pencil-and-paper drawings as part of the problem-solving process suggests that free use of these drawings when expressing a novel idea gives rise to additional thoughts and concepts that help them solve the given problem (Casakin, 2012; Landay & Myers, 2001).

Drawings, which result from the thinking process of users and therefore contain user-selective information, have multiple roles in the problem-solving process. Drawing and sketching by learners were found to be effective in facilitating memory and generating visual models as part of higher-order thinking skills (Ainsworth & Scheiter, 2021; Heideman, Flores, Sevier & Trouton, 2017). Studies have shown that by using graphic representations during problem-solving, not only can solvers develop the skills required to obtain the final solution, but they can also incorporate ideas and concepts from the content field in which the problem is addressed (Jitendra, 2002). In addition, studies of learning through representations indicate a relationship between high student performance and the use of appropriate representations (Ainsworth, 2006; Schmeck et al., 2014).

Sketching in problem-solving in the life sciences

Learning a biological principle, e.g. energy in the human body, may be challenging due to different organization levels: from the mitochondrion organelle to the intercellular energy production process. Thus, students practice proficiency related to scientific understanding, from a cellular organization level to a systematic organization level (Rea-Ramirez, 2008). According to Schmeck et al. (2014), students' sense-making of scientific texts improves when they are asked to draw illustrations or sketches that represent the content they read; this allows them to select, organize, and integrate information, which are a set of actions that contribute to comprehension.

Complex problems in fields such as technology and design involve objects and visual elements. Consequently, most of the research that deals with drawing for problem-solving focused on these fields (Verstijnen et al., 1998; Sangiorgi et al., 2012). Nevertheless, based on the connections found between drawing and problem solving across disciplines (Ainsworth, 2006; Ainsworth & Scheiter, 2021) and in biology (Kindfield, 1994a; Quillin & Thomas, 2015), there is much potential in the use of sketching in the life sciences (Schmeck et al., 2014).

In this study, we wanted to further understand whether sketching can help learners grapple with some of the inherent difficulties of understanding biological processes. We were interested in whether sketching could be used as a tool for understanding when people try to learn new topics when the need arises in their everyday lives. Therefore, we examined how people understood the mechanism through which Aspirin affects the human body by reading an expository text and viewing a video. We compared participants who augmented their reading and viewing with sketching to participants who did not sketch.

Methods

Participants

The group comprised sixty students from the undergraduate subject pool of the Department of Education. The participants included 58 females and 2 males (this reflects the gender composition of the student body) whose high school background was in the Humanities and Social Sciences. I.e., we tried to ensure that participants did not have much prior knowledge in biology.

Materials

Task scenario

To reflect the types of everyday situations in which a person may need to learn a new topic, or understand a biological mechanism, we set the learning within a fictional scenario. Participants were instructed that they run an online discussion group concerning health and nutrition. A discussion thread came up considering whether it was possible to develop a natural alternative to Aspirin. Specifically, whether salicin extracted from the bark of the white willow tree could be used for such a purpose. Following this thread, several users asked for an explanation of how these medications work to evaluate whether the natural remedy could be an adequate alternative to Aspirin. Participants were asked to learn about how Aspirin works and to compose a detailed post responding to these queries, and to include a description of the mechanism of each of the medications in the response.

YouTube video

All participants were shown a two-minute YouTube video describing the primary uses and chemical mechanism of action of Aspirin. We included this video in the experiment for several reasons: (1) to reflect the type of resources people encounter and use in everyday life (Dubovi & Tabak, 2020; Liu et al., 2018; Shoufan, 2019); (2) we wanted all participants to benefit from viewing dynamic visualizations of a biological process as a way to focus on the unique contribution of sketching above and beyond exposure to visual information; (3) we wanted to examine whether visual information influences the content of participant sketches.

Biological reasoning task

Participants received an identical, two-page explanation that provided basic background knowledge in plain language as well as context for the problem. It described two similar medicines— Aspirin and Salicylic Acid— and their chemical mechanisms of action. The text consisted of approximately 538 words (in Hebrew) and was divided into seven paragraphs. The two versions of these informational pages varied between "sketchers" (experimental) and "non-sketchers" (control) in two ways: (1) the inclusion of an implicit sketching prompt in the form of a sketch embedded in the informative description (see Figure 1); and (2) an explicit sketching prompt in the instructions.

The sketchers' informational background included a sketch (drawn by the experimenter) depicting a schematic drawing of the chemical structure of Aspirin (Figure 1). This author-generated sketch was intended to serve as a prompt to encourage sketching, and as a model of how one might approach the task of sketching the biological mechanism depicted in the problem.

Figure 1
Chemical Structure of Aspirin Sketch Included in Sketchers' Instructions

Following Schmeck et al. (2014), we took measures to ensure that participants in the control group had the same amount of information as participants in the sketching group. For this reason, the author-generated sketch was also described verbally in the informational text that was the same for both groups. The informational background was followed by two versions of the problem statement:

"Non-sketchers" received the problem statement: "You must write a detailed answer comparing the two drugs, including a description of their mechanism of action."

"Sketchers" received the problem statement followed by a statement (translated from the original): "In order to help online readers understand the mechanism in depth, it is necessary to draw or sketch the method of action of both medicines, even if it means a simple/schematic drawing."

Procedure and analysis

To control for prior knowledge effects and ensure comparability between randomly allocated experimental and control groups, participants answered a short multiple-choice pretest. Participants with low (0–2/11) or high (10–11/11) scores were excluded.

All participants viewed the same YouTube video, then read an informational text that differed by condition as described in the Materials. They were asked to read the text carefully to answer an open-ended question on an online forum: "Could Salicylic Acid's mechanism of action function as an adequate alternative to Aspirin?" Participants were asked to compare the two mechanisms of action while including a detailed description of each.

Each written solution was segmented into distinct biological statements: (a) Aspirin's mechanism of action, (b) Salicylic Acid's mechanism of action, (c) comparison between the two medicines, and (d) scientific mistakes. 0.5–1 point was awarded for each correct statement, or deducted for each mistake, the sum was the total biological sense-making score. Repetitions did not add or deduct points. Following Schwamborn et al. (2010), ideas that were represented in sketches were counted and added to the total number of statements (in the sketching group alone), but only if they made a point different from those noted in the textual response.

12% of the solutions were coded collaboratively with a second independent coder who is an expert in biology. Afterwards, each coder independently coded 25% of the solutions blind to condition, and a Cronbach's alpha interrater reliability of 0.900 was achieved.

Results

A major goal of this task was to examine whether asking non-biologists to generate sketches as part of their reasoning solution is a more effective learning strategy than asking non-biologists to write a reasoning solution with biological text alone. An independent-samples t-test analysis indicated that the use of correct statements from criteria (a) and (b), mechanisms of action, was significantly different between the two groups, respectively [t(52)=-4.228, p<.001], [t(52)=-3.124, p<.01]. Mean proportion correct and SDs on the biological reasoning task for both condition groups are presented in Table 1 and Figure 2. The sketching group used a significantly higher number of scientific statements related to Aspirin's mechanism of action (M= 6.268, SD= 2.0206) and to Salicylic Acid's mechanism of action (M= 3.269, SD= 1.4121) than the control group (M= 4.000, SD= 1.9131), (M= 2.173, SD= 1.1397). The sketching group also made a significantly lower number of scientific mistakes (M= .286, SD=.7127), p<.01, than the control group (M= .962, SD=.9584). However, the number of scientific statements used for comparison was not significantly different between the two groups. Furthermore, the sketching group scored significantly better (M= 11.179, SD= 3.8205) than the control group (M= 7.115, SD= 3.6778), p=.000).

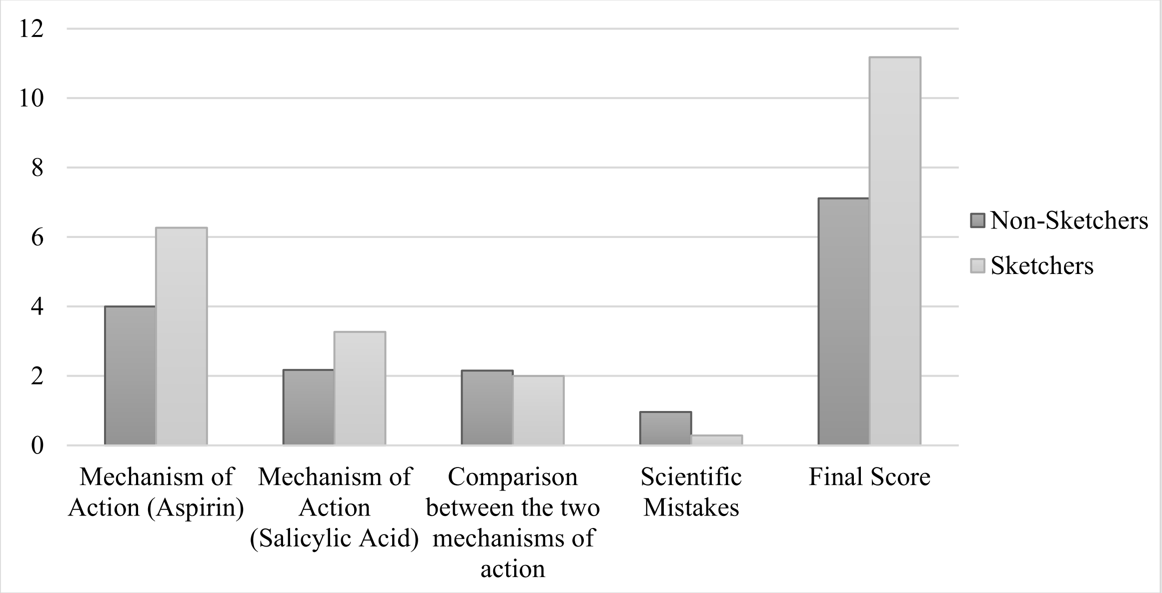
Table 1
Mean proportion correct on the biological reasoning task for two groups

	Condition			
	Non-Sketchers *n*=30		Sketchers *n*=30	
Criteria	*M*	*SD*	*M*	*SD*
Aspirin's mechanism of action	4.000	1.9131	6.268***	2.0206
Salicylic Acid's mechanism of action	2.173	1.1397	3.269**	1.4121
Comparison between the two mechanisms of action	2.154	1.0749	1.999	1.3792
Scientific Mistakes	.962	.9584	.286**	.7127
Final Score	7.115	3.6778	11.179***	3.8205

Note: Asterisks (*), (**), (***) indicate significant difference from control group at *p<.05, p<.01 and p<.001*, respectively.

Figure 2

Use of categorized scientific statements and scientific mistakes in the biological reasoning task.



The results show that the prompt to sketch had two significant effects on the quality of the biological reasoning task: (a) It improved the scientific knowledge of the given mechanisms; and (b) it reduced the amount of possible scientific mistakes made as part of describing an unknown biological mechanism. Accordingly, it improved the novices' biological thinking and scientific sense-making, as they selected information, organized, and integrated it in a verbal solution.

As part of the reasoning solution, participants were instructed to formulate subjective advice for their "online readers" on whether Salicylic Acid can constitute a natural alternative to Aspirin. A chi-square analysis indicated that there were no significant differences between the two groups in composing subjective advice as part of their reasoning solution [$\chi 2$ (6,N=60)=2.336, p=.31]. This result indicates that the prompt to sketch did not affect the integration of advice as part of the solution, therefore, it did not affect the quality of the solution in that sense.

Some participants used scrap paper to take notes and write down information from the text that they thought might be important or helpful. Most papers showed the participants were trying to understand the relationship between components mentioned in the text, such as acetyl and OH as functional groups, COX enzyme, prostaglandins, thromboxane, and platelets. There were no striking differences between the "draft notes" of the two groups, as the same amount of drafts were found in each group (n=7).

After writing their biological solution, the participants were asked if they felt that they were missing information and if so, what information might have helped them create a better solution or understand the scientific text. There was no significant difference between the groups in claiming they needed more information [$\chi 2$ (1,N=60)=.002, p=.965]. That the groups showed no difference in their need for additional information, may further support the conclusion that the differences in the quality of their understanding resulted from the condition of sketching.

Discussion

The main goal of this research was to explore whether sketching can serve as an intermediary factor that enables non-biologist learners to understand and reason about biological processes in biological problem-solving. We were interested in pursuing this question, because sketching is a practice that people could employ as they try to learn new complex information through self-directed learning from online resources. Results indicate that the prompt to sketch affected the quality of the biological reasoning task. In particular, it facilitated the understanding of given mechanisms as well as reduced scientific inaccuracies in describing the biological mechanism. Accordingly, it improved the novices' biological thinking and scientific sense-making, as exhibited in the way that they selected information and organized and integrated it in a verbal solution. So why is sketching as part of biological reasoning and problem-solving better for biological thinking than learning from scientific texts alone?

Biological processes and mechanisms are known to occur differently at different levels of organization as a result of multi-factor interactions (Rea-Ramirez, 2008). Therefore, biology, as a field of phenomena explained by mechanisms (Sheredos & Bechtel, 2017), includes complexities that challenge comprehension (Quillin & Thomas, 2015) and holds many inherent challenges for learning and understanding (Mayr, 1998). These challenges, such as lack of proficiency in biological terms and inter-level interaction and effects, are easier to handle during problem solving when aided by a self-drawn visualized model of a described mechanism, especially for those who do not have prior knowledge to rely on (Eick & King, 2012). This is due to some of its most prominent attributes:

a. Sketches function as part of a users' self-dialogue that occurs during work on a task, in order to visualize ideas (Fish & Scrivener, 1990), to represent a novel idea (Forbus & Ainsworth, 2017) and to promote thinking processes, making it easier to solve problems in different content areas (Landay & Myers, 2001; Jitendra, 2002; Ainsworth, 2006);

b. Sketches contain user-selective information, and by creating a two-dimensional set of visual-spatial symbol relationships in order to explain three-dimensional ideas, principles, processes, and models, these sketches play a focal role in the biological problem-solving process (Kindfield, 1994a; 1994b; Quillin & Thomas, 2015);

c. Sketches enable one to track the many factors involved in a biological process and make the hidden more visible and the complex simpler (Quillin & Thomas, 2015);

d. Sketching, as a modality of representations, assists learners who actively process a load of information (Ainsworth, 2006) in developing memory and generating visual models as part of higher-order thinking skills in biology (Heideman et al., 2017);

e. Sketching creates a mental model (Mayer, 2009), as it actively involves learners in the cognitive process of selecting, organizing, integrating learned information (Schmeck et al., 2014) and generates an external model (Quillin & Thomas, 2015).

Our findings suggest that sketching is not necessarily spontaneous, as we did not see a high incidence of sketching in the control group. The only subject that used sketches in the biological reasoning solution (and who, as a result, was analyzed as a "sketcher") used procedural sketches (e.g., chemical mechanisms of action—COX's irreversible deactivation by Aspirin or partial deactivation by Salicylic Acid and its effects) that were similar to other sketches found and analyzed in the sketching group. It is worth mentioning that the subject did not receive an author-generated text, while the other sketchers, who used similar sketches in their biological reasoning solution, did. Furthermore, 25% of sketchers indeed used an inspired form of the author-generated sketch in their biological reasoning solution. Following Schmeck et al. (2014), the present study encourages science instructors and educators to incorporate sketching practices as part of textual literacy, which they call the generative drawing effect. By providing an author-generated sketch augmenting the biological text, we provided a practical sketching strategy for the non-biologists "sketchers." An important implication is that non-biologists may need visual guidance for their sketching activity.

Some limitations and potential future directions of our study should be addressed. This study shows consistent evidence that after reading a scientific text, non-biologists who are asked to generate and combine sketches as part of their biological reasoning solution perform better than non-biologists who read without an embedded sketch and the prompt to sketch. However, two additional condition groups, such as "sketchers" without an embedded sketch in the text and "non-sketchers" with the author-generated sketch, might have extended the generative drawing effect according to Schmeck (2014) and Quillin and Thomas (2015). The added value of the aforementioned conditions could reveal the role of the embedded sketch in biological problem-solving and its effect on the quality of the biological solutions of the other condition groups.

Conclusion

This study aims to contribute to the understating of the promising role sketching plays in biological reasoning and problem-solving. We have found that a rudimentary use of sketches, without training or assistance, can improve biological thinking and reasoning among non-biologists. Participants who used sketches as part of their problem-solving performed better in biological reasoning than participants who did not sketch. These effects were present even after one-time, minimal exposure to such prompting. The results suggest the strong potential of using sketches in biology learning and understanding. Moreover, if learners are encouraged to develop sketching as a habit of mind for facilitating understanding, then this might prove as a useful tool to enhance self-directed learning from online resources.

Catalyzing Teachers' Evidence-Based Responses to Students' Problem-Based Learning in STEM

Nicole M. Hutchins, Vanderbilt University, nicole.m.hutchins@vanderbilt.edu
Gautam Biswas, Vanderbilt University, gautam.biswas@vanderbilt.edu

Abstract: This paper examines the processes middle school STEM teachers employ to interpret student learning and problem-solving activities during a problem-based learning unit and then design evidence-based lesson-plan customizations. Utilizing inductive and constant-comparative analysis of teachers' think-aloud data, we identify *catalyzing links* that support the transition from interpretation to enactment. We provide a contrasting case between an experienced and a novice teacher, and discuss how the results can inform STEM PBL professional development and teacher-support technology development.

Introduction

Prior research has demonstrated the importance of teacher engagement as students develop ideas and use of strategies to support their STEM learning in problem-based learning (PBL) environments that emphasize student-centered learning. This can pose challenges to classroom teachers, who have to interpret and respond to student progress in ways that target their learning and problem-solving needs while also adhering to the intent of the PBL learning design (e.g., not always addressing a specific knowledge gap through direct instruction) (Chen et al., 2021). Technology-enhanced approaches can assist in handling these challenges by logging student activities in a computer environment, and then using learning analytics to help teachers visualize student learning and problem-solving behaviors over time. This information can then be combined with orchestration technologies, such as teacher dashboards (Wiley et al., 2020) to develop subsequent instructional plans. However, more research is needed to target the complex task of translating our findings as researchers into a language that classroom teachers can interpret and convert to actionable information (Wiley et al., 2020).

Understanding how teachers use dashboards to develop and apply their evidence-based teaching practices in technology-enhanced curricula is critical for improving teacher support and preparation (Campos et al., 2021; Farrell and Marsh, 2016). This serves as the context for our research. In the study presented in this paper, a researcher (i.e., author 1 of this paper) interacted with eight teachers to understand how they used the Responsive Instruction for STEM Education (RISE) dashboard to assess and respond to students' learning and use of strategies as students worked on building computational models of water runoff in the C2STEM block-based coding environment. Teachers completed a series of five *Planning Period Simulations* that leveraged the co-designed dashboard to track students' learning progress and behaviors. We implemented think-aloud protocols using semi-structured interview questions enabling the teachers to verbalize their thought and evaluation processes (Charters, 2003). Our analyses targeted the following research question: *What processes do teachers use when making decisions by analyzing current student data for customizing subsequent lesson plans?* We conducted inductive analysis and constant-comparative analysis (Charmaz, 2006) to provide initial, exploratory patterns in the reasoning processes teachers used when transitioning from interpretations of student results to selecting evidence-based pedagogical responses, i.e., lesson plan customizations grounded in their domain-specific and pedagogical content knowledge and the student results visualized on RISE. A contrasting case between an experienced and a novice teacher explores and highlights these processes.

Background

A careful analysis of prior research models representing dashboard-supported responsive teaching identifies key research opportunities identified in Figure 1 (adapted from Campos et al., 2021). The first research area (Figure 1, in green) targets the impact of an educational event in the classroom by visualizing student data on a dashboard. Research in the area has targeted co-design methods for using teacher insights into developing and presenting such visualizations (Wiley et al., 2020), improving transparency in algorithm development (Holstein et al., 2019), and supporting teacher agency in the representations shown on the dashboards (Ahn et al., 2021). In our research, we have implemented a multi-step co-design process for the creation of RISE (Hutchins & Biswas, 2023).

Another research opportunity involves a deeper understanding of how teachers make sense of the information provided on dashboards and how we can support their interpretation processes (Figure 1, in blue). Campos et al. (2021) conducted a study with teachers and educational coaches to examine sensemaking processes and developed a typology of responses to different data visualizations. Others found sensemaking heuristics, which include comparing, monitoring, and exploring by teachers as they leveraged tools to support technology-supported collaborative learning (Voyiatzaki and Avouris, 2014). Molenaar et al. (2019) investigated how teachers make data visualizations actionable. Specific to our work, Chen et al. explored teacher dashboard use to support problem-based collaborative learning at the college level (Chen et al., 2021). Simultaneously, research on supporting teachers' interpretation process for improved decision making has recently received attention. For instance, researchers have evaluated the impact of different interpretive aids on teachers' sensemaking to support collaborative learning (van Leeuwen et al., 2019). Although we do not focus specifically on this research opportunity, we believe a deeper understanding of how teachers transition from learning analytics-based data visualizations to pedagogical decisions can aid in the future development of such tools and resources.

Finally, there is a need to understand how resulting teacher interpretations of dashboard visualization facilitate evidence-based pedagogical actions (Campos et al., 2021). To our knowledge, limited research exists that explores what teachers notice from classroom data and then generate evidence-based responses (identified with a star in Figure 1) to support students' learning and problem-solving strategies for K-12 science PBL curricula. As such, this research provides novel, exploratory findings on example pedagogical responses resulting from the noticing, interpretation, and reasoning about student data during a problem-based, middle school science curriculum.

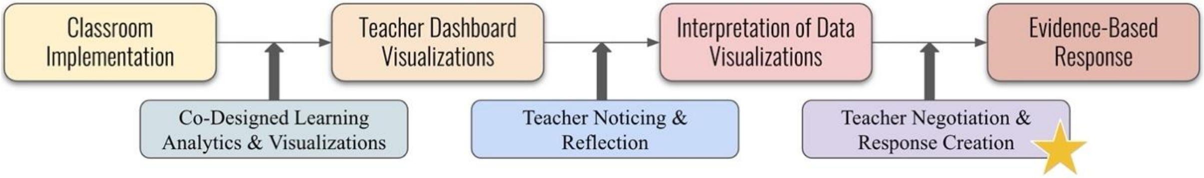
A dashboard-supported responsive teaching process model



Instructional context

Science Projects Integrating Computing and Engineering (SPICE; spiceprojects.org) is a three- week, NGSS-aligned curriculum unit that challenges students to redesign their multi-functional schoolyard using different surface materials to minimize the amount of water runoff after a storm, while adhering to a set of design constraints (McElhaney et al., 2020). The problem-based learning curriculum consists of five core units. These units include: physical experiments, conceptual modeling, paper-based computational thinking tasks, computational modeling of the water runoff phenomenon, and engineering design, in which students use their computational models to design their schoolyard.

The dashboard simulations in this paper focused on supporting lesson plan customizations during the computational modeling task in SPICE, which were implemented in the C2STEM block-based coding environment (c2stem.org). In this task, students needed to initialize total rainfall and the absorption limit of the material they would test with their computational model. Students were required to construct their computational model with three conditional components corresponding to situations where the total runoff would be greater than, equal to, or less than the absorption limit of the selected material. Students tested their computational models as they built them by clicking on the green flag (similar to Scratch; scratch.mit.edu). Analysis of prior SPICE implementations highlighted the importance of (1) linking students' work during computational modeling to their prior science and unplugged CT work and (2) using productive computational modeling strategies (e.g., testing their models with different values of rainfall and materials) (Biswas & Hutchins, 2022). These findings were used to highlight relevant analytics during co-design of the RISE dashboard with teachers.

Co-designed dashboard components

The co-designed RISE dashboard (Hutchins & Biswas, 2023) consists of three core student result pages. The Story provides an overview of the class performance based on key immediate feedback needs recommended by teachers. This included text-based feedback highlighting class successes and opportunities for improvement based on performance measures (items scored by pre-defined rubrics) and strategies used (productive and unproductive strategies pre-defined based on the impact on student learning results). We included interactive data visualizations, such as the grouping of students based on strategy use with additional performance-based results (bottom right of Figure 2), based on teacher recommendations. The Strategies page provided a progression of student performance over the course of the curriculum (e.g., up to the "day" simulated in each planning period simulation) and their grouping by current strategy use. The strategy groups, e.g., Divers implemented unproductive, depth-first model construction strategies (c.f., Grover et al. 2016), were derived by previous analysis (Biswas & Hutchins, 2022). Finally, the Standards page provided a data table of all students with their scores on each completed curriculum task and identified strategy groups. All data visualizations based on artificial intelligence and machine learning methods include an explanation of the analysis approach to give teachers insight into the underlying mechanisms being visualized (e.g., a modal pops-up with the information when the blue button with an "i" is clicked).

The RISE dashboard is equipped with a Reflection Tool in which teachers can add reflections as they review the results (identified as the "Reflection Form" in Figure 2) and select categories for the type of reflection. Submitted forms were populated on the Reflection page based on the category selected (the page link is identified on the left-side menu bar in Figure 2). In the Reflection page, teachers can re-order and reorganize reflections as they see fit to support teacher engagement. Finally, teachers are also provided with a Response page. This page includes the current class plan for the next class day and tools to plan for any adjustments they deem necessary based on student performance. Teachers have access to a number of curriculum resources that include learning objectives and lesson plans relevant for the "day" to aid in their evaluation process.

Methods

Eight middle school STEM teachers (5 female, 3 male) participated in the study. The teachers were from varying urban and rural locations in Tennessee, Illinois, Virginia, New York, Wyoming, and the US Virgin Islands. While all teachers had prior experience with teacher dashboards, four teachers also had prior training and experience in implementing a computational modeling curriculum in their science classrooms, so we labeled them as experienced teachers, and four teachers had no prior training or experience with computational modeling in science, therefore, we labeled them as novice teachers. All teachers consented to participate in the Vanderbilt University IRB-approved study.

Planning period simulations

We focus this paper on five Planning Period Simulations in which teachers enacted five 15 minute "planning periods" by utilizing the RISE dashboard to review and reflect on student, group, and class performance and then developed lesson plan customizations for the "next" class day. These simulations were inspired by the Teacher Moments research at MIT (Benoit et al., 2021). Student data used for each simulation was pulled from prior SPICE studies using an approach similar to the Replay Enactment protocol (Holstein et al., 2019). Student data from the prior implementations were de-identified and students were given gender-neutral names. The five simulations were selected based on class averages in summative assessment performances in science and CT (e.g., one simulation used data from a class that had an above average pre-test performance in science, but below average pre-test performance in CT).

Each teacher first completed a 90-minute professional development session led by the research team in which they learned about the SPICE curriculum. For each simulation, a research team member first described the class scenario, including the class performance on the pretest and other class results prior to the simulation "day" (e.g., performance on the science conceptual models). Using a think-aloud protocol, teachers reviewed student results and feedback provided on the RISE dashboard, interpreted what they saw, and customized class lesson plans for the next day (as they saw fit). Prior research has noted the benefits of think-aloud protocols on tasks involving building interpretations (Charters, 2003; Campos et al., 2021). To obtain verbalizations that accurately reflected the cognitive processes teachers implemented during responsive teaching, we refrained from providing detailed instructions or interpretation of results. Instead, we utilized prompts such as "what possible actions would you take with this group?" and answered questions about technology that did not impact class evaluations (e.g., describing how to use the reflection form). This helped minimize issues concerning bias in data if researcher support or feedback impact teachers' responses (Sherin and Russ, 2014).

Finally, researchers completed an observation sheet during the simulations. The observation sheet consisted of a table for researchers to identify the (1) discussed idea (e.g., computational model scores), (2) visualization targeted, when applicable (e.g., bar graph of class performance), and (3) keywords used or links made (e.g., poor initialization of science variables score during computational modeling relating to prior science performance). These observations were used to support our analysis approach, discussed below.

Data collection and analysis

All Planning Period Simulations were conducted virtually and recorded on a video conferencing platform. In total, we had approximately 12 hours of video data, which we transcribed with an online transcription service. For this paper, we formulated the base unit of analysis by segmenting the transcripts into episodes of pedagogical reasoning (Horn and Little, 2010). An episode of pedagogical reasoning started after the researcher's opening statement about the class scenario and ended when the teacher submitted their customized lesson plan.

We used methods of inductive coding and constant-comparative analysis (Charmaz, 2006) as opposed to theoretically developed codes due to the exploratory nature of the work and a dearth of prior research examining how the resulting interpretations facilitate pedagogical actions. This approach led us to identify catalyzing links that teachers used to transition from their interpretations of AI-generated data visualizations to evidence-based lesson customizations. We develop conjectures about these links and their implications on teacher responses. Team members met to discuss episodes and the links that teachers applied in these episodes. We created analytical memos (Hatch, 2002) to help us then compare teachers' catalyzing links. In the discussion of the links identified, we reviewed the literature on processes that support learning in integrated domains to refine our understanding of the links to help us define the emerging patterns. In the context of the full picture of all pedagogical episodes, we noticed the recurrence of similar patterns as catalyzing links (e.g., supporting learning through multiple, linked representations) and planning period simulations, which suggested patterns exist in the relationship between interpreted classroom needs and class performance distributions.

Results

Utilizing the exploratory analysis process described above on episodes of pedagogical reasoning from all eight teachers, the team identified five key catalyzing link patterns that combined students' learning performance and use of strategies. The teachers utilized these links to support the decision-making processes that transitioned from interpretation of AI-based analysis of students' results to evidence-based lesson plan customizations. These links include: **Supporting Student Understanding Across Multiple, Linked Representations** (MLR; implemented by 4 experienced and 1 novice teacher), **Leveraging Student Successes** (LSS; implemented by 3 experienced and 2 novice teachers), **Representing, Addressing, and Leveraging Productive Failure in PBL** (PF; implemented by 3 experienced and 3 novice teachers), **Weighing responses for different levels of social interactions** (LSI; implemented by 3 experienced and 4 novice teachers), and **Integrating real-world contexts** (RWC; implemented by 2 experienced and 2 novice teachers). We describe each and provide example teacher quotes in Table 1.

Table 1
Identified catalyzing links supporting teacher transitions from noticing to response creation

Link	Description	Example Quote
MLR	Supporting students' understanding across multiple, linked representations (e.g., science, computing, engineering) based on students' performance across multiple assessments and their use of strategies during the computational modeling task	[reviewing Strategy Grouping Figure] *"I'm still thinking about the materials. How to get them to transfer that original [engineering] grid you'd set up so that they have to have different values for the materials. Because it's still more than half [that aren't testing]. I think those overt connections between the lab experiment [in science] and the [computational] model. We make those [connections] implicitly as adults, but I think it needs to be more obvious for a younger brain to connect the model to the real thing."*
LSS	Planning lesson plans to promote future success and/or motivating and engaging students who were not known to be computing enthusiasts or were new to	[reviewing Domain-Specific Score Figure] *"Well, I think in two, you probably need to reflect on the success of the [initializing variables]. Because they did. They were successful for the majority, but I think it would be good to reflect [on that] because that may push them to do better on this, the equal*

	computing (leveraging the “Successes” dashboard feature)	*to condition. Does that make sense? So it’s important to have reflection on initializing variables as a class. Because if you focus on success, it drives success. Rather than say, Oh, y’all did a good job, let’s go on to the next one."*
PF	Understanding, addressing, and utilizing productive failure during PBL to motivate and engage students in the difficult problem-solving process	[reviewing “Opportunities” Text Feedback] *“The other thing that I look at a lot is normalizing mistakes. And so if I would, it becomes tricky. And it really you have to normalize it from the first day. We all make mistakes, but mistakes can help us get better at it and have someone share a mistake related to the materials where everybody looks at it together to figure out."*
LSI	Determining the optimal pedagogical response targeting different levels of social interactions (e.g., lecture, group activity, or individual support)	[reviewing Strategy Grouping Figure] *“When you look at the dashboard, and you see those bigger amounts of needs, that’s when you have to go triage time, and you got to think about okay, I’m gonna have to do something much different here. Because I’ve got a lot of misconceptions. Yeah, that’s where a bigger [class-level] action will occur."*
RWC	Connect the real-world context of the curriculum’s problem to create customizations that support collaborative work and allow for students to reinforce their knowledge	[reviewing Domain-Specific Score Figure] *“Because the whole framing of the problem is, you are a project manager and you’re designing a playground. So you’re gonna work with this team. And you’re, you know, it’s okay that you (a student that finished the computational model first) are a consultant. You are a part of the team that knows computing really well”*

The identified patterns in our exploratory analysis provide an initial framing to understand how teachers transitioned from their data interpretations to evidence-based pedagogical responses. In this section, we explore these transitions in more depth by comparing two episodes of pedagogical reasoning: one by an experienced teacher and the other by a novice teacher. Both cases involve an evaluation of a class that was low performing on the pretest in science, but high performing on the computing pretest.

This first example represents an experienced teacher. After the researcher provided the Simulation Scenario, the teacher began their think aloud process:

> TEACHER: *I always like looking at graphs first…I’m gonna go to that* [reviewing Domain-Specific Score Figure]. *So they had this same problem with initializing their variables. They did better at equal to, and then less than and greater than so not too bad. And this is probably reflecting that they were [science conceptual model group]…So yeah, knowing that, I would say because they did a not so great job here but they did a better job here. So they are getting some of this computing stuff. I would add in a quick physical demo showing the difference between absorption for a sponge and a paper. So they can just understand why they need to test more materials. So let me put in that.*

In this first segment, the teacher linked students’ prior performance in science with issues concerning the initialization of science variables in the computational model. The teacher then checked student behaviors to identify if any other data was available to explain this issue. They then clicked to add a Reflection (a technical issue arose) and the teacher then added a reflection noting they would need to conduct another science demonstration to show the difference between the absorption of different materials to help students understand why they would need the science variables in their computer models. As such, the teacher utilized the process of ***Supporting Student Understanding Across Multiple, Linked Representations*** to generate a possible evidence-based response. At this point, the teacher had only viewed bar graphs illustrating the number of students who got initial variables and the conditions correct and the number of students who tested more than 2 materials. The teacher continued.

> TEACHER: *TEACHER: Let me look at behaviors* [reviewing the Computational Model Testing Figure seen in Figure 2]. *So yeah, I think that I’m going to add [a reflection]. So this is an opportunity [for students[to see more physical examples. So I think that’s really important. Because they did a better job here. And yeah [reviewing the Student Groups Based on Strategy figure in Figure 2], we’ve got a lot of* [bad CT strategy group]. *So we need to fix that again. And I’m going to add an activity. Let’s do Palmer. So they’re gonna show and talk through their*

> *code. I think this is the nicest thing. I'm going to tell you why I like this…what I'm trying to do as a teacher is I am trying to get kids to be more* [good CT strategy group] *and getting comfortable with coding… So seeing who's doing those techniques is really going to help me and then seeing who changes because sometimes in the moment, I'm only picking on the kids that I know are strong in CT, to show examples. And I think that can be a bit demoralizing for other students. So like as this goes on, let's say Kendall, all of a sudden jumps* into [good CT strategy group] *or something like that, that's like a great thing. But if I'm able to see like, someone made the jump from here to here, I can then highlight them and hopefully give them as you know, some nice positive praise, reinforcement kind of thing that I think would be really helpful.*

In this segment, the teacher further acknowledged the need to understand why testing different materials, now from the perspective that a lot of students did not test their computational models. The teacher connected science practices and computational practices, and in addition to conducting the science activity, she elected to do a class presentation in which a student was selected to demonstrate their code and testing practices. Using the ***Leveraging Student Successes*** approach, the teacher selected a student who changed to a more productive strategy group to promote the students' good work and improvement. The teacher concluded with their customized lesson plan:

> TEACHER: *All right. So we still have the initializing variables, and the two thirds are [bad strategy group]. Okay, so I think let me go to reflect. Yeah, so I think having that physical example is really important for this class. And then maybe Palmer you know, maybe I bring in Palmer towards the end of class instead, for this group, and it because maybe the physical demo will help more. And then I can add Palmer in to wrap up.*

To address a conceptual issue regarding initializing variables and poor strategy performances by the class, this teacher used the processes of ***Supporting Student Understanding Across Multiple, Linked Representations*** and ***Leveraging Student Successes*** to determine and finalize an evidence-based lesson plan customization.

In the second example, we discuss a novice teacher presented with the same class simulation. The teacher utilized the links ***Weighing Responses at Multiple Social Levels*** and ***Integrating Real-World Contexts*** to create an evidence-based customized lesson plan for the class. The episode began with the teacher reviewing the Computational Model Testing Figure (seen in Figure 2) and identifying a class issue:

> TEACHER: *Would it help to have samples of those materials on display in the classroom? Are they already doing that?*
> RESEARCHER: [researcher describing that materials are available]
> TEACHER: *I mean, it looks to me that the biggest need for the next day is to address the materials portion. And I like that this makes it clear.*

The teacher began with a curriculum question about the availability of physical materials. The teacher identified that the lack of testing the computational model with different materials was a problem. The teacher continued:

> TEACHER: [reviewing the Student Groups Based on Strategy figure, Figure 2] *And I always worry about those students in the classroom who are done. Okay, now, what do you do now that you're done? I would be assigning them to work with someone who needed more support, so day Reese is going to be an expert. You can consult an expert with your work and bring in a consultant. And you can ask them three questions.*
> RESEARCHER: ... [researcher agreement]
> TEACHER: *You got to explain. But I would put a constraint on it. I think that's a challenge, that's why this could be really valuable to know that they're completed… But kind of put a constraint on it, like, you can only ask a consultant a question, they can't just tell you stuff. Yeah. And it can't be a question like, how do I write the code? Yeah.*

In this segment, the teacher applied Weighing Responses at Multiple Social Levels to reason about a potential lesson plan customization. The teacher also utilized pedagogical content knowledge (the consultant activity was described by the teacher in prior discussions during SPICE training) to determine a productive response. In discussing the idea further, the teacher said:

> TEACHER: *And this I think, I like also, because you can see who needs the most support. Yeah, you know, that they're kind of stalled … I like looking at the written feedback that you're pinpointing, you know, where there are opportunities, but that can also help you target the consultant. Yeah. I like that, because the whole framing of the problem is, you are a project manager and you're designing a playground. So you're gonna work with this team. And you're, you know, it's okay that you're a consultant. You are a part of the team that knows the computing really well.*

In this segment, the teacher described the opportunity presented by this pedagogical approach - being able to listen in on what consultants (students that finished the code) and project managers (in-progress students) were saying during this paired activity to identify students that may need additional support. The teacher reasoned about the choice of lesson activity by ***Integrating Real-World Contexts***. The teacher concluded:

> TEACHER: *Yeah, I think this is kind of invaluable. Alright, so the lesson plan is [coming together] I think the lesson plan for this is more, we'll have the consultants and the students that need work will create the three questions. And yeah, to have more complete testing behavior. Make sure everyone has like I also call them experts. calling you an expert. I do let them [talk to me] if they're stuck, I do become a spy but, don't do that often there.*

The teacher reiterated the response reasoning and acknowledged the underlying, student-centered design of the curriculum by noting that they should intervene when necessary but limit the number of interventions.

Comparison of the two teachers demonstrates key catalyzing links implemented by the experienced versus the novice teacher and highlights the differences in their approaches. For this simulation, the experienced teacher utilized the catalyzing links of ***Supporting Student Understanding Across Multiple, Linked Representations*** and ***Leveraging Student Successes*** to determine their lesson plan customizations, while the novice teacher utilized ***Weighing Responses at Multiple Social Levels*** and ***Integrating Real-World Contexts*** in their lesson plan customization. This seems to indicate that the experienced teachers leveraged their experience and comfort with the curriculum and technology (i.e., domain-specific knowledge) to notice and focus on multiple dimensions of student learning, while the novice teachers may have compensated for their lack of SPICE experience by leveraging their pedagogical content knowledge in PBL to discuss curriculum changes (e.g., discussing normalizing mistakes in Table 1, link PF), deciding on social level responses as gaps grow between groups of students, and leveraging the real-world context of the problem. We believe these results extend on Campos et al.'s (2021) findings by pointing to potential future research in (1) exploring how the provision of different types of teacher-created responses utilizing different catalyzing links post-simulation can help experienced and novice teachers critically reflect on their response choices and discuss how they might change, if at all, and (2) developing tools to aid in teachers' noticing by interpreting the complex learning analytics (e.g., van Leeuwen et al. 2019) that target their background and experience.

Results

This research presents a novel exploration into the processes teachers take from noticing and interpreting learning analytics from a co-designed dashboard to reasoning and enacting evidence-based pedagogical adjustments through lesson plan customizations. In particular, this exploratory work provides a preliminary framework for identifying and evaluating catalyzing links teachers implement to decide and create evidence-based pedagogical adjustments based on AI-based analyses of student learning and problem solving. Distinct from prior work in technology-enhanced responsive teaching (e.g., alerting teachers of individual student errors or disengagement) (Holstein et al., 2019; Van Lehn et al., 2021), these examples demonstrate that the dashboard supported teachers in implementing class activity that (1) increased class or group discussions and (2) supported the development of productive problem-solving strategies, both key for supporting PBL curricula.

We recognize limitations in our work. On the one hand, the low number of teacher participants in this study resulted in analyses focused on depth instead of breadth. Future work should increase the participant cohort to further validate our results and to ensure that teacher preparation is inclusive and supports equity in PBL applications. In addition, in terms of the selection of classes for each simulation, we recognize a limitation in the use of a high- vs low-performing dichotomy in the selection of classes as that approach may not fully represent the nuances of learning and problem-solving behaviors from a classroom context. Future work in selecting data for simulations (and co-design) can evolve more nuanced approaches to evaluating classes, groups within classes, and individual students. Finally, we aim to complete a full, iterative cycle in which the participating teachers will implement SPICE (supported by the RISE dashboard) in their classrooms to holistically examine the dashboard impact on lesson plan customizations and implementations.

Epistemic Excursions as Agentive Meaning Making within a Digital Plate Tectonics Curriculum

Abstract: Models and modeling are essential for mediating knowledge-building processes about geologic phenomena (Stillings, 2012). We draw on constructs of expansive learning (Engeström, 1987) and personal excursions (Azevedo, 2006) to analyze a case in which two secondary students develop geologic explanations using Seismic Explorer, a tool for visualizing information about earthquakes and volcanic eruptions. We present four episodes in which the focal students conjecture and test ideas through modeling plate tectonics phenomena. Using methods of interaction analysis (Jordan & Henderson, 1995) we describe how the students actively build and revise their moment-by-moment explanations. Our analysis contributes to a deeper understanding of how the design of geologic models and data visualizations for classroom contexts can support sensemaking as a kind of journeyed relationship-building with the phenomena, associated data, and with peers, through relational events that we term *epistemic excursions*.

Introduction

Making sense of geologic phenomena—including plate tectonics, global oceanic and atmospheric patterns, and other cycling of matter requires reasoning about systems that are distributed across vast spatial and temporal scales (Anderson, 2006; Herbert, 2006; Stillings, 2012). Developing understandings of earth science requires learners' competence in thinking about complex interrelated behaviors of Earth's systems. Earth science educators can use models and simulations to make phenomena accessible at more human scales, bringing the challenges of large spatial data sets and massive time scales into manageable forms, especially for learners in classrooms (e.g., LaDue & Clark, 2012; Stillings, 2012).

Expansive learning (Engeström, 1987; Engeström & Sannino, 2017) accounts for processes of human learning in which participants create new targets of learning as the interaction unfolds. As explained by Engeström and Sannino (2017), learners "construct a new object and concept for their collective activity, and implement this new object and concept in practice" (pp. 48 - 49). This is in contrast to vertical movement toward prescribed learning goals that characterizes many school learning environments. With the metaphor of expansion in mind, we investigate two high school earth science students' work in an online learning module about plate tectonics. We are interested in deeply describing how they came to engage in a spontaneous process of epistemically-rich activity using an interactive computer-based data visualization of geologic phenomena. We are especially interested in the ways that students use and relate to models, specifically data visualizations, to approximate legitimate professional geological practices. We draw on episodes in which students display epistemic agency (e.g., Miller et al., 2018) in conjecturing and testing ideas through modeling plate tectonics and actively revise their explanations based on information generated from their interactions with models of data. We describe the ways that they attempt to develop model-based explanations of geologic phenomena through four epistemically meaningful personal excursions (Azevedo, 2006). Our analysis seeks to answer the following research questions: *How do excursions with geologic modeling and visualization tools begin and unfold? In what ways are the excursions fruitful for students' agentive work to build, test, and refine geoscientific explanations through interaction with models and with one another?*

Theoretical background

Modeling is central to professional geoscientists' understanding of geologic phenomena (Stillings, 2012). For more than 30 years, learning environments have leveraged computing tools for students to engage in modeling (e.g., Wilensky & Resnick, 1999) and use of data visualization software (e.g., Lee & Wilkerson, 2018) as activities for learning in many scientific domains. Model-based reasoning, at its fullest, requires learners to engage with content through production of scientific knowledge, so that the ideas and explanations that the models represent are "testable, revisable, explanatory, conjectural, and generative" (Windschitl, et al, 2008). Explanation-building across multiple sources of evidence is at the core of the work of geoscience. However, orchestrating learning environments in which students enact epistemic agency in proposing, testing, and revising evidence-based explanations using modeling practices remains a central challenge in science education (Russ & Berland, 2019; Windschitl et al., 2008). As argued by Hall (1996), discursive theory-building exchanges can be especially generative for understanding how learners develop competencies for the production of knowledge, especially in discipline-specific contexts.

In geoscience especially, phenomena of study often occur at very large scales of time and space (Herbert, 2006). For instance, scientists have difficulty directly engaging with mountain building in real time as it occurs beyond the scope of a human's lifetime. As a result, plate movement and mountain building have traditionally been taught using historical second-hand data (data collected by others) over long periods of time. While many may argue that first-hand data collection is more meaningful for learners and representative of geoscience practice, Lee and colleagues (2021) have demonstrated that "students do engage data collected by others in deeply personal ways" (p. 664). Learners' work with second-hand data requires complex engagements on several layers: personal, cultural, and sociopolitical (Lee et al., 2021). On a personal level, learners relate to their direct experiences with data and measurement. On a cultural level, learners recognize routines of practice and technologies associated with a data set's collection and use. Finally, on a sociopolitical level, learners recognize political narratives that may influence how data is interpreted and used.

Learning scientists have demonstrated that data science education becomes more meaningful and equitable when students experience data science as relational work (Wilkerson & Polman, 2020; Rubin, 2020). Students build relationships with the data they are working with in order to locate themselves in relation to the data and to "see" the data from the perspective of others (e.g., other students). They make personal connections, ask questions, and generate their own ideas based on data. These relationships are embedded in the specific context of the data, knowledge about the larger domain (e.g., geology), and the concepts that exist in the interaction—which are often tentative and not fully worked out. A relational view of learning in activity gives way to contexts of expansive learning (Engeström, 1987). Relationships with and to the object of study forge pursuit of individual interests, what Azevedo (2006) has termed personal excursions. Personal excursions are diversions from the initially framed activity that generate a second activity—that is, an excursion. This second activity may bring forth meaningful connections to the original goals. It is through these personal excursions that many students develop and extend connections between the content of learning activities and their own identities and interests, often positively impacting learning along stated learning goals (Azevedo, 2006; Farris & Sengupta, 2016). Personal excursions allow students to build "pragmatic, conceptual, and question-generating resources so that more extended, coherent personal pursuits are possible and more likely to take place" (Azevedo, 2006, p. 93).

Methods

The context of this study concerns learning within an interactive Plate Tectonics curriculum (https://learn.concord.org/geo-platetectonics), part of the Geological Models for Explorations of the Dynamic Earth (GEODE) project. Approximately twenty 10th and 11th grade students, along with their teacher, engaged with the curriculum within their earth science class in a public school in the Southeastern U.S. The duration of this instructional unit was approximately ten class periods of forty minutes each. We analyze video and audio recordings from one focal teacher's classroom. Students worked in pairs on one laptop. The teacher selected three pairs for recording. The teacher's selection was based on consistency in attendance and the likelihood that the students would share their ideas with one another through talk. Recordings were generated using the embedded laptop camera and microphone. Students' screens were recorded using QuickTime Player.

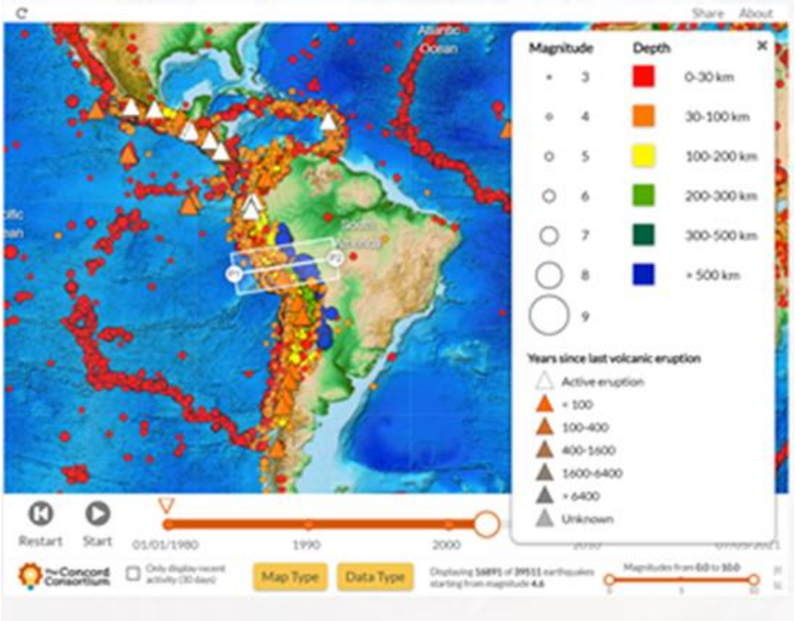
In this interaction analysis (Jordan & Henderson, 1995), we seek to understand how one pair of students––Noah and Zach—work beyond the curricular prompts to ask questions that are personally meaningful to them. We selected these students as focal students based on their talkativeness and consistent attendance. We first synchronized the screen capture and student video data to create multimodal transcripts of key moments of interaction. We describe the practices through which they share tentative sensemaking knowledge and engage in a spontaneous pattern of proposing, testing, and revising evidence-based explanations using the digital representations in the curriculum. We highlight four episodes of interaction, selected because they illuminate the ways in which Noah and Zach generate geoscience explanations as relational and sensemaking work. The episodes concern the students' conjecture relating mountain formation to volcanic activity (Episode 1), their emergent theory that seismic activity follows the leading edge of continent movement (Episode 2), their proposed mechanism of earthquake depth (Episode 3), and their explanation for the formation of the Andes Mountain range (Episode 4). These occurred on Days 2 and 3 of the 10-day curriculum.

The model: Seismic Explorer

The Plate Tectonics curriculum includes Seismic Explorer, an interactive data visualization tool. Seismic Explorer (Figure 1) is a time-oriented data visualization of earthquake epicenters, volcanic eruptions, and plate movements.

Students can view location, depth, magnitude, and frequency of earthquakes on a two-dimensional map of the world as well as in a three-dimensional cross-section. Other data included within Seismic Explorer is direction of tectonic plate movement and volcanic eruption data. We characterize Seismic Explorer as both a data visualization and a computer-based model of geologic information. The Plate Tectonics curriculum was intentionally designed to use the Seismic Explorer iteratively in support of student problem solving related to key driving questions.

Figure 1
Seismic Explorer representing volcanic eruptions and earthquake epicenters in the Andes Mountains. Students can create a cross-section as shown by the rectangular selection marked in white.



Analysis and findings

In this section, we follow four episodes that illustrate how Noah and Zach relate to models and data representations in order to sensemake within plate tectonics. In these episodes, they are at the point of the curriculum in which they are working to develop an understanding of plate interactions through historical data about plate tectonics. Each of these episodes constitutes an excursion from the prescribed activities in the curriculum, characterized by building relationship with the phenomena, associated data, and with peers. Drawing on existing work on students' epistemic agency (e.g., Miller et al., 2018) and personal excursion (Azevedo, 2006), we have termed these events *epistemic excursions*.

Epistemic excursion 1: Testing ideas of phenomena against local connections

In this episode, Noah and Zach are working with Seismic Explorer to describe the location of volcanic eruptions in the Andes Mountains, as prompted by a question in the online curriculum. Noah immediately notices that "they [the volcanoes] go along the Andes Mountain range," (see Figure 1) and Zach suggests manipulating the map to "go back up and see if any volcanoes are near the Appalachian Mountains and the Rocky Mountains." The students live within the Appalachian Mountain range. Zach recognizes that volcanoes and mountains are both located in the Andes, prompting the idea that volcanoes are associated with mountains.

Noah and Zach proceed to test the idea that volcanoes occur along mountain ranges. They use Seismic Explorer to examine volcanic history in the Appalachians and Rocky Mountains. They claim that the Appalachian Mountains are "clear [of volcanoes]" and the Rocky Mountains have "a little bit [of volcanoes]." We see this as a form of seeking coherence between curricular questions about the Andes and personal knowledge about other mountain ranges. Through this exploration of the data visualization, they conclude that there is no record of "active" volcanic activity in the Appalachian Mountains and minimal volcanic activity near the Rocky Mountains, contradicting Zach's initial theory that volcanoes are closely associated with mountain formation. This episode represents an excursion in which Noah and Zach seek to relate the correlation between mountain formation and volcanoes in the Andes Mountains to the Appalachian Mountains (where they live) as well as the Rocky

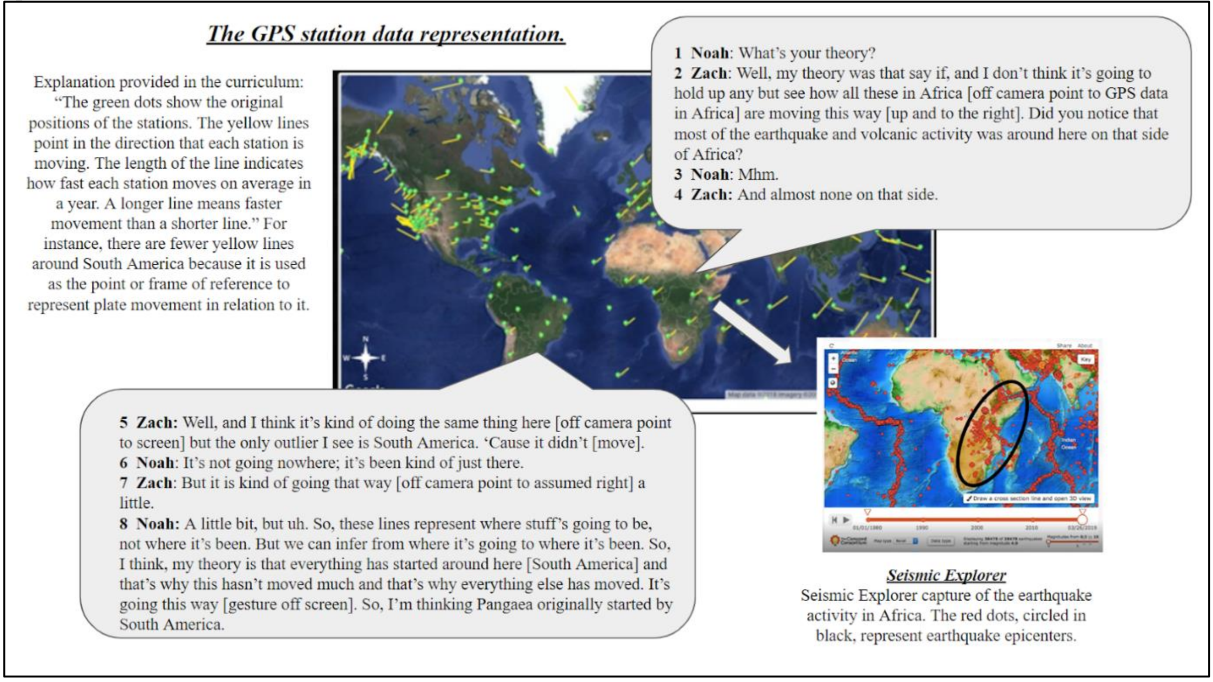
Mountains (which they have heard about). Noah and Zach begin to build a relationship to the data in which they test their emerging ideas in connection to geographies that are personally and contextually relevant to them.

Epistemic excursion 2: Presenting and refining personal theories across models

In this episode, we follow Noah and Zach's theory building talk across two days. Noah and Zach worked with Seismic Explorer to describe the patterns of earthquakes and volcanic eruptions in the Andes Mountains, as prompted by a question in the online module. Zach deviates from the exploration of the Andes Mountains and has Noah zoom in to only view the earthquake activity in Africa. After viewing this, Zach exclaims, "Ooh, I think my theory might be holding up." Noah prompts him to explain what he means. Zach says "okay, now my theory is…see Africa's going that way, right?" (see Figure 2). Zach points to the Southeast coast of Africa as he continues: "Look where all the volcanoes and earthquakes are. They're on this side." Zach has Noah then revisit South America and they compare the pattern in Southeastern Africa to South America. Noah asks "…so the way they are going determines where the earthquakes are?" to which Zach confirms "that's the theory so far." The class period ends, interrupting further discussion.

As soon as Noah and Zach begin working the next class day, they pick up the discussion of their "theories" (their word for initial claims). Zach decides he wants to test his theory developed from Seismic Explorer during the previous day against a model they saw earlier in the curriculum, the GPS station map (see Figure 2). Figure 2 shows how Noah and Zach built a "theory"—that is, a scientific claim—through talk and action as they revisit their initial ideas and this earlier representation of GPS motion data. Zach clarifies and justifies to Noah his claim that the direction and relative movement of the GPS station data suggests where volcanoes occur and adds earthquakes to his explanation. He points to the yellow traces of northeasterly station movement in Africa to convey his thinking. In Turns 2 – 7, Zach indicates that there is almost no movement in South America, highlighting the important information related to his unfinished ideas about mountain formation.

Figure 2
Epistemic Excursion 2



The GPS station data representation.

Explanation provided in the curriculum: "The green dots show the original positions of the stations. The yellow lines point in the direction that each station is moving. The length of the line indicates how fast each station moves on average in a year. A longer line means faster movement than a shorter line." For instance, there are fewer yellow lines around South America because it is used as the point or frame of reference to represent plate movement in relation to it.

1 **Noah**: What's your theory?
2 **Zach**: Well, my theory was that say if, and I don't think it's going to hold up any but see how all these in Africa [off camera point to GPS data in Africa] are moving this way [up and to the right]. Did you notice that most of the earthquake and volcanic activity was around here on that side of Africa?
3 **Noah**: Mhm.
4 **Zach:** And almost none on that side.

5 **Zach:** Well, and I think it's kind of doing the same thing here [off camera point to screen] but the only outlier I see is South America. 'Cause it didn't [move].
6 **Noah:** It's not going nowhere; it's been kind of just there.
7 **Zach**: But it is kind of going that way [off camera point to assumed right] a little.
8 **Noah:** A little bit, but uh. So, these lines represent where stuff's going to be, not where it's been. But we can infer from where it's going to where it's been. So, I think, my theory is that everything has started around here [South America] and that's why this hasn't moved much and that's why everything else has moved. It's going this way [gesture off screen]. So, I'm thinking Pangaea originally started by South America.

Seismic Explorer
Seismic Explorer capture of the earthquake activity in Africa. The red dots, circled in black, represent earthquake epicenters.

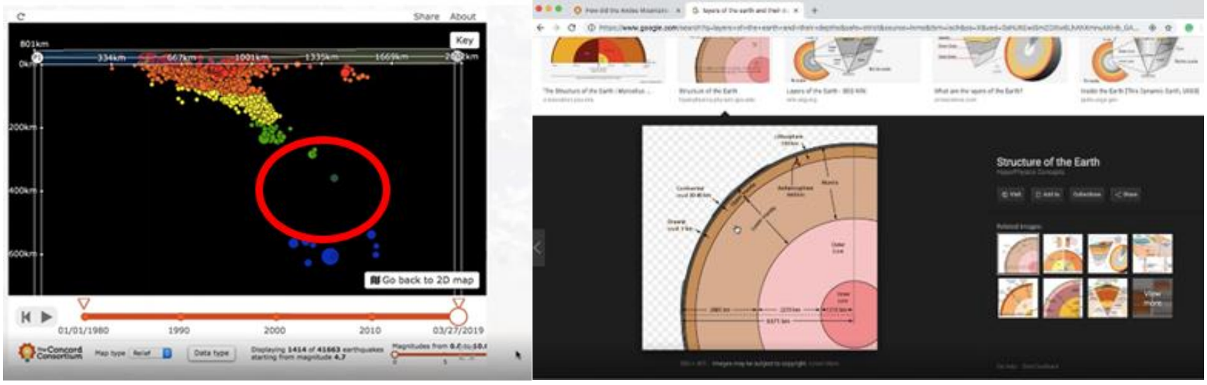
This explanation fuels Noah's own developing theory, arising from their return to the GPS station data. Referring to the relative movement and direction of continents, Noah proposes that the initial location of Pangaea (Turn 8) was around the current location of South America. However, we note that Noah and Zach's initial conceptions were based on their misinterpretation of the GPS station map as they did not consider that in order to identify movement, something needs to serve as a point of reference. The data points in South America indicate no movement because South America is the frame of reference. However, the students interpret the representation to mean that South America is stationary. However, this misinterpretation still promotes interesting theory-building conversation, even though it leads the students to an explanation that does not reflect the widely accepted perspectives of geoscientists. Our focus here is not that students develop normative explanations instantaneously while working with models, but that they iteratively test and refine their emergent theories as they move towards more sophisticated explanations and starting points for further development.

This episode highlights how Zach and Noah worked through two related instances of theory work: (1) the direction and relative movement of plates and (2), the spatial origin of Pangaea. In the first theory work, they relate their current thinking about the location of earthquakes and volcanic eruptions, which are represented in Seismic Explorer, to the relative direction and movement of tectonic plates using the GPS station representation. While the curricular questions are focused on the Andes Mountains, Noah and Zach explore other areas of the world through Seismic Explorer to gain insight on additional geologic data, such as earthquakes in Africa. This suggests that they understand that it may be useful to use information beyond the specific place-based phenomenon in the question. They choose the southeastern coast of Africa as a similar case and generate a comparison. This investigation allows the students to relate to their own personal ideas and examine a theory that Zach has regarding patterns of earthquakes and volcanic activity using Seismic Explorer. They then proceed to work on a related theory about the origin of Pangaea, against another visualization of geologic data that they had engaged with earlier in the curriculum. Noah and Zach refine their theories after discussing the GPS station map, in which the discussion leads to the development of a new theory, one initiated by Noah. Noah uses the GPS station map to "theory build" about the initial location of Pangaea, suggesting that it originated around South America due to its lack of movement. This connection to Pangaea is not part of the curriculum, suggesting that their interactions with these visualizations also prompt connections to prior knowledge. The pair iteratively relate to the personal questions that they have and to other sources of data in order to support their claims.

Epistemic excursion 3: Meaningful inquiry and connections, non-canonical ideas

In this episode, the pair return to the curriculum prompts. They use Seismic Explorer to create 3D cross sections, shown in Figure 3, in order to see the depths and magnitudes of earthquakes along the Andes Mountains as directed by the curriculum. However, Noah and Zach recognize a "gap" in the number of earthquakes at certain depths below the Andes (typically between 350-500 km below the surface). Unprompted by the curriculum materials, they question why there is a lack of earthquakes in this "gap" and wonder if this phenomenon can be explained by the layers of the Earth. Noah then seeks out a reference from outside the curriculum, using a new browser tab to search for images of the layers of the Earth. Noah asks, "what layer of the earth is that far below ground?" to which Zach responds, "you have the crust, the mantle, outer core, inner core or at least that's what I know." They continue as they investigate by clicking on several images of the layers of the Earth. Noah exclaims, "this [the gap of earthquakes] is all happening around the upper mantle." Zach then adds "that's magma, it's molten rock. What's the core supposed to be like? Nickel? Was it nickel?" The two students then debate whether the core is solid material or not, since "the core's really high pressure and heat," before returning again to the task directed by the curriculum.

Figure 3
The "gap" circled in red & a sample internet image that the pair reference.



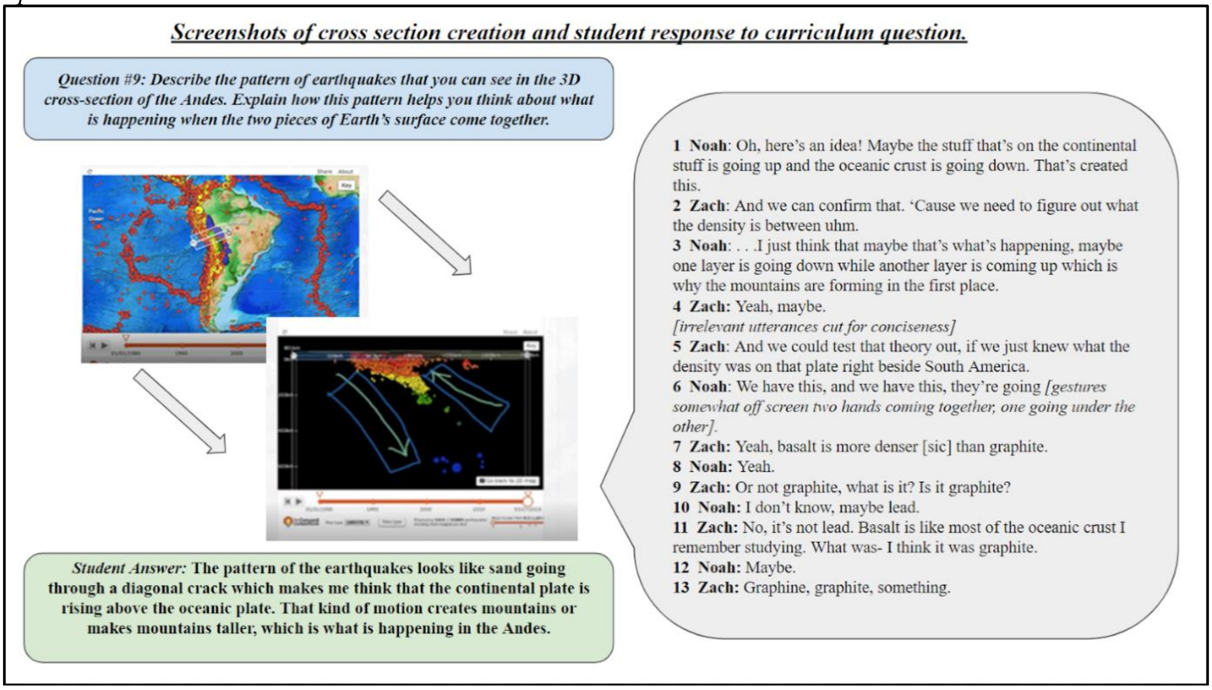
We see in this episode that Noah and Zach seek to investigate a question that is elicited by the earthquake data in Seismic Explorer. The two recognize a pattern within the cross section that there are relatively no earthquakes. They specifically relate this data-prompted investigation to their prior knowledge of the layers of the Earth. They iteratively seek to make sense of what they are seeing within the model by reaching out and referencing outside information found in their spontaneous internet search. They engage in talk about their knowledge of the layers and attempt to reach a shared understanding of the makeup of the upper mantle. This episode highlights Zach and Noah's attempts to connect existing knowledge resources about the layers of the Earth and their relative depth to earthquake activity as they work towards generating and refining shared explanations.

Epistemic excursion 4: Expansive learning full circle

The next task in the Plate Tectonics curriculum is to use Seismic Explorer to create a cross-section of earthquakes occurring underneath the Andes Mountains, prompting Noah and Zach to "describe the pattern of earthquakes that you can see in the three-dimensional cross-section of the Andes. Explain how this pattern helps you think about what is happening when the two pieces of Earth's surface come together." Figure 4 shows the selected area of the Andes Mountains using Seismic Explorer, a snapshot of Noah and Zach's cross-section, and their associated talk. The students call the two relevant tectonic plates "pieces," and specifically refer to them as the "continental stuff" and the "oceanic crust" [Turn 1] as the term "plate" is formally introduced after this task.

While looking at their cross-section, the students recognize that the trend line of the earthquake events likely corresponds with the boundary between the two plates. In cross-section view, the plates and their boundaries are invisible (see Figure 4). Noah verbalizes his idea that as the two tectonic plates converge, the continental layer (on the right side of the trend of earthquakes) is going "up" while the oceanic layer (on the left side of the trend of earthquakes) is going "down" (Turn 3). Zach then offers that they could test their theory about this relative movement if they knew the densities of the two plates to determine which plate is denser (Turn 5) and would subduct under the other. In Turn 6, Noah gestures with two hands to mimic how they expect these plates to interact, with one going under the other. In Turns 7-13, Zach and Noah discuss the geologic makeup of the oceanic plate in terms of density. As they continue to work out this idea, Noah inscribed two yellow arrows on their screen (See image of arrows on graph snapshot of cross-section in Figure 4) on each side of their earthquake depth model to represent this movement trend.

Figure 4
Epistemic Excursion 4



Screenshots of cross section creation and student response to curriculum question.

Question #9: Describe the pattern of earthquakes that you can see in the 3D cross-section of the Andes. Explain how this pattern helps you think about what is happening when the two pieces of Earth's surface come together.

Student Answer: **The pattern of the earthquakes looks like sand going through a diagonal crack which makes me think that the continental plate is rising above the oceanic plate. That kind of motion creates mountains or makes mountains taller, which is what is happening in the Andes.**

1 **Noah**: Oh, here's an idea! Maybe the stuff that's on the continental stuff is going up and the oceanic crust is going down. That's created this.
2 **Zach**: And we can confirm that. 'Cause we need to figure out what the density is between uhm.
3 **Noah**: . . .I just think that maybe that's what's happening, maybe one layer is going down while another layer is coming up which is why the mountains are forming in the first place.
4 **Zach:** Yeah, maybe.
[irrelevant utterances cut for conciseness]
5 **Zach**: And we could test that theory out, if we just knew what the density was on that plate right beside South America.
6 **Noah**: We have this, and we have this, they're going *[gestures somewhat off screen two hands coming together, one going under the other]*.
7 **Zach:** Yeah, basalt is more denser [sic] than graphite.
8 **Noah:** Yeah.
9 **Zach:** Or not graphite, what is it? Is it graphite?
10 **Noah:** I don't know, maybe lead.
11 **Zach:** No, it's not lead. Basalt is like most of the oceanic crust I remember studying. What was- I think it was graphite.
12 **Noah:** Maybe.
13 **Zach:** Graphine, graphite, something.

This episode illustrates how Zach and Noah draw on their experiences with Seismic Explorer to build a normative explanation of tectonic plate subduction in the Andes Mountains. But what makes this expansive? Similar to Episode 2, Noah and Zach draw upon shared terminology that is not introduced at this point within the curriculum, including scientific language related to plate composition and density. They garner one another's' support for the development of a theory of subduction, which, while normatively correct for this plate boundary, is beyond the intended curricular goal of this question, which was asking students to focus on the patterns evident in the depth of earthquakes that occur along the mountain range. They draw on knowledge from some experience that was not part of the Plate Tectonics curriculum concerning the ocean crust being made of basalt, which is going down (subducting) under the less dense continental plate. This episode illustrates students' use of the visualization tools within the modeling environment to examine patterns in the depth of earthquake events, and secondly, to begin to explain the phenomenon at the convergence. The match between the representational affordances of the environment and the prompt to guide what students were supposed to do with the environment supported the students to realize normative key concepts in a process of refining theories of geologic phenomena. We argue that each of these resources contribute to their decision to highlight the relative density of the plates as a key causal mechanism of plate subduction.

Discussion and conclusion

In order to craft geoscientific explanations, learners build relationships with the data they see and their sensemaking talk across representations. For Noah and Zach, using the interactive computer-based data visualization tools of Seismic Explorer and the GPS station map to think about complex geologic phenomena is a process of iteratively making, testing, critiquing, and refining explanations of what they notice. In each of the episodes, we have highlighted how Noah and Zach relate to the data directly or are prompted to relate based on their own personal excursions adjacent to or outside of the designed module. They often deviate from the curriculum to sensemake with their own emergent inquiries and curriculum-driven questions. Across these episodes, we have illustrated that Noah and Zach seek to relate to varied intertextual resources—including other models within and outside of the Plate Tectonics curriculum, their own personal geographical connections, and other existing knowledge resources—in order to sensemake around geologic data visualizations. They search to investigate their own questions as they relate to the data. In doing so, they establish their developing theories by drawing out naïve understandings and scientific language, exploring their emerging ideas within Seismic Explorer, and testing these ideas against additional interactions with the tools within the curriculum. The varied visualizations in which the students interact serve to drive forward their proposal of new explanations. Their shared theory building about geologic data transcended the given dataset and tools, yet approximates (Grossman, et al., 2009) ways that professional geoscientists leverage modeling environments (Bokulich & Oreskes, 2017; Stillings, 2012). In sum, Noah and Zach sensemake across data models, personal experiences, and their own ideas to form a disciplinarily acceptable explanation of a process of subduction near the Andes Mountains.

We argue that the fruitfulness of Noah and Zach's interaction in these episodes is largely driven by the freedom and sense of agency with which they tested tentative ideas against external sources. They demonstrate a high level of epistemic agency to draw upon additional sources and investigate their own questions. This process of relating to each other and relating the curriculum to other sources and experiences drives their sensemaking, which we argue, is instrumental in supporting their progress along disciplinary learning aims. Furthermore, we also note that many of the sources and experiences that Noah and Zach spontaneously relate to the curriculum were "conceptually risky," meaning that they were loosely connected to the phenomenon by analogy and or inference creating an indirect path toward canonical ideas.

Our focus here is not that students develop normative explanations instantaneously while working with models, but that they can iteratively test and refine their emergent theories as they move towards more sophisticated explanations. Epistemic excursions, as we have illustrated, were highly unpredictable. A real-time observer would have been unlikely to predict how these episodes were going to unfold. The "ends" of excursions were inconsistent in the degree that they led to disciplinarily key ideas about geologic phenomena. Excursions 1 and 3 contain sensemaking resources that are quickly and wisely abandoned. If analyzed in isolation, they could be deemed rabbit holes or even off-task work.

Our analysis contributes to a deeper understanding of how the design of geologic models and data visualizations for learning can support sensemaking as a kind of journeyed relationship building with the phenomena, associated data, and with peers. In these episodes, the supports of the curriculum and collaboration fostered generative epistemic practices in questioning and modeling geologic phenomena. The cases, furthermore, illustrate how excursions can be a key support for disciplinarily-relevant epistemic practices, especially within a digital learning environment. Epistemic excursions, including those that might be viewed as misaligned with canonical science, are important in a broader and more relational view of learners' sensemaking processes. Gaining insight into how students negotiate the excursion process is a step towards supporting all students with greater epistemic agency and ownership of their own processes of figuring things out in environments with extensive modeling and visualization tools.

Revisions in Scientific Explanations Using Automated Feedback

Xuesong Cang, Dana Gnesdilow, Sadhana Puntambekar
xcang@wisc.edu, gnesdilow@wisc.edu, puntambekar@wisc.edu
University of Wisconsin, Madison

Abstract: Writing and revising scientific explanations helps students integrate disparate scientific ideas into a cohesive understanding of science. Natural language processing technologies can help assess students' writing and give corresponding feedback, which supports their writing and revision of their scientific ideas. However, the feedback is not always helpful to students. Our study investigated 241 middle school students' use of feedback as well as how the feedback affected their revisions and improvements in writing. We found that students made more content-related revisions when they used feedback and these revisions resulted in improvements in their writing. However, fewer students made integrated revisions. Finally, many students did not address the feedback in their revisions. Additional support to assist students to understand and use feedback, especially for students with limited science knowledge, is needed.

Introduction

Writing science explanations is an integral part of learning and doing science (NGSS, Lead States, 2013). Students need to explore, understand, and explain why scientific phenomena happen using scientific ideas. Writing scientific explanations provides opportunities for students to integrate their disparate scientific ideas into more cohesive and deeper understandings of science topics (Braaten & Windschitl, 2011; Linn, 2006). Though it is often challenging for students, making revisions of science writing can prompt them to connect their initial ideas to new ideas, see the connections between scientific ideas, and strengthen their understanding of science (Linn, 2006; Tansomboon et al., 2017). The development of skills in science writing and revisions of writing has been found to benefit students' long-term science learning (Rivard, 1994). Despite the importance of writing in science and making revisions, students usually get minimal support in writing and revising their science ideas in the classroom. This is likely because it is challenging for teachers to read and provide individualized, constructive feedback in a timely manner to students given limited class time and the number of students teachers have (Gerard et al., 2022). In recent times, Natural Language Processing (NLP) technologies are being used to provide timely and detailed feedback.

NLP tools can provide feedback to support students in understanding the gap between what they have written as well as what they have missed in their explanations (Hattie & Timperley, 2007; Roscoe et al., 2015). NLP tools can provide just in time feedback based on a student's progress, which is a key aspect of providing support within a Zone of Proximal Development (Vygotksky 1978). However, students often face difficulties in using automated feedback. Some students find it challenging to understand computer guidance and trust the feedback. Consequently, students ignore it (Zhu et al., 2017). Other students may struggle to make revisions based on automatic feedback because they do not understand the science well (Zhu et al., 2020). Further, students' revisions of science writing are influenced by writing practices in school, where revisions are most often viewed as accumulating ideas (Gerard et al., 2022). Students and teachers may have different understandings about what it means to engage in revisions of science writing and may take different approaches. As a result, automated feedback is not always helpful in supporting students to make in-depth revisions (Shute, 2008). This may, at least partially, explain why students tend to either simply add new, relevant ideas without integrating them into previous writing or elaborate on the existing ideas repeatedly without modifying their initial writing (Gerard et al., 2016). Further, some other students choose not to revise their ideas when they are supported with automatic feedback.

Prior studies have provided little information about how students use feedback based on automated assessments and if the use of feedback influences the types of revisions that students engage in. It is important for researchers to understand how students' revise their scientific explanations so they can enhance the effectiveness of automated assessment and feedback as well as better design supports that students need to engage meaningfully in writing and revising their science ideas (Tansomboon et al, 2017). Therefore, we need to understand how students actually engage in revisions after getting feedback, and whether students' revisions improve their writing (Lee et al., 2019, 2021). The goal of this study was to understand the ways in which students revised their scientific explanations in an essay based on automated feedback provided by a natural language processing software, called PyrEval (Gau et al. 2018; Singh et al., 2022). Our research questions were as follows: 1) How do students revise their explanations based on automated assessment and feedback? 2) To what extent do students use feedback in their revisions? and 3)What are the differences in the types of revisions students make?

Methods

Participants and study context

Three 8th grade science teachers and their 262students (N_{T1}=95; N_{T2}=78; N_{T3}=89) from two semi-rural public-school districts in the midwestern United States participated in this study. The students for whom we did not have full data were excluded, resulting in data from 241 students (N_{T1}=90; N_{T2}=67; N_{T3}=84) for our analyses. Students from Teacher one's (T1) classes were in a different school district from Teachers two and three's (T2 and T3). All teachers received the same professional development before the implementation of a physics unit in their classes. The teachers' professional development was related to the physics unit and use of our NLP automatic assessment to provide students with feedback for their writing.

During the design-based physics unit, students designed a safe and fun roller coaster based on what they learned about physics during the unit. The unit was taught over approximately fifteen 45-minute class periods. Throughout the unit, students used a digital notebook and conducted virtual experiments using a roller coaster simulation (Figure 1), and recorded data based on their experiments in the simulation. Students learned crosscutting concepts about energy and energy transfer within a roller coaster system (i.e., The Law of Conservation of Energy, potential energy, and kinetic energy). Students wrote essays to explain their roller coaster design based on the science they learned during the unit and received feedback on their essays from our NLP system, PyrEval (described below). We provided students with prompts for their writing to help them understand which science ideas and relationships they should include in their essays, such as explanations about how height influences potential energy, or how energy transfers as the roller coaster car moves down the initial drop. The sequence of the unit was as follows: students a) were introduced to the roller coaster design challenge; b) conducted five virtual experiments to learn relationships between important science concepts that would help them to design a fun and safe roller coaster; c) wrote their roller coaster essays; e) received feedback from PyrEval the day after writing their essays; and e) revised essays.

3. What did you learn about the relationship between mass and energy?

Your response

3a. Explain how you know this with data from your trials.

Your response

○ Slow
● Normal
☐ Force Vectors

Kinetic 0 J
Potential 1845 J
Thermal 0 J
Total 1845 J

Drop 3.75 m
Loop 2.50 m

Mass 50 kg
Friction 0.00

Weight 493 N
Normal Force 492 N
Friction Force 0.0 N
Net Force 28.6 N

Speed 0.01 m/s
Acceleration 0.57 m/s²
Max Accleration 0.6 m/s²
Max Speed 0.0 m/s

The NLP software we used to assess and provide feedback on students' essays, PyrEval, was developed to identify weighted vectors of key content units (CUs), i.e., ideas and relationships that students should include in their essays using a wise-crowd method (Gau et al. 2018; Singh et al., 2022). PyrEval parsed students' writing into propositions and assessed whether each proposition was a fit with each of 15 key content units that we identified as important for students to include in their essays (See Table 1 for some of the important CUs). A binary score of 1 or 0 was provided in PyrEval logs, presence of an idea was marked as a 1 and an absence was marked as 0. Students got feedback based on whether PyrEval identified important CUs in their essay. If PyrEval did not find any one of these 4 most highly weighted CUs, that were grouped into themes from the original 15 CUs (See Table 1), it provided students with feedback for improvement. Students were also provided with positive feedback if any of these CUs were detected. The feedback consisted of high-level, general statements and questions aimed at getting students to reflect on which concepts they explained and where they could improve based on PyrEval's assessment of their writing. The feedback that students got was similar to this example:

> "*You did a great job explaining Law of conservation of energy! You also wrote that the initial drop height should be higher than the hill height. Now, can you explain how PE at the top and KE at the bottom are related? Also write about how mass affects PE and KE.*"

Table 1
Most Highly Weighted 4 CUs PyrEval Used to Generate Feedback

CU#	Science Idea / Relationship
CU0	Potential and kinetic energy transform back and forth as the car moves and changes height
CU1	Greater mass mean greater energy
CU2	Explaining the Law of Conservation of Energy
CU3	Initial drop must be higher than the hill to have enough energy to make it to the end of the ride

Data sources and measurement

Number of CUs per essay

Students' essays were analyzed automatically using PyrEval. As mentioned above, up to 15 CUs could be identified by PyrEval. We analyzed the total number of CUs that PyrEval identified in students' essays as the *initial CU score* (from the final essay) and *revised CU score* (from revised final essays) to understand if PyrEval detected more key CUs in students' revised essays. At the same time, we also generated a *CU change score,* which was calculated by subtracting the *initial CU score* by the *revised CU score*. The *CU change score* shows the improvement of content units. The change score could be either positive or negative, depending on whether more or fewer CUs were identified in the revised final essays.

Revised or not

Some students revised their essays while others did not revise their essays. We developed a binary code, *Revised or Not*, to capture if students revised their final essays.

Types of revisions

We analyzed the data using a coding scheme that was generated using both inductive and deductive approaches. We first used the categories of revisions identified in Gerard et al. (2016) and then inductively developed our coding scheme to fully capture the types of revisions found in our dataset. We developed a binary coding scheme that captured four types of revisions that students engaged in: (1) *surface-level revisions,* making changes in spelling or word choice; (2) *added similar content,* repeating an existing science ideas or relationship that was already in their essay; (3) *added new content*, including new science ideas or relationships that were not in their initial essay; and (4) *integrated revisions,* reformulating ideas to improve the science ideas and relationships that were already written in their essay (See Table 2). Students could engage in multiple forms of revisions and receive multiple codes.

Table 2
Examples of Types of Revisions

Revisions	Examples	Notes
Surface level revisions	**Feedback:** "You did a great job relating height with PE and KE! … can you explain how mass affects PE and KE?" **Final Essay**: "when the potential energy went up the kintetic would to affecting in the speed being higher" **Revised Final Essay**: "when the potential energy went up the **kinetic** would to affecting in the speed being higher"	Student corrected spelling of "kinetic" in the revised essays but did not address the feedback that suggested explaining how mass affects PE and KE.
Added similar content	**Feedback:** "…Can you explain how height affects PE and KE while explaining Law of conservation of energy? …" **Final Essay:** "I believe that the initial drop should be 3 because it's fun and safe, it also will give a higher amount of PE which helps it have enough energy to go up the hill." **Revised Final Essay:** "I believe that the initial drop should be 3 **meters** because it's fun and safe, it also will give a higher amount of PE which helps it have enough energy to go up the hill. **When**	Student explained height affects PE in the final essay without stating a direct relationship. Then the student added a sentence which explained a higher height means more PE in their revision,

	you have a higher hill height, you get more PE because there is more potential for energy because the hill is higher.”	which made the writing more precise.
Added new content	**Feedback:** “You did a great job explaining Law of conservation of energy! …Also write about how mass affects PE and KE.” **Final Essay:** NO writing about how mass affects PE and KE **Revised Final Essay:** “**On the other hand though, mass effects potential and kinetic energy. The heavier the mass is, the more potential and kinetic energy is created**.”	Student did not explain how mass affects PE and KE in the initial essay. Then added a sentence about it in their revision, based on the feedback.
Integrated revisions	**Feedback**: “… Can you explain how height affects PE and KE while explaining Law of conservation of energy? …” **Final Essay:** “When we have 4ft at the starting drop, it makes the KE at the bottom the same as the PE at the top because all the PE is transferred into the KE at the bottom because the law of conservation of energy states that energy can be transferred but not created nor destroyed” **Revised Final Essay:** “When we have a **4ft higher height** at the starting drop height, it makes the **PE at the top greater as well as the KE at the bottom** because all the PE is transferred into the KE at the bottom because the law of conservation of energy states that energy can be transferred but not created nor destroyed”	Based on the feedback, the students explained that height is directly related to potential energy by explaining “4 ft higher height…make the PE at the top greater as well the KE at the bottom” in the revised essays, thereby reformulating their previous writing.

*Students’ revisions have been bolded for emphasis.

Use of automated feedback

Though students received automated feedback to help them revise their writing, students did not always use or follow it. We developed a second coding scheme to capture whether students used the feedback they received from PyrEval. Students either: 1) used the feedback by writing about the science concepts that they were asked to address, or 2) did not use the feedback. This coding was binary as well, with students receiving a 1 for using feedback and 0 for not using it. Each student could only have one type of code. Interrater agreement was established for both sets of coding categories. For each set of codes two researchers independently coded 15% of all revised essays and achieved almost perfect agreement (Stemler, 2001) on the types of revisions and the use of automated feedback codes (Kappas of .826 and .817, respectively). All discrepancies were resolved through discussion and the two researchers coded the remainder of the data.

Data analyses

We identified how many students revised their final essay. Of the 241 students who wrote the final essay, 87 of them revised their essays in some way. From here, we generated two sets of data: 1) a full dataset containing 241 students, and 2) a subset of the full data containing the 87 students who revised the essays. These datasets were used in different analyses described next.

First, we wanted to compare the *initial CU scores*, the *revised CU scores* as well as *CU change scores* between students who revied and did not revise. To do this, we conducted an independent two-sample t-test using the full dataset. Second, for the eighty-seven students who revised their final essay, we wanted to understand how they used the feedback as well as the types of revisions they made. We calculated the percentage of students who engaged in each category of the types of revisions and whether they used the feedback. Beyond providing descriptions of students’ use of the feedback and types of revisions they made, we also wanted to understand how the types of revisions may have been related to students’ use of the automated feedback. We conducted four pairs of chi-squared tests of homogeneity for each type of revision and use of feedback: 1) surface-level revisions and the use of feedback, 2) added similar content and the use of feedback, 3) added new content and the use of feedback, and 4) integrated revisions and the use of feedback. Third, we wanted to more deeply explore if other factors along with the types of revisions and the use of feedback may have influenced the number of CUs that students mentioned in their revised final essays. To do this, we conducted a stepwise regression analysis, which included three fitted models.

Results

Comparison in the number of CUs in essays

We first conducted an independent t-test using students’ *initial CU scores* and *Revised CU scores* to compare any if there were any differences between students who did or did not revise their essay. This test was appropriate since the CU scores were normally distributed. Based on PyrEval's assessment of students' essays, we found that students who revised their essay included significantly more CUs in their initial essays ($t_{(239)} = 2.00$, $p = .05$). Similar results were found for the revised final essays; the 87 students who revised had significantly higher *revised CU scores* than students who did not revise, $t_{(239)} = 2.76$, $p = .005$ (see Table 3). Further, we conducted an ANOVA to examine the *CU change score* between students who revised or not. The results showed that students who made revisions had significantly higher *CU change scores* than students who did not revise their essays ($F_{(1, 239)} = 7.95$, $p < .001$).

Table 3
Mean of CU Scores and t Test

	N	*Initial CU scores*	*Revised CU scores*	*CU change scores*
Revised	87	4.93 (2.64)	5.26 (2.76)	.33 (0.81)
Did not revise	154	4.16 (3.00)	4.16 (3.00)	0 (0)
t-test sig.	241	$t_{(239)} = 2.00$ $p = .05$	$t_{(239)} = 2.76$ $p = .005$	$t_{(239)} = 5.07$ $p < .001$

Understanding students' revision behaviors

To understand how students revised their essay, we examined two dimensions: (1) the *types of revisions* that students engaged in (e.g., surface-level revisions, adding similar or different ideas etc.), and (2) *use of feedback* (e.g., used the feedback or not). For the types of revisions, we found that students most often revised by adding similar content (57.47%) or by making surface-level revisions (40.23%). However, fewer students added new content (26.44%) or made integrated revisions in their essays (21.84%) (See Figure 2a). For the use of feedback, we found that more students used the automated feedback (63.21%) than students who did not (36.78%) in making their revisions (Figure 2b).

Figure 2
Percentage of types of revisions ((a); left) and use of feedback ((b); right)

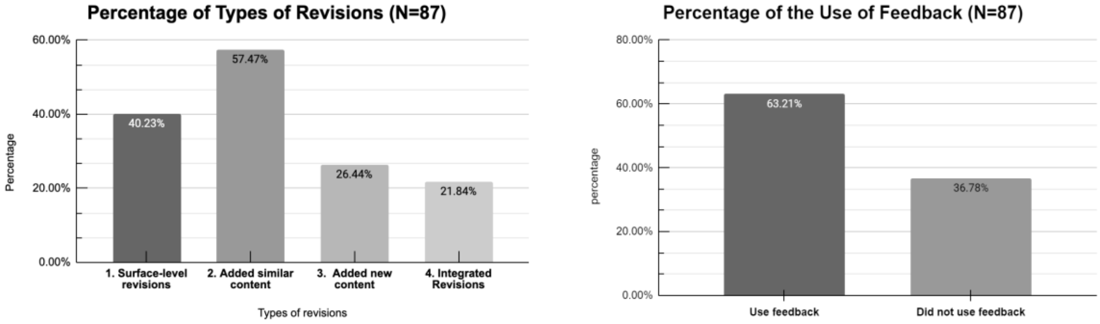

Table 4
Chi-square Omnibus Tests

	Surface-level revisions	Added similar content	Added new content	Integrated revisions
The use of feedback	$X^2_{(1, n=87)} = 11.96$ $p < .001$ **	$X^2_{(1, n=87)} = 15.99$ $p < .001$ **	$X^2_{(1, n=87)} = .98$ $p = .32$	$X^2_{(1, n=87)} = 1.79$ $p = .18$

Notes: ** is significant at .05 level and *** is significant at .01 level

Relationship between types of revisions and use of feedback

To examine if there was a relationship between whether students used the feedback from PyrEval and the types of revisions they made, we ran four pairs of chi-square tests (Table 4). We found that there were statistically significant differences for two of the four tests: surface-level revisions and the use of feedback ($X^2_{(1, n=87)} = 11.96$, $p < .001$), and adding similar content and the use of feedback ($X^2_{(1, n=87)} = 15.99$, $p < .001$). There were no significant differences for adding new content or making integrated revisions and the use of feedback. We found students who did *not* use feedback were significantly more likely to make surface-level revisions than students who used or followed the feedback. We also found that students who added similar ideas were significantly more likely to have used the feedback than students who did not use feedback to inform their revisions.

Exploring factors that influence students' science writing

As prior studies have shown, engaging students in revising their science writing is an important practice to help them improve their science writing and learning. To understand the factors that might have affected students' scientific writings (*CU change score* as the dependent variable), we conducted a stepwise regression analysis by using factors including (i) types of revisions (*surface-level revisions, added similar content, added new content, integrated revisions*), (ii) use of feedback, and (iii) teacher (see Table 5).

We first conducted a multiple linear regression to better understand to what extent the variation in students' increased CU scores could be explained by four types of revisions. A significant regression equation was found ($F_{(4, 82)} = 2.38$, $p = .05$), with an R^2 of .10. Students' predicted *CU change score* was equal to - .11 + .28*(*surface-level revisions*) +.54*(*Added similar content*) + .30*(*added new content*) -.29*(*integrated revisions*), where all the independent variables were coded as: 1 = presence of the type of revisions, 0 = absent. However, only one category of types of revisions, *added similar content,* was a statistically significant predictor. Students' *CU change score* increased .54 if students *added similar content* in the revisions.

Next, we examined whether the *use of feedback* was a predictor that explains CU scores in students' revised essays. For model 2, we excluded the non-significant predictors (*surface-level revisions, added new content, integrated revisions*) and added the *use of feedback* to predict the *CU change score*. But we did not find that model 2 was significant. Neither *added similar content* (one type of revisions) nor the *use of feedback* were significant predictors of *CU change score.* Based on the results from model 1 and model 2, we could see that only one type of revision, *added similar content,* was a predictor that explained students' CU change scores. In model 3, we further explore one more factor, teacher, and excluded non-significant predictor, use of feedback. Students' predicted *CU change score* were significantly predicted by this model 3 with an R^2 of .16. However, the factor of teacher is the only significant predictor.

Table 5
Regression Models to Predict Improvement in Scientific Explanations

	Outcome	Predictors	Regression Model results
Model 1	CU change scores	Surface-level revisions; Added similar content; ** Added new content; Integrated revisions	$F_{(4, 82)} = 2.38$; $p = .05$; ** $R^2 = .10$; Adjusted $R^2 = .06$
Model 2	CU change scores	Added similar content; Use of feedback	$F_{(2, 84)} = 2.74$; $p = .07$. $R^2 =. 06$; Adjusted $R^2 = .04$
Model 3	CU change scores	Added similar content; Teachers ***	$F_{(3, 83)} = 5.24$; $p = .002$. $R^2 =. 16$; Adjusted $R^2 = .13$

Notes: ** is significant at .05 level and *** is significant at .01 level

Discussion

While researchers have emphasized that writing scientific explanations and making revisions can help students integrate and connect scientific ideas (Braaten & Windschitl, 2011; Linn, 2006), these competencies are challenging to middle school students (Tansomboon et al., 2017). Students possess limited knowledge about how to revise their ideas to improve their writing (Hattie & Timperley, 2007). Further, teachers often do not have the time to provide students with detailed feedback to help them improve their writing (Gerard & Linn, 2022). To better support students and teachers, many researchers have developed technologies to automatically assess and provide feedback to students to help them improve their writing (Gernard et al., 2016). In this study, we wanted to know more about: 1) the types of revisions students made to their scientific explanations, 2) whether students used the feedback, 3) the relationship between these two aspects, and 4) how revisions may have led to improvements in writing to inform our work in better designing scaffolds to support their writing.

Our exploration of the revisions based on feedback and if the writing improvement showed that students were more likely to simply *add similar content* to their original writing and make surface-level revisions as opposed to making integrated revision. These results are aligned with prior studies that students find it challenging to: 1) see the gap between what they have written and what is missing and 2) connect scientific ideas, which means they tend to revise as if the science ideas are isolated or disconnected from what they wrote originally (Hattie & Timperley, 2007; Gerard & Linn, 2022). But we found that *added similar content* is an important type of revision that resulted in the detection of more content units by conducting multiple regression analyses. Even though students did not integrate these scientific ideas into their original writing, when they added similar content, they improved their writing by explaining ideas more specifically so that PyrEval could better detect the content units. Despite prior studies suggesting that integrated revisions aid in science learning (Gerard et al., 2016; Gerard & Linn, 2002), our findings demonstrated that reflecting on and revising scientific ideas by adding similar content can also lead to improvement in students' writing. Revisiting and revising explanations based on feedback likely helped students to better integrate their ideas, making them more cohesive (Braaten & Windschitl, 2011; Linn, 2006). Additional support is required to assist students in comprehending how to make integrated revisions, rather than simply concatenating similar ideas. Further, it could also be the case that since so few students made integrated revisions, there was not enough power to detect its effect on improvements in students' essays related to the number of content units detected by PyrEval.

We investigated feedback use and found that many students did not use it, which is aligned with prior studies showing challenges in understanding and addressing it (Zhu et al., 2020). Some students may have simply not followed the feedback because they didn't know what to do, there may have been too much to address, or they simply did not know how to improve their ideas. We further explored how the use of feedback may have been related to the types of revisions students made, which has not been widely studied thus far. Even though prior studies indicated that some students tended to have superficial revisions with the support of automated feedback (Gernard et al., 2016; Shute, 2008), our study showed that the use of feedback did help students to make more content-related (i.e., added similar or new content), instead of surface-level revisions (i.e., fixed spelling). But using the feedback to make revisions was less effective in making integrated revisions, as few students did so in our study. Additional support can be designed to help students to reflect on what they have written in reference to the automatic feedback and assess whether they have explained their science ideas and, if not, fix what they have written in an integrated way.

Our results showed that students improved their writing based on the assessment of CUs from PyrEval. It indicates that making revisions helped students to improve their writing. However, the fact that students who did not revise had lower initial CUs scores in their original final essays may indicate that they may have not addressed the automated feedback because they had limited prior knowledge, which was also a finding from Zhu et al. (2017). This may indicate that students struggled to clearly write about the science ideas in a way that could be detected by PyrEval, because perhaps they did not understand the ideas very well. In addition, we also found that the teacher was a significant factor that predicted students' improved writing. This indicates that helping teachers to better support students to understand the feedback and make revisions is essential (Shute, 2008). Support can be provided at a whole class, group, and individual level. For example, before students revise, teachers can discuss this process more deeply in a whole class discussion. This kind of scaffolding may be essential especially for students with lower prior knowledge (Gerard & Linn, 2022). Though it is challenging to write and revise scientific explanations, the use of automated feedback with teachers' facilitation provided students in our study with the opportunity to practice writing scientific explanations and making revisions in the classroom, which is rare (Gerard et al., 2019). Our findings show a potential for helping a large number of students to engage in this complex practice in science learning by using automated feedback.

Conclusions

Writing and revising scientific explanations helps students to strengthen their understanding of science. However, there are many factors that impede the implementation of this practice, such as the number of students that one teacher needs to give feedback in the classroom or the limited knowledge students may have about science and / or about how to revise their science writing. We provided students with the automated feedback by using a NLP software, PyrEval, to provide feedback to help students to revise their writing. Our investigation of the types of revisions students made demonstrated that automated feedback can positively shape students' approaches to revising their writing (i.e., focus more often on the scientific content and have less superficial level of revisions). However, the effectiveness of the tool still needs to be improved because it was less successful in getting students to make integrated revisions, which requires the students to reformulate their original writing. Based on our findings that improvements in students' scientific writing were associated with certain types of revisions (added similar content), we could focus more on helping students understand how to use the feedback to meaningfully revise and integrate their science ideas to further improve their scientific writing and learning.

Abstract: This study investigates connections between fabric crafts and the breadth and depth of mathematics involved in pursuing the crafts with a particular focus on quilting. The authors became participant observers in crafting circles, conducted 65 semi-structured interviews to investigate crafters' mathematical insights in their projects, and analyzed artifacts through close manual examination and photographs to deepen these insights. We ask the questions: (1) How do crafters observe the interplay between mathematics and the process of a craft? (2) How can crafters' products illuminate the breadth and depth of mathematics? The findings suggest that the different ways in which mathematics and craft intersect either bear the form of a craft-forward approach, as crafters produce patterns and explore it through changes in the patterns or in the form of a math-forward approach, in which crafting directly draws on mathematical concepts guiding the work toward the improved performance or modeling of math concepts.

Introduction

Girls report lower levels of interest and perceived ability in mathematics in secondary and higher education contexts (Fredricks and Eccles, 2002; Else-Quest et al., 2010; Guo et al., 2015; Ganley and Lubienski, 2016) due in large part to a lack of sense of belonging to the field (Cheryan, Drury, Vichayapai, 2012) even when they perform on par with men (Good, Rattan, & Dweck, 2012). As such, body of research focuses on the sociocultural context of learning and of doing mathematics outside of school contexts. However, it is rife with tensions and dilemmas (Boaler, 2007). These tensions culminate in colonized hegemonic ways of learning math through gendered and racialized categories. For example, fabric crafts are not usually included as a viable option for the study of math in informal and formal structures, despite research that demonstrates integrating mathematics with crafts and designs helps learners form a personal and meaningful connection with mathematical concepts (Shaffer, 1997; Elliott & Bruckman, 2002). Textile crafts have also contributed to generating new mathematical knowledge, including the modeling of hyperbolic planes using crochet (Taimina, 2009; Wertheim, 2005). Yet, in mathematics learning contexts, fiber crafts have largely been overlooked and their intellectual merit is still to be explored.

To pursue epistemic diversity of learning and being, it is necessary to recognize that crafting circles present opportunities to do mathematics within a diverse range of contexts (e.g., seeing domain concepts within fiber crafts) as well as recognizing and valuing action within these contexts as a form of mathematical doing that could lead to mathematical insights that are different from but not less important than traditional forms of mathematics. Our research interrogates the extent to which the culture of crafting can produce the learning conditions of Papert's (1980; 1993) Mathland to inform our understanding of the disconnect between mathematics as taught in school and everyday mathematics. The land metaphor within the term Mathland refers to the possibility of learning a language associated with a particular geographic region. Thinking of mathematics as a land where things are done in a particular way invites the possibility that there can be multiple languages and, by extension, multiple lands of mathematics. Additional Mathland-inspired principles have shaped efforts that seek to promote deep mathematical engagement. Earlier efforts to instill mathematics learning into craft have leaned heavily on technological interventions to make the mathematical principles of crafting salient to the learner. However, the larger work to which this paper contributes argues that crafting in itself is a technology that privileges patterned mathematical engagement and is supported by a social structure and broader crafting culture that rests on deep historical roots (Peppler, Keune, Thompson, 2020). In this paper, we analyze the mathematical concepts crafters use in their projects and how they form mathematical connections with their craft. To this end, we asked: (1) How do crafters observe the interplay of math and craft? (2) How can crafters' products illuminate the breadth and depth of mathematics?

To answer these questions, we draw on our ethnographic data that includes observational notes, semi-structured interviews with 65 crafters, and analysis of artifacts created by our participants. Crafters predominantly talked about mathematical engagement through craft terms (e.g., describing the pattern and arrangement of units into the overall pattern). They worked within an understanding of the process they were participating in and in pursuit of the project they wanted to create. For instance, while crafters may not have explicitly mentioned interlocking tessellations by name as part of their math/craft insights, they were able to intricate shapes which required the elegant application of the principles of translation, rotation, and mirroring while working on the structure of their pieces, including in the seam lines, sewing order, and assembly. This study provided us with an understanding that craft is a promising context for creating Mathland which can serve as initial starting points about the processes through which engagement with math could be supported through crafting.

Background

Giving learners powerful tools for creative expression by designing personally meaningful projects and sharing them with others is a central tenet of constructionist approaches to learning (Papert 1980;1992). Papert's constructionist approach draws on cognitivist and sociocultural perspectives by considering how a range of socio-material contexts support cognitive possibilities (e.g., domain learning) through ways of doing that are characteristic of the material context (Holbert, Berland, & Kafai, 2021). Crafting is a learning culture organized around the production of new artifacts and connecting with others in the process. Crafting promotes ties to one's cultural heritage, shaping learning and participation in ways specific to regional crafting traditions. Studies show that people engaging in fiber crafts apply mathematical ideas, but the nature of their engagement is distinct from traditional mathematics (Uttamchandani & Peppler, 2018.; Thompson, 2022; Keune, 2022; Peppler, Keune, Thompson, & Saxena, 2022). Mathlands within the constructionist tradition are learning environments in which rich doing of mathematics happens along the way of performing and practicing cultural practices that are deeply interconnected with mathematics. Papert (1980) describes Mathlands as microworlds where certain types of mathematical activities could develop with "particular ease" and the learner is involved in creative exploration of ideas. He compares children's learning of mathematics in a computer-based Mathland to learning their first language. This model acts against dissociated learning that takes place in schools that does not take into account activities such as mental and physical, resulting in epistemological alienation. Mathlands not only change the way we teach and learn mathematics, but also the way we situate learning in a cultural context.

Methodology

Our longitudinal, multi-year ethnography as learner-practitioners positioned us both relationally and cognitively into crafting communities. Observing and learning with and from skilled crafters provided a multitude of opportunities to draw deep connections between aesthetically, intrinsically woven patterns, and mathematics. Our intention was to adapt the practices of the crafters and grasp crafting as a research process that includes creativity and experimentation to coproduce knowledge (Puwar & Sharma, 2012). These helped us to envision crafting circles as Mathlands that initiated mathematical conversations similar to learning a language (Papert, 1980), and their intergenerational and sociocultural features that have the potential to decolonize ways of learning, knowing, and doing. Participating in communities of practice and care that created artifacts for their loved ones or for social causes (e.g., Keune, Yankova, & Peppler, 2022) allowed us to understand the social and relational aspects of artifacts. For example, knitting covers for trees to spread love and care for nature, crafting donation quilts to distribute to community members in need, or making sweaters for the unhoused. The work as embedded ethnographers resulted in audio notes, detailed, field notes, and crafting photographs and videos of crafting processes. Data sources also included interviews. Using snowball sampling and contacts provided by crafters in the guilds, we reached out to potential interviewees, the majority of whom (90%, n=59) lived in urban areas. Of the 65 crafters we interviewed, 57 were White, three were Asian, four were Black, and one did not disclose their race; 60 identified as women, four as men, and one as non-binary. Their ages ranged between 20 and 72-years-old. The average length of the interviews was 59 minutes (minimum 19 minutes and maximum 166 minutes).

Following Carspecken's (1996) approach for semi-structured interviews, we analyzed our data in two phases. The first phase included demographic information (length of the interviews, age and generation, gender, occupation). In the second phase, we conducted segment analysis to divide interview transcripts into emerging themes followed by iterative thematic analysis. In addition, we analyzed artifacts and observational notes from our work as embedded ethnographers. The artifact analysis included talking about the projects with crafters and asking them to highlight mathematical actions and patterning within their crafts. Further analysis of artifacts and their photographs demonstrated mathematical insights beyond those articulated by the crafters. The following section describes how the crafters see mathematics in their craft and how we analyzed mathematical content in their finished projects leading to ways of reconstructing and transferring knowledge in new contexts through Mathlands.

Findings

How crafters observe the interplay of math and craft

Through an emergent and iterative thematic analysis of the summaries related to the larger theme of math in the craft, we identified that some crafters describe the interplay as math forward and some as craft forward. Thus, two themes emerged around *math shaping the craft* and *craft shaping the math*. We saw crafters as meaning that crafts shape math when they talked about crafts as drivers of mathematical insight and as math shaping the way crafts are designed and conceptualized. We found that 22% (n=14) of the interviewees considered craft as shaping math, nearly a similar number of crafters considered math as shaping crafts (23%, n=15), and over half of the interviewed crafters (54%, n=35) talked about their engagement as both craft shaping math and math shaping craft.

Crafters talked about craft as shaping math in five distinct ways: (1) Repetitive action to produce a pattern, (2) craft as materializing math, (3) craft as producing math, (4) craft as giving math purpose, and (5) craft as containing math. Most frequently, crafters mentioned patterns that produced math through repeating material actions (32%, n=21). For example, Julie talked about quilting: "Math is about recognizing patterns and coming up with formulas to predict those patterns in the future." This example suggests that the crafting practice produces a pattern that could not have been foreseen without the craft. Following the production of the pattern through craft, the pattern can be translated into symbolisms (i.e., “formulas”) that help crafters reproduce the pattern.

Another way crafters articulated how crafts shaped math (15%, n=10) was in how craft materialized math and helped get a feeling for math by creating shapes. For example, Fiona (51 years old) spoke about sewing: “You can make changes (...) to make the fabric do something different. Individual stitches, that’s where I see mathematical thinking constantly at work.” It was the performance of the stitches that led to variations and changes in physical forms that supported Fiona and other crafters in getting a physical and material sense of a math concept. It was the production of the concepts and the possibility to vary through stitch combinations that clarified math through materialization. Others (12%, n=8) considered the way crafts shaped math as a longer-term production process in which crafting led to the slow discovery of math. Crafters (12%, n=8) also considered that crafts gave math a (personal) purpose, meaning that crafting gave them an opportunity to apply math in everyday life. Finally, 3% (n=2) said that craft contained math, meaning that math is always part of the craft but that crafters can choose whether and to what extent to actively engage with it. Across the board, for crafters who considered craft as shaping math, to engage with and know math with craft was neither tied to academic math understanding nor to an ability to point to academic math concepts in crafts. Math was part of crafts and lent itself to the discovery of math at their chosen speed.

Crafters talked about math as shaping craft in six ways: (1) math as improving craft, (2) math as externalized, (3) math as a prerequisite for craft, (4) absence of math hinders craft, (5) math as simplifying patterns, and (6) non-discrete math. These ways of math shaping craft are further explained below. Most commonly, crafters (35%, n=23) said that math improves their craft, meaning that applying math concepts enhances the quality and the range of the craft. For example, Veronica talked about sewing:

> There is nothing like really understanding on an incredibly deep level how bad you are at spatial relations because you realize you just sewed the pocket inside out because you just don't understand shapes in 3-dimensional space.

As Veronica grew in her understanding of the concept of spatial relationships while learning her craft, over time she would become able to iterate fewer times and produce the kind of artifacts that she wanted to see more rapidly. In other words, here, improving math skills leads to improving craft skills.

Next, eight crafters (12%) said that math was externalized through crafting. This meant that crafters could use tools for mathematics that were made by others, including specific calculators. In these cases, crafters described how math intersected with craft and was required for craft but can be facilitated and externalized through specialized tools, for example, online quilting or weaving calculators or even tools invented by the crafters themselves (see also Keune, Yankova, & Peppler, 2021). Just as frequently, eight crafters (12%) said that math was a prerequisite for crafting. With this, they meant that knowing math was vital and necessary for performing a craft. It was not possible to perform the craft without knowing math. For instance, 33-year-old Susan said that “I do a lot of circle skirts so you have to solve for X like in the circumference equation to figure out because you need the inner circle to match the diameter of your waist and then the outer circle is the edge of the circle.”

Less frequently, five crafters (8%) said that the absence of math hindered craft, five crafters (8%) said that math simplified patterns and made them more accessible, and one crafter (2%) said that math was non-discrete and that several concepts were in use at once. Interestingly, while crafters demonstrate several concepts at once in their craft and may name several mathematical insights as described above, here, they do not seem to often name the non-discrete nature of their work, suggesting an inherent fluidity between mathematical concepts when translated to a materialized form.

Where the examples above show how crafters considered craft as shaping math and math as shaping crafts, the majority of crafters (54%, n=35) did not exclusively consider either one of these perspectives in their practices. The perspectives most frequently came together and complemented one another. For instance, Phoebe (30 years old) sometimes led with math while sewing: "If you're trying to decide on the dimensions of an object that you're going to make and you look at an object that you like and then you measure the ratios of height to width."

To produce an object, Phoebe measured and calculated the ratios to aid in the production process. Yet, as with other crafters who shared both perspectives, she also discusses instances when starting with the craft led to math discoveries:

> I made the whole potholder but then I wanted to put quilting stitches in it in a rectangular array. I didn't really plan it. I just started putting them at a spacing that seemed relevant but then I realized that it was a 7 x 7 array. That would have been 49 stitches and I decided to do 48 stitches instead.

Phoebe started to craft and then realized that the physical performance of the pattern could be formalized. The craft led her to discover the math through the production of the craft. This was representative of the other crafters whom we coded as both craft shaping math and math shaping crafts. Fluctuation between perspectives, leading with craft and leading with math, happened frequently, indicating that both perspectives played an equal role for these crafters.

These different ways math and craft came together showcase different ways mathematics can be explored through craft. This can come in the form of a craft-forward approach as crafters produce a pattern, explore changes in shapes through changes in these patterns, or talk about the purpose of mathematics in relation to a personally meaningful project. These observations can also happen in the form of a math-forward approach, in which the process of crafting directly draws on mathematics concepts toward the improved performance or the modeling of math concepts. A Mathland needs to incorporate these multiple entry points to ensure accessibility. Practicing math through crafts can start with math as well as with craft and one approach does not exclude the other.

Illuminating the breadth and depth of the mathematics involved in craft projects

A breadth and depth of multiple mathematical concepts became visible in individual crafted projects. For example, Julia (56 years old) said "I've got to figure out the math ratio based on the 60-inch dimension of my fabric," illustrating the use of *ratios and proportional* relationships. In Julia's remark, she refers to the use of the size of the fabric to determine the proportional size of other design elements (see Figure 1). To create the quilt in the figure, the maker must determine the final desired length and width of the quilt (e.g., 60" x 60"). This square then is made up of an equal number of circles and half circles, with inwardly curved diamonds appearing within the circles. The shape formed between two adjacent diamonds is referred to as a leaf.

Figure 1
English Paper Piecing Quilt

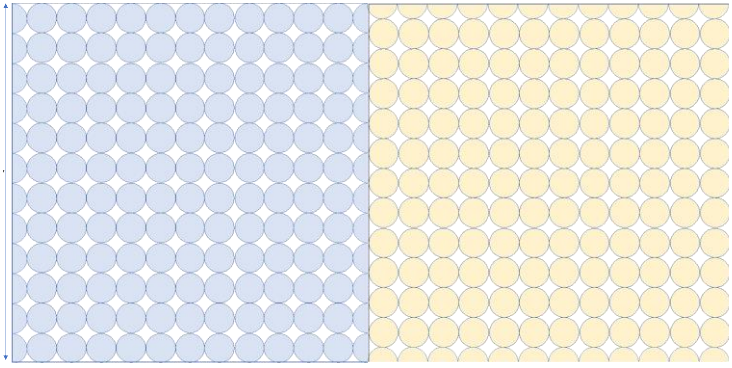
To determine how many of these shapes are necessary to complete a quilt, the maker must calculate the ratio of the diameter of one circle to the length of the full quilt. In Figure 1, it can be seen that 12 circles fit across the full length of the quilt. If the quilt is 60 inches long, the diameter of one of the circles must be 5 inches (i.e., 60” length/12 circles = 5” per circle). These circles are the primary units of the design. However, the mathematical task is not as simple as computing the size of the unit circles. The circles are made of two layers of fabric, and each has a different color or design, which leads to different designs on the two faces of the circle. The individual pieces of circular fabrics are then stitched together, while the display sides of both fabrics are in contact. Then, the stitched two-layered circles are turned inside out through a slit and are carefully cut along the edge of the inside square of one of the circular fabric layers. Turning them inside out results in a displayable circle of 5 inches in diameter. However, as the quilter cuts out the individual circular pieces, a seam allowance of 0.5 inches, which surrounds the circumference of each starting circular piece, must also be accounted for. Thus, without allowing for waste, the total starting fabric size needed is 66 inches by 66 inches, and the ratio of starting circle to the finished quilt edge is 0.092 (or 5.5” per circle /60” length = 0.092).

Note that the placement of the diamond shapes shown in Figure 1 also alternates, such that every other row ends with two half-circles at the quilt edge instead of twelve full circles all the way across. For the row that has 12 full circles, the dimension of the quilt is 60 inches due to the 12 full circles (12*5 = 60), while for the row that has 11 full circles and 2 half circles, so the quilt is still 60 inches (11*5 + 2*2.5 = 60) across (see Figure 2).

Further examination of the pattern shown in Figure 1 indicates that the mathematical insights used by Julia incorporate geometric translations as well. The pattern could be visualized through overlapping the two sets of circle configurations as shown in Figure 2. The first set of circles are configured so that they make up twelve columns and twelve rows, with one column split into two columns of half circles that make up the first and last column (see Figure 2a). The diameter of each circle is 5 inches, and the periphery of the circles in each column touches those in the adjacent columns. Thus, the dimension of the sheet of circles is 60” x 60”. The precision of these initial measurements has consequences for the quilt’s aesthetics, and its feasibility. Every error in measurement will compound over time. The size and dimensions of the quilt as a whole will be irreparably altered if a mistake is made anywhere.

Figure 2

Blue component with semicircles on the sides (a), yellow rotated component with semicircles on top and bottom

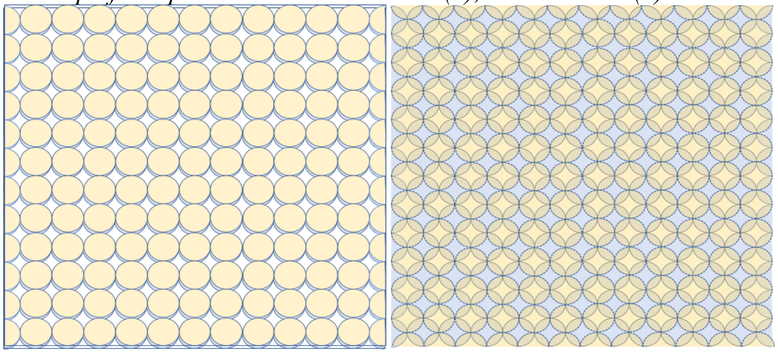


(a) *(b)*

To begin this pattern, Julia arranged twelve yellow circles with a diameter of 5 inches to a sheet of blue circles, but rotated by 90 degrees. The second configuration, while still producing aggregate dimensions of 60 inches by 60 inches, shows the half circle row at the top and the bottom, demonstrating a geometric rotation (see Figure 2b). The rotation of one of the sheets produces a pattern when the two sheets in Figure 2 are superimposed (see Figure 3a). The blue and yellow overlapping components form leaves within circles, and the area not covered by the leaves in each circle has a diamond shape with curved edges. Thus, a leaf and a diamond are created in each of the yellow and blue circles (see Figure 3b).

Figure 3

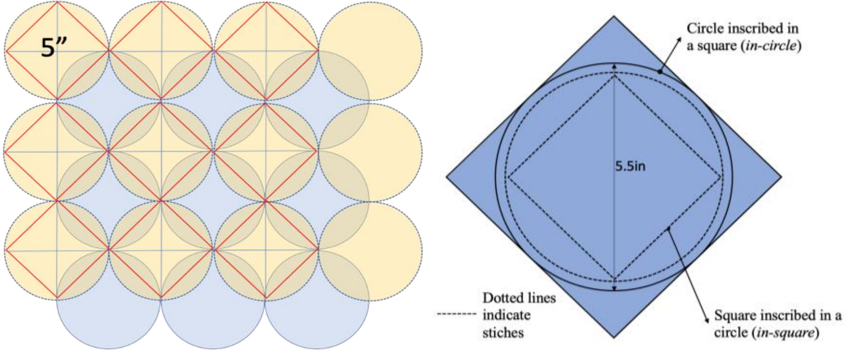
Overlap of two patterns without rotation (a), with rotation (b)



(a) *(b)*

Figure 4

Fabric planning for producing unit circles



(a) *(b)*

The circular fabric pieces seem to be inscribed in square pieces of fabric. The circles thus inscribed are called *in-circles*; in these, the edge of the square has the same length as the diameter of the circle (see Figure 4). There are 12 such adjacent circles along a 60-inch quilt edge, so that each circle is 5 inches in diameter. Each of the in-circles is cut out from a 5-inch by 5-inch square piece of fabric (5.5 inches square with an allowance of a 0.25 seam on each side to form a two-layered circle). The finished circles with a 5-inch diameter are then attached through a seam along the circle’s chord (the edge of the inner square) to produce leaves. Notably, the pre-planning calculations that go into the design of the quilt have deep ramifications for the crafter, in that the exacting manual tasks performed in each quadrant of the quilt are repeated several times and over a long duration of time. To understand the ramifications that inexactitude has for later labor on the quilt, crafters need to consider other aspects of the design, whether this be noticing interrelationships between shapes and space or planning ahead for other calculations (e.g., seam allowances and how they impact the overall dimensions of the quilt). As the crafter engages with the given product for a sustained period, the practice of iterative mathematical production allows deeper insights to emerge.

In sum, we observed crafters using proportional reasoning; properties of circles, incircles, and squares; spatial reasoning (mental rotation, spatial visualization, and spatial orientation); geometric translation; and aesthetic randomization of patterns. Producing quilt designs had the following salient components: First, the leaves in the quilt design are all of the same color, whereas the diamonds are of several colors. This requires choosing two fabric patterns in such a way that one side of the circles all have the same color/pattern (forming the leaves), whereas the reverse side has a diverse color and pattern (forming the diamonds). Second, the colors of the diamonds across the quilt, while they are to be nearly randomly distributed, should also be aesthetically pleasing. A mathematically random choice of arrangement must be supplemented by human judgment for aesthetics when selecting the placement of diamonds of different colors across the quilt. If all red diamonds are clustered together in one area of the quilt, even though this may be the output of a mathematically random algorithm, it may not be pleasing. How a crafter selects aesthetically pleasing but seemingly random distributions calls for further research.

Discussion

This work helped develop our understanding of crafters' relationship with mathematics, whether and how their relationship to academic mathematics compared to the mathematical insights that they reported using and experiencing in crafts, the types of mathematical concepts that crafters connected to crafting, how these intersect in action, and the breadth and depth of the mathematics involved in their finished projects. We gathered perspectives regarding whether and how craft is a promising context for mathematics learning. Crafters frequently fluctuated between explaining "math shapes craft" and "craft shapes math" demonstrating that both aspects play an equal and crucial role in their crafting practices. Our mathematical analysis of the English piecing quilt illuminates the impact of taking two-dimensional mathematics into three dimensions. Mathematical concepts of proportional reasoning, properties of circles, incircles, and squares, spatial reasoning (mental rotation, spatial visualization, and spatial orientation), geometrical translation, and aesthetic randomization of the patterns to include different colors were used in a variety of ways in various crafts and contexts. It is important to note that studies show that when trained on spatial skills, the subjects showed significant improvement in mathematics (Lowrie, Logan, & Ramful, 2017; Mix, Levine, Cheng, Stockton, & Bower, 2020). Crafts can be a context for training such skills. This line of inquiry resonates with what scholars have called for in "life-wide" STEM learning, in which attention is paid to learning experiences that connect to other areas of life, such as home and heritage, that transpire outside of the school day (Banks et al., 2007). A Mathland that is dedicated to pursuing crafts can provide a low floor for novices to enter with their mathematical skills and work their way through to make intricate quilts and reach a high elevation, disrupting mathematics learning as we see it in schools today. Such a Mathland can also provide wide walls to honor populations whose voices have been discounted and unheard in an effort to reify histories of knowledge hierarchies.

“I’m Not Trying to Sell Anything”: Technology Tycoons’ Discourses of Urgency and Heroism in the Shaping of Education Policies and Utopias

Fabio C. Campos, New York University, fabioc@nyu.edu
Paulo Blikstein, Columbia University, paulob@tc.columbia.edu

Abstract: This paper examines the narratives conveyed by three technology leaders of past and present: Steve Jobs, Bill Gates, and Salman Khan. Based on frameworks of technology discourse, we employ critical discourse analysis (CDA) to explore how such leaders communicate challenges and potentials of education, and what ideological markers can be discerned. We find and discuss four narrative genres that influence education policy and politics, and suggest key implications for the Learning Sciences.

Introduction

The relationship between technologies and education has become increasingly complex: while technologists try to dictate system-wide change through new products and practices, their discourses are often rife with faulty pedagogies and unwarranted claims (Blikstein & Blikstein, 2021). By force of repetition, and backed by mass media, ideologies about "good teaching" and the optimal locus of technology in schools – are being rapidly normalized. More importantly, such technocentric narratives set new expectations: the “classroom of the future” is one of many metaphors that suggest the revamping of teaching, learning, and education management by claiming that the centrality of technology is inevitable. This paper contributes to understanding which technology and schooling discourses are reinforced and disseminated by prominent technology leaders of past and present. To this end, this study treats discourses not just as acts of communication but also as capable of affecting social practices (Anderson & Cohen, 2018). Starting from Roderick’s (2016) idea of “Great Men” – embodiments of progress who move society towards betterment – this paper analyzes public talks of three influential technology leaders of the last decade: Bill Gates, Steve Jobs, and Salman Khan. Based on their manifested views about education, we employ critical discourse analysis (CDA) tools and well-studied technological narratives to create semiotic descriptions of an emerging EdTech ethos towards schooling. Gaining deeper insight into the discourses propagated by such technology leaders is not only key to understanding their influence over education practice and politics, but also an invitation for learning scientists to challenge such assumptions and propose new ideas about the politics, affordances, and limitations of technologies for teaching and learning.

Background

Discourses are conceptual systems that manifest through knowledge, language, and communication (Fairclough, 1992; Gee, 2010). While discourses are shaped by sociocultural practices, they are also *socially constitutive*, or capable of influencing practices and determining how individuals experience the world (Fairclough, 1992). Individuals, however, are not always aware of their own conceptual systems (Lakoff & Johnson, 2008), or the values and ideologies they might be reproducing through communicative acts (Freire & Macedo, 2005). In this sense, discourses need to be approached as silent communicators of “master narratives” (Brown & Gilligan, 1993), knowledge systems that convey culturally dominant, socially accepted norms, practices, and identities.

Power structures are often created, transmitted, and reinforced by discourses (Van Dijk, 2008). Foucault’s (2007) social semiotic approach foregrounds how discourses become accepted truths and exert control over individuals and institutions. Foucault also explains how discourses are internalized by individuals and develop into subtle forms of surveillance and control. In this context, knowledge is inseparable from power, with power being exercised through ways of understanding the world. The same phenomenon is seen in education technology discourses: ideologies and practices around learning with technology become naturalized and integrated into common sense views about education as inevitable.

Critical approaches to analyzing discourses

The language of everyday speech is complex and symbolic (Lakoff & Johnson, 2008; Morris, 1946). The fields of Linguistics and Semiotics traditionally break down discursive acts (e.g., spoken language, written text, nonverbal communication, etc.) in two dimensions: *signifier* (the material, or visible aspects of language) and *signified* (the underlying meanings) (Saussure, 2011). This layered approach finds echo in Gee (2010), who separates the observable elements of communication (e.g., word choice, tone of voice, syntactic construction, aspects of genre, etc.) from "Big D" discourses, or the ideologies and beliefs that are enacted through communication and social practices. Under such layered view, how should learning scientists approach the complexity of discourses to reveal underlying narratives and belief systems?

Gee (2010) proposes that discourse analysis should start with a reflection about Big D discourses and then descend into other discursive layers, such as text and meaning. Similarly, feminist theorists suggest that analysts should seek both master narratives and contrapuntal voices – divergent discourses that deviate from norms and conventions – when approaching a corpus of text (Brown & Gilligan, 1993). Both views are examples of Critical Discourse Analysis (CDA), a method that focuses on issues of ideology, power dynamics, and influences of one societal domain (e.g., technology) over another (e.g., public education). CDA takes into consideration not just bodies of written text but also considers the sociopolitical context in which messages are conveyed. As Fairclough (2013) proposes, acts of communication such as public talks or interviews should be examined as social practices through the lens of CDA. This study considers that analyzing the outer (i.e., written text) and inner (i.e., underlying meanings) layers of discourses are complementary parts of CDA and that, together, might reveal how speakers communicate and contribute to received views of technology and education.

Technology discourses

Technology cannot be merely understood as tools or industrial processes, but as a lens individuals use to make sense of the world (Heidegger, 1977). As with any other aspect of culture, individuals receive and reproduce discourses about what technology is and what purposes it serves. One of the most persistent of such discourses portrays technology as a neutral, pragmatic means to inevitable ends. The idea of **Technology as Progress** (Roderick, 2016; Slack & Wise, 2005) understands "progress" as tied to society's betterment and advancement towards the future. In this sense, humanity is seen as moving *forward* providing that technological innovation is achieved. This genre of technological discourse facilitates strong personality cults, with railroad tycoons and Big Tech CEOs being the *Great Men* of their respective ages (Roderick, 2016). Progress, however, demands *inevitable sacrifices* of resources, and people. It is widely documented how such narratives have been utilized and continuously recycled to justify colonialism, armed conflict, and negative impacts on the environment.

Common sense frequently attributes causative powers to technology. The idea of technology as an actor in society, capable of producing change alone, is an example of Technological Determinism (Roderick, 2016; Slack & Wise, 2005). This discourse gives rise to other ideas such as technological solutionism (i.e., "if there's a problem, there's an app for that") and technological revolution (i.e., social practices need to "start from scratch", be "disrupted", "transformed" and "fundamentally changed"). Individuals also tend to personify technology, attributing to it causative powers and capabilities that exceed their actual technical affordances (Lakoff & Johnson, 2008). Roderick (2016) describes this phenomenon as Technological Fetishism: ascribing an autonomous personality to the technological artifact and manifesting a desire for sublime and magical properties. Any similarities to the expectations towards generative AI (e.g., ChatGPT) in education are not a coincidence.

Why discourses matter in education

Discourses are not innocuous acts of communications but might have real impact on education practice and research. Several scholars have studied how discourses directly shape or construct frameworks for education policy (Anderson & Holloway, 2020), in matters that range from curricular choices, teacher training, district management, and technology adoption, to cite a few (for examples, see Levin, 1998; Priestley, 2002; Sam, 2019; and Selwyn, 2013). Even aspects of teacher identity might be influenced by such narratives about teaching, learning, and technology (Marsh, 2002). What is more, the effects of discourses over education policy are not bound to a school district, a state, or a nation, but may quickly spread internationally, much like an *epidemic* (Levin, 1998).

One key (but subtle) discursive practice identified by scholars is the establishment of schools and teachers as antagonists to progress. This is often achieved by disseminating stereotyped views of school systems, which are described as ineffective, "analogic," and anachronistic (Blikstein & Blikstein, 2021). Terms such as "transformation," and "the future of education", and the discourses they belong to, bear significant negative influences on public education by positioning innovative technologies over and above "traditional" school systems and "slipping into pejorative views of schools and teachers" (Vossoughi & Bevan, 2014, p. 38).

Discourses that antagonize public school systems are often accompanied by a slow and steady push to change established curricular practices. A general trend is to suggest educational technology (EdTech) products as the "medicine" to what is described as a malfunctioning and outdated education system, or to appeal to gaps in the nation's workforce in the future. This is precisely the case of Apple and Microsoft, which pushed coding into the US curricular standards by warning against an imminent blackout in computer science majors (Singer, 2017). Treating technological progress as the answer to a broken system echoes the idea of *necessitarianism* advanced by Munck (2003), or the notion that "there is no alternative" (TINA) to technocentric reforms. The mass media play a key part in giving rise to such manufactured crises by giving rise to personality cults and creating **Discourses of Derision**: narratives of moral panic that drive public opinion and shape the political agenda (Wallace, 1993).

Discourses about EdTech also amplify market-based views about schooling, with technology (or its lack thereof) being employed to justify attacks on the public sector. Williamson (2018) explains how Silicon Valley entrepreneurs often reinforce the need for "radical disruption" of schools. The new prototypical "smart school" is not only a fruit of a technocratic ethos but a reflection of "corporate education reforms that have sought to create 'shadow schools' as competitive alternative marketplaces to state schooling" (pg. 233). Similarly, Anderson and Cohen (2018) maintain that the widely accepted discourse of managerialism creates a need for a New Public Management (NPM), or the transfer of well-established market principles to the public sector. When thinking about schools, these views of the public sector as *in need* of the private sector echo Roderick's (2016) idea of inevitability: to pave the way for "schools of the future", sacrifices will need to be made.

Methods

Following Roderick's (2016) concept of Great Men, this article examines the discourses enacted by three of the most influential technology leaders of the last decade: Bill Gates, Steve Jobs, and Salman Khan. Two selection criteria guided the choice for these individuals: first, all of them have significant influence not only in the realm of technology but also in the public and private spheres. Second, each represents a particular segment: the private sector, venture philanthropy and foundations, and education startups (Table 1).

Table 1
Corpus of data used in this study

Data	Context / Length	Perspective
Steve Jobs: *Computerworld Awards Oral History Project* (1995)	Interview: 20min (excerpt), 3,214 words	Private sector
Bill Gates: *"Teachers Need Real Feedback"* (2013)	TED Talk: 10min, 1,518 words.	Venture philanthropy
Salman Khan: *"Let's use video to reinvent education"* (2011)	TED Talk: 20min. 3,608 words	Education Startup

Data sources

The corpus of data utilized in this study (Table 1) is composed by online videos, selected in accordance with their topic, availability, and potential influence. The first source – Steve Jobs' interview – is one of the first to reflect how technology leaders from Silicon Valley view the role of public education in contributing or hampering what they deem as progress or innovation. The interview was given in the context of the 1995 Computerworld Awards and covers topics that range from the voucher system, the role of teachers, and school competition in a free market. Despite being more than two decades old, this interview is still the most complete and extensive material containing Job's views on education available on public domain. Considering that video platforms did not exist at the time of the interview, it is unlikely that Jobs was aware of the potential reach of his words. Also, Jobs' interview was given in a time in which business leaders were much more "naïve" about what they said publicly, without more carefully-crafted language we see today in similar interviews, likely prepared with the help of PR departments and public image consultants.

Gates and Khan's videos are TED talks, where speakers have full control over their presentations and, with rare exceptions, do not take questions from the audience. In his 2013 talk, Bill Gates defends that American teachers should access video recording of their classes as a form of automated coaching and professional learning. Gates criticizes public schools for letting teachers drive blind, without a close support of video-coaching, such the one developed by his foundation. Similarly, Salman Khan's 2011 talk advocates for the use of free instructional videos to relieve the work of teachers and personalize learning. He explains the benefits of self-guided learning using web-based movies prior to formal classes, a practice that is introduced as "flipped classroom".

Data analysis

This study aimed to make underlying discourses visible by creating semiotic descriptions of how messages were built and conveyed, intentionally or unintentionally (Fairclough, 2013). The analysis of the videos adopted an intentional critical stance, based on Fairclough's (1992) and Gee's (2010) CDA. First, we adopted a deductive approach to identify "Big D" discourses (Gee, 2010), mainly those previously studied by Roderick (2016) and Slack and Wise (2005), and discussed in the previous section of this paper. For each discourse, we coded "DISC", plus a short memo describing the nature of that instance. The second movement was also deductive: we looked and coded for specific vocabulary choices that reflected those present in Selwyn's (2013) and Williamson' (2018) analyses. For example, words such as "traditional" or expressions such as "traditional classroom" were coded "TEXT/VOC" and connected to one of the macro narratives identified in phase 1 of the analysis. Third, we took an inductive, bottom-up open coding approach, where text-features such as additional vocabulary choices, allegories, and metaphors were identified and grouped (Gee, 2010) under parent codes such as "AL/MET" for allegories and metaphors and "GEN", for generalization language. One example is "all our students," which is repeated across all three sources and is indicative of a generalization. These codes were then recombined into four categories, which are presented in the following section. Finally, in step 4, we actively listened for *contrapuntal voices* (Brown & Gilligan, 1993), or discourses that deviated from the main narratives identified in step 1. One example is found in Jobs' interview: while defending solutions as a needed addition to traditional classrooms, he views humans – and not computers – as fundamental to mediate learning. In this step, both authors also discussed their own biases as learning scientists, creators of both knowledge and products. Although we acknowledge intentionally conducting the analysis from a critical standpoint — as proposed by the CDA tradition — we kept each other under check to avoid any conclusion that was not based on the data.

Emergent discourses

The textual and contextual analyses of the videos rendered four macro narratives, which we present below:

Discourses of antagonism: Schools are broken

Consistent with the literature, all three videos advanced a narrative that depicts the American public school system as broken, inefficient, and incapable of delivering what is needed in the Information Age. At the vocabulary level, employing CDA revealed several cases of synecdoche, a literary device typically employed by speakers to create generalization language (i.e., the part representing the whole). For instance, words such as "traditional" were combined with others such as "model" and "classroom" to represent entire pedagogical paradigms and school systems, respectively. The lines below, from the Khan talk, illuminate this case:

> "The traditional model penalizes you for experimentation and failure… In a traditional classroom, you have homework, lecture, homework, lecture". (Khan, 2011)

The commonplace discourse that vilifies schools and their communities is usually coupled with comparisons between the US and other countries in international assessment. Without contextualizing the nature, size and conditions of each school system, influential figures such as Bill Gates make all-encompassing assertions about the current situation of education in the country. Consider Gates' words about international rankings:

> "Consider the rankings for reading proficiency. The U.S. isn't number one. We're not even in the top 10. … So, there's really only one area where we're near the top, and that's in failing to give our teachers the help they need to develop their skills." (Gates, 2013)

Gates' message deviates from Khan's previous excerpt in one key aspect: it explicitly incorporates elements of moral panic by connecting "the system we have today" with a risk to the country in the global arena.

> "The system we have today isn't fair to them. It's not fair to students, and it's putting America's global leadership at risk." (Gates, 2013)

Similarly, Jobs suggests that, if teachers were as good as corporate workers, they could be earning higher salaries. Jobs also suggests that mid-career educators are not suitable for teaching anymore, as they "lost their spirits".

> "I'd like the people that are teaching my kids to be good enough that they could get a job at the company I work for, making a hundred thousand dollars a year. Why should they work at a school for 35/40 thousand dollars a year if they could get a job here at a hundred thousand dollars a year? … Unfortunately, the side effect of pushing out a lot of 46-year-old teachers that lost their spirit 15 years ago and shouldn't be teaching right now…" (Jobs, 1995)

Another textual feature present in Jobs' interview is the constant use of "they" (marked in bold), suggesting a conspiratorial school system focused on limiting creativity and controlling students.

> "School was pretty hard for me at the beginning…. And **they** almost got me, **they** really... almost... they came this close to really beating any curiosity out of me. … **They** tested me, and **they** decided… I could skip one grade." (Jobs, 1995)

Discourses of urgency: "Kids can't wait"

In all videos, discourses of broken schools converged to a single point: if rapid changes are not made, students will suffer. Similarly, if investments are not made to professional development, educators will suffer. The possibility of educators and pupils being at risk was reinforced by two textual features: *generalization language*, materialized by expressions such as "everyone" and "we all" (italicized below), and *conditional language*, as evidenced by the verb "need" and other expressions in past tenses, such as "wanted" and "could" (in bold):

> "*Everyone* **needs** a coach" (Gates)
> "No reason why it really **can't happen** in *every classroom in America*" (Khan)
> "And this **could happen** in *every classroom in America* tomorrow" (Khan)
> "We **wanted to donate** a computer to *every school in America*." (Jobs)
> "One day, we **would like** *every classroom in America* to look like that." (Gates)

The idea of a whole generation "in the dark" is intensified by a *sense of urgency* and *prospect of loss,* as seen in Jobs' and Gates' words below:

> We realized that a whole generation of kids was going to go through the school before they even got their first computer. So, we thought: The kids can't wait. (Jobs, 1995)
> But this system would have an even more important benefit for our country. It would put us on a path to making sure all our students get a great education, find a career that's fulfilling and rewarding, and have a chance to live out their dreams. (Gates, 2013)

Discourses of corporate heroism

The attacks on public management pave the way for multiple flavors of necessitarianism and reinforce cults of personalities. These discursive allegories resemble Roderick's (2016) Great Men, thus resonating with the American collective imaginary. Khan, for instance, uses the stage to recount his organization's foundational myth, or the story about how he left a career in a hedge fund to start Khan Academy. The archetype of the benevolent capitalist is evident when Khan explains his decision of offering instructional videos for free, as a means to achieve "*something of social value*". In what resembles an infomercial – which informs and advertises – he explains:

> I want to talk about how I started. … I saw no reason to make it private.… Here I was, an analyst at a hedge fund. It was very strange for me to do something of social value. You can go to the site right now, it's all free, not trying to sell anything. (Khan, 2011)

The use of *heroic language* is not exclusive to Khan. In his interview, Jobs recounts how he tried to change a federal law for the benefit of students, illustrating how public figures actively influence federal regulation. Jobs' refusal to hire a lobbyist adds to the narrative, reinforcing the idea of a powerful leader (Jobs himself), fighting the government ("*they*"), and willing to invest his own wealth in America's schools and students ("*the kids*").

> We could give a hundred thousand computers away, one to each school in America. (…) We literally drafted a bill to make these changes… We called it 'the kids can't wait bill.' (…) I refused to hire any lobbyists. I went back to Washington myself and actually walked the halls of Congress for about two weeks. (Jobs, 1995)

Jobs suggests that it takes entrepreneurship, capital, and good intentions to "transform" education, with no mention that pedagogical knowledge is necessary for such endeavor. Resonant with his views of young *versus* old professionals, he suggests that graduates from elite universities should found schools and outperform teachers:

> If you go to Stanford Business School, they have a public policy track. They could start a school administrator track (…). You could have twenty-five-year-old college kids, very idealistic, full of energy, instead of starting a Silicon Valley company, they start a school. And I believe they would do far better than many of our public-school teachers do. (Jobs, 1995)

Similarly, Gates incarnates another well-established archetype in the American imaginary: the activist. By using language commonly seen in civil rights marches and political campaigns (“fair”, “just”, “deserve”), Gates conveys a message in which he is the caregiver, one who advocates for the rights of educators:

> [teachers have] one of the most important jobs in the world. This wouldn't just make us a more successful country. It would also make us more fair and just too. I'm excited about the opportunity to give all our teachers the support they want and deserve. (Gates, 2013)

Gates' activist-like discourse mirrors Khan’s words when both declare teachers deserve more, but diverges from Jobs, who posits that teachers are fundamental but not good enough.

Discourses of disruption: Recreating the public school

In their approach and ideologies about education, technology leaders tend to overemphasize *curiosity*, *creativity, failure,* and *discovery* as opposed to what is seen as “*traditional schooling*”. The data, however, showed different variations of this type of narrative. Jobs, for instance, resists the view of technological determinism by positing that curiosity and discovery should be sparked by human agents, and not machines. Khan defends a balance between mastery, experimentation, and failure, in opposition to what he describes as traditional schooling.

> The most important thing is another person that guides and feeds your curiosity. Machines cannot do that ... The elements of discovery are around you. (Jobs, 1995)
> The traditional model penalizes you for experimentation and failure, but it does not expect mastery. We encourage you to experiment and fail. But we do expect mastery. (Khan, 2011)

Looking into the social practice of teacher preparation, Gates proposes one single technology – video feedback systems – as a remedy to gaps in teachers’ coaching and professional development. In his presentation, however, there is no indication about how teachers would interpret their own data, whether they would be coached by a human agent based on the images and, ultimately, what are the desired behaviors that could lead to the improvement of teaching practices. Gates’ propositions are inconsistent with the body of Teacher Noticing literature, which upholds that intentional, visible scaffolds need to be in place for teachers to benefit from video recording of their practices (see, for example, Sherin & Van Es, 2005).

Jobs' version of how to recreate the school system incorporates elements of the neoliberal reform agenda, namely competition and choice. He uses words such as “freedom” and “boring” and alludes to the tensions between “equal opportunity and equal outcomes” to communicate views about education policy and equity. The antagonism with unions is self-evident, and a reflex of the first genre of discourses identified in this study:

> I'm a big believer in equal opportunity as opposed to equal outcome. … I believe very strongly that if the country gave each parent a voucher, a check for forty-four hundred dollars they could only spend at any accredited school… But the problem of course is the unions. The unions are the worst thing that ever happened to education; because it's not a meritocracy. It turns into a bureaucracy, and teachers can't teach, and administrators run the place, and nobody can be fired. … We need to attack these things at the root, which is people and how much freedom we give people; the competition that will attract the best people. (Jobs, 1995)

Discussion

By employing Critical Discourse Analysis tools, this study found four macro narratives present in the speeches of influential technology leaders. Representing technology corporations, startups, and venture philanthropists, Steve Jobs, Salman Khan, and Bill Gates portrayed public schools as the establishment, inefficient, and in need of corporate support (Anderson and Cohen, 2018; Munck, 2003). In essence, **Discourses of Antagonism** use generalization language to paint a picture of a malfunctioning school system, governed by inefficient educators whose aim is to exert control by limiting students’ creativity. This type of discourse gains traction by establishing school systems as an adversary to progress-oriented reforms (Blikstein & Blikstein, 2021). With the antagonist identified, **Discourses of Urgency** establish an impending nefarious future for the country (e.g., “the kids can’t wait”) and urge society to *demand* change, immediately, or else something terrible will happen.

The **Antagonism-Urgency** discursive pair has been extensively described by linguists, philosophers of language and learning scientists. Bakhtin (1984), for example, while exploring the politics, aesthetics, and morality of deeds, saw *dialogism* as a fundamental characteristic of human communication: in everyday acts of speech or language use, speakers often position themselves in relation to another. This *I-for-the-other* serves not only to establish and reinforce the speaker's identity but, most importantly, to justify certain actions or urges to act. In the case of EdTech, the Antagonism-Urgency pair serves to justify the urge towards products and ideas without the need to describe current educational systems in more precise and accurate ways, nor to provide robust evidence of *how* these products will fulfill their goals (Blikstein et al., 2022).

What follows in the discursive sequence observed in our data are **Discourses of Corporate Heroism,** in which technology leaders establish themselves as Great Men. Represented as corporate heroes and activists, technology tycoons resort to language that establish education reform as a mission suitable only for young entrepreneurs, college graduates, or savvy technologists, who offer their skills to serve the public good. Finally, **Discourses of Disruption** establish how particular views of education – as well as products and partnerships – are fundamental to prevent the otherwise unavoidable tragedy in education. In essence, Corporate Heroism and Disruption are discourses that result in one single narrative, where the hero is typically not concerned with tranquil negotiations nor complex understanding of nuanced contexts. As in century-old stories, such archetypal heroes have a rebellious, outlaw side, who needs no permission to abruptly disrupt, "move fast and break things." In our data, we observed a common stance towards schooling models towards participation in a "market society." Interestingly, Mautner (2010) reminds us that even "The Market" is often discursively reified as an anthropomorphic entity and a cultural model used to regulate behavior — another entity that is inconsequentially authorized to "break things".

Beyond typifying narratives, this study identified several discursive mechanisms and moves employed by technology leaders to communicate technology-oriented education reform narratives. For example, discursive strategies such as comparing countries in international education rankings and the use of words such as "just", "fair" and "deserve" create the framework needed to establish technology leaders as key partners to policy makers (Anderson & Holloway, 2020). The analysis also revealed how technologists mimic the language typically associated with politicians (e.g., "everyone needs") and equity advocates (e.g., "education for all", "no child left behind".) to justify the urgent need for their proposed technologies, and policies (Singer, 2017).

The portrayal of public education systems as in need of *constant saving* can be decomposed into several elements. First, as seen repeatedly throughout the analysis, such narratives often imply that public schools should be modeled after private corporations (Anderson & Cohen, 2018; Levin, 1998; Munck, 2003; Priestley, 2002, Rudd, 2013). Unfortunately, these claims typically "displace other education stakeholders from setting the agenda" (Blikstein & Blikstein, 2021, p. 22), and silence nonconforming voices at schools and districts (e.g., "The unions are the worst thing that ever happened to education", as declared by Jobs). Second, as shown by several studies, advocates of "radical disruption" often seek to shape narratives about learning in ways that are disconnected from evidence-based claims (Anderson & Holloway, 2020). It is important to note that EdTech is not inherently wicked, nor every entrepreneur or technology leader a disseminator of the narratives identified by this study. However, the key challenge academics are faced with is to identify instances when learning technologies are appropriated to legitimize power and corporate interests (Rudd, 2013).

Implications for the learning sciences

While this study focused on three leading Silicon Valley technology leaders, their discourses reach far beyond the US. Anderson and Cohen (2018), Levin (1998), and Priestley (2002), have demonstrated how trends in education have assumed an international character, with policies – and their underlying discourses – migrating across the globe. As suggested by Levin (1998), discourses that propose the radical transformation of education systems have the power to spread fast, like an *epidemic*. So, what responsibility falls on us, members of a global Learning Sciences community? First, we have a duty to understand how such discourses shape our own practices, within the lab, across schools and in the many research-practice partnerships we engage in. More than understanding, the research community may contribute to "strengthening the public mind on education to increase 'resistance' to 'infection' by superficial but seemingly attractive policies." (p. 139). Much like in a pandemic, the response to the rapid spread of educational technology discourses – and their pervasive influence on policy, business, and management – lies on the idea of *prevention*, or opposing fictive narratives with evidence-based claims. Understanding that any new educational trend — from Automated Tutors to Personalized Learning — is "half technical and half a narrative" (Blikstein et al., 2022) is a consideration we invite our peers to make.

Design and Evaluation of a Conversational Agent for Formative Assessment in Higher Education

Seyma Yildirim-Erbasli, Concordia University of Edmonton, yildirim.erbasli@concordia.ab.ca
Carrie Demmans Epp, Okan Bulut, Ying Cui
demmanse@ualberta.ca, bulut@ualberta.ca, yc@ualberta.ca
University of Alberta

Abstract: In recent years, there have been attempts to design and use conversational agents for educational assessments (i.e., conversation-based assessments: CBA). To address the limited research on CBA, we designed a CBA to serve as a formative assessment of higher-education students' knowledge and scaffold their learning by providing support and feedback. CBA was designed using Rasa — an artificial intelligence-based tool — and shared with students via Google Chat. The conversation data showed that CBA produced high standard accuracy measures and confidence scores. The findings suggest that ensuring the accuracy of CBA with constructed-response items is more challenging than CBA with selected-response items. In addition, a cognitive walkthrough of CBA provided preliminary evidence for the use of CBA as an interactive assessment tool. According to survey responses, most of the participating students reported positive attitudes toward CBA and its use to improve their assessment experience and learning.

Formative assessments and interactivity

An assessment is formative if it allows teachers or students to gather, analyze, and apply information about students' learning to choose an instructional strategy that is likely to be more well-founded than those they would have made otherwise (Black & Wiliam, 2009). Teachers use formative assessments to periodically measure and monitor what their students know and are capable of doing and to provide feedback to better help students. The design, administration, and scoring of formative assessments have all been improved due to technological advances. Through their advanced and accelerated use at many levels of education, computers have digitized the conventional formative assessment format (i.e., paper-and-pencil testing). Research has found that students tend to be more motivated to take a computerized assessment than a paper-and-pencil assessment (e.g., Octavio, 2022). A computerized format does not, however, ensure that all students will be highly motivated and make a significant effort to do well on an assessment, in specific, formative assessments (Eklöf, 2010). As a result, researchers have started to seek alternative strategies to keep students motivated while completing a computerized formative assessment. Research studied gamification to promote interactivity in formative assessments and reported increases in student motivation (e.g., Zainuddin et al., 2020). In addition, timely interventions like sending students a proctor message to their computer screens can help keep students motivated during the administration of a formative assessment (e.g., Wise et al., 2019). A timely interaction is still required for sustaining or boosting student motivation, as opposed to repeatedly undertaking reactive interventions. The lack of interactivity in assessments can be addressed by using technologies including artificial intelligence and natural language processing. Giving students the chance to participate actively in the testing process can boost their engagement during the assessment process, leading to more diligent test-taking behavior and reliable test results that accurately reflect student ability levels (e.g., Wise et al., 2019; Zainuddin et al., 2020).

Conversational agents and assessment

The research into technology-based support in education has been motivated by the increasing demand for supporting diverse and personalized educational needs. The intelligent tutoring system (ITS) was one of the first attempts in this regard. In the late 1970s, ITSs were introduced as a computerized learning environment that could optimize each student's learning (D'Mello & Graesser, 2013). ITSs blend instruction and assessment for instructional purposes to adaptively respond and give immediate feedback to student responses and guide them on what to do next (Graesser et al., 2014). Although ITSs provided great potential for personalized education, they could provide deeper interaction. To address this limitation, researchers have attempted to integrate more advanced interaction methods.

Conversational agents are one of these techniques, and their use in ITSs has been shown to support learning processes (e.g., AutoTutor; Graesser et al., 2014). Because conversation is a channel through which nearly all students are accustomed to expressing themselves, the use of dialogue is a major component of conversational agents and thus can allow students to focus on the learning task better (Kerly et al., 2008). Previous research has shown that the interactive structure of conversations creates an ideal environment for information exchange and reveals student knowledge (Graesser et al., 2008). Consistent with these findings, conversational agents can provide tailored support to each student and improve engaged and independent learning by building on each student's strengths, interests, and abilities (Kerly et al., 2008).

Although conversational agents are mainly designed for instructional purposes — such as virtual teaching assistants, tutors, and peers (or learning companions) — they have a wide range of potential applications in education. There are now efforts underway to investigate and harness methods for modeling conversations for assessment purposes (i.e., conversation-based assessments: CBA). CBA creates an interactive assessment environment where assessment takes place between a student and a computer agent (Jackson et al., 2018). It can measure student learning and provide feedback through the computational agent's automated or adaptive moves. CBA combines assessment and feedback to improve student learning while assessing student knowledge and providing timely feedback (e.g., Jackson & Zapata-Rivera, 2015). Thus, the use of conversational agents advances computer-based assessment by integrating interactive feedback to enhance student learning.

Benefits of conversational agents

Student learning

Students can shoulder the responsibility for learning by participating in learning activities through active engagement and social interaction (Vacca et al., 2011). Previous studies reported that using conversational agents, as a means to improve student engagement and social interaction, could improve student average learning gains by nearly one letter grade compared to reading the textbook for an equivalent amount of time (Graesser et al., 2008). Interacting with a conversational agent also supports gains for deep levels of comprehension in comparison with reading nothing, starting at the pretest, or reading the textbook for an amount of time equivalent to that involved in interaction with a conversational agent (Graesser et al., 2014). In addition, a comparison of a conversational agent and novice human tutors showed that the student average learning gains were virtually equivalent on the same topic (VanLehn et al., 2007). In another project, Ruan et al. (2019) contrasted a conversational agent to a flashcard app and discovered that students gave more correct responses when they used the agent. In a similar study, researchers investigated the potential benefits of a conversational agent and found that interaction with an agent allowed 41% of students to submit a more complete response to constructed-response items (Jackson et al., 2018).

Student motivation

Human-like features, such as interactivity and natural conversation, are often perceived as social attributions and thus motivate students to prefer social responses and behavior (e.g., Ruan et al., 2019). In a recent study, students stated that the virtual agent was more beneficial for learning and chose to spend more time with the agent when given the option, although it was more time demanding (Ruan et al., 2019). Ruan et al. (2019) suggested that students may prefer conversational agents because they enhance learning and motivation. The motivating effects of conversation are supported through a prior study (Heffernan, 2003). This study also found a strong positive impact on learning and reported that students who used a conversational agent solved fewer problems but learned as well as or better than students who were simply given the solution. This finding has been characterized as "less is more". In other studies, students found conversational environments were an engaging and easy way to practice and learn English as a second language (e.g., Forsyth et al., 2019; Hong et al., 2014). Students who interacted with the digital agent were shown to be more actively engaged in learning activities and outperformed those who did not (Hong et al., 2014). Moreover, students expressed an interest in using digital agents in their other subjects. Going beyond motivation, the emotional states of students who were interacting with conversational agents have been investigated (D'Mello & Graesser, 2013). Among the emotional states observed, engagement (or flow) was the most frequent state followed by boredom and confusion.

Feedback

Even though instructors often assume that students can understand the feedback given (i.e., feedback literacy, Carless & Boud, 2018), students may not be able to understand that feedback. Researchers investigated the role of feedback in conversational agents and found that when students interact with an agent, they were under the impression that the agent cared what the student communicated, and thus they were more engaged with the feedback provided (Graesser et al., 2008). Previous research showed that most students appreciated how well the agents asked follow-up questions and provided guidance and feedback to help them comprehend the questions (Lopez et al., 2021). It has been suggested that feedback helps enhance the testing effect in CBA regardless of whether the attempted answers are correct or not (Ruan et al., 2019).

Current study

CBA advances conventional digital assessments by simulating human teachers to increase student learning and motivation through interactivity and assistance that are often missing in digital assessments. CBA can provide personalized help to each student while also assessing their learning. Furthermore, CBAs can build on each student's strengths, interests, and abilities to enhance learning and motivation. Through the natural flow of conversation, they can hold social interactions with students, ask questions, provide hints, direct students on what to do next, and provide feedback on the quality of responses (Jackson et al., 2018). Despite the aforementioned mounting evidence that conversational agents help students learn and enhance motivation, these systems have yet to become a standard feature of classrooms. In addition, most conversational agents are designed for tutoring purposes (e.g., AutoTutor which focused on the role of conversational agents in learning rather than assessment). Scientific evidence and knowledge of CBA are limited and incomplete. To address this gap and contribute to the literature on the utility of CBA in monitoring student learning and understanding student attitudes toward taking an assessment in an interactive environment, this study designed, implemented, and evaluated a new CBA in higher education. This study aimed to design a CBA that can measure student knowledge and provide support and feedback to scaffold their learning.

Methodology

Question 1: How was the performance of CBA in answering student responses?

A new CBA was designed for two sections of an undergraduate-level course at a Canadian university. The course content was educational assessment, where students in elementary and secondary education programs learn about concepts, issues, and instruments to assess learners' knowledge and skills. CBA consisted of two constructed-response and three selected-response tests following the previous research that designed conversational agents with both formats (e.g., Lopez et al., 2021; Ruan et al., 2019) and also the preference of the course instructors. CBA was offered to students as an additional and optional formative assessment tool by the course instructors in the 2021-2022 academic year, and participation in CBA was voluntary. Table 1 shows further details about each test including the availability as well as the number of items in each test.

Table 1
A Summary of the CBA Designs

	Availability	Number of items
Selected-response test 1	Sections 1 and 2	8
Selected-response test 2	Sections 1 and 2	7
Selected-response test 3	Sections 1 and 2	8
Constructed-response test 1	Section 2	3
Constructed-response test 2	Section 2	4

Selected-response tests combined assessment and feedback to measure student knowledge and provided timely feedback. The back-and-forth dialogue was intended to be a turn-taking conversation where the agent asked a question, the student responded, and the agent provided feedback and asked the next question. Constructed-response tests combined assessment, scaffolding, and feedback to measure student knowledge, give a second attempt for their initial incorrect or out-of-scope responses, and provide feedback. CBA with the selected-response tests was available for both sections of the course while CBA with the constructed-response tests was available for only the second section following course instructors' availability and preference to use CBA in their sections. The total number of students who took selected-response and constructed-response tests are 98 and 21, respectively. Table 2 shows the number of participating students in each test.

Table 2
Number of Students in CBA by Each Test and Section

	Total	Section 1	Section 2
Selected-response test 1	67	51	16
Selected-response test 2	77	61	16
Selected-response test 3	58	42	16
Constructed-response test 1	19	0	19
Constructed-response test 2	7	0	7

Conversation data from each test was used to calculate the intent classification and confidence score to investigate the functionality of CBA in interpreting student responses accurately. Considering the binary classification of student response to each item can be either positive (i.e., classification of student response as correct) or negative (i.e., classification of student response as incorrect), true positives (TP; the number of correctly classified correct responses), false positives (FP; the number of incorrectly classified correct responses), true negatives (TN; the number of correctly classified incorrect responses), and false negatives (FN; the number of incorrectly classified incorrect responses) were calculated. Using these indices, similar to previous work (e.g., Abdellatif et al., 2021), the standard classification measures — precision, recall, and F1-score — were calculated for intent classification to evaluate CBA performance. A human coder assessed the performance of CBA in classifying students' responses and calculated the corresponding performance measures.

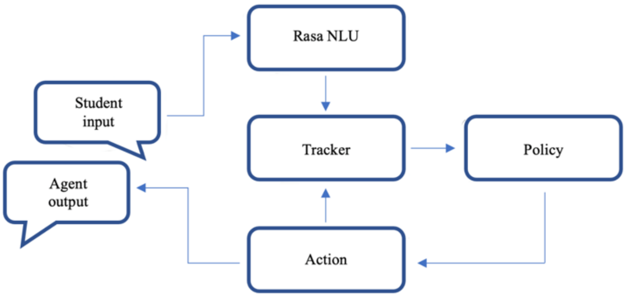
Standard classification accuracy measures and median confidence scores were calculated to understand the functionality of CBA in interpreting student responses, but with slightly different purposes for each CBA format (i.e., constructed-response and selected-response). In terms of constructed-response format, these measures were calculated to evaluate the performance of CBA in understanding and processing students' written responses. For the selected-response format, the goal was to evaluate how accurately the CBA design was implemented. Thus, even though there were no written responses, the aim was to check the accuracy between system design and system implementation in CBA with the selected-response format.

Rasa framework

Previous research examined the performance of the most commonly used natural language understanding (NLU) tools, namely IBM Watson, Google Dialogflow, Rasa, and Microsoft LUIS (Abdellatif et al., 2021). Among those, Rasa had the highest confidence scores for accurately classified intents. Rasa includes two separate modules: Rasa NLU and Rasa Core. Rasa NLU extracts structured information (i.e., the intent) from unstructured student responses using machine learning and NLP approaches (Abdellatif et al., 2021). Rasa Core handles dialogue management, which entails choosing what actions the CBA should take in response to student responses (Shahriar Khan et al., 2021). Rasa processes student responses in a series of phases, as shown in Figure 1 (Bocklisch et al., 2017). Rasa NLU performs only the first step while Rasa Core performs the rest. After CBA was written in Rasa, the trained NLU and Core modules were deployed to a hosted web server and connected to Google Chat. Conversations were stored in a password-protected computer using an SQL database.

Figure 1

Phases from Input to Output in Rasa; Note. Adapted from "Rasa: Open source language understanding and dialogue management", by Bocklisch et al. (2017), arXiv preprint, p. 3.



Question 2: How usable is the CBA?

CBA was shared with students (n = 106) enrolled in an undergraduate-level computing science course focusing on a user-centered approach to software design. This course requires students to conduct cognitive walkthroughs for different software designs. A cognitive walkthrough is an analytical inspection procedure for a user interface to test and evaluate usability issues (Atiyah et al., 2019). It shows if a first-time user can understand and use the tool without any training or background knowledge (e.g., Ren et al., 2019). Evaluators test different actions, and they can detect more potential problems than a user would come across in a single experience. Thus, this method helps to identify user experience issues so that they can be addressed (e.g., Shekhar & Marsden, 2018).

Students were grouped into 21 teams and performed the cognitive walkthrough method as a preliminary validation of the system by evaluating its usability for potential usage scenarios (i.e., actions). CBA with one selected-response test was shared with students because the other tests were not completed when teams conducted their cognitive walkthrough to reveal possible usability flaws. They were not trained on how to use CBA. Teams performed the cognitive walkthrough method: (1) try to produce a goal (e.g., answer a question), (2) search for actions available (e.g., click or type a response), (3) select a suitable action to progress (e.g., type a response), and (4) perform the selected action and evaluate if the progress has been made toward the initial goal (e.g., receive feedback) (Lewis & Rieman, 2011). Each team prepared a report including what they were able to do and not able to do for the actions they attempted. Reports were examined to determine which topics (i.e., usability indicators and issues) were discussed. They were analyzed inductively from a particular to a more general perspective: from codes to themes.

Question 3: What were student attitudes toward taking an assessment with CBA?

CBA invited participating students to complete an experience survey through a link it had provided. As indicated above, the unique total number of students was 98 for the selected-response and 21 for the constructed-response format. The unique total number of students who completed the survey is 61 — a response rate of 51% — with only three responses for CBA with the constructed-response format. The survey consisted of background questions related to demographic information (e.g., age, gender), technology use, and content knowledge. Students were asked a series of questions to better characterize their engagement and overall experience with CBA. For example, they were asked to score their level of agreement with statements concerning general engagement with the CBA. Ethical approval was obtained from the Research Ethics Office for the use of survey data and secondary use of conversation data. Participation in the study indicated participants' consent to use the conversation data and survey responses.

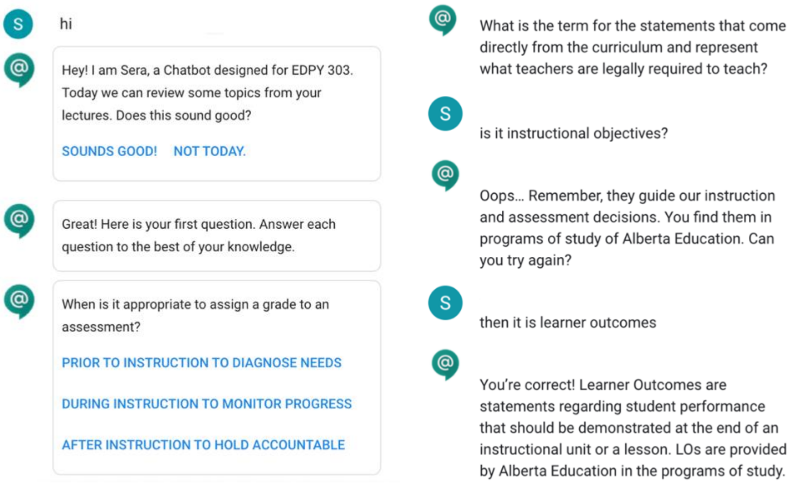
Findings

Performance of CBA

Figure 2 shows examples of selected-response and constructed-response items. For CBA with the selected-response format, the precision, recall, and F1-measure of CBA were all 100%. The median confidence scores for each intent were about 1, meaning that the NLU is entirely confident in classifying each input. For CBA with the constructed-response format, the recall for each item was 100%, meaning that CBA correctly identified correct responses as correct. However, the precision measures of constructed-response items ranged from 80% to 100%, and F1-measure values ranged from 89% to 100%. That is, there were misclassifications of incorrect responses by CBA. These misclassifications in the conversation paths occurred due to the overlapping responses between student responses and expected responses for a different item. In addition to intent classification, the median confidence scores for each correctly classified response ranged from 0.30 to 0.99 for correct responses and range from 0.59 to 0.98 for incorrect responses.

Figure 2

Examples of Selected (a) and Constructed-Response Items (b)



hi

Hey! I am Sera, a Chatbot designed for EDPY 303. Today we can review some topics from your lectures. Does this sound good?

Great! Here is your first question. Answer each question to the best of your knowledge.

When is it appropriate to assign a grade to an assessment?

What is the term for the statements that come directly from the curriculum and represent what teachers are legally required to teach?

is it instructional objectives?

Oops... Remember, they guide our instruction and assessment decisions. You find them in programs of study of Alberta Education. Can you try again?

then it is learner outcomes

You're correct! Learner Outcomes are statements regarding student performance that should be demonstrated at the end of an instructional unit or a lesson. LOs are provided by Alberta Education in the programs of study.

(a) (b)

Preliminary validation of CBA

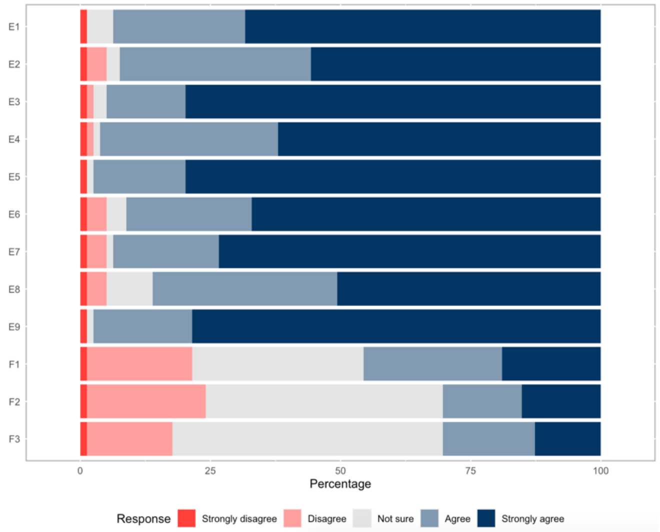
The cognitive walkthrough was performed by external evaluators and each team prepared a report that included what they were able to do and not able to do for the actions they attempted. The teams observed no major usability issues and reported some suggestions to improve the usability of CBA. Fortunately, participating students did not encounter any of the potential issues when they interacted with CBA. We still reported the possible usability problems from the preliminary validation of the system to inform researchers, designers, and practitioners so they can enhance students' assessment and learning experience with CBA.

Some teams attempted to perform actions that CBA was not designed for and thus the agent failed to follow these actions (i.e., default response or inaccurate conversation path). In terms of the usability problem for the action of *clicking an option from a previously answered question*, teams suggested making the options of the previous questions unclickable once a student chooses their answer. One team attempted to type "skip", "help" and "leave" the assessment and suggested adding buttons for these options. These suggestions should be considered for further improvement of CBA. However, even though a solution to these concerns could be more buttons, the solution also depends on the purpose of the assessment and the instructor. For example, the instructors did not suggest skipping a question while developing the questions.

In general, most teams found the action of *answering questions* is clear to users due to several reasons: (1) a common known format (i.e., selected-response items), (2) clickable options with blue color, larger font size, and full capitalized letters, (3) a red dot to indicate an unread message, (4) a loading animation once a student types or selects an answer (see Figure 2). They also reported that it is not clear how to respond to the questions: type or click. Their concern is important for the future use of CBA and thus the system should be updated following their suggestions: (1) explain how to respond to questions at the beginning; (2) make the text box unavailable for the selected-response items or (3) update the CBA script to make sure students will be directed to the correct conversation path if they type to answer a selected-response item. Another potential usability problem was the lack of information about the total number of items on the test and the question number they were answering. Even though the agent indicates "FIRST, NEXT or FINAL QUESTION" to direct students in the assessment, CBA should be updated by numbering the questions. The final concern was the lack of information about their performance, and the teams recommended a score bar showing their performance. Even though this concern is reasonable from the user perspective, the goal of CBA is to provide an interactive environment for students to assess their knowledge and also scaffold their learning.

Teams also reported valuable suggestions in general to improve user interaction with CBA. They suggested more social interaction at the beginning before the agent asks if students want to take an assessment or not. The decision regarding short social interaction was made based on the literature (e.g., the trade-off between engagement and efficiency; Ruan et al., 2019) and the discussions with the course instructors. In addition, one team suggested giving students more time to read the feedback or adding a follow-up question to confirm if users read and understood the feedback before sending the next question. This had not been done because a follow-up question for feedback can be judged as protracted by students and previous research has discussed the negative impact of excessive interaction (e.g., Katz et al., 2021). The other suggestion was to send a reminder message to users if they do not respond for some time without ending the assessment. This action of CBA would help make it more interactive and human-like. CBA could be updated by scheduling a reminder to be executed after a certain time if the user stops interaction without completing the assessment.

Figure 3
Distribution of Student Responses to Survey Items



Student attitudes toward CBA

To answer the third research question — student attitudes toward interacting with CBA, the student responses to 12 survey items were analyzed (see Figure 3). Nine of the items (E1 to E9) are experience-related, while the remaining three items (F1 to F3) focus on the comparison of CBA and more familiar assessments. Overall, students reported positive experiences with CBA and found CBA helpful and engaging.

Student responses to the experience-related items were high and at similar percentages (see Figure 3 for items E1 to E9). Most students found the feedback (94%; item E1) and summary answer (95%; item E3) helpful and indicated that the summary answer helped them to improve their understanding (97%; item E4). This positive trend regarding student experience with content feedback suggests the importance of real-time assessment and feedback to increase the impact of intended outcomes for formative assessments, considering their use for *assessment for learning* rather than *assessment of learning*. Most students indicated that they were engaged during the assessment (91%; item E6) and CBA was helpful for them to stay focused (86%; item E8). They also reported that they felt comfortable (98%; item E5) and found taking an assessment with the agent straightforward (98%; item E9). These results are aligned with the previous research regarding the impact of conversational agents on learning (e.g., Ruan et al., 2019), motivation (e.g., Forsyth et al., 2019), and feedback (e.g., Lopez et al., 2021).

Despite their positive reactions to CBA, their responses to comparing CBA with more familiar assessments (e.g., online quizzes) varied (see Figure 3 for items F1 to F3). Forty-six percent of the students said they would prefer CBA to a regular assessment (item F1). Only 30 percent of the students indicated that they would perform better (item F2) and would be more accurately evaluated using CBA compared to a regular assessment (31%; item F3). About half of the students showed neutral reactions to this comparison. This result could be interpreted as students viewing CBAs as not ready to replace regular formative assessments but to support their intended outcomes on student learning.

Conclusion

To date, conversational agents in education have been mainly used for instructional purposes and thus they blend assessment with instruction rather than focusing solely on assessment. This study designed, implemented, and evaluated a CBA that can provide both interactivity and assistance, which are missing in conventional digital assessments. By providing both interactivity and assistance, CBA can offer a more engaging and personalized approach to formative assessment, highlighting the potential for conversational agents to transform assessment practices and enhance the assessment experiences of students.

The results from this study suggest that CBA can be administered to motivate students to take assessments by holding conversations with an agent and thereby enhancing their assessment experiences. However, CBA was unable to handle all students' written responses and thus failed to direct students to the accurate conversation paths. Future research should address the technology-related limitations and focus on improving the performance of CBA. In addition, the aversion from some participants to CBA in comparison to regular assessment formats calls for research that comprehensively compares the two approaches (e.g., survey data collected for both CBA and regular assessments). At last, the cognitive walkthrough revealed several usability issues associated with CBA. Among these, the reports highlighted the need for a comprehensive introduction at the beginning. Future research should explore this suggestion to improve the performance of CBA. In conclusion, more conversational agents will be used in education going forward to support students during all learning phases, including teaching, assessment, and feedback. As technology develops, it is anticipated that CBA will become more widespread and more capable, playing an important role in the future of education and assessment.

Teachers as Co-Designers: Forming Equitable Participation through the Lens of Relational Trust

Tugce Aldemir, Susan Yoon, Kate Miller, Jooeun Shim
taldemir@upenn.edu, yoonsa@upenn.edu, kmmiller@upenn.edu, jshim@upenn.edu
University of Pennsylvania

Abstract: Collaborative design is a research-practice partnership with partners having equal decision-making power. However, creating and sustaining equitable participation in codesign partnerships is a significant challenge for further research efforts. Thus, this exploratory research investigates a trajectory from imbalanced participation to an increasingly equitable and collaborative one in a three-year research-practice partnership that aimed to design and implement a STEM-integrated bioinformatics high-school curriculum through the lens of relational trust. We adapted a multidimensional relational trust framework and followed an inductive approach to analyze a corpus of interviews with two teachers who participated in the codesign sessions and three researchers who facilitated the curriculum implementation and codesign processes. Our results suggested the partners shared authority as they collaboratively redesigned the curriculum and, by further reframing the relational trust dimensions intersected with the shifts in partners' participation, offered a preliminary conceptualization of multidimensional and multifaceted relational trust for equitable participation in codesign partnerships.

Introduction and background

Collaborative design (codesign) is one way for teachers and researchers to act as design partners and share decision-making power to develop technologically-enhanced innovative learning experiences that promote transformational change in school and district practices (Penuel et al., 2007). Research has documented ways that sustainable and effective codesign can support teacher agency (Voogt et al., 2015) and pedagogic knowledge and practices (Penuel et al., 2011). However, it is challenging to develop and sustain a productive codesign partnership as its premise of bridging research and practice by creating equitable participation in decision-making processes depends on the extent to which such equitable participation is fostered through shared status and authority over decisions regarding the collaborative process and its outcomes (Farrell et al., 2019). At the same time, without having intentional efforts to cultivate equal positioning of the codesign partners in the design, implementation, and refinement of learning experiences, tensions can arise between the partners, leading to breaches in trust, even bringing the partnership to a halt (Denner et al., 2019; Ko, 2022).

A growing body of literature has been exploring codesign participation as a context of knowledge and capacity building for teachers and researchers (Goldman et al., 2022), examining the shifts towards more equitable relationships with the increasing agency of teachers over the course of collaborative partnerships (Gomoll et al., 2022; Ko, 2022). One pivotal element of supporting equitable relationships is developing and maintaining trust between stakeholders (Denner et al., 2019). However, even with its wide recognition, trust is predominantly described in general terms, leaving its multidimensionality and multifacetedness implicit (Lezotte et al., 2022). Thus, how partners develop and facilitate the conditions for enabling and sustaining trust in their relationships to foster equitable participation remains underexplored (Lezotte et al., 2022). In response, this exploratory study attempts to develop a preliminary understanding of relational trust, a multidimensional and multifaceted social process (Edwards-Groves et al., 2016; Edwards-Groves & Grootenboer, 2021), in a teacher-researcher partnership and its role in cultivating equitable participation of the partners. Here, equitable participation involves recognizing teachers and researchers as experts with different domain knowledge and skillset as well as learners who need to develop adaptive expertise to collaborate on equal footing (Ko et al., 2022).

This study builds on a longer study on developing a high-school STEM integrated biology curriculum on the topic of bioinformatics and professional development (PD) activities (e.g., Yoon et al., 2023). All participating teachers implemented the curriculum designed by researchers during the project's first three years. Following the third-year implementation, three teachers were selected to collaboratively re-design the curriculum with the researchers. Here, we aim to explore this shift in the role of teachers and researchers as they create a more equitable way of making design decisions about the curriculum and develop a preliminary understanding of the role of relational trust in this process. We followed an inductive approach to analyze a corpus of interviews with the teachers who participated in codesign sessions and the researchers that facilitated these processes. More specifically, this paper seeks to answer the following research questions: (RQ1) To what extent was equitable codesign participation achieved, as reflected in teachers' and researchers' experiences? (RQ2) How was relational trust cultivated to support equitable codesign participation? Building on the need for infrastructures to support equitable participation of codesign partners (e.g., Tabak, 2022), this work could help fine-tune our understanding of how relational trust can be developed over time in a research-practice partnership that fosters more equitable roles and participation in collaborative design partnership. This work could also offer a preliminary conceptualization of relational trust's multifaceted and multidimensional nature in research-practice partnerships.

Forming equitable participation and relational trust

Researcher-practitioner collaborative designs seek to involve teachers and researchers as partners with equal roles in design decisions. Previous work has examined how partners develop new ways of thinking about design, pedagogy, and research to assume equal roles (Coburn & Russell, 2008; Farrell et al., 2019). Lack of trust is a primary issue that substantially limits the equal positioning of codesign partners (Denner et al., 2019). However, even with the recognized value of trust, its intricacies and dynamics with the equal positioning of teacher and researcher roles in research-practice partnerships remain underexplored (Edwards-Groves et al., 2016). Our work is situated in this problem space, as it explores the cultivation of trust in the shifts of partners’ participation and roles.

Trust is a "psychological state comprising the intention to accept vulnerability based upon positive expectations of the intentions or behavior of another" (Rousseau et al., 1998, p. 395). Building on this definition, relational trust is trust situated in interpersonal relationships and develops through repeated social exchanges between different role groups (e.g., teachers and researchers) (Schneider et al., 2014). Here, we focused on relational trust by recognizing trust's interrelated and interdependent nature in social, political, and intellectual realms of codesign practices and relationships (Lezotte et al., 2022). Edwards-Groves and colleagues (2016, 2021) conceptualized relational trust as a multidimensional phenomenon situated at five dimensions of relationships: pragmatic (e.g., proposing practical, relevant, and achievable goals), interactional (e.g., sustaining safe spaces for collaboration), intersubjective (e.g., demonstrating collegiality through shared language), interpersonal (e.g., demonstrating empathy), and intellectual (e.g., conveying self-confidence and professional knowledge). However, their original framework focused on how middle leaders in school partnerships develop unileteral relational trust; thus, it was limited in offering a more comprehensive lens to examine mutuality or reciprocity in trust building. In this study, we adapted this multidimensional relational trust framework to guide our exploration by redefining the dimensions of relational trust to uncover how they interrelated with shifts in teachers' and researchers' roles towards a more equitable form of participation.

Methods

Context

This study is part of an ongoing NSF-funded research project that undertakes the design, implementation, and revisions of a STEM-integrated bioinformatics curriculum that is implemented in high school environmental science and biology courses. The curriculum had 20 lessons that aimed to guide students in a problem-based learning inquiry on the issues of air quality and asthma in urban environments. Throughout the curriculum unit, the students investigated problem scenarios by collecting local air quality data through a mobile app connected to carbon monoxide and particulate matter (PM 2.5) sensors, analyzing and visualizing these data, and they learned about bioinformatics research on asthma and air pollution as well as environmental and sociocultural factors impacting pollution level and asthma rates (e.g., Yoon et al., 2023). The curriculum was initially designed by researchers at a university and then implemented by three cohorts of teachers in three subsequent years. Professional development (PD) workshops for each teacher cohort were held in the summer prior to their classroom implementation during the school year. Researchers served as facilitators and supported the pre-implementation planning, classroom implementation, and after-implementation reflection phases. In the first year, five teachers implemented the curriculum; the year after, four new teachers and two cohort-1 teachers were involved in the project; and in the third year, six new teachers, four cohort-2 teachers, and one cohort-1 teacher taught the curriculum. At the end of the third year of implementation, one cohort-1 teacher with three years and two cohort-2 teachers with two years of curriculum implementation experience were invited to participate in the collaborative design sessions to redesign the curriculum. The initial purpose of the codesign sessions was to shorten the original curriculum since it was an issue posed by our participating teachers, particularly one of our codesigner-teacher, Will. Later, the scope of the sessions shifted as the codesigners redesigned most of the curriculum. Three codesign sessions were held in person with these three teachers and one research team member. Each lasted roughly three or three and a half hours.

Participants

We interviewed two teachers who participated in the codesign sessions and three research team members who facilitated teachers' pre-planning, implementation, and after-reflections. One of the researchers also participated in and facilitated the codesign sessions with teachers. Due to a schedule conflict, one codesigner-teacher, Cassie, did not participate in this research but will be interviewed at a later date. The participating teachers (both males), Jimmy and Will, taught biology and environmental science in two separate urban schools in PA and have 17 and 21 years of teaching experience, respectively. Will had a curriculum design certificate, while Jimmy did not have curriculum design experience.

The three researcher-participants (all females), Sarah, Jessica, and Jenny, designed the initial curriculum and coached the teachers throughout all the phases. Sarah, the PI of the project, is a learning science professor at a university in the Northeastern United States, and Jessica and Jenny were two learning sciences doctoral candidates in the same institution at the time. Even though all research team members interacted with and supported all participating teachers, Jessica worked more closely with Will, while Jenny worked more closely with Jimmy as their facilitator.

Data source and collection

We conducted five semi-structured interviews with the teachers (*n*=2) and researchers (*n*=3) four months after completing the codesign sessions. The interviews were conducted by the first author, who recently joined the research team and did not participate in the codesign sessions. Thus, she conducted the interviews as an external observer. The protocol included questions designed to elicit participants' experiences in the codesign sessions, shifts in their roles over the course of their partnership, their interrelational and interactional relationships, how and why they sustained their partnership over three years (e.g., why teachers came back for another year of implementation; why researchers wanted to work with them again), and what factors shaped teachers' decision to participate in codesign sessions and researchers' decisions of involving these three teachers. The interviews were held and recorded on Zoom, each of which took roughly 45 minutes. The zoom transcriptions were reviewed by the first author for accuracy and then used for the data analysis.

Analytical approach

We conducted a thematic analysis to discern the (1) participants' reflections on their codesign experiences and (2) relational trust behaviors they described as enacted in their interrelational and interactional relationships that shaped their roles and participation in the project. We adapted a multidimensional relational trust framework (Edwards-Groves et al., 2016; Edwards-Groves & Grootenboer, 2021) to guide our analysis in addressing RQ2. However, since the framework did not fully capture the meaning provided by the participants for this context, we used it as a measure of credibility, and following Saldaña's (2016) two-cycle coding, we redefined its dimensions and identified the associated behaviors. Moreover, unlike the original framework, we identified whether the behaviors were mutually exerted by teachers and researchers, i.e., teachers' trust in researchers and researchers' trust in teachers. For that, we open-coded the interview transcripts, followed by focused coding to determine what initial codes made more analytical sense based on our research goals and prior literature. Thematic analysis was conducted independently by the first author and one external researcher who was not involved in the researcher-teacher partnership for investigator triangulation (Patton, 2015), and through multiple short debriefings, the discrepancies were resolved between the two coders, and the findings were merged (Saldaña, 2016).

Findings

Here, we first describe to what extent equitable codesign participation was achieved, as reflected in teachers' and researchers' experiences in codesign sessions (RQ1). Then, we present the two main themes outlining how relational trust was cultivated over a three-year partnership of the teachers and researchers in a way that supports equitable codesign participation (RQ2).

RQ1. Shared power and authority through democratic and collaborative interactions

Throughout the collaborative design sessions, codesign partners came together in a dialogic space where they collectively re-designed the curriculum. Participants underlined three primary characteristics of these sessions: safe space for democratic dialogue, collaborative discussions, and shared authority and power. All participants described the sessions as a safe dialogic space where they felt comfortable sharing, discussing, and negotiating diverse challenges, needs, and practices and incorporating them into their collective design decisions. Reflecting on this aspect, Will, for example, noted that he expressed his concern about the previous curriculum comfortably, "I just said, there's so much in here… and it should be divided up into two different programs: the bio component and environmental component…". His concern was then taken as an action item in the codesign sessions as the redesigned curriculum was considerably shorter, with 12 lessons, compared to the previous curriculum, with 20 lessons. Jimmy further commented on how their diverse styles contributed to the design by saying, "I think it worked well…we maybe had different styles. And so, we got like an interesting diversity of types of lessons."

These collective decisions were also enacted through collaborative discussions, where codesign partners were "...all putting ideas forward…" (Jimmy), "...building off each other's thoughts and ideas about what would make the curriculum work" (Jessica), "...listening to each other." (Will), posing and negotiating alternative perspectives, and collectively making the decisions. Jessica further described these collaborative dynamics, saying:

> We collectively built this outline…we worked through the first lesson literally as a group. There'd be a conversation happening about the order, and then Cassie would briefly drop out of the conversation. And then she would come back in and be like, I just found a video… they each would do that…they totally took ownership of that…it was a really collaborative process.

Here, Cassie's behaviors suggest that the codesign team members were invested in producing a high-quality design, and they worked together to accomplish it. Jessica's description of this situation, i.e., "they totally took ownership of that," was interesting as it further suggested that team members shared authority and power in the decision-making processes. This was also reflected in the experiences of Jessica, Jimmy, and Will, as all of them repeatedly noted having an equal say on the decisions throughout the sessions. For example, Jessica referred to an instance where Jimmy shared a disagreement with Jessica by posing an alternative design idea:

> I had started writing stuff on sticky notes and sticking them to the wall, Jimmy got up and… started moving them around, adding sticky notes of his own as we were talking… he didn't ask permission or anything like that… He just like got up, and it was like, no, no, I think they should go in this order…which is exactly what we wanted to have happened.

This excerpt indicates that Jimmy was comfortable with posing a problem in Jessica's idea and taking action to fix it by adding his sticky notes. However, the fact that "he didn't ask permission…" suggests that this was not a normative behavior of teacher-partners, and there was a shift in their power dynamics toward a more equitable form. Jimmy also echoed this shift by saying, "I felt like there were four people in the room that were equals that just kind of through our ideas."

RQ2. Cultivation of relational trust

Here, we describe two main themes regarding how relational trust was cultivated over the three-year partnership that developed and facilitated the conditions for equitable participation in the codesign sessions described earlier.

Theme 1. Commitment to supporting partners' diverse needs and interests

All participants emphasized the critical role partners' commitment to supporting each other's diverse needs and interests played in the sustainability and evolution of their partnership. For example, Will pointed out the research team's, particularly his facilitator, Jessica's, commitment to support his needs and interests as his primary rationale to sustain the partnership over multiple years, "Jessica was just perfect… She listened. She understood. the whole team is great; that's why I'm still here." Two relational trust dimensions were prominent pertaining to this theme: interpersonal and pragmatic. While demonstrating their commitment to supporting diverse needs and interests, the partners attended to the interpersonal dimension of trust by reciprocal reliability, demonstration of genuine caring and mutual personal regard, and the pragmatic dimension of trust by targeted activities and professional support and investment in research efforts.

Participants described reciprocal reliability as teachers and researchers being responsive and timely in communicating with each other and fulfilling their obligations. This was an influential criterion for researchers in their selection of the codesign partners; e.g., "... teachers' commitment was critical [in their selection] ...whether they are timely responsive to us… Because we're working as a whole group and there are a lot of time pressing preparations…" (Jenny). In her sentiments, Jenny depicted their partnership with teachers as teamwork and emphasized teachers' timely responsiveness in ensuring effective teamwork. Pointing out the other facet of this behavior, Sarah underlined the significance of the researchers' timely fulfillment of their obligation towards teachers, "Another thing that is very important to me is… paying our teachers fast enough." The second interpersonal relational trust behavior was demonstrating genuine caring, which was described as researchers putting effort into empathizing with teachers' experiences, struggles, and needs. For example, Will expressed his appreciation for Jessica’s constant efforts to acknowledge his needs and struggles, “She understood when I said, I'm just fried. I need to take a couple of days off of doing this because my kids… were overwhelmed with a lot of it… [She said] no problem.” Similarly, Jessica emphasized the importance of acknowledging teachers’ struggles and needs and offering support when needed, "I know that you are not given as much support as you need [in your institutions]. I've been there. I know what that's like, so how can I help you?" Here, she empathized with teachers’ frustration by acknowledging their lack of support in their institutions and further demonstrated her caring by offering support to address this problem. Genuine care was often coupled with partners' willingness to go beyond their immediate obligations to support each other, bringing us to the final and most commonly reported interpersonal relational trust behavior: mutual personal regard. It was enacted in the partners' interrelational dynamics in the form of teachers and researchers being accessible and flexible for each other's needs. For example, Jimmy reflected on how Jenny, his facilitator, was always available and flexible to address his needs, "she has a schedule… But at the same time, she always kind of had like a drop everything…. she was willing to come in when she couldn't come…help out." Personal regard, as the participants further highlighted, was mutual as the teachers also made themselves available to support researchers' needs, e.g., "... she [Molly] was very… flexible, and try to be available most of the time" (Jenny). Demonstrating genuine caring and personal regard were interrelated with the pragmatic dimension of relational trust since they were often followed by targeted activities and professional support or investment in research efforts.

Targeted activities and professional support was described as researchers' investment in tailoring project-related activities and professional support to the teachers' needs, goals, and interests. For example, Will appreciated how Sarah adapted the expectations based on teachers' feedback by saying, "Sarah's really good… listens to us, and doesn't just pacify us if it can't be done. she's very good on the teacher side of it, listening and taking our feedback" (Will). Will further expressed his appreciation for the professional support the research team offered by reflecting on how having Jessica regularly in the classroom supported his teaching practices, which ultimately helped them develop a collaborative partnership with shared authority.

> when I was delivering the information, Jessica was there… She noticed that I was struggling with something, and she chimed in… she didn't mind helping out… we're going over the formulas… and I said mean. She said, no, it's average. There's no mean. That's right… that relationship that we had was really good, that it was almost like a second teacher. It didn't make me feel like I was being judged.

Here, Will shared an incident where he used the wrong terminology in class, and Jessica corrected him. However, as he further posed, being corrected did not bother him as he did not feel judged; on the contrary, he enjoyed having Jessica as a second teacher in the class. This might suggest (1) the presence of a collaborative partnership between Jessica and Will, as he did not feel threatened to be corrected in the class, and (2) the shifts in the partners' roles, as Will shared his authority with Jessica as she gained the role of co-teacher.

The second pragmatic relational trust behavior for this theme was the investment in research efforts, and it was described as teachers' willing contributions to the research activities. The three researcher-participants emphasized this behavior as one of the main criteria for choosing the codesign partners. Jenny further explained this behavior's role in forming their codesign partnership, "We asked teachers to provide feedback. Some teachers would just give a line or two, but some teachers really put a lot of thought on it, and they give really in-depth feedback… an indicator for their commitment."

Theme 2. Affinity building with a respectful and supportive environment

All participants underlined affinity building and fostering a respective and supportive environment as the conditions for partners’ autonomy building and taking ownership of the collaborative process and outcomes, thus, shifting the role and power distribution of the partnerships towards a more equitable form. For example, Jimmy discussed how researchers’ expression of their confidence in and respect for his professional expertise fostered his autonomy during curriculum implementation and encouraged him to take ownership of this process:

> I might have just modified entirely what that plan was. She [Jenny] was fine with that...What I did with the virtual year…I didn't really ask for permission. I felt that I had a lot of freedom from the team to kind of do what I wanted… I don't think I had a ton of failures, but at the same time, I was fine with the results either way. I don't think that I was explicitly told any of that, but it was definitely implied, like, ‘You've been doing this for a while. We think you're great. You can keep doing what you want.’ I think that that's been helpful throughout.

Jimmy's reflection on his experiences with the research team indicates that the team demonstrated their respect for and confidence in Jimmy's expertise by giving him the freedom and space to make changes in the curriculum and try different paths, fail, and try again. They also repeatedly vocalized their confidence in his abilities and appreciation for his efforts, which ultimately fostered his autonomy, as evident with his exclamation, "I didn't really ask for permission." The interview data further yielded three prominent relational trust dimensions pertaining to this theme: intersubjective, interpersonal, and intellectual. In their efforts to build affinity with a respectful and supportive environment, the partners attended to the intersubjective dimension of trust by identification through shared participation, the interpersonal dimension of trust by rapport building and demonstrating respect and appreciation, and the intellectual dimension of trust by recognition of expertise.

The participants described identification through shared participation as positioning teachers and researchers as members of an affinity with a shared goal. For example, emphasizing the shift in the research team's positioning of teachers in the partnership, Jenny noted, "as a whole team, we put a lot of effort really not just to consider our teacher participant as like research participant. It's not that anymore. They are part of our team." She further explained how their shared participation in the project fostered their sense of belonging:

> They [teachers] all acknowledged that this is exploratory… Jimmy would also say it is a guinea pig that he is testing out the curriculum whether it works. And then he knows this is a process that we are all in together, teachers and researchers. Altogether, we are, as a team, trying to figure out what's the best way to teach this to our high school students. So that sense of belonging.

Here, referring to her conversation with Jimmy, Jenny reflected on how the exploratory nature of the project prompted partners to unite as a team to handle the ambiguity of their explorative experience better, and this joint exploration prompted their sense of belonging. The emphasis on the 'We' language, as exemplified in Jenny's reflection, was also effective in supporting partners' identification, which was echoed by Sarah's sentiments about their partnership with teachers, "One of the things that I do is a very intentional language which has to do with 'We' us all of us working together."

Interpersonal relational trust was the second dimension associated with affinity building, and two related behaviors were identified: rapport building and demonstrating respect and appreciation. Rapport building was described as teachers and researchers demonstrating personal interest in each other and spending social time together. For example, when asked how he and Jessica developed their relationship over time, Will posed Jessica's interest in his personal life, "...she never met my family, but every time we talked, she asked 'How's your wife? How are kids?'" and his personal updates, "...I had to take my son to an urgent care. He cut himself really bad…two weeks later, we had our next meeting, and she asked about him." All participants further pointed out spending social time as a prerequisite for rapport building. For example, Jessica reflected on how her relationship with a teacher in the project developed over time through their social interactions after the class sessions:

> I was like helping Hallie to reset the chairs in her classroom for her next class… She would just talk, and I would talk, and… that developed a real rapport when we were in their classroom because you just got a chance to sort of talk to catch up and all of that. So, I definitely think that [I have] a much stronger relationship with Hallie.

The second interpersonal relational trust behavior was demonstrating respect and appreciation, which was described as researchers acknowledging and appreciating teachers' efforts, time, and accomplishments. For example, Will commented how the facilitators' encouragement and positive feedback eased his stress during the implementation process, "I was nervous… I don't think they [students] have done anything like that. They [facilitators] were like Your students are awesome. Just getting that feedback when things didn't go well…" Jimmy further underlined the role of positive feedback and encouragement in his motivation to invest in the project by saying, "...just getting like really positive feedback like you guys are really good teachers, or you're really doing a good job is sometimes really really helpful because they [teachers] might not be getting it from their administration…."

The final relational trust dimension associated with affinity building was the intellectual dimension, and one predominant associated behavior was the recognition of expertise, which was described as researchers demonstrating confidence in and respect for teachers’ expertise and experiences as practitioners. One example quotation was shared earlier by Jimmy, where he discussed how researchers’ confidence in and respect for his professional expertise fostered his autonomy.

Discussion

By investigating the formation of equitable participation through the lens of relational trust over multiple years of partnership, as reflected in the partners' experiences, this study is an exploratory attempt to contribute to the emerging body of research efforts to foster equitable participation in research-practice design partnerships (e.g., Gomoll et al., 2022; Ko, 2022) and the need for developing a systematic understanding of how trust is enacted, experienced and maintained in codesign partnerships (Lezotte et al., 2022).

Our first research question concerned the extent to which equitable participation was achieved in the codesign sessions, as reflected in teachers' and researchers' experiences, and the findings suggested that the participating partners shared authority and power as they collaboratively redesigned the curriculum through democratic and collaborative dialogues. However, the partners did not always interact with each other in ways that created and facilitated the conditions for shared authority and power since the initial partnership was not formed as a collaborative design partnership. Over the course of three-year curriculum implementations, a trajectory from imbalanced participation to an increasingly equitable and collaborative one was attained. This trajectory has often been examined during the codesign interactions of the partners (e.g., Kyza & Agesilaou, 2022), which are highly facilitated, and the roles of the partners are clearly defined (Matuk et al., 2016). Alternatively, this research positioned codesign interactions as the equitable and collaborative end of the trajectory attained over the course of teachers and researchers' three-year imbalanced partnership and building on the significant role of thrust in the sustainability and evolution of partnerships (Denner et al., 2019), it used relational trust situated at the interpersonal interactions of the teachers and researchers as a lens to understand this trajectory.

Accordingly, our second research question concerned how relational trust was cultivated throughout a three-year partnership in ways that facilitated equitable participation during the codesign sessions. Our findings yielded two primary ways of cultivating relational trust for equitable participation: commitment to supporting partners' diverse needs and interests and affinity building with a respectful and supportive environment, and further identified and redefined five dimensions of relational trust (Edwards-Groves et al., 2016; Edwards-Groves & Grootenboer, 2021) and the associated behaviors to cultivate equitable participation. Other bodies of literature, such as school leadership and action research with community partners, have long valued and recognized the multidimensional and multifaceted trust in shaping the efficacy and sustainability of the partnerships (e.g., Edwards-Groves et al., 2016; Edwards-Groves & Grootenboer, 2021). However, the contextual and relational differences challenge the utilization of those theories in the researcher-teacher design context (e.g., Jardí et al., 2022). Moreover, the original relational trust framework focused on how middle leaders in school partnerships develop unilateral relational trust; thus, it was limited in offering a more comprehensive lens to examine mutuality or reciprocity in trust building, which is an increasingly demanded focus of research in design partnership literature (Goldman et al., 2022).

Similarly, many of the identified behaviors have already been documented to cultivate trust in partnerships, such as rapport (e.g., Slater & Gazeley, 2018) and personal regard (Bryk & Schneider, 2003). However, our findings offered contributions to the literature by (1) showcasing the interrelated, multilayered, and multifaceted nature of relational trust developed over time between the partners in an authentic setting and (2) offering a preliminary conceptualization of relational trust situated in the interpersonal dynamics of the partners. This conceptualization might further offer implications for creating infrastructures to support the equitable participation of codesign partners (e.g., Tabak, 2022).

Finally, the findings of this study should be interpreted with caution, mainly because of three reasons. First and foremost, it was a small exploratory study that focused on the organically evolved shifts in partners' roles over time and thus, the participant pool was limited to three teachers and three researchers, and one teacher-partner could not participate in the study because of a time conflict. We will continue our exploration by applying the same lenses to our other projects, as the same procedures were followed in those projects. Second, our only data source was the corpus of interviews with the partnering teachers and researchers. However, the findings suggested other potential data sources that could be used to explore the cultivation of relational trust (e.g., recordings of the after-implementation chats). Thus, we will further triangulate our findings with these resources.

The Impact of Collaboration on Students' Processing of History-Related 360°-Videos

Valentina Nachtigall, Selina Yek, Nikol Rummel
valentina.nachtigall@rub.de, selina.yek@rub.de, nikol.rummel@rub.de
Ruhr University Bochum

Abstract: History-related 360°-videos are characterized by immersive features and an emotionalizing presentation of the content. These features bear the risk to emotionally overwhelm learners, preventing them from critically evaluating the video content. In the present quasi-experimental study, we explore whether a collaborative examination of a history-related 360°-video affects students' critical processing of the content. Based on inconsistent findings on the effects of co-viewing and collaborative learning, one could assume that a collaborative evaluation of the 360°-video either promotes a more cognitive (especially critical) and less emotional engagement with the content or vice versa. To investigate these assumptions, we compare the processing of an emotionalizing history-related 360°-video between students who collaboratively conduct a written analysis of the video with students who analyzed the video individually. Our findings suggest a positive impact of collaboration showing that students who worked collaboratively examined the 360°-video in a more critical way than students who worked individually.

Introduction and background

Imagine yourself being imprisoned in a former remand prison of the GDR State Security Service. Prison guards yell at you and aggressively interrogate you about your motives for wanting to flee the country. You might imagine feeling discomfort and anxiety. This is exactly the situation that students experience when they use history-related virtual reality (VR) media, such as 360°-videos (see Figure 1), as these media are designed to create presence (Cummings and Bailenson, 2015). This sense of being present in a virtual world (Slater and Wilbur, 1997) is achieved through immersive features of the VR technology, such as the first-person perspective or a wide field of view (Cummings and Bailenson, 2015). Due to these immersive features, history-related VR media promise that users can travel in time and, thereby, re-experience or even witness historical events (Bunnenberg, 2018). In addition, the history-related content is often presented in an emotionalized way in order to promote empathy and identification with historical figures (Brauer, 2019). This impression of (emotionally) reexperiencing and participating in historical events can help learners to "feel more connected to the narrative" (Parong and Mayer, 2021, p. 1436) which may increase their attention and learning outcomes (Parong and Mayer, 2021).

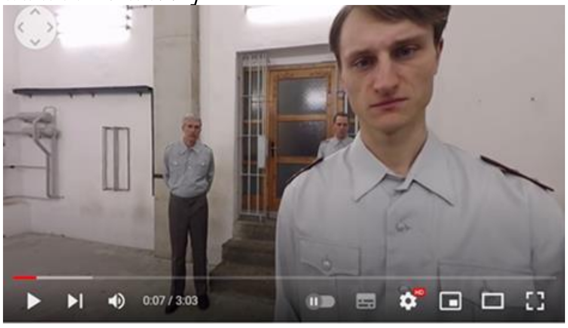
Screenshot of the 360°-video "Was wollten Sie in Berlin?" ["What did you want in Berlin?!"]



However, the immersive and emotionalizing features of history-related VR media can overwhelm learners (see Bunnenberg, 2018), leading to a more emotional and less cognitive processing of the content (Parong and Mayer, 2021). Specifically, the immersive and emotionalized presentation of the content can prevent learners from critically questioning and distancing themselves from the represented content (see Bunnenberg, 2018). Thus, in order to avoid an unreflected adoption of the presented perspective(s) on certain historical events or situations (Bunnenberg, 2018), it is necessary to find ways that help learners to process history-related VR media more cognitively and less emotionally.

Based on research on the effects of co-viewing and collaborative learning, the present study explores whether collaboration has an impact on students' processing of history-related VR media. More specifically, we investigate whether a collaborative examination of an emotionalizing history-related 360°-video promotes a more cognitive and less emotional processing of the content.

Findings from research on the effects of *co-viewing* suggest that being around other viewers and communicating with them while watching a high-arousal video can reduce their perceived suspense (Zillich, 2014). Findings from Gehrau et al. (2014) also showed that the perceived emotional intensity differed between viewers who did or did not communicate with each other while watching a video. Based on these findings, Gehrau et al. (2014) concluded that talking about emotional experiences while watching a video constitutes a way to distance oneself from the presented content, leading to a more critical opinion about the content. Research on the effectiveness of *collaborative learning* further suggests that collaboration can promote critical thinking through interactive discussion, clarification, or evaluation of each other's contributions. As a study by Glokhale (1995) demonstrated, students who worked in small groups more likely clarified, analyzed, and evaluated information than students who worked alone. Also, a study conducted by González-Cacho and Abba (2022) demonstrated that students who created a social-media posting in small groups relied more strongly on critical-thinking processes (e.g. reflecting on assumptions and conclusions or evaluating different perspectives) while creating their postings than students who worked alone. Collaborating with others and being around others when examining a high-arousal video might be particularly important for processing immersive 360°-videos. These videos are usually designed for being watched with head-mounted displays (HMDs), whereby the users could feel isolated from others (Rothe et al. 2021). This isolation could increase the feeling of being overwhelmed and, thereby, hinder a reflective, critical, and distanced processing of the content of 360°-videos. Hence, based on the aforementioned findings from research on co-viewing and collaborative learning, one could assume that a collaborative examination and analysis of a history-related 360°-video may help learners to focus less strongly on their feelings aroused by the emotionalizing and immersive video (due to a decreased perception of emotional intensity) and instead to concentrate more strongly on critically discussing and evaluating (due to increased processes of critical thinking) the presented perspective(s) on the historical event.

However, research on *co-viewing* has also shown that watching a video together can increase the feeling of transportation into the narrative and the identification with characters of the narrative. More specifically, findings from Tal-Or (2016) showed that the feeling of being absorbed into the world of the narrative and the identification with its protagonist increased when the co-viewer reacted positively and enthusiastically about the movie while watching it. Moreover, research on *collaborative learning* suggests that working in groups can cause different cognitive challenges. For instance, paying attention to the contributions of other group members can block one's own thinking process (see Nokes-Malach, 2015), and sharing ideas in a group brainstorming process can restrict the breadth of ideas and lead to conformity with other contributions (Kohn & Smith, 2011). Considering these findings, one could assume that a collaborative evaluation of a history-related 360°-video leads to a more emotional (due to an increased feeling of transportation into the narrative and a high identification with the characters) and a less cognitive (due to production blocking and conformity with other contributions) processing of the content.

Given these inconsistent findings from research on co-viewing and collaborative learning, the present study aims to explore the effects of a collaborative analysis of a history-related 360°-video on students' processing of the video (Research Question 1). Based on the two contradicting perspectives outlined before, we are particularly interested in investigating how students who collaboratively examine a history-related 360°-video handle their emotions raised by the video, that is, whether they process the 360°-video more emotionally or more cognitively than students who individually analyze the video (Research Question 2).

Method

To investigate our research questions, we analyze data from a quasi-experimental study that was conducted as part of a larger project in which students underwent different training interventions to promote their cognitive processing of history-related 360°-videos. The analyses presented in this paper focus on video analyses that students conducted individually or collaboratively prior to the training interventions. Thereby, we are enabled to examine the mere effect of collaboration on students' processing of immersive and emotionalizing 360°-videos.

Participants

Data were collected in an out-of-school lab at a university in Germany. The participating secondary school students visited the out-of-school lab with their whole class to attend a day-long project on "Virtual Time Journeys - Experiencing History through 360° Videos?". Our sample consists of 145 secondary school students (female: 57.2%; age: $M = 17$, $SD = 1.05$) from grades 11 and 12 (eight classes in total).

Design and procedure

Classes were randomly assigned to two conditions: individual video analysis (ind) and collaborative video analysis (collab), leading to the following two subsamples: ind: *n* = 87 individual students; collab: *n* = 58 students in *n* = 17 small groups. The random assignment to these two conditions was conducted prior to the main study where we compared different training interventions as mentioned above.

Students in both conditions first received an introduction to the topic of the project and the procedure of the study and then watched a neutral 360°-video about swimming dolphins with VR glasses for mobile devices (e.g. smartphone, iPod) in order to familiarize with the VR technology. Afterwards, they watched the history-related 360°-video "What did you want in Berlin!?" which is available on YouTube and is about the former remand prisons of the GDR State Security Service. In the video, the viewer takes on the role of a prisoner who is interrogated about his/her motives for leaving the country (see Figure 1). The students were then asked to analyze and evaluate the video - depending on the experimental condition - either collaboratively (in small groups of three or four) or individually. For their analysis, students were provided with a laptop and a Microsoft-Word template which included the instruction for the analysis (see Table 1).

Table 1
Procedure in both conditions

Condition	Prior to the Analysis		Analysis	
(1) Individual video analysis (ind)	Introduction + Test video *360°*	History-related video *360°*	Instruction: "Take on the role of (a) history expert(s) who professionally deal with history-related 360°-videos. Analyze [1] the 360° video 'What did you want in Berlin!?' and evaluate [2] whether or not it is suitable for learning about imprisonment in the GDR. Think about the aspects that, in your opinion, constitute a good analysis and evaluation. (Select one person who takes on the writing.)"	
(2) Collaborative video analysis (collab)				
Duration:	15 min.	30 min.	30 min.	

Measures

To investigate our research questions, we assessed the elements of students' video analyses. For this purpose, we used an extended version of a code book that we had developed in a previous study (Nachtigall et al., 2022). The code book includes both codes derived inductively from students' written video analyses and deductively generated codes building on the literature, for instance, elements from film analysis and based on the definition of historical learning. Specifically, to assess the elements of the students' video analyses, we used the 11 codes described in Table 2. The code book includes categories that can be characterized as (1) content- and medium-related, (2) task-related (focusing on the second part of the task that asks students to evaluate the video), (2) emotion-related (3) reflective-evaluative, and (4) unreflective-evaluative. We look at all codes in order to investigate our first research question. With respect to our second research question, we particularly look at the categories pointing to an emotion-related or reflective-evaluative processing of the video. We coded students' video analyses in a binary way, that is, we assessed whether elements occurred (1) or not (0). Two raters coded 100% of the data and reached satisfying agreements ranging between $\kappa = 0.74$ and $\kappa = 0.96$ prior to discussion. Afterwards, all disagreements were resolved by discussion.

Results

Prior to investigating our research questions, we examined whether the length of students' written video analyses differed between the two conditions, as students in both conditions had the same amount of time for analyzing the 360°-video. Thus, the collaborating students had to split up their time for both analyzing the video and coordinating tasks in the group (e.g. choosing one person for typing down their joint analysis). However, an ANOVA revealed that the word count of the written video analyses did not differ between students who conducted the analysis collaboratively ($M = 152.28$, $SD = 70.96$) and students who examined the video individually ($M = 162.55$, $SD = 80.22$), $F(1,103) = 0.253$, $p = .62$, $\eta^2 = 0.002$.

To investigate our research questions, we conducted two analyses. We firstly conducted Chi-square tests of independence and examined whether certain elements of the analysis were more likely to occur in the video analyses from students of the collab-condition versus the students of the ind-condition. We secondly conducted an Epistemic Network Analysis (ENA). ENA measures and visualizes the connections between the categories used for coding a dataset by weighting the structure of these connections and illustrating this structure in dynamic network models (Shaffer, Collier, & Ruis, 2016). ENA, thereby, enabled us to identify the interplay between the elements that students included in their analyses and to investigate whether these patterns of included elements differed between the two conditions.

Table 2
Codebook used for assessing the elements of students' video analysis

Code		Definition
Content-/medium-related	Summarizing	Students summarize the content of the video.
	Examining the representation	Students describe/analyze features of the medium (e.g., first-person perspective) and their influence on the representation.
	Examining the atmosphere	Students describe the atmosphere or analyze how different features of the representation (e.g., sound) have an impact on the atmosphere in the video.
Task-related	Formulating conclusions	Students draw reasoned conclusions about the video.
	Describing learning outcomes	Students describe things that can or cannot be learned from watching the video.
Emotion-related	Describing emotions	Students describe emotional impressions (e.g., sadness, boredom) of the video.
	Analyzing emotionalization	Students analyze features of the representations that trigger certain emotions while watching the video.
	Transportation	Students make statements that suggest empathy for the characters of the narrative and a feeling of being absorbed into the narrative.
Reflective-evaluative	Reflecting transportation	Students describe the feeling of transportation as a learning outcome, but in a reflective and distanced way.
	Critical conclusions	Students formulate critical conclusions about the video.
Unreflective-evaluative	Accepting the represented past	Students make statements that indicate an adoption of the video content as a valid representation of the past.

Differences between conditions in elements of the video analysis

To investigate the differences between collab-students and ind-students with regard to each element of their video analyses, we conducted three Chi-square tests of independence in order to address potential difficulties underlying the comparison of small groups with individual students (see Kenny et al., 1998). Specifically, we compared (1) the groups in the collab-condition ($n = 17$) with the individual students of the ind-condition ($n = 87$), (2) the individual students of the collab-condition ($n = 58$) with the individual students of the ind-condition ($n = 87$), and (3) the groups in the collab-condition ($n = 17$) with nominal groups composed of individuals of the ind-condition ($n = 27$). For the second analysis approach, we assigned the result of the coded video analysis of the group multiple times, namely to each member of the group. The use of nominal groups in the third analysis approach was inspired by research on knowledge convergence in collaborative learning (e.g. Jeong & Chi, 2006) and refers to an artificial and post-hoc construction of small groups containing students who did not actually collaborate with each other. We created nominal groups containing three to four students of the same class. Per element of analysis, the means of *each* nominal group were either rounded up to 1 (when $M > 0.5$) or rounded down to 0 (when $M < 0.5$) in order to ensure comparability to the binary coded video analyses of the real small groups of the collab-condition. Table 3 shows the descriptive statistics for the elements included in students' video analysis.

The first Chi-square test (i.e., small groups compared to individuals) revealed significant differences between the small groups in the collab-condition and the students of the ind-condition with regard to the following three elements of the analysis: summarizing ($X^2(1) = 9.11$, $p = .003$, $\varphi = .30$), describing learning outcomes ($X^2(1) = 5.99$, $p = .01$, $\varphi = -.24$), and reflecting on transportation ($X^2(1) = 9.00$, $p = .003$, $\varphi = -.30$). Thus, students of the ind-condition focused more strongly on summarizing the content of the video in their analyses, while groups in the collab-condition focused more strongly on describing the potential of the video for learning something as well as on evaluating the feeling of transportation into the narrative in a reflective and distanced way (see Table 3).

The results of the second Chi-square test (i.e., individuals compared to individuals) showed again significant differences in summarizing ($X^2(1) = 29.16$, $p < .001$, $\varphi = .45$), describing learning outcomes ($X^2(1) = 13.93$, $p < .001$, $\varphi = -.31$), and reflecting on transportation ($X^2(1) = 14.39$, $p < .001$, $\varphi = -.32$). But additionally a significant difference with regard to the element of examining the representation ($X^2(1) = 5.64$,

$p = .02$, $\varphi = .20$), showing that students of the ind-condition more often included an examination of the features of the medium in their analysis than students of the collab-condition (see Table 3).

The third Chi-square test (i.e., small groups compared to nominal groups) demonstrated again significant differences with respect to the elements summarizing ($X^2(1) = 14.01$, $p < .001$, $\varphi = .57$), describing learning outcomes ($X^2(1) = 5.80$, $p = .02$, $\varphi = -.36$), and reflecting on transportation ($X^2(1) = 6.99$, $p = .008$, $\varphi = -.40$), but also a significant difference in drawing critical conclusions ($X^2(1) = 5.45$, $p = .02$, $\varphi = -0.35$). Thus, the small groups of the collab-condition formulated significantly more often critical conclusions about the video in their analysis than the nominal groups of the ind-condition (see Table 3).

Taken together, the results of the three different Chi-square tests all suggest that students of the ind-condition focused more strongly than students of the collab-condition on describing rather obvious and content-related aspects (as well as medium-related aspects) of the video in a factual and technical way by summarizing the content (and examining the representation). In contrast, students of the collab-condition focused more strongly than students of the ind-condition on task-related aspects by describing potential learning outcomes as well as on reflective-evaluative aspects by reflecting on the feeling of transportation in a distanced way (and by drawing critical conclusions).

Table 3
Descriptive statistics for the elements of students' video analysis

	Collab-condition		**Ind-condition**	
	Small groups (*n* = 17)	Individuals (*n* = 58)	Individuals (*n* = 87)	Nominal groups (*n* = 27)
Elements of the analysis	Relative frequencies in %			
Summarizing the content	47.1	36.2	62.8	96.3
Examining the representation	35.3	36.2	48.3	59.3
Examining the atmosphere	52.9	48.3	42.1	44.4
Formulating conclusions	52.9	48.3	49.0	51.9
Describing learning outcomes	70.6	70.7	51.7	33.3
Describing emotions	52.9	48.3	51.0	55.6
Analyzing emotionalization	17.6	15.5	13.8	7.4
Transportation	64.7	63.8	55.9	40.7
Reflecting transportation	23.5	24.1	11.7	0
Critical conclusions	35.3	32.8	26.9	7.4
Accepting the represented past	70.6	69.0	59.3	48.1

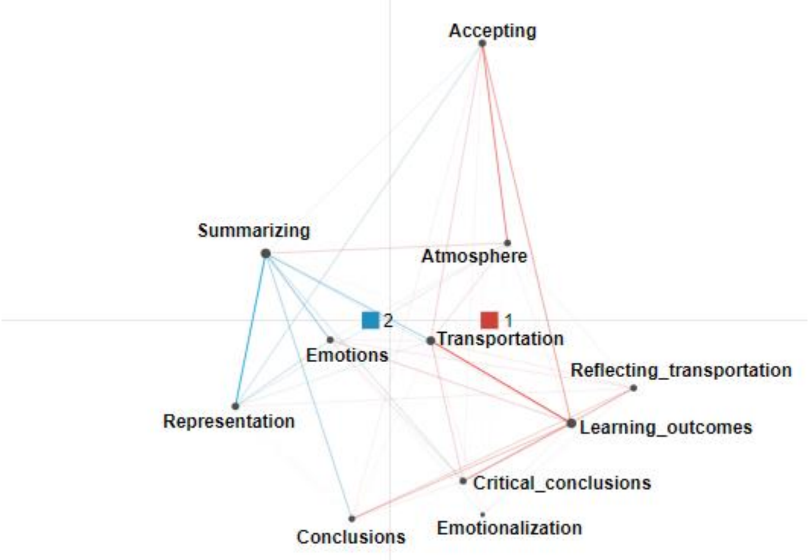
Differences in the interplay of elements of the video analysis

As the results of the three different Chi-square tests revealed highly similar results and as the first analysis approach - the comparison of groups to individuals - constitutes the most strict and sound procedure, we decided to conduct the ENA accordingly. For the ENA, we first constructed mean epistemic networks for each condition and then subtracted the networks in order to make the differences between the groups in the collab-condition and the individual students of the ind-condition salient. In the resulting difference graph (see Figure 2), the darker and thicker lines display larger differences in the strength of connections, and the color of the lines demonstrates in which network the connections are stronger (Shaffer et al., 2016).

As Figure 2 shows, the video analyses of students in the ind-condition (blue) show strong links from summarizing to four further elements of the analysis, namely examining the representation, describing emotions, transportation, and (although less strong) formulating conclusions. On the contrary, the analyses of groups in the collab-condition show strong connections from describing learning outcomes to the following four analysis elements: transportation, critical conclusions, accepting the represented past, and (although less strong) formulating conclusions. They, moreover, show a strong connection between describing the atmosphere and accepting the represented past.

A Mann-Whitney test demonstrated that groups in the collab-condition ($Mdn = 0.41$, $n = 17$) significantly differed from students of the ind-condition ($Mdn = -0.05$, $n = 87$) on the first (x) dimension with a large effect ($U = 1255.00$, $p < 0.01$, $r = -0.70$). This significant difference on the first (x) dimension suggests that students of the collab-condition have their strongest connections in the right part of the space (see red network in Figure 2) and students of the ind-condition in the left part of the space (see blue network in Figure 2).

Figure 2
ENA difference graph for the coded video analyses of collab-groups (red) and ind-students (blue)



Discussion

In the following, we discuss our findings from the ENA and the Chi-square tests in light of examples from students' video analyses. The ENA results supported the findings of the Chi-square tests suggesting that students of the ind-condition focused more strongly than their counterparts of the collab-condition on content- and medium-related aspects of the video in their analyses (i.e., giving a summary of the content and describing the characteristics of the medium) in a rather technical and factual than critical and reflective way. However, the ENA results additionally demonstrated that students of the ind-condition linked these content- and medium-related aspects to emotion-related elements by describing their emotions and feelings of transportation. The following exemplary video analysis (example #1) from a student of the ind-condition nicely illustrates this interplay of content-/medium-related as well as emotion-related elements:

> "The video [...] is about a person who ends up in prison [...]. It describes the situation of the imprisoned people: It begins by showing how it is to live in a prison [SUMMARIZING]. [...] The intention of the video is to look through the perspective of the prisoners. There is a guard who watches over the prisoners [...] [EXAMINING REPRESENTATION]. In addition, they have to live in a room with a toilet, a bed, and a sink [SUMMARIZING]. I found it quite scary there and I felt sorry for the prisoners as they were yelled at [DESCRIBING EMOTIONS]. I kind of empathized with them [TRANSPORTATION]."

The ENA results further supported the findings of the Chi-square tests as they suggested that students of the collab-condition included more strongly than students of the ind-condition task-related (i.e., describing learning outcomes and formulating conclusions) as well as reflective-evaluative (i.e., reflecting on transportation and drawing critical conclusions) aspects. This finding is exemplified in the following video analysis (example #2) of a group in the collab-condition:

> "[...] You can get a sense of reality [TRANSPORTATION] [...]. In addition, it can lead to a better remembering and understanding of the learning content [DESCRIBING LEARNING OUTCOMES] because of the emotional involvement [TRANSPORTATION]. […] On the other hand, not every historical event can be represented by those videos [REFLECTING TRANSPORTATION]: For example, in the case of failed attempts to escape across the border, or even the execution of people, cannot be represented and one must resort to photo sources or the like. In conclusion, VR videos can be a good way to better engage with the topic [FORMULATING CONCLUSIONS] which leads to the need to find a good balance between video sources and other sources [CRITICAL CONCLUSIONS]."

However, the ENA additionally demonstrated that some students in the collab-condition also evaluated the video in a less critical and distanced but more emotional and unreflective way as they referred in their descriptions of the learning outcomes to the feeling of being absorbed into the narrative and the conviction that the video constitutes a valid representation of the past. This might be illustrated by the following exemplary video analysis (example #3) of a group in the collab-condition which includes the elements "describing learning outcomes", "transportation", and "accepting the represented past":

> "[...] In the video, we find ourselves in the situation of the prisoner [TRANSPORTATION] who was questioned and badly treated by the authorities. They spoke with the prisoner in a very derogatory manner and treated him as a serious criminal, based on an assumption that turned out to be false in the end [SUMMARIZING]. The video is very depressing [DESCRIBING EMOTIONS] and it shows how bad the situation was in the GDR at that time [LEARNING OUTCOMES; ACCEPTING]. In summary, the video helps to put yourself in the situation of a prisoner [TRANSPORTATION; FORMULATING CONCLUSIONS] [...] and to empathize with what people had to go through and had to experience [TRANSPORTATION]."

Taken together, with respect to our research question 1, the results of both the Chi-square tests and the ENA point to an effect of collaboration on students' processing of an emotionalizing and immersive 360°-video. Specifically, the Chi-square tests and the ENA demonstrated significant differences between the ind-condition and the collab-condition with regard to the elements included in students' video analyses. Students of the ind-condition included significantly more often content- and medium-related elements in their analyses, while students in the collab-condition included significantly more often task-related and reflective-evaluative elements in their analyses. With respect to our research question 2, both tests showed that students differed in their cognitive processing, as students in the collab-condition examined the video in a more reflective-evaluative way than students of the ind-condition. Regarding students' emotional processing, the Chi-square tests demonstrated no differences between the two conditions, and the ENA also illustrated that students in both conditions included emotion-related elements (especially "transportation") in their analyses. Moreover, the ENA and the exemplary video analyses showed that collaboration does not per se lead to a more cognitive and less emotional processing of 360° videos, pointing to differentiated impacts of collaboration: While some groups in the collab-condition indeed examined the video in a critical, reflective-evaluative, and distanced way (see example #2), some groups processed the video in a more emotional and less critical way (see example #3).

Conclusion

The impact of collaboration on students' cognitive processing of an immersive and emotionalizing history-related 360°-video, as demonstrated by the findings of the present study, can be nicely described through the lens of both the ICAP framework (Chi & Wylie, 2014) and Bloom's taxonomy of educational objectives (see Krathwohl, 2002). However, these frameworks have to be treated with care due to the difficulty of empirically examining their theoretically assumed dimensions of cognitive engagement and processing (see Chi et al., 2018). Consequently, these two frameworks did not constitute our initial theoretical lens and, thus, did not affect the present investigation. Instead, they merely provide an interesting perspective on the interpretation of our findings. According to the ICAP framework, Interactive behaviors (i.e., arguing, debating, and discussing) and Constructive behaviors (i.e., generating "new ideas that go beyond the information given", Chi & Wylie, p. 222) constitute modes of high cognitive engagement with the learning material at hand. As collab-students focused more strongly than ind-students on evaluating the 360°-video in a reflective and distanced way by formulating their own critical conclusions, their cognitive processing of the video might be described as constructive and interactive. In contrast, as ind-students focused more strongly than collab-students on describing rather obvious and striking features of the video by summarizing its content and describing the features of the medium, their cognitive processing might be described as active. The ICAP framework describes activities in which learners only Actively repeat contents of the instructional material or just Passively receive instructions as modes of low cognitive engagement (Chi & Wylie, 2014). Moreover, according to Bloom's Taxonomy, activities such as summarizing constitute less cognitively complex processes than activities such as evaluating (Krathwohl, 2002). Consequently, ind-students' analyses of the 360°-video point to lower levels of cognitive engagement and complexity, while collab-students' video analyses suggest higher levels of cognitive engagement and complexity. This conclusion is also in line with the findings from Gokhale et al. (1995) showing that working in small groups promotes more critical-thinking processes than working alone.

However, although our findings suggest that a collaboratively conducted video analysis promotes a more cognitive processing of a history-related 360°-video than an individually conducted analysis, our results did not demonstrate significant differences in students' emotional processing of the video. Therefore, one could conclude that collaboration does not result in either more cognitive or more emotional processing of 360°-videos but that both processes can run in sequence (e.g. emotional followed by cognitive processing as in example #2). Alternatively, and as already discussed above, one could conclude that collaboration has differentiated effects on students' processing of 360°-videos and that these effects depend on the collaboration processes. This conclusion is in line with the "interactions paradigm" (Dillenbourg et al., 1996) emphasizing that collaboration is not per se effective for learning but rather particular interactions and processes during collaboration. To get insights in collaboration processes that promote either a more cognitive or a more emotional processing of history-related 360°-videos, it would be interesting to record and analyze the group discussions. As this was limited by feasibility due to the whole-class situation in the present study, it might be useful to collect process data of students' discussions in a lab setting in addition to the data from the field in a future study.

Abstract: Often intangible and invisible, relationships are pivotal in connecting soft/hard realities in ways that allow for participation in learning that imparts material and lasting impacts for marginalized youth experiencing complex, multidimensional barriers. We present the case of an immigrant Latinx youth who experienced *freedom of movement*—"supporting crossing physical boundaries of location, domain-specific boundaries of different topical areas, and conceptual boundaries of value and goodness of fit" (Pinkard, 2019, p. 40)—in an understudied area: culinary learning. We expand on the concept of *connective tissue* by analyzing a youth's movement across the Healthy Learning Ecosystem Framework to render visible the *relational connective tissue* that afforded freedom of movement across *infrastructures* of learning (Pinkard, 2019). Through an ecological life history case study approach, we demonstrate and discuss the potential that theorizing relational connective tissue holds in surfacing the assets Communities of Color bring to educational experiences, which presents implications for designing more equitably around how nondominant learners access freedom of movement across space, time, and multiple axes of marginalization.

Introduction

Prior work in the learning sciences that addresses equity through understanding how nondominant communities experience learning has pointed to the need to "understand how complex learning ecologies support learning," particularly for youth most overlooked by educational and learning systems, including "immigrant youth, dual language learners, and youth from under-resourced schools and communities" (Gutiérrez & Jurow, 2016, p. 566). This paper builds on how relationships affect how marginalized youth experience physical, social, and cultural realities—and by extension, how their learning is supported or constrained across their ecosystems and lifetimes (Pinkard, 2019).

Scholars studying geospatial space in tandem with sociocultural aspects of learning have created frameworks of analysis to render visible and improve upon the "interactions, routines, and practices" that afford or constrain learning (Erete et al., 2020, p. 1630). However, these social practices are deeply tied to relationships across the lifetime—which, despite holding deep political and materially transformative possibilities in learning (Freire, 1970), are often invisible and thereby difficult to track, and thus understudied in discourse around marginalized youths' learning experiences (Vossoughi et al., 2020).

We address this need by attending to how relationships inform realities of learning in a life history case study of an immigrant Latinx youth's learning ecology in an understudied area of the learning sciences, culinary arts. We apply an ecological framework that posits agency and exploration in learning as *freedom of movement,* and which makes explicit the various physical, topical, social/cultural boundaries (understood as *hard* and *soft infrastructure*) that youth traverse in their learning, as well as the strands of *relational connective tissue* that make such movement possible (Pinkard, 2019). We recognize the many possible forms connective tissue can take, and build on Pinkard's (2019) conceptualization of the concept to focus on theorizing connective tissue through the lens of relationality. We theorize relationships as central to connecting these infrastructures, and identify what we call *relational connective tissue* as invisible, intangible agreements and dynamics which constrain and afford various degrees of freedom of movement in a learning ecosystem. For learners from Communities of Color who experience disparities in accessing educational opportunities due to missing connective tissue, we highlight relational connective tissue as refigured stepping stones demonstrating rich cultural assets, typically overlooked by deficit lenses. The following question guides our inquiry into our case study: *What relational connective tissue mediated freedom of movement across physical, topical, and conceptual boundaries in an ecosystem of culinary learning for an immigrant Latinx youth?* This paper analyzes the retrospective life history case of Elias (pseudonymized), an alumnus of an out-of-school culinary arts program in Los Angeles. By identifying the essential role that relational connective tissue plays in bridging infrastructures of learning, we render visible inequities that shape the ways marginalized youth experiencing complex, multidimensional barriers (often preordained or transformed by relationships) experience and access learning across an ecosystem and lifetime.

Conceptual framework

We build on scholarship that makes visible the social practices that undergird learning, to consider what Vossoughi et al. (2020) refers to as the *relational histories* of learners and stakeholders in space. Specifically, we focus on the pivotal, connective role of relationships in learning across the lifetime—thereby expanding upon the ways sociocultural learning scientists theorize the role of relationality in the ways nondominant learners access and experience learning across time, as well as across the physical, social, and cultural spaces which comprise their learning ecologies (Nasir & Hand, 2006; Pinkard, 2019; Vossoughi et al., 2020).

We gravitate to the space of out-of-school culinary making for the dynamic, quotidian, and deeply imbued cultural nature of its learning—which lends to its significant potential for democratized, interconnected learning across a variety of domains, knowledge spaces, and critical competencies across the lifecourse. Of consequence, according to the US Bureau of Labor Statistics, nearly 30% of those employed in the food/service industry in 2021 were Hispanic/Latinx, 13% were Black and 7 % were Asian. While scholars like Scribner (1985) have documented the robust forms of learning and distributed expertise amongst dairy farmers, the extant literature in the learning sciences around culinary learning view it as a means to access more meaningful STEM learning (Clegg et al., 2010; Clegg et al., 2014; Yip et al., 2012). Though innovative, this focuses on an output of domain-specific learning in a controlled setting rather than what Pinkard (2019) refers to as *movement of learning*, which refers to a sociocultural conceptualization of learning across multiple physical and social boundaries from an ecosystemic lens.

We apply this view on learning to a case study of an immigrant Latinx youth to understand how culinary learning occurs across the lifecourse and beyond physical, social, and cultural spaces. Specifically, we focus on the concept of learning as *freedom of movement* in this paper to refer to the degree to which youth are able to engage in exploration and participation across a variety of boundaries—"physical boundaries of location, domain-specific boundaries of different topical areas, and conceptual boundaries of value and goodness of fit" (Pinkard, 2019, p. 40). We apply the Healthy Learning Ecosystem Framework (HLEF) to our case study to map movement across these boundaries and make explicit the factors that allow for such movement. HLEF consists of five domains strung together by *connective tissue—stakeholders*, *soft infrastructure, information infrastructure, hard infrastructure*—all leading to *outcomes* (Pinkard, 2019). This paper focuses on the operationalization of soft/hard infrastructures in order to further theorize connective tissue. Soft infrastructures consist of the abstract and institutional agreements which make learning possible, (*domain-specific/topical boundaries* and *conceptual boundaries of value and goodness of fit*). Hard infrastructure consists of the *physical or material boundaries* of learning such as the buildings, roads, and physical spaces through which learning occurs. Connective tissue serves then as the binding force between infrastructures, and can take many forms including but not limited to: caring adults in spaces that plan carpooling systems to shuttle youth between physical spaces of learning. Nonetheless, connective tissue may go overlooked in the design of learning opportunities, or center dominant forms of access and experience that lead to inequitable outcomes. We highlight these structural inequities and demonstrate some of the ways they are bridged by community stakeholders through the development of relational connective tissue across a learning ecosystem.

HLEF was intended for the collective sensemaking, improvement, and design of collaborative learning environments across different stakeholders of a learning ecosystem. We expand on this purpose by making explicit the pivotal roles various stakeholders play across the learning ecosystem in how learning outcomes are accessed and experienced, which can serve as focal points of design in learning ecologies. For the purposes of this paper, we further theorize connective tissue to focus on the concept of *relational connective tissue*—the relationships that often go "unnoticed," or unacknowledged, particularly within Communities of Color—to get at the often-invisible dynamics and (re)negotiated solidarities forged between community members, essential to tying together hard/soft infrastructures which constrain and afford freedom of movement for marginalized youth (Pinkard, 2019, p. 44). Our application of the framework presents an opportunity to understand how a marginalized youth experienced learning across an ecosystem across their lifetime, and elucidates some of the many essential relationships and intimacies within their community which connected them to experiences and opportunities which manifested into lasting, material impacts on their future.

Data and methods

This case study was one of 102 retrospective life history interviews, conducted ten years after concluding program participation, as part of a larger project around the long-term effects of participating in community arts programs. Given its holistic, reflective nature, our life history approach lends itself to understanding how learning was experienced and understood by a participant over the life course, and informed by their movement across physical, domain-specific, and conceptual boundaries. From the start, we bookmarked cases indicating tensions reflective of structural issues of marginalization across domains of their life to better understand how inequities shaped the learning experiences of the youth whom these programs most aimed to serve, both during and beyond the program space and time. Echoing factors of marginalization outlined in the extant literature, many of these cases tended to feature themes around immigration, dual language learning, socioeconomic status, and complex cultural narratives which came in tension with participants' interests and career choices (Gutiérrez & Jurow, 2016).

The study for this analysis was chosen as the only one in the sample for its focus in an understudied area in out-of-school culinary making which encompassed the aforementioned themes, and seeks to generate new insights around learning within this domain. The case is a life history interview with Elias, who at the time of the interview was a 22-year-old former participant of an out-of-school culinary arts program in the urban Los Angeles area. In a two-hour interview, the lead author asked Elias reflective questions spanning various life domains (i.e., home life, childhood, academic experiences, experiences in the OST program, current life and perspectives) to capture the role of relationships in his movement across a culinary learning ecosystem through seemingly disparate, yet interconnected nodes of his life.

Elias's case was chosen for analysis because it centers on how a nondominant learner navigated and experienced infrastructures usually taken for granted in learning: language and cultural acclimation to local space and culture. As a Latinx immigrant who did not know English moving through spaces of learning which lacked formal infrastructures fit for his needs, Elias nonetheless resisted in many ways and formed relationships that helped him participate meaningfully in culinary learning and all that came with it—traversing xenophobic negotiations of acclimation around language and local social dynamics, as well as cultural, gendered narratives around interests, and career aspirations. Through his time in the program and the relationships across his ecosystem, Elias learned English to deepen his culinary learning, and went from being a shy, introverted youth to one who starred in videos speaking enthusiastically about various curricula within the program—and who would later return as an alumnus employed in the culinary industry to speak about his experiences.

We chose Elias's case because it demonstrates the pivotal role of relational connective tissue in allowing not just access to learning opportunities, but *meaningfully experienced* learning for often overlooked marginalized youth that arose through relational histories to supplement minimal or lacking connective tissue in under-resourced areas. Elias's case exemplifies not only freedom of movement across various physical, cultural, and social boundaries for a nondominant learner—but also demonstrates the transformative potential of relationships on learning through the lifecourse across multiple barriers/axes of marginalization.

Analysis

Interviews were audio recorded, transcribed, and deductively coded for *soft infrastructure, hard infrastructure,* and *relational connective tissue* (Bingham & Witkowsky, 2021). In the context of our analysis, soft infrastructures consisted of school offerings, out-of-school culinary arts program offerings, and peoples' assumptions of culinary learning (i.e., learning about different countries and their cultural norms/cuisines, hydroponics gardening techniques, business pitch activities, field trips, etc.). The hard infrastructure consisted of the school, the culinary program space, the roads and transportation to each site, the tools students would use in their culinary learning, and the farmers markets, restaurants, and photo stores students would visit to learn about multiple aspects of the food industry. Relational connective tissue was mapped backward from interactions and routines featuring various stakeholders which made it possible for Elias to access these soft and hard infrastructures across the ecosystem (i.e., the friends who walked with him to school and the program through the city).

The lead author wrote reflective memos around excerpts, coded for relational connective tissue to surface insights around how relational dynamics shaped experiences around infrastructures, then clustered these memos and excerpts into the following three specific categories of boundaries traversed under hard and soft infrastructure which relational connective tissue bridged: *physical* boundaries (nested under hard infrastructure), and *domain-specific* boundaries and *conceptual/value-based* boundaries (both nested under soft infrastructure) (Pinkard, 2019).

Findings

In this section, we walk through the relational connective tissue which served as bridges for Elias's movement through physical boundaries, domain-specific boundaries, and conceptual/value-based boundaries. At the time of writing this paper, Elias works as an ingredient consultant and chef at a market/cafe in Los Angeles which offers produce and grocery products from around the world. He immigrated to California from Honduras in 2015, and experienced challenges to his participation in his educational pursuits across familial and academic spaces. In addition to difficulties in acculturating to a new space and common language, he was often bullied at school by peers, and even by educational staff, for his difficulties with English—describing his experience at school as being "traumatized with being in a cage." Elias found a "safe spot" in an after school culinary arts program in Los Angeles, and described the many ways his relationships with people in his life were central to moving through culinary learning. We emboldened excerpt segments exemplifying relational connective tissue for emphasis.

Relational connective tissue across physical boundaries

In this section, we analyze Elias's movement across physical boundaries, and relational connective tissue that aided and hindered such movement across the lived challenges of hard infrastructure for youth situated in downtown Los Angeles. He recalls the distance between his home, school, the culinary arts program, and the relationships around movement between these physical infrastructures (see Table 1).

Table 1

Finding 1: Relational Connective Tissue across Physical Boundaries of Hard Infrastructure

	Excerpts from Elias's interview	Researcher comments on relational connective tissue
1a	So, but **I had to walk like [...] around 10 blocks** from my house to the school and **I was feeling too scared because I, when I was going to school, I was going with my, one of my best friends**, that he is **still one of my best friends**, since we met in 2017. So we're still friends, so we were going, he was living close to me [...] sometimes he was like, because schedules change, so we have to um, um go in group because it was nice, you know, sometimes it was still, **the light was up**, but…[the program] was, it was close to my house, it was not too far, not too close.	Elias experienced safety concerns surrounding hard infrastructure as a lone youth getting around in the city, especially when it got dark. A close friend and group of friends accompanying him on his walk served as relational connective tissue connecting physical boundaries to help him get safely between home, the program, and school.
1b	**Sometimes [the program director] was also giving us a ride home** so she was very kind and, and very care person that she was like sometimes taking us home if it was super late and we were living super far and we were on her way.	Caring adults like the culinary arts program director comprised additional relational connective tissue between physical boundaries of the program space and home.

This finding exemplifies the importance of considering within a learning ecology how peers' and adults' solidarity around youth needs of accessing hard infrastructure play key roles in the ways youth are able to move across spaces of learning. In excerpt 1a, Elias refers to a reality and challenge which many youth face around transportation and safety in the city, and the commonly understood safety practices for youth getting around on foot—to "go in [a] group," and to do so when "the light was up." Elias refers to a relational history with one of his best friends that has continued "since [they] met in 2017" when describing the relational connective tissues tacitly understood by marginalized youth in urban settings (walking with friends) bridging his home, school, and subsequently the culinary arts program, which is located near the school.

Elias also speaks of another relational connective tissue to the physical space of culinary learning which highlights the unique affordance of the out-of-school space: the relationships youth form with caring adults in this space that are neither parents, teachers, nor caretakers. The resulting relational connective tissue between material spaces described in excerpt 1b are, in fact, made possible through *affective informality* (Chew et al., 2022) in the space—moments of rupture centering a political commitment to care, which result in new possibilities and intimacies—furthered by the familiar, typically domicile practice of culinary making. There is something to be said about the ways relational connective tissue is negotiated between stakeholders and hard infrastructures in urban settings around marginalized youth—the ways safety and varying resources among stakeholders are tacitly understood and arranged to result in relational connective tissue that makes freedom of movement across physical boundaries of learning possible.

Relational connective tissue across domain-specific/topical boundaries

In this section, we speak to the ways that relational connective tissue bridged physical boundaries to domain-specific/topical boundaries in Elias's learning. Throughout our talk, Elias spoke of the ways that not knowing English shaped the ways he was able to engage in educational spaces, and the ways people engaged with him—like the peers who bullied him, or the teachers who "[spoke] Spanish but [who] didn't want to speak Spanish to

[him].” In contrast to these in-school experiences, Elias recalls how relational dynamics differed in the after school culinary arts program, and how they aided his movement through various topical boundaries (see Table 2).

Table 2

Finding 2: Relational Connective Tissue across Topical/Domain-specific Boundaries in Soft Infrastructure

	Excerpts from Elias’s interview	Researcher comments on relational connective tissue
2a	It was super cool because **the environment in the program was about making feel people loved and welcome** and every time I would say, I wish I can, and I was telling everybody I wish I was, I was, like you, that you know the language you understand everything and if I was you, I would be able to answer all these questions and be on top of it, but unfortunately I am not. **And then people were helping me translating to [our program director], [to]** our interpersonal person that was helping us with our personal interpersonal skills, you know, it was, it was just a very lovely environment there.	Elias’s ability to access domain-specific knowledge shared in the culinary program is blocked by language barriers unaided by a lack of hard infrastructure in translation services. However, surrounding peers and program staff contributed to a positive environment through their patience and translation—serving as relational connective tissue for Elias to move across topical and domain-specific knowledge: linguistic, culinary, cross-cultural, agricultural, and socioemotional learning.
2b	And then **my English got better, then my anxiety got a little bit down, we learn how to do hydroponics, and interpersonal skills, uh, information about ingredients from other countries’ food, from other countries**, and it went so deep that it got my attention so much that [...] it took my mind off a little bit from the depression that I was going through, the anxiety I was having, it helped me a lot.	

In excerpt 2a, Elias highlights how his ability to access domain-specific knowledge is blocked by structural barriers of language (“if I was you, I would be able to answer all these questions [...] but unfortunately I am not”). This, in itself, reflects the barriers Elias experienced as an immigrant youth in acknowledgement of the missing connective tissue in place for him to move through culinary learning. However, in contrast to the complex language-based alienation he experienced in school settings, he emphasizes the *relational* connective tissue that allowed him access—the “lovely environment” people around him created which made him feel “loved and welcome,” and the translation that his peers would take up on their own accord since the program director and staff did not speak Spanish.

This finding exemplifies the importance of considering how proximal community members’ attitudes and actions around brokering soft infrastructure affect the degree of freedom of movement youth experience in learning. Where there was no connective tissue to soft infrastructures in place, endeavors of patience and care from the peers and adults in the program knit together the relational connective tissue that allowed Elias to move across topical, domain-specific knowledge (i.e., the linguistic, agricultural, interpersonal, and cross-cultural culinary learning as described in excerpt 2b). This cross-domain learning served meaningful in each domain-specific instantiation, and served as a solid foundation for culinary knowledge and learning which would later assist Elias in his professional journey through the culinary arts. Nevertheless, it also coalesced into an outcome more than the sum of its parts for Elias in the moment: helping him through the depression and anxiety reinforced by his experiences of acculturation. This movement, in tandem with Elias’s other movement through boundaries, exemplifies the potential of how broadened freedom of movement in culinary learning can be experienced, materially leveraged for future goals, and its felt restorative potential for marginalized youth experiencing a complex constellation of structural oppression lived in everyday ways.

Relational connective tissue across conceptual boundaries of value/goodness of fit

In this section, we speak to the relational connective tissue that worked in tension and tandem with Elias’s movement across conceptual boundaries of his values and perceived goodness of fit in culinary engagement. Elias reflects on his movement through how he perceived his goodness of fit in culinary spaces, as impacted through conflicting messages from family members and teachers (see Table 3).

Table 3

Finding 3: Relational Connective Tissue across Conceptual Boundaries of Value/Goodness of Fit in Soft Infrastructure

	Excerpts from Elias's interview	Research comments on relational connective tissue
3a	My dad at first, he wanted me to be a doctor [...] because my dad was a type of person that, who was [like] [...] **you have to do something that a man does because the kitchen is only for women** because when you come to the home when you, once you're married the woman has to have your food ready. **Because, it's a woman thing, you shouldn't be cooking.** So a couple of times, he hit me really bad because he found me in the kitchen.	Elias's relationship at home with his father constraints movement across culinary learning. His father expresses gendered perspectives around interests and future careers and punishes him for violating them—instilling in Elias negative perceptions of his goodness of fit in culinary spaces.
3b	But my grandma teaches something else right [...] my grandma was so patient, she was like your dad is wrong [...] So my grandma teach me how to cook. She showed me that not only womans cook, and **she showed me the movie Ratatouille,** and she said, you see all those people in there? **There's only one woman cooking. The rest are mans. Your dad is wrong.** And **she showed me Master Chef**, where I met one of my friends from the competition, and she said, "you see? **There's womans and mans cooking, your dad is wrong."**	Elias's relationship with his grandmother in the same familial space grants him movement across cooking, pop culture, and media spaces which allows him to renegotiate his goodness of fit in culinary spaces as a young boy with interests in cooking.
3c	So I got here, and one of my teacher, one day, my ELD teacher, she asked me, "**Elias, what do you want to do for life? For your life, for living in your future?**" I was like, "I don't know. I…I love cooking," but I felt afraid because of my dad. And I was not living with my dad anymore—but [...] I still felt scared and afraid for my dad—what if he finds out that I'm cooking, and he comes and hit me?	This excerpt highlights the role of caring adults in the learning ecosystem. These adults help Elias reframe his focus on what he wants to do for his future work. This interaction leads to further questions Elias has to negotiate in himself around what he values, is interested in personally and professionally.

In excerpt 3a, Elias describes the ways his relationship with his father around the domain of culinary engagement—and by consequence the gendered narratives his father expressed and punished him for violating—instilled fear and apprehension around the ways Elias regarded his values and goodness of fit in culinary engagement and spaces as a young boy. However, as exemplified through excerpts 3b and 3c, his relationships with his grandmother and ELD (English Language Development) teacher across domestic and in-school settings, Elias was introduced to different conceptual spaces to traverse, and found different narratives and cultural values that countered those shared by his father (that men *can* and *do* cook, and to center what *he* wants to do for the rest of his life) that asserted his personal feelings around goodness of fit in the culinary landscape. His grandmother's use of various food-centered media (Ratatouille, Master Chef), further introduced digital, popular cultural spaces which Elias moved through to renegotiate his understandings of how he fit in culinary spaces as a young boy negotiating gendered conceptions around culinary practice.

These interactions demonstrate the ways that relational connective tissue set up conditions for Elias to move across considering culinary practice as an interest to a career possibility. Despite strong, reinforced discouragement from his father, Elias's relationships with other caring adults in his life who centered and supported his interests in their interactions allowed him to focus on honing his emerging personal values and explore how he perceived his goodness of fit, and ultimately his career path, in the culinary arts. Excerpts 3b and 3c demonstrate how relational connective tissue facilitated movement across conceptual values, which was pivotal in the negotiation of meaningful, lasting material decisions a marginalized youth made around his professional career directions. This finding exemplifies the importance of considering how the conceptual narratives around participation, values, and goodness of fit youth are exposed to through their relationships affect the ways youth are able to and ultimately decide to move—or not move—through learning.

Conclusion, limitations, and future directions

Through our analysis, we demonstrate how theorizing relational connective tissue highlights an undiscussed point of focus in the design and improvement of learning: the roles that various stakeholders play in how marginalized youth may access and experience movement across a learning ecology, across the lifecourse. Elias's case demonstrates the ways in which relationships often undergird lasting, material outcomes on the decisions, directions, and development of marginalized youth. His movement across physical, topical, and conceptual boundaries of culinary learning was made possible through pivotal interactions—not purely one-off, serendipitous interactions, but interactions rooted in relational histories and tacit interpersonal negotiations. Moreover, this mode of navigation speaks to the community cultural wealth (Yosso, 2005) inherent in marginalized communities—that of Elias, his friends, family, and peers—which is apparent through the ways Communities of Color knit relational connective tissue to hold one another, and supplement where connective tissue may otherwise be missing.

By understanding how relational histories tie stakeholders, infrastructures, and outcomes together, frameworks such as HLEF can be leveraged by stakeholders across learning ecologies to ensure that expanded learning opportunities are accessed and meaningfully experienced by marginalized youth in urban settings. Our ecosystemic analysis signals the importance of bringing together various community stakeholders, spaces, and opportunities in the design and support of freedom of movement across a learning ecosystem for youth facing varied, complex barriers to access and participation. Stakeholders across in-school and out-of-school settings can work together to surface the ways relationships are currently supporting or constraining the ways youth access learning infrastructures. With these insights, stakeholders can collaboratively design intentional safeguards and policies that function in ways similar to relational connective tissue to more systematically and equitably support the ways marginalized youth are accessing and experiencing learning across the ecosystem.

Elias's case demonstrates the unique affordance of out-of-school culinary learning as a naturalistic, culturally-imbued venue of learning dynamically cultivated through familial histories, (re)negotiation of tensions, values, and solidarities—rich with potential to study how sociocultural learning map onto issues of equity for nondominant learners through the learning sciences. Future work around culinary learning which examines quotidian relationships "through the prism of race, class, geography, and history" (Pinkard, 2019, p. 44) can speak to ways the domain can be leveraged for democratized learning opportunities and design which support freedom of movement in and beyond currently conceptualized boundaries and spaces, as well as speak to the experiences and realities of people from a range of diverse, marginalized populations.

Constructing “Kinds of People” With Data in Classroom Talk: Operationalizing Racial Data Literacy

Josh Radinsky, University of Illinois Chicago, joshuar@uic.edu
Iris Tabak, Ben Gurion University of the Negev, itabak@bgu.ac.il

Abstract: In this conceptual paper we use vignettes from classroom interactions to examine the construct of *racial data literacy*. Two cases of teaching and learning with data visualizations about racialized populations in the United States – African Americans and Mexican Americans – are used to illustrate the ways racial literacy and data literacy can intertwine in classroom discourse, with stakes for learning and learners. Examining our own teaching, the paper invites the Learning Sciences community to take up the project of further operationalizing racial data literacy, and building a shared understanding of how we can promote it in classroom practice.

Introduction: Where are we with *racial data literacy*?

In 2016 Philip, Olivares-Pasillas and Rocha published the paper “Becoming racially literate about data and data literate about race” (Philip et al, 2016), which has been cited over 100 times. In part a cautionary tale, they argued that the push to integrate data literacy into school subjects has overlooked the ways race and data come together in classroom talk. Their call for “racial data literacy” has been echoed by many learning scientists (e.g., Lee, Wilkerson & Lanouette, 2021; Warren, Vossoughi, Rosebery, Bang & Taylor, 2020), but much work remains to articulate how such a literacy develops. Philip et al’s *racial data literacy* includes the capacity to critically interpret data that invokes the concept of race, while recognizing the ways societal meanings of race can be reproduced, challenged, or transformed through the use of data. It combines sensitivity to the operations of power and ideology in racialized discourse, with awareness of the ways data are used to construct models of social phenomena.

In this paper, we advance the understanding of racial data literacy by examining our own attempts to develop it in instruction, using examples of classroom interactions to highlight particular attributes of race-talk with data. This is primarily a conceptual paper elaborating the construct of racial data literacy, using classroom vignettes as illustrations of these ideas. We present two classroom discussions of data visualizations in which racialized identities become both the focus of instruction, and also the field of identity positionings made available for participants in the discourse event. The depictions of teaching and learning in the vignettes are not presented as models of exemplary practice, nor as empirical evidence of learning, nor as cautionary pitfalls to be avoided. Rather, they offer insights into moments in classroom talk in which racial literacy and data literacy come together. We explore them for the purposes of more clearly operationalizing the construct, and better understanding the sometimes-complex interactional dynamics that accompany data-mediated discussions of race and racism.

Theoretical framing: Making up “kinds of people” with data

Philip et al (2016) illustrated the ways racial identities and ideological discourses are negotiated and contested in moment-to-moment classroom interactions. While any text can be invoked in these processes of positioning and contestation, data play a particular role in sense-making about race. Representational practices involve the interpretation of data to invoke a “represented world” in the shared discursive space (Latour, 1999). We follow Radinsky (2020) in operationalizing data as “representations of quantity, space and time – numbers, charts, graphs, maps – as they are mobilized for inquiry and argumentation” (p. 375), with a particular focus on the kinds of demographic data used in the social sciences. Hacking (2007) points out that *kinds of people* get “made up” through processes of creating and using such data. The categories are brought into being by institutions and experts, with consequences for the experiences and identities of the people to whom these categories get applied.

Data literacy and racial literacy are competencies that often fail to come in contact with each other (Benjamin, 2019): one can be a highly competent data scientist in other respects, yet incompetent in recognizing ideological and interpersonal racial dynamics, and vice versa. Racial data literacy requires an awareness of the processes of “making up people,” by which categories of people are brought into being through classification systems, and the ”looping effect” by which “the classified people enhance and adjust what is true of them” (Hacking, 2007, p. 289) *(1)*. Making sense with social-scientific data involves participating in these processes.

Methods: Data collection and analytical approach

The classroom discussions analyzed here are drawn from a program of design-based research in which online geographic information system (GIS) tools were deployed in the development of curriculum to study migrations of different populations in the history of the United States. The project included middle school, high school, and college classrooms, and involved collaborating teachers at each level in the design of curriculum materials and assessments, as well as co-teaching lessons. The excerpts analyzed here are drawn from one of the middle school classrooms (Case 1), and one of the first author's undergraduate, pre-service classrooms (Case 2).

Class sessions were videotaped by a research assistant and transcribed by a member of the research team. The two classroom discussions analyzed here were among several identified in the larger data corpus as events in which racialized people were the focus of the historical discussion, and in which racialized identities were at stake in the discursive event. For the present analysis, the authors coded each transcript to identify discursive moves that invite, model, or give feedback on racial characterizations; take up, shift, or challenge racializations of people and/or data; or exemplify data visualization practices explicitly or implicitly valued in the lesson. We focus on the ways racialized identities of the people in the room might be engaged by these moves: risks, exposure to extant racial narratives, opportunities for epistemic agency, and constructions of agentic racialized identities.

The first author's analysis of race talk in classrooms is mediated by his identities as a White educator, a co-teacher in Case 1, and instructor in Case 2. Facilitating classroom conversations about race, particularly as a White teacher with students of color, creates power dynamics that can undermine honest, open discussion of race and racism, requiring work to build trust and establish shared norms and understandings (Conklin, 2022). Given the prevalence of White educators in American schools, we see this as an opportunity to understand how racial data literacy can develop in such classrooms. There is also a risk of teacher-researchers telling stories of their own practice being overly self-congratulatory, overly self-critical, or otherwise untrustworthy. In studies of race talk, there is a risk of a White research perspective perpetuating dominant narratives about people of color and White people alike. The second author was not present in either classroom, and her White identity is nuanced by being Israeli, affording an "insider-outsider" perspective on race talk in American classrooms, challenging and exploring the interpretations of the first author, and making implicit assumptions explicit for inspection. We seek to leverage insights from these contrasting perspectives, while maintaining a non-evaluative yet critical analytical stance.

Illustrations: Negotiations of racial data talk in two classrooms

Case 1: Co-constructing 100 years of Black and White people on a US map

The focal lesson was the first day of a 7th grade social studies unit in a neighborhood public school whose enrollment was identified by the district as 99% African American, in a hyper-segregated Black Chicago neighborhood. In a whole-class discussion, the teachers used an exploration of a USA population data map, created with the website *Social Explorer (2)*, to introduce historical African American migrations. The classroom teacher and co-designer of the unit was a Black woman, and the researchers were a White man (co-teacher, first author) and a Black woman (research assistant). Five aspects of the discourse are illustrated here: 1 normalizing talk about race; 2 making it OK to talk about White people; 3 maintaining an inquiry stance through strong emotional reactions; 4 adopting a Black perspective in sense-making about a represented world of Black people; and 5 looking closer at surprising data.

1.1. Normalizing talk about race

The data talk in the lesson included repeated and specific references to people as "African American" and "Black," the two terms used interchangeably by both co-teachers. While students would initially refer to the data as "people" without any racial indicator, the teachers modeled making "clear and specific observations" that included racial identifiers, and scaffolded students' use of the labels when they left them out:

63. Student: There's a lot of people over there [*pointing to map*]
64. Co-teacher A: There's a lot of people over there. Specifically? [*pointing to data legend*]
65. Multiple students: African American people
Similarly:
89. Student: More people in Louisiana than in Washington
90. Co-teacher A: He picked two places, Louisiana and Washington. Louisiana had more -- ?
91. Student: Black people
92. Co-teacher A: More Black people in -- ?
93. Multiple students: 1910
94. Co-teacher A: In 1910. Now we got a nice, specific comparison: Louisiana had more African American people than Washington in 1910.

This modeled the appropriateness of mentioning race, as part of data practices. Altogether there were 77 mentions of racial identifiers in the 20-minute discussion, with an increasing share of them coming from students as the lesson progressed. In the context of building racial data literacy, it is hard to overemphasize the prevalence of "colorblind" discourse in American classrooms (Bonilla-Silva, 2006; Stoll, 2014). When teachers use euphemisms for racial categories, students may also avoid mentions of race, or use them as potent, counter-script disruptors. Having Black and White co-teachers both insisting on clear and consistent use of these labels with the data created a context in which talking about race became normalized. The interchangeable use of the terms "Black" and "African American" also supported this normalization, as "Black" better matched discourse norms in the larger community, offering a less formal name for students' own identity.

1.2. Making it OK to talk about White people

A key development in the progress of the lesson was when a student introduced White people into the discussion: "Arkansas had African American and Whites, but more African Americans because it was a little bit darker at the bottom [*gestures*] than at the top." Another student picked up the idea and asked about states that had very few Black residents in 1910, and both teachers encouraged the questioning:

119. Student 2: The other states, they're all White people there?
120. Student 3: Yup
121. Co-teacher A: In these other states, does that mean it's all White people? [*pointing to map*] Up here? Over here? …
123. Student 4: No
124. Co-teacher A: Well, she asked a question, that's how you do research – you ask a question because you're curious about it. [*Reads through population variables in the map, finds % White.*] You want to check and see?
125. Students: Yeah … …
127. Co-teacher B: Predict – how do you think it's gonna change?

This shift to attending to the White population persisted through the rest of the discussion. American taboos often prevent teachers from talking about race, but we have noticed that many teachers are more likely to racialize Black people in classroom talk than White people. Students' move to ask about White people in the map, and the teachers' endorsement of the query, created space for more authentic questions about racial history.

1.3. Maintaining an inquiry stance through strong emotional reactions

The switch of the 1910 map from representing African American population to White population, in response to the question by Student 2, created a strong reaction in the classroom. Figure 1 juxtaposes the two maps.

Figure 1

Reproductions of maps: (a) African American % by county, 1910, (b) White % by county, 1910

(a) *(b)*

The map depicting White population (Figure 1b) makes the Black population (1a) appear tiny, beyond the reality of the data: many of the 90-100% White counties in the map's center (darkest color) had very small total populations, while large Black population concentrations in the southeast are not discernable in the visual language of the choropleth map (see Radinsky, Loh & Lukasik, 2008, on design tradeoffs of choropleth versus scaled centroid maps). The reveal of the overwhelmingly-White map created a palpable feeling of diminution of the Black people in the represented world, reverberating into the classroom. The volume and energy rose, with cries of "Daang!," "Woah!" and "That's crazy." The teachers pushed students to describe what they observed:

131. Co-teacher A: What happened? … [*to Student 2*] Did you get an answer to your question?
132. Student 2: Yeah
133. Co-teacher A: OK, let's listen to her
134. Co-teacher B: OK, what did you conclude from that? Your observation? You asked the question, is the rest of the United States all White. …What have you observed?

The first observation, co-constructed by the class, was that "The majority of … the United States in 1910 was … White." In this moment, there was a danger of this simple observation being interpreted as "the point" of the data visualization, foreclosing further investigation. Both teachers quickly pushed for more close observations:

> 140. Co-teacher A: Anyone want to make a more – this is an interesting map, this is very different from the other ones …
> 143. Co-teacher B: Make some observations about this map.

1.4. Adopting a Black perspective in sense-making about a represented world of Black people

Student 5, whose hand has been strenuously raised for some time, shares an explanation:

> 145. Student 5: I think that, we observed that the population, most of the population was down in the South, most of the Black people. Most of the slavery was down there — slavery had just ended, and since most slaves ran away, they didn't know, {in the North} they didn't have a place to go so they stayed in the South.

Student 5's narrative offers an explanation for the concentration of the Black population in the Southeast (Figure 1a), contextualized by the overwhelmingly White population outside that area (Figure 2b). His comment shifted from the shock of the 1910 White map to a reflective, historical account from the perspective of Black people in 1910, post-enslavement yet still concentrated in the South, trying to find another place to go. Both teachers ratified Student 5's comment as a "very good observation."

1.5. Looking closer at surprising data

Student 2 raises her hand and, rather than build on Student 5's comment, returns to the overwhelmingly-White 1910 map with a question: "In Illinois it was all White … in Chicago?" Co-teacher A models how to click on the map to find data values, confirms Chicago's location in Cook County, and clicks to get the 1910 White population:

> 156. Co-teacher A: Cook County, we're in Chicago. Let's see if I can click on it, just as an example, here we go [*clicks, data window appears*]
> 157. Student: Dang!
> 158. Co-teacher A: [*pointing to data window*] In Cook County in 1910 there were 2,405,233 people in Cook County. Out of all those people, how many of them were White people?
> 159: Students: 98%
> 160. Co-teacher A [*pointing to data window*]: 98%
> 161. Student 2: So the other 2% was what?
> 162. Co-teacher A: The other 2% was what? I don't know. Could be Black? What else?
> 163. Multiple students: Hispanic. Mexican. Puerto Rican

Whereas Student 5 drew back from the data to seek a historically-referenced explanation, Student 2 zoomed closer into the data map to seek a data point relevant to her life in Chicago. Having asked if it was "all White" and then found that it was 98% White, she immediately sought clarity about the other 2%, thereby helping the class think beyond a Black/White binary of race. We return to these observations in the cross-case discussion.

Case 2: Accounting for missing Mexican people in US census data

The focal lesson in Case 2 was part of a curriculum unit in an undergraduate, pre-service, elementary education, social studies methods course taught by the first author, examining the theme of migrations. In it, pre-service teachers (PSTs) represented their own family migrations to Chicago on maps and timelines; read Takaki's (2012) *A Different Mirror: A History of Multicultural America*; and used children's literature on African American, Mexican, and other migrations. The class was racially and ethnically diverse, with a majority of Latinx students.

Through a jigsaw lesson, the PSTs used the GIS website *Immigration Explorer*, a free, online resource created in 2009 by the *New York Times* for browsing historical census data for the years 1880-2000, to study waves of immigration. The GIS displayed the number of people identified as foreign-born in the census for each US county in each decade, from 23 countries-of-origin. After a preview of the site, each group of PSTs chose one country-of-origin immigrant population to study. The analysis here focuses on one group's discussions in their small group, consisting of two PSTs who self-identified as Mexican (Rogelio and Yesenia, pseudonyms) and one non-Mexican, White PST (Jesse, pseudonym), as they examine the data for Mexican-born people *(3)*. Six aspects of the racial data discourse are illustrated here: 1 seeking an explanation for a data anomaly; 2 questioning candidate explanations for data patterns; 3 personalizing “horrible data”; 4 attributing agency to Mexican-born people in the represented world; 5 maintaining an inquiry stance through strong emotional reactions; and 6 narrating racism and oppression into the represented – and representing – world.

2.1. Seeking an explanation for a data anomaly

One of the notable features of the “Born in Mexico” data set is the disappearance of nearly all counties’ data in 1930, reappearing in greater numbers in 1940. The group discusses possible explanations for this anomaly. Rogelio has read in the Takaki book that Mexicans were deported in large numbers at the start of the Great Depression, and Yesenia and Jesse contemplate the enormity of Rogelio’s explanation for the missing data, deportation, which has the authority of a history text to support it, and the specificity of 400,000 deportations:

> 291. Yesenia: They deported all the Mexicans?
> 292. Rogelio: Not all of them, they, um, 400,000 of them
> 293. Jesse: In the United States as a whole?
> 294. Yesenia: That’s insane, look at that [*waves hand around counties in the Southwest with Mexican-born population in 1920*], they like, they were pretty –
> 295. Jesse: They were all over! [*hand gesture showing data distribution*]
> 296. Yesenia: Yeah!
> 297. Jesse: I think – I mean --
> 298. Yesenia: Look at this!
> 299. Rogelio: They weren’t just deport - After the Great Depression they *started* deporting them

2.2. Questioning candidate explanations for data patterns

Some doubt remains about whether deportations could account for the disappearance of nearly all the data in 1930, or whether they might be seeing a decrease in total population rather than just the population of immigrants:

> 378. Jesse: Well you gotta look at the population as a whole, though, cause we’re only looking at the immigration, but the [*gestures*] population might be getting cut short too so I mean –
> 379. Yesenia: That’s a good point. So it’s at – … …
> 383. Jesse: Because I think these circle sizes are relative, are the immigrants relative to the total population, so –
> 384. Yesenia: [*checking total population*] No! It’s still – no, the total population stays the same.

Yesenia remains unconvinced that deportation accounts for the 1930 data anomaly, returning to the topic. Yesenia weighs Jesse’s candidate explanation (an overall drop in total population); disproving it with the data; doubting the adequacy of Rogelio’s deportation explanation (despite his insistence); and questioning the data visualization as possibly distorting the data (“Maybe it’s just the mapping?”):

> 414. Yesenia: I’m confused – I still want to know what happened in 1930
> 415. Rogelio: Like I said, the deportation -- deportation
> 416. Yesenia: Deportation, was it just that though?
> 417. Rogelio: Well, the Great Depression, the Great Depression, people were probably leaving too, there wasn’t that many jobs anymore
> 418. Yesenia: Was it only that? Maybe it’s just the mapping? Let’s check that

2.3. Personalizing “horrible data”

Yesenia is unable to find another immigrant group with a similar disappearance in 1930, eliciting a teasing joke from Jesse (the only non-Mexican group member):

> 426. Yesenia: So yeah. So it’s really just Mexicans
> 427. Jesse: Sorry guys! [laughs]
> 428. Yesenia: That’s horrible {data}. That’s ridiculous.

It is unclear whether Yesenia’s reaction (428) is in frustration with not finding an explanation, or irritation at Jesse’s personalization of the data about Mexican-born people as representing Rogelio and Yesenia (“Sorry guys!”). This may make Yesenia feel vulnerable by belittling the disappearance of Mexican-born people.

2.4. Attributing agency to Mexican-born people in the represented world

Rogelio seems to pick up on her vulnerability, and extends the narrative beyond their disappearance:

> 429. Rogelio: Yeah but in the '40s they came back, they came back in the '40s, they say in the book you know, they found it easy to cross back to the U.S. anyways, so they just did that
> 430. Yesenia: And they even started expanding toward the Midwest [*gesturing on 1940 map*]

Here Rogelio and Yesenia recover the narrative of the Mexican-born people who may have been deported out of the 1930 map, using the Takaki book and the 1940 map as resources to replace them in the historical narrative with greater agency ("they came back"; "even started expanding"). When the instructor (first author) comes to talk with them shortly afterwards, Yesenia offers another possible reason for the data disappearance:

> 464. Instructor: So did all those deported people get back across the border?
> 465. Yesenia: Or maybe they just didn't report themselves
> 466. Jesse: That's, that's another possibility. Cause if they didn't want to be {deported}

This explanation goes further in attributing agency to the represented Mexican-born people. Their absence in the data may be explained by their own decision not to "report themselves" to census takers, especially in the context of widespread deportations described by Rogelio. The attribution of agency to Mexican-born people clearly gave Yesenia a sense of pride in her personalization of the data. This was seen earlier, when she navigated to the 1970 map and moused over Cook County, where a large bubble indicated a growth in the Mexican-born population of Chicago: "This is when young Pops came, in the '70s. Boom! My dad was part of that." This connection is not only an individual celebration of her father, but also tied to her Mexican identity: the "Boom" is a celebration of the visible growth of the Chicago Mexican community.

2.5. Maintaining an inquiry stance through strong emotional reactions (again)

Bubble maps like *Immigration Explorer*, when animated to show change over time, sometimes elicit emotional responses. For example, when another student presented her group's findings about the Ireland-born population decreasing by decade in the 20th century, her animation of the maps brought a round of laughter from the class: "And then as the years go by the waves of immigration are starting to decrease. … [*sliding the timeline control forward through the decades*] And then as you can see its still getting smaller -- smaller – smaller – smaller – smaller" [*general burst of laughter*]. The historic progression of the Mexican-born bubble maps presents a very different animation (Figure 2). The growth of these absurdly oversized county-centered circles elicited strong reactions ranging from giggles to laughter to sounds of alarm during the whole-class presentation. Some students used sounds like "Boom!" which appeared to show pride or joy at the giant circles, but others seemed to react to the image as menacing. In a different class, a student referred to the 2000 map image as "messed up," suggesting that it made Mexican immigrants seem dangerous. This animation could thus intersect with extant racist narratives that provide specific, racialized meanings to the data graphics (Radinsky, 2020).

Figure 2
Maps showing increasing Mexican-born populations by decade: (a) 1970, (b) 1980, (c) 1990, (d) 2000

(a) *(b)* *(c)* *(d)*

During small group work, Yesenia seemed to react to the overwhelming bubble size in the 2000 map. She sought data that would show a decrease in Mexican-born populations in the years after 2000. Yesenia's desire for data that she believes must exist ("I want to see a decrease," 497) drives her to go beyond the GIS, wanting to find a decrease in Mexican-born population to counter the map's implicit narrative:

> 495. Yesenia: You know what I'm looking for, I'm looking for the … I don't see them -- I don't see them decrease, like, I don't know where {to look for that …} Remember about that law?
> 496. Rogelio: I think between this [*2000 census*] and the 2010. You were probably seeing –
> 497. Yesenia: No but like the decrease. I want to see a decrease in it. [*gesturing on the map*]
> 498. Rogelio: You'll probably see it in the next one, 2010 census. I think so between 2000-2010
> 499. Yesenia: What's that law called?

500. Rogelio: A lot of the stuff came out after the whole Patriot Act [*Yesenia googles the act*]

2.6. Narrating racism and oppression into the represented – and representing – world

Jesse comments that the Patriot act "instilled the fear of foreigners," which elicits a direct, personal explanation:

501. Jesse: Oh yeah, the Patriot Act, yeah. Instilled the fear of foreigners, yeah.
502. Yesenia: Do you know how bad it is? It's horrible. That's why my friend moved over here
503. Jesse: What's horrible?
504. Yesenia: Like they, they just like, they hunt you down basically
505. Jesse: Uh -- where? Or -- the - immigration?
506. Yesenia: I guess -- there'll just be kids who look Hispanic, or look non-White, and then just go like, flump! [*hand gesture*] You're for deportation. And apparently they warn each other, so if they're like at a grocery store they'll warn each other – that sort of thing
507. Jesse: In Arizona?
508. Yesenia: [*Nods*] That'd be, that'd be {inaudible}
509. Rogelio: Even if you aren't [undocumented] it would just be
510. Yesenia: It would just be scary. What if they don't believe you?
511. Rogelio: No, cause that's what even -- cause some of the people who got, like, sent back during that time period, during the 1930's, some of them were United States citizens and they still got sent to Mexico
512. Yesenia: See? See that is a possibility. They don't believe me, like, "Oh, what are --"
513. Jesse: Oh, I mean it's a little bit more far-fetched today, because there's different – [*awkward hand gesture and smile*]
514. Yesenia: You'd think so –
515. Jesse: You'd think so. Of course there's gonna be, there's gonna be those select few people that are like, "Send them all home," but –
516. Yesenia: I remember my sister went to go get her taxes done, and the guy was like, "Are you a legal citizen?"

In this exchange Yesenia and Rogelio build on Jesse's comment "Instilled the fear of foreigners, yeah" (501) by shifting the tone from one of detached, historical investigation to one that is immediate and personal. Yesenia locates the "horrible" racism in her friend's need to move from Arizona, where "they hunt you down" if you "look non-White." They emphasize how this would feel (lines 508-510), and Rogelio underlines the reality of the scenario by corroborating it with the historical record from the 1930s (511). Jesse shows doubt about this account being relevant today (513, 515), calling it "far-fetched" and attributing racism to "those select few people," prompting Yesenia to offer the example of her sister being confronted by her own tax preparer. Importantly, this clarification about the realities of racism is directly relevant to the data-based inquiry they are engaged in. This racial awareness is necessary for the group to evaluate alternative interpretations of the data set.

Discussion: Emergent themes for teaching and learning racial data literacy

Numeracy and statistical competencies are interdependent with racial competencies

In each of these classroom discussions we see specific competencies for reasoning with data: making clear and specific observations, distinguishing among available variables, distinguishing intensive from extensive measures, questioning the reliability of data sources, and evaluating competing interpretations. We also see specific competencies for reasoning about race: naming and distinguishing racial categories, contextualizing racialized experiences in historical contexts, considering the impacts of racism on racialized people, questioning whether the "kinds of people" represented in a dataset accurately reflect the people in the represented world. As Philip et al (2016) suggest, these sets of competencies should not be considered separately from each other in understanding the learning opportunities available in this classroom talk. They necessarily must advance in tandem, in order for these learners to make sense of a racialized social world with these data.

Managing the social-emotional risks and vulnerabilities of racialized data

In each case there were moments when the data interpretation was placed at risk by an emotional response to an unanticipated impact: the reactions of "Daang!" "Woah!" "Boom!" "That's messed up" – or simply laughter. Palpable in such moments is the risk created for learners whose identities are at stake in the societal narratives that are invoked, with a risk of students of color withdrawing from discussion. The cases above suggest possibilities for how classroom talk can maintain an inquiry stance through such moments, allowing learners to process both their emotional responses and the inquiry focus. In Case 1, after being encouraged to make more careful observations from the overwhelmingly-White 1910 map (beyond "The US was mostly White in 1910"), Students 2 and 5 each offered a next step for making sense of the realities of Black people in 1910. In Case 2, Yesenia pushed her group-mates to help her go beyond the off-putting impact of the giant circles on the Born-in-Mexico map to construct a counter-narrative ("the decrease"), and to take seriously the racism inherent in narratives about dangers of Mexican immigrants that lie behind unjust deportation policies.

Curricular positioning of different racial identities

Teaching with data that offers personal connections can provide deep opportunities for learning. When the connections invoke racialized identities, people who are racialized differently – learners and teachers – are positioned differently. A Black teacher and a White teacher position students differently when they ask them questions like, "Is the rest of the United States all White?" (Case 1, lines 121 and 134). Similarly, the discussion in Case 1 would proceed very differently with an all-White class than an all-Black class, in ways that need to be explored empirically. Similarly, Yesenia and Jesse experienced different emotional involvements with the data as they explored the history of Mexican migrants. Jesse, who is White, joked with his Mexican group-mates about them disappearing (line 427). Yesenia, on the other hand, had to manage strong emotional reactions to the "horrible data" (428), and reveal painful realities faced by her friend, sister, and imagined self being deported due to racism. This inequality of stakes and vulnerability is an essential consideration for teaching racial data literacy.

Conclusion

Studying our own teaching, and building a clear and explicit set of considerations to inform the design and enactment of lessons, units, and practices, are promising directions for deepening our understanding of racial data literacy. This paper invites to the larger learning sciences community to take up this project together.

Endnotes

(1) Hacking's (2007) mechanisms for "making up people" exclude consideration of "race science," but his framework accounts for the categorizations in the U.S. census, from which the data in these classrooms were drawn, and the corresponding dynamics of individuals, institutions, knowledge and expertise.

(2) Social Explorer^{TM} (http://www.socialexplorer.com) is a public-use and privately-licensed online resource with a free census data browser (used in Case 1), as well as a for-profit company which licenses a paid version. The first author has no financial interest in this company, but has a long-term research collaboration with Dr. Andrew Beverage, its CEO.

(3) Distinctions among national, ethnic and racial categories are constructed, contested (Chávez-Moreno, 2021), and change over time. Mexican and Mexican-born are not recognized in social-scientific parlance as racial categories, but anti-Mexican narratives common in US politics, discussed by the PSTs, are racist, and racialize Mexican identity.

Maker Identity Development: What and How?

Ashita Bawankule, University of Illinois Urbana Champaign, anb8@illinois.edu
Mike Tissenbaum, University of Illinois Urbana Champaign, miketissenbaum@gmail.com

Abstract: Focusing on developing maker-identities, especially for historically marginalized students in the computational field, can empower them to recognize and take ownership of their space in the field. Drawing from identity related literature in maker and computing related fields we identified seven factors of maker-identity - interest and motivation, competence and performance, confidence and self-efficacy, recognition, utility value and meaningfulness, perceptions of community, and external factors. Using this, we analyzed semi-structured interviews of students who participated in our summer makerspace camp to understand how these identity factors manifested in their reflections of the camp. We tie back our findings of positive impacts on maker-identity structures to the design structures of our makerspace such as co-design of the space, use-modify-create strategies, and open-ended design projects.

Introduction

Despite efforts to allow for participation and engagement of historically marginalized racial, ethnic and gender groups in STEM and computing fields, its demographic distribution is nowhere close to reflective of the general population. NACME's 2021 Research Brief showed that despite over 30% representation of underrepresented minorities in the United States, they only represent 18% of computer (CS) and information (IS) sciences and 15% of engineering bachelor's degrees. Hispanics or Latinos earned only 10% of CS and IS and 11% of engineering degrees, and Black or African Americans only earned 8% and 4% respectively.

Makerspaces are one approach that scholars, practitioners, and administrators recognize as having the potential to address this issue given their ability to provide students with access, resources, expertise, and a space to engage in hands-on computing and STEAM activities (Halverson & Sheridan, 2014; Blikstein, 2013; Presidential Proclamation - National Day of Making, 2014).

However, lack of access is only one of the innumerable barriers that minoritized youth must face when navigating the fields of STEM and computing. Despite their potential to bring more people into CS and engineering, makerspaces continue to be mostly dominated by White and Asian males. Thus, with systemic racism and traditional gender norms having impacted these fields over the years, access to makerspaces alone is not going to allow traditionally minoritized youth to recognize it as a space for them and to start engaging in these activities as their own. To make these spaces more inclusive and inviting to these young learners, we need to design these spaces and their curriculum in ways that are more culturally responsive and empower them to engage with the material on their own terms (Scott et al., 2015).

Various factors impact how students learn. As highlighted by Vermunt (1996) and Trujillo & Tanner (2014), cognition, metacognition, and affect play a role in learning; cognition being the mental process associated with learning, metacognition being the awareness of those processes, and affect dealing with the feelings arising when learning. In the case of historically marginalized students, who have received implicit and explicit messages about their participation in STEM and computational settings, affect is a very important factor to consider. As detailed by Trujillo & Tanner (2014), the affective domain consists of - but is not limited to - self-efficacy, sense of belonging, and science identity. Further, as discussed by Nasir & Hand (2008), identity, engagement, and learning are heavily intertwined such that when an individual feels that their identity is linked to a setting, they are more engaged and learn more. Additionally, while there has been research recognizing the importance of identity in CS and engineering (Mason & Rich, 2020; Godwin, 2016), there has been far less research on how this manifests itself in computational makerspaces specifically, and even less on what specific constructs define one's maker identity. In response, as part of a two-week long makerspace with students from Black/African American and Hispanic/Latinx communities, we aimed to understand the following two research questions:

1. Which factors of our participants' computational maker identity did our makerspace impact and how?
2. What particular design structures of our makerspace and curriculum resulted in these impacts?

In this paper, we refer to the development of computational maker identity as an expansion of computational identity (Tissenbaum et al., 2019), to include crafting, building and other non-computational skills.

Background

Identity as described by Gee (2000) is being recognized as a certain kind of person in a given context. A simple breakdown of this definition indicates that identity is contextual. Gee (2000) outlined four different ways to view identity, one of which is Affinity-identity, which he describes as a way of looking at who the person is. He suggests that those with a specific A-identity are a part of an affinity-group i.e., a group of people who share little besides their interest in something i.e.: the affinity. Along the same lines, Nasir & Hand (2008) define practice-linked identities as those that are linked to participation in particular social and cultural practice.

With makerspaces becoming a popular community of informal learning and tinkering over the last decade or so, scholars like Pinkard et al. (2017) are doing valuable work to incorporate identity, sense of belonging and computing empowerment into makerspaces like Digital Youth Divas. However, there is still work to be done to recognize what constitutes a “maker-identity.”

Factors impacting identity development

In order to develop a framework for operationalizing identity in our computing makerspace we reviewed the research into science and engineering identity (Carlone & Johnson, 2007; Hazari et al., 2010; Godwin, 2016), computational identity and empowerment (Kong et al., 2018), coding attitudes and identity (Mason & Rich, 2020; Washington et al., 2016) and engagement and persistence of minority students in certain STEM fields (DuBow et al, 2017; Nasir & Hand; 2008). Students in our makerspace utilized a variety of these computing topics when engaging in making. Conducting a thematic analysis of prominent computational identity literature, we extracted and grouped the various identity factors under seven broad themes that would contribute to computational making identity development in our makerspace (see Table 1).

Table 1

Factors influencing computational making identity

Theme	Description
Interest & motivation	Defined as “A person’s likes, preferences, favorites, affinity toward, or attraction to a subject, topic, or activity” (Godwin, 2016, p. 4). Interest is used by Godwin (2016) and Hazari et al. (2010) as a measure of engineering and physics identity respectively, and by Mason & Rich (2020) and Washington et al. (2016) as a construct to measure students’ coding attitude, and CS attitude and identity respectively. Talley et al (2017) use motivation as a measure of self-efficacy when measuring the change in maker-identity in college students.
Confidence & self-efficacy	Confidence has been shown to impact coding attitudes (Mason & Rich, 2020) and identity (Washington et al., 2016). Talley et al. (2017) used self-efficacy as a measure of change in maker identity. Kong et al. (2018) measure creative and coding self-efficacy as factors of programming empowerment.
Competence & performance	Competence and performance are defined as “students’ beliefs about their ability to perform the practices of their discipline and understand the content of their discipline” (Godwin, 2016, p. 4). Used by Godwin (2016), Hazari et al. (2010) and Carlone & Johnson (2007), as a measure of science/engineering identity development. Nasir & Hand (2008) suggest that becoming competent in a subset of activities is essential to the engagement and practice in the space.
Utility value & meaningfulness	Entails the students’ ability to see the practice fit or apply into their current or future lives (Wigfield & Cambria, 2010). Used by Mason & Rich (2020) to measure student coding attitude and identity. Kong et al. (2018) use meaningfulness (Schiefele, 1998) and impact as factors of programming empowerment.
Recognition	A key measure in science and engineering identity framework (Carlone & Johnson, 2007; Hazari et al., 2010; Godwin, 2016), recognition has been defined as the feeling that others see you as a good science or engineering student.

Perception of the community	Mason & Rich (2020), Washington et al. (2016) and DuBow et al. (2017), show that how a student perceives the community (stereotypes about it, and what being a part of it means to outsiders) impacts a student's willingness to identify with the community.
External environmental factors	Factors such as access to domain, social support, preparation, family influence, structural barriers, social value, school attitude towards the practice play a significant role in whether a student engages and eventually identifies with the community and practice. (Mason & Rich, 2020; DuBow et al., 2017; Nasir & Hand, 2008)

Methods

Study design

The Connected Spaces makerspace curriculum was conducted over two weeks in the summer of 2022. The participants were 18 middle school students, who were recruited from two local community organizations: DREAAM, working primarily with African American/Black and Latinx/Hispanic boys and The Well Experience with African American/Black and Latinx/Hispanic girls. The makerspace was set up on the campus of a large Midwest public university. The students participated in maker activities from 9am to 12pm for 10 weekdays, followed by lunch at a university dining court. Learning from a similar camp run the previous summer, we knew that significant support would be needed, particularly for students' final projects. To this end, 6 researchers and 3-4 mentors from the community organizations were present throughout to support the students.

The structure of the makerspace was intentional, but also flexible, with the researchers debriefing at the end of each day, to modify the next day's activity. For Week 1 of the camp, the students engaged in a modified use-modify-create structure (Lee et al., 2011), in which they started by making a simple mini project centered around the Circuit Playground Express microcontroller (with basic maker components such as LEDs, Neo pixels, sounds, touch sensors, and motors) by following instructions, that they would then modify and add onto. The choice of the microcontroller was driven by its compatibility with block-code, which we concluded would work best for middle-school students. On Day 6, students took part in mind-mapping activities to help them think about their own identities and values. On Day 7, the students were provided outline worksheets, on which they brainstormed their final individual project ideas and started thinking of the materials they might require. The last three days were spent building their final projects. On Day 10, community members, parents, and university staff were invited to an "open-house" of the students' projects, where the students demoed their projects. They also created display boards, to talk about their process and intention of creating these projects.

Data collection

On the last two days of the camp, we interviewed five of the eighteen students. These students were chosen due to a variety of factors: consistent attendance (with some variation), prime demographic (age), and being relatively representative of the entire group (previous skill and experience). The semi-structured, one-on-one interviews were recorded and transcribed. Each interview lasted approximately 10 minutes and mainly consisted of questions regarding their makerspace experiences and final projects. We conducted a thematic analysis (Nowell et al., 2017) of the literature above to derive 36 initial factors (some repeating) indicating or influencing identity. After an initial inductive qualitative (Thomas, 2006) review of the transcripts, 18 of the factors were shortlisted as being present in the interviews. These 18 were then further grouped down into 7 categories (see Table 1). The interviews were then coded with these 7 categories each time a student indicated an impact on or due to a category. Iterative review of literature and analysis of coded data led to in vitro coding of the subcategories for each of the five students analyzed (see Table 2). Reflecting on the researcher debriefs after each camp day, as well as the planning documents and conversations, we were able to connect our findings to the curriculum design and decisions we made while creating the makerspace. Other data such as field notes, observations, photos, videos and audio recordings were also used to support these findings and connections to our makerspace design.

Findings and discussion

In this section, we will highlight some of the key instances in the interviews, where students indicated how certain factors of their identity were impacted, or in turn played a role in their makerspace experience. We will also further analyze the design decisions and structures of our makerspace that might have led to these impacts. Table 2 shows the maker identity factors each student mentioned in their respective interviews.

	Making interfered with other interests			*		

Figure 1

Final Projects: Alexandra's dog collar project (a) and Leo's trash-pick-up robot project (b)

(a) (b)

Interest and motivation

All five participants were able to tie in their experience at the makerspace to some previous interest that they already had. Some talked about how their interests could be impacted through making, while others created final projects that integrated making into something they were passionate about. For instance, Alexandra decided to make a dog collar (Figure 1(a)) that would light up in different colors based on the dog's health conditions because she “[wants] to be a vet. [She wanted] to invent something for animals, especially dogs, because [she] has a dog.” Leo created an automated trash-pick-up robot (Figure 1(b)), inspired by a video game he enjoyed. Four of the students came in with previous interest in either electronics, making, or inventing and the same students showed interest during the camp. When Jasmin was asked about her interest before the camp, she “thought [making] was boring,” but at the end of the camp her view changed to it being fun and her stating “I want to come back!”

These experiences can be tied back to several of our early design decisions for the camp. For instance, based on earlier co-design sessions with other youth at these organizations, we creatively grounded the mini-project activities into pop-culture (like Marvel) to make them more relevant and build interest in the students about the tools being used. Secondly, the success of the open nature of the final projects seems to have stemmed from the two days of self-reflection of their identities, interests, and values. Examinations of the students' mind maps largely showed a tight connection between what they wrote during these sessions and their final projects.

Confidence and self-efficacy

We anticipated that having students engage in the use-modify-create in each mini project during Week 1, would enable them to develop their confidence by allowing them to progressively take on more personal and creative agency in their work. Students could build a simple basic project by following a step-by-step guide, and once they gained confidence in that skill, they could modify their projects in their own ways. This allowed for a low-floor-high-ceiling model where the students could slowly increase their confidence. The success of this approach was shown in students recognizing their growing confidence in making as they went through the camp. For example, Jasmin stated that the camp “changed me, ‘cause like I didn’t know [before the camp]… like… me? doing this?! It's hard. But now it’s like, kind of easy for me to understand stuff and how it comes together and makes lights and movement.” Some students also showed increased confidence in mentoring others, with Jasmin indicating excitement around being able to teach others how to do what she learned.

Competence and performance

Based on observations from the previous summer's camp, we recognized that students often failed to build their competence if their learning was not scaffolded first. This prompted us to have Week 1's curriculum expose the students to various maker components in low-stakes, scaffolded projects. This was also in response to the “keychain syndrome” which highlighted that students tended to fixate on basic projects they are first introduced to (Blikstein & Worsley, 2016). When interviewing students and examining their final projects, we found that they were able to extend the components and their making skills in exciting ways. All five of the students indicated that they were competent or developed competence through their projects and the maker activities. When Alexandra was asked what valuable skill she learnt, she said “coding is really easy when you just like pay attention.” Alexandra also showed surprise at her own performance that she “actually just made a dog collar like this”, which used several of the Week 1 components (light sensor, temperature sensor, LEDs) in ways that extended far beyond the originally scaffolded activities. Across all the students' projects, we observed similar outcomes where they extended the maker skills, they learned in Week 1 in new ways around personally relevant projects.

Utility value and meaningfulness

Researchers observed that many of the students were able to see the utility value and meaningfulness in their making through the intentionally open-ended final projects. Most students created projects that were driven by their previous interests and communities, which they identified during the two days of project brainstorming and self-reflective mind-mapping activities. For instance, Alexandra weighed in on her dog-collar’s utility: “It will help vets, it’ll help new or first-time dog owners … Or like people that don’t understand dogs’ body language. So, this will help them, like if your dog is overheating […] it will turn red for you so you will know.” Three of the students indicated that they could see the utility of making in their future lives. Jasmin said the camp was valuable in helping her see how making could be useful in their lives in the future “Cause like when they [students] grow up and are like ‘I don’t know what I want to be’ and they remember that they took this class, it’s going to be easier.”

Figure 2

Mind map of a student (a) and all the Mind maps displayed with feedback from peers (b)

(a) (b)

Recognition

To foster a sense of recognition, researchers provided opportunities for the students to recognize each other as makers, as well as allow them to show community members their work. After the mind-maps were created (Figures 2(a) & 2(b)), we stuck them up on a wall and encouraged them to walk around and give feedback and recognition to their peers. We also built in some peer feedback into the project brainstorming day, where students had to explain their idea to a partner. On the last day, we invited parents, community members and university staff to visit our makerspace and talk with our makers about the projects. This allowed the participants to receive a lot of feedback and recognition from the people they look up to. The interviews highlighted how this process resulted in recognition across students' experiences. As quoted above, Alexandra surprised herself with her ability to make a dog collar, stating she never believed she could do something like that. Jasmin wanted to feel recognized for her maker skills, saying she made her project "to show that I can actually make something." Trinity recognized the competencies of her peers, directly stating that Alexandra did not need help because "she got it so fast". Keith mentioned how he valued the recognition from the facilitators and how this impacted his self-perception noting that "Mr. C said that I did a really good job for my first time ever!"

Perception of the community

Two of the makers showed that they had preconceived notions of who could and could not work with electronics, neither believing themselves to be a part of the community to begin with. However, for both Alexandra and Jasmin, their perceptions changed and they felt like they could make on their own too, with Alexandra stating that "At first I thought I wasn't going to be able to get it, because you know, I thought I wasn't one of those kids that are like good at technology and stuff, but it's like really simple like when you get the hang of it. So that's something I changed. I feel like I can do coding more, outside of this". This highlights how participation in the camp changed their own perceptions of what a community of makers is and their inclusion in it.

External environmental factors

Keith had never coded before. Leo had never worked with electronics. Alexandra believed she had coded before, but never worked with electronics. Jasmin had worked with both before. Trinity indicated that she never liked working with electronics. Even though the participants had various levels of access to makerspace activities, they were all able to engage with the space and tools on their own terms. To this end, it was important that the makerspace feels like a place where the students can collaborate with their peers, while having fun. Alexandra indicated that access to the makerspace gave her the resources to build her ideas. She said that although "this [dog collar project] was something I'd thought about making before, I just didn't know quite what I wanted to make, but now […] I found what I wanted to make"; the makerspace gave her the resources to actually find out what she wanted to make: "'Cause when they said LED lights, I'm like what can I use for a dog or animal in general that I can use LED lights with? I can use a collar and stick the lights on it and make something out of that." Leo and Trinity stated that they enjoyed the social aspect of the makerspace, with Leo expressing joy that he "made a couple of friends."

Challenges

Despite showing positive impacts in creative self-efficacy and competence, and showing meaningfulness in her project, and recognition of one of her peers, Trinity indicated a strong dislike for making, saying: "I don't like coding and I don't like building stuff. I don't know why I don't like it, but I just don't like it. It's not my thing, that's why I don't like it." Whether we can attribute this to her lack of interest, preconceived notions of making, or some other factors, would require a deeper dive into her experience and mindset. Some other student hesitations included conflicts with previous commitments, for instance time at the makerspace for Keith was replacing time at his job. This goes to show the importance of situating making in a flexible environment, without hindering students' ability to participate in other parts of their identity. Lastly, brainstorming, mind mapping and peer-feedback were challenging for the students to grasp initially, suggesting that the work of maker-identity building, could have been incorporated into the curriculum and discussion from day one. This might have eased the students into it and allowed them to frame making as a reflection of their identities, instead of having it be separate from the identity construction parts of the camp.

Limitations and future work

While finding the general themes for the identity framework used in this paper, research focused on the technical side of making: i.e.: science, coding and computing were focused on. However, making is broader than that - it involves art and creativity along with collaboration and problem solving. Future work will focus on reviewing identity frameworks in those domains in addition to more identity frameworks in the STEM domain, to find commonalities and differences, to then investigate those structures of identity within our makerspace implementations. A large amount of data, including screen recordings, audio recordings and video recordings, along with photos of the makerspaces, projects, and mind-maps were collected during the two weeks of the makerspace. Due to space constraints, only the semi-structured interviews of five students were included, along with our review of photos and planning material to support our findings. More work could be done to triangulate additional data (e.g., whole camp video and audio recordings) with respect to this identity framework. Future work involves setting up another makerspace of a similar structure during the summer in 2023, with ongoing after-school makerspace activities during Fall 2022 and Spring 2023 semesters. With everything that we have learned about how our 2022 makerspace impacted their identity, we are working to incorporate structures that better allow for identity development. We will continue to investigate the impacts of our makerspace on identity, with more intentional and pointed observations and interviews, based on the realized framework.

Conclusion

Identity plays an important role in the learning process and engagement of students (Nasir & Hand, 2008). With the development of makerspaces, built to serve marginalized communities and youth, it is essential to engage their pre-existing identities with the practice-linked maker-identities that are being constructed in these makerspaces. Scholars such as Blikstein (2013), Halverson & Sheridan (2014), and Pinkard et al. (2017) are doing important work in constructing makerspaces that allow marginalized students not only access, but also agency to create in these spaces. The importance of considering affective factors that impact student engagement and learning in making for marginalized students is highlighted by these scholars. Our goal of tying identity with making is in line with such important work. Making personally relevant projects tied to one's identity allows for students' computational empowerment (Tissenbaum et al., 2019, Kong et al., 2018) empowering them to decide what they want to make and why, creating a more equitable approach to computing. Through this study, we attempted to find common factors that impact students' computational maker identity development, so that they are taken into consideration when building an equitable makerspace. We recognize that various factors of identity, including but not limited to - interest and motivation, competence and performance, confidence and self-efficacy, recognition, utility value and meaningfulness, perceptions of the maker community, external factors - can be impacted when the makers engage in the space. Keeping these factors in mind when designing makerspaces and their curricula can allow for computational identity development of students from all backgrounds, by grounding their maker identity in computational action (Tissenbaum et al., 2019).

Further, this study showed that structures such as co-designing the makerspace, open-ended projects, use-modify-create mini-projects, reflection and brainstorming activities can impact the utility value, interest, confidence and competence factors positively. Ensuring that the students receive feedback and are able to collaborate with each other, mentors, and community members, can provide additional opportunities for them to feel recognized. Creating a fun, open, and engaging atmosphere while allowing the students to build with access and agency, may allow them to discard preconceived notions of maker communities and build their identities as valued members of the making community. Structuring the design of makerspaces with the intentions of developing the students' maker identities across the factors highlighted in this paper, while they explore and tinker is key to ensuring that the students engage and learn in these spaces with agency as they begin developing their maker identities.

Emotion Recognition in Educational Written Dialogues on Civic and Social Issues

Efrat Firer, The Hebrew University of Jerusalem; Hadassah Academic College Jerusalem, efratfi@edu.hac.ac.il
Baruch B. Schwarz, The Hebrew University of Jerusalem, baruch.schwarz@mail.huji.ac.il

Abstract: In this study, we explore emotion recognition (ER) processes in educational dialogues on civic and social issues (EDCSI) by assessing the accuracy of ER and the factors that affect ER of external readers. Twenty speech-therapy students with linguistic and emotional training were asked to read a written EDCSI in which they had not participated, to rate the emotional intensity in each speech turn, and to explain which markers affected their rating. A positive correlation was found between the discussants' self-ratings and the mean ratings of the readers, although inter-rater reliability was low. The analysis of the reports of the raters showed that they based their rating on markers at the levels of the local turn, the entire discussion, and the broader context of the author's identity. The findings provide basis for a comprehensive framework to identify emotions in EDCSI and to train teachers to moderate and regulate emotions in EDCSI.

Introduction

The importance of discussions revolving around civic and social issues was recognized two decades ago (Parker, 2003). Such discussions are generally emotionally loaded. Slakmon & Schwarz (2019) provided a theoretical framework they call *Deliberative Emotional Talk* to study a new type of educational dialogues about civic and social issues (hereinafter EDCSI), as they perceive the regulation of emotions in such discussions both as a political need and an educational goal. However, research on such dialogues is still embryonic. The emotions that arise during discussions dealing with civic and social issues are relevant to the participants' lives, and often make salient personal and cultural differences. As such, these discussions are fueled not only by the emotions triggered by the issues discussed, but also by the emotions created during the interactions among discussants with different, and often conflicting, viewpoints. The idea of *intersubjectivity* – shared beliefs during social interactions – has been recognized as crucial for human communication. We conjecture that the sharing of emotions is crucial too, especially in discussions about civic and social issues. However, research in this domain is scarce.

The ability of the participants to feel empathy towards other participants and to understand their positive and negative feelings are much dependent on their ability to identify and recognize the emotions of others. Accordingly, the emotion recognition (ER) ability of interlocutors is one of the bases for their emotional perception, which enables them to understand and respond to the emotions of others. It is especially important in EDCSI, as ER mechanisms can affect the participants' ability to create an encouraging and supportive environment for discussing and learning. Moreover, the ER mechanism is a valuable tool for teachers to use in moderating discussions. It increases awareness of possible biases, and promote the development of socio-emotional competence of the students.

In face-to-face discussions, ER relies on linguistic, para-linguistic, and extra-linguistic cures. However, EDCSIs often take place in digital environments where the text is not supported by para-linguistic and extra-linguistic information, and ER is based solely on the linguistic information produced from the written text per se (Farahani, 2003). Relying on the written text alone may produce gaps in the discussants' understanding of each other and affect their sense of freedom to express themselves, their dialogic moves, and the emotions they feel during and following the discussion (Firer et al., 2021).

To understand ER during digital EDCSI, markers indicative of emotions in written discourse must be characterized. Attempts to do so have been made in linguistic research, but these attempts have usually been applied to texts written by a single author, rather than discussions conducted by multiple authors interacting with each other. Existing research on emotions in written texts primarily focuses on linguistic markers, but pioneering research indicates that in EDCSI the emotional processes are much affected by interactions between participants, as well as their identity and personality (Firer et al., submitted). Accordingly, ER in EDCSI is extremely complex.

Social Emotional Learning (SEL) programs flourish in Western countries, and professionals such as speech therapists, psychologists, or even teachers are trained to recognize and regulate emotions. Our general research direction is to understand ER processes in digital EDCSI, and specifically, to investigate the effect of training on ER, by investigating commonalities among individuals with professional training. To do so, we asked participants with linguistic and emotional training to rate the emotional intensity level they identified in discussions that they had not participated in, but which were marked by participants as emotional. They were asked to explain what markers affected their decision. We raise the following questions:

1. Does the identification of the intensity of discussants' emotions in EDCSI by trained external readers correlate with the discussants' identification of the intensity of their own emotions in such discussions?
2. What are the linguistic markers the readers use to identify the emotional intensity level in written EDCSI?
3. What other factors affect the reader’s ER in written EDCSI?

Theoretical background

Emotion recognition

Understanding the inner emotional state of others in conversations and their emotion regulation strategies is a complex task that depends on recognizing and interpreting the expressions of these emotions. Extensive research focuses on linguistic, paralinguistic, and extralinguistic markers for recognizing emotions in interactions. Extralinguistic markers include, for example, facial expressions (starting from Ekman's research, e.g., Ekman & Oster, 1979) and physiological activation (e.g., Törmänen et al., 2021). Paralinguistic markers include elements such as intonation (Bänziger & Scherer, 2005) and vocal elements (Scherer, 2003), and language markers include lexical and grammatical modalities, as well as other contextual and pragmatic elements that may attest to the presence of emotions (Argaman, 2010; Martin & White, 2005). Subsequently, theorists and researchers perceive language both as an object for studying emotions and as a research tool (e.g., Enfield & Wierzbicka, 2002). Moreover, Lindquist & Gendron (2013) review neurological evidence for the constitutive role of language in emotion perception from typical and impaired emotion perception research, as well as from research on developmental processes in children.

In face-to-face interactions, the perception of the emotions of others is dependent on a combination of linguistic, paralinguistic, and extralinguistic information, and it relies not only on the content and expression of the speaker, but also on the interpretation of the interlocutor (Tubbs & Moss, 2006). ER in interactions in digital media is substantially more challenging. Readers cannot rely on non-verbal clues or on the speakers' tone, and their ER is entirely dependent on the text. Early research claims that words provide only 7% of the information in face-to-face communication (Mehrabian, 1971). Though this percentage may be controversial, it gives perspective to the problematic task of ER based on written texts alone.

Regarding political and civic discourse in digital media, the picture may be even more complex. Digitally mediated interactions magnify the affective aspect of civic life (Papacharissi, 2010, 2015) and therefore render accurate ER even more important, given that discourse in digital media is often quarrelsome. Moreover, even in designed and regulated written discussions, like EDCSI, participants often misinterpret the authors' emotions (Firer et al., 2021) and identify different levels of intensity than those reported by the authors themselves (Slakmon et al., 2022). Therefore, it is extremely important to examine whether trained readers of e-EDCSI share some perception on the authors' emotions in EDCSI, what affects their ER, and what the theoretical and practical repercussions are.

Emotions in written texts

Previous research on emotions in written texts provides information on language markers that can imply the presence of emotions in texts. Martin & White (2005) mention that systemic functional linguistics (SFL) identifies three modes of meaning which operate simultaneously in all utterances – the textual, the ideational, and the interpersonal. Regarding the interpersonal meaning, they provide a comprehensive theoretical framework for analyzing writers' emotional stance and appraisal, and the way they position their readers to do likewise by using linguistic mechanisms. Bednarek (2010) draws on SFL but links it to cognitive approaches that refer to emotion schemata, which are created from the organization of people’s actual emotional experience and from observing emotional experiences of others as well as the exposure to discourse on emotions and other socializing processes. As she explains, "the different linguistic resources work conventionally to realize affective meanings because speakers are aware of the various components of such schemata (and vice versa, exposure to such discourse contributes to the construal of such schemata, even if not exclusively)". Nevertheless, SFL and emotion schemata do not provide an applicable framework for ER in EDCSI, since they refer to emotions from the speakers' perspective, mostly in personal narrative texts, and thus seem inappropriate for the treatment of emotions arising in group discussions.

Other attempts have been made to create emotional lexicons that enable the identification of emotions in texts. For example, the Linguistic Inquiry and Word Count (LIWC-22) (Boyd et al., 2022) provides a computerized text analysis tool for understanding socio-emotional states by identifying words, word stems, phrases, and select emoticons in the text (see also Strapparava & Valitutti, 2004; Mohammad & Turney, 2010 for other tools). However, these tools do not apply to the unique linguistic characteristics of Hebrew – the language used in the present study.

Argaman (2010) explored relationships between the intensity of emotions and the lexical modalities for expressing those emotions. She identified linguistic markers for emotions in Hebrew texts that were written after watching films that evoke feelings of sadness and joy. The markers she identified consisted of intensifiers, lexical reducers, lexical repetitions, first person singular, emotion words, the Hebrew root "feel", similes and metaphors, exclamatives, words and phrases expressing exclamation, and outstanding graphical symbols. These markers may serve as a basis for the identification of emotions in EDCSI in Hebrew.

Nevertheless, referring to the linguistic level may be insufficient regarding conversations. Poria and colleagues (2019) point out that even models of artificial intelligence aimed at analyzing emotion in conversations provide a limited analysis as they struggle to address linguistic means that cannot be identified without context and interpretation (e.g., sarcasm). As they explain, ER in conversations must refer to the context of the utterance within the conversation. Indeed, Polo et al. (2016) refer to some of the linguistic markers identified by Argaman (2010) in their theoretical model of group emotions in collaborative learning activities, namely the use of first person singular, but they also refer to context-dependent dialogue-level markers such as the use of justifications, the elaboration of arguments, etc. These findings suggest that argumentative moves may also serve as markers when analyzing learning discussions.

The ER challenges that are consistent in written conversations – the lack of paralinguistic information, the need to refer to the text within the context of the conversation, the specific features of the language – are intensified in the context of written discussions, and especially in EDCSI. Personal factors, design-related factors, and the encounter with the 'other' and their group affiliations often affect the emotional processes (Firer et al., submitted) and the emotional perception of the other participants, who sometimes project their perceptions and beliefs on the author (Keynan et al., 2022). In this research we would like to examine whether prior knowledge of linguistics and emotional processes affects the ability of readers to identify emotions in written EDCSI.

Method and analysis

Participants

Participants were twenty speech-therapy undergraduate students. They were all orthodox Jewish females in their twenties, in their third year of study or in the first semester of their fourth year, which is the last semester of the degree. All students spoke Hebrew as their native language or passed a Hebrew proficiency test upon their admission to college. As a part of the curriculum in assessment and intervention of speech, language, and communication disorders, all of the students had completed courses in linguistics and psychology, and had supervised sessions during their clinical education, in which they discussed emotional processes in interactions as part of their training as clinicians. The courses in linguistics provided them with a theoretical background on language components (semantics, morphology, syntax, phonology, and pragmatics).

Materials

The research materials consisted of two non-moderated written digital discussions given as assignments in two different undergraduate university courses. The first discussion served as the basis for an analysis of ER at the episodic level and will be discussed in another paper.

The second discussion was the basis for the analysis of a turn-by-turn ER. It dealt with the topic of Holocaust education in early childhood and involved five participants. This discussion was chosen from the two discussions described by Slakmon et al. (2022) for ER by participants, because it contained a larger number of participants who produced a larger number of speech-turns. The participants were asked whether the Holocaust should be taught in kindergartens. The discussion was a-synchronous, took place on a shared Google doc and contained 12 turns.

The discussants were interviewed after the discussion and were asked to state the level of emotional intensity they felt (low, medium, or high) in the turns they composed and in the other discussants' turns.

Procedure

The participants in the present research received the two written discussions by email and were asked to read them. In the episodic discussion they were asked to mark specific turns or sequences of several turns that they identified as emotionally loaded, and to write down what they thought had happened in these episodes. In the turn-by-turn discussion, which dealt with the teaching of the Holocaust, participants were asked to read the discussion and rate the emotional intensity they felt was present in each turn (low, medium, high). In both parts they were asked to explain based on the emotions they identified.

The participants were given the liberty to code the level of intensity and were not provided with a specific practice set or a defined rating criterion. The goal was to examine the participants' intuition and their ability to apply the knowledge they had acquired in their professional training in a written context.

After the participants coded and explained their choices in writing, they were interviewed and were asked to elaborate their answers. At the end of the interview they were asked whether the professional knowledge they acquired had helped them in the task.

The interviews were conducted and recorded, partly via ZOOM and partly in person.

Data analysis

A statistical analysis was conducted to determine whether the identification of the intensity of discussants' emotions by trained external readers correlates with the discussants' identification of the intensity of their own emotions.

The Krippendoff's alpha test (Hayes & Krippendoff, 2007) revealed that inter-rater reliability was low ($\alpha = 0.3401$), indicating that the external readers did not agree on the level of emotional intensity they observed in the various speech turns. Although reliability was low, and since the data was not normally distributed, a non-parametric correlation was run on the discussants' self-ratings and the mean ratings of the external readers, as will be presented below.

To determine what markers the readers used to identify the emotional level in written EDCSI and what other factors affected their ER, an extensive qualitative analysis was conducted. The analysis yielded references to visible cues as specific words, marks, phrases, as well as discourse moves the participants considered or interpreted as testifying on the existence of emotions. These references were classified into (1) turn level markers, namely, linguistic markers the participants identified within the text of the speech-turn, depending on Argaman's (2010) classification, (2) discourse level markers that were related to the context of the turn in the discussion, and (3) aspects related to the readers' world views, mostly their view of the author's identity, that contributed, influenced, and biased ER.

We then differentiated between markers for high, medium, and low emotional intensity.

Findings

Identifying emotions – accuracy

All the participants identified emotions in the discussions they read. They rated the intensity of emotions in each turn and explained their rating.

Table 1 presents the details of the various turns that were rated according to emotional intensity, along with the self-ratings of the authors of those turns and the average ratings of the external readers.

Table 1
Details of various turns rated according to emotional intensity by each turn's author and by external readers.

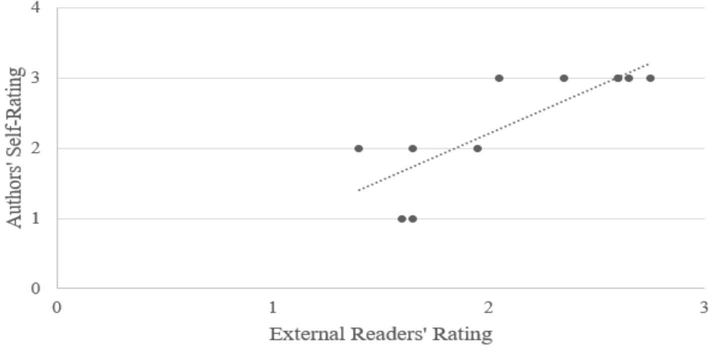
Turn	Author (pseudonym)	Author's Self-Rating	External Readers' Mean Rating
1	Toni	1	1.7
2	Dalit	2	1.4
3	Toni	3	2.6
4	Chen	3	2.7
5	Toni	3	2.1
6	Dalit	1	1.6
7	Moran	3	2.8
8	Dalit	3	2.6
9	Toni	2	2.0
10	Suha	3	1.5
11	Chen	3	2.4
12	Moran	2	1.7
Mean (SD)	N/A	2.4 (0.8)	2.1 (0.5)

Note. SD=standard deviation; N/A=not applicable

A Kendall's tau-b correlation was run on the discussants' self-ratings and the mean ratings of the external readers, excluding Turn 10, where the readers based their rating mainly on the Arab identity of the author instead of on the content she delivered. A strong, positive, and significant correlation was revealed between the two variables [$\tau_b=.71$, $p=.007$; see Figure 1], indicating that the higher the discussants rated their own turns, the higher the external readers rated those turns.

Figure 1

The relationship between the authors' self-rating of the emotional intensity in their turns and the mean rating of external readers of the same turns.



Identifying emotions – emotion markers in written dialogues

Participants were asked how they recognized the presence of emotions in the discussion. Because they were referring to a specific discussion, the answers were limited to the content of this specific discussion, the specific vocabulary, and the arguments used by the authors, etc. Nevertheless, the readers' answers were rich and diverse, and yielded three sets of factors that helped them to detect the presence of emotions – turn level, discourse level, and author's identity level.

Turn level

The first set of markers contained of *linguistic* markers that participants reported to confirm the presence of emotions. These markers were visible in the text, regardless of the context or the position of the turn in the flow of discussion. They were consistent with markers reported in research on narrative and personal texts (e.g., Argaman, 2010; Martin & White, 2005).

Some of the markers at the turn level concerned the *content* of the turn. The readers referred to *semantic* component of language, such as lexical items they identified as indicative of the presence of emotions. These included specific emotion words ("pride", "emotionally shaking") and words that participants defined as 'strong' or 'harsh' (e.g., "violent", "forcing", "dangerous"). Participants stated that the presence of such words in the text implied that the authors were emotionally involved when writing their opinion. Some of them also indicated that the lack of such words showed a low level of emotions (participant 18: "it's written rationally, without emotional words").

Another feature mentioned in relation to the content of the turn was the sharing of *personal stories* by the authors. Telling a personal experience was perceived by the readers as reflective of emotional involvement (participant 19: "her opinion relies on her own experience of how distressing it is, how scary it is").

Other markers concerned the *form* of the writing, namely grammatical and visual markers. The readers referred to *morphological* components, such as the use of first person ("us", "our families") as indicators of emotional involvement (participant 12: "she doesn't say 'the victims' families', she says '*our* families'…It's not in the third person, it's really present"). The lack of use of the first person was perceived as indicative of a low level of emotions (participant 1: "she doesn't say 'in *my* opinion', or '*I* think'. She says '*much has been said*'").

Participants also referred to *graphical* markers, namely the use of quotation marks (participant 2: "she uses quotation marks a lot…I would say she was really offended by what she said") as well as the use of question marks (participant 1: "the question mark shows me that there is emotion here") as suggestive of the presence of emotions.

The last marker that was found at the turn level was the *length of the response* and the level of *detail*, which were also identified as indicators of emotional involvement (participant 12: "she wrote a lot…it seems she really cares. She was very detailed and explained why she thought that way").

Discourse level

The second set of markers concerned the content of the turn and its location in relation to the other turns in the discussion. The readers perceived *argumentative moves* participants made as containing different levels of emotional intensity. For example, participants referred to expressions of disagreement and clarifications of one's opinion as containing high emotional intensity (participant 2: "she refines her words. It sounds like she's really afraid of being misunderstood and of being perceived as being against teaching the Holocaust...It's something that really bothers her, something that is very significant for her, so she is not willing to hear that the Holocaust shouldn't be taught; it's difficult for her to ignore it"). In contrast, agreement was perceived as containing less emotions (participant 18: "she's calm…she uses 'I agree with you' a lot…it doesn't seem to have a significant emotional effect on her"). Additionally, addressing opinions from both sides without taking a stance was perceived as less emotional and more balanced.

The *location* of the turn in relation to other turns provided additional information that affected the readers' rating. For example, the first turn was associated with less emotions because the author expressed her opinion but had not yet opposed anything because she there were no opinions to oppose (participant 19: "she states a strong opinion here but she's just starting the discussion so there is no objection here yet").

Reader's world view level

The last factor that affected the readers' rating of the intensity of emotions was the way they perceived the authors' connection to the topic of discussion based on their identity. Two of the participants revealed personal details about themselves during the discussion. One of the participants stated that her grandparents were Holocaust survivors, and the other identified herself as an Arab. The readers inferred the identity of the author from the text, but in contrast to the personal story that was part of the content, we chose to refer to the reader's view of the identity of the author as an extratextual factor that affected the judgment. In the turn written by the Arab student, the identity of the author led to a discrepancy between the author's report on the level of emotional intensity she felt when writing that comment, and the mean level of emotional intensity the readers rated. Only 15% of the readers rated this turn as the author did, and most of them explained their rating as dependent on her identity, sometimes even consciously ignoring other markers that were present in the text like strong words (participant 2 "she says '…I don't underestimate what happened in the Holocaust', 'It is a shocking event and against humanity', but the way she says it, it doesn't sound like she really feels it"; participant 19: "'Conflict' is a word taken from the Arab-Palestinian conflict, it's not related to the Holocaust at all").

The effect of the professional training

Forty five percent of the external readers pointed out that their professional training helped them to identify markers of emotions in the written discussion. Fifteen percent stated that their training affected their ability to identify those markers to a limited extent. Twenty five percent stated that their professional training had no effect on their ability to detect emotional markers at all. Fifteen percent did not answer the question.

Discussion

In this research, we investigated ER in digital written discussions. We asked whether the identification of the intensity of emotions in written EDCSI by trained external readers who had not participated in the discussions correlate with the discussants' identification of the intensity of their own emotions in such discussions. We also asked which markers readers use in the process of identifying emotions in written EDCSI, and what other factors influence their ability to identify emotions.

Twenty students with linguistic and emotional knowledge acquired during their professional training were asked to read a written discussion and rate the emotional intensity of each turn. We also asked them to indicate the markers that enabled them to identify the emotional intensity, and whether their professional knowledge helped them in the task.

The results showed a correlation between the average rating of the readers and the participants' rating of their own level of emotional intensity, indicating that the higher the self-reported emotional intensity of the authors, the higher the average rating of the external readers concerning these authors' level of emotional intensity.

To some extent, this correlation suggests an author-reader agreement about ER and opens the first steps into the inquiry of emotional intersubjectivity in EDCSI.

We are aware that the inter-rater reliability in this research was low, and there was no consensus among the external readers about the rating of the various turns, which seems indicative of a very weak model of ER in EDCSI. We attribute the low inter-rater reliability to two main factors. First, participants were not provided with a practice set in order to familiarize themselves with the task before rating the actual experimental items. Second, rating criteria were not clearly defined. Out of fear of "contaminating" participants' intuitions concerning the levels of emotional intensity in the experimental items, the experimenter refrained from providing examples for each level of emotional intensity (low, medium, and high) or clear characteristics for each of those levels. It is plausible that more specific training would have increased reliability. This assumption is supported by the fact that different readers used the same words and excerpts for ER but rated them differently on the emotional intensity scale. We also hypothesize that a larger sample of trained readers would increase inter-rater reliability and further strengthen the correlation found between the average rating of the readers and the participants' ratings. Meanwhile, we suggest that the readers' average rating be considered as representative of the readers' rating. Moreover, we believe a stronger indicator of inter-rater agreement in our case should lie in the cues based on which the external readers based their ratings, rather than on the ratings themselves.

External readers identified emotions using linguistic and content-related cues and considered the identity of the author and the position of the turn in the sequence of the discussion when determining the level of emotional intensity. The reports of the trained readers enable a deep understanding of the different factors that influence ER.

The linguistic and content-related cues that were identified as well as the readers' response to whether their acquired professional knowledge indicate that the professional linguistic and therapeutic knowledge may have helped the readers in the process of ER. This suggests that training with meta-linguistic and meta-emotional knowledge can be useful in the identification of emotions in EDCSI.

Nevertheless, the readers also based their rating of emotional intensity on the author's identity. This phenomenon of considering the identity of the authors while evaluating the emotional intensity they felt is described in detail in Keynan et al. (2022) and referred to by Slakmon et al. (2022) as the attributed closeness and sense of belonging of the authors to the topic of discussion.

Previous studies have shown that some of the emotions in EDCSI are directed towards participants while interacting with them at the inter-personal and group levels (Firer et al., submitted). In this study, the readers had no personal acquaintance with the participants in the discussion, except for the information revealed through their comments. Naturally, these details revealed characteristics specifically relevant to the subject matter. Not knowing the authors in person made the readers activate their system of beliefs, opinions, and perceptions about the authors' identities and influenced the way they rated the level of emotional intensity of the discussion and the way they interpreted the authors' intents. The details the authors provided served as emotional content markers. Moreover, these details evoked stereotypic preconceptions concerning the authors, which caused the readers to attribute strong feelings to those who are personally "related" to the subject matter and weak emotions to those who "have no right" to have an opinion on the subject, reverberating interactions taking place in the digital social media.

Although the readers activated their professional linguistic and therapeutic knowledge, under certain circumstances, when there was a contradiction between the professional knowledge and their personal opinions, the trained readers related to the author's identity rather than to the cues embedded in the text. Personal opinions influenced their ability to examine the content of the discussion objectively. The 'self', the personal identity, of the readers influenced their perception of the topic and their perception of the discussants, while their professional knowledge has not yet become part of their identity. Additionally, attributing a close connection or sense of belonging to the topic under discussion can imply that EDCSI emotionally activated both the participants in the discussion and the external readers.

The third aspect that affected ER was the position of the turn in relation to the other turns in the discussion. Martin & White (2005) describe three modes of meaning that operate simultaneously when perceiving the interpersonal meaning in language – the textual, the ideational, and the interpersonal. These modes are consistent with the linguistic, contextual, and identity markers we have identified. However, participants' reliance on the position of the turn in the sequence of turns in rating the emotional intensity, is a component that exists only in conversations. This component should thus be taken into consideration at the methodological level. The analysis of emotions in EDCSI, therefore, cannot rely solely on the turn level, but has to take the situational level into consideration. The importance of taking the situational level into account is consistent with findings from additional studies that have recently been submitted (Firer et. al., submitted).

The current study has theoretical and pedagogical implications. In the theoretical realm, it sets a basis for a comprehensive framework for the identification of emotions in EDCSI since it refers to the different levels of cues and information they consist of: linguistic markers, discourse level components, and socio-cultural influences. Considering how closely participants identified specific markers, the model may serve as a model-in-action, for which the emotions detected are checked through actions of the teacher. Considering the viability of the model as a tool for formative rather than summative ER is an exciting research path we are currently engaged in. In the pedagogical realm, the model can serve as a basis for training teachers to identify emotions in written discussions, and to increase their awareness of possible biases, especially in socio-culturally diverse groups and enable teachers to moderate EDCSI and to promote the development of socio-emotional competence of their students. Further research should include a larger sample of readers, which should help differentiate between the influences of emotional training and linguistic training as well as the ability of untrained teachers to identify emotions. Such studies should also examine the effect of training according to the three levels we have identified on the ability of discussants and external readers to identify emotions accurately.

Abstract: Integrating computational thinking (CT) in accessible and inclusive ways has been a challenge for elementary science teachers. To promote equitable integration of CT in elementary science lessons, we delivered a five-day professional development (PD) workshop for teachers to practice applying CT and culturally responsive teaching (CRT) in their science lesson designs. In this study, we examined how two elementary science teachers' understandings of CT- and CRT-infused science teaching changed during the workshop. We compared two teachers' understandings of CT, CRT, and the levels of CT-CRT integration reflected in their lesson plans using our integrated framework. Drawing on data gathered from surveys, observations, artifacts, and interviews, we found that the two teachers had varied growth in their understandings of CT and CRT from their different entry points and through distinct pathways. This paper illuminates effective PD interventions, presenting opportunities for elementary teachers to integrate CT and CRT into their science lessons.

Introduction

Promoting pedagogical practices that engage all students, especially students historically excluded in computing fields (underrepresented genders and Black, Latino/a/e/x, and Native American/Alaskan Native [BLNA] students), is essential for broadening participation in computing. Science lessons that integrate computational thinking (CT) are one way to expand computing education beyond traditional computer science classrooms (Lee et al., 2020; Yadav et al., 2018). According to Wing's initial definition of CT (2006), CT "involves solving problems, designing systems, and understanding human behavior by drawing on the concepts fundamental to computer science" (p. 33). CT's definition has changed over time, but researchers agree that CT is an effective on-ramp for younger students and teachers to first introduce computing concepts before teaching foundational computer science (CS) content. However, our research team's earlier project on CT-integrated science PD indicated the necessity of using equity-centered approaches to address the concern that some elementary science teachers believed that CT is best suited for only high-performing students, rather than for all (Ketelhut et al., 2020).

One way to address inequitable integration of CT in elementary science lessons is to co-develop culturally responsive science lessons with the teachers themselves. Gay (2002) claims that educators who apply culturally responsive teaching (CRT) practices to their teaching and situate students' lived experiences within the learning environment make learning more personally meaningful, interesting, and engaging. Moreover, various studies show that CRT is a powerful pedagogical mechanism for providing students, particularly BLNA students, with the academic and social support they need to meaningfully learn and enjoy science (Charleston et al., 2014; Ladson-Billings, 1992; Stanley & Brickhouse, 2001).

The successful implementation of CT, CRT, and science together requires elementary teachers to have an understanding of science, CT, and CRT knowledge in addition to a deep awareness of their personal teaching practices (Gay, 2002). A report evaluating K12 CS teachers' beliefs towards CRT practices showed that only 57% felt they could successfully implement CRT practices (Koshy et al., 2021). Hence teacher professional development (PD) focused on CT/science integration is needed to support teachers in integrating CT, CRT, and science into their lesson designs with a focus on equity and inclusion. As the initial launch of a 3-year PD project, we designed and implemented a five-day PD workshop to prepare elementary teachers to integrate CT and CRT by adapting their existing science lessons. This paper analyzes data from two of the participating teachers, both of whom teach fourth grade and developed similar final lesson plans by the end of the PD. This paper aims to answer the following research question: *How do elementary teachers' initial understanding towards CRT- and CT-integrated science instruction evolve throughout a 5-day PD workshop*?

Theoretical framework

Our research team drew extensively from Gay's (2018) definition of CRT to develop an integrated framework of CRT, CT, and elementary science (Mak et al., 2023). We saw CRT as a powerful pedagogical approach to engage all students in CT-integrated science learning and to build teacher awareness of structural barriers that may arise from their lessons. Specifically, our research team created a conceptual wheel that includes three main practices for teachers to apply CRT in their CT-integrated science curriculum: Equitable Instructional Practices, Student-Centered Content, Inclusive Relationships & Communities (Mak et al., 2023). Table 1 lists the three main opportunities and the surrounding seven CRT practices as outlined by Gay (2018).

Table 1
The Framework of CRT (Table Format)

Reflect on One's Cultural Lens		
Equitable Instructional Practices	**Student-centered Content**	**Inclusive Relationships & Communities**
Model high expectations	Incorporate student experience to promote respect for differences	Collaborate with family and local community
Draw on students' cultures to shape CT and science practices in the classroom	Bring real-world issues and experiences into the classroom	Speak up about and respond to prejudice, bias, and stereotypes
		Honor multiple modes of sensemaking and expression

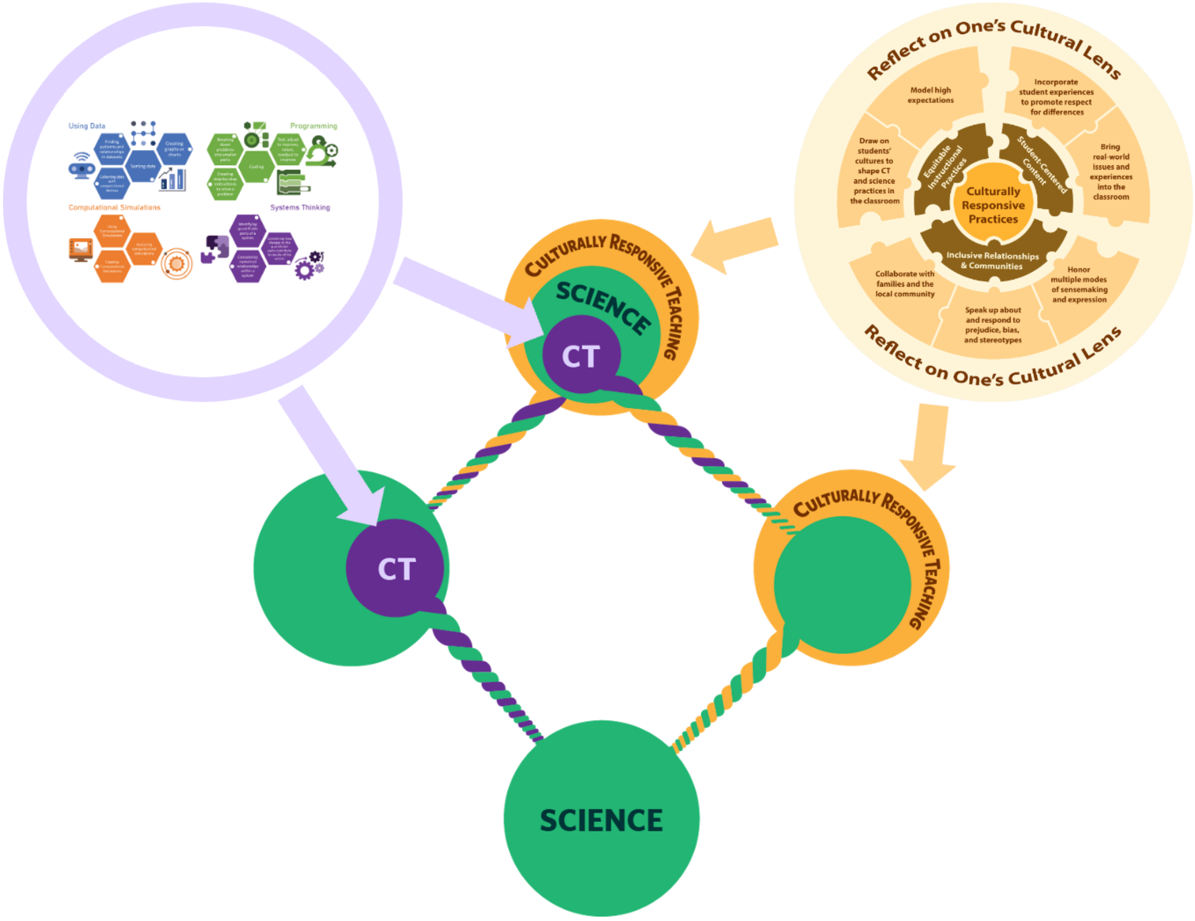
In addition to building a comprehensive understanding of CRT as it relates to elementary science instruction and teacher PD, the research team also developed a shared understanding of how CT fits into culturally responsive science instruction. Our team designed a CT framework that explicitly aligns with elementary science teaching (Ketelhut et al., 2020) when compared with other more general CT frameworks (e.g., Weintrop et al., 2016). This CT framework consists of four major CT practices: using data, programming, computational simulations, and systems thinking (Table 2).

Table 2
The Framework of CT (Table Format)

Using Data	**Programming**	**Computational Simulations**	**Systems Thinking**
Finding patterns and relationships in datasets	Breaking down problems into smaller parts	Using computational simulations	Identifying quantifiable parts of a system
Collecting Data with computational devices	Creating step-by-step instructions to solve a problem	Assessing computational simulations	Considering numerical relationships within a system
Sorting data	Coding	Creating computational simulations	Considering how changes to the quantifiable parts contribute to results of the system
Creating graphs or charts	Test, adjust to improve, retest, readjust to improve		

Our integrated framework takes the CT framework a step further by considering how each CT practice can be intentionally integrated to promote inclusivity and equity in each science lesson (Mak et al., 2023). CRT practices and CT practices intertwined with science and each other to arrive at a CT, CRT, and science-integrated framework, serving as a lesson reflection tool for teachers (see Figure 1). This framework allows teachers to start integration at multiple entry points depending on their prior knowledge of CT and CRT and to choose different approaches to CT and CRT-infused science teaching. Teachers may start from any one of the four circles and add a new CT or CRT layer to their lessons, or they may break an integrated lesson down to CT and CRT elements to work on. This study explores how our integrated approach influenced elementary teachers' understanding of CT- and CRT-infused science teaching changed throughout the PD.

Figure 1
The Integrated ACT-Lesson Reflection Tool (refer to Tabe 1 and Table 2 for texts in the frameworks)



Methods

We used a multiple-case study approach (Yin, 2018) to provide detailed descriptions of how teachers' understanding of CT and CRT infused science changed in different ways during the PD workshop. An overview of the PD agenda is listed in Table 3. Among the 24 elementary science teachers from two school districts in a Southwestern state, we intentionally chose two teachers, Ms. Casey and Mr. Alex (aliases), mainly because 1) they teach within the same grade band, both teaching 4th Grade; 2) they possess similar length of teaching experience, both having taught for about 20 years; 3) they created a final science lesson plan poster using the same initial lesson. Both teachers are White. They teach in the same large urban public school district with diverse array of schools, but in different schools: Ms. Casey teaches at K-8 school within a high socio-economic neighborhood in the northern part of the district boundary while Mr. Alex teaches at a K-6 school in the southernmost part of the district boundary with lower socioeconomic status. During the workshop, Ms. Casey and Mr. Alex engaged in most PD activities and group discussions separately as they were seated apart, but they collaborated with the other 4th grade teachers during lesson-planning times every day. Among all teachers, Ms. Casey and Mr. Alex had the most similar starting points in terms of their background and lesson plans. Comparing their cases will inform us of how their personalized self-reflections mediate their understandings of CT and CRT, which potentially leads to different approaches to and outcomes of integrated science teaching. We selected Ms. Casey and Mr. Alex in this case study as an initial exploration, through which we look for patterns and theories that will inform future larger-scale analyses involving more teachers within this first site of implementation and across multiple sites.

Data were collected from multiple sources: pre-workshop survey data, daily Google reflection forms, final lesson plan designs, and post-PD focus group interview recordings. Prior to the PD workshop, a pre-survey was sent to teachers to collect their basic information (e.g., district, school, years of teaching), initial understanding, and classroom practices related to CT and CRT. On each day of the PD, teachers were asked to submit responses to a series of reflection questions through Google Forms. Teachers wrote exit tickets at the end of each day. Observation notes were taken by 2-3 members of the team in turn. In the first four days, every day in a dedicated time, teachers adapted or designed their individual lesson plans to integrate CT and CRT components and get feedback from other teachers in the same grade band. On Day 5, each teacher presented their lesson plan in a final poster gallery walk activity. At the end of the workshop, teachers participated in semi-structured focus group interviews with their table mates. The interview questions were designed to capture changes in their understanding of CT, CRT, and their integration in science. The interviews were videotaped and transcribed for analysis.

Two researchers first conducted deductive coding for the data based on the three CRT opportunities (Equitable Instructional Practices, Student-Centered Content, Inclusive Relationships & Communities) and the four areas of CT practices (Using Data, Programming, Computational Simulation, Systems Thinking) in the frameworks guiding the PD design (Ketelhut et al., 2020; Mak et al., 2023). Based on the initial deductive categories, the two researchers conducted another two rounds of inductive coding, in which they looked for new themes to capture teachers' evolution of thinking. After the independent coding process, the two researchers discussed each code, converged on the coding scheme, and reached full agreement on the resulting codes.

Table 3
Overview of the PD agenda

Days	CRT focuses	CT focuses	Integration activities
Day 1	Overview of CRT	Overview of CT; CT and citizen science	Introducing everyone's name and animating it using Scratch
Day 2	A deeper dive into CRT; Equity in CS education	Data practices about weather using Micro:bits and data visualization tools	
Day 3	Providing language support in science; Teachers' journey to equity; CRT in a physics lesson	Simulations and systems thinking in science using SageModeler and Phet simulations	
Day 4	Identifying teachers' values	Programming using Edison Robot and Micro:bits	Integrating all aspects of CT and CRT in a lesson about urban heat islands
Day 5	Cultural affinity map		Poster presentation of teachers' integrated lesson plans

Findings

Case 1: Teacher ms. Casey

Prior to the PD workshop, Ms. Casey had an emerging but vague understanding of CRT. She was motivated to create an inclusive classroom as her yearly goal, describing her approach to this goal mainly as to "help foster unity and help students open up about their thoughts and feelings" (Pre-workshop survey, June 2022). Similarly, although she had not heard about the term CRT before, she speculated that CRT means "showing respect and acceptance to all students" (Pre-workshop survey, June 2022). She maintained this interpretation of CRT throughout the PD: across the five days, she consistently focused on creating a safe classroom environment for students to open up and share, yet she did not describe in detail what practices she might adopt to achieve inclusiveness or student-centered content. Rarely did she reflect on equitable instructional practices in her written responses.

Her broad understanding of CRT was explicitly observed on Day 2 when a facilitator explained in-depth the characteristics of CRT defined by Gay (2018), which includes acknowledging the value of students' cultural heritages, bridging between home and school experiences, using various student-centered instructional strategies, and teaching students to appreciate each other's culture. After hearing the facilitator's interpretation, Ms. Casey shouted: "...It makes me sad that we still have to talk about this because it is just good teaching (Observation note Day 2, June 2022)." While believing CRT is "good teaching," she did not expand on the deeper meaning of CRT or any concrete approaches to achieve it. She held onto helping students open up in her classroom as a key element of CRT, which was reflected in her lesson plan and focus group interviews expanded in the next sections of this paper.

With CT, Ms. Casey presented a complicated attitude. Although in the interest form and pre-survey she expressed excitement about integrating more technology into her science lessons, she tended to express discomfort when learning about new technological tools. On Day 1, she was asked for the first time to use Scratch (a block-based programming language that supports the creation of interactive stories, games, and animations) to create a short animation. When she could not make the objects on the screen move in the way she planned, she seemed very frustrated, talking aloud to the facilitators in an angry tone. But then, after the facilitators helped her solve the problem, she quickly returned to her normal voice with a more polite attitude and continued to focus on the project. She had similar reactions again in the following days when she experienced other new tools such as Data Wrapper (a data visualization tool that teachers used to create a local sandstorm frequency map) and Edison Robot (a programmable educational robot), but her reactions were not as intense as the first day. In the end, despite her initial resistance, she successfully completed all the technology-infused activities in the workshop. One of her group mates commented in the focus group interview on Day 5 that Ms. Casey "has changed tremendously" in terms of her acceptance of technology.

Ms. Casey's mixed attitudes towards technology were interwoven with her understanding and confidence in CT integration into science. Compared to her interpretation of CRT, she gradually adopted the language in our CT framework to describe CT-infused teaching practices in detail, but most of the time her responses solely focused on using data, which had already been part of her daily science teaching practices (as indicated in the pre-survey). Her self-reported comfort level with CT on Day 3 was 2.5 on a 1-5 scale compared to a mean of 3.15 among the 24 teachers, lower than her CRT comfort level of 3. Although she saw the value and need to expose students to CT activities, she still perceived CT as harder for her due to a major concern that CT-infused activities could not easily align with standards-based science learning. In her opinion, "many of the items I've been introduced to this week seem to be more STEAM related than specific standards I need to teach (Reflection Form 3, June 2022)." Correspondingly, she also reflected on not feeling comfortable with doing hands-on activities because students could not be directly assessed through formal grades.

Based on our observations, we only saw one instance in which Ms. Casey showed the idea of combining CT and CRT together: when her focus group talked about the benefits of involving computers in science teaching, she pointed out that collecting and charting data on a computer not only gives more meaning and real-life connection to students, but also makes students feel more responsible for the task. Other than that, she tended to consider CT and CRT separately in elementary science.

Case 2: Teacher mr. Alex

Before the PD workshop, creating an inclusive learning environment was already mentioned in Mr. Alex's teaching philosophy and science teaching practices reflected in his pre-survey responses. He emphasized collaboration and engagement for all learners in his classroom, specifically using game-based learning approaches to ensure equal participation in science activities. Although he mentioned no prior exposure to formal training on CT or CRT, he had provided examples of using CT and CRT practices in his lessons. For instance, students in his classroom were given hands-on opportunities to engage in real-world science topics (e.g., "students work in collaborative groups to build functioning water wheels in the Water & Climate unit," Pre-workshop Survey, June 2022). He also incorporated student experiences to promote respect for differences to some degree (e.g., "I also embed discussion time during morning meetings to allow students to share their opinions, differences, etc. We work in cooperative teams and learn to listen and appreciate each other's experiences and stories," Pre-workshop Survey, June 2022). When he learned more about CT and CRT, Mr. Alex quickly related the two concepts to his past efforts. In addition, he seemed to be comfortable with the new technologies introduced in the workshop, completing most workshop activities without technology assistance.

In the self-reflections he wrote, we found that Mr. Alex demonstrated an improved, concrete understanding of implementing CT and CRT practices:

> It's important to use a CRT lens to reach all our different learners in our classrooms. We have such diverse children in our room and finding a way to make science accessible is important. We need more representation in the math/science fields. The challenge right now is not knowing who are (our) students are and what the make-up of my class will be. Also there is internal diversity in our classes that we don't always know about. I also think teachers sometimes don't integrate CT in their lessons because there's a lack of knowledge and access to data and what to do with that data and how students can take ownership of their own data and use it in a way to make inferences. (Reflection Form 2, June 2022)

In this reflection, his written response implied two opportunities for adopting a CRT lens: 1) through creating student-centered content and making science accessible to all types of learners (i.e., he emphasized incorporating diverse children's experiences to promote respect for differences and giving students a sense of ownership of their learning processes); 2) through building inclusive relationships and communities (i.e., he recognized the need for using more representations or encouraging multiple modes of expressions). His reflection also demonstrated that he perceived CRT as inclusion with a central focus on diversity and designing lessons to improve representation in science and math.

In the focus group interview, he rated himself as super confident in teaching CT- and CRT-integrated science lessons in the upcoming school year. He showed clear intentions to create more opportunities for English language learners (ELLs) and special education (SPED) students in his class. Specifically, he appreciated the Activity before Concept (ABC) - Concept before Vocabulary (CBV) model introduced in the workshop and stated that he would modify and make accommodations for his ELL and SPED kids based on the ABC-CBV conceptual model. Moreover, Mr. Alex constantly emphasized the importance of establishing career awareness for all students, noting the importance of expanding CRT beyond one-off lessons in the classroom to long-term student participation in the STEM pipeline.

Mr. Alex's journey in the PD started with a strong recognition of the relationship between technology and learning, and an awareness of creating an inclusive atmosphere for diverse student learners (i.e., ELL and SPED learners). At the end of the PD, he presented a model of integrating CT and CRT more aligned with the framework facilitators presented in the PD.

Lesson plan comparison

Both teachers chose seasonal weather as their lesson plan poster topic. They also selected similar starting lesson plans, both containing some CT and CRT components. For instance, both original lesson plans asked students to analyze their local weather data in four months (Student-Centered Content), consider weather differences across the country (Inclusive Relationships & Communities), and emphasized inputting data into Excel to create bar graphs (Using Data). After the coding analysis, we noticed some similarities and differences between the two teachers' extensions of the lesson plans in terms of using CT and CRT practices. These similarities and differences are summarized in Table 4.

Table 4
Comparison of the Two Teachers' Lesson Plans

	Ms. Casey	**Mr. Alex**
CT	Both teachers highlighted data practices and included sorting data and creating graphs or charts in their lessons.	
	• Used Google Sheet as the main computational tool (*Using Data*) • Did not apply any new computational tools introduced in the workshop (*Using Data*)	• Stressed the importance of finding patterns and relationships in datasets (*Using Data*) • Extended the use of computational tools from recording and organizing data in Google Sheet to building visual map models with DataWrapper (*Using Data*)
CRT	Both teachers expanded the lesson by having students look at weather data in other places in the U.S. (relating local weather patterns with weather patterns elsewhere).	
	• Stressed the inquiry-based approach when expanding the topic to weather across the U.S. (*Student-Centered Content*) • Posed a question on weather differences across the U.S. and described a case scenario about unusual weather patterns (*Inclusive Relationships & Communities*)	• Emphasized bringing in local and national scientific data into the lesson so students can draw patterns and relationships between their communities and others around them (*Student-Centered Content*) • Stressed being aware of differences when comparing local weather to the national weather (*Inclusive Relationships & Communities*)
Integration	Emerging	Intermediate

The comparative analysis demonstrates that although the two teachers made similar adaptations to their original lesson plans, they integrated CT and CRT at various levels and interpreted their changes from different angles. Ms. Casey chose to enhance the inquiry-based approach of the original science lesson. She created opportunities for students to share their different experiences by expanding the source of data from local to nationwide. In comparison, Mr. Alex adapted his lesson plan to explicitly include more CT practices with a culturally responsive lens by purposefully incorporating more CT tools and creating opportunities to articulate the rationales behind the CRT elements with students.

Cross-case comparison

Other data further support findings from the comparisons between the two teachers' lesson plans. In focus group interviews, for example, when prompted to describe the changes in CT and CRT understandings, both teachers expressed that this PD workshop affirmed their past practices, but they showed multiple pathways to extend their science teaching by including CT and CRT practices. In Mr. Alex's case, he stated affirmation of his past CT-related practices:

> The layer of CT is already in our science lessons. So I just need to add a bit more tech pieces and the world view thing (Focus group interview Day 5, June 2022).

In Ms. Casey's case, she described the changes in her understanding of CRT as:

> I do it over the whole class period, but not maybe specifically to science. But it's gonna make me look at it a little bit differently and maybe make sure that I look for those opportunities when I need to (Focus group interview Day 5, June 2022).

Drawing back to the ACT integrated model (Figure 3), we could recognize that Ms. Casey and Mr. Alex started at different entry points and chose different approaches towards CT- and CRT- integration in science. Ms. Casey had relatively high confidence in CRT but was initially frustrated by CT tools. Hence, she developed a lesson plan based on her understanding of CRT by expanding the CT components, showing a science→CRT→CT pathway in the ACT model. On the other hand, Mr. Alex started with greater recognition of technology and developed a more nuanced understanding of CRT during the PD. His lesson plan focused on using data practices to promote cultural responsiveness, showing a science→CT→CRT approach.

However, despite emerging signs of CT- and CRT- integration, both teachers still understood CT and CRT in limited aspects and held misconceptions to various extents. Their interpretation of CT and CRT tended to remain general and vague, especially for Ms. Casey. For example, one of the few shared moments for them regarding equity was when a facilitator showed images of old White male figures that appeared in a Google Image search for "scientists." Both of them mentioned becoming aware of the prevalent use of such images and the importance of reducing stereotypical conceptions, which was an opportunity for them to examine their own identities as science teachers. Mr. Alex extended this topic by reflecting on the representations of ELLs and SPED students in the classroom and differentiated support for them. In contrast, Ms. Casey discussed little about who her students are and how her past or present teaching practices could support their different needs or promote socio-political consciousness. In addition, although the PD workshop embedded multiple scaffolded activities for teachers to share and reflect on their own cultural lenses, both teachers rarely mentioned how their own experiences could influence their perception of CT- and CRT-integrated science in their final lesson plan and focus group discussions.

Conclusions & implications

Ms. Casey and Mr. Alex's journeys to culturally responsive and computational thinking infused science teaching are diverse. Ms. Casey started with emerging conceptualizations of CT and CRT; during the workshop, she overcame great challenges to master the technology tools but remained relatively constant in her understanding of CRT. In contrast, Mr. Alex embraced technologies to a greater extent prior to the workshop; while feeling confident in integrating CT, he developed a finer-grained and multi-layered understanding of CRT.

The growth in understanding of CT and CRT in the workshop were not even for both teachers, drawing attention to the inherent differences between the two concepts and the role teachers' personal experience plays in their learning. We suggest there is a gap between teachers' perceived difficulty and actual understanding for both concepts, but the gaps in CT and CRT exist in different ways. Although CT has initial barriers for teachers who do not possess high self-efficacy for using technologies, it is more tangible and explicit for teachers to develop a concrete understanding. CRT, however, can be easily perceived by teachers as “just good teaching” despite it being much broader and deeper than that. CRT is more nuanced and multifaceted, highly dependent on the teacher’s active reflection on their own cultural lenses and experiences. Moreover, teachers tend to believe they are already integrating the whole of CRT when they are just working on one aspect of it. Both CT and CRT are complicated constructs with multiple layers, but they take effect in different mechanisms. While elements of CT can be extracted and implemented separately, different dimensions of CRT work as an organic whole, which requires fundamental changes in teachers’ beliefs and philosophies. Our research will continue to examine the ongoing evolution in teachers’ understanding of CT and CRT in classrooms and how their self-efficacy changes in the process. We suggest that future work should focus on providing teachers with more personalized and sustainable support for CRT in order to build CRT- and CT-infused science classrooms.

Abstract: The effects of educational anxiety have been observed across multiple disciplines; anxiety negatively influences cognition, self-regulation, performance, and educational outcomes. However, there has been limited research on anxiety within the context of interactive learning environments. In the current research, we expand this by assessing whether and how trait-level anxiety (assessed as a pre- and post-measure in a year-long study) is related to students' self-regulated learning strategies, behaviors, belief, and achievement in the context of an open-ended math problem-solving platform, called CueThink. Results indicate that anxiety is negatively related to key constructs involving math achievement. Altogether, our findings generally imply that students with higher anxiety may avoid interacting with their stressors, in this case, math content, effectively contributing to poorer outcomes. We discuss our findings within the context of research and pedagogical and system design.

Introduction

Anxiety is generally defined as the affective reaction to overwhelming cognitive and motivational demands that are tied to highly valued academic situations (González, Fernández, & Paoloni, 2017; Pekrun & Perry, 2014; Zeidner, 2014) often resulting in decreased performance (Hong, 2010). Individuals prone to anxiety are purportedly less likely to effectively manage uncertainty leading to difficulties around decision making, which contributes to negative outcomes on performance, motivation, and attention across various subject areas (e.g., Ashcraft, 2002, Na, 2007; González et al., 2017; Pardo, Han, & Ellis, 2016; Taylor, & Fraser, 2013; Woolf et al., 2010). Anxiety around specific subject matter, such as math or science, can also lead to avoidance behaviors, both in daily life and within educational settings (Ashcraft, 2002; Brunye et al., 2013). This can then impact competence and academic success (Plake & Parker, 1982; Brunyé et al., 2013). When learners engage with a subject in which they experience anxiety, they are more likely to underperform as a result of hyper-focusing cognitive and attentional resources on apprehension and concern regarding the demands of an educational task instead of strategies for problem solving (Ashcraft, 2002; Beilock & Carr, 2005; Jelici et al., 2004).

Although previous research has established the impact of anxiety on learning, few studies have examined this phenomenon within the context of interactive learning environments (ILEs; with some exceptions, see Andres et al., 2021, Hutt et al., 2021b). As ILEs become more prevalent at all levels of education (Allen & Seaman, 2014) it is important that we consider how individual differences between students may impact their experiences, so that ILEs can be designed to better support students' needs. The effects of anxiety may also be compounded in ILEs where there may be reduced immediate feedback from instructors and increased demands of metacognitive skills, proficiency with technology and complicated software (Hsu et al., 2009). The fine-grained data collection by ILEs allows for insights into the interactions and relationships between learner cognition and affect (Hutt et al., 2021a; Sinha, Jermann, Li, & Dillenbourg, 2014). For example, extensive work has considered the relationship between learning, interaction and epistemic (or academically-relevant) affective states (e.g., boredom, confusion, delight, engaged concentration, and frustration) in ILEs. However, this work has generally not considered anxiety.

By better understanding how anxiety may manifest in ILEs, we gain not only a better understanding of the phenomena, but the potential to respond to and scaffold students experiencing anxiety. Affect-sensitive interventions have produced better learning gains (D'Mello & Graesser, 2012; Clavel & Callejas, 2015; DeFalco et al., 2018), and support positive self-perceptions and attitudes (Karumbaiah et al., 2017). Additionally, interventions have been designed to impact constructs such as motivation (De Vicente & Pain, 2002) and self-efficacy (Beal & Lee, 2005).

This paper thus examines the effects of anxiety within a digital learning application called CueThink, an open-ended math problem-solving platform. Specifically, this study leverages a multi-faceted correlational approach to understand what constructs are related to anxiety in the context of a math-focused ILE. Specifically, we collected a broad range of measures that may be related to anxiety in order to identify how anxiety relates to:

1) survey measures to identify how trait-level anxiety relates to changes in student usage, belief, achievement, learning, and performance; 2) previously-developed detectors of self-regulated learning behaviors; 3) usage behaviors in the ILE (e.g., response patterns and language). Through these analyses, we attempt to build a better understanding of how anxiety can influence learners within an ILE and how features of learner experiences can be used to eventually build systems that can identify and mitigate the influence of the effects of anxiety.

Methods

CueThink

CueThink is a digital learning application that scaffolds math problem-solving and encourages mathematical discourse through open-ended problems and corrective feedback. Students are asked to think aloud while they solve math problems to create a shareable screen-cast video of their overall problem-solving process as well as their final answer. Within CueThink, students work on Thinklets, step-by-step processes for solving math problems. Each Thinklet consists of four phases: Understand, Plan, Solve, and Review. This was developed in line with the Winne & Hadwin model of SRL (Winne & Hadwin, 1998) and scaffolds a problem-solving process that includes unpacking the problem, choosing a strategy, and creating a plan. Students can move freely across the four phases, including going back to a previous phase or skipping phases.

The Understand phase asks students to structure their conceptualization of the problem by asking three questions: (1) “What do you notice?” (2) “What do you wonder?” and (3) “What is your estimated answer to the problem?” In the Plan phase, students are asked to select strategies they will use to solve the problem (either from a pre-written list or self-defined) then write a plan on how they will use the strategies to solve the problem. In the Solve phase, students explain and present their answer. During this phase, the students create a screencast video using an interface that provides them with a whiteboard and mathematical tools (i.e., number lines, ruler, etc.). Lastly, in the Review phase, students provide the final answer to the math problem and reflect on the accuracy of their answer, the clarity of their responses, and record this reflection using checklists.

Once students have completed the problem, they share their screencast explanation for Peer Review. Teachers and peers are encouraged to annotate both the textual responses and video with the goal of prompting the student to identify their underlying reasoning or for using specific methods. These annotations are then sent back to the video’s author for possible revision of the video.

Sample

A total sample of 213 of students (115 sixth grade and 98 seventh grade) participated in the larger study. However, as is common in classroom studies, not all students completed all measures. As a result, a varying number of students were included across statistical analyses in order to maximize the availability of data per analysis; final N’s for each test are reported alongside the results in the following sections. All students were drawn from three middle schools from a large, suburban school district located on the West Coast of the United States. The participants identified their gender as male (40.8%), female (53.1%) or non-binary (1.9%) or other (2.8%), with 1.4% of participants electing not to specify a gender. The participants also identified as Hispanic/Latinx (29.6%), Middle Eastern (28.6%), 2 or more races (16.4%), Asian (6.6%), Black/African American (4.2%), or White (2.8%), with 11.7% of participants preferring not to specify their ethnicity.

Pre-test and post-test survey measures were administered within the course of this study (details below). Students were given approximately 75 minutes to complete three different survey components. The first was a paper-and-pencil mathematics assessment developed by Illustrative Mathematics (approx. 35 mins.), followed by an online set of questionnaires distributed over Qualtrics (approx. 20 mins). This form contained prompts from the modified Abbreviated Math Anxiety Scale, Indiana Math Belief Scale, i-Ready Diagnostic, and Junior Metacognitive Awareness Inventory. For consistency across the varied scales, each item from all self-report surveys were reported on a scale from 1-100. Lastly, the third component was Adaptive Cognitive Evaluation, to measure executive function (UCSF, 2022). The content of the pre-test surveys and post-test surveys were identical. The three components were administered in no particular order. Pre-test surveys were completed anytime within a two-week period between November and December 2021 and the post-tests were completed anytime within a three-week period in May 2022.

Research instruments

Executive function

Executive function (EF) was measured using the Adaptive Cognitive Evaluation (ACE; Younger et al., 2022). ACE is implemented through a series of game-based cognitive tasks around three core EFs: inhibition, working memory (change detection), and cognitive flexibility (task switching; Miyake et al., 2000). Mean and standard deviation scores were calculated for both reaction time and accuracy measures.

Content knowledge

i-Ready diagnostic assessments were used a proxy for mathematics content knowledge by the partnering district (Curriculum Associates, 2022). The i-Ready (CDE, 2022) instrument is an adaptive assessment tool used to identify math topics students are struggling with. It examines students' understanding of mathematical sub-domains, including numbers and operations, algebra, geometry, and measurement. This assessment was administered three times throughout the school year. These testing periods were conducted towards the beginning (September), middle (December to January), and end (May) of the academic year.

Metacognition

An abbreviated version of the Junior Metacognitive Awareness Inventory (MAI, Jr.; Rhodes et al., under review; Sperling et al., 2002) was administered to record subjective metacognitive and cognitive strategies applied by learners. Objective metacognition was separately recorded through the use of confidence judgements wherein students estimated how well they would perform on problem-solving exercises and would evaluate their performance immediately after the task. Scores for objective metacognition were calculated by computing the absolute value of the difference scores between an individual's confidence judgements and their actual performance.

Affective instruments

Anxiety and mathematic epistemological beliefs were recorded using the modified Abbreviated Math Anxiety Scale (mAMAS; Carey et al., 2017), and belief scales 1, 5, and 6 of the Indiana Mathematics Beliefs Scales (IMBS; Kloosterman & Stage, 1992), respectively. The mAMAS uses a two factor structure that uses two subscales: learning math anxiety (Learning subscale), and math evaluation anxiety (Evaluation subscale; Hopko et al., 2003; Carey et al., 2017). The scale has shown good internal consistency, with an overall Cronbach's α 0.85, a Cronbach's α of 0.77 for the Learning subscale and Cronbach's α 0.79 for the Evaluation subscale (Carey et al., 2017; Cipora et al., 2015; Szczygieł, 2019). The scale was developed for children between 8 and 13 years old (i.e., overlapping with our research sample) and consisted of 9 items. The mAMAS was slightly modified to change adapt words to American English (e.g., "maths" to "math").

The IMBS measured beliefs around mathematics, more specifically about whether students believe they can solve time-consuming problems, about whether effort increases ability, and about the usefulness of mathematics in their lives, respectively. Students were also given five questions about their feelings about mathematics and the classroom and a question about how close they felt to the subject of mathematics. An abbreviated version of the IMBS (Rhodes et al., under review) was administered to reduce testing fatigue.

Problem solving measure

Members of the research team developed 3-item problem solving measures for each grade. All items for this measure were drawn from mathematics problems developed by Illustrative Mathematics (IM) and included in the current measure based on A) their cognitive demand and overall rigor, B) their alignment with district standards for the given grade level, and C) the degree to which students were required to explain their thinking. Each problem was scored for accuracy (IM accuracy) using IM answer keys. Problems were also scored by external researchers who assessed the degree to which a student demonstrated appropriate and sufficient mathematical understanding, regardless of their final answer (IM understanding). Each student received both scores.

Self-regulated learning behaviors

In addition to these surveys, we also analyzed the relationship between anxiety and students' self-regulated learning (SRL) behaviors, using a set of behavior detectors developed using qualitative codes of SRL behaviors originally developed by Zhang and colleagues (2022) and validated for generalizability using 10-fold student-level cross validation (summarized in in Table 1). Results were calculated for each fold and averaged to yield one AUC ROC score per detector; all the values in the table show relatively high accuracy for each SRL behavior.

Table 1
Detector Performance Measured by AUC ROC with Standard Deviations (Zhang et al., 2022)

SRL Indicator	AUC ROC	Working Definition
Numerical Representation	0.894 (.078)	Representation notes numerical components and how these are used in the math problem
Contextual Representation	0.813 (.132)	Representation notes contextual details (setting/characters/situations) in the problem
Outcome Orientation	0.761 (.076)	Only a numerical estimate of the final answer (suggests a focus on output over process)
Data Transformation	0.815 (.163)	Information is manipulated to find a solution (suggests active problem solving)

Usage data and linguistic features

Throughout this study, we extracted the amount of time each student spent completing tasks within each phase of their Thinklets. This data was recorded in seconds and summarized at the student level per phase (Understand, Plan, Solve, Review). Students' text responses were also analyzed for linguistic features using the Linguistic Inquiry and Word Count (LIWC) program (Pennebaker et al., 2015). LIWC analyzes 100 different lexical categories (Pennebaker et al., 2015) and uses a combination of computing methods and dictionaries that automatically tabulate text files for word counts and important psychosocial constructs and theories with words, phrases, and other linguistic constructions (Boyd et al., 2022). We attempted to minimize Type 1 errors by selectively choosing the lexical features under the *Cognition* category of LIWC (Boyd et al., 2022). This category reflects the different ways people refer to their thought processes. Table 2 below summarizes the subcategories that are included in this category as well as some of the same words that are recorded and coded for each of these.

Table 2
LIWC categories and most frequently used exemplars (Boyd et al., 2022)

Subcategory	Most frequently used exemplars	Subcategory	Most frequently used exemplars
Cognitive Processes	but, not, if, or, know	Differentiation	but, not, if, or
Causation	how, because, make, why	Memory	remember, forget, remind, forgot
Discrepancy	would, can, want, could	Insight	know, how, think, feel
Tentative	if, or, any, something	All-or-None	all, no, never, always
Certitude	really, actually, of course, real	Number	one, two, first, once

Statistical analyses

Spearman's Rho was used to correlate the survey-level and detector-based SRL behaviors with anxiety scores (pre-test and post-test scores). Spearman's Rho is commonly used in analyses where the assumptions of normality are not met. Linear regressions were used to regress interactions between anxiety scores and time spent in each phase onto measures of achievement, SRL behaviors, and linguistic features. Specifically, linear regression was used to examine the strength of the interaction of anxiety and time spent on the different outcome variables.

Results

Correlations with anxiety

Anxiety scores and survey measures were analyzed using Spearman correlations and Benjamini and Hochberg post hoc corrections (see Table 3). We find that pre-test and post-test anxiety positively correlate with one another ($\rho = 0.56$), where higher anxiety scores at the beginning of the school year corresponds to increases in anxiety scores later on in the school year. This is not surprising when considering the relative stability of trait anxiety. Higher anxiety before using CueThink is negatively correlated with math epistemological beliefs (IMBS scores) and achievement (iReady and IM scores), indicating that increased anxiety scores at the beginning of the study correspond to poorer mathematics performance and more negative beliefs around mathematics. A similar though less salient relationship can also be observed between post-texts of anxiety, as they negatively correlate to IMBS scores and achievement. The reduced effects of anxiety may potentially indicate that learners gain a better understanding of the requisites for solving mathematical problems throughout the study. Correlations between anxiety metrics and linguistic features were also conducted, however, did not yield any significant results.

Table 3
Spearman correlations for student level survey measures (p < .05, non-significant results were omitted from the table, red cells indicate negative correlations, blue cells indicate positive correlations)

Usage data

Correlations and post hoc corrections were calculated to examine the relationship between the different survey responses and the amount of time students spent (in seconds) in the Review and Solve phase of their Thinklets. The results indicate that more time spent in these phases is associated with students engaging more frequently in specific SRL behaviors (see Table 4). Additionally, increased time spent in the Solve phase negatively correlates to math performance on the IM metric. The relationships indicate that despite the increased opportunity of students to engage in SRL behaviors, this may not necessarily correspond to improved performance.

Table 4

Correlations between time spent and survey responses and detectors (non-significant results were omitted from the table, red cells indicate negative correlations, blue cells indicate positive correlations)

	Time Spent (Review)	Time Spent (Solve)	Anx (pre)	Anx (post)	IM accuracy (pre)	IM accuracy (post)	IM understand (pre)	IM understand (post)	Numerical Rep.	Contextual Rep.	Outcome Orient.	Data Trans.
Time Spent (Review)	1	0.44	0.04	0.04	-0.18	-0.01	-0.04	0.03	0.33	0.09	0.23	0.11

N		179	165	134	153	156	153	156	179	179	179	179

Linear regressions were also conducted to examine the influence of anxiety (pre-test and post-test) and time spent in the Solve phase, as well as their interaction, on outcomes of achievement and SRL behaviors. The regressions between pre-test anxiety scores and time did not reveal any significant relationships between the anxiety and the outcome variables. The linear regressions examining the interaction between post-test anxiety scores and time spent in the Solve phase on achievement and the SRL behaviors reveal that post-test anxiety had a significant interaction effect with time spent on Solve phase. A simple slopes analysis reveals that this interaction effect was predictive of increased math achievement ($p = .034$, $R^2 = .097$) where more anxious students who spend more time in the Solve phase are likely to perform better on their iReady scores where the students who take less time are more likely to perform worse. Urgency, perceived threats of failure, or avoidance (Dickerson & Kemeny, 2004; Chrousos, 2009) resulting from anxiety may lead to poorer performance on math tasks and metrics. Regressions were also conducted to predict linguistic variables using anxiety scores and time spent in the Solve phase; however, there were no significant results from this analysis.

Table 5

Discussion and conclusions

The effects of anxiety within education are pervasive and diverse, however it remains to be comprehensively examined within ILEs. This work attempts to further research in this area by demonstrating the influences of anxiety on achievement, usage, and SRL within the CueThink platform. Overall, the combination of findings captures the influences of anxiety independently and in tandem with other significant interaction variables. Through this analysis, we found that higher pre-test anxiety corresponded to lower achievement scores within the math-based platform, and that a large proportion of the sample experienced anxiety. Though not a particularly surprising finding, these results are important in contextualizing the influence of anxiety within this kind of platforms and to better understand which aspects of the platform, usage, or content contribute to anxiety the most will be valuable to developing learning platforms that reduce student anxiety.

Further analysis shows that higher anxiety and changes in the time spent completing responses correspond to varying math achievement. More specifically, the results of this study indicate that students with increased levels of anxiety take more time in Solve phases but perform better on math-based assessments. Anxious students generally tend to avoid stress-inducing materials (Ashcraft, 2002; Brunyé et al., 2013), negatively impacting their academic outcomes (Plake & Parker, 1982; Brunyé et al., 2013). However, students who are able to overcome anxious reactions are also able to mitigate the effects of anxiety on their performance (Brunyé et al., 2013). The inclusion of time may aid in identifying anxious students and offer helpful interventions in response.

Overall, these results demonstrate the importance of student anxiety within ILEs. Our work seeks to highlight the differences in interaction that emerge among students based on their experiences of anxiety and how these, in turn, can impact various aspects of their learning experiences and outcomes. Future work should examine anxiety at the same level of the actions completed by students within the platform to support the development of automated detectors of anxiety. These detectors would support fine-grained analyses that can parse moment-by-moment experiences of anxiety and its influences on behavior, allowing educators, researchers, and designers to build anxiety-sensitive interventions to enhance educational experiences for anxious students.

Rutgers University

Abstract: Modeling science phenomena serves as a tool to support science practices, where classroom environments and youths' relations with each other and those in positions of power shape how the activity unfolds and what models are created. Grounded in a relational ontology, we build on justice-oriented approaches to studying youths' learning towards their Rightful Presence by examining the expansive and political ways of knowing youth draw on while modeling. We followed a group of four middle-school youth and traced the human-human and human-more-than-human powered relations that shaped their models of short and long-term stress created across two multi-day lessons. We illustrate how models emerged as more-than-human entities with identities shaped through youths' intra-group, student-teacher, and human-more-than-human relations, entangled with who and how youth are in and with this world. We also argue ceding power to youth to re-author their and their models' rights supported more expansive understandings of youths' learning.

Introduction:

"Developing and using models" as outlined by the *Next Generation Science Standards* encourages learning science by engaging in embodied practices that integrate disciplinary content and processes, amongst other epistemic considerations (Gouvea & Passmore, 2017). In classrooms, models are considered representations of phenomena that serve as a tool to support learners' inquiry and exploration practices as they engage in sense-making around science phenomena (Guy-Gaytán et al., 2019). However, modeling is a social activity where classroom environments, pedagogical decisions, and youths' relations with each other and those in positions of power shape how the activity unfolds and what models are created (Shim & Kim, 2018). Both the act of modeling and the model created are not neutral processes or products, instead shaped by and through powered dynamics. While there is emerging scholarship that examines how social relations shape modeling practices, Schwartz et. el. (2022) argue that we need to be more explicit about *how* powered dynamics shape modeling activities so that we can support more "expansive, meaningful, and equitable modeling practices" in classrooms (p. 1087). Our study builds on this call by examining the sociopolitical and sociocultural powered dynamics that shaped how youth engaged in modeling practices in ways that led to the emergence of a model as a relational onto-epistemic entity. We develop expansive understandings of youths' learning to illustrate the "dimensions of knowing [that] are not currently valued in modeling competency frameworks and assessments" (Schwarz et al., 2022, p. 1089). Given calls for an expansion of our understanding of modeling and modeling practices, we learn from Indigenous scholarship to highlight the how youth are already engaging in these expansive and political ways of knowing when modeling in science classrooms. We ask: *How do powered human-more-than-human relations shape the emergence of a model on short and long-term stress created by middle-school youth?*

This work is grounded in a relational ontology, recognizing humans as existing in and with the world (Marin & Bang, 2018). From this purview, knowledge creation emerges in relation with the More Than Human (MTH; Bang et al., 2015) – in our case, the MTH in the classroom included laptops, digital tools like jamboard, poster papers, markers, etc. Through interaction analysis (Jordan & Henderson, 1995) we followed a group of four youth who named themselves the 'GLAY' group, making biology models of short-term and long-term stress across two multi-day lessons. We present three episodes to show how their poster-paper models emerged. Per the NGSS-aligned curriculum, the science content learning goal was for students to 'develop and/or use a model to describe phenomena'. We traced the powered relations that shaped the first paper model (of short-term stress) into 'GLAY - a genderless alien, everything and nothing at once, the center of the universe' and the second paper model (of long-term stress) into 'Maria/GLAY Jr. – a universal Goddess and GLAY the second'. When reflecting on the unit, the youth described their group and models as relations across space and time, where who they were as individual humans and as a "mis-functional Spanish family" group were not separate from but emerged in relation with and through their intergenerational family of paper models. Through this study, we illustrate how models were not just neutral tools for reasoning about science phenomena, but MTH entities with identities shaped with and through the youths' intra-group, student-teacher, and various human-MTH relations.

Theories that inform this work

We learn from Indigenous ways of knowing, to shift from a focus on human action to the relations between and within humans and the MTH world in our understanding of how reality emerges (Bang et al., 2015). Our understanding of the MTH is framed through braiding (Kimmerer, 2013) ways of knowing in Turtle Island (Marin & Bang, 2018) with Rishi's ancestral knowledge systems to reflect multiplicities and resonances in how we understand our experience in and with this world (Krishnamoorthy, 2023). Focusing on relations and the MTH as a unit of analysis helps us "expand understandings of how experience is constructed, and knowledge is generated as people interact in/with place" (Marin, 2020, p. 281) and therefore attend to human-human *and* human-MTH relations in knowledge creation as a whole-body activity across time and space. In doing so, we "recognize a multiplicity of histories, foster mutuality rather than extraction, and support theories that account for the role of more-than-human relatives in human development and learning." (Marin, 2020, p. 309). We also recognize our responsibility to learn from Indigenous scholarship as settlers on stolen lands, and work to resist the (re)production of colonial ways of knowing in how we study learning (Krishnamoorthy et al., 2021).

Guided by the Rightful Presence framework (RP; Calabrese Barton & Tan, 2020), we attend to how power shapes human-MTH relations through close attention to the ways in which historically sedimented powered dynamics are resisted and/or reauthored in classrooms. The RP framework takes a critical-justice oriented stance, challenging the positioning of youth as outsiders (guests) in classrooms where teachers are the hosts who author and extend rights to youth (to engage in practices such as modeling). Extending rights to youth and 'including' them into already sedimented classroom norms and practices limits the depth and breadth of youths' whole selves valued, in ways that can (re)produce existing inequities in education and the dominancy of canonical Eurocentric ways of recognizing learning (Tan & Calabrese Barton, 2020). The RP framework advocates for shifting guest-host student-teacher power differentials with adults working as sociopolitical allies by ceding power to youth, who reauthor their rights around ways of being and knowing such that their whole selves are valued in learning spaces. Using the RP framework, we trace sociopolitical and cultural powered dynamics that are de/settled in the classroom by examining human-human *and* human-MTH relations to illustrate the expansive and less extractive ways that youth engage in knowledge creation in science lessons.

Methods

This work was part of a grant-funded study that drew on critical participatory design research methods (Bang & Vossoughi, 2016) to create a 7th grade science unit focused on a health issue of concern to the local community – stress. The pilot unit was co-designed with eight youth and three teachers from local schools, and eight university partners from various institutions (Krishnamoorthy et al., 2022). Using a storyline approach (Reiser et al., 2021), the NGSS aligned unit drew on the RP (Calabrese Barton & Tan, 2020) and AIR (Chinn et al., 2014) frameworks such that youth learned about the biological phenomenon of stress as entangled with structures, policies, and procedures in the environment. Pilot data was gathered during Spring 2022, in one 7th grade science classroom, located in a sanctuary city in the NE-USA with 90.2% Hispanic students (2). Data included field notes, post-unit group interviews and video of whole-class and four focal youth's interactions: Batman, Ren, Star and Mario. Batman and Ren were long timers at the school, considered 'smart' by their peers while Star and Mario were new to the school that year. Youth had not worked together prior to this study. Adults included the science teacher (a cis-female Middle Eastern immigrant), a support teacher (a Black and African American cis-female), Rishi (a trans/genderqueer [they/them] South Asian) and Ravit (a Middle Eastern immigrant cis female).

Episodes analyzed were of youth modeling short-term and long-term stress (9 hours). Drawing on interaction analysis methods (Jordan & Henderson, 1995), we analyzed human-human and human-MTH interactions to trace the co-operative (Goodwin, 2017) construction of the models as emergent and non-neutral MTH phenomena in the classroom. Examining how youth built on, decomposed, and transformed each other's' substrates (Goodwin, 2017), layered with an analysis of how settled guest-host relations were de/settled illustrated the powered human-human and human-MTH relations entangled with the modeling activity. The three hot spot episodes highlight: 1) Team GLAY, a human community shaped by relations with each other and the classroom, 2) GLAY the short-term model, a MTH entity shaped by youths' intra-group and adult-youth powered dynamics, 3) Maria/GLAY Jr. the long-term model, a MTH entity with personhood, part of an intergenerational family.

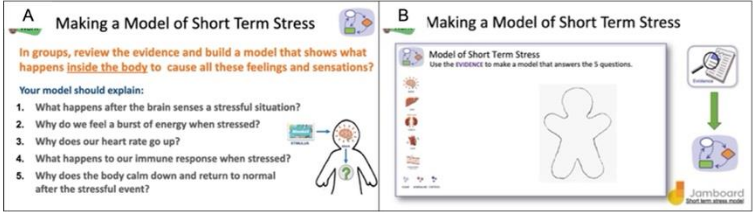
Findings:

GLAY: Mis-functioning Spanish family time

In the short-term stress lesson, youth reviewed evidence provided to them and built a model to show 'what happens inside the body that causes the sensations associated with short-term stress' (see Figure 1A). Youth were provided the option of a Jamboard with a ginger person and some visuals (see Figure 1B), or poster paper to make their models. The short-term lesson was the first time Mario, Star, Batman, and Ren worked together as a group and GLAY emerged as the group's team name – created from the first letter of each youth's name.

Figure 1

A) Slide with instructions and B) Jamboard provided to youth



A Making a Model of Short Term Stress

In groups, review the evidence and build a model that shows what happens inside the body to cause all these feelings and sensations?

Your model should explain:

1. What happens after the brain senses a stressful situation?
2. Why do we feel a burst of energy when stressed?
3. Why does our heart rate go up?
4. What happens to our immune response when stressed?
5. Why does the body calm down and return to normal after the stressful event?

B Making a Model of Short Term Stress

Model of Short Term Stress

Use the EVIDENCE to make a model that answers the 5 questions.

Jamboard

Short term stress model

Initially, team GLAY encountered some struggles navigating their group dynamic, disagreeing about how to draw the head of the model. Mario suggested they trace his head onto the sheet of paper, but his head was too big in relation with the body they had already drawn, and the poster dimensions. While passing by Rishi commented:

> [1] Rishi: Man, I love your group
> [2] Ren: It's a. It's a. It's like a family.
> [3] Rishi: Yeah, I like it
> [4] Mario: It's a drama! Because they couldn't even trace my head really good!
> [5] Star: Okay we good. What are you talking about you couldn't even do none of us!
> [6] Ren: it's just it's just..it's just a family! It's just a very…. misfunctioning family
> [7] Batman: okay you know I..I..
> [8] Rishi: ((to Ren)) Aren't all families misfunctioning families?
> [9] Star: I live in a Spanish household. This is worse. ((Rishi laughs and walks away))
> [10] Batman: I like his brain. I like his brain ..it's too small.. You know it's fine I guess.

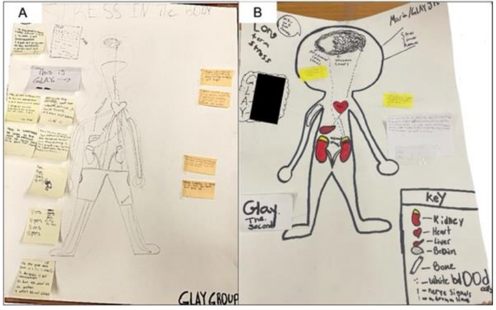
Rishi's utterance [1] affirmed the group's dynamic as desired [3] in the classroom space by; 1) Challenging traditional deficit framings of student discord during group work and 2) Reifying adult-student powered relations where adults author the forms of behavior allowed in classrooms. This substrate [1] was taken up by Ren who reframed it as "like a family" [2], transformed into a "drama" [4] by Mario because of his group mates' inability to trace his head onto the paper. Mario's utterance [4] and Star's retort [5] illustrated their group's "misfunctioning family" [6] dynamic, worse than the "Spanish household" [9] that Star lived in. Yet despite their arguments, their misfunctioning dynamic created a brain that may have been too small but was "fine" in the end [10]. GLAY emerged through human-MTH *and* human-human non-neutral powered relations. The poster enacted power in its relation with Mario by virtue of its dimensions rendering Mario's head a non-viable resource for creating the model. Rishi-youth relations (re)produced sedimented adult-youth power dynamics when they ratified the youth's intra-group (i.e., student-student) relations as desirable [1,3]. Furthermore, youths' cultural identities, histories, and family relations framed their dynamic as a family, "misfunctioning" and "worse" than a "Spanish household". This interaction illustrated the modeling task as not separate from their intra-group and teacher-student interactions, also involving human-MTH relations (i.e., Mario's head's-poster relation). GLAY emerged as a family through their powered relations with each other, the adults, and with the MTH (i.e., the poster) as well.

As the unit unfolded, meaning-making around GLAY as a Spanish family continued. Youth assumed roles shaping their individual relations with the MTH: Mario the artist, engaged in human-poster relations through which etchings on the paper emerged; Ren the "brain", who authored the messages on the model through human-curriculum relations, Batman the "getter'", who brought MTH resources (i.e., markers, etc.) into relation with the model, and Star the "heart", whose relations with the others brought decorative etchings of 'GLAY' into relation with the model. In this sense, the curriculum task, and expectations around what the model should be, the size of the poster, the quality of markers, and their intra-group and adult-youth relations, shaped who GLAY was as a family *and* the MTH entities that emerged (i.e., the models). Next, we illustrate how focusing on relations as the unit of analysis foregrounds youth-curriculum relations as shaping the emergence of models as MTH entities.

GLAY the original: A genderless, universal god and alien

As the short-term modeling activity unfolded, GLAY emerged not only as the group's team name, but the name the model they constructed – a genderless, universal GOD and alien (See Figure 2A).

Figure 2
Short-term (A) and long-term stress (B) models



'GLAY' first emerged on the poster when Batman suggested, "instead of writing our names, we can just put our team-name". Then, GLAY was shaped into a 'being' – first a human, then a ginger person (i.e., genderless ginger cookie), then an alien – through the youths' relations with the instruction slide (See Figure 1) and their negotiating how to represent the being. When beginning the modeling activity, the Jamboard slide was open on Ren's laptop and Mario began to "pre-draw" a sketch of their model on a small whiteboard. Ren clarified to Batman that their task was to "make a model" "based off of this ((the slide)) about how the body functions when we're stressed". Ren's attention then shifted towards Mario's sketch on the whiteboard:

> [11] Ren: ok Mario we're not gonna give him pants. We're just gonna
> [12] Mario: ok he's naked then.
> [13] Ren: yes he is naked
> [14] Mario: blurred
> [15] Ren: no we don't need to blur

With no pants [11], Mario's noting that the model would be "naked" [12] was ratified by Ren, indicating both youths were aligned in their authoring of the model as a 'naked' being. However, Mario's subsequent utterance that the model be "blurred" [14] indicated a disjuncture between how Mario and Ren had gendered the emerging model. To Mario the naked model – a gendered entity – would necessitate censoring to be appropriate for the classroom context. Ren however did not agree [15] as he later noted, "it's genderless, it's a cookie! You think you're gonna have private parts on a cookie?" That is, although Mario and Ren were aligned in their understanding of the model as a *being* of some sort, Ren drew on the representation on the slide (See Figure 1B) animated as a "gingerperson" by their teacher, to frame the model as a genderless cookie. Mario rejected this framing by voicing the disjuncture around the model's gender and personhood arguing, "I don't wanna do a cookie. I wanna do a person". The youth continued to argue until ultimately Ren resigned to Mario's persistence and the model was framed as a "person" (albeit still a "ginger person" [23] according to Ren) whose gender was under construction. Once the 'pre-drawing' of the model was complete, Mario held up the whiteboard to his groupmates and uttered:

> [16] Mario: I put in extra details
> [17] Ren: Why did you give him abs?
> [18] Mario: what?
> [19] Ren: Why did you give IT abs?
> [20] Mario: oh.. that's how you call them?
> [21] Ren: IT
> [22] Mario: I never knew…
> [23] Ren: it is genderless. It is a genderless ginger person. We call it a… IT. Them.
> [24] Mario: There..((shows Ren the whiteboard))
> [25] Ren: It's. it's non-binary.

When critiquing the 'pre-drawing', Ren authored the model as an "it" [19, 21] and "them" [23], building on his earlier positioning of the model as a "ginger person" who was now "genderless" [23] and "non-binary" [25]. Mario, less versed in pronoun use, expressed not knowing [22] and the interaction around the model's gender was driven though Ren's enacting power as a knower and author around gender, despite not having resolved the distinction between the model being 'genderless' [23] and/or 'non-binary' [25]. After this interaction, the group did not directly discuss the model's gender however the model emerged as 'genderless' through their negotiating the model's name. Star suggested "his name's gonna be GLAY", which Ren transformed to "GLAY the alien" because GLAY could be a "boy or girl" name, as noted by Batman. Therefore, GLAY the model emerged through the co-operative interaction between youths' relations with the curriculum slide, and their intra-group powered relations – Mario the artist insisting on the model's personhood, Ren authoring the model as genderless, and Star naming the model GLAY. GLAY the alien's identity was then ratified in the larger classroom space through the group and model's interactions with the adult facilitators the next day, when Rishi asked the group "what's gonna happen on this episode of the lives of GLAY?" Looking at their poster, Mario responded:

> [26] Mario: I mx. I like the shorts. And then he says he's genderless. While.. and he says.
> [27] Rishi: oh sorry I misgendered GLAY my bad
> [28] Mario: [No he. No but I]
> [29] Batman: [No it's GLAY is GLAY]
> [30] Ren: No. And he keeps saying he ((points to Mario))
> [31] Mario: Then. And then I'm saying that he's a boy and he's like [he's genderless.]
> [32] Batman: [GLAY is everything]
> [33] Ren: [GLAY is a. GLAY is an alien]
> [34] Mario: [So they put him shorts]
> [35] Rishi: ((looking at Mario)) GLAY is an alien!
> [36] Ren: GLAY is the alien
> [37] Mario: I know and then so then I put him like a blurred and then he's like. He's. Genderless.
> [38] Rishi: ((Rishi laughs)) So wait. Aliens don't have gender?
> [39] Batman: No. Just. He's everything.
> [40] Ren: No!
> [41] Rishi: I didn't hear you what? ((moves around in between Batman and Ren))
> [42] Batman: He's everything ((nods yes))
> [43] Ren: [he's eve. He's]
> [44] Rishi: [He's everything! Woah!]
> [45] Ren: He's at the ss.. GLAY is at the center of the universe
> [46] Batman: Nothing but everything at the same time..
> [47] Rishi: ((looks over to Batman with wide eyes)) Yo.. that's lit.

Mario's reanimation of the group's negotiations around gender [26] indicated the possibility of something unresolved for him, that he "never knew" [22] regarding gender and the emerging model. For Mario, the tension around the model's gender emerged in relation with representing the model's clothing [34] and Ren's authoring the model as genderless [31]. In the interaction, Batman and Ren positioned themselves as animators and knowers of GLAY's gender and identity and co-operatively constructed GLAY an alien [33], "everything" [32, 39, 42], the "center of the universe" [45], and "nothing but everything at the same time" [46], who was not to be referred to using 'he' pronouns [30]. Importantly, this interaction revealed how the youth's roles within the group and intra-group powered dynamics shaped how and who GLAY the MTH entity with personhood emerged. Batman and Ren were considered the 'smart people' of the group (animated – voiced – by Star the previous day) while Mario was the artist and, in this interaction, less of a 'knower' regarding GLAY's gender. Mario's concerns regarding GLAY's gender emerged through his role as the artist and shaped GLAY into assuming personhood through his decisions around the necessity to draw shorts [34], or whether to blur [37] certain regions of the entity. Ren and Batman built on these substrates through their powered authorship, co-operatively constructing GLAY's identity as an alien. GLAY the model's identity was also ratified through the adult's sociopolitical allyship towards youths' authoring their rights in the classroom space – through Rishi apologizing for having misgendered GLAY [27], re-animating GLAY as an alien [35], and legitimating their construction as "lit" [47].

The next day when youth continued modeling, GLAY emerged as an entity that didn't use pronouns, was just called "GLAY", and whose physical appearance was co-operatively constructed by gender and curricular expectations. For example, GLAY the model was shaped into being shoe-less, because as Mario noted "we can't put him shoes ms, because this is the part where the blood stream goes circle like you know?" as he traced his fingers along GLAY the model's extremities. Therefore, in addition to the youths' intra-group relations and adult-youth powered relations (human-human relations), the youths' relations with the curriculum (human-MTH relations) shaped how GLAY as an entity emerged. In this episode we build on recent scholarship on youths' social relations that shape modeling activities (Shim & Kim, 2018) by illustrating how youths' intra-group, adult-youth, and individual and group powered relations with the curricular materials shaped the emergent model entity. Their model represented the required biological systems (i.e., short-term stress). It was also a MTH entity with personhood (or alien-hood) that emerged through powered human-human and human-MTH relations. Next, we illustrate how youths' relations with macro sociopolitical powered dynamics also shaped the model that emerged.

Maria/GLAY jr.: GLAY the second, a universal goddess

In the next lesson set, the youth read a story about a character 'Maria', who was experiencing symptoms of long-term stress. The group's task was to create a model of long-term stress based on evidence pieces that the character Maria encountered in the story. This modeling activity and the model's identity emerged through the youth and model's relation with the previous lesson on short-term stress, evidenced by the youth negotiating the long-term stress model's name. Mario noted, "since we're gonna do another model, we can name him GLAY Jr.". However, Batman and Ren were not convinced, and the group debated whether the model's name would be GLAY Jr., or GLAY the second (who wore a top hat). Ultimately, the long-term stress model emerged as a MTH entity shaped through the youths' relations with the curriculum and the story character Maria (human-MTH relations), Star's relations with Batman, Ren, and Mario and larger sociopolitical powered dynamics (human-human relations), and the model's positioning as the 'second' of its kind following GLAY the original (MTH-MTH relations).

[48] Star: Like GLAY had a small brain that means he had no thing like..
[49] Mario: He had. He was dumb now
[50] Star: Exactly
[51] Ren: Its not a he. it's not a the.
[52] Star: It's not a he, they or she
[53] Ren: universal God give them some respect
[54] Star: we might as well. we might as well give him a gender because like..
[55] Ren: Give GLAY the universal God uh God respect
[56] Star: GLAY should be a female
[57] Mario: GLAY? a FEMALE? Excuse me? ((pauses drawing, leans back, and looks at Star))
[58] Star: GLAY should be a female. There's already three boys and there's only one girl. ((moves forward, points to Mario, Ren, and Batman and then herself))
[59] Mario: FINE
[60] Ren: It's women's history month. Ya gotta..

Star's initial relation with and meaning-making around the model's head being too small to draw in a brain [48] was reanimated by Mario as the model being dumb [49]. However, Ren took up this substrate and transformed it into a correction of Star's use of GLAY's gender [51], reanimated and expanded by Star from "he or "the." [51] to "he", "she" or "they" [52]. Ren, looking for the appropriate way to address GLAY, built on Star's animation from using "them" pronouns [53] to no pronouns [55]. Star however, transformed Ren's negotiation of GLAY's gender into an opportunity where they "might as well give him a gender" [54]. While Star's reasoning for gendering GLAY was not revealed, she re-asserted that GLAY should be female [56]. In response to Mario's dramatized surprise [57], Star drew on her position as a female in the group as consequential towards GLAY being gendered as female [58]. Building on this substrate, Ren's utterance entangled "women's history month" [60] and in doing so, larger sociopolitical powered dynamics around female representation, with the emerging 'gendering' of their model. The model emerged as a female through its relations with the gendered dynamics within the human family – GLAY – *and* the macro sociopolitical dynamics and histories informing the institution of women's history month. As such, GLAY emerged as a "universal Goddess", named by Ren moments later.

The model's physical shape emerged through the youths' relations with the evidence sets, when deciding how much clothing the model would need, and how to depict neural signaling loss due to long-term stress. At the end of the lesson, the teachers instructed the youth to "add a title" – a model criteria (Rinehart et al., 2016) agreed upon by the class. They decided that "her" name would be Maria since they were modeling the curriculum story character's experience. Being the second model their group created, the youth deemed it important to place a notecard indicating the model was "GLAY the second" inscribing her name as Maria/GLAY Jr. (See Figure 2B). Unlike the short-term stress model, they wrote their names on the poster sheet, a symbol of their pride in their work. The youth noted that Maria/Glay Jr. illustrated who the youth were (through their initials on the poster) and served as a window into their memories of struggles as a Spanish family learning to work with each other, a tv-drama unfolding daily. Maria/GLAY Jr. was not just a neutral epistemic product (model) representing youths' knowledge nor was it just a tool used to learn about stress. She was a MTH entity with personhood, a universal Goddess and the descendent of GLAY the original. Team GLAY's long-term stress model emerged through their intra-group and adult-youth (human-human) relations, their relations with macro sociopolitical powered dynamics, and youth-curriculum relations across this curricular unit (i.e., human-MTH relations across space and time).

Discussion

Centering a relational ontology in curriculum design and enactment supported the youth to continually engage in 'the right to reauthor rights', a Rightful Presence tenet (Calabrese Barton & Tan, 2020). While the science curricular learning task was to construct a model to first explain the biology of short-term stress and then long-term stress, the ways in which GLAY members engaged with their modeling suggested that they were probing for understandings beyond the biological phenomenon. They were simultaneously *modeling* – figuring out in real time – who they were, who they could be and wanted to be, in relation with whom and with what (i.e., configurations of human and MTH resources), as Spanish speaking youth in an urban classroom. Through a relational ontology, we suggest that the GLAY youth were engaging in *multi-scale onto-epistemological modeling*. That is, in their performing of the GLAY group, the youth entangled the following: a) their Hispanic identities with familial, playful repartee; b) their strength-based distributed expertise with the group work (Mario, friendly and tentative speaker but a recognized artist; Ren and Batman as the 'good science students' offering ideas, and Star as the friend-of-all leader who directs and oversees); c) their chosen spatial-material resources, including claiming the largest round table in the classroom on which they stuck a notecard with their name "GLAY" written on it, and preference for large poster paper and markers to draw a model (vs using Jamboard).

On another scale, the emerging creation of "GLAY the original as a genderless, universal God and alien" model of short-term stress suggested that the youth set much store on who and what GLAY the model represented, beyond the biological systems they were drawing inside the model. Here, GLAY further entangled and brought classroom epistemic discourse, issues of gender identity and (non)rightful presence as new arrivals. Their discussions of GLAY the model as "genderless", "non-binary", as "it", as "GLAY", is a continued thread that emerged from a prior lesson the youth grasped onto and elevated during this modeling activity. In the prior lesson, the class had discussed whether it would cause survey takers stress to disclose their gender, and whether the categories of "male, female, other" were marginalizing to people who identify as queer. Two members of GLAY also have same-sex parents. In these episodes, the youths' stance to depart from the normed heteropatriarchy of a default male Eurocentric scientific model was made starkly apparent. In addition, two of the GLAY youth were also recent arrivals to the school, suggesting an ontological thread in attending to tropes of power and alienation, rightful or non-rightful presence between the youth negotiating the identity of GLAY the model as a "universal GOD and alien" and their real-time, embodied experiences of figuring out how to fit in at the school.

Between short and long-term stress modeling, the youth explored stories as a part of the curriculum that fleshed out impacts of long-term stress on fictional characters one of whom was a Maria – a young Hispanic girl with younger-sibling care responsibilities. Long-term stress Maria/GLAY Jr. emerged from GLAY the original – a genderless, universal God and alien – held in dialogue with the Maria story, with whom the GLAY youth resonated. Star's decision to spotlight her lone female representation in the group with Ren's recognition that it was "women history month" led to a third scale of modeling as GLAY youth negotiated and collectively made sense of what it might mean for Maria/GLAY Jr. the model to be female, and Hispanic, instead of a genderless universal God and alien. The model was recognized as a MTH entity with personhood, and gendered and racial identities, both still a departure from the Eurocentric default white male model.

Implications

Struggles of gender identities and rightful presence are formidable sources of stress for youth in schools. The GLAY youth showed their wisdom in unabashedly making these embodied struggles (for some of them) central to a modeling activity on the biological phenomenon of stress. Their actions reflect their desire for authoring a Rightful Presence in middle school science, illustrated through centering a relational ontology. Who youth are, can be and want to be, with whom and what spatial-materials, are ineluctably bound up in the processes of epistemic meaning-making. In short, it is impossible to divorce ontology from epistemology, and it is imperative to attend to historical injustices and its contemporary reproductions through interrogating normalized science classroom practices and assumptions. With our study, rather than only considering scientific models as a tool for students to make sense of scientific phenomena, we argue for the need to understand models as deeply entangled with who and how youth are in and with this world. Furthermore, we advocate for acting as sociopolitical allies and ceding power to youth to reauthor both their and their models' rights in the classroom space as one way we can support this more expansive understanding of youths' learning and their world selves in classroom spaces.

Endnotes

(1) By examining human-MTH relations, we identify the many histories of coloniality (re)produced in science classrooms.
(2) Youth identified broadly as Hispanic, preferring more specific national identities (e.g., Dominican, Puerto Rican etc.).

De/settling Powered Differentials and Disciplinary Practices Through Rightful Presence: Examining How Power, Emotions, and Resistance Shaped Emerging Epistemic Ideals in Middle School Science

Rishi Krishnamoorthy, Penn State University, rkrish@psu.edu

Abstract: There is a growing body of scholarship in science education that attends to the role of emotions and affect as shaping youths' negotiation of and experiences with disciplinary science practices towards more expansive understandings of how youth make-meaning around science phenomena. This study builds on this growing scholarship by examining how power and positionality shapes emerging emotional configurations in classroom spaces. Grounded in a larger study involving implementing a justice-oriented middle-school biology unit, we utilized interaction analysis methods to examine how care for the well-being of the 'other' co-operatively emerged as an epistemic ideal when creating a community ethnography and was shaped by de/settling powered differentials; disciplinary practices; and youth and facilitators' powered positionings in relation with macro sociopolitical worlds. This work contributes to our collective understanding of sense-making in science classrooms by nuancing the complex nature of engaging in allied sociopolitical struggles in explicitly justice-oriented learning spaces.

Introduction and motivation for the research

There is a growing body of scholarship in the learning sciences that attends to the role of emotions and affect as shaping youths' negotiation of and experiences with disciplinary science practices towards more expansive understandings of how youth make-meaning around science phenomena. For example, Jaber and Hammer (2016) document the importance of 'epistemic affect' in encouraging and sustaining youths' engagement in science practices, arguing for affect as entangled with conceptual and epistemological dimensions of science learning. Building on this and drawing on the relations between emotions - conceptualized as "the way that 'affect' becomes mediated, categorized, and meaningful to individuals and collectives as a matter of learning" (Vea, 2020, p. 236) Lanouette (2022) illustrated how children's science practices were shaped by place and emotion. That is, emotions and affective dimensions of lived experiences not only encourage and sustain engagement, but shape how youth engage in science practices, and the directions their investigations follow. Taken together, this growing body of literature illustrates the importance of emotions in science learning and has challenged how scholars understand the commitments and values that inform science practices, for example modeling science phenomena (Pierson et al., 2022). This study builds on this literature by attending to the role of emotions in shaping disciplinary practices, with a focus on how power and positionality shape emerging emotional configurations in classroom spaces. Grounded in a larger study examining the implementation of a justice-oriented middle school biology unit, we examine the role of 'care for the other' in shaping disciplinary science practices. Specifically, we ask: *how was care for the well-being of the 'other' when creating a community survey in an explicitly justice-oriented curriculum shaped by powered differentials; disciplinary practices; and youth and facilitators' powered positionings in relation with macro sociopolitical and cultural worlds and towards what ends?* Through interaction analysis of two lessons where adults and youth were constructing a community survey, we traced how different participants enacted their Rightful Presence (Calabrese Barton & Tan, 2019) in the classroom, through negotiating emotional configurations (Vea, 2020) towards co-operatively constructing (Goodwin, 2017) epistemic ideals (Chinn et al., 2014) as part of the survey design. Overall, this work contributes to more a critically nuanced understanding of how different powered differentials and emotional configurations shaped the emergence and sedimentation of disciplinary practices through an explicitly justice-oriented middle school science curriculum.

Theories informing this work

We drew on three distinct theoretical frameworks to inform our analyses of the community-survey episodes: a) Rightful Presence (RP; Calabrese Barton & Tan, 2019), b) Emotional Configurations (Vea, 2020) and c) Aims, Ideals, and Reliable Processes (AIR) model of epistemic cognition (Chinn et al., 2014). Together they illuminated how feelings and sense-making around care were shaped by powered relations, discipline-informed epistemic aims, and resistance and rightful presence.

The RP framework works towards making visible and disrupting settled powered differentials (e.g., teacher-student) that position youth as ‘guests’ and adults as more powered ‘hosts’ who extend rights to youth. Challenging this ‘inclusive’ approach requires adults working as sociopolitical allies ceding power to youth to re-author the “rules of the game” in these spaces (Calabrese Barton & Tan, 2019). Working towards RP is central to consequential learning and entails shifting powered relations such that students’ whole selves are legitimated and valued as central to learning (Tan et al., 2019). We drew on the RP framework towards identifying the ways in which youth re-authored their rights through disrupting powered hierarchies and disciplinary norms, along with tracing the adults’ moves towards allied political struggle in the negotiation of the community survey.

Learning from Tanner Vea’s (2020) work, we take up emotional configurations to analyze emotions as situated in and shaped by (and shaping of) social practice, and the meaning-making around that practice. We understand emotional configurations as embodying the relationships between feeling, sense-making, and practice, shaped by norms and powered relations. What feelings are permissible, by whom, and towards what ends are therefore determined and shaped through sociopolitical relations. Emotions and emotional configurations are thus political and can serve to guide sociopolitical action, shaped and guided in learning environments. That is, ‘guided emotional participation’ in learning spaces entails “cultivating arrangements between feelings, sense-making and practice” (Vea, 2020, p. 332) towards particular learning goals. In this view, emotion is both a condition for learning and a target of teaching that can drive sense-making. This framework provided a lens to analyze the ways in which feelings were entangled with sense-making around the practice of constructing a community survey and how differentially powered participants in the classroom guided and shaped these emotional configurations.

The AIR model posits that knowledge-building communities hold norms about what counts as worthy epistemic aims, reliable processes to achieve those aims, and ideals (criteria) used to evaluate the quality of the epistemic products and determine whether the aims have been achieved (Chinn et al., 2014). A community’s epistemic ideals and reliable processes may change over time as new ways of doing and knowing develop and may also be in tension with each other. We drew on the AIR framework to trace how aims, ideals, and processes were shaped by members of a classroom community within the disciplined (science) context of survey development.

Study context

This work is part of a larger grant-funded project to develop a middle-school science unit through critical participatory design research methods (Bang & Vossoughi, 2016) in collaboration with youth and teachers from the local area. After a year of collaborating online, the design team of middle-school youth, teachers, and university researchers developed a 7th grade science unit on stress in our bodies and community (Krishnamoorthy et al., 2022). The unit was piloted in Spring 2022, in one 7th grade science classroom at Oak elementary school, located in a sanctuary city in the NE-USA where 90.2% of the students in the district identify as Hispanic (1). While youth did not often openly discuss gender and sexuality, one youth identified as transgender. At the time of this study, the science teacher - a cis-female immigrant from a middle eastern country – had taught the youth for half a year in-person. The support teacher – a Black and African American cis-female – began working at the school a week prior to the unit enactment. Along with the teachers two university researchers – Rishi a genderqueer [they/them] South Asian immigrant, and Ravit a white cis-female Israeli immigrant – helped facilitate discussions.

The unit investigated stress as a non-neutral biological phenomenon shaped through various structural systems of oppression (racism, classism, sexism etc.), by supporting youths’ RP and epistemic agency in the classroom towards making consequential changes to inequitable and discriminatory issues in their local (classroom) community. The episodes analyzed occurred two weeks into the unit, when youth were tasked with creating a community survey to collect data on “what causes stress in the community”. Over two days, Rishi and Ravit co-facilitated the class’s creation of a pilot survey through a combination of small and whole-class group work. The initial survey was piloted with other 7th graders in the school, revised by the class, and sent out to community members across the city. The episodes analyzed include the pilot survey creation and revision lessons.

Methods

Data for this study includes field notes, material artifacts (PowerPoint slides), and audio and video recordings of whole class discussions and 2 focal youth (Batman and Ren). We analyzed episodes that involved whole group meaning-making around the creation and revision of the survey and used interaction analysis methods (Jordan & Henderson, 1995) to trace the emergence of care as an epistemic ideal in deciding reliable processes for learning about stress in the community. We traced how meaning-making around ‘care for survey takers’ feelings’ was cooperatively (Goodwin, 2017) constructed through utterances in the whole-class public space and focal youths' interactions with each other, across the lessons. Briefly, co-operative action refers to the co-operative construction of something (in this case an epistemic ideal) through joint-activity that involves humans "performing specific operations – most importantly decomposition and reuse with transformation – on materials provided by another" (Goodwin, 2017, p. 6). In the analysis, we identified how various youth and adults took up substrates – the "local public configuration of action that is operated on to build the next action" (Goodwin, 2013, p. 11), and transformed them towards the co-operative construction of 'care' as an epistemic ideal (AIR) through shifting emotional configurations. We then examined the participation frameworks (Goffman, 1981) of the adults and youth through shifting speaker roles (i.e., author and animator) to examine how power was enacted in (re)producing and de/settling powered differentials (e.g., teacher-student power dynamics, RP). Briefly, the 'animator' is a voice box through which an utterance is produced whereas the 'author' is the originator of the content of the utterance (Goffman, 1981). Furthermore, at any given moment a speaker can assume one or more speaker roles "based on their understanding of their own involvement and of others' involvement in an encounter" (Marks, 2012, p. 3). Analyzing speaker roles helped trace shifting participation formats towards the illustration of how participants negotiated powered dynamics through meaning-making as a joint-activity. The two hotspots analyzed illustrate how sense-making around care: 1) emerged through youths' resistance to extractive data collection practices by re-authoring teacher-student powered differentials and 2) was shaped by an adult's recruitment of their positionality as a minoritized person in relation with macro sociopolitical worlds.

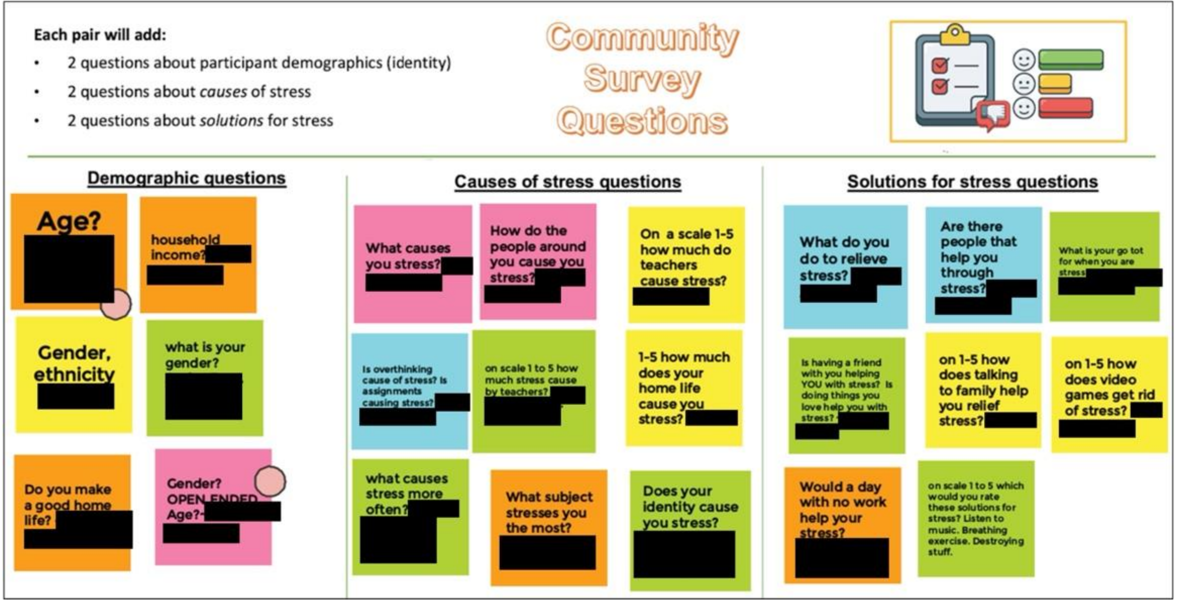
Data analysis and findings

"that's just gonna make them upset": Care for the 'other' as an epistemic ideal

When beginning the 'community ethnography' lesson, Ravit facilitated the activity set-up and explained "you already know what is causing stress for you. But remember yesterday […] there were differences and not everybody gets stressed about the thing, the same amount […] so we wanna find out what do other people in our community […] what is stressing them out" because "ultimately at the end what we wanna do is come up with some solutions" to issues that caused stress in the school. In this way, the adults' enacted power towards shaping the epistemic aims of the survey – to extract data regarding stress from the youths' communities that would help the youth create solutions to issues in their school. That lesson, youth worked in groups of four to propose questions for the survey. Then, Rishi and Ravit took up each group's proposed questions in a class discussion to select and finalize the pilot survey (See Figure 1).

Figure 1

Slide displayed in front of the class with each group's proposed questions



Each pair will add:

- 2 questions about participant demographics (identity)
- 2 questions about *causes* of stress
- 2 questions about *solutions* for stress

Community
Survey
Questions

Demographic questions

Age? [redacted]
household income? [redacted]
Gender, ethnicity [redacted]
what is your gender? [redacted]
Do you make a good home life? [redacted]
Gender? OPEN ENDED Age? [redacted]

Causes of stress questions

What causes you stress? [redacted]
How do the people around you cause you stress? [redacted]
On a scale 1-5 how much do teachers cause stress? [redacted]
Is overthinking cause of stress? Is assignments causing stress? [redacted]
on scale 1 to 5 how much stress cause by teachers? [redacted]
1-5 how much does your home life cause you stress? [redacted]
what causes stress more often? [redacted]
What subject stresses you the most? [redacted]
Does your identity cause you stress? [redacted]

Solutions for stress questions

What do you do to relieve stress? [redacted]
Are there people that help you through stress? [redacted]
What is your go tot for when you are stress [redacted]
Is having a friend with you helping YOU with stress? Is doing things you love help you with stress? [redacted]
on 1-5 how does talking to family help you relief stress? [redacted]
on 1-5 how does video games get rid of stress? [redacted]
Would a day with no work help your stress? [redacted]
on scale 1 to 5 which would you rate these solutions for stress? Listen to music. Breathing exercise. Destroying stuff.

The first hotspot episode began when Ravit oriented the class to a proposed question about survey takers' income (See Figure 1, under the 'demographic questions' column). Initially, the class spent a few moments sensemaking around the word 'income': "money" (2), transformed to "paycheque" and "how much" one earns, relating the ideas to data they explored the prior lesson that showed how income was related to stress. Then, for the remainder of the episode they discussed whether to ask survey takers about: 1) what their income was and 2) if so, how to ask the question. Through the discussion, youth were initially resistant to asking about income as it would be "weird" to ask middle schoolers who did not earn money about their income. However, as a whole class, they reasoned through this issue by adding the option of "teleporting" middle-schoolers to versions of the survey that did not ask about income. On the verge of a resolution in deciding whether to ask about income, Ravit called for the class to pause, and "trouble it a bit more". She asked, "do you think people will feel comfortable saying exactly how much they earn". Ravit's question leveraged the emotions of the 'other' (i.e., survey taker) to guide youths' sense-making in their negotiation of reliable processes regarding what and how to ask questions. The youth were quick to agree with Ravit, that a question on income could cause survey takers discomfort, raising issues about data surveillance and privacy so often abused by "companies" who ask for "too much information, bro". In taking up Ravit's bid to consider a survey taker's experience of discomfort, youths' sense-making around survey-takers imagined feelings were shaped through their (the youths') relations with macro sociopolitical powered dynamics concerning data surveillance and privacy and became consequential in shaping the group's epistemic ideals around care for survey takers' well-being. That is, youths' relations with extractive practices enacted through powered entities such as corporations shaped: 1) how they collectively made sense of Ravit's bid to care for the 'other' and 2) the epistemic ideals that emerged as a result.

In the next few moments, tensions emerged within the group, with some youth arguing to keep the question on income by asking it in a generalized way (e.g., income ranges) so that it could protect survey takers' privacy, while also meeting the task aims – to collect information from the community. Others however, argued that it "still won't work". Finally, Travisloot appealed to Ravit, who invited him to share his "reservation":

> Travisloot: Cause like don't like, most people like if they wanna like. Paycheque has to come like they're like stressed, and like you like ask like is your income like low high like then like if their income is like low that's just going to make them upset and they're not gonna want to continue to like.. because… they are not going to want to..

Travisloot's resistance animated the feelings of stress that a person might experience when their 'paycheque has to come', as being invoked when having to answer a question about whether their income was low. His argument not only took up the sedimenting epistemic ideal of considering survey takers' feelings of comfort when designing the questions, but also argued that not attending to this ideal would result in the survey epistemic aims not being met – that people would not continue in filling out the survey. Travisloot's resistance not only addressed consideration for the survey-takers' feelings but positioned it as necessary for the goals of the activity as determined by the facilitators (in positions of power). Eurocentric framings of data collection have procedures around not causing harm (e.g., IRB protocols), reasoned against what is 'necessary' for the research aims. Asking about income to ascertain whether it is a source of stress would classify as a 'necessary' process. Yet, when consideration of survey takers' feelings sedimented as an epistemic ideal, the boundaries of what counted as 'necessary' processes in data collection shifted - re-authored through youths' resistance. Positioning feelings (of the 'other') as integral to sense-making challenged ethical boundaries that shaped what was sensible to ask survey takers. Youth challenging ethical boundaries through resistance continued as the interaction unfolded.

Initially, Ravit argued that "we can leave that question to the end", a practice she admitted was a "bit of a trick" to ensure participants would continue the survey despite the emotional cost. However, Travisloot's resistance persisted, arguing that "if we put it at the end then we're gonna run into the same problem. They might just like leave the quiz like unanswered and we'll never get their answer". Through his resistance, this youth's utterances desettled adult-youth power differentials – where many members of the class including the adults were pushing for the question to be included – by skillfully arguing for a consideration of survey takers' well-being as aligned with the aims of those in positions of power (and Eurocentric science ways of knowing). The epistemic ideal (care) was not only shaped through "how important [that] information [is] for us", as Ravit asked moments later, but also whether – as Travisloot argued – it would contribute to the data extraction aims of the survey. Ultimately, another student suggested the question be taken out, which the whole class agreed with. When framed as aligned with disciplinary goals by the youth, consideration of survey-takers' wellbeing was ratified by the adults in power as an ideal in developing reliable processes to learn about stress through the community survey.

"i don't wanna judge peoples' gender": Care for the minoritized survey taker 'other'

In the next episode ‘not causing stress’ emerged as a sedimented ideal in developing reliable processes and was recruited by Rishi towards advocating for the well-being of gender-minoritized community members. The hotspot occurred the next day when youth were analyzing the pilot survey results and refining their questions to make the final survey. The whole class was analyzing responses to the open-ended survey question “what is your gender”, where one responder wrote in “transformer” as their gender (See Figure 2).

Figure 3

Whole class (public space) and private conversation between Ren and Batman. Public space utterances listed with line numbers and private space utterances listed with alphabets.

Whole Class	Ren, Batman
[1] Rishi: Ok so with this question, what is your gender, who which groups had suggestions for this question. Who was not happy with it? **[2] Student**: me [3] **Rishi:** Ok lets start with you, Recorderboy. **[4] Recorderboy:** ((points to Juan white wall)) no, him **[5] Rishi:** No you say it! **[6] Recorderboy:** Him **[7] Rishi:** nods ok **[8] Juan White Wall:** Okay. Uh people fooled around and not putting a valid answer so uh I said we could just have three categories. Male/Boy. Female/Girl. And others, and have a text box of options. **[9] Rishi:** Ok so we have one option from Juan White Wall who says people start to fool around. I saw a transformers there I don’t wanna judge peoples gender, you can identify as a transformer if you want to, but maybe that’s not so helpful for our survey. That’s a suggestion here. So Juan White Wall is saying lets have three categories, lets have Boy/ (1.0) Male? Girl/Female, and then an Other. What do other folks think of this. Rose you had your hand up	**[A] Batman:** hmm ((sigh chuckle)) transformer ((looking up at board)) ((Ren raises his hand, Batman smirks and turns to Ren)) **[B] Batman:** [inaudible] **[C] Ren**: The [fact] that someone put transformer ((turned towards Batman, laptop in his lap)) **[D] Batman:** [nah] ((nods no)) **[E] Batman:** What do you mean? **[F] Batman:** ((taps left fist on table, looks at Ren)) ah Yeah. ((Grabs plexiglass and slides hand down)) I-I like that one **[G] Batman:** I’m a T-Rex. ((Ren giggles, fidgeting with his pen)) **[H] Ren:** I’m an attack helicopter **[I] Batman:** You’re an other? ((Whispered surprised tone, turns to Ren)) **[J] Ren:** Other? (2.0) Can you be like LGBTQ- **[K] Batman:** -((clicks teeth))No just do other ((points hand at board))

Initially, in both the whole class discussion and the private space with Batman and Ren (See Figure 3), the youth took up some of the utterances as not “valid” [8], where “the fact that someone put transformers” [C] was an illustration of survey takers having “fooled around” [8]. In their private space, Batman, and Ren – through humor – elaborated on transformers being an invalid option with Batman authoring himself as a T-Rex [G], and Ren, as an attack helicopter [H]. In the public space, Rishi re-animated Juan White Wall's utterance but re-authored him as "not wanting to judge peoples' gender" which positioned "transformers" as a potentially valid gender option [9]. That is, Rishi enacted power – as an insider who is trans and an adult in the room – by re-authoring the youths' meaning-making around transformers as him *not* wanting to enact a deficit positioning of survey takers' intentions. In this move, Rishi authored care for survey takers – that they are not judged by their choices – animated through their transformation of Juan White Wall's substrate. Yet while care for survey takers was framed as important, transformers remained an invalid option since it did not align with the goals of the lesson activity [9]. That is, while 'judgement' around survey takers' intentions were not ratified as a reason to discard transformers as a gender choice, 'helpfulness for the survey' was. Therefore, the unreliability of the process – asking an open-ended question about gender - shifted from survey takers' affordances for fooling around to being less helpful in attaining the survey designers' needs for information. In doing so, the boundaries around gender options that *would* be valid were defined by whether they or not they were 'helpful' for the survey.

What ensued thereafter was whole class – and informal small group chatter – around the categories that should be listed in the close ended question. Male/boy and female/girl were suggested as two options by Juan White Wall [8] and a few other students in subsequent utterances, and sedimented as the taken as accepted first and second options. Youth then struggled to decide on other options to propose. Some suggested 'other' as a category in both the private [K] and public spaces [8] (as examples), while others suggested "transgender", "unsure", "non-binary", "pronouns" and then "gay, lesbian, LGBT, asexual". As the youth broke out into dispersed chatter, Rishi raised their voice and appealed to the whole class (See Figure 4).

Figure 4

Whole class and private conversation between Ren and Batman. Public space utterances listed with line numbers and private space utterances listed with alphabets.

Whole Class	Ren, Batman
Students talking all at once, Micky raises his hand and Rishi walks up to him, bends down and listens **[10] Micky:** So I put like uh a bunch of options [[inaudible]]	**[L] Batman**: I sure, not sure and then you coulda ha- you should have other still [because what if] somebody wants to be a T rex? ((Gazing at Ren as he talks)) **[M] Ren:** [Because someone] ((Ren giggles)) **[N] Ren:** What if someone wants to be a T (.) rex (.) ((Batman leans into Ren)) **[O] Batman**: No but actually WHAT if someone wants to be som-
[11] Rishi: Ok so we have one more. Y'all this a really important question, right, and I am saying this as someone who is trans, like when I have to pick my gender on a on a survey, often the option I want is not there. cause I identify as genderqueer. That's actually like what I call my gender, and so this question is actually really important because we're asking about stress. We're asking about how people identify, and as Travisloot said last time we don't wanna ask questions in a way that may cause stress. Right? So we gotta think real carefully about how we phrase these questions. what options we give people so that we can consider how it might make them feel to answer them right? And So I like what you are saying we should have lots of options. We can have male, female. No sorry male or boy, girl or female, transgender, unsure, and then you said nonbinary, right? Are there any other, cause I don't know how y'all talk about gender right? how your generation talks about gender. Are there any other ways that people identify. that you know of?	**[P] Batman:** Just say other!

Across this [L-P]and their previous [A-K] private space interactions, both Batman and Ren reasoned through the options for gender through humor, taking up substrate from the whole class discussion towards a serious consideration of 'not judging' survey takers' intentions [9] when answering a question on gender. In this interaction, Batman built on the sedimenting options for the question, but argued for keeping an open option – "other" – because 'what if someone wants to be a T Rex?' [L]. Initially received as a humorous response – evidenced through Ren's giggling [M] – Batman then re-animated his question, 'what if someone wants to be' [O]. While his utterance was cut off by Rishi speaking into the whole class space, Batman built on the play he and Ren engaged in earlier [G, H] – where transformers could be a possible and valid option. If so, then providing an open space for survey takers to express an unlisted or unexpected gender would be necessary, as evidenced through his growing support to 'just say other' [K, P] as an option for gender.

In the public space, Rishi authored themselves as an explicit insider and knower of a specific survey taker's experience – a trans person who did not have their gender identity listed on a survey [11]. They framed this context and insider knowledge as important by shifting their positionality to that of a survey designer – with the youth ("we") – making a survey about stress. Considering non-cisgendered survey takers' feelings was important *because* the survey they were designing was about stress, informed by Rishi's previous experiences with answering questions about gender. Furthermore, Rishi framed meaning-making around how to ask about gender as important by recruiting Travisloot's resistance the previous day as the source for the epistemic ideal of care for survey takers' feelings as necessary for survey design. For the question on income (previous episode), consideration of participants' well-being was legitimated (by the adults) as an ideal in building reliable processes because it would not help the group meet the epistemic aims of the survey. In this turn of talk however, care for survey takers was positioned as important regardless of the aims of the survey through Rishi guiding youths' emotional participation (Vea, 2020) in considering how trans people – like Rishi – would feel not having their gender in the survey. It was no longer the emotions of a generalized 'other', but Rishi's feelings – an adult in a position of power– that the class needed to consider in designing reliable processes for their survey. This epistemic ideal also emerged as the hierarchy in gender categorizations was sedimenting.

While Rishi positioned the youth as the experts who knew how their "generation talks about gender" [11], neither of the gender binary categories were questioned (boy/male; girl/female). Instead, they emerged as obvious options, indicating an assumed acceptance and shared orientation around heteronormativity structured into their understandings of gender (Ahmed, 2006). This emergent gender hierarchy is also mirrored in broader data collection practices that often (re)produce harm towards and the invisibility of non-cis-gendered identifying communities through the powered heternormativity (and heterosexuality) that structures quantitative methods (Guyan, 2022). In this episode, reliable process for asking about gender necessitated youth recognize their power over survey takers' (like Rishi's) feelings, by carefully considering how to ask about non-cis-gendered identities. Batman and Ren's playful sensemaking around gender options, and Batman's growing insistence on 'other' being a more open and inclusive option (that would allow responses like transformers so as not to judge survey takers intentions) is indicative of the youths' careful consideration and care for the survey takers' feelings. Ultimately, Rishi proposed "my gender is not listed here" as an option that would "honor that we did not know" someone's gender identity, which the class agreed on.

Discussion and significance

Explicitly justice-oriented curricula necessitate adults work as sociopolitical allies towards youth reauthoring their rights in classroom spaces. In an activity such as designing a community survey, this involved youth and adults negotiating what and how to ask questions to survey takers. In this classroom, 'care for the other' emerged as an epistemic ideal through youths' increasing resistance to extractive data collection practices. That is, explicitly working to desettle adult-youth powered differentials resulted in emotions emerging as integral to sense-making around the ethics of knowledge creation towards more just ends. However, as evidenced in the first episode, this epistemic ideal was not ratified until the youth skillfully reasoned it as aligned with the aims set by the adults in positions of power. At the same time, when care for the 'other' sedimented as an ideal, aligned with disciplinary aims, it afforded the adult to advocate for the well-being of non-cis-gendered youth both within the classroom space and those taking the survey. That is, through the ideal of care, gender-alienation through the politics of data collection was elevated as an important consideration in survey design.

What 'care for the other' entailed, in nature and degree, was emergent and contingent on classroom interactions. First, survey-takers' assumed anonymity was reconsidered when youth focused on the locality of their survey catchment area – in their own community. They were not designing a survey to be sent into the void but asking salient questions about stress to their own community. Second, what it meant to care for the well-being of survey-takers gained deeper meaning when the issue was literally fleshed-out – embodied in the personhood of a classmate who identified and performed as queer (a transgender student in the class), and in Rishi- with whom students were relationally entangled. We suggest that a direct interaction of such relational nature solidified for youth the significance and importance of parsing how and why, and to what ends, gender questions ought to be asked in a survey. Third, the tensions between caring for the survey-taker because of its ethical imperative and caring that the survey yielded authentic data because the youth care about the phenomenon of stress in their community, was apparent and tricky to navigate. Across these three considerations, we see evidence of a braiding of emotional configurations with care for the other as an epistemic ideal, towards a more rightful presence for the local community of survey-takers and youth and adult as nested within said community.

Our analysis suggests that attuning to the youths' resistance through bids to re-author their rights in the classroom space along with the role of emotional guidance in shaping whole-group discussions was consequential towards illuminating the ways in which power and positionality shaped the direction of and sense-making around scientific practices. It also points to the complex nature of engaging in allied sociopolitical struggles. Even as student-adult power differentials were obvious, the kind and degree of power differentials made manifest along particular axes (e.g., conceptions of income, gender, the goals of a class survey instrument) were embodied and informed the actions of stakeholders in ways that gave texture to the overall student-adult power differentials. Thus, student-student power differentials; adult-adult power differentials and the potential myriad configurations of such are all productive towards unpacking the nature of allied political struggles towards rightful presence as well as the import of emotional configurations and de/settling epistemic ideals in and through these processes. How do we intentionally and systematically tease out power differentials that undergird such rightful presence authoring work? What are the significant roles that emotional configurations play, that designers of justice-oriented learning experiences need consider, and imbricated in what ways with epistemic ideals? Zooming out, how do we as a field continue to disrupt white Eurocentric scientific teaching and learning with these insights?

Endnotes

(1) None of the youth in the class identified as white, and a large portion of them identified broadly as Hispanic, though they preferred more specific country-based identities (e.g., Dominican, Puerto Rican, Ecuadorian etc.). While from the same school district, the design team youth were not in the same class or school where the curriculum was piloted.
(2) All quotes are from youths' utterances unless otherwise specified
(3) Rishi uses they/them pronouns

Abstract: For the past decade, learning scientists have come to understand the relationships between learning and space — usually outside of schools and classrooms. More recently, scholars in teaching and teacher education have called for research that considers how space and movement shape teaching and learning. In this paper, we integrate concepts and methods across the learning sciences and teacher education. We examine the relationship between classroom spatial design and the enactment of ambitious and equitable mathematics teaching. Specifically, we apply a case study approach to outline how an experienced teacher's use of space reflects her pedagogical judgment. Findings and discussion outline six key ways this teacher considers space in her classroom design and her facilitation of classroom interactions. We suggest this study has implications for future efforts to characterize classroom spaces in ways that integrate ideas in the learning sciences and teacher education.

Introduction

Over the past decade, learning scientists have come to understand the relationships between learning and space — usually outside of schools and classrooms. Some characterize diverse ways young children and families make places for learning as they move through built and natural environments such as urban settings, museums, or the natural world (e.g., Gutiérrez et al., 2019; Leander et al., 2010; Marin et al., 2020; Taylor, 2017). Others have begun to explore the connection between physical space, technologies, learners, and learning goals in designed learning experiences and the role physical space plays in a designs' distributed intelligence (Pea 2004; Tissenbaum et al., 2021). Still others are developing methodological approaches that better consider the relation between physical space and learning (Keifert & Stevens, 2019; Kelton, 2021; Shapiro et al., 2017).

Scholars in teaching and teacher education have called for research that considers how space and movement shape teaching and learning (e.g., Weiland & Poling, 2021; Shapiro & Garner, 2021). In particular, there is a need to understand how classroom spatial design can support the enactment of different pedagogies. In this paper, we integrate concepts and methods across the learning sciences and teacher education to examine the relationship between classroom spatial design and the enactment of ambitious and equitable mathematics teaching. Using an extreme case (Flyvbjerg, 2006) of an experienced teacher who is a former architect, we analyze how her use of space relates to her pedagogical judgment.

Theoretical perspectives

Our analysis integrates two theoretical perspectives. First, we take a situative perspective on teaching, with particular attention to teachers' pedagogical judgment. Second, we also draw on concepts and methods developed in the learning sciences and related fields that allow us to consider how the built environment shapes the interaction of people and things. By bridging these theoretical perspectives, we aim to add more nuanced understanding to each. Examining teachers' use of space sheds light on an undertheorized aspect of teacher learning, while bringing teachers' reasoning into studies of classroom spaces allows us to understand the practical implications of teachers' use of space and explore new avenues to understand teachers' sensemaking.

Teaching as a situative practice requiring pedagogical judgment

To understand teachers' sensemaking about their classroom space, we draw on situative theories of teacher learning. Importantly, we conceptualize teaching and learning as culturally, historically, and institutionally situated (Cazden, 2001; Lampert & Cobb, 2003; Lave & Wenger, 1991; Ma & Singer-Gabella, 2011) and as a social and interactional accomplishment (Cohen, 2011; Greeno, 1998). In this view, teaching is inherently complex and uncertain — particularly for teachers who aspire to ambitious and equitable instruction (Horn & Garner, 2022; Lampert et al., 2011). Ambitious and equitable instruction is that which supports all students — especially those who are often marginalized or minoritized — to engage in meaningful disciplinary practices. This vision of instruction requires teachers to be responsive to students' diverse needs as they implement rich tasks that support students' conceptual understanding. As a result, we do not seek to develop 'best practices' or 'ideal types' of spatial design for the classroom, but rather to connect teacher sensemaking to spatial pedagogy through pedagogical judgment (Horn & Garner, 2022).

Pedagogical judgment consists of three interrelated components: (1) *pedagogical action* (or what is visible in classroom activity), supported by (2) *pedagogical reasoning* (or teachers' rationales), and rooted in (3) *pedagogical responsibility* (teachers' sense of moral, ethical, and institutional obligations). Although these components are entangled, they are distinct enough to warrant separate analysis. For instance, teachers may enact the same pedagogical action — e.g., arranging students' desks in small groups — based on different pedagogical reasonings and responsibilities: One teacher may arrange groups because they use groupworthy tasks and expect students to collaborate in solving them, perhaps reflecting a pedagogical responsibility to support students' engagement in high-level mathematical thinking. Another teacher may arrange groups due to a school-wide expectation to do so, reflecting a pedagogical responsibility to follow institutional requirements. While this hypothetical example suggests such a connection, there is little empirical research that actually examines teachers' pedagogical judgment in relation to the spatial environments of their teaching contexts. We seek to address this gap by adding a spatial element to our analysis of a teacher's pedagogical judgment.

Toward more expansive understandings of classroom space

Historically, studies of classroom space that do exist have typically focused on physical arrangements of furniture, but with less attention to how teaching and learning unfolds in the built environment. A notable counterexample is Liljedahl's (2016) work on "thinking classrooms." Lijedahl offers strategies for designing classrooms to maximize student engagement and student thinking — e.g., by using "vertical non-permanent surfaces" for student collaboration. In response to recent calls for a spatial turn in teacher education (e.g., Weiland & Poling, 2022), we aim to expand an understanding of space in relation to pedagogical judgment.

To do this, we build on work in the learning sciences and related fields that use qualitative methods to foreground space and movement in studies of classroom contexts. Notably, we draw from work that characterizes learning spaces primarily in out of school settings as fluid entities comprised of assemblages of bodies, physical space, and movement over varying scales of time (e.g., Gutiérrez et al., 2019; Leander et al., 2010; Marin et al., 2020; Shapiro, Hall & Owens, 2017). Such characterizations, for example, lead us to consider how pedagogies are enacted across the physical classroom environment and enable or restrict movement in ways central to teacher sensemaking and student learning. We also draw from concepts that characterize how physical classroom spaces can (dis)empower students, such as *built pedagogy* (Monahan, 2005). Notably, this work focuses on characterizing physical spaces through photographs to show that classrooms are empowering when teachers and students are able to adapt, personalize, and move through them. Similarly, we draw from research arguing that *spatial pedagogies* — how teachers use space during instruction — shape the enactment of lessons, including students' learning opportunities (Lim et al., 2012). Yet, this research also shows that teachers may not be fully conscious of their own spatial pedagogies. Finally, we draw upon methods of interaction geography to conceptualize teachers' movement over space and time as an additional tool for reflection about space and movement (Shapiro & Garner, 2021). Together, this allowed us to examine our focal teacher's use of space alongside her pedagogical judgment, adding further insight to our understanding of each field.

Data and methods

This case study is part of a larger research project studying experienced secondary mathematics teachers' learning in a large urban US school district. Participating teachers are part of a professional development organization with an explicit commitment to ambitious and equitable math teaching. For this analysis, we selected one participating teacher, whom we call Linda Simmons, and observed her classroom in May 2022. We collected photographs, detailed fieldnotes, and used methods of interaction geography to manually transcribe and dynamically visualize her movement. We also conducted a two-hour interview with Linda to understand her use of space. During this interview, we asked questions pertaining to the history of the physical classroom space she worked in and how she approached supporting learning through designing physical space using a dynamic visualization tool called the Interaction Geography Slicer to further support reflection about these questions.

Focal case: Linda Simmons

We selected Linda Simmons as an extreme case (Flyvbjerg, 2006). She is atypical in two important ways: First, she is a veteran teacher, with over 20 years of experience teaching secondary mathematics; in that time, she has developed a strong commitment to ambitious and equitable pedagogy. Second, Linda was a professional architect for many years before she became a teacher. As a result, Linda is particularly attentive to the built environment, including the ways she uses classroom space to support her pedagogical goals. So, unlike many teachers (Lim et al., 2012), we anticipated that Linda would be keenly aware of her spatial pedagogy.

Previously, Linda participated in a year-long interview study of teachers' experiences during remote instruction at the start of the COVID-19 pandemic (Schneeberger McGugan et al., 2022). During this study, Linda described deep commitments to ambitious and equitable math teaching and collaborative learning. She also discussed the difficulty of remote teaching, largely because she and her students could not use the physical classroom space. This further underscored the relevance of spatial pedagogy for her pedagogical judgment.

Linda's pedagogical judgment

In previous interviews, we recognized that Linda's pedagogical judgment — including pedagogical action, pedagogical reasoning, and pedagogical responsibility — aligned with ambitious and equitable instruction.

Linda described her pedagogical responsibility, or her moral and ethical commitments, as twofold: 1) caring for students as full human beings, and 2) supporting students' authentic and meaningful mathematical engagement. Linda is committed to creating a safe classroom environment for all students, where they know that "[they are] welcome here, and [they] matter here" (May 2020 Interview). Her pedagogical responsibility to care for students by creating a welcoming classroom environment is deeply connected to her second responsibility of designing for and supporting deep mathematical learning. One aspect of her role as a caregiver to her students is a responsibility to foster rich student engagement with mathematics: "I really truly want to hold myself accountable to that idea of inviting every kid to engage meaningfully with what we're doing. And not just invite them, but actually have a way for them to do that" (November 2020 Interview).

Linda's pedagogical actions and pedagogical reasoning reflect these responsibilities. She prioritizes collaborative learning and is intentional about designing her lessons and classroom space to support groupwork: "All of their work is collaborative. All of their work, while they're sitting in tables — aside from when we're taking assessments — I expect them to be talking" (May 2020 Interview). In Linda's classroom, groupwork reflects both her commitments to a welcoming classroom environment and deep mathematical thinking, as she cultivates collaboration to build positive student-to-student interactions and to support their engagement with rich mathematical tasks. As Linda discussed how she tried to develop norms for collaboration online, she lamented the loss of her physical classroom during remote teaching: "I have built a very intentional learning space that has particular things on the walls. It has a particular arrangement of the tables" (November 2020 Interview) and "[My teaching is] very driven by the stuff on the tables" (August 2020 Interview). In sum, analyses of Linda's pedagogical judgment revealed her understanding of her teaching practice is rooted in her classroom space, making her an ideal case for analyzing our phenomenon of interest.

Analytic methods

To understand the relationship between Linda's use of space and her teaching practice, we conducted several lines of analysis and in this paper, report on a thematic analysis in the grounded theory tradition (Charmaz, 2006; Glaser & Strauss, 1967). Specifically, we transcribed and iteratively analyzed video recordings of our interview with her, as well as photographs and fieldnotes from our observation. We conducted an open coding process, identifying themes relevant to Linda's use of space and her pedagogical judgment. We then iteratively discussed and refined these themes to produce the findings presented in this paper.

Findings

In our analysis of Linda's teaching practice, we found that her pedagogical judgment influenced both her intentional design of classroom space (i.e., the spatial organization of her classroom) and her subsequent facilitation of classroom interactions (i.e., the enactment of instruction within that space).

Designing classroom space for ambitious and equitable instruction

We identified three key features of Linda's classroom design: *reorienting* the classroom, *de-fronting* the classroom, and *valuing* diverse mathematical identities and ways of thinking. Each of these design choices reflects Linda's pedagogical judgment, as she organized her classroom for ambitious and equitable instruction.

Reorienting the classroom

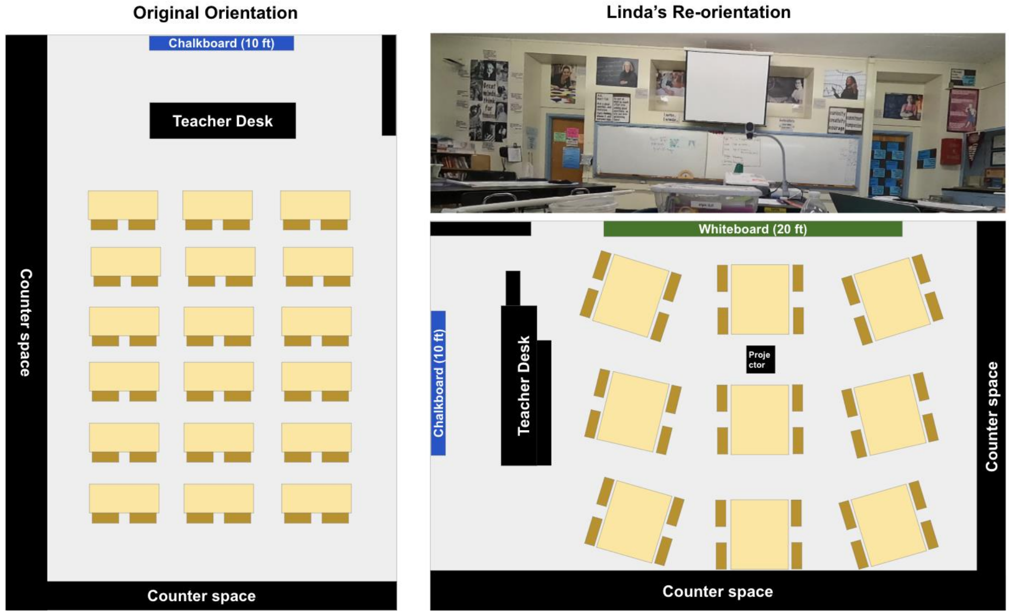
When Linda's school was first built in the 1950s, classrooms were planned as a long rectangle, with students facing a chalkboard on the shorter side of the room (Figure 1a). Students were separated from the chalkboard by a large built-in desk, which teachers could use for demonstrations. This combination of a smaller, distant chalkboard and an authoritative, imposing teacher desk conflicted with Linda's pedagogical responsibility:

namely, a commitment to creating a safe space where students feel comfortable and invited to participate. Indeed, she described the teacher desk as feeling like “a wall” that “divides” her from her students.

To better align with her pedagogical responsibility, Linda reoriented the classroom as a wide rectangle (Figure 1b). She installed a whiteboard on the longer wall which she uses to display important information — e.g., when giving instructions or showing a task from the projector at the center of the room. The chalkboard still exists, but is no longer the focal point of the room; Linda instead uses it to hang student work. Notably, Linda is the only teacher in her building to reorient the classroom in this way.

By reorienting the classroom, Linda is able to enact her pedagogical responsibilities. As she teaches, she is physically closer to students — no longer separated by a 10-foot barrier — which allows her to develop a sense of social closeness as she attends to and cares for her students. Furthermore, it brings students closer to the mathematics: In her re-orientation, students’ desks are never more than 20 feet from the whiteboard, in contrast to 30 or more feet from the old chalkboard. While Linda has worked to de-emphasize the importance of the front of the classroom, the whiteboard can serve as a place to record students’ findings — e.g., when students “generate the entire trig table from scratch” — or display important information. Bringing students physically closer to her and to the whiteboard allows Linda to better enact her pedagogical commitments to cultivating an inclusive classroom community and supporting students’ engagement with rich mathematics.

Figure 1
Original orientation of Linda’s classroom (a), with chalkboard (blue) at the top of the floorplan and student desks (yellow) in rows. Linda’s re-oriented classroom (b), with a large whiteboard (green) at the top of the floorplan and students’ desks (yellow) in groups.



(a) (b)

De-fronting the classroom

In addition to reorienting her classroom, Linda has worked to “de-front” the room — that is, to diminish the importance of the front of the classroom as a source of authority and a focal point for students’ attention. Instead of turning to her or to the whiteboard for information or correct answers, Linda has arranged students’ tables so they can turn toward each other for most of their mathematical activity.

Linda’s students are seated in groups of four, with some tables angled slightly (Figure 1b) so that “there’s not a single kid facing the front of the room.” Linda described this as a way to help students “value the conversations in their group more than they focus on [her] delivery from ‘on high’.” While each student can turn to see what is on the whiteboard, they face one another in their default position. Moreover, each table has a dry-erase surface, which students can use to work out ideas together. Linda referred to the dry-erase surfaces as students’ “shared thinking space.” When we observed Linda’s class, many students wrote on the dry-erase surfaces as they collaborated — and they were well-worn, suggesting this was a frequent occurrence.

De-fronting the room further reflects Linda’s pedagogical judgment, demonstrating her pedagogical responsibility to supporting students’ authentic and meaningful mathematical engagement. Linda’s reasoning suggests that, for her, delegating authority — that is, allowing students to recognize their own and their peers' strengths and ideas — is central to mathematical engagement. Linda's classroom design — specifically the arrangement of desks, with shared writing surfaces — encourages students to turn toward one another as they collaborate, rather than relying on Linda or the textbook as the primary source of information.

Valuing diverse mathematical identities and ways of thinking

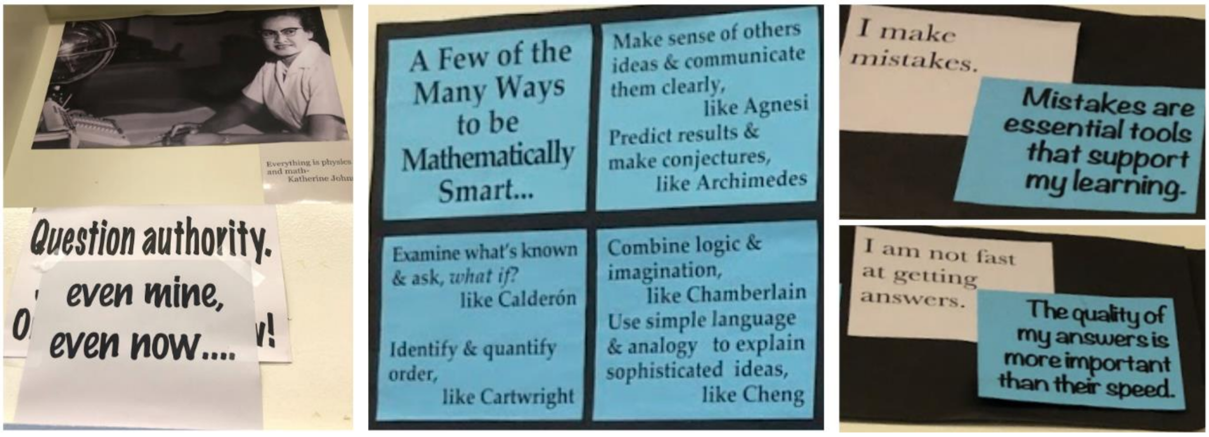
In addition to the thoughtful arrangement of furniture, Linda designed the walls of her classroom to reflect her pedagogical commitments. Linda emphasized her desire for students to feel comfortable, welcome, and represented in her classroom; she wants them "to see this as our space." In this endeavor to support students' sense of belonging, Linda has decorated the walls with posters of diverse mathematicians and scientists, particularly highlighting people of color and women in STEM — including Katherine Johnson (Figure 2a), Emmy Noether, and Benjamin Banneker — as well as people in fields tangentially related to STEM. Linda displayed her intentionality in this endeavor by describing it as "a place to start, not a place to end;" she said she regularly adds posters, seeking out mathematicians who share her students' identities.

Linda also represents diverse ways of participating in mathematics. One large poster highlights ways people can be mathematically smart, including: "Make sense of others' ideas and communicate them clearly (like Agnesi)," and "Examine what's known and ask *what if*? (like Calderón)" (Figure 2b). The suggestions reference specific contributions from a diverse set of mathematicians. Another poster offers ways to reframe negative self-talk, e.g. "I make mistakes" to "Mistakes are essential tools that support my learning" (Figure 2c).

Another important sign in Linda's classroom says "Question authority. Even mine, even now" (Figure 2a). Linda uses the poster to highlight her goal of supporting students' critical thinking; telling students each year: "Every single day, I want you to walk out of here being a more critically thoughtful person, and that includes the fact that just because somebody says, 'This is the way it is' — How dare you let somebody else describe for you what your world is?" Originally, though, the second line on the sign said, "Except mine, or at least not now." After the tumultuous summer of 2020 — and the violent murder of George Floyd — Linda reflected on what it meant to "hold [herself] accountable" to encouraging students' critical thinking. She decided that asking students to not question her authority conflicted with her pedagogical responsibility, so she revised the sign. She intentionally chose to leave the revision visible, so students can clearly see the change.

The wall hangings in Linda's room are not merely decorative; she regularly refers to the posters and reinforces their ideas through her pedagogical actions. For example, in addition to encouraging students to question authority, Linda described referring to the mathematical smartnesses poster when she assigns competence — noticing and naming when students do interesting things. When she does not invoke the poster, Linda said that students do not take her compliments seriously: "Somehow they think, 'Oh, you're just blowing smoke. You've just made up a reason to tell me I'm doing something [good].'" But when she can refer to a specific mathematician who shares that skill, Linda "can tell them who those people are and what they've done and whatever, then all of a sudden it's like, 'Whoa, I'm just like whoever!'"

Figure 2
Wall hangings in Linda's classroom: A photo of Katherine Johnson above the "Question Authority" sign (a), a portion of the Mathematical Smartnesses poster (b), and a portion of the positive self-talk poster (c). This is just a small portion of the posters in (b) and (c); they each contain many more examples.



(a) (b) (c)

Ultimately, these wall hangings support Linda's pedagogical responsibility to create an inclusive and welcoming classroom where students' various and intersecting identities and academic strengths are valued. By displaying images of a diverse collection of mathematicians, Linda shows that all students — regardless of their identities — can be successful in mathematics. Perhaps even more importantly, Linda's classroom design communicates that she values students' ways of thinking, helping them recognize that their strengths are valuable in mathematics. Linda also regularly reflects on her classroom decor, ensuring that the ideas her posters communicate still reflect her pedagogical judgment, and making adjustments or revisions when they do not.

Facilitating ambitious and equitable instruction within the built environment

We found that, in addition to designing her classroom space to support ambitious and equitable instruction, Linda facilitates movement and interaction within the built environment in ways that reflect her pedagogical judgment. She does this through three pedagogical actions: providing students' *access* to materials, encouraging their *unrestricted movement* around the room, and inviting students to contribute to *classroom decor*.

Providing students' access to materials

Linda has organized her classroom space so that students have ready access to whatever materials they might want for mathematical exploration. In addition to dry-erase surfaces, tables have boxes with mathematical tools, including straight-edges, compasses, markers, glue sticks, and so on. Having these materials readily available allows students to decide what tools they need and when they need them. Indeed, when we observed Linda's class, students frequently used these materials — and other resources around the room — to engage in the task.

Linda described this pedagogical choice as a way to empower students: "I don't want it to be, 'I'm going to hand you protractors, but I'm not going to hand you compasses,' or, 'I'm going to hand you rulers, but you aren't going to get tape measures.' I want all of it in there, because that way, it's their decision what's the best tool for them to use for a particular thing." She went on to argue that directing students to use specific tools tells "them so much that they should have to figure out for themselves." By giving students access to a variety of materials — and encouraging them to use whatever tools they see fit — Linda's pedagogical actions support her pedagogical responsibility to facilitating students' engagement in meaningful and authentic mathematics. She helps students exercise their agency and authority to determine what they need for mathematical sensemaking.

Encouraging students' unrestricted movement around the room

In Linda's class, students are able to move about the room as they wish. They are free to get replacement materials or consult with other groups; Linda even keeps a cabinet of snacks in case students are hungry. Students are not expected to interrupt the flow of the lesson to ask to get tissues, a new marker, or even more expensive materials like graphing calculators. In our interview, Linda described being "neurotic" about assigning calculators earlier in her career. But now, she trusts her students to get materials and return them when they are finished. Especially by the end of the year, "they should feel very comfortable just getting what they need and not having to ask permission constantly to get what they need." These norms were apparent during our observation, as students moved freely about the room, with a constant hum of cheerful mathematical activity. Each group worked on building different three-dimensional geometric figures, so students frequently checked with other groups to see what they had done with their shapes.

Linda also allows students to come to her classroom at any time, even during other class periods. Earlier in the year, the boys' restroom had been out of soap for weeks. Linda has a sink in her room, and she said that students "would come over just to wash their hands, and I told them that it's totally fine. They just come in, they wash their hands, they leave, and it's just in the middle of class, just doing their stuff — totally fine. I'm delighted that they're washing their hands." During our interview, a student stopped by Linda's room to get a snack and to borrow some knitting needles, which Linda had for an after-school knitting club that she runs.

Linda described students' unrestricted movement as a way to cultivate a welcoming and inclusive environment. She wants students to see her classroom as "*our* space," rather than *her* space. By recognizing students' autonomy and giving them opportunities to exercise it, she invites them to participate in classroom activities — whether social or mathematical — as they choose. Moreover, Linda's attention to students' needs — whether hygienic, nutritional, or extracurricular — demonstrates her care for students as full human beings. Linda's students know that they are welcome in her classroom at any time of day, and for any reason.

Inviting students to contribute to classroom decor

Finally, Linda invites students to decorate the room with things they care about. Though she has cultivated representations of diverse mathematical identities and experiences, she also asks students to contribute. She has a designated bulletin board titled, "We hold these truths" and invites students to post things important to them

(Figure 3). As Linda described, “that bulletin board is not *my* bulletin board — that’s *our* bulletin board.” During our observation, we saw that students had contributed artwork, images, and quotes.

By inviting students to publicly share and connect over what they each find important, Linda fosters a socially collaborative environment. This pedagogical action highlights her commitment to cultivating an inclusive classroom community, as students take ownership over the space. While some students shared things that are somewhat related to math — e.g., geometric art and origami — additional items, like a signed photo of a football player and a flier for an extracurricular organization — show students’ interests in other areas. This reflects Linda’s pedagogical responsibility to care for students as full human beings. In addition to supporting students’ mathematical identities, Linda encourages them to share other aspects of their lives, as well.

Figure 3
“We hold these truths” bulletin board, with contributions from students, including origami, graphical designs, and an athlete.

Discussion

In this case study, we found that Linda’s use of classroom space is intimately tied to her pedagogical judgment, including her conceptualization and implementation of ambitious and equitable mathematics teaching. We identified six key features of how Linda uses space and movement in her pedagogy, which fall into two groups: design of classroom space (i.e., the spatial organization of her classroom) and facilitation of classroom interactions (i.e., the enactment of instruction within that space). Taken together, these findings underscore the importance of considering the built environment in planning and implementing instruction and more generally, how we conceptualize teaching and teacher sensemaking.

While Linda is an extreme case, with unique experiences in spatial design and ambitious and equitable pedagogy, we argue this analysis has important implications for research on teaching and teacher education. Most studies of ambitious and equitable pedagogy — even those accounting for teachers’ contextual sensemaking — overlook the physical environments where teaching and learning take place. By understanding how built environments intersect with pedagogical judgment, researchers can better understand the embodied and situated nature of teaching. Moreover, our analysis demonstrates the value of integrating concepts and methods in the learning sciences with teacher education to foreground the role of physical space in classroom teaching and learning. In particular, our analysis highlights implications for how theories and methods in the learning sciences expand how we conceptualize concepts such as pedagogical judgment and support teachers’ reflective professional practice. Notably, theories in the learning sciences informed our approach to supporting teachers’ reflective practice during interviews and our use of the Interaction Geography Slicer served as a facilitation tool to further support the kinds of conversations about space and movement with one teacher. Likewise, our findings expand an understanding of concepts such as built pedagogy, which focus on the design of physical classroom spaces without an emphasis on how teachers adapt those spaces during classroom lessons.

This study has several important limitations. While we sought to supplement Linda’s descriptions of her use of space with our own observations of her instruction, we only observed one class period. Additional observations of different lessons and classes may reveal new themes that we did not uncover. Moreover, such data may highlight elements of Linda’s spatial pedagogy that even she is not fully conscious of — or, perhaps, ways that her spatial pedagogy does not have the intended impact on her students. And while the single-case nature of our study design is not a limitation, *per se*, we note the need for additional research in this area. Other teachers — especially those in different settings and with divergent goals — may use space very differently. To address some of these limitations, our current work is expanding diverse methods and analyses, including cross-case analyses and exploratory visualization methods, in collaboration with more teachers and classrooms.

Increasing Preservice Teachers' Computational Thinking Lesson Design Capacity Within a Research-Practice Partnership

Rachael Dektor, University of California, Santa Cruz, rdektor@ucsc.edu
Samuel Severance, Northern Arizona University, Samuel.Severance@nau.edu

Abstract: This study examines efforts by a research practice partnership (RPP) in the western US to develop preservice teachers' (PSTs) capacity to design computational thinking (CT) instruction for K-5 students. Using a sociocultural perspective, we analyzed interview and survey data to examine 6 preservice teachers' enculturation into a future community of practice where teachers value and can adeptly design CT instruction. RPP supports, such as co-design opportunities with RPP members and an accessible CT summary chart, mediated PSTs' successful planning and implementation of a CT lesson, although conflicts between their coursework and RPP activities proved a significant barrier to deeper engagement. PSTs also demonstrated a working definition of CT and beliefs around their own sense of efficacy and understanding of coherent CT instruction. This study provides evidence of a scalable approach to teacher education in CT instruction for RPPs and highlights areas where additional supports would further scaffold teacher learning.

Introduction and motivation

Despite widespread recognition of the importance of computing to students' futures (NASEM, 2018; Wang et al., 2016), and despite policy reforms intended to galvanize the development of more inclusive opportunities (e.g., ACM et al., 2016), many communities remain underrepresented in computer science (CS). In the US, frustratingly little progress has occurred in terms of increasing the diversity of those seeking and attaining careers involving computing (Google/Gallup, 2016). Understanding how to create meaningful trajectories for learners in computing – from K-12 to careers – has long remained an urgent need (NASEM, 2021; Wilson et al, 2010). CS learning opportunities at the K-12 level in the US remain particularly sparse for underrepresented students (CtE, 2016), with efforts all too often faltering due to schools prioritizing other academic goals and the lack of teachers prepared to teach CS (Wang et al., 2016). Visions of equity in CS will remain empty aspirations until K-12 school systems have sustainable and scalable materials and approaches to create meaningful CS learning experiences for their students (Tissenbaum & Ottenbreit-Leftwich., 2020).

Increasing the capacity of K-12 school systems to engage their students in meaningful CS learning will require overcoming systemic barriers, particularly in terms of teacher preparation and curriculum design and implementation. Research-practice partnerships (RPPs; Coburn & Penuel, 2016) focused on design work hold particular promise for attending to barriers holding back innovation within school systems. In this paper, our context centers on a RPP in the western US focused on creating equitable learning opportunities in CS for their K-5 students, particularly multilingual students from Latinx backgrounds. To overcome limited resources and instructional time, members of this RPP envisioned K-5 students engaging in computational thinking (CT; Grover & Pea, 2013) – the sort of thinking a computer scientist would use – not within a separate CS class but productively integrated within existing subjects and over time (e.g., science, math). Similar design approaches that embed CS into core subjects at the K-12 level have shown promising outcomes (Century et al., 2020). Indeed, a major science education reform in the US, the Next Generation Science Standards (NGSS Lead States, 2013), identifies engaging in computational thinking as part of a core set of science and engineering practices students should engage with in science. In terms of capacity-building, the RPP sought to position teachers to collaboratively design CT into core subject lessons with support from RPP members. Practicing teachers, however, proved too overburdened with competing initiatives to engage in new design work.

Aware of the potential upside of having *student* or pre-service teachers (PSTs) receive training on CT (Yadav et al., 2017), the RPP approached PSTs in partner schools to engage in co-design work. RPP members hypothesized that PSTs may not only have more flexibility to test out the utility of the RPP's co-design approach versus practicing teachers but that this experience could prove particularly impactful in developing student teachers' design capacity for integrating CT into curricula and in shaping their beliefs and self-efficacy for CT instruction. This paper asks: (RQ1) *What aspects of the design space facilitated (or hindered) student teachers' engagement in productive CT lesson design?* and (RQ2) *How did student teachers' understandings and beliefs about CT instruction change over time?*

Theoretical framework

Our study focuses on PSTs' learning as they engage in design work within the context of a RPP and during their teacher credentialing program. Drawing on sociocultural conceptions of learning, notably the situated learning notion of communities of practice (Lave & Wenger, 1991), members of the RPP envisioned the formation of a community of K-5 teachers with the capacity to adeptly integrate CS and CT into their classroom in meaningful ways for all students, notably multilingual learners. Included in the RPPs' conception of a community of practice are the students, multilingual learners and English speakers, who are active participants within the community (Téllez, 2007).

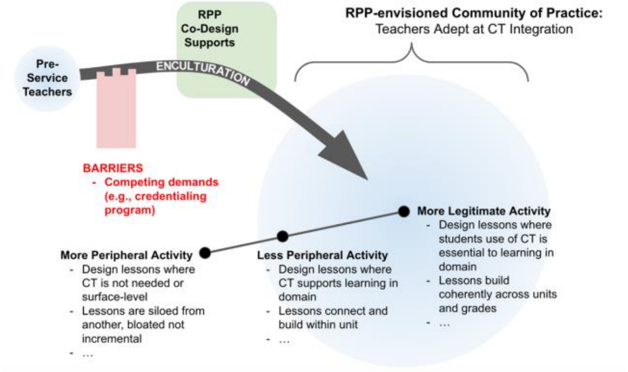
In line with situated learning, in terms of both our design and analysis, we view learning as changes in activity and participation of participants – such as teachers demonstrating an increased sophistication in their professional language (Little, 2002) – where they move from the peripheral position of an envisioned community towards one of increased participation where they more expertly engage with the skills and cultural practices of a particular community (Lave & Wenger, 1991). Members of the RPP organized design opportunities for PSTs to become increasingly immersed, or enculturated, into the community of practice envisioned by the RPP through participating in lesson design and implementation with support from RPP members.

We also utilize Vygotsky's (1978) conceptions of tools and mediation to frame the design and analysis of activities that supported PST participation and movement within a community of practice. According to Vygotsky (1978), people utilize tools (e.g., symbolic representations including speech, drawing, and number systems but also physical tools with cultural knowledge embedded within them) to mediate their learning and activity. Prior work has shown the promise of focusing on mediation and tool use in examining teacher learning (Orland-Barak, 2014). We see supports and structures within the RPP – namely elements in our design process and aspects of CT – as tools to mediate PSTs learning and support their movement from peripheral participation to deeper and more complex participation within the community of practice envisioned within the RPP.

Methodology

Approach to design activities

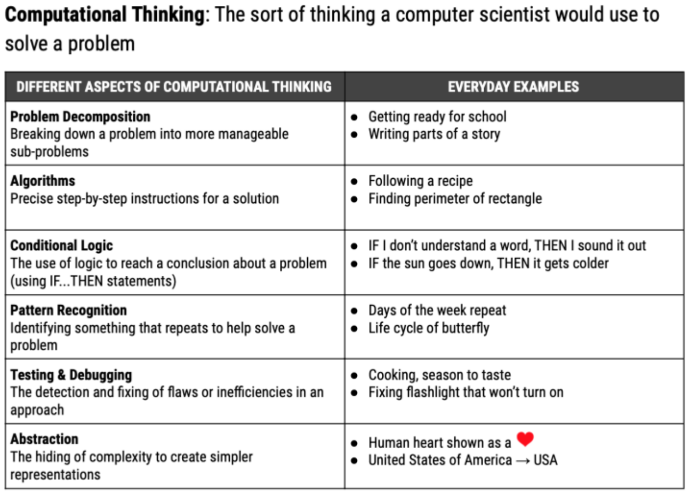
Figure 1
Theorized movement of PSTs towards becoming teachers integrating CT



The RPP that serves as the context of this design study is composed of K-5 teachers, district and school administrators, and researchers from local universities and not-for-profit institutions. For the past several years, members of the RPP have sought out ways to develop district teachers' capacity to integrate CS/CT into their instruction with the ultimate aim of forming a professional community of teachers adept at designing meaningful and inclusive CS/CT learning experiences. With PSTs, the RPP saw an opportunity to design and test ways to support novice teachers' "enculturation" (Russ et al., 2016) into this future community (see Figure 1). Following prior work on the benefits to teachers via collaborative design (Severance et al., 2016), members of the RPP developed tools and structures that positioned PSTs as lead co-designers of lessons that integrate CT with support from researchers and district personnel. The RPP wanted to see how this approach helped (or hindered) PSTs' capacity for designing CT learning opportunities, which echoes recent professional development models centered around CT integration through joint work (Love et al., 2022).

The support PSTs received over the course of three months ranged in form but all sought to spur PSTs development towards becoming teachers adept at CT integration. At the outset of their involvement, PSTs participated in a three-hour researcher facilitated workshop introducing them to the idea of computational thinking along with design ideas and tools. One notable tool researchers introduced – a one-page summary CT chart defining CT with everyday examples – purposefully built off of an activity where PSTs used their own knowledge and experience to recognize different facets of CT in their everyday lives and educational experiences (see Figure 2). This workshop also introduced PSTs to the notion of "coherence" in learning, that is a progression for learning where learning builds and becomes more complex over time (Fortus & Krajcik, 2012), by having PSTs analyze CT lessons across a primary grades science unit. After the workshop, PSTs worked closely with cooperating teacher mentors the credentialing program placed them with to plan how to integrate CT into an upcoming lesson. An additional support structure included hour-long one-on-one design sessions between PSTs and researchers and district personnel from the RPP. In these sessions, members of the RPP offered ideas, suggestions and instructional tools that PSTs could incorporate into their lessons.

Figure 2
Introduction to computational thinking summary chart handout for pre-service teachers



Computational Thinking: The sort of thinking a computer scientist would use to solve a problem

DIFFERENT ASPECTS OF COMPUTATIONAL THINKING	EVERYDAY EXAMPLES
Problem Decomposition Breaking down a problem into more manageable sub-problems	• Getting ready for school • Writing parts of a story
Algorithms Precise step-by-step instructions for a solution	• Following a recipe • Finding perimeter of rectangle
Conditional Logic The use of logic to reach a conclusion about a problem (using IF...THEN statements)	• IF I don't understand a word, THEN I sound it out • IF the sun goes down, THEN it gets colder
Pattern Recognition Identifying something that repeats to help solve a problem	• Days of the week repeat • Life cycle of butterfly
Testing & Debugging The detection and fixing of flaws or inefficiencies in an approach	• Cooking, season to taste • Fixing flashlight that won't turn on
Abstraction The hiding of complexity to create simpler representations	• Human heart shown as a ❤ • United States of America → USA

Approach to data collection and analysis

This is a multiple case study designed to explore a single phenomenon through the exploration of several cases (Creswell, 2007). Six PSTs (five at the primary level, one at the secondary level) participated in this research study. In terms of participant selection, the RPP was interested in working with PSTs who were engaged with students in the classroom and who could teach a lesson to their students. Working directly with students was an important feature in participant selection because of the emphasis on students as members and collaborators within a community of practice (Téllez, 2007).

Primary sources of data include 30-minute semi-structured interviews with participants after their enactment of the CT lesson, transcripts and artifacts from the 3-hour workshop, and PSTs' responses on surveys given pre and post participation in design activities. All six PSTs participated in the support activities organized by the RPP (i.e., PSTs participated in the initial workshop, worked with a collaborator within the RPP, and received support from the cooperating teacher mentor their credentialing program placed them with).

In terms of data analysis, we coded transcripts from the initial workshop and semi-structured interviews as well as pre and post survey responses for each participant. This coding process involved rounds of inductive and deductive coding of available data (Emerson et al., 2011), leading to the development of a codebook. Examples of codes include aspects of CT ("algorithms", "conditional logic") as well as codes that identify how PSTs talked about CT integration and instruction ("explicit", "implicit"). To ensure the reliability of our codebook, we used a set of our codes and Dedoose's interrater reliability test to achieve a pooled kappa score of 0.85, demonstrating a high consistency of our code application across various excerpts (De Vries et al., 2008). Throughout the data analysis process, we engaged in the creation of written analytic memos to discern potentially key data for further analysis. After discerning patterns of data triangulated across all sources of data, researchers engaged in the co-reconstruction of meaning from these data patterns.

Data and results/findings

We found that the mediating supports organized by the RPP supported the PSTs' capacity to engage in CT design work over time. While enabling in some capacities, the RPP and other programmatic structures were constraining in other aspects. We also found that PSTs demonstrated learning through their movement towards a future community of practice and the development of CT specific beliefs and definitions.

Claim: Design supports enabled productive CT lesson design but competing program demands across the RPP inhibited design in some ways

We found that (1) the structure of the RPP supported PSTs' capacity for engaging in CT design work, scaffolding their movement towards the center of the community of practice; however, (2) certain aspects such as PSTs Masters/Credential program requirements, number of meetings with RPP mentors and sustained support throughout the process acted as possible constraints on the design space.

Supports organized by RPP greatly promoted PST design

At the outset of the project, PSTs' pre-survey responses revealed very little to no capacity for designing quality lessons that integrate CT. The PSTs had simple ideas about what CT instruction should look like only saying, "*using technology integrated into the curriculum meaningfully (PST 4, Pre survey)*" but showing little capacity for designing lessons. Indeed, three of the six PSTs reported having virtually no knowledge of CT let alone knowledge of how to design lessons supporting CT learning. By the end of their participation three months later, however, each participant credited several aspects of RPP's program of support as key to increasing their design capacity for working with CT. Notably, PSTs acknowledged the utility of the workshop and tools introduced there like the CT chart and the benefits of co-designing with members of the RPP and their cooperating teacher mentors.

During the initial workshop, PSTs were supported by RPP mentors facilitating the workshop. PSTs were presented with information about CT and asked to think about the ways CT is already integrated into aspects of life and schooling. With these supports in place, PSTs were able to articulate ideas about CT integration, One PST was asked to focus on algorithms and shared that algorithms are universal:

> *Are most things that they do… they're actually writing How-To books and learning to be very clear with their step by step instructions in their writing…it's kind of meta, but I had to teach them the steps to writing their How-To books, which needed to include step-by-step instructions on teaching someone how to do something (PST 1, Workshop transcript).*

The structure of the workshop, including opportunities to think about current practices in relation to the new information about CT, supported all PSTs thinking about the ways CT was already integrated or embedded in the daily things they do in the classroom. This demonstrated the efficacy of the workshop as a support for PST learning. Three participants discussed the usefulness of the CT summary chart in supporting their ability to integrate CT into a lesson, saying "*there's a PDF that was provided that was really helpful for me in breaking down what each of the terms meant and then the practical application*" (PST 3, Interview transcript), which demonstrates the utility of the CT chart as a tool to mediate learning and lesson design.

After the workshop, PSTs were expected to plan and teach a lesson integrating aspects of CT. In their interviews, all PSTs talked about working with at least one person involved in the RPP to develop the lesson. Members of the RPP were available to support PSTs with lesson development and design as needed. During the semi-structured interview, one PST shared how a researcher from the RPP supported their design process:

> *I was glad that I reached out to [name redacted] and kind of got a little bit more support with what to do. I'd ask 'what should this look like?', 'what should some of my goals be?', 'what would be a good thing to use?' So I guess just kind of having someone more on the inside who could be like a soundboard to run ideas off with (PST 2, Interview transcript)*

During another interview, a PST explained the ways their cooperating teacher mentor (i.e., the teacher PSTs were placed with as part of their credential program) supported their enculturation into a future community of practice where CT integration is expected. While their cooperating teacher mentor was unfamiliar with CS and how to integrate CT, they supported the PST in learning and developing understanding in that area:

> *My cooperating teacher offered a lot of help because she was the one that thought we should try it out. She was there to tell me we should do it and learn something new. She helped me with the broad ideas of what we could do and how we could go about doing it (PST 4, Interview transcript).*

Across five of the six PST learning trajectories, PSTs reported the same pattern: RPP mentors supported CT integration and cooperating teacher mentors supported lesson planning and implementation. The PSTs reference to RPP members and cooperating teacher mentors in a supportive role highlights the ways that members of the RPP may have functioned collectively as something of an "old timer," someone established in a community of practice supporting the enculturation of "newcomers" (Lave & Wenger, 1991).

With these supports in place, PSTs successfully developed and taught a CT lesson, something that they previously admitted having little capacity for doing. The supports organized by the RPP functioned as mediating tools and means (Vygostky, 1978). These supports greatly aided PSTs in developing an increased design capacity to integrate CT into their instruction, which supported their movement towards the center of an envisioned community of practice (Lave & Wenger, 1991) – a community of teachers in the RPP where a focus on inclusive and meaningful CT instruction would be the norm.

Certain RPP structures inhibited PSTs capacity for inclusive CT design

Despite the successes of the structures of the mediating supports, there were aspects of the organization of the RPP's program of support that made reconnecting with the PSTs after the workshop and supporting them in additional ways a challenge. One PST noted the difficulty of moving forward immediately after the workshop:

> *I think that my cooperating teacher and I were having a hard time at the beginning thinking about what it meant to incorporate computational thinking into a lesson, I think we were just overthinking it. We were just unsure of where to start, even after we had been to the intro meeting and gone through that meeting, We were just so confused (PST 4, Interview transcript).*

Three other PSTs reported feeling similarly, saying that having more examples of lessons that integrated CT would have been helpful. The RPP team had planned to connect with PSTs after the initial meeting to build on the introduction of CT and support the integration process but faced scheduling conflicts due to the work expectations of the credentialing program (e.g. classes, student teaching and completing credentialing tasks).

Notably, even though the RPP had a vision for providing inclusive CT learning opportunities for all students – particularly for multilingual learners – PSTs did not attend to providing those opportunities in the same depth they thought about CT integration. During interviews, PSTs were asked what English Language Development (ELD) strategies they integrated into their lesson plan and they provided examples like using visual representations or aids as well as examples of shapes or directions. One PST shared, "I went around and talked with students about shapes. Talking with their groups and peers just helps them be able to engage with the vocab." Given the focus of the RPP on providing language opportunities for multilingual students in the CT learning context, we expected to see more evidence of planning for rich opportunities to engage in talk.

Claim: PSTs 'experiences increased their understanding of certain aspects of CT and coherent instruction, and shaped self-efficacy beliefs about CT instruction

Beyond examining how the supports organized by the RPP supported (or not) PSTs' capacity to engage in CT design work, we also saw patterns indicating the sort of knowledge the PSTs acquired and how their experiences shaped beliefs about CT instruction. Five of the six PSTs reported not knowing much about CT and what integration would look like, saying "*I couldn't explain this to anyone*" (PST 3, Pre survey). By looking at participants' engagement with the RPP structures and supports, we can trace PSTs development of understanding as they moved from the periphery of a community more towards the center. We argue that PSTs (1) demonstrated an increase in understanding of CT instruction, (2) developed beliefs around the feasibility of CT integration, and (3) began to grasp the concept of coherence.

Developing a definition of CT and knowledge about CT integration

The pre-survey responses served to document PSTs' baseline knowledge of CT integration. One question asked what experience they had with CS or CT with one PST reporting a dearth of experience in working with CS:

> *Not very much! I took a digital media course in my undergrad and learned a bit about binary and such, but my knowledge about CS is fairly limited overall. I have taken about 3 statistics courses, two in my undergrad at [redacted] and feel rather comfortable with stats (PST 2, Pre-survey).*

This was a characteristic response across five of the six participants. In response to the pre-survey question asking what it would look like to have students use and learn about computational thinking in the classroom, one PST shared, "*My best guess is working with data/computers/potentially coding*" (PST 2, Pre-survey), which demonstrates a general idea about what CT integration and instruction might look like without any specific grounding knowledge about CT. We argue that PSTs' ability to design and enact a lesson by the end of the program shows the movement within a community of practice as well as increased understanding of CT.

By the end of their participation, all PSTs articulated a working definition of CT and aspects of CT, which they had developed as they moved through supports organized by the RPP. One PST defined CT as:

> *The ways that people of any age are able to think about the technical parts and steps of any sort of task or activity. Just the ways that we think in strategic, step-by-step ways. It's not just computer science thinking, but it's any way that people engage in thoughtful thinking (PST 2, Interview transcript).*

This particular definition describes the algorithmic aspect of computational thinking. It demonstrates the development of a conceptual understanding of CT that was missing in PSTs' pre-survey responses.

Even though PSTs articulated accurate definitions of CT and successfully planned and taught a CT lesson which demonstrates an understanding of CT, one PST expressed that the most challenging part was making sure the CT was apparent and clear to students. They said, "*I think the computational thinking could have come across as more of a language scaffold so I think I need to make sure to include the computational thinking in a way that's purposeful*" (PST 4, Interview transcript). This response demonstrates areas where PST thinking and understanding of CT integration may need to be supported more throughout the RPPs' program of supports.

Developing PSTs' self-efficacy beliefs about CT instruction

At the end of their participation, all six PSTs expressed a desire to implement CT into their future classrooms, citing their beliefs that CT integration is important for their students. This following response was characteristic of the other PSTs beliefs about the integration of CT into their future classrooms:

> *I think that it's definitely doable and worthwhile to do. I think it's fun to get students to think in these kinds of ways and to see their abilities to try new things. And just knowing that [CT] happens naturally in so many ways (PST 2, Interview transcript).*

In this response, the PST says that CT is happening "naturally in so many ways" which is characteristic of how CT was discussed in the initial workshop. Flowing from PSTs understanding of aspects of CT and a recognition of the ways that they may already be teaching CT, PSTs' developed beliefs about their own ability to implement CT in their future classrooms. This PST noted the importance of CT to students' futures:

> *I would be really excited to implement CT into my future classroom. I think that it's really important, especially for minorities like women and people of color to have these skill sets and to help them get ahead in life. Especially when it's so male dominated (PST 6, Interview transcript).*

This response not only reflects the PSTs' belief in the importance of teaching CT to younger students but the feeling of excitement illuminates the "mastery" experience this PST had in teaching a CT lesson, increasing their sense of efficacy (Bandura, 1994). Research on self-efficacy points to a link between self-efficacy and classroom practice (Washburn, 2006 cited in Téllez & Manthey, 2015), therefore the expressed feelings of self-efficacy are a positive outcome of the RPP structure. Given the evidence that experiences can shape beliefs (Pajares, 1992), the development of PSTs' efficacy beliefs about CT instruction highlight how supporting structures in the RPP mediate PSTs' learning and experiences within structured co-design work.

PSTs develop a basic understanding of coherence in curriculum

In addition to developing a definition of CT and increased feelings of self-efficacy, PSTs also developed a basic understanding of the importance of teaching CT coherently. One PST said that CT instruction should happen over time, across different content areas, so that it can "*build up to a project at the end of the year*" (PST 6, Interview transcript). Another PST equated teaching CT to painting, saying, "*you would start always on the back layer, and then you would work your way up creating the frontal layers*" (PST 5, Interview transcript). The other PSTs had similar responses, articulating that CT is built over time. While all PSTs articulated that CT should not be taught in just one lesson and needs to develop over time, PSTs did not specifically talk about the slow increase in complexity of concepts nor the ability to develop more complex models (Fortus & Krajcik, 2012).

Discussion and conclusion

This study examined the efforts of a RPP to overcome challenges in providing all students with CT instruction, namely a lack of CT curriculum and teachers underprepared to facilitate CT instruction, and offers promising evidence for approaches that can begin to attend to these challenges. Specifically, this study provides evidence for how PSTs can be included in RPP work focused on CT instruction and support the aims of RPPs. Notably, our study showed how working with PSTs can provide a RPP with additional capacity and maneuverability – particularly when in-service teachers lack the time and space to participate fully – and also allow for the development and refinement of approaches that may support all teachers in designing CT instruction. This systems-level thinking and unorthodox arrangement of a RPP's resources echoes calls for 'infrastructuring' (Penuel, 2019), or the redesigning of existing elements within an educational system into new forms that can better support ambitious educational initiatives.

The approaches to support PST learning in CT highlighted in this study serve as a response to calls to redesign how PSTs learn CT (Yadav et al., 2017). Unlike past approaches in teacher education which present CT in a module-like manner largely separated from practice (Yadav et al., 2015), this study provides a tangible program centered on developing PSTs' capacity for engaging in authentic complex CT lesson design and implementation over time. The results corroborate the history of research examining teachers' pedagogical design capacity (Brown, 2009); however, the examination of PSTs' learning of not just CT ideas but design principles for CT instruction is new. In particular, this study builds on previous work in science on the topic of curricular coherence (Fortus & Krajcik, 2012), and shows how PSTs can fruitfully engage with this principle within the context of CT integration (though new additional supports are needed). Aligning with previous work on teachers' beliefs around CT integration (Love et al., 2022), this study also offers evidence that the supports PSTs engaged in to integrate CT led to positive outcomes not only in terms of their learning but their beliefs' and self-efficacy about CT integration.

The co-design features of this study were crucial for PSTs in developing their design capacity for CT integration. Co-design between teachers and other experts like researchers has recognized benefits for in-service teacher learning and building the capacity of educational systems to implement reforms (Severance et al., 2016). This study strongly indicates that a well-scoped co-design approach can provide a rich professional learning experience for PSTs in the area of CT and CS instruction. Future research on how best to engage PSTs in design work in ways that does not prove too time-consuming would prove beneficial. PSTs engagement in intensive design activity, such as co-design, proved somewhat burdensome and reflects a larger pattern. While in-service teachers had virtually no chance of participating in the RPP activities completed by PSTs, the competing demands and responsibilities on PSTs from their routine program coursework and student teaching was substantial.

This study shows that tangible design supports are likely needed to support design work around equity in terms of CT (Google/Gallup, 2016). We surmise that the RPP's heavy focus on CT integration may have overshadowed the importance of designing for language development, resulting in PSTs focusing more intently on CT integration than a pressing issue of equity for multilingual learners. Bringing language learning and opportunities for meaningful engagement with language front and center to the design space and principles would prove an important step moving forward to ensure that lessons are designed with more intentional focus on the language opportunities students engage in.

The goal of the RPP was to test certain supports and structures providing guidance for future work with specific attention to areas of the RPP that can be strengthened. We encourage other RPPs with visions of CT or CS instruction similar to the RPP here to engage in similar explorations, particularly with regard for the scaling up to support a larger group of teachers or PSTs in learning about CT integration. Such efforts will provide additional evidence for approaches that can move RPPs closer to having a robust community of teachers capable of creating meaningful CT and CS learning opportunities for all students.

Vector Addition in Stories: Exploring Knowledge Application After a Concreteness Fading Intervention

Yilang Zhao, University of Wisconsin–Madison, yilang.zhao@wisc.edu
Jamie Gibson, Horizon Science Academy Columbus Middle School, gibson@hsacm.org

Abstract: Concreteness fading, as an instructional approach, can enable students to develop grounded understandings of new concepts, yet the effects of a concreteness fading intervention have been rarely researched. In this study, we designed a concreteness fading intervention to teach middle schoolers vector addition and added an extra task to allow students to demonstrate their understanding through a storytelling activity. As a result, we discovered that students could develop some understanding of the topic. The stories they created served as a medium to provide them with a context to apply their newly gained knowledge.

Introduction

Among all the secondary-level mathematics topics, vector addition is a challenging but essential mathematical skill because of its vital role in postsecondary STEM education. Current secondary mathematics educators, however, often rely on formal notations in their classroom, which is criticized as "formalism first" (Nathan, 2012). Supposing students' understanding goes beyond those symbols of vector arithmetic during their middle or high school math class, they will likely have fewer difficulties with college-level vector arithmetic (see Knight, 1995). Therefore, developing an intervention that empowers students to gain a deep understanding of vector addition that they can demonstrate to the instructor is critical to secondary-level vector addition teaching and learning. In this study, we designed an intervention by incorporating an instructional approach, concreteness fading, and added an extra task in which students apply their newly gained knowledge to construct artifacts. By paying particular attention to the extra task, this study aims to examine how students demonstrate their knowledge gained from a concreteness fading intervention and contribute to the concreteness fading literature.

This study has a potential contribution to the domain of vector addition learning, both theoretically and practically. The potential theoretical contribution is that we explored a new way to examine how students can demonstrate their mathematical understanding gained from a concreteness fading intervention, which has not been studies before. As for the potential practical contribution, this study depicts a new approach to teaching vector addition and understanding students' vector addition learning for secondary mathematics educators.

Theoretical framework

When introducing vector addition to students, this topic can be complex for them to start since it is highly conceptual and inaccessible in their daily lives. Bruner (1966) proposes three stages –enactive, iconic, and symbolic–for learners to perceive new concepts. Inspired by these three stages, there is an instructional approach called concreteness fading (CF) that refers to a learning process in which students start learning a new concept or skill with concrete learning materials related to their previous knowledge, and gradually transition to abstract learning materials (Fyfe et al., 2014). In a CF intervention, students will first encounter something they are familiar with. Then the same learning content will be presented to them with its concreteness level gradually fading. When they are familiar enough with different forms of the notion, formal notations can be introduced without making them feel intimidated. With a learning process that gradually fades concreteness, students can develop their understanding in the intervention. A CF intervention can strengthen the advantages and avoid the disadvantages of both concrete and abstract learning (Fyfe & Nathan, 2019). As no previous studies researched how to implement CF to teach vector addition, it can be promising to implement a CF intervention to teach vector addition.

Since previous CF studies seldom examine the knowledge application after a CF intervention and the assessment of learning from a CF intervention often replies on a worksheet with formal questions (e.g., the knowledge assessment questionnaire in Jaakkola & Veermans, 2018), we believe an activity that incorporates constructionism can be promising because it allows students to demonstrate their grounded understanding in a personally meaningful way. Constructionism, proposed by Papert (1980), is a learning theory that states deep learning emerges when students explore and play with ideas by creating personal self-driven projects in which students make their own object-to-think-with (Ackermann, 2001), a physical representation of their understanding of the learned content. When designing a constructionist learning activity, the learning environment should ensure that learners can start with something easy (low-floor) , have space for them to increase the complexity of their construction (high-ceiling), and support their building of various types of projects that fit their interests and learning types (wide-walls) (Resnick et al., 2009). Therefore, by combining "concreteness fading" and constructionism, our research question is how students demonstrate their understanding of vector addition from a CF intervention in a constructionist story creation activity.

Methods

Participants

This study had nine 8th graders from a charter school in a large Midwestern city in the U.S. The participants had learned the coordinate plane in 7th grade and never learned vectors in math class. They were evenly divided into three random groups to participate in this study.

Study design

The participants formed a group of three to complete three CF learning tasks (see Table 1). First, the task Enactive Physicality provided participants with cardboard tiles and a football to experience vector addition through physical activities (see Figure 1). Next, the same problem was presented in the task Iconic Depiction through a football simulation game (see Figure 2). Finally, in the task Abstract Representation, participants had similar problems on a worksheet (see Figure 3).

Table 1

CF Learning Tasks

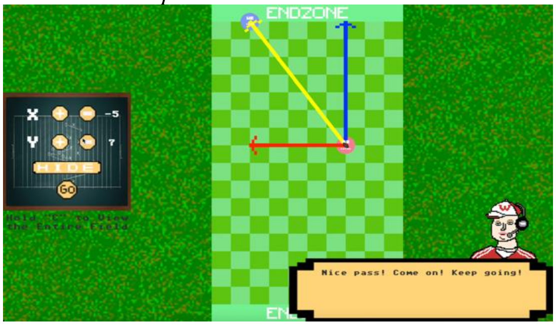
Task	Activity	Duration
Enactive Physicality	The participants tiled the floor with light and dark green cardboard tiles and randomly selected two tile's vertices to stand on and figure out a way to describe their position. Then they played a game in which they passed a football to experience informal vector addition.	20 mins
Iconic Depiction	The participants played a video game built on similar concepts that introduced some formal representations, such as axis and unit vectors.	20 mins
Abstract Representation	The participants worked on a question sheet with similar settings and more formal notation and symbols.	20 mins

Figure 1

Task Enactive Physicality

Figure 2

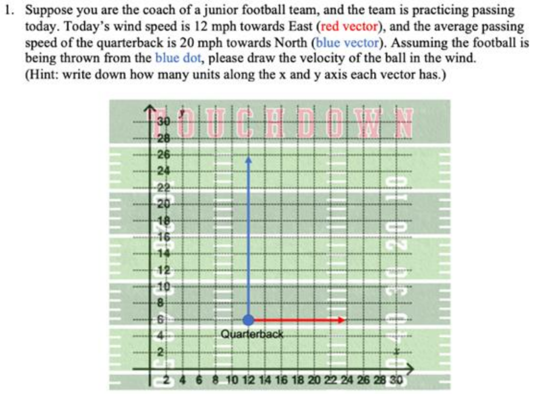
Task Iconic Depiction



Hold "C" to View the Entire Field

Nice pass! Come on! Keep going!

Figure 3
Task Abstract Representation



1. Suppose you are the coach of a junior football team, and the team is practicing passing today. Today's wind speed is 12 mph towards East (red vector), and the average passing speed of the quarterback is 20 mph towards North (blue vector). Assuming the football is being thrown from the blue dot, please draw the velocity of the ball in the wind. (Hint: write down how many units along the x and y axis each vector has.)

After the CF learning tasks, there was an extra 30-minute "constructionist problem design" (CPD), in which participants built a story together to demonstrate what they learned today. We designed the learning activity following the constructionist design principles of "low-floor," "high-ceiling," and "wide-walls." The participants were asked to start with any rough ideas by considering one of the learning objectives in the conceptual story design sheet we provided (see Table 2) and use the materials–crafting sticks, IKEA artist's figures, color markers, and blank paper–we provided to build up their story. This fit the idea of creating a "low-floor" for the participants because they could start designing their story with any ideas in mind. When the participants first made up a story and built it with materials, we asked some prompt questions (e.g., how to describe the positions of your characters?) to enable them to iterate their story by adding more mathematical concepts (high-ceiling). Here, we are constrained by the study time that the task had to be finished within 30 minutes. Catering to that, we designed five contexts for them to choose from, and engage them with freestyle storytelling (wide-walls). By providing predefined contexts, the participants could start their story constructing quickly rather than spending time figuring out a context for their story. After they completed their iterative story building, the researcher asked every participant to retell the story and inform what kind of mathematical concepts they added into their story.

Table 2
Conceptual Design Tool

Item	Option	
Learning objectives	a.	How to describe the movement (resultant) in terms of x and y?
	b.	What are the most important things about vectors?
	c.	(We can describe any location in space using a coordinate system.) What does your friend need to know about the coordinate system?
Contexts	a.	Robotics
	b.	Fashion
	c.	Bicycling
	d.	Soccer
	e.	Basketball

Data collection and analysis

Three two-hour study sessions were conducted from February to March 2022 after regular school hours. For each study session, we obtained consent from the participants' parents and the participants themselves before the study. Then we followed the procedure mentioned above to let participants work on the CF learning tasks. Before the CPD task, they had a 10-minute break. After the break, they were provided materials and worked on the CPD task together. During the study session, video cameras and audio recorders were used to capture the video and audio data produced by the participants.

After the data was collected, audio tracks were transcribed. In this study, we concentrated on the addition task–CPD. We conducted a qualitative analysis of all the transcripts of the CPD task. By applying a bottom-up method, we first reviewed the videos and selected clips that included conversations related to this task. Then, we did a round of open coding, identified codes with similar themes, and categorized our open codes into more focused codes. The below coding scheme (see Table 3) was then developed and used to recode the data. The unit of our analysis was the entire group, who built up their artifact together. To ensure the validity of our analysis, two researchers with an educational research background coded the same set of data separately, and the coding results were cross-validated.

Table 3
Coding Scheme

Codes	Definition	Example
Link to Prev. Activity	The participant mentions an activity or an element from the previous CF tasks.	P3: And we can use the sticks, like **make the tiles again**.
Link Context to Math	The participant says something that contains explicit mathematical terms or concepts.	P1: Looks more **like an exponential function**.
Coordinates-related	The participant says something related to coordinates or the coordinate plane.	P3: We should place him at **the origin** and then we'll say like something like **five, seven (5,7).**
Vec Components	The participant says something related to distance and directionality	P1: Mane's vector is **five x plus seven y**. And Salah's vector is **zero x and**…
Vec Addition	The participant says something related to vector addition either explicitly (e.g., 5x plus 6y) or implicitly (e.g., eight units along that direction).	P1: You were standing here and then your vectors, like four X plus seven Y. You're not going to do like four X, seven Y. You're going to **start from this position and move four times horizontally and seven Y vertically**.
Link to Sports	The participant says something that includes sports elements, such as teams, athletes, scores without mathematical context.	P1: Let's do **Liverpool vs. Arsenal**.
Contextual Explanation	The participant attempts to use something specific in the context to explain a mathematical concept.	P2: We are basically using distance. So, we have to **measure how far and how soft or hard he has to throw the ball for P3, so he's able to catch it and shoot the ball in**. So, he has to throw the ball over his head so that P3 can catch it.

Results

We segmented the transcripts by identifying the end of a meaningful conversation and coded 23, 22, and 15 excerpts for three study sessions (Group 0218, Group 0222, and Group 0325). All the groups picked learning objective *a. How to describe the movement (resultant) in terms of x and y?* as the learning objective of their story. The below table (Table 4) shows the counts of each code in every group. In addition, two groups (0222 and 0325) selected basketball as their context, and one group (0218) chose soccer. One of the stories (Group 0218) is like this:

> P1: So this is Mane and this is Salah. This guy passes ball to this guy and then this guy kicks it and then they hit P2's head.
> P1: And then this guy, and then these two are Liverpool. And then P2 is the goalkeeper of Man United. And then like this guy made a vector. It was five x plus seven y.
> P1: And this guy he scored it. He gets...
> P3: 4, 14?
> P1: The vector was like eight blocks and then P2's position was 4,14. And Mane's position is...
> P3: 6,7.

Table 4
Code Counts

	Link to Prev. Activity	**Link Context to Math**	**Coordinates-related**	**Vec Components**	**Vec Addition**	**Link to Sports**	**Contextual Explanation**	**Total**
Group 0218	2 (4.3%)	13 (28.3%)	6 (13.0%)	7 (15.2%)	3 (6.5%)	10 (21.7%)	5 (10.9%)	46

Group 0222	7 (19.4%)	10 (27.8%)	2 (2.8%)	0 (0.0%)	0 (0.0%)	3 (8.3%)	14 (38.9%)	36
Group 0325	5 (11.6%)	12 (27.9%)	11 (25.6%)	4 (9.3%)	0 (0.0%)	0 (0.00%)	11 (25.6%)	43

Group 0218 was the only group that incorporated the concept of vector addition into their story. They drew a grided coordinate plane and placed the figures in two positions on the plane as two soccer players on a soccer field. Then they explained that they had a vector for one player to pass the ball to the other player and the other player had a vector to score a goal. Therefore, at the beginning of their design, a couple of codes–*Link to Prev. Activity*, *Link to Context to Math*, *Coordinates-related*, and *Vec Components*–emerged. There were a lot of *Link to Sports* coded when the participants enriched their story by adding more details. At the end of this activity, they had several codes of *Vec Addition* when they explained how a character in the story kicked a ball from its position to another position on the coordinate plane by adding a new vector to the current position of that character. The below excerpt shows how they embrace their understanding of vector addition in their story.

> **0218P1**: You were standing here and then your vectors, like four X plus seven Y. You're not going to do like four X, seven Y. You're going to start from this position and move four times horizontally and seven Y vertically, like seven.

Group 0222's story was different from group 0218's. They barely used the mathematical language in their story. Their story had a scenario in which a figure represented Kobe Bryant, and another figure was one of the participants. In their story, Kobe passed to the participant, and the participant shot a game-winning three-pointer. The dominating code in their transcript was *Contextual Explanation*. The participants knew that reaching another position relies on appropriate angle and distance, but they relied on the context in their story to elucidate their understanding. The below excerpt is a good example.

> **0222P3:** Oh, the distance. Since it's five to eight meters, he's gonna have to throw it really, really, really hard and really, really with the amount of power. So it can get to me. Because if he doesn't, if he throws you a light, it's not gonna get to where he needs it to go. If he throws it to really, really hard, then it's gonna go out of bounds. He has to throw it with medium strength, so it can get to me because it's like five to eight meters and a little bit more than this.

Although a couple of *Link Context to Math* codes were from the conversations of the participants in Group 0222, they referred to mathematical concepts for adding numerical details to their story, such as counting the sticks placed between two figures and stating the distance was 11 inches. They also made connections to previous tasks when constructing the story, as the below except shows, to make their story similar to the physical activity they had done.

> **0222P2**: So like when we did the tiles, he had to measure the distance and how far it was and the way that we are facing. Kobe had to pass the ball to him. So he had to throw it, he had to know how far he had to throw it for P3 to be able to catch the ball and stuff like that.

Group 0325's basketball story differed from the previous groups'. Their two-part story had a lot of *Coordinates-related* codes that densify their use of coordinates in the story. For instance, in the below excerpt, they were able to embed the coordinate plane and units on the coordinate plane well in their story.

> **0325P3**: So Brad and Bob are trying to play basketball at the park, but there is trafficking in the way. Brad has to throw the ball 10 units, 10 units on the coordinate plane.

Their use of *Vec Components* is restricted to a single way of describing the distance along a direction. For example, the below excerpt illustrates that P2 knows that the movement along a direction on the coordinate plane relies on the units along that direction, but she needs the story context to help her explain this idea.

> **0325P2:** They're playing basketball. Bob jumping up to dunk on Brad. So it shows how far he has to go. Like the distance, how many units he has to go to reach the basket to dunk.

Discussion

The story the participants created revealed that they had different understandings of how to describe movement in terms of x and y on a coordinate plane. All the groups drew a grid coordinate plane which they were familiar with and had been exposed to in the previous CF tasks. They also placed the figures on the coordinate plane like what they had done physically in the first task *Enactive Physicality* and had seen in the second task *Iconic Depiction*, but Group 0222 did not include coordinates for their figures in their final story because they focused more on the plot of their story and simply ignored this part. Utilizing a coordinate plane to describe positions is the first thing they learned from the CF intervention. Some may argue that they have learned the coordinate plane in their 7th-grade math class, but facing such an open design task, using the coordinate plane to describe positions is more likely from the intervention as all three groups made connections to previous CF tasks in the process of their story creation.

Vector addition with formal notations seems hard to all the groups. Group 0218 seemed more comfortable with vector-related mathematical vocabulary, so they used vector components to describe the ball-passing distance between the figures on their coordinate plane. Although they did not explicitly state that adding a vector to a point could get to another position, what they embedded in the story indicated they knew this addition would work. On the other hand, Group 0222 and Group 0325's understanding was not apparent. Group 0222 focused on the story's details and showed their understanding of reaching another position on a coordinate plane through their rich story details about how to pass the ball with the right strength and angle. They used a lot of general mathematical terms, such as five to eight meters or six squares, but they did not show the clear idea of the effect of traveling a distance along a direction. Group 0318 had a similar story but differed because they concentrated on using units on their coordinate plane to describe the distance. They also pointed out that they needed a distance of several units along a direction to pass the ball to the other figure, demonstrating they understood the vector's directionality. Thus, on the one hand, the physical activity in the first CF task Enactive Physicality impressed the participants most and made all three groups create a story of passing a ball. On the other hand, although the third CF task Abstract Representation was temporally closest to the CPD task, there might be too many unfamiliar symbols, so the formal notation of vector was not in any of their stories.

Another point worth noting is the affordance of the story they designed. Unlike the context of a word problem, the contexts in their stories are crucial to their mathematical understanding demonstration. As mentioned above, Group 0222 rarely used mathematical language to tell their story, but the contextual explanation in their story revealed how they understood the ball passing between two players (with the right strength and angle) and reflected what they had experienced in the previous activities (football passing on the tiles and in the simulation game). Although Group 0218's story manifests that they know the effect of adding a vector to a certain point on the coordinate plane, they still enjoyed the story creation process by adding real soccer players and real soccer game details to their story. Group 0325 had two very similar parts in their story. Both parts included passing a ball to a target with certain units on the coordinate plane, showing they qualitatively understand how vector addition works. Thus, in such a constructionist activity, the story context allows them to start with something they are familiar with and interested in and then iterate the story by adding mathematical ideas.

There are also limitations in this study. First, due to the time limit of the entire study session, the participants had to use one of the predefined contexts to build up their story. For more personally meaningful story creation, future studies should consider allowing students to choose their own contexts to increase their engagement level during story creation. Second, the facilitator should have more prompt questions to encourage participants to use more mathematical language to build their stories. For example, when group 0222 said Kobe needed the right height and speed to pass the ball, the facilitator could ask a follow-up question–could you use x and y to describe the right height and speed? By asking follow-up questions, students will likely involve more mathematical language in their stories and present their mathematical thoughts in a more straightforward way. Third, it is worth exploring how exactly the process of concreteness fading influences the participant’s story-making and storytelling. This study primarily examines the understanding of vector addition from students’ storytelling and does not explore how the progressive vector addition learning–from physical activities to abstract mathematical symbols contributes to the following story-making. Future studies may further investigate the relationship between the concreteness fading intervention and the constructionist storytelling.

Concluding from our findings, the theoretical contribution of this study resides in the creation of an approach to examine the potential knowledge gained from a CF intervention. 1) This study incorporates an innovative story-creation activity that encompasses constructionism to assess learning from a CF intervention. Previous CF studies only include two or three stages (Suh et al., 2020), and most of those studies rely on a worksheet with symbolic questions and statistical tests between the pretest and posttest to assess the knowledge development from a CF intervention (e.g., Jaakkola & Veermans, 2020). 2) Our qualitative analysis supports a better understanding of the learning process through students’ iterative story creation instead of examining the learning outcome from a knowledge test. 3) While constructionism is often used as a theoretical framework to design a learning activity, our study shows constructionism could be used in learning assessment as well. From a practical perspective, a constructionist story creation activity establishes a safe and comfortable environment in which students are able to demonstrate their learning with the-object-to-think-with. Compared to using a worksheet to measure the learning outcome, implementing a design activity is likely to create a more engaging and authentic learning assessment process.

Conclusion

In this study, we added an extra task to a traditional three-stage CF intervention that teaches vector addition. The additional task incorporates constructionism and assesses students' learning from the CF intervention. By scrutinizing the stories students created, we discover that students still have difficulty with formal mathematical notations even after a thorough CF intervention, but they can embed the mathematical concepts that they are familiar with deeply into their story. In addition, the story creation activity enables them to use their own knowledge to show what they gained from previous activities. Future studies can also consider adding an extra part to a typical CF intervention for learners to exhibit their learning.

Gestural Replays Support Mathematical Reasoning by Simulating Geometric Transformations

Abstract: Actions relevant to conceptual ideas can promote thinking and learning, whether *internally generated* when spontaneously produced by learners (i.e., gestures), or *externally generated* when prompted to perform directed actions. Few studies have explored how prompting students to predict their future actions influences their thinking. This study compared the effects of internally generated predicted actions versus externally generated directed actions on undergraduate students' (N = 67) geometry proof performance. We investigated the role of *gestural replays* as physical re-enactments of one's prior actions involved in mathematical transformations. Gestural replays provide evidence of mental simulation processes of past actions. Quantitative models revealed significant benefits of gestural replays that depict students' prior mathematical transformations on proof performance, which extended to both externally generated directed actions and internally generated predicted actions. Qualitative analysis further illustrates ways gestural replays support embodied simulations that can bridge concrete actions and generalizations needed for mathematically valid proofs.

Introduction

Theories of grounded and embodied cognition (GEC) propose that cognitive processes are rooted in perceptual and motor systems (Wilson, 2002). One way mathematical ideas are grounded and embodied is through gestures. Teachers and students spontaneously use hand gestures to formulate their thoughts (Alibali & Nathan, 2012) and express their current and emerging understanding (Church & Goldin-Meadow, 1986). Gesture production generates new ideas (Novack & Goldin-Meadow, 2015), creates cohesion (Walkington et al., 2014), and promotes learning for a range of mathematical ideas (Goldin-Meadow et al., 2001; Smith, 2018).

Another line of evidence in support of GEC comes from studies showing that physical movements can be used intentionally to influence learning (Nathan, 2017). For example, students directed to move their eyes or arms (i.e., directed actions) in patterns that are compatible with the strategy for solving insight problems were more successful at generating correct solutions (Thomas & Lleras, 2007). Moreover, directing students to perform specific bodily actions tied to conceptual ideas but unrelated to a specific solution strategy can also facilitate the learning of abstract concepts in statistics (Zhang et al., 2021). However, Walkington and colleagues (2022) found that relevant directed actions by themselves did not directly improve high school students' (n=85) mathematical proof performance. Only when students' explanations included gestures of previous directed actions did the relevance of those actions become beneficial. These mixed results raise an important question: **How do *specific* body-based processes influence *specific* mathematical reasoning**?

We explore this question in the context of geometry proof, where participants were asked to either *perform* directed actions or *predict* actions that simulate geometric transformations as they reason about universal claims regarding the nature of space and shape. This study investigates the effect on proofs of students' spontaneous *gestural replays* -- physical re-enactments made during their explanations of one's prior actions of mathematical transformations (Beilock & Goldin-Meadow, 2010; Walkington et al., 2022). We report quantitative and qualitative analyses that examine the role of gestural replays and illustrate the ways that gestural replays can support participants' geometric reasoning and broader aspects of mathematical cognition.

Theoretical framework

Assumptions about cognitive processes

This work builds upon some assumptions about cognitive processes. First, cognitive processes operate within a predictive architecture. Rather than passively waiting for input to think, people continually anticipate what is to come in streams of sensory input and are poised to proactively respond (Clark, 2015). This predictive stance orients people to engage in sensorimotor simulations that project how one's behaviors will change the world and how the world will change in response to these behaviors.

Second, cognition is grounded and embodied. Barsalou (2008) proposed that meaning derives from perceptual and motor experiences from interactions with the world. This model also holds for *offline cognition,* when task-relevant inputs and outputs are no longer physically present (Barsalou, 2008; Wilson, 2002). Many of these cognitive tasks are accomplished through mental *simulations* of actions. For example, in language comprehension, reading action words (e.g., *kick*) activates neural pathways of the relevant sensorimotor systems (e.g., leg); readers automatically simulate these actions stated in words and ground arbitrary symbols and sounds to their cultural meaning (Glenberg & Gallese, 2012). Similarly, during mathematical reasoning, many mathematical concepts and symbolic systems of notation gain meaning by being grounded in perceptual systems and actions, including gestures and movement (Abrahamson & Sánchez-García, 2016; Alibali & Nathan, 2012).

Gestures as simulated actions for fostering mathematical reasoning

Spontaneous gestures have been shown to predict conceptual reasoning and learning by contributing to different types of mathematical reasoning (e.g., Cook & Goldin-Meadow, 2006; Ottmar & Landy, 2017; Smith et al., 2014). For example, children encouraged to gesture while explaining their solutions to mathematics equivalence problems were more likely to express new and correct problem-solving strategies compared to those told not to gesture and those told to explain their solutions with no mention of gestures (Broaders et al., 2007). Restricting gestures impairs model-based inference-making but not fact retrieval (Nathan & Martinez, 2015).

Some gestures arise from mental simulations of actions or perceptual states (Hostetter & Alibali, 2008). As simulated actions, gestures can highlight the spatial-temporal information from actions (Beilock & Goldin-Meadow, 2010) and help schematize relevant information to facilitate encoding (e.g., So et al., 2014) and generalization (e.g., Novack et al., 2014) of cognitive processes. Specifically, *dynamic depictive gesture*s (Garcia & Infante, 2012) enact spatial-temporal transformations of mathematical entities. For example, merely tracing a triangle highlights its static properties, whereas a dynamic depictive gesture can portray the invariance of the sum of its interior angles by re-scaling (transforming) its size, thus supporting generalization and abstraction. By simulating geometric objects and transformations, dynamic depictive gesture production predicts the formation of generalized mathematical proofs (e.g., Nathan et al., 2021; Pier et al., 2019).

Directed actions affect gesture production and non-verbal cognition

While people's movements can reveal their thinking, directing them to perform directed actions as part of an intervention also affects thinking and learning. Some studies have shown that directed actions from earlier training leave a legacy in gesture production in subsequent performance (Donovan et al., 2014). Cook and Goldin-Meadow (2006) found that children were more likely to produce gestures when given instructions that included actions about a solution strategy. Moreover, children's gestures were "picking up on, and reproducing, the content of the instructor's gesture" (p. 217). Performing gestures, in turn, led to better problem-solving performance on a post-test compared to children who expressed a solution strategy in speech only.

When relevant to conceptual ideas, performing directed actions, even without conscious awareness of their relevance, can facilitate learners' performance (e.g., Thomas & Lleras, 2007; Zhang et al., 2021). For example, Nathan and colleagues (2014) experimentally investigated the influence of performing directed actions on undergraduate students' proof performances. All participants were directed to perform either *task-relevant* actions or *task-irrelevant* actions prior to tasks. Task-relevant actions embodied the conceptual relations that underlay the proof tasks, while task-irrelevant actions were matched using the same number of steps and touch points but did not embody the same conceptual relations. Participants who performed task-relevant actions were more likely to generate correct intuitions (i.e., snap judgments) and key mathematical insights for subsequent tasks than those who performed task-irrelevant actions. This finding suggests that relevant directed actions facilitate intuitive and nonverbal processes. However, performing directed actions alone was ineffective for generating valid proofs that required students to consciously describe their chain of reasoning.

Gestural replays moderate cognitive relevance of directed actions

Walkington and colleagues (2022) also examined the influence of performing relevant directed actions on geometric reasoning in the context of an embodied video game that tracked high school students' movements. They observed that some of the explanatory gestures made by players were actually "replays" of the directed actions that were elicited during game play. These replays could be exact copies -- as when players' crossed arms matched the crossed arm movements they performed in the game -- or recreations of the same relations using different body parts, such as crossed hands or fingers. The investigators found that although performing relevant directed actions did not *directly* cause learners to produce more gestures or improve their performances, participants who produced gesture replays of previous cognitively relevant actions during their explanations showed significantly better insight and higher proof performance. Moreover, this effect was most consistent for insight and proof when those replays were dynamic depictive gestures. These findings suggest that the presence of gestural replays derived from relevant directed actions *moderated* the effect of those actions on proof performance. These gestural replays appeared to support embodied simulation by bridging the concrete actions performed in gameplay to the generalized reasoning used to establish mathematically valid geometry proofs. Walkington and colleagues concluded “that engaging in these ‘gestural replays’ of their actions during explanations--even when those replays were not identical recreations of the original actions--changed participants’ encoding for the mathematical principles of the task and subsequent task performance” (p.27).

Research question

In prior research (Xia et al., 2022), we found that prompting participants to predict possible actions for geometry conjectures produced a marginally significant effect on the generation of valid proofs (Cohen’s *d* = .25, p = 0.07) compared to actually performing the relevant directed actions. Moreover, neither condition led to more gestures, suggesting that gesture is not a mediator. We and others (e.g., Walkington et al., 2022) also observed the prevalence of gestural replays during students’ explanations. In light of these findings, we revisit the data post hoc to investigate: **How do specific body-based processes influence specific mathematical reasoning**? We hypothesize that gestural replays of directed or predicted actions made during students’ explanations provide a bridge between these actions and generalized mathematical reasoning that can enhance proof performance. We explore this hypothesis using both quantitative and qualitative analyses.

Methods

Participants & procedure

Participants were undergraduate students from a large university in the Midwestern US who participated in a 2X2 design comparing Directed Action Yes (DA) or No (DA') and Predicted Action Yes (PA) or No (PA'). For this secondary analysis, we focus on the two diagonal cells: DA+PA' (directed actions without predicted actions; n = 30) and DA'+PA (predicted actions without directed actions; n = 37) because it would be impossible to tell the source of the gestural replays in the DA+PA group, and there are no replays in the DA'+PA' group.

All participants were prompted to individually read each of the eight geometry conjectures, statements that are false or always true, with order varied by a Latin Square. DA+PA' participants were directed to mimic relevant actions comprised of a sequence of three animated poses without any prompt to make predictions (see an example in Figure 1). DA'+PA participants saw no directed actions and were prompted to predict the pose sequence for each conjecture (see an example in Figure 2). Participants completed each conjecture task by judging the conjecture's veracity (i.e., false or always true) and providing a verbal justification. Finally, each participant was asked to complete surveys about demographics, math history, and spatial skills.

Coding

Proof validity

Video recordings of participants’ explanations for each conjecture were transcribed and coded (0/1) for mathematically valid proofs (reliability κ = .96) based on Harel and Sowder’s (2005) characteristics of valid deductive proofs that must be simultaneously logical, operational, and generalizable.

Gestural replays

Spontaneous gestures made during mathematical explanations were first coded as *gestural replays* or not (1/0). Gestural replays were further coded at two levels: (1) exact replays exactly matched the directed (DA) or predicted actions (PA); (2) corresponding replays matched DA or PA to different body parts (e.g., DA crossed arms could match crossed hands in the explanation). Gestural replays coded were further classified as either *non-dynamic* or *dynamic* depictive gestures (0/1), as described earlier. Inter-rater reliability is forthcoming.

Results

Quantitative analysis

We ran mixed-effects logistic regression models (Snijders & Bosker, 2011) to predict participants’ proof performance. Our earlier analyses showed that *dynamic gestural replays*, either of DA or PA, were significantly associated with proof performance; while performing DA or PA did not cause more dynamic gestural replays, suggesting that dynamic gestural replay is not a mediator. Our current analysis explores how gestural replays influence the effects that DA and PA have on proof performance, using a model with an interaction between *dynamic gestural replay* and *experimental condition* (Walkington et al., 2022). *Participant ID* and *conjecture* were included as random effects. *Students' most advanced previous math course* and *spatial thinking* were retained in the model as covariates that significantly reduced the deviance of our model. We report odds ratios that are exponentiated raw coefficients and effect sizes using d-type measures (Chinn, 2000).

$$
\begin{aligned}
&logit(P_{ij}) = \gamma_{00} + \gamma_1 \times (experimental\ condition) + \gamma_2 \times (dynamic\ gestural\ replay) \\
&+ \gamma_3 \times (experimental\ condition) \times (dynamic\ gestural\ replay) + \gamma_4 \times (math\ course) + \\
&\gamma_5 \times (spatial\ thinking) + U_{0j\ participant} + T_{0j\ conjecture} + \boldsymbol{\varepsilon}_{ij}
\end{aligned}
$$

The results show that for DA+PA' trials, making dynamic gestural replays had a significant effect on generating mathematically valid proofs (*OR* = 2.76; *d* = 0.56, *p* = .006). For DA'+PA participants, making dynamic gestural replays also had a significant effect on proof performance (*OR* = 8.59, *d* = 1.19, *p* < .001). In contrast, for trials where students did not produce gestural replays, performing DA or PA was not significantly associated with proof performance. In trials where participants did perform dynamic gestural replays, DA'+PA participants significantly outperformed DA+PA' (*OR* = 3.11, *d* = .63, *p* = .019), even when controlling for math education and spatial ability. Gestural replays appear to strongly influence proof performance.

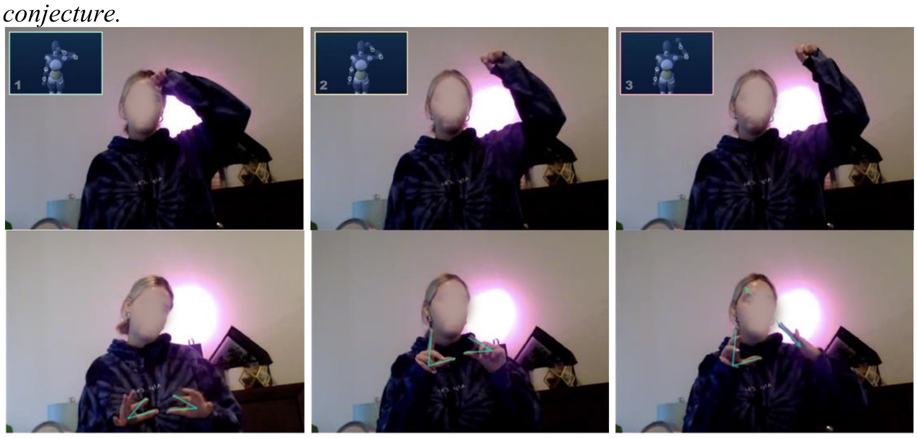
Qualitative analysis

To gain additional insight into how gestural replays might bridge actions to generalized mathematical reasoning, we qualitatively examined two cases. One participant produced gestural replays of directed actions that were *externally generated* (i.e., designed by researchers); the other produced gestural replays of predicted actions that were *internally generated* by the participant.

Case 1: Student's gestural replays from externally generated directed actions

We focus on this student's (S1; Figure 1) reasoning process after they have mimicked the relevant directed actions designed for the conjecture, *In triangle ABC, if Angle A is larger than Angle B, then the side opposite Angle A is longer than the side opposite Angle B*.

Figure 1
(Top Row) *Student performing externally generated directed actions shown in the picture inset.* (Bottom Row) *Student replaying modified versions of directed actions while evaluating the conjecture.*



(a) **(b)** **(c)**

Transcript #1 of S1:

[1] ((*Reading the on screen text*)) In triangle ABC, if Angle A is larger than Angle B, then the opposite side, the side opposite Angle A is longer than the side opposite Angle B, um, ((*performing movements for 27 sec*)), true.
[2] ((*Reading the on screen text*)) Explain why the statement is always true or false.
[3] Because if Angle A is opened up more than Angle B and it's bigger, doesn't even matter what side, then that line opposite would span a longer distance than would the line of Angle B.

Figure 1 (Top Row) includes an inset (upper left corner) that shows how participants were directed to mimic the on-screen avatar by raising their left forearm, bent at the elbow, to open up the angle created by the upper and lower portions of their arm. This sequence of motions was designed to highlight a key relation: as one angle of a triangle opens up, the side opposite the angle necessarily becomes larger.

After performing the directed actions, S1 contemplated aloud "if Angle A is larger than Angle B" (Line 1) while gesturing with the thumb and index finger of her right hand to form Angle A. Next, she compared this angle to a smaller Angle B that she formed using the thumb and index finger of her left hand (Figure 1a; Bottom Row). Juxtapositioning these two angles, the student moved the thumb and index of the right hand to open (increase) and close (decrease) Angle A while gazing at the changing angles. This illustrates a transformation of directed actions by juxtaposing the actions (i.e., angles) that originally occurred sequentially (Nemirovsky & Ferrara, 2009) and changing an angle by expanding and contracting. This process helps the student ascertain that the mathematical conjecture is true.

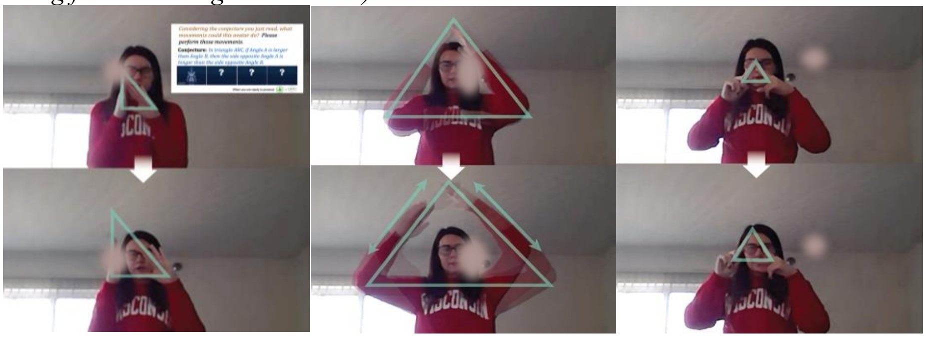
In her follow-up explanation (Line 2), S1 continued to justify that the conjecture is true: "... if Angle A is opened up more than Angle B and it's bigger" while holding the pose of Angle B and moving her right index finger up to make Angle A bigger (Figure 1b). Although the student performed a modified version of the original directed actions (i.e., switching from arms to hands and fingers), her *dynamic depictive gestures* constitute "corresponding gestural replays" that glean the relevant perceptual-motor information from the directed actions, which embody the key mathematical relation. She continued that it "doesn't even matter what side," suggesting that she was generalizing the mathematical relationship between angle size and side length for all triangles -- not just this particular example. In this way, the gestural replay may serve as a bridge between directed actions and generalized reasoning. In a second dynamic depictive gesture (Figure 1c), S1 moved her left hand back and forth to depict a "line opposing" the angle (Line 3), reinforcing that a larger angle always produces a longer opposing side length.

Case 2: Gestural replays from internally generated predicted actions

In this case, S2 read the following conjecture: "*For a triangle that is similar to triangle ABC, the side opposite to angle B must have the same length*" (a false conjecture). Then, S2 was prompted to predict possible actions for the conjecture but given no instructions on what movements to predict (see the inset in Figure 2a). Thus, unlike the DA condition, the movements in the PA condition were internally generated.

Figure 2

*Starting (*top*) and ending (*bottom*) poses of three different sets of predictions using (a) hands, (b) arms, and (c) fingers (with graphic overlays of the geometric objects being formed through movements).*



(a) (b) (c)

When asked to predict a series of movements for the conjecture, the student created a few different options, each building off the previous ones. For the first sequence (Figure 2a, Top), S2 created a triangle with her left palm and the fingers of her right hand. Then (Figure 2a, Bottom), S2 created a second, similar triangle by spreading her hands apart horizontally and using a pointing gesture as she described, "extend[ing] my fingers out" to complete the triangle. For the second set of predicted actions (Figure 2b, Top & Bottom), S2 made a set of similar triangles using her arms and moved both arms outward to make the triangle bigger with the same angles. In her third and final sequence (Figure 2c, Top), S2 used three fingers to first represent a triangle and then (Figure 2c, Bottom) made the triangle sides longer by moving her fingers outward while trying to keep the angles the same. Across all three predicted action sequences (Figure 2a, 2b, 2c), S2 made *dynamic depictive gestures* to demonstrate geometric transformations of geometric objects that explored general properties of triangles. We also noticed S2's representations ultimately refined to smaller body movements (i.e., fingers).

The reasoning also progressed to a generalized proof. After correctly identifying the conjecture as false (Transcript #2, Line 7), S2 explained "because although the angles will stay the same, the side lengths will change…" (Line 8). She then added that "the side length has to get bigger" (Line 9) while her gestures quickly shifted from gross-motor usage of the forearms to using three fingers to represent all three sides of the triangle. She then shifted from a self-oriented process of ascertaining, to a social-oriented process of persuasion directed at the researcher, saying that "if you're extending it out but want to keep the angles the same, the side lengths have to change" (Line 9). While speaking, S2 spread out her fingers to make the side lengths longer. This *dynamic depictive gesture* sequence is an "exact gestural replay" that exactly resembles the third representation of S2's internally generated predicted actions (compare Figure 2c to Bottom Row of Figure 3). Upon analysis, we see that S2's verbal explanations explicitly said, "side lengths [can] change" while replaying the predicted actions. However, her speech in the prediction phase focused on "similar triangles" and "same angles," though her movements embodied the idea that the side lengths can change. This suggests that the gestural replay helps bring the nonverbal forms of knowledge into verbally coded awareness, and that the combination of nonverbal, intuitive forms and verbal forms of knowledge leads to a valid, generalized mathematical proof (Nathan, 2017).

Figure 3
(Top Row) *Starting, Intermediate, and Ending poses of the third set of predicted actions from Figure 2(c).* (Bottom Row) *Student replayed the predicted actions during verbal justifications.*

Transcript #2:

[1-6] … ((*S2 first reads the conjecture and then predicts actions while speaking rationale*))
[7] This statement is false.
[8] This statement is false because although the angles will stay the same, the side lengths will change, that's what makes triangles similar.
[9] The side length has to get bigger because if you're extending it out but want to keep the angles the same, the side lengths have to change.

Discussion

Embodied interactions offer promising pathways for improving mathematical thinking and learning. As these approaches proliferate (Abrahamson & Trninic, 2015; Nathan & Walkington, 2017; Ottmar & Landy, 2017; Smith, 2018) -- in classroom curricula, video games, for example -- scholars in the learning sciences need to move beyond assertions that embodiment either *does* or *does not* improve learning and address a theoretical need to identify *how* these interactions recruit body-based resources as part of a broader understanding of embodied learning, and a practical need to identify *when* embodied interactions benefit mathematical reasoning. In answer to the research question, we found evidence supporting the claim that gestural replays provide a kind of "bridge" between actions and verbalizable conceptual reasoning that is critical for articulating mathematically valid proofs in geometry. This applied to both externally generated directed actions (DA+PA') and to internally generated predicted actions (DA'+PA). This investigation contributes to a growing body of empirical research showing that it is not mere *movement* but the type of movement and its conceptual meaning that is most consequential (e.g., Walkington et al., 2022; Zhang et al., 2021).

In geometry proofs, students must offer arguments that are logical, operational, and generalizable in order to defend universal claims about properties of space and shape. To achieve this, interlocutors rely upon physically enacted simulations of transformations of imagined objects in the form of *dynamic gesture replays*. Each term in this phrase has a theoretical import. That they are *gestures* indicates that students' conceptualizations of the relevant ideas are body-based, challenging traditional notions that privilege symbolic and verbal accounts of knowledge and abstractions and offering instead a more distributed account that extends notions of cognition to encompass non-symbolic body movements and the sensorimotor processes associated with these nonverbal behaviors. That they are *dynamic* indicates the power of enacting transformations on imagined mathematical objects to support the type of generalized thinking that is often attributed to abstract formalisms (and often regarded in contrast to concrete experiences). That they are *replays* indicates that students reinvoke these behaviors as a valuable cognitive resource, often preserving the original relational information even as they are gesturally "revoiced" using different body parts.

This study also explored the influences on embodied mathematical reasoning in terms of the history of these movements. Many embodied curricula and game-based interventions use externally generated movements to bring about the desired behaviors, prompting students to mimic the actions of another, touch certain locations, or follow certain patterns (e.g., Cook et al., 2006; Nathan et al., 2014; Thomas & Lleras, 2007). The present study is one of the very few that compare the effects of performing externally generated directed actions to performing internally generated predicted actions. The results are notable: When producing dynamic gestural replays, participants who predicted actions showed superior proof performance compared to those who mimicked cognitively relevant directed actions that had previously been shown to be advantageous to proof performance. Enactivist theoretical accounts (e.g., Abrahamson & Sánchez-García, 2016; O'Regan, & Noë, 2001) are likely involved, as these hypothesize the ways that sensorimotor behaviors such as dynamic gestures emerge as a solution to an interaction problem, influenced by feedback from the environment (including one's own actions) that guide future actions (including gestural replays). For example, students may come to experience an appropriate geometric transformation because of the actions they perform (e.g., expanding one's hands away from one another while they each form the shape of a vertex between the thumb and fingers) rather than acting on a priori images of geometric objects (e.g., dilating a triangle).

The qualitative analyses illustrate how gestural replays can bridge concrete actions and generalized geometric reasoning. For example, S1 replayed the externally generated directed actions, thus re-enacting the movements into personally meaningful gestures. S2's internally generated predicted actions engaged body-based resources to simulate the possible solutions and operationalize her own geometric thinking, which may have also helped to bring S2's nonverbal ways of reasoning into conscious awareness (Aleven & Koedinger, 2002), leading to a multimodal explanation that served as a mathematically valid proof of her claim. In each case, gestural replays simulate and schematize generalizable mathematical relations embodied by the relevant actions to enact mathematical transformations supporting generalizable geometric reasoning.

These findings need to be replicated across different populations and tasks. Still, this study offers two insights for the design of embodied learning interventions. First, there is value in directing students to perform relevant actions, but explicit prompting for them to replay those directed actions through personally meaningful gestures that enact mathematical transformations strengthens the influences of directed actions for proof. Second, simply encouraging students to predict actions for corresponding tasks may benefit learning, expanding the forms of embodied interventions that can benefit thinking and learning.

Tracing a Path Toward Social Empathy: The Development of the Multicultural Awareness and Empathy Orientations Model

Carrie L. James, University of Illinois at Urbana-Champaign, cljames2@illinois.edu
Jadyn Laixely, Miami University, laixelj@miamioh.edu
Saadeddine Shehab, University of Illinois at Urbana-Champaign, shehab2@illinois.edu

Abstract: This paper describes the process of developing the Multicultural Awareness and Empathy Orientations Model (MAEO) to support the analysis of pre-service teachers' uptake of human-centered design practices and multicultural awareness as part of an education and social justice course. This conceptual model is informed by Segal's (2018) theory of social empathy. It is also informed by sociopolitical theories associated with anti-racism, identity, and multicultural and culturally responsive education, with an emphasis on identity and difference within educational systems. This conceptual model theorizes the intertwine between cultural empathy and an emerging critical multicultural awareness of historically excluded communities. The model provides a potential tool to aid in the design of multicultural or social justice-oriented courses at all educational levels. It also serves as an assessment tool to track one's progress toward social empathy that is guided by macro perspective taking of those who have lived experiences in historically excluded communities.

Introduction

Preparing preservice teachers (PSTs) to teach in increasingly diverse communities calls for PSTs to understand and empathize with the social worlds of their students, particularly those from historically excluded communities. This is particularly important since the majority entering the teaching profession continue to identify as white and female (Reyes &Aronson, 2022). As a response to this need, many teacher preparation programs (TPPs) have required PSTs to take courses in multicultural education, social justice, and equity. Anti-racist education scholars also recommend ongoing training in culturally sustaining pedagogy (e.g., Basile et al., 2019; Blake et al., 2011). However, some questions regarding these courses still need answers. For example, how might their effectiveness be assessed? How might empathic growth be measured during courses that seek to prime PSTs to empathize with students from historically excluded backgrounds? These questions drove us to develop an evidence-based conceptual model – the Multicultural Awareness and Empathy Orientations Model (MAEO). This model, we argue helps to assess both an individual's progress toward social empathy and the effectiveness of these courses to promote social empathy.

As part of a partnership with the instructors of a course focused on identity and difference in education, we designed a digitally interactive instructional booklet (James, Shehab, & Rost, 2021) that is currently in its third iteration. It engaged undergraduate students - the majority of whom are PSTs - in human-centered design (HCD) practices and course concepts centered on multicultural awareness of historically excluded communities. The booklet engaged the undergraduates in weekly activities that blended empathic practices with their emerging understandings of marginalized communities. In Fall 2021, we began a study to analyze the impact of this intervention on PSTs' development of social empathy and empathic techniques (Hess & Fila, 2016; Segal, 2018), which includes multicultural awareness of people who have vastly different lived experiences from their own.

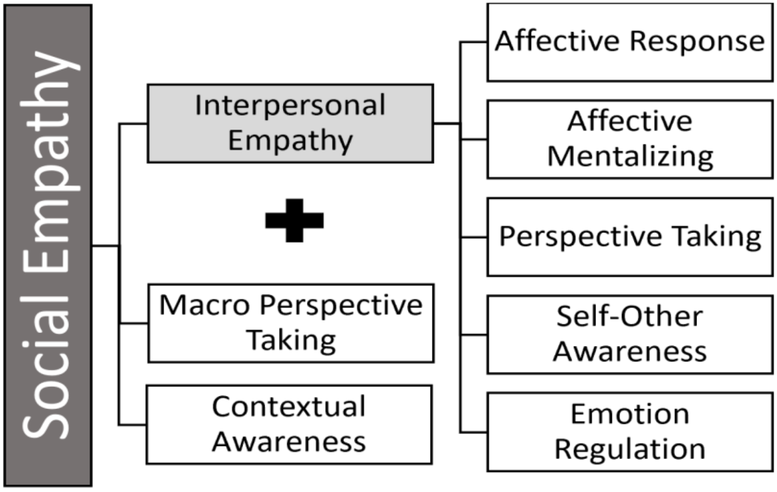
As part of this work, we designed a conceptual framework to help us understand and trace the undergraduates' trajectories as they navigated the course and this instructional booklet. This paper outlines the design of this conceptual model, grounded in theories of social empathy (Segal, 2011, 2018; Segal et al., 2017) and sociopolitical theoretical frameworks centered on anti-racism (Dunn et al., 2021; Kendi, 2019; Love, 2019), critical race theory (CRT; Delgado & Stefancic, 2001; Ladson-Billings, 2009; Stovall, 2016), social justice (Davis, 2003; Gewirtz, 2006; Kumashiro, 2001), desire-based theory (Tuck, 2009) and culturally sustaining education (Ladson-Billings, 1995; Paris, 2012). This work is also grounded in conceptualizations of HCD that describe it as an empathetic and human-centered problem-solving approach that embraces an iterative and collaborative process with all stakeholders (Brown, 2009; Lawrence et al, 2021). Below, we outline the process of analyzing the current literature and how that analysis informed the creation of the MAEO model that foregrounds the relationship between sociopolitical, multicultural awareness and social empathy. We believe that this evidence-based conceptual model has potential to map PSTs' multicultural awareness and empathic orientation toward historically excluded communities and trace their growth.

Literature review

Defining (social) empathy

Many scholars have explored the concept of empathy and its role in both teacher education and enacting culturally sustaining teaching (e.g., Arghode et al., 2013; Dolby, 2012; Dunn & Wallace, 2004; Warren, 2014, 2018). These scholars focus on what can generally be described as cultural empathy, and what Segal (2011) defines as social empathy. She built her conceptual model of social empathy on the theoretical framings of empathy, or interpersonal empathy, developed by scholars in the fields of psychology, cognitive neuroscience, and social work (e.g., Coplan, deWaal, Singer, and Lamm). In her conceptualization of interpersonal empathy, Segal describes a cognitive-affective model made up of five processes. She asserts that empathy includes two affective components: affective response and affective mentalizing. Affective response describes the initial emotional response we have to something we have observed (such as feeling sad when we see someone else crying). Affective mentalizing describes being able to have those same feelings when we visualize it in our heads (such as hearing about someone crying over the death of their parent and, after visualizing it, having an affective response). Her interpersonal empathy model also includes three cognitive processes: self-other awareness, emotion regulation, and perspective taking. Effectively engaging in these cognitive processes allows someone to put themselves in the perspective of someone else while regulating their own emotional response and being aware of themselves in relation to the person(s) they are trying to empathize with. In her conceptualization of social empathy, Segal (2018) adds two additional components: contextual understanding and macro perspective-taking (see Figure 1). These two components act in concert, allowing someone to be able to consider and understand the perspectives of those outside their own sociocultural spheres. They can do this best, Segal argues, by developing contextual understanding of others' lived experiences, including "the historical events that shaped the group and contributed to its members' identities today" (p. 19). This includes awareness and acknowledgement of the systemic barriers those from historically excluded and marginalized communities face. Segal's conceptualization of (social) empathy distinguishes itself from responses frequently mistaken for empathy such as sympathy and judgment.

Figure 1
Visual Representation of Segal's (2018) conceptualization of social empathy.



Many fields outside of psychology and social work have explored the ways that social (cultural) empathy figures into the work they do. For example, Hess and Fila (2016), engineering educators, conducted a study where they observed the empathetic practices of engineering students as they engaged in a service-learning project to develop an accessible zipline for campers with disabilities. They identified 12 different empathic techniques: direct observation, interaction, empathy by proxy, projection, simulation, empathic concern, synthesizing empathic knowledge, designing for user-centered criteria, integration, refining user suggestion, checking with users, and imagined use. Five of these techniques played a role in the design of the instructional booklet we designed for the course (see Table 1). Each week of the semester, PSTs engaged in activities that centered one or more of these techniques. These activities were initially scaffolded to build confidence in their ability to engage in HCD on their own. For example, one week they practiced interacting with peers in the class before interacting with someone that could be identified as an educator in the field. In reflections, they might have been asked to engage in projection (i.e., perspective taking) and they would then get feedback from their instructors. By engaging in these practices and techniques explicitly, we believed it would help orient the PSTs toward empathy across diverse communities.

Design sciences scholars also embrace conceptualizations of empathy in their work. Brown (2008) initially conceptualized design thinking and human-centered design as an empathy-based approach for problem solving. “[Designers] can imagine the world from multiple perspectives—those of colleagues, clients, end users, and customers (current and prospective). By taking a “people first” approach” (p. 3). Going further, Lawrence and colleagues (2021) conceptualized an HCD taxonomy that consists of five spaces: Understand, Synthesize, Ideate, Prototype, and Implement. The Understand Space centers designers’ practice of understanding their stakeholders and includes exploration, observation, empathy, and reflection processes. By engaging in these processes and adopting the empathy techniques (Hess & Fila, 2016), designers make it easier to take the perspectives of those who are part of the design process in empathetic ways.

Table 1

The empathic techniques adopted from Hess and Fila (2016) in the design of the HCD booklet.

Empathic Technique	Definition	Examples of Activities
Direct Observation	Observe a specific context and those within that context	Observe the context of your community placement
Interaction	Engage in conversations with those who have a direct stake to learn about their perspectives	Interact with participants at a community placement
Empathy by Proxy	Engage in conversations with intermediaries who have knowledge of primary stakeholders	Interact with administrators or volunteers at community placement
Projection	Mental perspective-taking where we try to imagine ourselves in others’ shoes	Put yourself in the shoes of the participants at your placement
Synthesize Empathic Knowledge	Making sense of information gathered and identify patterns that lead to user insights	Identify patterns in what you learned at your community placement

A sociopolitical framing of multicultural awareness

Over the past several decades, teacher preparation programs have attempted to address the issue that arises when an increasingly diverse student population is taught by predominantly white, middle-class females (Reyes & Aronson, 2022). Requiring PSTs to take multicultural education, minority studies, or social justice courses is one way that TPPs have addressed this need to better support all teachers, particularly those from dominant cultures, in working with racially, ethnically, and linguistically diverse communities (Kretchmar & Zeichner, 2016). These courses adopt one or more critical theories to help support PSTs develop social empathy and multicultural awareness. As such, we considered the need for a focus on the following sociopolitical theories: social justice education, culturally sustaining pedagogy, and critical race theory (CRT) – including critical whiteness studies and anti-racist pedagogy – as we made sense of the PSTs’ work.

Multicultural social justice education, for example, is often grounded in “guiding students in critical self-reflection of their socialization” into hegemonic constructs such as those based on race, class, gender, and ability (Sensoy & DiAngelo, 2009, p. 350). Courses that adopt a social justice frame to multicultural awareness might consider Gewirtz’s (2006) aspects of social (in)justice: distributive, recognitional, and associational justice. Distributive justice can best be described as equitable distribution of resources. It is also “defined as the absence of exploitation, marginalization, and material deprivation” (p. 74). In taking up distributive justice, PSTs could investigate whether state funds are distributed to schools across a state. Recognitional justice would be defined as “the absence of cultural domination, non-recognition and disrespect” (p. 74). Culturally sustaining pedagogy would be an example of recognitional justice. Finally, associational justice centers on fostering democratic and equitable participation within a community in such a way that everyone can fully participate in decision making, particularly those that have been historically excluded from participation and decision making.

Many multicultural education courses are also grounded in critical race theory (CRT), which embodies important pedagogical frames including anti-racist pedagogy, intersectionality, and critical whiteness studies (CWS). CRT, which had its beginning in legal studies, has long been a part of educational research. “Many in the field of education … use CRT's ideas to understand issues of school discipline and hierarchy, tracking, controversies over curriculum and history, and IQ and achievement testing" (Delgado & Stefancic, 2001, p. 3). CRT brings to the forefront issues of racism and oppression that exist in U.S. educational systems. One of the tenets of CRT is intersectionality (Crenshaw, 1989), which defines the multiple and intersecting ways in which people from historically excluded communities are discriminated against, both legally and socially. Since separate laws for the protection of race, ability, gender, sexual identity, and other historically excluded groups exist in the U.S., and levels of protection vary by state, an understanding of this inconsistency is important for educators. A gay, Black, disabled woman cannot split her identity into individual facets of herself; she embodies all these identities at once, and therefore the laws are not currently designed to recognize her wholeness (Crenshaw. 1989).

Work in both anti-racist pedagogy and critical whiteness studies is also situated within the umbrella of CRT. Both incorporate framings for what it means to develop multicultural awareness and include knowledge and active disruption of systems of oppression, particularly in educational spaces (Blakeney, 2011; Dunn et al., 2021; Kendi, 2019; Love, 2019). Anti-racist educators decenter hegemonic practices in educational spaces while at the same time fully addressing the "historical constructs that facilitate inequalities and seeking to create an antiracist paradigm that in time will serve to historically condition a new antiracist society" (Blakeney, 2011, p. 120). CWS brings to the forefront a theoretical lens for making sense of white people's discomfort with exploring white privilege, white saviorism, and the ways that they implicitly (and explicitly) support systemic racism and oppression (Matias et al., 2014; Reyes & Aronson, 2022). Within education, CWS interrogates the complacency and complicity of teachers, the majority of whom are white, middle-class women, in maintaining structures of systemic racism and oppression (Reyes & Aronson, 2022).

Finally, we draw attention to what Tuck (2009) calls the suspension of damage-based thinking. Tuck encourages researchers and educators to focus on the desires and goals - "the hope, the visions, the wisdom of lives and communities" (p. 417) and not just focus on people's "pain and brokenness" (p. 409). In doing so, scholars move beyond the damage of historically excluded individuals and communities and look for the counter-narratives and the realization of imagined worlds. When research is damage-centered, it "simultaneously reinforces and reinscribes a one-dimensional notion of these people as depleted, ruined, and hopeless" (Tuck, 2009, p. 409). Taking up Tuck's framework gave us a way of theorizing the impact of developing multicultural awareness when PSTs demonstrate sympathy rather than empathy.

Building the multicultural awareness and empathy orientations model

In the Fall of 2021, we began a study of the intervention we collaboratively designed with instructors of a social justice in education course that is required as part of the TPP at a large land-grant university located in the Midwest. As part of that study, we collected participants' instructional booklets and their four cumulative assessments, which were critical reflective essays. In the spring of 2022, we began to examine the PSTs' work in the booklets and assessments. Adopting Tracy's (2020) phronetic iterative analysis approach to qualitative coding, we did a first read-through to see what emerged in the data. Then we moved onto the second stage by returning to the research literature, as described above, to help flesh out potential codes. In doing this, a conceptual model that would assist us in tracking PSTs' progress toward social empathy throughout the course as well as determine where they ended up at the end of the semester started emerging.

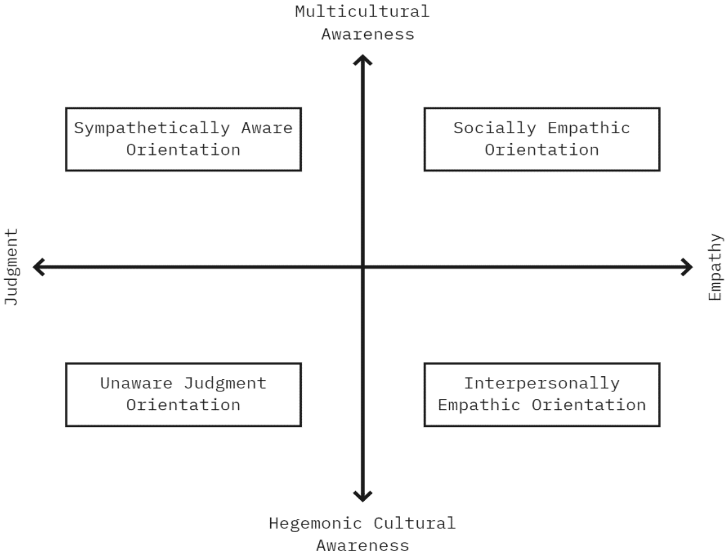
In developing the Multicultural Awareness and Empathy Orientations Model (MAEO), we considered what we knew about empathy and multicultural awareness from the literature and sought ways to integrate them into our data analysis to assess both white PSTs and those of color. Our goal was to create a framework to help us assess PSTs' progress toward developing social empathy. Segal and colleagues (2017) clearly outline interpersonal empathy and the cognitive-affective components that make up empathy generally. Segal and colleagues also offered a solid reference for responses that frequently get confused for empathy (e.g., sympathy, pity) and those responses that are antithetical to empathy such as judgment and manipulation).

However, in defining the components of social empathy – macro perspective-taking and contextual understanding – we added to Segal's (2018) conceptualization of social empathy based on the sociopolitical research described above. Segal (2018) argues these two components work in concert with each other. For one to enact social empathy it requires them to have "both the desire and the interest to learn about people who are different" (p. 20). This contextual understanding, she argues, sets one up to be able to consider the "large-scale view of situations" (e.g., historic and systemic barriers) when taking on the perspectives of those from historically excluded communities. The sociopolitical theories we describe above would argue it is not enough to have a desire and interest to learn, but that one needs to confront and resist and disrupt to truly have contextual understanding, which we refer to as multicultural awareness. In this way, we add to Segal's (2018) conceptualization of social empathy, which is reflected in the model we describe below.

Out of this analysis approach, our model started to emerge with two variables – empathy and multicultural awareness, which we viewed as two continua that intersect, creating four orientations. As visualized in Figure 2 below, the MAEO model consists of both a horizontal and vertical axis. We began by mapping out the terrain of the empathy spectrum as defined by the research literature. Many affective responses are confused for empathy, as Segal and peers (2017) described - sympathy and pity, for example. An inability to empathize, the authors argue, often manifests as judgment, which occurs when one cannot put themselves in another's shoes. This represents the left side of the continuum, with judgment situated furthest. We take up Segal and peers' (2017) conceptualization of interpersonal empathy, represented by all five traits described above, as the embodiment of the right side of the spectrum. While responses such as pity and judgment would reside on the left side, practices such as perspective taking and self-other awareness would situate further to the right.

Conceptualizing the vertical axis required further consideration of Segal's definition of contextual understanding, which focuses on a developed awareness of others' lived experiences and systems of oppression that impact them. As stated above, we considered the sociopolitical theories of critical scholars and their work in multicultural education, social justice, and antiracist pedagogy as well as CRT and its sub-theories (e.g., CWS). Initially, we conceptualized the two end points. At the bottom, we have situated hegemonic (e.g., white, patriarchal, heteronormative, ableist) cultural awareness. It is characterized by a lack of multicultural awareness, and instead predominantly aligns with a hegemonic understanding of the world. Basing this on critical theories, the lower half of the spectrum includes avoidance, which CWS describes as white people's unwillingness to discuss racial issues (Matias, et al., 2014, Reyes & Aronson, 2022). Tied to a lack of recognitional justice (Gewirtz, 2006), this end of the spectrum would reflect those who perhaps had limited exposure to the lived experiences of those from historically excluded groups. The top of the spectrum would account for high levels of multicultural awareness grounded in a deep understanding of systems of oppression (Delgado & Stefancic, 2001), the willingness to act to disrupt these systems (Blakeney, 2011), and the ability to engage in macro-perspective taking (Segal, 2018). As a person develops their multicultural awareness, they move along the spectrum, perhaps enacting a white savior mindset, demonstrating an awareness of hegemonic systems and ways of being or even confronting and resisting these systems. This is one way that this work has added to Segal's (2018) conceptualization of "contextual understanding." Sociopolitical theories make it clear that it is not enough to be aware of systems of oppression. Instead, one must act and disrupt based on that awareness in order for it to be considered a true demonstration of social empathy.

Figure 2
Multicultural Awareness and Empathy Orientations Model



As Figure 2 demonstrates, each quadrant of the conceptual model defines an orientation. This orientation, within the context of our study, described the orientation that a PST demonstrated in a particular moment of their work throughout the course. However, these orientations can describe more than just where an individual is situated (e.g., it could map where a particular course or program is oriented on the axes). Table 2 (below) describes each of the four orientations.

Table 2
A description of the four orientations in the Multicultural Awareness and Empathy Orientations Model

Orientation	Description
Unaware Judgment Orientation (Bottom left)	This orientation is characterized by a narrow-world view and exhibits deficit thinking. There is little evidence of critical reflection. It also reflects avoidance of or distancing of self in conversations on systemic oppression and white privilege.
Sympathetically Aware Orientation (Top left)	This orientation views historically excluded communities as victims. While there is an increase in multicultural knowledge, there is a focus on feelings of sympathy and pity for these communities because of the oppression they face. This may result in a white savior mindset while orienting themselves as social justice allies or advocates.
Interpersonally Empathic Orientation (Bottom right)	This orientation, due to a lack of multicultural awareness, focuses on in-group perspective taking. This orientation demonstrates a willingness to see systems of oppression but through a limited, hegemonic lens. Likewise, this mindset focuses on achievement (or lack thereof) as individual and merit-based rather than framed within systems of oppression.
Socially Empathic Orientation (Top right)	This orientation embraces macro perspective-taking fueled by an ability to not only grasp systemic oppression but also act to disrupt it and imagine anti-oppressive systems. People within this orientation decenter whiteness and asset and desire-based framing.

The conceptual model in action

Sydney (a pseudonym) is one participant from our study on the social justice in education course that we described above. She identifies as a white female seeking licensure in early childhood education. She took the social justice in education course we studied during the fall of 2021 as part of a prerequisite to entering the major in her junior year. Using the MAEO model described above, we were able to trace Sydney's path throughout the course as she navigated course concepts on identity and difference. We used her work both in the interactive instructional booklet and the four cumulative reflective assessments to map her orientations throughout the course.

Initially, Sydney demonstrated many aspects of the interpersonally empathic orientation, which situated her close to the intersection of both axes. She frequently described herself as a social justice advocate in the early reflections within the instructional booklet but lacked awareness of what it means to enact social justice. This manifested in her frequently describing things through hegemonic lenses. "Being caucasian in this education system, as well as being english [sic] speaking and of a well-known religion [Catholic], gives me a spot in the 'social norm' category" (Sydney HCD Book 1, p.13). So, while she demonstrates awareness of hegemonic systems, she also frames them in ways that signal a hegemonic mindset, particularly when she uses the phrase "social norm."

As Sydney continued through the course, her multicultural awareness increased, particularly demonstrated through her ability to talk about the oppressions that people with disabilities and women of color face. However, rather than confronting these systems, she demonstrated awareness of them and showed signs of sympathy in how she spoke of those experiencing this oppression. "Whether the discrimination is intentional or not, there are groups of people who are judged, fall silent, and face inequality because of who they are; these are underrepresented groups" (Sydney Assessment 2, p. 1) This framing demonstrated the ways that she both othered them and felt sorry for their situation, which placed her more in the orientation of sympathetically aware. At times, Sydney did show a glimmer of the socially empathic orientation, particularly when she spoke of challenging dominant discourses by bringing in multicultural literature, but this was hampered by her frequent centering of herself as the person who could help children of color see their value (an example of white saviorism).

In practice, this conceptual model allowed us to trace Sydney's journey toward a socially empathic orientation. Each instance of grappling with social justice and multicultural concepts signals an orientation, and using this model made space for us to trace her journey and pinpoint moments of growth. This can help make visually clear the complexity of these journeys, as learning is not a linear process, but one that shows wobble (Fecho et al., 2005) as people take up new concepts and orient them in their understandings of the world.

Implications for practice and research

Despite evidence that the majority of TPPs have adapted their programs to include at least some multicultural education as part of a teacher's preparation, many scholars have pointed out the variance across programs in terms of breadth and depth in multicultural education (e.g., Cochran-Smith & Zeichner, 2005; Kretchmar & Zeichner, 2016). "Many teacher preparation programs attempt to infuse multicultural perspectives by simply adding one or two courses in multicultural education and/or requiring teacher candidates to complete assignments that explore surface-level differences in culture and language" (Assaf, Garza, & Battle, 2010, p. 116). This conceptual model provides a useful tool for creating and assessing multicultural education courses and programs. In essence, this model could be used as a guide for designing courses based on the features of a social empathy orientation as well as act as an assessment tool to determine where courses and programs are oriented in practice. For example, we adopted this model to help us evaluate the course once we realized that many of the participants were oriented more toward Sympathetically Aware on the map. This allowed us to identify aspects of the course (e.g., course readings) that shifted students toward damage thinking (Tuck, 2009) and encouraged othering. We were also able to use this model to make recommendations to the course instructors that might help shift the PSTs' trajectories toward the Social Empathy Orientation.

Secondly, there is a continued need to assess PSTs' abilities to be able to support and provide equitable, culturally sustaining teaching practices once they enter the teaching profession as in-service teachers (Paris, 2012, Reyes & Aronson, 2022). This model could be a helpful tool to track a PST's progress as they navigate a course or program. By using this model, teacher educators could help adjust a PST's trajectory before they enter the field. For example, a teacher educator could have encouraged Sydney to critically reflect on her work, helping her to reflect on those moments she painted people from historically excluded communities as victims. In this way, she would have adopted the critical lenses advocated by critical scholars. It can also act as a self-reflection tool as well for PSTs as they could consider their own positionality in the world and their emerging abilities in macro perspective-taking and contextual understanding.

In terms of research, this conceptual model adds to our understanding of social empathy, particularly what it means to have contextual understanding – what we call multicultural awareness. By synthesizing social empathy with theories from CRT, social justice education, critical whiteness studies, and antiracist pedagogy, we can recognize the importance of action and disruption, which is a vital aspect of truly enacting social empathy in teacher education and learning sciences more broadly. For instance, this model opens many avenues for learning sciences scholars interested in sociopolitical work to study the ways that learners explicitly or implicitly develop particular orientations on the model. For example, CWS scholars might explore what learning processes and experiences shape youths' orientation within the model. It could also inform the design of interventions that might alter that trajectory, allowing scholars to use the model as a program evaluation and data analysis framework (as we used it). This model might support participant recruitment by giving researchers a frame for participant selection across all four orientations. Finally, this conceptual model is still in flux and leaves the door open for additional research with multicultural education courses and programs to help refine both the model and the ways in which each orientation is conceptualized.

Abstract: A core practice of science is planning and conducting investigations. This practice needs reconceptualizing, to account for where work happens between identifying a phenomenon and designing an investigation, and between gathering and analyzing data to support developing an explanation of that phenomenon (Manz et al., 2020). Teachers, supported by curriculum materials, need to engage students in becoming more involved in the decisions related to what data to choose as evidence, how to represent data to answer specific questions, and what conclusions can be drawn from data. We present results of a design study in which students investigated a dataset to answer a question about a major change to an ecosystem, using a technology tool, CODAP. We explore how the curriculum and teacher supported students in taking up different facets of data practices that support figuring out a phenomenon while moving between investigating and developing explanatory models.

Subject/problem

Historically, students' experience of science investigations follows a "cookbook" lab approach that involves following procedures given to them by teachers, with little opportunities for grappling with issues that scientists do of choosing measures and kinds of analyses to perform, or taking up questions of how to handle missing data (Banilower et al., 2018). That is, school science investigations give students little opportunity to gain a "grasp of scientific practice" (Ford, 2008) or gain a feeling for the work of science (Jaber & Hammer, 2016). This is a problem because recent reforms in science education reflect a "practice turn" (Ford & Forman, 2006), which views science learning as bringing students into the community of scientific practices through experiencing for themselves how and when to use such practices to understand a compelling, natural phenomenon. Engaging in disciplinary practices is intended to support students to see science as an enterprise concerned with improving understanding of the natural world through mutually supporting practices.

One of the core practices emphasized in *A Framework for K-12 Science Education* (NRC, 2012) is planning and carrying out investigations. Manz et al. (2020) argue that this particular practice needs reconceptualizing in science education, to account for where real work happens in identifying a phenomenon, designing an investigation, and gathering and analyzing data to support developing an explanation of that phenomenon (Figure 1). Aligning work across the elements in Figure 1 represent areas of uncertainty but also opportunities for students to be more involved in the decisions that occur in authentic scientific investigations which in procedural lab activities remain largely unseen. For instance, before analyzing data, students need to decide what data are relevant to answering questions.

In this paper, we explore how a curriculum and teacher supported students in engaging in data modeling (red box in Figure 1) within an investigation, where students define measures and articulate how such measures can help them make progress in understanding a phenomenon, and where they draw conclusions from data they represent. In this design study, students were given opportunities to consider how data could answer a question they had, represent data using a technological tool, and draw conclusions from it. We sought to understand how a curriculum, teacher, and students can work together to take up different facets of data modeling for making sense of a phenomenon while investigating and developing explanatory models.

Conceptual framing

In drawing upon a vision of science education that sees the importance of bringing students into the practices of science, we build on Manz et al.'s (2020) work towards conceptualizing the investigation as "developing alignments between phenomena, empirical models, data models, and explanatory models" (p. 1166-7; Figure 1). Much scientific practice unfolds in moving between these elements, and since the decisions and assumptions around methodology are often obscured from view, this 'alignment' work is needed to highlight the interconnected, interdependent, and iterative nature of moving between these elements as new questions arise and explanatory models get refined. Accordingly, there is a need for helping students engage with scientific practice in moving across these spaces, characterizing the facets of practices occurring there, and subsequently learning how to support teachers and students through curriculum and professional development.

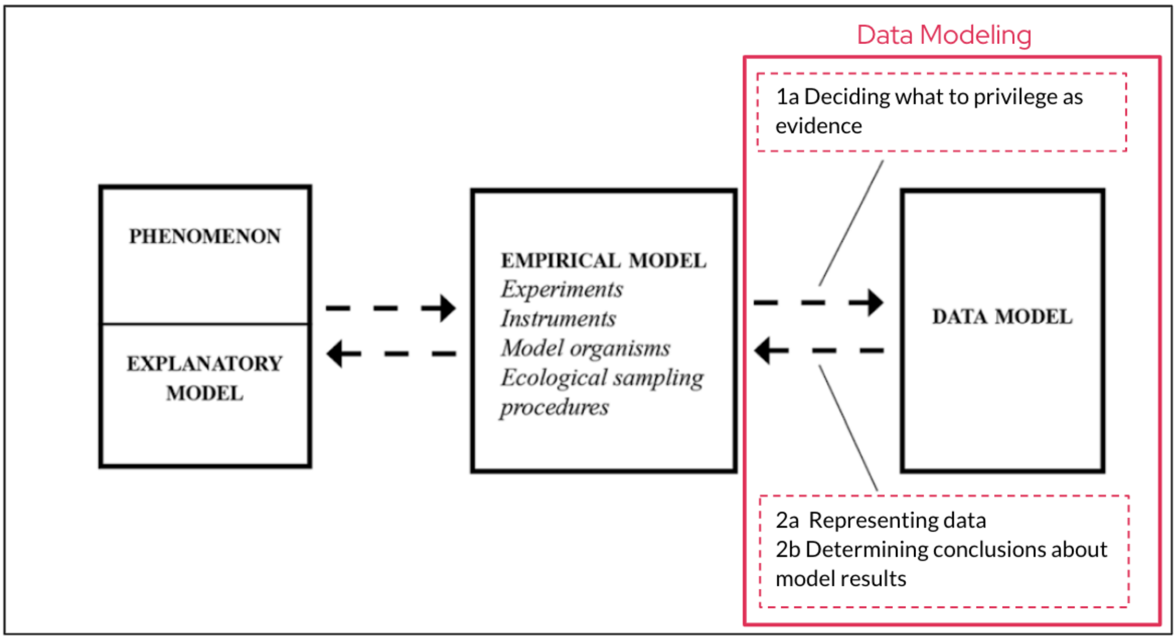
As we are concerned with supporting students in developing data practices, we focus on data model*ing* as occurring across the act of developing a data model. In our context, the data model is where students coordinate different artifacts from the lesson and try out different data presentations in the Common Online Data Analysis Platform (CODAP), a free, web-based data visualization tool developed by Concord Consortium (2019) that functions as a 'sandbox,' where students can explore and make sense of data. The alignment work taking place during data modeling serves to support students in developing a data model in the context of understanding a phenomenon, that is, engaging in such acts as defining measures, visualizing data, and constructing explanations with data. Of particular importance are data modeling activities that help students with moving from an initial, empirical model of a phenomenon towards specifying and then interpreting evidence from data models to draw conclusions that help students update their explanatory model of a phenomenon.

Teacher moves and curricular supports for specifying a data model

We are particularly concerned with studying how students are supported to engage with real world, messy data sets in the context of a curriculum that supports figuring out an ecological phenomenon. The data students engage with were collected by scientists to answer different questions, so one practice we focus on in specifying the data model is deciding what to privilege as evidence (1a in Figure 1) in response to *students'* questions.

Both curriculum materials and the teacher play crucial roles in supporting students' alignment work. Curricular tasks that engage students in determining, defining, and operationalizing data as evidence and help them grapple with decisions about what data to consider as evidence are important for facilitating students' scientific work in this alignment work (Manz et al., 2020). Teacher moves to problematize or make clear what is at stake in these decisions can help students see how the work is meaningful (Reiser, 2004). Talk moves that re-voice students' ideas about appropriate measures can also help students to narrow in on evidence needed to answer a given question (Watkins & Manz, 2022).

Figure 1
Investigations Framework; in red, we highlight the data-related practices occurring during data modeling. Adapted from Manz et al., (2020)



Teacher moves and curricular supports for interpreting evidence implied by the data model

Another key alignment involves investigating ways to represent data (2a) and drawing conclusions about data (2b), particularly to be able to communicate to themselves and to others how their data model helps explain part of a larger phenomenon (see Figure 1). The need to focus on these moves arises from both the opportunities to give students a feeling for the challenges scientists face in doing so and from prior research, which suggests interpreting and communicating data model results is difficult for students (Zangori et al., 2013).

There are a number of strategies for organizing curriculum activities and teaching that can facilitate this move from data model to explanatory model. In deciding how to represent data, students can be supported in grouping or “binning” cases in the dataset in various ways in order to surface different relationships (Erickson et al., 2019). Other strategies include inviting students to consider how the results of an investigation bear on the phenomenon at hand and addressing the gaps between their investigation models, evidence, and focal phenomenon (Manz et al., 2020). Talk moves can support students in expanding their initial thoughts towards pointing to the evidence that supports their claim (Michaels & O’Connor, 2017; Windschitl et al, 2020). We aim to better understand how curriculum tasks and teacher facilitation can work synergistically and with students to align an updated data model with the empirical model.

Methods

This embedded, single case study as part of a larger, multiple case study design (Yin, 2009) focused on one enactment of a lesson as part of a unit of study on ecosystems in which students engaged with real-world data about rainfall and large herbivore populations in the Serengeti between 1960 and 1975. The case is a paradigmatic one, chosen to illustrate what rich data modeling opportunities can look like in a classroom.

We address three primary questions based on the areas of alignment surrounding the data model: How did the teacher, curriculum, technology tools, and students work together to: (1) Decide what to privilege as evidence to answer the question? (2) Represent the data?, and (3) Generate tentative conclusions about what the data model reveals about the phenomenon?

Participants

The focal participants in the study were a teacher and students in a single classroom. The teacher was one of seven teachers who participated in a field test of materials as part of a larger initiative to develop open access (OER) materials aligned to the Next Generation Science Standards (NGSS Lead States, 2013).

The teacher in the study, Melissa, taught in an urban high school serving primarily Latinx students in a large school district in the Mountain West of the United States. At the time of the study, she had been teaching for 13 years, 12 as a high school science teacher. Melissa identifies as white and female. There were a total of 23 students in Melissa’s ninth grade biology class. Of these, 11 identified as female, 11 as male, and one as gender nonbinary. Nearly all identified as Latinx (20), with one Black student, one Asian American student, and one white student. She had three students with identified learning disabilities and one gifted student.

We chose this teacher for two key reasons. First, we had multiple sources of data available from her enactment: a video recording of the full lesson and multiple student work artifacts from her classroom. Second, her own teaching to us embodied a general approach of opening up investigations for students, where students were asked to make key decisions about data with her support, rather than simply follow her directions.

Intervention

We took a design-based approach to developing and co-designing with teachers a set of *data excursions* and accompanying tools and routines for supporting students’ data literacy skills within two lessons of a widely used, open access, storyline-based high school biology curriculum. These data excursions were intended to allow students to interact with existing datasets to query their contexts, change the way they are aggregated and represented, and explore their properties, in order to explain changes to the Serengeti ecosystem that led to a dramatic increase in the populations of two large herbivores, buffalo and wildebeest, between 1960 and 1975. Rather than present students with cleaned up data, we sought out the original data for students to engage with to more closely approximate how scientists think about and use data (see Figure 2).

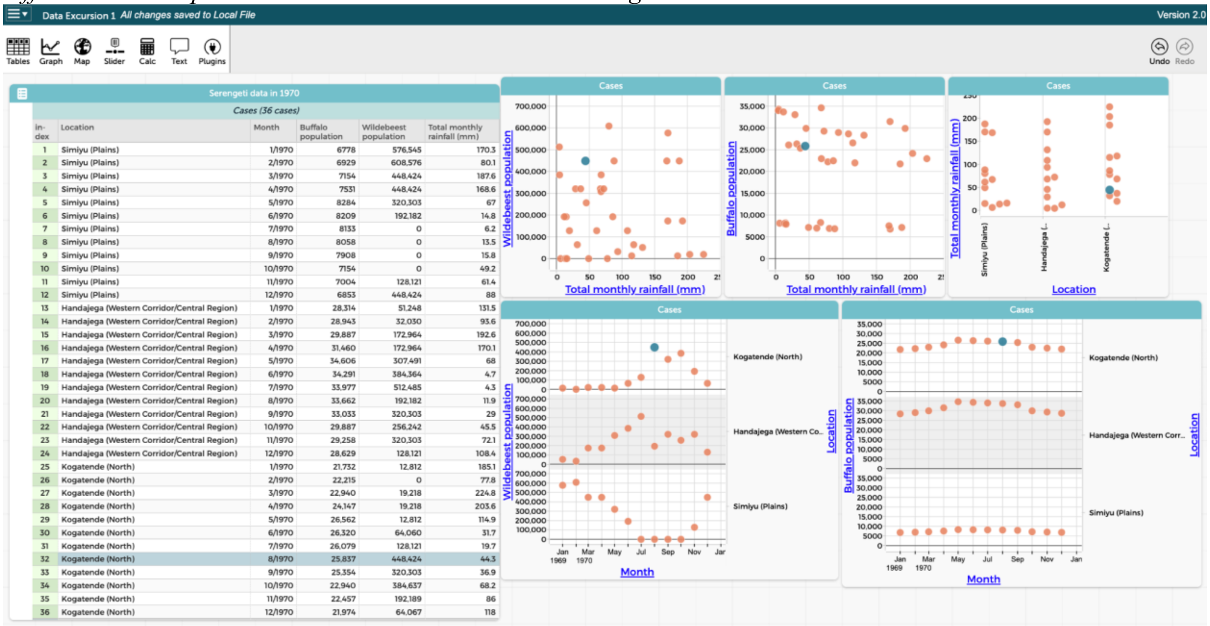
In the focal lesson, students addressed the question: “Was the increase in population of wildebeest and buffalo caused by an increase in the availability of food?” After an initial discussion to consider what data they might need to answer the question, students watched a video from an ecologist who studied the Serengeti during that time period, who said they did not have data on food from 1960-75, so they had to estimate food availability by looking at data on rainfall.

Students were then introduced to CODAP, which features a drag-and-drop interface that simplifies creating and modifying graphs of the dataset. All representations in a document—tables and graphs—are linked so that any data points highlighted in one representation are simultaneously highlighted in the others. Both the software’s ease of use and this “linked representation” feature is intended to help keep students focused on the meaning of the data and support their ability to see and interpret patterns in the data (see Figure 2).

The curriculum included a handout for student groups, to specify what data they planned to analyze, what patterns they noticed in the data, and their explanations of the lesson-level question in a “claim-evidence-reasoning” format (McNeill & Krajcik, 2012). After collaborating in small groups, the whole class discussed the groups’ ideas to arrive at a consensus explanation.

Figure 2

CODAP platform with dataset for the lesson 2 data excursion, and student work examples demonstrating the different visual representations that students created during lesson 2.



Serengeti data in 1970

Cases (36 cases)

index	Location	Month	Buffalo population	Wildebeest population	Total monthly rainfall (mm)

Data sources

This case study relied on multiple sources of data, stemming from the enactment of lesson 2 in Melissa’s class. Prior to the first author entering her classroom, Melissa underwent consenting procedures with her students. The first author captured video recordings of the lesson, which spanned two fifty-minute periods of instruction over two consecutive days. The camera was set up towards the front of the room and focused on Melissa to protect the privacy of students who had not consented. The first author created activity logs while observing the lesson over the two days. We made transcripts of the video recordings to support analysis through the Vosaic video analysis software. Melissa provided graphs from nine different student groups, each of which had between 2-3 students, and student notebooks from 11 students in the class which captured their responses from the handout described above. Lastly, we also drew on the curriculum materials as a data source.

Approach to analysis

The first two authors undertook an interaction analysis (Jordan & Henderson, 1995) to help us identify key moves made by the teacher and students to decide on what data to privilege as evidence and also to develop conclusions from the data, focusing especially on the moves made by the teacher to support student sensemaking related to data modeling. We relied on both inductive and theoretically-driven coding, guided by the Manz et al. (2020) framework. We also looked to Lehrer and English’s (2018) data modeling framework for explicit data modeling moves - posing questions that can be answered with data, grappling with decisions about the design of investigations, and building understanding of the available attributes.

We began with an initial viewing of the lesson 2 videos to develop ideas about the teacher moves supporting data modeling. We then undertook an iterative process of developing a coding scheme and segmenting the video, resulting in a refined coding scheme allowing us to identify moments of moving across question, evidence, and explanation. Identifying moments moving across these elements highlight where students can be involved in scientific activity. The decisions around investigating support alignment - where students identify the relevant part of the larger phenomenon to investigate, decide how a dataset can help answer this part of the phenomenon, and develop an explanation based on data representations and conclusions. Table 1 represents these movements within our coding scheme. As we moved back and forth between developing our coding scheme and watching the video, we also noticed moments that did not align necessarily with these transitions but were necessary for supporting next steps - where certain knowledge or skills were needed for students to move forward. The first two authors discussed the coding together and adjudicated all disagreements. As a form of member checking, we shared our account with Melissa, who provided additional interpretations of her actions and students' experiences.

Table 1
Identifying Moments of Alignment Moving Across Data Modeling Coding Scheme

Code	Description / *Examples*
For Specifying the Data Model	
Deciding What to Privilege as Evidence	Build understanding of available attributes; Understand what the scientists did who collected the data; Identify the attributes that are best for answering their question; Predict or anticipate what the data might look like. Examples: *Students connect factors that affect food availability with how to measure it; Melissa problematizes this measurement dilemma, bringing students into this practice*.
For Interpreting Evidence from the Data Model	
Representing Data	Land on the data representation(s) that can communicate the claim with the data set. Example: *Some students graphed the relationship between rainfall AND population*
Determining Conclusions	Make sense of what the data and data representations tell in relation to their question. Example: *Melissa pressed for evidence-based explanations: "How do we know they are moving around?"*
Background Knowledge and Skills	Integrated as needed for supporting alignments and next steps: Using a new tool. Example: *Curriculum provided support for using CODAP*; Additional background information Example: *Curriculum and Melissa provided context of the Serengeti*; Connections to prior learning and students' everyday experiences. Example: *Student compares drought to Dust Bowl.*

Analysis and findings

We present our findings as a "play-by-play" (Derry et al., 2010) of the teacher enacting and students engaging in the lesson 2 data excursion, focusing on data modeling. We answer our research questions by describing how the teacher, curriculum, and students worked together leading up to and *specifying the data model*, in part by deciding what to privilege as evidence, and subsequently *interpreting evidence from the data model*, in deciding what data to represent and determining conclusions about the data model.

Specifying the data model

On the first day of this lesson, Melissa began by re-engaging students about the larger phenomenon under study, as called for in the curriculum. Having noticed there was a huge population increase in wildebeest and buffalo from 1960-75 in the previous lesson, she prompts students to consider why scientists wanted to investigate that. She asks, problematizing the phenomenon itself, "Why was that weird? Why did they start studying it?" Melissa then asked students to recall, "What did we think we should look at first?" Here, there is work in aligning the phenomenon to an initial investigation model, by helping students determine the relevant parts of the phenomenon and deciding what next steps are needed to build an explanation of it. Students came up with ideas like, "food, predation, and climate," as starting points for investigating the phenomenon further.

Melissa and the students agreed that the class should start with whether an increase in food caused the increase in wildebeest and buffalo populations. The curriculum calls for students to generate ideas for what the data would need to show, if the increase in food was in fact the cause of the population increase. As prompted in the materials, Melissa asks, "What changes would tell us that food was a reasonable cause for the [population] growth?" This prompted students to consider the attributes that are best for answering their question and beginning to anticipate what the data might look like.

This was a challenging thought experiment for students, so Melissa problematized how to answer the question for students, making clear this was not an easy task for scientists either. She started by asking, "How could they measure this?' and, "What might be challenging about measuring it?" One student puts forth, "have a robot do it?" Melissa, while acknowledging the idea, reminded students that this took place from 1960-1975, meaning the technology couldn't do that. Melissa followed with, "If they couldn't measure it directly, how could they estimate food availability?" These moves supported students in understanding what the scientists did and the context for collecting the data. Students seemed to struggle in coming up with a proxy for estimating this attribute, so she asks, "What do we think influences it the most?"

Melissa noticed a moment of needing to draw on prior background knowledge and explicitly invites students to make connections to what they've learned about how plants grow and thrive. Students drew on their prior everyday and school-based knowledge - responding with "sun, soil, water, and it depends on the weather." Melissa named this as similar to the real work of scientists: "This skill of figuring out what data to look at to answer a question is not an easy one. This is what legit, actual scientists have to do. Of all this data, how do we make sense of it? What do we need to pull and use and what do we need to be able to put aside?"

Before engaging in any graphing, Melissa asked students to consider what questions could, and couldn't be answered by the data at hand, as called for in the materials. Here, she supported deciding what to privilege as evidence (in this case, the attributes available) about whether the main investigation question could be answered with the given dataset. Also, as the curriculum directed, students made a plan for what relationships to graph and anticipate what the graphs would be likely to say, if more food is the cause of the increase.

In this part of the lesson, Melissa and the curriculum both supported students in aligning an investigation question to constructing a data model, by scaffolding what attributes would be helpful as evidence, bringing students into the uncertainty that the scientists grappled with around measuring food availability in a place as large as the Serengeti, and asking them to anticipate what the data model will show if food was the driver of the population increase.

Interpreting evidence from the data model

On day two, students made graphs focused on discovering, as the teacher put it, "what they can about the ecosystem," or as directed in the materials, whether there's a relationship between rainfall and buffalo and wildebeest populations (a question for which the dataset can provide an answer).

Students first watched a video explaining how to create and manipulate graphs in CODAP, providing the skills needed to access the tool, and modeling how to look at the population of buffalo and wildebeest over the course of a year in three locations in the Serengeti. Then, students made CODAP graphs in small groups. Melissa instructed them to construct "other graphs to better understand what was happening in the Serengeti." The graphs students produced mostly imitate the video tutorial in visualizing some attribute over the course of the year in the three locations. Students chose wildebeest population, buffalo population and monthly rainfall as the attribute to visualize in this way, but only two of the eight student groups made graphs that looked at both wildebeest (or buffalo) population AND rainfall simultaneously, which would be necessary to investigate the relationship between rainfall and population. In the subsequent discussion, Melissa called on those two groups to share what these particular graphs showed.

As students turned towards making sense of the data and representations, Melissa's interventions suggest they need reminders of what the data actually convey, and in some respects, the students' struggles with producing graphs that could help them see the patterns the curriculum intend prove to be a stumbling block for collective sensemaking. Melissa asked students to try and account for the relationship of rainfall and population through a line of questioning. Melissa pushed them for mechanisms, too, though it's not clear that they could answer the question she posed to them from the data at hand, she asks, "How do we know they are moving around? What are their needs that are different?" Student responses here included, "Wildebeest are in the plains in the wet season and then go to the other regions in the dry season," and, "They go to the other regions because there's water there," connecting to previous observations that there were rivers in certain regions.

She also pressed students to go beyond the simple statements of patterns they are seeing, and to specify what the connection between rainfall and population would be if food were the cause of the population increase: "We still haven't made a connection between them, though. So, what is the connection?" She started the sentence, "When the rainfall increases, they…" Here, we see Melissa guiding students in making sense of what the data and data representations tell them in relation to their question.

Towards the end of this lesson, Melissa invited students to go back to the Driving Question Board (DQB), a record of their own questions from the first lesson developed to guide their investigations, as a resource to remind them of the bigger question they came to the lesson with: whether the rapid increase in population from 1960-75 was due to an increase in rainfall. She asked, "Do we have data over several years?" "No," students say. In fact, the lesson did present them with such data, but students hadn't figured out successfully as a class which graphs would help them answer their question. She followed with, "What questions do we still have? What have we still not figured out? Let's go back to our DQB. Do we know why they are increasing? Remember, this is where we started."

In this part of the lesson, students interpreted evidence from their data models in order to answer the question about whether they see a relationship between rainfall and population size, and once they answered that, they considered if they can attribute food as the cause for the large growth in population size from 1960-75.

Melissa and the curriculum supported this ‘narrowing in’ on a piece of the phenomenon, taking a deep dive into the data, making sense of the data in order to explain this one aspect of the phenomenon, and then expanding back out to the central phenomenon of the unit, explaining the increase in buffalo and wildebeest populations on the Serengeti. Further, we see how students can be made aware of and be involved in some of the decision-making around data, and we see how the curriculum and the teacher support alignment in moving from question to evidence to explanation.

Discussion

Through this case study, we have analyzed how sensemaking about data can be supported in a high school biology unit focused on ecological systems. In addition to considering the complexities of using previously-collected data, we consider how data analysis is particularly challenging in the context of ecology, in which multiple time scales are relevant and simple causation is elusive. We have highlighted, too, how both curriculum and teacher moves can support navigating this complexity.

While Manz and colleagues (2020) and Lehrer and English (2018) wrote about contexts in which students collect firsthand data, our study provides the opportunity to showcase the complexities of presenting students with real-world datasets collected by scientists and what it can look like to engage students in understanding the circumstances under which the data were collected. We see here that the curriculum and the teacher are doing some of the “heavy lifting” students might have done if they had instead collected their own data. For example, the problems of measuring relevant quantities are highlighted to them in the materials, in the form of a video presentation and teacher moves that problematize how to measure food availability. The teacher, for her part, poses questions highlighting decisions needed to be made and why they are not simple to make.

In addition to the explicit data modeling moves outlined in Lehrer and English, we observed moves teachers can make to notice trends in data that then facilitate students’ sensemaking. We saw how Melissa was responsive to her students’ needs and took time to provide students with language and routines for looking at graphs, in one instance, not mentioned in our findings, introducing language around ‘positive’ and ‘negative’ relationships. As we have continued to revise the data excursions based on field testing, such instances have helped us realize that we need to provide more support for looking at and noticing patterns in data. Further, our coding helped us realize how the investigations framework does not yet account for a “time for telling” (Schwartz & Bransford, 1998), to provide students the background knowledge and skills they need to participate, while not giving away what we are hoping students can figure out together.

This case also highlights the zooming in and out that the teacher supports, so that students can see the big picture of what they are doing. This is a form of navigation (Reiser et al, 2021) – that is, helping students anticipate continuously where they are headed, so that they make sensible decisions in the present. This is especially salient in phenomenon-based units taking place over several weeks.

Though there was limited direct evidence of a broad range of students’ participation in the classroom from the video, Melissa expertly made space for students’ diverse ideas and frequently revoiced students’ contributions, so we were still able to get a sense of the ways students participated. However, it was not clear that this bid to engage in sensemaking was necessarily taken up by all students and we have more to uncover about how students’ own framing of the activity may have shaped their participation (cf., Munson, 2021).

Further, we saw many of the data modeling moves take place, but it is partly due to the intentional design of the curriculum and the skillful moves of the teacher, placing the heavy lift on the curriculum and teacher here, rather than on students. This may come at a cost for students’ opportunities to plan and carry out investigations, even if it is how science sometimes takes place in using data collected by others. It would be interesting to see how students work with collecting data firsthand, in contrast to a case like ours, where students are provided the datasets and the conditions of the scientists’ investigation model to work with.

Conclusion

This case study highlights some of the work needed to support the “practice turn” as part of current science education reform efforts, and reconceptualizing planning and conducting investigations, with particular attention on including students in the decision-making taking place in aligning questions to evidence to explanation. Such alignment work also mutually supports the use of the other science and engineering practices; for instance, we saw how students were engaged in asking questions and arguing from evidence while deeply engaged with data.

It is clear that students need support for data modeling even in a well-orchestrated classroom. This teacher played an active and nimble role in being responsive to students' needs as they grappled with data modeling, moving from phenomenon to explanation. We need to deepen our understanding of how teachers and curriculum work with students in moving away from ‘doing school’ and towards being actively involved in making and understanding the decisions surrounding data-based investigations.

Anti-Black Racism & Mathematics: Designs for Intentionally Fostering Courageous Conversations in a Knowledge Building Community

Thelma Akyea, Toronto District School Board, thelma.akyea@tdsb.on.ca
Leanne Ma, OISE/University of Toronto, leanne.ma@mail.utoronto.ca

Abstract: In recent years, there has been growing attention in the learning sciences to address fundamental assumptions surrounding the nature of knowing and learning together, with renewed urgency to intentionally design for more equitable classroom practices. This study explores the implementation of a principles-based approach to designing an anti-racist mathematics classroom focused on fostering students' critical data literacy skills. Over the course of one semester, a grade 8 teacher engaged her students in critical conversations about carding in Toronto through sustained engagement with authoritative sources, real-world datasets, student-generated theories in Knowledge Building circles and Knowledge Forum. Qualitative analyses reveal the power of using analytic tools to restructure power dynamics in the classroom, as well as the critical role of idea diversity in helping students arrive at rise above theories of systemic oppression. Educational and moral implications of this work are discussed within the context of growing inequities in today's societies.

Introduction

Traditionally, science and mathematics have been taught as apolitical bodies of knowledge – as disjointed sets of facts, rules, explanations, and theorems for students to learn and acquire. Not only are these methods not effective for promoting deep and lasting learning (Bransford, Brown & Cocking, 2000), they fail to acknowledge two core issues: the cultural-historical systems of power upon which knowledge was built and the emergent, dynamic sociotechnical systems that are actively reshaping and advancing these bodies of knowledge in our societies today. More recently, there has been renewed attention in the learning sciences to address fundamental assumptions surrounding the nature of knowing and learning together. For example, "What "should" people learn?", "Who determines whose knowledge counts?", and "Which pedagogical approaches promote "good learning"?". As Esmonde and Booker (2016, p. 1) assert, "The learning sciences, therefore, must necessarily center conceptions of equity, diverse experience, and the dynamics of power and privilege expressed in and through learning environments."

Race, class, age, and gender have been critical issues in STEM education for a number of years, while renewed urgency to combat anti-black racism persists in many classrooms. In direct response to this pressing challenge, learning scientists have been working with teachers to critically engage with epistemological assumptions, values, and dispositions. One powerful outcome of such partnerships is the reframing of diversity as a pedagogical asset in classrooms, with teachers prioritizing the community funds of knowledge during curriculum design to create learning environments that connect with and reflect the lived experiences of their students (Nasir et al., 2006). Examples of such practices include the use of embodied imagining and argumentation to bootstrap scientific sense-making practices with youth from non-dominant groups (Bang, et al., 2012); the use of cultural datasets to leverage local knowledge during the problem solving process (Lee, 2008); the repositioning of students as "doers" of mathematics by anchoring learning activities in everyday cultural practices (Gutiérrez & Rogoff, 2003); and the exploration of social histories interwoven with data such as "family geobiographies" (Kahn, 2019) and personal data narratives (Stornaiuolo, 2019).

The proliferation of open datasets offer a realm of possibilities for students to extend their practices from "doers" of mathematics to "doers" of data science (Wilkerson & Polman, 2020). Not only is it a moral imperative "to empower students as informed decision-makers and stewards of their own data" (Ma et al., 2021), it is essential for them to engage in critical data literacy practices – to actively represent, interpret, and manipulate data (Wise, 2020) and to cultivate awareness of the ideological, historical, and political layers involved in data production (Irgens et al., 2020). In particular regard to mathematics, inequity is measurable. Critical conversations around real-world datasets enable students to conceptualize complex issues at the intersect of race, class, age, and gender and to engage more directly in conversations about social justice, the growing inequities in today's societies, and the lived experiences of marginalized groups in their own neighbourhoods. Furthermore, the place-based, authentic nature of locally collected datasets can inspire students to take transformative action (Phillip et al., 2013; Taylor, 2017).

Theoretical framework

The current study aims to extend this emergent line of work on critical data literacy by adopting a humanistic stance toward data science (Lee et al., 2021). More specifically, we used the Knowledge Building principles (Scardamalia, 2002) as an evolving framework for intentionally designing epistemic norms in data learning activities to unpack anti-black racism and empower marginalized voices to speak up in the mathematics classroom, with the ultimate goal of raising our collective critical consciousness.

We chose Knowledge Building as the pedagogical framework for this study because we view it as a fundamentally anti-oppressive approach to designing learning environments. Knowledge Building goes beyond socializing students as "doers" of disciplinary practices to nurturing students' identities as inventors of new disciplinary practices and creators of new knowledge (Bereiter & Scardamalia, 2014). For example, the principles of *real ideas, authentic problems* and *idea diversity* prioritize students' lived experiences and ideas as funds of knowledge worthy of time, reflection, and careful investigation by the entire community. The teacher fosters a culture where racial diversity and individual differences are viewed as strengths and encourages students to bring their unique perspectives to enrich discussions and promote idea development (Zhang et al., 2011; Tarchi et al., 2013). In doing so, the teacher engages in a continuous process of restructuring of power dynamics in the classroom to realize the principles of *epistemic agency, democratizing knowledge,* and *constructive use of authoritative sources.* Whereas in traditional classrooms, the teacher is positioned as the sole authoritative source of knowledge, in a Knowledge Building community, each and every member is positioned as a legitimate contributor to the community knowledge with students finding creative, idiosyncratic ways to contribute meaningfully to advance collective understanding (Zhang et al, 2009; Ma, Matsuzawa, & Scardamalia, 2016).

By intentionally de-centering ideas in the curriculum prescribed by experts (Teo, 2014) and shedding light on the promisingness of student's ideas (Chen et al., 2015), the teacher creates a safe and expansive space for all voices to be heard, acknowledged, and valued. Working closely with their students, the teacher also co-designs flexible discourse structures that encourage emergent collaboration, participatory leadership, and reflective restructuration (Tao & Zhang, 2020). For example, during *Knowledge Building discourse*, students are invited to set community goals, ask thought-provoking questions, build on each other's ideas, take risks with their learning by critiquing experts' ideas, and help each other generate better ideas, more coherent explanations, and *rise above* solutions that benefit not just themselves, but the community as a whole. In a Knowledge Building community, students develop a shared sense of belonging, interdependence, and ownership over their community knowledge – they find comfort in relying on one another for critical feedback and joy in supporting each other's learning through *symmetric knowledge advancement*.

In this paper, we elaborate on the exploratory and iterative processes involved in implementing a principles-based approach to designing an anti-racist mathematics classroom focused on fostering students' critical data literacy skills. More specifically, we follow the journey of Thelma Akyea, a secondary teacher in Toronto, Ontario dedicated to fostering a Knowledge Building community rooted in the principles of *epistemic agency, collective responsibility*, and *Knowledge Building discourse*. Over the course of one semester, Thelma engaged her grade 8 students in critical conversations to deconstruct authoritative sources and build theories about carding in Toronto based on local datasets derived from different neighborhoods. The ultimate goal was to deepen students' understandings of what the data really represented and how they can effect change in their everyday lives. Our research questions are: How did engaging students in critical data literacy deepen their awareness of anti-Black racism in Toronto? And What new insights and/or perspectives did students gain from their critical conversations?

Study design and implementation

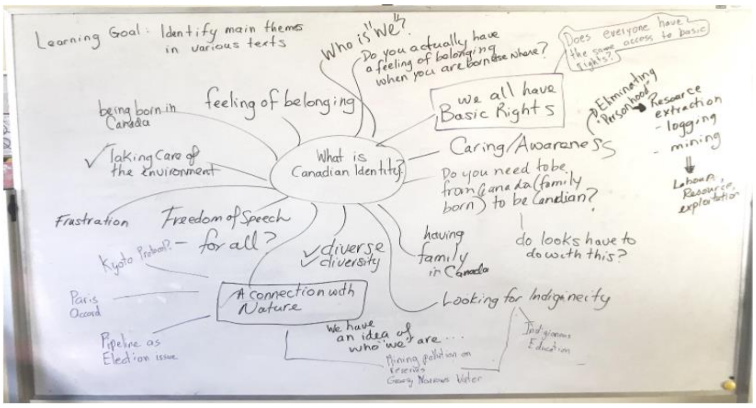
Using classroom-based design methodology (Barab, 2014) and the dual-layer Knowledge Building approach to teacher learning and co-design (Tan et al., 2016), Thelma and her colleague engaged in a mini Knowledge Building cycle of their own to explore the big ideas surrounding carding in Toronto. They experimented with strategies from the KB Gallery (Resendes & Dobbie, 2017), such as Knowledge Building circles; gathered online resources to map possible directions for deepening inquiry on Knowledge Forum (Figure 3b); and practiced holding critical conversations about anti-black racism to anticipate where students might go with their ideas. Additionally, Thelma worked with her colleague to ensure that her teaching practices themselves were equitable through regular check-ins to integrate students' interests, equity concerns, and lived experiences into her evolving classroom design. Her colleague also provided supports in the classroom for students with special learning needs. In the following section, we elaborate on each principles-based design iteration. Whereas the goal of the first design iteration was to co-create norms of interactions and use real-life provocations to initiate student discussions in Knowledge Building circles, the goal of the second design iteration was to foster inclusive ways of thinking and deepen students' empathy and reflexivity through sustained discussions on Knowledge Forum.

Design iteration 1: Critical conversations and KB circles

Epistemic agency, Idea diversity, Constructive use of authoritative sources, Knowledge Building discourse

As part of the design intervention, Thelma integrated Singleton & Linton's (2006) framework for courageous conversations as a layer on top of their classroom discourse, with the four commitments – stay engaged, speak your truth, experience discomfort, and expect and accept non-disclosure – serving as the explicit norms for their Knowledge Building circles. In reviewing key concepts, such as equity and inclusion, racism, anti-black racism, and microaggressions (Kendi, 2019), Thelma encouraged her students to adopt an anti-oppressive lense by being mindful of their own privilege and the space they occupied in their Knowledge Building circles (i.e., who speaks when and to whom). This meant that students agreed to be open to the possibility of feeling uncomfortable and agreed to be respectful and non-judgmental with their peers, even when they were being challenged. Thelma also provided assurance that her classroom was a safe space to take risks and make mistakes. Together, they would practice compassion and be gentle with each other throughout the process.

Figure 1
Diagram showing connections between students' ideas during their KB circle on Canadian identities



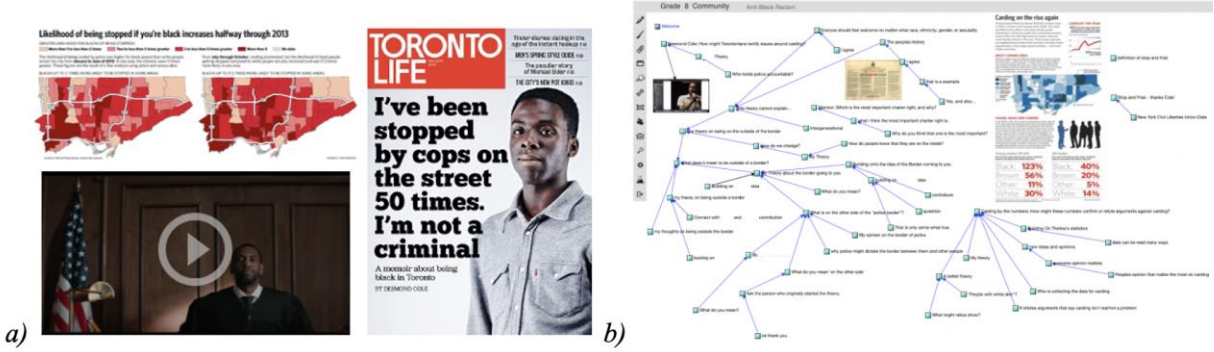
The first Knowledge Building circle was on the broad topic of Canadian identities to draw out students' lived experiences and funds of knowledge. Students provided numerous popular ideas of what it means to be Canadian, including basic rights, freedom of speech, a sense of belonging, and environmental stewardship (see Figure 1). Building on this first discussion, Thelma encouraged her students to unpack the notions of freedom and belonging by exploring how these concepts might be experienced by members of marginalized communities. For example, "Does everyone really have the same access to the basic rights?" and "Who is "we"? Do you actually have a feeling of belonging when you are born elsewhere?". Students read articles and opinion pieces online, including an essay about carding and anti-black racism in Toronto written by a prominent local journalist, Desmond Cole (2015), and together, they watched a debate about carding in Toronto (Figure 2a). Students then self-organized into small groups to dig deeper into articles of their choice by examining various infographics and making sense of the demographic data presented to address claims that anti-Black racism exists in Toronto.

Design iteration 2: Knowledge Forum and metadiscourse

Democratizing knowledge, Community knowledge, Improvable ideas, Rise above, Embedded assessment

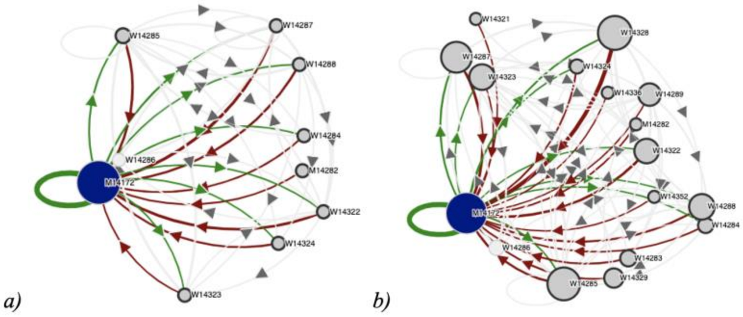
Thelma invited her students to continue their critical conversations on Knowledge Forum (Figure 2b) where they collectively unpacked what it meant to be carded by the police. Students shared and integrated information and multimedia between groups and actively worked toward improving their theories and explanations through use of epistemic scaffolds such as "My theory", "I need to understand", "This theory does not explain," and "A better theory". At one point in their discussion on anti-Black racism, students decided to return to their original theories about Canadian identities after re-examining the Canadian Charter of Rights and Freedoms with a more critical lense. They decided to create a new view in Knowledge Forum to share their revised theories of what it means to be Canadian and what it means to belong in Canada, including having a more nuanced discussion on the relations between identities, rights, and freedoms. This discussion prompted them to consider racism in a new light, with students expanding their conversation to think more deeply about what individuals, grassroots communities, and governments can do to protect the interests of people in marginalized communities and what changes must be made at each level to realize a more socially just society in Canada.

Figure 2
a) Authoritative resources on anti-black racism and b) students' discussion in Knowledge Forum.



At the beginning of this iteration, students were primarily building on the teacher (blue node in Figure 3a), but after a metadiscourse session facilitated by the social network visuals, students renewed their four commitments to critical conversations and worked more intentionally to build on each other's ideas as a way to democratize knowledge and foster a more inclusive community. Figure 3b shows the redistribution of ideas in the community, with more students (grey nodes) appearing the same size as the teacher (blue node) and denser, more mutual connections between students (green and red edges). Students also began renaming note titles to include "Building on [student's] idea" and using the scaffold "Putting our knowledge together" more frequently to intentionally seek coherence between the different ideas and perspectives represented in Knowledge Forum.

Figure 3
Social network of class a) before metadiscourse and b) after metadiscourse.



Data sources and analyses

Because this study focuses on fostering and sustaining critical conversations in the mathematics classroom, we collected various forms of discourse data to examine the community's evolution of thought over the course of the two interventions. Using teacher notes and teacher reflections from Knowledge Building circles and student notes in Knowledge Forum, we conducted content analysis to identify emergent themes and concepts in students' discussions. In an effort to maintain the holism of the classroom design, we adopted a complementary mixed methods approach (Creswell & Plano Clark, 2007) to triangulate results across the different data sources and seek convergence in addressing the research questions. More specifically, we integrated qualitative analyses of teacher notes and student notes with quantitative analyses of expert corpora, teacher notes, and student notes in Knowledge Forum to explore the conceptual space of student ideas. Students wrote almost 200 notes over the course of 4 months. On average, each student wrote 7.5 notes and read 5 notes for every note they wrote.

Student discourse in KB circles and Knowledge Forum

Figure 4 shows a comparison of word cloud's between Desmond Cole's article, Thelma's discourse, and the student discourse. In Desmond Cole's article, he challenged the idea of Toronto as "a post-racial city, a multicultural utopia where the colour of your skin has no bearing on your prospects" by sharing his personal experiences of being carded and interrogated by police for more than 50 times over the span of living in Toronto for almost a decade. He goes on to explain how "that unwanted scrutiny, that discriminatory surveillance, [makes him feel like] I'm a prisoner in my own city". In response to this article, Thelma's discourse was focused on issues of barriers and access of members in various marginalized communities, including black, indigenous, people of colour, and LGBTQ+ folks. Students' discourse, on the other hand, was focused on the issue of belonging: Who is considered on the inside/outside of borders? and Who gets to decide where a border starts and ends?.

Figure 4

Word Cloud of a) Desmond Cole's article, b) teacher discourse, and b) student discourse in Knowledge Forum.

To address these questions, students searched the official city website as an authoritative source to explore the datasets referenced in their articles and infographics to learn more about specific marginalized communities. Students drew from their understanding of Toronto's different neighbourhoods to parse out high- and low-income communities to compare and contrast patterns. One group visited the Toronto Police website to gather more data to learn more about other safety statistics in various Toronto neighbourhoods. Across all the groups, student consistently found a correlation between being a Black boy and the neighbourhood where they were carded. In their initial theory, they thought that Black boys would be more likely to be carded in all neighbourhoods, but a closer, more critical examination of the datasets suggested that was not the case. To their surprise, the income of the neighbourhood was a key mediating variable in the likelihood of a Black boy being carded. That is, they found that Black boys were more likely to be carded when they were in high-income areas and less likely to be carded when they were in low-income areas. This improved theory also surprised Thelma, and she encouraged her students to continue their conversation on Knowledge Forum to further upack the implicit gatekeeping purposes of carding and borders. Below is an excerpt of student discourse in Knowledge Forum, where students juxtaposed ideas of belonging from their conversation about Canadian identities with carding to understand who cards whom, when, where, and why:

> **Student A**: [My theory]: I would say that these stats confirm a big issue around carding. That is, black people get stopped and carded far more than white people. If you look at this data you can clearly see that out of all males carded 40% are black and only 14% are white.
> **Student B**: [A better theory]: What the numbers show is what is the portion of black people carded to the portion of the people with white skin. What is the ratio?
> **Student C**: [My theory]: We think that being on the outside of a border means that you weren't originally from the community/place that you are trying to cross to. I also think that to be on the outside of a border means you don't feel accepted or comfortable in that community.
> **Student D**: [This theory cannot explain]: How some people can be 5th generation Canadians, and they still have that feeling of exclusion based on race, religion, sexuality, gender, etc. That feeling of alienation does not mean they are not from that place, but rather that people are making them feel like they don't belong.
> **Student E**: What I think I means to be outside the border… I think that emotions comes with some of the part and I feel like a lot of people feel nervous and scared just because maybe they think they might get stopped or questioned.
> **Student F**: [My theory]: I would like to build on to Student D's theory that the police border can decide whether to let people in or not. I agree with Student D and I think that the police sometimes deliberately choose to let people through because of people's background or any other reason.
> **Student G**: [Putting our knowledge together]: it seems that being carded is like having a scary unmovable border approach you and you have no way of avoiding.
> **Teacher**: [I need to understand]: how we can change these feelings of being outside?

As can be seen from this excerpt, students really began to see the arbitrary nature of borders, how it takes away agency and alienates those it serves to exclude, and by extension, the hurtful and traumatic consequences these practices have and will continue to have on marginalized communities for generations. A compassionate reflection from a student, “I would say that everyone can have a different theory or opinion of carding, but I would say that the opinion that truly matters is the opinion of the people being carded.” was brought to a heated discussion in a Knowledge Building circle, where students touched upon the issues of microaggressions and racial gaslighting. One student asked, “I wonder what the percentage of people who were carded was dressed well… I feel like if someone could look like not a threat and they still could be carded” to which a student quickly responded, “I think… it’s not really the kind of irrelevant… they shouldn’t be pulling people over because of how they dressed. Flipping it, it would be weird no matter what it is – not the dress – I think police officers making that excuse is counterproductive”. Another student then added “Even if they look like a threat that doesn’t make it okay. Even if the police were justified in what they were doing”. It was at this point that students began to uncover the “self-perpetuating cycle of criminalization and imprisonment” of Black bodies in Toronto, and that “identities are not the same for everyone, although we should have the same rights and freedoms”. Through sustained discussions around Desmond Cole’s article and critical investigations of multiple datasets, they came to understand that carding affects the daily livelihoods of Black people living in their communities. As a Knowledge Building community committed to anti-Black racism, they began digging deeper into the Canadian Charter of Rights and Freedoms and started generating new discussions on Knowledge Forum on what they could do to be more intentional about combating anti-Black racism and reducing discrimination in their local neighbourhoods.

Discussion and implications for future work

This study aimed to extend the work on power and privilege in the learning sciences to explore how we – teachers, researchers, and students – can engage each other in iterative design for more equitable, anti-racist mathematics classrooms. Over the course of one semester, a grade 8 class engaged in critical conversations around real-world datasets to problematize the notion of Toronto as a “postracial city” and to unpack social, political, economic, and historical dimensions of “belonging” in Canada. By exploring and generating statistical trends in local demographic data, students grappled with complex issues at the intersect of race, class, age, and gender and reflected deeply on their roles in creating equitable, justice-oriented communities. To return to Esmonde and Booker’s (2016) three questions: Within the context of the secondary mathematics education, it is our view that students should learn critical data literacy (among other key mathematical competencies); students’ funds of knowledge should serve as the foundations of curriculum; and Knowledge Building offers one way to integrate the first two aims while helping students see themselves as legitimate creators of knowledge (Scardamalia & Bereiter, 2006), which bears with it a civic duty to create and advance ideas for public good.

It should be noted that even if the teacher is not at the center of classroom discussions, the teacher plays a central role in creating a safe space for having critical conversations with their students by setting explicit expectations on how they can hold discomfort, compassion, and mutual respect for one another; using a variety of strategies to reflect on and restructure power dynamics in the classroom (e.g., showing students the evolution of classroom dynamics and who is occupying a position of power during discussions), and co-creating inclusive and equitable practices with her students by extending her position of power to them and inviting them to listen deeply to one another’s ideas and build on each other’s ideas with intention, care, and kindness. For example, Thelma and her students responded differently to Desmond Cole’s article. Instead of directing her students along known paths of idea development, she placed trust in their collective potential and encouraged them to self-organize according to their emergent interests and shared community goals. Therefore, the principles of epistemic agency and idea diversity were key to driving students’ idea improvement, idea cohesion, and the generation of rise above perspectives on the broader implications of belonging, citizenship, and anti-Black racism in Canada. That is, students would not have been able to go deeply with their ideas had they not been given opportunities to pursue authentic issues they cared passionately about and reflect on the connections and direct consequences they had in their everyday lives – for themselves, their friends, their families, and neighbours in local communities.

A recent critique of Knowledge Building pedagogy suggests that taking an ideas-centered, principles-based approach (Hong & Sullivan, 2009) disregards the person-centeredness of learning (Hod et al., 2018). However, this case study proves that this cannot be further from the goal of engaging students in community knowledge advancement to raise critical consciousness. In this study, students engaged in critical data literacy with real-world datasets to develop a nuanced understanding of Canadian identities, freedoms, and rights; sense of belonging in communities; and policing practices that promote fear, alienation, and racism in the everyday lives of Black people, as well as the intergenerational effects of racism on communities of colour. Consistent with past work that aims to adopt a learner-experience-centered approach to data science education (Wilkerson & Polman, 2020), our study indicates that using a Knowledge Building approach can equally enhance students’ epistemic agency, social awareness, and expansive understanding. Put differently, our work readily aligns with what Lee and colleagues (2021) propose as a humanistic approach to data science, with students moving seamlessly across constellations of personal, cultural, and sociopolitical layers of data engagements during class discussions and learning activities. Furthermore, we contend that any type of humanistic account for learning must transcend systems of oppression so that all members of the human race – regardless of age, class, gender, ethnicity, religion, etc. – can thrive in mutually supportive and sustainable futures. Each and every student has a role to play in this vision and it is the moral responsibility of educators and learning scientists to design more equitable and inclusive learning environments to realize this vision in schools, at all levels of education. As we have stated previously, the classroom culture "co-created by [the teacher] and her students are not merely a reproduction of existing realities outside the classroom, but rather, a re-imagining of what life in a knowledge society can look like when all ideas are valued and all members are empowered to contribute equitably to the advancement of collective goals. For this to happen, Knowledge Building must be a way of life for the teacher as well as her students" (Horner & Ma, 2020).

To further this vision, a third design intervention with Thelma's class is underway to explore how the global pandemic has amplified inequities in Canadian societies, including access to health in marginalized communities. Thelma is working with more advanced open datasets and public dashboards, such as providing students with options to calculate and generate indices to measure inequities in Toronto and go deeper with issues at the intersect of race, class, age, and gender. Likewise, learning scientists must continually work with educators like Thelma and invite new teachers to unpack power and privilege in classrooms. As Farrell and colleagues (2021) note, research-practice partnerships must actively work toward reducing inequities in educational systems. What's more, research-practice partnerships offer us the space to intentionally create misalignments in education systems so that new re-alignments can be created (Tan et al., 2020) – ones that will restructure power dynamics to eradicate inequities, make knowledge accessible and pervasive for all, and enhance symmetric advances within and between communities toward building more inclusive and sustainable knowledge societies.

Abstract: Mobile technologies that include photo-taking elements help to support children's observation and exploration of the natural world; however, how families engage with digital photo-taking features has not been fully explored. We investigated how 22 families engage with digital photo-taking features of a MAR app that prompts place-based observation of the outdoors. Families' interactions with the app were qualitative coded and then two vignettes from different place-based micro-learning locations were developed to understand learning practices related to photo-taking. Findings show that families were deliberate in taking photos that recorded their observations of the outdoors; however, the environment and features within the app impacted families' observational talk and excitement levels during the photo taking activities themselves. These findings contribute to the understanding of the importance of photo-taking activities during MAR experiences.

Introduction

People use photographs to document the natural world, capturing their observations for later reflection. Scientific photo-taking, along with other tools, supports record-taking and encourages children to develop scientific observation skills (Eberbach & Crowley, 2009). Photo-taking features in mobile technologies, while providing an activity that appeals to children, have been shown to help people learn to observe and identify the nature around them (Land & Zimmerman, 2015; Kawas et al., 2019). Mobile augmented reality (MAR) technologies support families' exploration and observation of place-based experiences by virtually augmenting digital features onto local science phenomena (Zimmerman, Land, Faimon & Chiu, 2022; Yun et al., 2022). When designing an MAR experience, small design decisions can impact learners' interactions with and movement through the environment. However, there is a lack of research exploring how families interact with photo-taking activities to encourage scientific observation within MAR. This study explores: *how do families engage with digital photo-taking features of a MAR app that prompts place-based observation of the outdoors?*

Conceptual framework

Our research was designed with the concepts of learning-on-the-move (LOTM) (Marin, 2020; Silvis et al., 2018) and sensory observation and engagement (Eberbach & Crowley, 2009). LOTM emphasizes how people learn collaboratively as they move within spaces where their learning is grounded, such as learner's experiences and relationships with nature and family (Marin, 2020), and how multi-site, multi-modal technologies are used as learning tools (Silvis et al., 2018). Learning experiences are anchored within and influenced by the environment and place that learners move through. In designing for LOTM we encouraged families to explore the needs of pollinators and build knowledge by moving within and engaging with native pollinator's habitats through observation, prompts, and other activities grounded in place.

Mobile technologies encourage families and youth's engagement toward nature and science in outdoor spaces through observation, science talk and discussion, and tactile investigation of nature (Land & Zimmerman, 2015; McClain & Zimmerman, 2016; Kawas et al., 2019; Yun et al., 2022). Learning experiences that are situated in a specific outdoor place help to support families' observations and knowledge building of the world around them (Marin & Bang, 2018). Tactile and visual sensory engagement help support children's scientific observation, encouraging them to use their everyday observation skills as connected to disciplinary knowledge brought in by a family member or tool (Eberbach & Crowley, 2009). Additionally, scaffolding parents' and families' conversational techniques can aid in supporting joint attention and talk as families make observations of the natural world (Eberbach & Crowley, 2017). Children observe their world every day, but supporting scientific observation requires more structured activities or family support (Eberbach & Crowley, 2017), such as encouraging record-taking of children's observations (Eberbach & Crowley, 2009) through taking photos of the natural world in the structure of a scientific observation activity (Kawas et al., 2019). Previous work (Land & Zimmerman, 2015; Zimmerman et al., 2022) has demonstrated how photo-taking as part of an analysis, scientific classification, or field journal framework can encourage scientific talk. Building on this work, we explore how families engaged with the photo taking activities throughout the app as a tool designed to support scientific observation and structured recording of observations and science content.

Methods

This analysis is situated within a larger Design-Based Research (Sandoval & Bell, 2004) study, SPACES, to create MAR applications for outdoor science education for rural families. This analysis focuses on the second iteration of an app about pollinators designed for Shaver's Creek Environmental Center (SCEC), a 7,000 acres (28 km^2) outdoor learning center associated with Penn State University, for use on walking trails around the main building.

Nature center, app, and photo taking app features

The study was held at SCEC which serves approximately 100,000 visitors annually. Our team of learning scientists collaboratively designed our MAR app on pollinators with pollinator researchers and SCEC staff. The app took families on an outdoor tour around the main educational building focusing on pollinator gardens and other environmental features that a pollinator would need to survive in meadows and forested areas.

The Pollinator Explorers App is focused on a specific type of native pollinator—solitary bees—and what they need to thrive in a forest and meadow habitat. Families in our study used the app to explore six different GPS-triggered micro-learning locations around the outside perimeter of the nature center and collected evidence (through photos) of what these native bees need to live and thrive in this habitat. Our app was built with the ten design conjectures in Table 1, as guides for the development of the Pollinator Explorers App, with this analysis focusing on design conjectures five and six.

Table 1
The ten design conjectures guiding the development of the Pollinator Explorers App; our analysis here focuses on conjectures 5 and 6 (bolded)

Overarching Design Conjectures	**Features in the MAR app**
1. Visualize 'seeing the unseen' scientific phenomena in digital simulations and animations.	After scanning a flower, a magnified view of a pollen grain is shown.
2. Place-based photographs, line-art, and text-based descriptions of the science concepts that connect to families' communities in the present day.	At all microlearning locations, content is given and then families engage in an observational activity to find real-world examples of the phenomena shown.
3. Immersion through AR filters and digital storytelling allows learners to imagine that they are in a new place or time.	A log is scanned and then the visitors can imagine the inside of a typical nest for a solitary, native bee is shown.
4. Use of movement across a space to represent unfolding storyline, aspects of a concept, or changes across time, space, or season.	A wayfinding map allows visitors to emphasize four critical ecological phenomena that come together to support how bees survive.
5. Sensory engagement via tactile and visual observation of objects or specimens on-site to support scientific noticing.	**At the log microlearning location, families use content provided to count and collect data on downed trees.**
6. Channel attention to key scientific phenomena through the families' photo-taking activities.	**The families use the content provided to identify pollen in the center of flower.**
7. Integrate on-site observations with digitally presented science content by creating a scientific journal.	The learners' photographs and bee observation checklist (of yes or no answers) are populated in a journal that they can review after the visit.
8. Discussion prompts or place-based activities that support sense-making and knowledge integration via focusing conversation on scientific phenomena and big ideas.	Families are encouraged to answer questions about the evidence of bees or other pollinators, talk about what they notice, the difference between a pollinator and human tongue, and what bees need in a habitat.
9. Discussion prompts support personalizing the experience via focusing conversation on prior experiences of the families.	Families are encouraged to connect their prior experiences with flowers, bees, and beehives/nests with the new content presented.
10. Discussion prompts, content, and digital activities to support environmental stewardship, personal connections, or community awareness.	Families discuss they humans could help maintain healthy bee habitats (e.g., by planting flowers that bloom at different points in the season).

Families navigated between micro-learning locations using a GPS map that tracked their location (Figure 1a) All micro-learning locations included text, photographs, and line art to support observations related what a bee needs to survive (I.e., food for self and young, water, diverse landscape, nesting locations) (Figure 1b). Micro-learning locations included digital augmented reality elements of science phenomena (i.e., bee nests inside of logs, microscopic pollen grain) layered over real-world objects to further families' observations and immerse them in more deeply understanding bee needs and habitats (Figure 1b). At the end of each micro-learning location, families took photographs that recorded what they learned and observed based on specific photo taking prompts (Figure 1d), which were then saved in their journal (Figure 1e). The first five micro-learning locations focused on a specific aspect of what a bee needs to survive in habitats like meadows and forests, while the sixth micro-learning location included discussion questions and activities that helped families bring what they had learned together and make connections across stops and the environment. For this analysis, we focus on the first five micro-learning locations where families were asked to take photographs.

Participants

Through our partnership with SCEC, the Center sent out Twitter, Instagram, and Facebook messages announcing the days and times that our team would be on-site conducting a research study. An article was included in the Center's member newsletter as well. Study recruitment bookmarks were placed at local libraries and a science center as well. Families had to have one child between the ages of 5-12 to participate and at least one of the adults who was present had to be the legal guardian or parent for all participating children. Families also had to be willing to be audio- and video-recorded; however, a legal guardian/parent had to opt-in to having their families' images shown in research-oriented publications such as this one. Families received one US $20 gift card for completing all study protocols.

Our team recruited 29 families on-site at the nature center; however, seven families were excluded from this analysis due to partial data. After written consent and children's assent was obtained, families borrowed an iPad^{TM} mini pre-loaded with the app, which also screen-recorded the family's tour experiences. At least one family member wore a GoPro mounted on a baseball hat to collect data from the learner's perspective. From the 22 families, there were 34 adults and 37 children. Of these families, their self-reported racial affiliation included White (77%), Hispanic or Latinx (6%), Asian (6%) and Other (1%). Children (male: 51%, female: 46%, nonbinary: 0%) were primarily 5-12 years old (78%; ages 0-4: 14%, ages 5-8: 49%, ages 9-12: 30%, ages 12+: 8%). Two families (7%) homeschooled their children. 68% of families had previously visited the nature center. All 22 families completed the MAR experience with just their consented family present and had full screen recording and GoPro — without interruptions of their recording due to battery, memory card, inadvertent shutting off screen recordings, or other common malfunctions.

Data sources and analysis

Data consisted of 14 hours of merged video data from 22 families. Post-visit interviews were conducted on-site and included questions about what families learned about pollinators as well as questions that asked families to reflect on their experience with the app to support further redesign. The families' screen recordings of the visit and GoPro videos were merged into side-by-side video files for researchers to consider both the outdoor environment and technological environment in the analysis. Post-visit interview files were created as well. The merged video files and post-visit interviews were transcribed professionally and checked by research team members for accuracy.

The merged data files were analyzed qualitatively by the first and second author. Researchers used a binary coding framework (I.e., yes/no questions) in Table 2 to analyze the recordings regarding if a) children were engaged during the photo taking activity, b) any family member made observations or connected to app content, and c) families or children expressed excitement during the photo taking activity for each GPS-triggered micro-learning location. Building on "blitzcoding" (Callanan, 2012), we used this binary coding scheme to quickly identify key learning locations throughout the data that could shed light on how families engaged with the digital photo taking features throughout the app experience. Prior to coding, the first and second author jointly viewed one video as a training session, and then independently coded five videos with 91% agreement. The coders worked through disagreement about discrepancies, and the code book was expanded and solidified. Next, the two researchers separately coded the rest of the videos with a shared understanding of the coding framework. We used the results from the coding to identify patterns across the families' interactions in the micro-learning locations. This coding analysis was then used to inform our selection of exemplar vignettes from two families at the different micro-learning locations. These vignettes served to expand upon the patterns in the coding analysis and to explore differences in family engagement and observations when taking photos with the MAR app. Post-experience interview videos were also reviewed to see how many families mentioned the photo-taking feature when asked for feedback about the app.

Table 2
Codebook for how families interacted with the photo taking app at each micro-learning location

Yes/No Questions	Description
Different photos?	The family takes three different photos (Ex: photos of three different flowers, photos of a log from three different angles)
Deliberate photos?	The family takes at least one picture that represents the photo taking prompt
Children engaged?	Engagement of at least one child in the photo taking activity. This could include taking photos, making observation, talk or non-verbal excitement or interest connected to the micro-learning location or photos during the activity
Scientific observation or talk?	At least one family member remarks about the app content or nature observed (Ex: "this one where there's a bug on it, that's the common milkweed.")
Children express excitement?	The children expressed excitement (Ex: running to find a flower, "Ooh, a bee!")
Other family excitement?	Other family members expressed excitement (Ex: pointing to a flower, "Ooh, a bee!")

Results

Overall, families enjoyed the ability to take photos, and the majority of families (55%) mentioned the photo taking activities as something that stood out to them when asked for feedback about the app. Throughout the MAR experience, families engaged with the photo-taking activities (Table 3) by taking the time to take different photos of aspects of nature they observed and make scientific observations or connections to the app content. While each micro-learning location included a similar photo-taking activity prompt around the selected ecological concept (Figure 1d, I.e., "take three photos of ___"), they all had different family discussion prompts and other activities that influenced families' interactions.

Table 3
Percentage of families that engaged with the photo-taking activity at each micro-learning location

Form of engagement	*Pollinators*	*Nectar*	*Nesting in Logs*	*Pollen*	*Diverse Habitat*
Different photos?	100%	100%	95%	100%	91%
Deliberate photos?	100%	100%	100%	100%	91%
Children engaged?	100%	95%	86%	100%	95%
Scientific observation/talk?	95%	86%	50%	95%	91%
Children's excitement?	73%	41%	27%	41%	73%
Other family excitement?	73%	41%	18%	55%	55%

The app asked families to take three photos but did not specify that those photos had to be of different things or at different angles (Figure 1d). Despite this all families did this at three of the micro-learning sites, and most did at the other two sites (95% at nesting in logs, 91% at diverse habitat). While families could have assumed that they were supposed to take three different photos, this practice could have also been driven by a desire to document different things that they had observed. At the other two micro-learning sites a small percentage of families did not take different photos, either because of an adult taking the same photo to get through that part of the app while the child was disengaged or because families were trying to capture one specific aspect of the location. All families also took "deliberate photos" or photos that represented the photo taking prompt at the first four micro-learning sites (Figure 2a, b, d), with two families not taking deliberate photos at the final micro-learning site. While one family was not engaged with the app at all, the other family was highly observant and engaged with the micro-learning location and photo taking prompt but was unable to find any pollinators to take photos of and just took pictures of the pond in general. Therefore, their photos did not fit our definition of "deliberate photos" despite the family spending a relatively long time trying to find a pollinator and making scientific observations about the location. Families with children that did not engage with the photo taking activity still could have one adult taking different or deliberate photos as a form of "rule following" but the children would be completely disengaged from the app. For example, one father took 3 different and deliberate photos at the nesting in logs micro-learning location but no one in the family spoke and their 8-year-old daughter was looking at something or watching her father take photos without engaging. Families could also have children that were engaged but did not take different photos. This only happened at the diverse habitat micro-learning location with two families while one of the children was attempting to take a close-up photo of the same pollinator that they had been observing (Figure 2c). Overall, 97% of families with children that were engaged with the photo taking activity also took different photos and/or deliberately took photos.

Diverse Landscapes
Your discoveries at the Pond
These are your observations of a pollinator finding food on flowers in a diverse landscape.

(a) *(b)* *(c)*

Individual micro-learning location analysis

The first micro-learning location about pollinators showed the highest levels of all coded aspects of engagement. This could have been because of the open-endedness of the photo taking prompt ("take three photos of insects"), the previous observation activity, or because it was the first part of a new learning experience. On the other hand, the solitary pollinators nesting in logs micro-learning location had the lowest levels of observation talk (50%), engagement (86%) and excitement (27% of children, 18% other family members). While families showed high levels of engagement during the rest of the activities at this micro-learning location, including an observation activity and an AR scan of the log, the photo taking activity did not elicit this response. This could have been because the families were still focused on the AR scan, or that the static nature of the photo taking prompt ("take three photos of logs") made this activity lackluster in relation to the other dynamic activities during this micro-learning location. The last photo taking location, covering diverse habitats at the pond, showed high levels of excitement (73% of children, 55% of other family members) and continued high levels of scientific observation and content comments (91%) but also showed a dip in taking different and deliberate photos (91%). These trends could have been influenced by this activity taking place late in the app experience (the fifth micro-learning location), children being excited to look at the other wildlife around the pond (frogs and turtles), or the two observation activities (family discussion and observation checklist) that preceded the photo taking activity at this micro-learning location. These trends demonstrate how families' experiences, talk, and engagement with the photo-taking as an observational recording tool differed based on app structure, environment, and family interactions at each micro-learning location. To investigate how families experienced the photo-taking activity, we analyzed vignettes from two families at different micro-learning locations in the tour.

Vignette 1: Photo-taking supporting observing flowers and pollinators on milkweed

At the nectar micro-learning experience (the second micro-learning location), families are introduced to two different forms of milkweed, common and swamp, that are planted locally as nectar for pollinators. The family of David (Father) and Amelia (6-year-old-girl) demonstrate how families used the photo-taking activity to continue their observations of pollinators that they did at the first find-a-pollinator location while adding in new content about milkweed and identification of flowers from the MAR app (Figure 3).

David: Milkweed ((points at the swamp milkweed))
Amelia: Okay. So, we'll first take a picture of the orange one with the bee on it. Got it. ((takes picture))
David: So that was the swamp milkweed, and then this one where there's a bug on it ((points to pink milkweed)), that's the common milkweed.
Amelia: All right. ((takes picture)) Now it said three photos. One more photo to do. Let's take a picture of two of them together. ((backs up to take a photo of the milkweed patch))

This family's interactions showed one way in which families engaged with the digital photo-taking features of a MAR app: supporting scientific observation by applying the content in the app with the specimens on-site. For instance, David brought together the content from the *MAR_app* with the local landscape during the photo-taking activity, referencing both types of milkweed plants (common and swamp) shown in the app when his family took pictures. While taking photographs, David and Amelia engaged in observations of the colors and types of milkweed flowers, as Amelia tried to take three different photos that captured what she observed. Their observations of pollinators on the flowers also influenced Amelia's choice of which orange milkweed to take a picture of, as she deliberately chooses the "one with the bee on it". In reviewing the photos, Amelia took in their journal, David remarked "those are great milkweed pictures", encouraging her photo taking and observation skills. In this way, the *MAR_app* supported families' sensory observation related to new science content such as the types of milkweed present on-site.

Figure 3
(a) iPad screen showing milkweed at the micro-learning location, (b) iPad screen of Amelia taking photos of the milkweed and pollinator, (c) David pointing out the milkweed, (d) journal showing their photos

There are two types of milkweed in front of you.

Can you find them?

Take 3 photos of the milkweed.

These are your photos of milkweed, an important source of nectar (carbohydrates and water) for bees.

Let's learn about meadow and forest habitats.

(a) *(b)* *(c)* *(d)*

Vignette 2: Photo-taking supporting identifying pollen on native flowers

During the photo taking activity at the pollen micro-learning location, families used visual observational practices to identify flowers containing pollen like those presented within the app. John (Father) helped his children, Maxwell (12-year-old boy) and Sean (6-year-old-boy) engage in these observations (Figure 4a, b). Both children showed excitement while photographing flowers containing pollen for their digital field journal.

John: Sean, are there any flowers over there, ready to find? Anything we can take pictures of? Sean, can you go over and see any flowers on that side?
Sean: I see purple! ((points to the flowers))
Maxwell: Oh, cool! ((excitement))
Sean: I want that one.
John: Okay, you got to take a picture of that. Good job, bud.

While helping the children select flowers that they could photograph, John shared prior knowledge in identifying the local flowers at the pollen micro-learning location. Through their visual observations, the children took photos of these flowers based on their interest and identification of pollen as seen across each flower.

John:	There's some more flowers right here. Did you see these ones?
Sean:	Oh yeah, I did.
John:	Those are daisies, maybe? ((points to the flowers))
Maxwell:	These are cool ones. I see a lot of pollen on these.
John:	That's right.

While reviewing their photos in the journal (Figure 4c) Maxwell showed excitement while saying "cool, right?" as he scrolled through the various photos that the family had taken up to that point in their MAR experience.

This family's interactions showed another way in which families engaged with digital photo-taking features of a MAR app: supporting scientific observation through prior knowledge and personal interests. Sean, for instance, focused on observing flowers that were a color he was interested in (i.e., I see purple!) and John was able to focus his family's second observation on daisies, something that Maxwell expressed interest in (i.e., These are cool ones.). By allowing the families to take multiple photographs, they connected the new content on pollen to each siblings' specific interests on-site.

Figure 4

Discussion

These findings demonstrate that throughout the MAR experience families were deliberate in taking photos that recorded their observations and the content of the app. Trends in across the micro-learning locations demonstrated how both the nature center environment and the features within the app impacted how families engaged with observations during the photo taking activities — especially the families' observational talk and excitement levels. As the two vignettes explored above demonstrate, families were able to use the MAR app's photo taking prompts to encourage observations of the environment and record-taking of those observations through the journal. In the first vignette, the photo-taking allowed Amelia and her father David to take photos that applied new scientific content of nectar and milkweed plants through their observations. In the second vignette, the photo-taking allowed siblings Maxwell and Sean and their father John to integrate their prior knowledge or personal interests with the new science content of pollen. These findings help to shed light on how families interact with photo taking, as a common design element in mobile technologies, within the broader MAR experience.

Returning to our orienting theory, the prior work has shown the importance of movement in outdoor education and science learning (Marin, 2020; Marin & Bang, 2008). Adding to this literature, this study's findings show that by designing for families to learn-on-the-move together, families could use digital photography to capture their observations of scientific phenomena. Table 3 showed that as family members moved through the gardens, all families took different and/or distinct photographs that captured their observations throughout the MAR experiences, moving through the space to take purposeful photographs that applied new scientific content.

Movement and sensory observations were important parts of the learning process as illustrated by John, Sean, and David pointing at flowers to orient family members observation. Families had to move around to capture different plants or pollinators, as shown by Amelia backing up to photograph both types of milkweed plants, and Maxwell moving around the pollen micro-learning location to photograph flowers in different locations. Other LOTM literature shows the importance of technologies such as GPS and mapping software (Silvis, et al., 2008; Taylor, 2017), as our work adds digital photography to the list of technologies that can help learners as they explore the outdoor places in their communities. While some prior work has shown the LOTM technologies can support interest (i.e., Kawas, et al, 2019), our work illustrates that having the opportunity to take multiple unique photographs may support families with siblings with different interests or ages (e.g., Maxwell and Sean), and that having directed photo-taking prompts may encourage families to look closer at their environment to connect content (e.g., Amelia), helping them stay engaged and focused on scientific observational tasks and ecological learning outcomes.

Our work has practical implications to informal science education. While AR and other related technologies have shown to support family learning (Kawas, et al, 2019; Yun, et al., 2022), our work demonstrates how an MAR technology including photo-taking, integrated into a specific location's walking trails, can support both science practices (i.e., observation) and science content (i.e., pollen and nectar as key food sources for native bees) learning outcomes.

Abstract: Amongst efforts to realize computer science (CS) for all, recent critiques of racially biased technologies have emerged (e.g., facial recognition software), revealing a need to critically examine the interaction between computing solutions and societal factors. Yet within efforts to introduce K-12 students to such topics, studies examining *teachers'* learning of critical computing are rare. To understand how teachers learn to integrate societal issues within computing education, we analyzed video of a teacher professional development (PD) session with experienced computing teachers. Highlighting three particular episodes of conversation during PD, our analysis revealed how personal and classroom experiences—from making a sensor-based project to drawing on family and teaching experiences—tethered teachers' weaving of societal and technical aspects of CS and enabled reflections on their learning and pedagogy. We discuss the need for future PD efforts to build on teachers' experiences, draw in diverse teacher voices, and develop politicized trust among teachers.

Introduction

As CS moves into K-12 education, most PD, curriculum, and research efforts have focused on teaching and learning CS content: concepts to understand principles and processes of computers and software (Seehorn et al., 2011). Yet injustices amplified by computing applications (e.g., Benjamin, 2019) demand that equal attention be paid to computing's "impact on society" (Seehorn et al., 2011, p. 1). This call has initiated a critical turn in K-12 CS education (Kafai & Proctor, 2022; Ko et al., 2022) that advocates for moving beyond the oft-adopted value-free stance on computing. Through pedagogical frameworks, researchers recently have proposed similar critical shifts in K-12 curriculum (Kapor Center, 2021; Madkins et al., 2020). Integrating a critical stance with technical learning is important when racist logics are embedded in computing abstractions and algorithms in computing tools often employed to 'solve' societal issues around policing and justice (e.g., Benjamin, 2019).

While many studies concerning K-12 student learning have added discussion units or even whole courses to examine computing critically (e.g., Vakil, 2018), far fewer have focused on teacher preparation to teach social justice issues within computing classrooms. Most current efforts in computing teacher preparation concentrate on inducting teachers certified in other disciplines, focusing on building teachers' technical CS knowledge (Menekse, 2015). A few recent studies highlight the challenges teachers face as they integrate computing with societal issues such as race and gender (Everson et al., 2022) and how White teachers may evade and deflect conversations around race within teacher PD (Goode et al., 2020). These findings suggest the need to better understand how computing teachers can learn to engage with and integrate critical ideas while learning to teach computing.

In this paper, we turn our attention to teachers (rather than students) as learners of critical computing. We analyzed one PD session where experienced high school computing teachers learned to teach an electronic textiles (e-textiles) unit. This innovated session, developed by a teacher-facilitator, integrated technical aspects of designing sensor-based physical computing artifacts with societal concerns, such as racism, that are embedded within inadequately designed sensor-based devices. Inspired by interaction analysis (Erickson et al., 2017; Jordan & Henderson, 1995) and sociocultural theories of teacher learning (Vygotsky, 1987), we conducted a collaborative video analysis of the PD session (with six teachers as participants/learners) to answer the research question: how do teachers learn technical and societal aspects of computing while participating in an electronic textiles PD?

Background

The design of the PD and the ensuing data analysis were informed by sociocultural theories of teacher learning, PDs as sites for teacher learning, and the teacher learning of critical aspects within computing.

Theories of teacher learning

A sociocultural perspective of teacher learning highlights how situated, social and cultural aspects shape professional identity development (Fishman et al., 2014; Shulman, 1987). Shulman (1987) viewed teaching as a practice and teachers as a part of communities of practice with shared understandings of teaching. He further framed teacher learning as developing fluency with practices of teacher communities, in interactions with one another and in a distributed fashion with expertise distributed across teachers (Fishman et al., 2014). These theories posit that teachers do not learn discrete, disconnected facts or skills but learn concepts as they relate to their teaching contexts, classroom dynamics, and personal experiences (Bukor, 2014; Enyedy et al., 2006).

Classrooms and teacher PDs are two prominent sites of teacher learning studied within learning sciences (Fishman et al., 2014). Studies that have explored teacher learning in classroom settings have examined teachers' interactions with both resources (such as curricular materials) and students in shaping their practice (e.g., Sherin & Han, 2004). Similar efforts involving PDs have either focused on different facets of teacher knowledge (e.g., Shulman, 1987) or on the social nature of teacher learning and the development of communities of practice (Fishman et al., 2014). Though attention to processes of teacher learning during PDs is important, scarce research details processes of how teachers learn to critically engage with disciplines or ask questions about the relationship between disciplinary knowledge and its interactions with communities and societies. This gap is especially significant in the case of in-service, experienced teachers who rely on PDs for professional learning opportunities to grow their ability to teach critical computing (Fishman et al., 2015; Goode et al., 2020). While studies related to student learning have highlighted the importance of, for instance, politicized trust—a race-conscious way of understanding, respecting, and being in solidarity with one another—in shaping learning of critical aspects (Vakil & de Royston, 2019), similar examinations of learning processes within teacher PDs are lacking.

PDs as sites for computing teacher learning

Previous research within computing education has highlighted key PD aspects that shape teacher learning: duration of the PD, connections to classroom practice, focus on learning methods and pedagogical content knowledge, and relationships within school districts (Menekse, 2015). This aligns with Fishman and colleagues' (2014) review of teacher learning within learning sciences that emphasizes extended durations, opportunities for engagement with content knowledge, practice-related aspects such as student learning, and reflection. But most research on computing teacher learning relies on teacher surveys and interviews as methods, revealing very little about the processes of computing teacher learning (Menekse, 2015; Yadav et al., 2016). Further, prior studies within computing teacher PDs focus primarily on disciplinary knowledge as a collection of technical aspects (Menekse, 2015), barely interrogating how teachers learn to expand the disciplinary boundaries and integrate critical societal concerns with technical aspects. An exception is Goode and colleagues' (2020) examination of teacher learning of critical issues in computing through an analysis of teacher discussions and interactions within PDs. With increased computing tools around us and heightened implications for marginalized communities (e.g., Benjamin, 2019), teacher preparation efforts should support teachers in critically engaging with societal impacts of computing. Recent equity-centered computing pedagogical frameworks underscore the need to "situate technology ideas within their sociopolitical context and give students opportunities to critique and explore issues that are relevant to them" (Madkins et al., 2020, p. 13). Buttressing this call, Goode and colleagues' (2020) study surfaces the need to support experienced high school computing teachers in engaging with societal aspects such as race during PDs. While limited prior studies highlight the struggles of teachers as they integrate technical and societal aspects (e.g., Everson et al., 2022; Goode et al., 2020), there is a need to further understand how to support teachers in critically analyzing the connections of societal and technical dimensions of computing.

Critical computing teacher learning

Mathematics and science education have explored how to engage teachers critically (Bianchini et al., 2015), laying a path for examining learning of critical computing. Questioning the relationships between computing, people, communities, and societies can support students who belong to historically excluded groups find their voices, engage with the discipline in personally meaningful ways, and contribute agentically to the discipline (Goode et al., 2020; Vakil, 2018). With concerns of teachers evading or deflecting race-related issues or blaming individual students for failures that have roots in historical and systemic racial oppression (Segall & Garrett, 2013), teachers should engage with societal issues such as race and racism, gender, and ability in computing.

While prior studies have proposed equity-centered pedagogies (Madkins et al., 2020) and critical pedagogical frameworks in computing (Kapor Center, 2021), we know very little about how teachers learn or develop critical perspectives at the intersection of technical and societal aspects of computing. Most efforts have been additive in nature—i.e., introducing the societal aspects in addition to the technical aspects—rather than integrating social and technical dimensions (e.g., DeHart, 2022). In other efforts where race-based conversations were purposefully integrated into teacher PDs, race-related issues were discussed in terms of recruitment and retention of students from marginalized groups—i.e., working on strategies to remedy the structural lack of opportunities—while computing concepts and constructs were discussed separately from how computing algorithms may encode racism and have implications for users from marginalized communities (Goode et al., 2020). Integrative approaches that consider programs and algorithms hand in hand with societal aspects that shape them, rarely studied, are limited to researcher suggestions of potential classroom activities and examples (e.g., Ko et al., 2022) rather than explored in action in PDs. Thus, we know very little about what goes on within such PDs, despite recent calls to integrate the societal and technical concerns and shift away from an additive approach of disconnected modules on equity and social justice within computing (Goode et al., 2020; Ko et al., 2022).

Methods

Context and participants

This study was conducted with the *Exploring Computer Science (ECS)* teacher community, developed over 10+ years to support teachers to teach *ECS* curriculum (an introductory computing course) built on three pillars: computing concepts, equity, and pedagogy (Goode et al., 2012). PDs involve a weeklong session for two summers with four day-long quarterly sessions between the two. Previous research has found this model useful to develop teacher communities (Goode et al., 2014). With electronic textiles (e-textiles) offered as an optional unit within *ECS* (Kafai et al., 2019), the e-textiles online PD was designed along similar lines: *ECS* teachers with prior e-textile teaching experience facilitated summer and quarterly sessions for *ECS* teachers new to e-textiles. As a part of a research-practice partnership (RPP), the PD had a diverse group of participants: university researchers and a non-profit partner, e-textiles-experienced teachers who were teacher-facilitators, and e-textiles-beginner teachers who were teacher-learners. Annie, Davon, Elisa, Julie, Leah, Maggie, Maria, and Leisha (all pseudonyms) were the teacher-learners with a wide range of experience teaching *ECS* (see Table 1 for their racial and gender identities, teaching experience and contexts). We analyzed teacher interactions during one of the quarterly PD sessions where teachers, except Maria and Leisha (unable to attend this session (1)), worked on a sensor-based e-textiles Human Sensor project and discussed technical and societal topics around it.

Yasmin and Joanna were senior researchers. Deborah and Gail, also senior researchers, partnered with teacher-facilitators to design and implement the PD. Kate works for a non-profit organization responsible for supporting PD online. Ben and Jesse, with Angela (not present during this session) were *ECS* teacher-facilitators with 4-6 years of e-textiles experience teaching. Ben facilitated the session on Human Sensor project. Leo, Mia (not present during this session), and Gayithri were three graduate student researchers. All of us identify as cis-women or cis-men. Among cis-women, Gail, Joanna, Deborah, and Kate identify as White, Gayithri as South Asian, Mia as Black, Angela as Asian-American, and Yasmin as Indo-European. Among cis-male, Ben identifies as White, Jesse as Latino-European, and Leo as Latino. Shaped by our teaching, learning, and research experiences within CS across diverse contexts, we are committed to center justice in CS education.

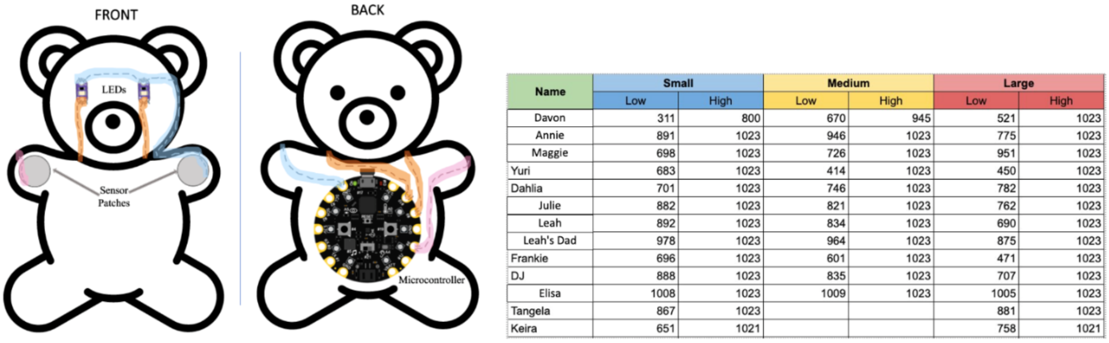
Table 1
Teacher-learner details.

Teacher name (Pseudonym)	Racial and gender identity	Teaching experience (years)	Teaching geography in the US	Student diversity[#]
Annie	White, female	26	Midwest suburban	40% RM; 30% FRL
Davon	Black, male	3	Southeast city	100% FRL
Elisa	White, female	10+	Northeast suburban	4% RM
Julie	White, female	19	Northeast suburban	33% RM; 20% FRL
Leah	White, female	28	Midwest suburban	7% RM; affluent
Maggie	White & Hispanic, female	8	Midwest city	Majority RM
Maria*	Black, female	6+	Midwest city	99% RM; 91% FRL
Leisha*	Black, female	20+	Southeast rural town	99% RM

The teacher-learners were working on the Human sensor project as a part of the constructionist-driven e-textiles unit (Kafai & Fields, 2019). As shown in Figure 1 (left), it required sewing a pair of aluminum patches to act as analog touch sensors when connected to the microcontroller pins and programmed using an Arduino programming environment. The teacher-facilitator team chose the lesson about computationally testing different sizes of aluminum patches as an opportunity for conversations about inclusivity of diverse users. By then, teachers had designed circuits and aesthetics to make 3-dimensional soft toys that would respond to different degrees of touch (no touch, soft, medium, and hard press). They tested sensors with family members and noted down the range of sensor values for different sizes of sensors (small, medium, big, Figure 1, right). The session after sensor testing was chosen for analysis since Ben orchestrated a conversation involving social and technical aspects of computing.

Figure 1

A human sensor project template (left) and analog sensor readings (right).



Name	Small		Medium		Large

Keira	651	1021			758	1021

Data collection and analysis

Screen recording of the online PD session (45 min.) is the primary data source. PD materials such as session agenda, teacher project designs, and teacher pre-PD interviews were analyzed to provide the video with context. As a first step, Gayithri analyzed teacher pre-PD interviews for teacher backgrounds and teaching contexts and examined project designs and the session agenda to contextualize conversations. The teacher group was the unit of analysis with a focus on group meaning making as discussions ensued during the session.

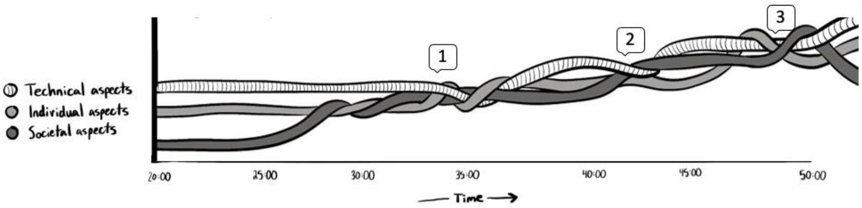
Inspired by interaction analysis (Jordan & Henderson, 1995), Gayithri structured collaborative video analysis (Erickson et al., 2017) supplemented by repeated individual viewing and interaction with the transcript. In this online PD session, interactions were multimodal, including verbal utterances, text-based chat, and screenshares, with embodied participation less visible. Gayithri initially viewed the video to prepare a multimodal transcript to capture talk, gestures, facial expressions, chat entries, and entries on shared documents. The transcript was elaborated with comments during three ~2-hour long iterative group viewing sessions attended by the author team. This allowed for cross-expertise discussions and exchanges of perspectives during video analysis (Erickson et al., 2017). The multimodal transcript served as a shared artifact that viewers interacted with while watching the video together, pausing the video for notetaking whenever required. Joint viewing sessions helped us identify three key episodes where the technical and societal dimensions interweaved in teacher discussions. Gayithri followed up with individual viewing sessions, rewatching the video in relation to the comments gathered, particularly to answer the research question. A visualization of the dynamics of the video was generated collaboratively by Mia and Gayithri (Figure 2) that represented the flow of the session, particularly how different aspects were initially individually discussed and then interweaved across the three episodes. The visualization was shared with the analysis group for further engagement with the emerging themes.

Findings

Teachers engaged with critical computing as they discussed inequities in technical designs and implications for diverse users within the context of their human sensor projects and real-world technologies, while anchoring discussions in their personal and classroom experiences (Figure 2 for visualization). Below we elaborate three episodes to demonstrate how teachers integrated the technical and the social aspects of computing, and how their experiences tethered their learning, supported by a trimmed version of the verbal transcript due to space limitation.

Figure 2

A visualization of the flow of the session.



Episode 1: Do you think everybody will be able to use your device the same?

During this episode, teachers grappled with technical decision-making around sensor value ranges within their individual projects and the implications of those decisions on different users. Upon designing the aesthetics, teachers had to determine the size of the analog sensor patches for their projects and program them to allow users to interact with them and generate four different light patterns. Towards that end, teachers were tasked with testing sensor patches of different sizes (small, medium, and large) with any family members around and noting the lowest and the highest values (Fig. 1, right). Ben asked teachers to determine four sensor value ranges that could be included within their programs to correspond to the four lighting patterns caused by different degrees of touch.

After the teachers determined the sensor ranges, Ben moved their attention towards the social aspects of the design. Connecting the numerical values to implications for users, he asked if "everybody will be able to use [the] device the same [way]?" (Table 2). While teachers had grappled with the dimensions of programming sensors at an individual level until now, they had to extend their individual observations and reasoning across their colleagues' datasets and discuss the human/social dimensions of these choices as they related to people who might interact with their projects. Design decisions, in this case, were couched inside the objective of not just making a functional project but one that includes diverse users. This brought in the broader societal issues of technology design in conversation with the technical details of programming, issues around who can and cannot use their projects. Teachers reasoned their choice of sensor value ranges in relation to their observations of their family members testing the sensors earlier and discussed implications of their decisions on such interactions. For instance, Davon noticed the effort it took him to realize a particular low value, reflected on how it might be difficult for Maggie's child who may not be able to exert the same pressure on the sensor. He said this led him to include the 0-500 range in his program to accommodate similar users. Maggie discussed her observations of her and her children's interactions with the sensor in terms of individual physiology and meaning making of possible interactions. Further, Davon acknowledged the limitation of sensor testing, i.e., he was the only person who tested his sensors (Figure 1, right) and how that further shaped his decisions around sensor value ranges for his project. Overall, in bringing the technical aspect of programming analog sensors in relation to users' interactions and experiences, social aspects were no longer a modularized concern but deeply integrated with the project code.

Episode 1 transcript excerpt at 34:24.

Verbal transcript	Verbal transcript
Ben: **Do you think that everybody would be able to use your device the same?** *Elisa, Maggie, and Leah shake their head to tell no.* Davon: Probably not [unmuted by mistake]. Oh! Ben: So why don't you talk to me, why not? What differences do you see? How are the decisions that we make in these light patterns going to manifest in terms of how people use the thing that we're making? Davon: Well, I know for me like I'm using the regular one [medium-sized patch], so I don't know… I had to squeeze real hard just to get my lower numbers, **somebody might not be able to squeeze.** Ben: [reading from chat] Your light pattern four is from zero to 500 right. Did anyone get down to below 500? Maggie: I didn't but my daughter did. And, so in our case, at home, we all did it differently. I was pressing on top of the table. My oldest was holding and squeezing…	Maggie: And then, the youngest was just like, barely touching it. No, I don't think we'll all get the same, because we all did it differently… **it depends on the individual**, it depends on how they want to do it… all those little details I think matter. Ben: So, it sounds like there are differences in terms of individual physiology, number one. Number two, the cultural ideas of how we do the thing… There's an environmental aspect possible like maybe if you're in like a drier area, things might be different than if you're like in a wetter area… there could be some other things happening here and it's all completely individualized. Davon: Yeah, and that's what I was trying to say… my strength might be stronger than a child, Maggie's child, you know, was different. So that's why I didn't want to eliminate that 500 and below because you never know… because **we're just one person that kind of check the data**. Ben: I love what you're saying.

Episode 2: Everyday technologies that are not inclusive

In addition to connecting sensor ranges to user interactions within e-textiles projects, teachers continued to weave societal and technical aspects as they discussed various sensor-based technologies that excluded or caused ineffective outcomes for certain user groups. Conversations around inclusive design of individual projects in the previous episode shifted to everyday technologies that "did not think through inclusiveness" (Table 3). Teachers drew from a range of personal connections and discussed how technologies in their lives did not include marginalized populations. For instance, Leah mentioned cell phone touch screens that assume certain physiological characteristics such as shape and sensitivity, and Elisa shared the lack of consideration of human aspects in the design of motion-sensor lights in her classroom. Further, Julie shared about her five-year-old with Down's syndrome and his struggle with voice assistants like Alexa.

However, lively conversations only occurred when teachers related their lived experiences. Otherwise, there was awkward silence. For instance, teachers barely engaged when Deborah and Ben presented examples from outside personal experience, such as pulse oximeters that "don't work well for dark-skinned people" and airport scanners that have "a much higher significant hit on Black women's hair" respectively. Perhaps bringing in external sources disrupted the conversation or perhaps the lack of personal connections among teachers in the room triggered the silence. Except Davon, all other teachers in the room identified as non-Black and not dark-skinned (two Black female teachers were absent: Maria and Leisha, see Table 1) which could have led to silence around topics related to Black community's interaction with technology. This alludes to the need for diverse teacher experiences within PDs and supporting non-Black teachers to engage with race-related topics.

Table 3
Episode 2 transcript excerpt at 40:49.

Verbal transcript	Verbal transcript
Ben: Can anyone think of any **technologies that you work with every day that did not think through inclusiveness**, where there might be some users who might not be able to use the device based upon some physical or cultural or human things? Leah: I would say, touch screens on cell phones and individuals who have like large fingers, or their fingers are starting to lose sensation, and **it's really difficult to accurately press the right keys on those keyboards**. Ben: Yeah… For sure. What else? What are some other examples that you know that you might notice differences in how people interact the technology? Elisa: So, lights in my classroom. Well, one of my classrooms, goes off and like leaves me in the dark and it's not enough to do this [waving hand]. I have to get up and walk to the right place. Ben: So, **the sensor on your light was not designed with your configuration in mind.** Elisa: **With actual people probably** [laughs] Ben: [laughs] With actual people in mind. Julie: My son, my five-year-old has Down's syndrome, so we have a lot of adaptive technology and a lot of adaptive supplies like scissors, for example, is something that's adaptive because he doesn't have as much strength, so he has special scissors. But as far as tech go, like higher tech, you know, **Alexa is really hard for him to communicate with**…	Julie: I think Google somewhere in Canada, they're having people with Down's syndrome… collecting different people speeches to try to advance those technologies. Ben: Does anybody else here, or their family have challenges with using Alexa, or Google or any of those speaking technologies? [Ben raises hand in response to his question, and other teachers including Davon, Leah raise their hands too. Julie smiles and nods in agreement] Ben: Yeah, my grandma was from Russia, and good god trying to watch her try to integrate with Alexa… really frustrating for her, because it didn't understand her very, very thick accent… I've seen Texans struggle with Alexa… you think that the only foreign people can't use. No, no, like, people, people in Boston have difficulty with Alexa, because it doesn't know what about a car [in Boston accent] is. Ben: The sensors that measure oxygen by touching your fingers the pulse oximeter [reading from the chat]. What about that Deborah? Deborah: Well, **they don't work as well for darker skinned individuals**… So, clearly their user sample's not very great. Ben: Or for example, those things in the airport, they go around you like that zzzz, to make sure that there's nothing on you. **There's a much higher significant hit on Black women's hair**. So, if you are a Black woman going through that security system, you have a significantly higher chance of being removed from line. [**silence in the room**]

Episode 3: Experiences as a tether

Throughout, personal and classroom experiences tethered teachers' weaving of societal with technical aspects. Making the project put the teachers in students' shoes and enabled reflections on their learning and pedagogy (Episode 1). Building on Episode 2, teachers drew from their personal experiences with everyday technologies to identify bias. Drawing these together, Ben prompted teachers to "link" between the two (Table 4). Coming back to technical implications around determining sensor ranges in their projects, teachers concluded the need for "inclusive sample for testing" and again grounded conversation in their personal experiences.

When Ben encouraged teachers to connect classroom practice and think about supporting their students to do the same, teachers drew from their prior teaching and learning experiences to derive lessons for classroom practice. Of particular note, Annie shared how her students in a different class designed a pair of sunglasses without considering gender diversity among testers (Table 4). Narrating this instance, Annie reflected on her knowledge of her students and how she "ignorantly… thought [her students] would get inclusive feedback." She instead concluded that "it's very important to help kids understand who should be in the sample size." Not visible in the transcript, other teachers like Leah discussed other pedagogical approaches such as asking "who's missing in the sample data" to support students through critical computing. Overall teachers' experiences—technical, personal and classroom—acted as a tether to learn to integrate technical with societal concerns during the PD.

Table 4
Episode 3 transcript excerpt at 46:15.

Verbal transcript	Verbal transcript
Ben: So, how is this conversation, based upon the activity that we just did, **what's the link?** Ben: [reading from the chat] Making sure we're being inclusive in our, in our designing.... So how having a mindset for that we need to be purposeful in our designs. Leah says using an inclusive sample for testing. **Was our sample inclusive?** If we were trying to create a product for all people in the United States, is our sample, inclusive enough? Davon: No. Ben: Yeah, so maybe the people that you're sampling needs to broaden, maybe we need to bring more people in when we test. Absolutely... **What would you do in your classes, in this moment, to bring out this conversation, to bring out these ideas?** How would you handle it, would you handle it? Do you think that this is a moment that's important, and that needs to happen? Annie: **I just have to share this happened in my class this week.** I teach a manufacturing class. And, it's all boys and a male teacher and me. And one of my groups are manufacturing wooden sunglasses. So, they've made some different prototypes of these sunglasses and their challenge this past week, was to test them with their friends… get some feedback. So, then they came back and they said yep, you know, based on all of our feedback, this is what we're going to go with…	Annie: And then they're working with a local company in town to actually manufacture 100 of these prototyped sunglasses. So, they said they're ready to go, they've done their research. So, I said, well, you didn't ask me to try them yet. So, I said let me try them and give them feedback, and I put them on and they immediately fell off my face. And I said you guys. I don't think we're good yet to say, we have 100 of these, like, let's talk about the sample of who you checked with. Well, then talking with them and in my ignorance when I said go ask your friends go out to the cafeteria get feedback. **I thought they would get inclusive feedback**. They only tried them on other boys. So, and other boys their age, who have a different head size than me. So, I said—now we're going to classrooms throughout the building and asking people through it out different classes. And, so we actually talked about sample size… We have to come up with sample sizes that are inclusive. Ben: Talking about sample, when we're talking about design. Annie: Right. Very much so **it's very important to design and helping the kids understand *who* should be in that sample size**. Because I mistakenly thought they would have a broad representation, and then they didn't on their own. And I think some of these companies too, you know, you think you're good. And then all of a sudden, oh wait, we're not good.

Limitations

A limitation of this study is the context which involved a particular group of teachers—experienced *ECS* teachers with an established sense of community, developed while attending *ECS* PD sessions together in the past. Further, they were attuned to equity and justice issues in computing education as they read and discussed *Stuck in the Shallow End* (Margolis et al., 2017) in *ECS* PDs and developed politicized trust (Goode et al., 2020). The findings presented above are couched in this context and further research is needed to understand how these findings relate to PDs with teachers not necessarily having already established relationships and commitment to equity.

Discussions and conclusions

This analysis sheds light on dimensions of PD activities that can support teachers to engage critically with STEM disciplines like computing. Across the three episodes, teachers made connections with their lived and classroom experiences as they engaged with issues of technology design with implications for diverse users. The significant role played by teachers' personal experiences is comparable to earlier studies (Bianchini et al., 2015; Bukor, 2014). In cases where such connections were absent, as seen in episode two, teachers struggled to converse about critical issues brought up by leaders. This connects with prior research that revealed the struggles of White teachers in engaging with race-related conversations within computing PDs (Goode et al., 2020). Of note, even in our group of six teachers—four White—who had experience with discourses of equity through prior PDs (which they had all led), personal experience seemed particularly important for grounding both technical and societal sides of conversations. Future PDs need to consider how to build on teachers' lived experiences and create new experiences, draw in diverse teacher voices, and develop politicized trust among teachers.

Having diverse perspectives in PDs helps build thought-provoking interactions (as noted in episodes two and three), just as diverse technology design teams mitigate biases in technology design. As teachers build on their personal experiences from their lives and classrooms during PDs, having diversity along those lines will expand the accounts discussed in PD settings, just as Julie's personal experience with her child's use of voice assistants brought in a particular perspective to discussions around inclusive design of technologies and projects in episode two or Annie's classroom experience added a particular perspective in episode three.

Yet another key contribution of this analysis are the contextual factors that shaped the findings, in particular, creating a common project (like the human sensor e-textile project) and building on existing teacher relationships with politicized trust (from earlier shared PD experiences). Sensor-based devices, by their design, can encode inequities based on who's included in user-testing and who's left out (e.g., Benjamin, 2019). The e-textile human sensor project, which involved programming analog sensors, enabled teachers to discuss and consider programming aspects with broader societal issues around sensor testing and to connect with the larger issue of myopically designed sensor-based devices such as voice assistants, enabling conversations grounded in but extending beyond e-textiles. At the same time, this focused hour of PD built on six prior days of relational work, with shared crafting times, reflections, family interruptions (characteristic of long video calls) and other shared experiences, including an explicit invitation to test their sensors with others in their household members. Combined, these shared technical and social experiences made room for teachers to grapple with issues of inclusive design while trusting the space as safe to discuss their perspectives. Doing similar work with other teachers in other contexts will mean designing and creating such spaces for teachers to engage in similar ways. Sharing materials like a book, e.g., *Stuck in the Shallow End* (Margolis et al., 2017), that allow for political conversations in relation to the discipline (Goode et al., 2020) and creating technical projects, such as the human sensor project, lay the groundwork for disciplinary integration. Building relationships over many days, as the *ECS* model does across 14 days over two years, can provide the grounding for tethering technical, personal and societal aspects of computing. These combined technical and relational underpinnings will allow for integration beyond the more traditional additive or modular means of bringing up equity and justice-related issues in computing-like disciplines (DeHart, 2022). Many more future PD and teacher-learning studies are needed to explore integrating societal issues with computing content in the effort to bring critical computing to the fore in K-12 education.

Endnotes

(1) Teachers could not be present during the session analyzed; ($^{\#}$) RM == Racial Minority; FRL = Free and Reduced Lunch.

Abstract: This paper uses an intersectional feminist lens to examine the discursive practices of a researcher and mathematician engaged in conversation about the practice of mathematics. The mathematician, a Mexican American woman of color, shared experiences of marginalization and belonging in mathematics, and how these were shaped by her racial, gendered, and cultural subjectivities. By focusing on how participants in the conversation co-constructed ideas around what it means to do mathematics from a location in the margins of mathematics, analysis reveals the social, collaborative, and cross-cultural dimensions of the practice. It shows how the learning of mathematics was facilitated by participation across different communities, settings, and contexts. Findings urge for a closer attention to mathematics as inherently social and political in order to counter processes of erasure in mathematics education.

Purpose

What does it mean to become a mathematician? What does it mean to become a mathematician in the political and social margins of the field? Recent research on marginalization in STEM environments has elaborated on the ways in which those disaffected by mathematics and science persist in those fields and resist their oppressive impositions (e.g., Gholson & Martin, 2019; Sengupta-Irving, 2021; Sengupta-Irving and Vossoughi, 2019). Such accounts have made visible the often untold stories of marginalized persons in STEM by adopting critical feminist methods that take the margin seriously as a site of political, practical, and social transformation. We draw on hooks (2015) when thinking of the margin as a place of empowerment, from which to “see and create, to imagine new alternatives, new worlds” (p.150). To theorize from the margin is not merely about occupying a subjugated location; it is also about what one does from such a location and how moving across subjugated locations shifts what we see, how we see, and the stories we tell (Haraway, 1988). For Haraway, “the standpoints of the subjugated are not ‘innocent’ positions,” and they are indeed preferable as a location from which to conduct research “because they seem to promise more adequate, sustained, objective, transforming accounts of the world” (p. 584).

This paper is part of a study invested in surfacing the gendered and racialized facets of mathematics teaching and learning. By examining the role of race and gender in the production of mathematical knowledge, it seeks to make contributions towards understanding the political processes through which people come to be included in or excluded from mathematical work. The analysis presented here traces one scholar’s construction of herself as a woman of color in mathematics by analyzing a conversation she has with the first author about her journey through mathematics. The broader study takes a feminist phenomenological approach to center consciousness, intention, and orientation as people navigate their various (cultural, social, and practical) worlds (Ahmed, 2006). By surfacing the stories of mathematicians who experience race-, gender-, and class-based marginalization in mathematics, it aims to better understand why mathematics remains, two decades into the twenty-first century, an elusive pursuit to Black and Brown folk and gender minorities (Gutiérrez, 2013; Leyva 2017; Martin, Gholson, & Leonard, 2010; Waid, 2020). We use such stories to explore how race, gender, and society shape learning, knowledge production, and practice in mathematics.

Theoretical framework

Two theoretical perspectives frame the analysis presented here. First, the project is premised on the idea that being a part of the social life of mathematics occurs through shifting participation in communities of practice (Lave & Wenger, 1991). Legitimate peripheral participation (LPP) advances the idea that thought, learning, and action are mutually constitutive processes that unfold against a blended background of time, place, social and cultural relations, and politics. An LPP lens held over communities of practice (such as the practice of professional mathematicians) views learning as particular to the concerns, goals, and practices of the community, so that all learning is understood as shifts in participation in community practices. This contrasts with traditional cognitivist understandings of cognition as an internalization process, offering instead that learning (and by extension engaging in a community of practice) "concerns the whole person acting in the world" (Lave & Wenger, 1991, p. 49) rather than acquisition of knowledge and practices. The idea of the "peripheral" in LPP therefore refers to all participation in a practice, and as an analytic lens as "a source of power and powerlessness" (p. 36) helps surface the different ways in which actors may engage in the labor of the practice by participating in activities across multiple intersecting communities.

The second lens in our theoretical framework considers how experiences of marginalization shape how persons come to be in mathematics. Drawing on Star (1991), we conceive of marginalization in mathematics as the simultaneous experience of both *belonging and not belonging* to the community of mathematicians. Star described the often-fraught negotiations one must engage in when one is both a member of a community of practice (say, of mathematicians) and marginalized (say, by race and gender) within it. Thus, the experience of marginality engenders multiple selves, and the encounters of these selves across various intersecting communities affect how one might access, act upon, resist, and make meaning across these communities. In the analysis presented here, we explore how opportunities to participate in mathematical work are refracted through participants' cultural experiences and social commitments across communities. Engaging with the marginal in this way—as a site of contestation that exists both within and outside the field of mathematics—helps illuminate mathematical tradition and convention and how these are regularly challenged and transformed by those who experience marginalization (Becker, 2014).

Together, the idea of learning as shifting participation and Star's conception of marginalization as a transformative experience construct a theory of becoming, or of "the historical production, transformation, and change of persons" (Lave & Wenger, 1991, p. 51). Our use of the word "marginal" is distinct from Lave and Wenger's conception of the "peripheral" in "legitimate peripheral participation." Whereas marginal participation is produced and reinforced by shared experiences of isolation and exclusion from wider communities, legitimate peripheral participation describes *all* participation in a community. Lave and Wenger commented that peripheral participation "is about being located in the social world. Changing locations and perspectives are part of actors' learning trajectories, developing identities, and forms of membership" (p. 36). Peripherality is thus a moving social location "at the articulation of related communities" (p. 36) that facilitates exchange across these communities. In other words, whereas marginality within the community of mathematicians is engendered by political and cultural subjectivities, peripherality helps articulate movement within a community through differing participation.

Data and methods

Data analyzed in this paper consists of one 43-minute conversation over a virtual video medium between the lead author and the focal participant, Carmen, as they discuss their experiences as mathematicians, researchers, and educators across contexts on a Monday morning in the fall of 2022. Carmen is a Mexican American woman of color and professor of mathematics at a public university in a midwestern city in the United States. In addition to these identities, Carmen's experiences as a mother, wife, daughter, sibling, and second-generation immigrant emerge as salient in the analysis presented here. The first author, who is in conversation with Carmen, is a graduate student and faculty of mathematics education at her university; she became a mathematics teacher after experiencing discontent in higher mathematics. The first author also identifies as a queer South Asian brown woman in the US. Also present during the conversation is the sixth author, a Chinese-American woman and first-generation college student in the Mathematics Education program at the same university as the first author. The remaining authors are members of a research group with a shared commitment (as educators and researchers) to questions of marginalization in mathematics (as belonging, not belonging, and possibility) and collaborated on analysis. We do better analysis when we're together, too.

Throughout the discussion, Carmen and the first author are engaged in conversation and make different claims about the social life of mathematics, weaving a narrative that oscillates between portrayals of the practice as sometimes lonely, sometimes explicitly social, and at other times resolutely solitary. Our goal was to examine the conversation for insights into how Carmen viewed her arrival in mathematics, especially looking for ways in which mathematical work and learning are transformed by racialized and gendered subjectivities. Analysis showed that learning to become a mathematician entails engaging in the practices of several communities at once, and that together these practices shape access and belonging in the mathematics community. We argue that mathematics is a social and cultural practice that, for Carmen, is facilitated by racialized and gendered marginality and possibility. We contend that we are able to surface this telling through anti-patriarchal methods premised on the idea that historical contributions, curiosities, and relations of women of color have been transformative of science and society (Prescod-Weinstein, 2021). For Carmen's telling, this approach illuminates the dually productive and inhibitive familial and academic relationships that propel mathematics.

Analysis

We attempt to tell Carmen's story of becoming a mathematician by looking for the social, relational, and affective negotiations Carmen made when describing her experiences of mathematics. We center Carmen's location in the margins and consider her peripheral participation from this location across a set of related communities. Our analysis begins with Carmen's affective experiences of mathematics. We then analyze what she referred to as "life-changing" events that contributed to her "survival" through intense periods of social and disciplinary loneliness. Following this, we look at the various "contradictions" she noted between being a Mexican American and being a mathematician; along with her difficulty in balancing the demands made on her by her work with those made on her as a wife, mother, and daughter. We go on to argue that the very aspects of her home culture that Carmen experienced as being "at odds" with her pursuit of mathematics helped sustain that pursuit. We conclude our analysis by focusing on Carmen's construction of "the place where [she became] a mathematician."

The first author began the conversation by describing her experiences with mathematics, followed by Carmen describing her experiences at a community college and in graduate school.

> **Carmen**: So I – I started at community college when I was a – an undergraduate, and it really had me confront the fact that I was very mathematically um immature. I did not have the right background to start taking, like, calculus courses or anything like that. But starting, you know, I like my first math class in college was intermediate algebra, and so I would tell this story that I remember being in class, and the – you know, the teacher is saying, okay, we need to factor a polynomial and to do so, we need two numbers that you know multiply to six, and add to five. And I was like – like good luck, like numbers don't do that like?
> **Author 1**: <laughs>
> **Carmen**: <scoffing> What are you talking about, two numbers that multiply the six, and that add to five? And like I have this attitude of like, where and am I ever going to use this like? Why is this helpful, like? I was just so jaded. Um! And then she was just so kind, like, that teacher was just amazing, and she was just like, no, no, no, like you should practice like. Write down some numbers that you know that add to five, and then multiply them and see what you get. So I, as I was doing that, like I just remember this, like, vividly this moment where I was like, huh! Oh wow, like this actually works. And she just, you know she just encouraged me like I. It was just like such a fleeting moment, but like it has stuck with me so much because I think about it often like how a lot of the the culture, or like the really terrible things that I've experienced, have sort of always been fleeting, too, like they're like comments in passing; something that gets said in the hallway. Something that happens at a department meeting, and they, they bombard me like there's so many little—little tiny things that happen all the time that I try to remember these small little things that also happen that were life changing and like that was one of them, and had she not reacted in the way she did, at that point like I hadn't built enough resilience to have survived, had she reacted in any other way. And so I – so you know. And then from there on, like I just kept taking math classes. And so my – my math background got better and better and better. Um! But it really was, like, from starting where I needed to start. That was really helpful.

Carmen's speech patterns in this excerpt point to the affective nature of mathematical work: her references to being "mathematically immature," "so jaded," "bombarded" by unsettling incidents, and about not having "built enough resilience to have survived" indicate that Carmen's experiences of mathematics were also deeply felt. More specifically, engaging in mathematics can produce different kinds of feelings in participants: we see this in the urgency and excitement with which she describes moments of clarity in doing mathematics and in the halts and pauses in her speech when discussing moments of dejection. These feelings described simultaneously as "(small) little (tiny) things" and as "life changing," shaped how she was able to approach mathematics. In addition to feeling, the social-relational also emerges as salient in this excerpt: Carmen traced her "survival" in mathematics to her "kind" and "amazing" community college teacher who "encouraged [her]." Being a part of the mathematics community, then, can evoke different kinds of feelings, often in response to the interactions one has with other members of the community.

Carmen described another "life-changing" event, one in which she encountered a Latina Professor in Mathematics for the first time. This occurred at a mathematics conference, one of many she had started to attend as a way of combating the intense social and disciplinary loneliness she was experiencing in graduate school:

> **Carmen**: And so I went, and it's the first time I got to meet another Latina professor… You know she had just graduated, and she had a poster, and I don't even know — it was like, you know, solving some sort of equations with elliptic curves like it was not at all related to anything I knew, but I was just like I just remember staring at her face and just being like she's Latina, and she speaks Spanish, and her parents are from Mexico, and like it was so life-changing that I think, had I had that earlier on, I probably would have like just felt happier? Because I was lonely, and I was just making the best of it. But once I found her I was just like, okay, like there are people like me that do math who have good careers and, like, understand how sometimes the culture of being Mexican American sort of is in contradiction to being a mathematician.

Carmen spoke of how the loneliness she had so acutely felt in graduate school up until the experience of this conference dissipated upon finding "another Latina professor," even though this person was not doing anything "at all related" to her field of mathematical study. Becoming a mathematician, then, it as much about the particulars of the mathematical ideas one is grappling with, as it is about the social-cultural location from which one engages in mathematical work. Here, again, the affective current in her narrative is striking, from being "lonely" to feeling "happier" upon encountering someone else familiar with her subjective racialized and gendered experiences. When the first author asked Carmen to say more about the "contradiction" she had noted between being a Mexican American and being a mathematician, Carmen alluded to the demands made on her time by her various roles:

> **Carmen**: So there's like, this – this, like, tug, because I had demands on my time to like, be able to do graduate school justice, but also demands on — the expected sort of behaviors of what it means to be a wife that were imposed on from my mom's culture right? Like for her it was – you are — you are not a good wife unless you are ironing your husband's clothes, making sure that you were packing him a lunch every morning, you know, and make sure that he eats before anybody else. He sits down at the table before anybody else. Like, all of these very sort of traditional wife roles that I just was like. If I do all of that, I cannot do the things that I want to do, because there's just not enough time in the day. Um! And so that part always just felt so in contradiction, like I would see my you know my colleagues and my friends at school like they didn't have those demands, or like additional cultural burdens on them in some sense, right? Um! They could just go out on a Friday to go get a beer and talk math and like I never could, like. I had to figure out how to balance those two things that just felt that such odds? I think that's, that's sort of the—the thing that I—I'm thinking in my mind when I think about how in contradiction these two things were where you're like, where the mathematical culture is. You dedicated wholeheartedly, wholeheartedly your life, your time, your energy, your whole being, to solving mathematical problems. Well, that doesn't leave any time to be this, like, perfect wife and mother and daughter, who, like, values family and, and goes above and beyond in that realm like there's just not enough time to do, you know, all that.

Carmen described experiencing the tensions between her "mom's culture" and "mathematical culture." The demands made on her by her work were, she noted, at "such odds" with the demands made on her as a wife, mother, and daughter. Empirically, the tension that Carmen spoke of experiencing exemplifies what Lave and Wenger (1991) refer to as legitimate peripherality being "a position at the articulation of related communities" (p. 36). In describing the responsibilities she had at home as being "in contradiction" with mathematics, there were suggestions of her home culture "as a place in which one is kept from participating more fully" (p.36). Lave and Wenger discussed such legitimate peripherality as a place of *flux*, where it can serve to empower or disempower members from participating in the activities of the community. In her speech above, Carmen constructed burdens that disempowered her participation in the community of mathematicians that she saw as resulting from her subjectivity as a Mexican American woman, mother, daughter, and wife. Mathematics, as Carmen initially encountered the practice, was not organized around the cultural values and expectations of this subjective position. Notably, Carmen earlier had emphasized that educational opportunities had been kept from her parents; while some opportunities may have expanded for her to enter a graduate program, more full participation in mathematics demands cultural negotiation for mathematicians who experience racialized, gendered, and class-based oppression.

Carmen's difficulty in balancing "those two things that just felt at such odds" also emphasizes Star's (1991) argument of how marginality is experienced by members of a community: as the simultaneous experience of being part of the community and being apart from it. Access to some of the more traditional, informal ways in which mathematicians engage (such as getting a beer on a Friday night with other students and professors of mathematics) was restricted for Carmen, not because of an active exclusion by the community of mathematicians (which is certainly one dimension of marginalization), but instead through a more veiled exclusion based on incompatibility with her responsibilities in other spaces that precluded her from participating in the informal social practices of the mathematics community.

From a feminist perspective, Carmen's allusions to the particulars of her responsibilities at home evoke Prescod-Weinstein's (2021) call for an attention to what sustains the labor of the scientist:

> We don't talk about the women at home making those Nobel Prizes and experiments and theories possible. The mothers and wives who kept sheets and clothing clean and did all the kid-related things so that their husbands could focus. (p.184)

In not talking about these things, we are simultaneously erasing the possibility of these very groups—the groups that sustain the scientific workforce—pursuing scientific thought and careers themselves. Carmen—who, as we noted earlier, operates from the intersection of multiple communities and subjectivities—is called on to perform both the labor of the mathematician and the labor that *sustains* mathematical work. The absence of the latter would mean having to forgo the former, impeding her access to legitimate peripheral participation in the community of mathematicians. When directly asked about how she navigated this tension, Carmen speaks of the people in her personal life who helped her with her responsibilities at home:

> **Carmen**: Yeah, I think it also comes back to… so I'm the oldest of three. And my sister and my brother are six years younger than me, so my brother's six years younger than me, and then my sister another five. So she's eleven years younger than me. And so by the time that I had my daughter, my sister was a teenager.
> **Author 1**: <eyes widen> hmmm.
> **Carmen**: And so one thing that yeah, and my brother as well, right, but like would help me a lot. Once I found out that math conferences were a thing, I could go away for three days, you know. I could be like, okay <brother, sister>, can you watch <name of daughter> like stay at my house? Just watch her for those two days, three days, so I can go to this math conference, and they were like, okay, sure, like they're not doing much. And they're just working with the kid. And so they would stay at my house, and then you know my dad and my mom would drive by and give them food, or whatever, and but they're just sitting there watching the baby for those two three days, and then I could go, and I had like no responsibilities…
> **Author 1**: Mmhmm

In the excerpts above, Carmen's relationships and community at home were transformed into resources through which she was able to access mathematics spaces. The struggles she described earlier—of having to balance responsibilities at home with the responsibilities of being a mathematician—were overcome through the support of the very culture that was making other demands on her time. Support systems and networks of relationships at home enabled her to dedicate time to being a mathematician and mathematician alone ("I am here for the math"). This reliance on support systems in her home community speaks again to Lave and Wenger's (1991) assertion that legitimate peripherality is lived at the articulation of several related communities of practice, and this location can either prove to be empowering or disempowering. The very community that had earlier been described as being in contradiction with the work of being a mathematician emerged as crucial to supporting her work in mathematics. Here, the housework to sustain mathematical work was being performed by the communities and families of the woman of color at the center of this analysis. Her Mexican-American culture, thus, became a resource that enabled Carmen's fuller participation in the mathematics community. It made possible a life devoted to mathematics without having to attend to other demands:

> **Carmen**: I am here for the math. I am here for the people. I would talk to everyone. I would go to like, maximize all the talks I could go to, and then the afternoon. It was like time to write all of the things that I needed to do, you know, for my, my own research, my own talks. And so those like those short periods of time became what I imagine traditional mathematicians have every day. <laughs while saying this>
> **Author 1**: <follows with laugh as well>

> **Carmen**: Hide and concentrate. And you know I could just, you know, like the conference organized the food. I mean. It was like I had a wife right like it did. I didn't have to clean the hotel room like I didn't have to do laundry. I didn't have to let the dog out. I didn't have to think about feeding the baby, or putting her to bed or bathing her like I literally could just go away for those three days and just – just – be a mathematician.

Being in community with mathematicians entailed also being in community with her home culture. The two cultures were no longer framed as being "at odds" with one another, and the sustaining force of her familial relationships helped her participate in the social life of mathematics the way she imagines "traditional mathematicians" do. Without the responsibilities of cooking and cleaning, conference life "was like [she] had a wife," so in the "here" of the conference she could "just—*just*—be a mathematician." The "here" in her framing was also an elsewhere, a place different from home or even her university. It is worth noting that this empowering elsewhere of the conference space was realized by the labor of those at home who were helping her with other duties, and the labor of service workers cooking and cleaning for conference goers, many of whom also experience racialized and/or gendered oppression (Prescod-Weinstein, 2021).

It was in this elsewhere of the mathematics conference space that she was able to find herself in community with practitioners and the practice, wherein she was able to spend time with both the people, "talking to everyone," and then subsequently, with mathematics, for which she needed to "hide and concentrate." The account shows how participation in the community of mathematicians entails participation in explicitly social activities as well as engaging in the solitude of thinking through and making sense of all that emerged in those social activities. We argue that both the social interactions Carmen had with other scholars as well as the solitude she enjoyed with her own mathematical ideas—as coupled practices that build on each other—are community practices. The social life of the mathematician is, thus, a crucial resource for learning to be a mathematician.

> **Carmen**: So I started really like curating the set of conferences that mathematically might, for anybody else, mathematically might not be the best options there weren't, I mean. I went to those too. I went to, like, very specialized technical conferences, and the feeling of being there was just anxiety, and so I just, like, hid in my hotel, and I would use that as like writing time. But I wasn't going to the talks. I wasn't meeting anybody because people weren't there to meet this, you know, graduate student from a low tier ranking institution like they weren't there to get to meet me or know me or mentor me in any way, and I kind of quickly learned like, which are the conferences to go. If I want to see myself reflected in the speakers, or if I want somebody to actually come up to me during the lunch and say, where are you at? You know what? What has it been like being a graduate student? Um. And so it was kind of a trial and error. But then, quickly, like, did that work? Yes, that worked. Okay. I will go to that one again next time, and then just making it a habit to like I was traveling all the time … <shakes head> …just as much as I could. It became like the – yeah – it be – it became the place where I was a mathematician, you know, like when I was home, and I was balancing school and everything else, like, I – I was no good at either thing, but if I was away I could at least be a good mathematician during those three days that I was gone.

Here, the elsewhere of a conference is described as "the place where [she] was a mathematician." Mexican American culture was thus framed as both inhibitive and productive of Carmen's becoming as a mathematician: on one hand, her home culture and the responsibilities it brought with it were characterized as getting in the way of Carmen's progression in her career—so much so that she needed to find a way to get away from it and be "traveling all the time." On the other hand, it was the very systems and support afforded to her by familial and cultural relationships (with her brother, sister, and parents) that allowed her to eventually spend time on mathematical work. In other words, going away from her home life was crucially facilitated by the very home life she was trying to get away from. Furthermore, Carmen's choice to be away for stretches of time in order to pursue mathematics speaks to a departure from more traditional ways of doing mathematics. Such references to departures from tradition resonate with her reflections on her own practice and how that compares with others' views of her work:

> **Carmen**: It's been so interesting to just be able to kind of reflect on that and then see sort of from the outside what people see about me, and they're like: Oh, look at all her math papers, or all the work she does with undergraduates. And I'm like, yeah. But see you're counting like articles. And I'm just thinking about all the stories, of the relationship I have with those people,

> and like the part of my life that they've like helped flourish, you know, like – it's not like — the theorem is sort of like a little cherry on a really wonderful solid cake <gestures with hands> that people tend to like, not even see. And that's the part that that I think is—is the thing that has kept—kept me in math, because the traditional, like, climate and culture of departments, I haven't yet found one that's like that right? That, like, values people above the—the mathematics. And I think there's, there's people in every department that are very much like that. But the majority at times that are very vocal and loud, are very much about—about—the thing that's important is the science. Anything that deviates from the science takes away from the science, and therefore it's bad, and, and I think they've just never experienced the other side of it right? Because somebody like me, who started at Intermediate algebra in college, shouldn't be out-publishing these MIT professors, right? These Harvard Yale Educated professors. It was… There's nothing brilliant about me other than, like, building community, and understanding that you know, when you support people — like we do better math when we're together, and we feel that we value each other, and, and it's not just for science' sake.

From Carmen's perspective here, within a traditional mathematics department, "the thing that's important is the science" and what "deviates from the science takes away from the science," including "valu[ing] people" and relationships. Whereas a traditional read of the productivity or generativity of a mathematical life may look to article counts—both in Carmen's telling and emphasized in hiring, tenure, and promotion decisions—Carmen here highlights relationships, such as with undergraduate collaborators. Far from "taking away from" the math, foregrounding the cultivation of relations in community had been what makes "better math" possible. Throughout the conversation this value was connected to cultural practices in Carmen's Mexican American family and community; being a mathematician at racialized and gendered disciplinary margins offered non-normative ways of doing mathematics that often go unacknowledged as part of mathematical practice in academia.

Discussion

Marginalization in mathematics across levels is experienced simultaneously as inclusion and exclusion—where one might be a mathematician but, also, say, antithetically, one is a woman of color (Gholson & Martin, 2019; Prescod-Weinstein, 2021; Star, 1991). The story of how Carmen became a mathematician is a story of social, relational, and affective negotiations and contestations within communities and across cultures. Our analysis of Carmen's interview reveals how the labor of the mathematician, especially that of mathematicians from marginalized groups, is sustained and shaped by several different forms of labor that are carried out in the cultural and social life of the mathematician by various actors. The labor that Carmen engages in—especially that which is not explicitly seen as related to the doing of mathematics—is a kind of reproductive labor that has often gone unrecognized and unacknowledged in social scientific studies of mathematical learning and practice (Federici, 2004; Prescod-Weinstein, 2021). Turning our attention to it here offers us a window into the systems that make the work of the mathematician possible. Carmen's experiences as a Mexican American woman of color in mathematics were necessarily formed at the intersection of, at the very least, mathematical culture, the culture of her home life, and the gendered and raced subjectivities of her social life. Together, these seemingly disparate aspects of her cultural life are mutually constitutive of her membership across communities, including the community of mathematicians. Her life as a mathematician is thus realized by the cultural and political negotiations she (and others around her) undertake from a variety of moving social locations. For Carmen, then, to be a mathematician is inseparable from being a woman of color, an immigrant, a wife, a mother, a daughter, a sibling, and Mexican American. It shapes not only her access to mathematics, but also what mathematics comes to be in her hands.

Significance

Our analysis of the conversation between Carmen and the first author offers insights into the cultural politics of mathematical work, further pointing to the gendered and racialized character of the practice itself (Damarin, 2008; Subramaniam, 2009). Conventional descriptions of mathematical practices tend to be decontextualized and monolithic, in which doing mathematics involves participating in a set of narrowly selected activities (Martin, 2014). Such descriptions portray mathematics as untouched by political, social, material, and cultural forces, offering little in terms of an explanation of how processes of marginalization and underrepresentation in mathematics endure. Empirical methods grounded in feminist epistemologies pose a challenge to such traditional conceptions and allow us to expand our understandings of what mathematics is by looking at it "from below," or from the vantage of those subjected to and by it (Harding, 2008). This vantage animates not only how mathematics education, as a regime, constructs those who pursue it (PMENA, 2020), but also how those who pursue it resist its impositions and through such resistance transform it. Such an approach allows us to tell the stories of those marginalized and oppressed by mathematics (e.g., Gholson & Martin, 2019; Sengupta-Irving, 2021) and of those recruited into its greater political agendas (e.g., Gholson & Wilkes, 2017; Sengupta-Irving & Vossoughi, 2019). Further research of the kind carried out here can help expand the literature on learning mathematics as a social and cultural activity by: (1) providing a feminist social practice theory of mathematics; (2) broadening understandings of the social origin of mathematical work and how this influences teaching, learning and pedagogy; and (3) elaborating on the relationship between racialized and gender-based subjugation and mathematical epistemology.

Abstract: Building the scholarship on design and equity in the learning sciences, our work attends to the role of languages, power, and historicity in the design process. In this paper, we discuss our design approach to challenge normative power dynamics by centering the concept of translanguaging in a land-based program with refugee children, on an urban regenerative farm. Our design is nested in the larger vision shared by participating teachers for reclaiming power and shifting normative power dynamics through languages. Guided by the corporeal and spatial expansion of languages, we focused on children's embodied employment of collective community practices, land-based knowing and full repertoires of semiotic resources in the presented co-fostered interactional moments. Through our interaction analysis, we highlight the child-led expansion of semiotic repertoires, embodied representations of community, identity and (re)connection to the land. These child-led moments forge new pathways for equity and design.

Introduction: Power and historicity in design

Design is never politically neutral. From benches in the park to algorithms ubiquitously used in our daily lives, design discriminates (Benjamin, 2019). As we consider design that either perpetuates or challenges oppression and discrimination, we need to attend to the "account[s] for critical historicity, power and relationality" (Bang & Vossoughi, 2016, p. 173). Designing learning environments for equity explicitly focuses on the vision for breaking down existing oppressive systems and examines transformational learning opportunities for people and communities to make sense of their identities as designers of possible futures (Gutiérrez & Jurow, 2016). Focus on power and justice in design have been highlighted in the forms of participatory design (Bang & Vossoughi, 2016), social design-based experiments (Gutiérrez & Jurow, 2016), and design justice (Costanza-Chock, 2020). In the process of design toward equity and justice, researchers may outline a viable learning trajectory, but the pathway must remain open-ended for the community members and learners to imagine and design their own futures as "lived experience is non-transferable" (Costanza-Chock, 2020, p. 83). As "equity is both ideal and pragmatic" (Gutiérrez & Jurow, 2016, p. 6); designing for equity is an ongoing process where researchers critically evaluate any reproductions of oppressive norms and navigate tensions between systemic constraints and need for social transformation (Bang & Vossoughi, 2016). Building on this body of scholarship on design and equity, our work adds to the discussion on the role of power and historicity in design, by focusing on the role of languages in the design process. In our design of the land-based learning pedagogy, *Soil Camp,* we intentionally positioned facilitators, and children as *co-learners in front of the land*. Soil Camp is a summer outdoor learning opportunity serving refugee children in Calgary, Canada and a designed network toward eco-social justice (https://www.soilcamp.ca/). Alongside predominantly racialized, multilingual educators, together we collectively reconnect with the soil, community and silenced histories on land, while deepening our understandings through relational and embodied transdisciplinary STEM experiences. This was intentionally created as an act of "deepening learning and contributing to a more equitable social world" (Gutiérrez & Jurow, 2016, p. 30). Given that almost all the children who participated in Soil Camp are Indigenous in their countries of origin, reconnecting with the land is the act of *presencing* (Nxumalo, 2019) their intergenerational wisdoms in the predominantly white farmland landscape. This act of presencing is intertwined with resistance, agency, and transformation in the everyday acts of Othered bodies-in-places by making their presence visible through occupying, gathering, and renewing the place (Nxumalo, 2019).

In this paper, we draw from the concept of translanguaging in our design, the agentic and dynamic linguistic practices of multilingual people, which cannot be confined to named languages (García & Wei, 2014). Translanguaging challenges colonial monolinguistic norms and dominant deficit discourses on language minoritized people and communities by recentering the speaker and their unique lived bilingual language experience and semiotic repertoires embedded in (their displaced) lands (Thraya & Takeuchi, 2022). In our design of Soil Camp, we closely attended to spatial aspects of translanguaging inspired by Wei (2011): "translanguaging spaces are not physical locations or historical contexts only, but are networks of social relations...that are created by individuals through distinctive (of the network) and shared (amongst the network members) practices for specific social purposes" (p. 1225).

An iterative process to design was employed using the aforementioned framing and guided by the voices of our co-learners, their organic languaging practices, and holistic identities. In our Year Two of the design, by bringing forth the notion of translanguaging design for equity, we attended to the aforementioned need for “critical historicity, power and relationality” (p.173) as discussed by Bang and Vossoughi (2016). The central thesis for this design saw translanguaging spaces as nested in the larger vision for reclaiming power and shifting normative and oppressive power dynamics. This co-fostering process challenged the colonial matrix of power that exists within educational spaces that continues cycles of oppression due to the differential power ascribed to peoples, languages, histories, and ways of knowing. Through this, as we will show in our Findings, democratized relationships emerged across these contexts. This paper is guided by the following inter-related and nested research questions:

1. How did facilitators and children enact participatory design in a translanguaging space that centers equity and shifted the normative power dynamics?
2. In the designed space, how did co-learners co-construct the translanguaging space?
3. How can co-fostered translanguaging spaces develop avenues for collective and individual (re)connection?

Framing languages in design for learning: Designing translanguaging spaces for equity

The designing of learning environments that carefully attend to and listen to polylingual repertoires can open up new pathways for non-dominant children’s identity and learning (Gutiérrez, Bien, Selland, & Pierce, 2011; Lizárraga & Gutiérrez, 2018). As Lizárraga and Gutiérrez (2018) have shown, children can open up the new learning as organizing possible futures in the spaces that embrace fluid boundary crossing and *nepantla literacies* (p. 39), which cannot be conformed into normative linguistic practices (e.g., the ones that have often been imposed on non-dominant children in school settings). Semiotic repertoires cannot be completely seen, but through design we can improve the accessibility to such resources. Our design and analysis share this orientation to in-betweenness, fluidity, and children-led space creation leveraging their already existing linguistic repertoires.

Thus far, the conceptualization of translanguaging has been anthropocentric, focusing on human communications yet can be reframed as “a pedagogical tool for (re)connection with each other, intergenerational knowledge, and more-than-humans" (Thraya & Takeuchi, 2022, p.616). Moving beyond our previous conceptualization, we push for viewing translanguaging from an embodied and historicized lens. Marin (2020) reminds us that those who research STEM education should develop systems of analysis and ways of seeing and listening that allow us to "re-member (Grande & McCarty, 2018; Wa Thiong'o, 2009 as cited in Marin, 2020) relationships between land, humans, and more-than-human relatives" (p. 31). As children engage closely with more-than-human lives on lands (Marin & Bang, 2018), they could engage in translanguaging practices that go beyond human-to-human communications. Based upon our findings from Year One, we continued to explore the extended notion of translanguaging to account for the relationality beyond human-to-human connection, to include more-than-humans, land and silenced knowledges (Thraya & Takeuchi, 2022). This theoretical push is increasingly pertinent with the current global influx of displaced refugee families embodying agricultural experiences who are stripped from their generational connection to more-than-humans through the resettlement process.

Scholars who study translanguaging have proposed an expanded view of translanguaging to include nonlinguistic modes including embodied communicative practices (Blackledge & Creese, 2017; Suárez, 2020). The attention to embodied communicative practices within translanguaging enables “a holistic focus (addressing ideologies, histories, potential and constraints) on action that is both multilingual and multimodal” (Kusters et al., 2017, pp. 11). As Suárez (2020) demonstrated, embodied translanguaging practices enable linguistically minoritized learners’ expansive expression of scientific models. Such embodied translanguaging can be spatially expanded "assembled in situ, and in collaboration with others, in the manner of distributed practice…beyond the linguistic to include all possible semioticized resources” (Canagarajah, 2017, p. 37). Canagarajah (2017) emphasizes on the spatial repertoires being “embedded in the material ecology and facilitated by social networks” (p. 37). The semiotic ecosystem of Soil Camp showcases “an assemblage” of “different trajectories of people, semiotic resources and objects [can] meet at particular moments and places” (Pennycook, 2017, p. 280). These assemblages (as Pennycook conceptualized based on Deleuze and Guattari’s posthumanist conception of assemblage) are powerful interactional becomings, which are highlighted in the chosen episode.

Methodology

We draw from participatory social design research methodology (Gutiérrez & Jurow, 2016) that centers historicity, diversity, equity and ecological resilience as design principles and aims to co-design just practices and futures in partnership with a range of communities. We are also guided by Indigenous ways of knowing and decolonizing methodology that acknowledge colonial relationships reinforced by research and honour and carefully listen to the voices of Indigenous people (Smith, 2001; Marin, 2020). Aligned with design-based research that values iterative cycles of development, implementation, and study of design (The Design-Based Research Collective, 2003), our design has emerged from multi-year collaborations and redesign. One of the foci of redesign was around linguistic practices through our reflections on linguistic design for equity and justice. Our methodological commitment oriented us to analyze interactional phenomenon of translanguaging (García & Leiva, 2014) while historicizing the phenomenon of translanguaging in light of macro histories. As we analyzed the interactions, we closely attended to the power dynamics surrounding the participants, colonial histories (between humans and between humans and MTH), and linguistic norms reproduced or challenged in particular interactions.

Since 2021, in total, 85 children (5 years old to 15 years old) and over 20 families joined our program, Soil Camp. All attendees were refugees from Syria, Northern Iraq, Kurdistan, New Guinea, Pakistan, South Sudan, Ethiopia, and Eritrea who had resettled in Canada within the last five years. Eighteen teachers and teacher candidates (who are mainly racialized multilinguals) joined as facilitators of Soil Camp. A team of researchers collected the following datasets from two iterations of Soil Camp that took place over two years. The video data was collected using three modes (Go-Pro cameras worn by both the participants and by the researchers, Handycam video cameras held by the participants and researchers, as well as still cameras that were stationed on tripods in the primary spaces of interaction). A total of 91 hours and 35 minutes of video data was collected by the research team. For this paper, we draw from video data collected during the second iteration of Soil Camp (totaling 5 hours of video data) to gauge emerging interactional phenomenon under the design that was intentional about leveraging participants' translanguaging experiences.

Our analysis started from our collective reflections on learning moments that speak to the analytic foci of embodied translanguaging practices. These focused learning moments are partially guided by our positionalities as researchers/facilitators. Sophia Thraya (Author 1) is a second-generation Canadian of the Lebanese diaspora and self-identifies as bilingual, holding both English and Arabic in her linguistic repertoire and dear to her heart. Her partially shared histories and previous engagements with and within the community has provided her with ethical engagement affordances, but more importantly the responsibility to continue to seek guidance. All the co-authors were racialized, multilinguals with the lived experiences of immigration. Although our positionality goes beyond what can be summarized in these few sentences, our analyses were guided by our personal and collective histories that shape reflexivity and sensitivity to certain aspects of learning. Drawing upon theories of learning and knowing, we take an introspective multi-level sociocultural approach to critically analyze micro-moments of interaction within the greater macro institutional and historicized climates across spaces. Our analysis emerged from analytical gazes wherein first-, second-, and third-person testimonies are intertwined (Espinoza et al., 2020). Our analysis was possible because we had shared experiences of being together on the land with children during summer camps over the past two years. These shared experiences allowed us to surface the layered translanguaging practices and the interactional co-fostering of the translanguaging space through collective movements-with-the-land.

After analyzing the data from Year One, there were many significant insights into the organic languaging practices and the power of such a stance in learning environments. As we pursued analysis of Year Two data, we paid attention to the enactment of redesign and intentional enaction of translanguaging practices. We then analyzed segments of data where the participants were bringing in non-dominant (and often censored) languages in institutionalized schooling spaces. Collective viewing of data and collective analysis were followed to bring multiple voices into video data analysis. Subsequent to these collective viewing sessions, we transcribed key segments of data as compelling enactment of translanguaging initiated by the participating children. Guided by the corporal expansion of languages, we attend to children's embodied employment of collective community practices, land-based knowing and full repertoires of semiotic resources in the presented co-fostered interactional moments. We examined how children provided glimpses of their semiotic repertoires which forge new pathways for embodied representations of community, individual identity and MTH (re)connection by moving beyond the planned activities.

Findings

Iterative design reflection: Enacting participatory design in translanguaging spaces

Integral to Year Two iteration was the co-fostered translanguaging through intentionally concretized design elements. From the Year One observations of ideational artifacts (Nasir, 2004), Thraya concretized key elements within the space that served as "transformational tool[s] for deconstructing the colonial views of what it means to learn in educational spaces and with what languages" (Thraya & Takeuchi, 2022, p. 7). Concretized elements were both explicit and agentic in nature.

The first concretized element to this iteration was the official statement of listening together to the histories, languages, and stories through anti-colonial relationality within Soil Camp's vision and grounding epistemes; directly connected to the central thesis for design centering power and presencing in the linguistic design for equity and justice. Prior to the start of Soil Camp, the preservice and in-service teachers and researchers became familiarized with our grounding episteme through professional development sessions to explicitly discuss the theory and pedagogy of translanguaging as a tool for (re)connection based upon the Year One findings. This integral dimension of the project was revisited daily and reflected upon throughout the iteration as our predominantly racialized multilingual educators co-enacted this episteme with the children. This episteme was presented to the children through various collective consciousness raising conversations and whole-group exercises. An example of this is when all participants, including facilitators and researchers, shared the languages that they held in their hearts which we termed "translanguaging hearts." Going around in a circle, children witnessed the meeting of individual and community multilingual identities. This was a key moment in the assembly of the Soil Camp spatial repertoire. Seeing others with similar as well as different repertoires to their own coming together in the space was transformative in abolishing English monolingual superiority. As a result, languaging coming from the peripheries became centered in the "learning space." Our collective stance was reminded to all through our daily affirmation which was modelled by facilitators and repeated by all in our morning arrival meeting. Such an explicit affirmative stance directly countered the macro-level oppression and deficit linguistic ideologies present in disciplinary spaces as part of broader colonial agendas. The affirmation read: *I will learn with my whole language heart, I will connect with my beautiful knowledges and speak with the words that flow naturally, I will (re)connect and make new friendships using my whole self, with all the living things I meet, we will share, love and be together on this land.*

The second concretized element was embodied transdisciplinary experiences where translanguaging was nested, spontaneous and agentic. This was done consciously as facilitators saw how it could easily be extractive if done in ways that were too direct, where children were asked 'to language' by the ways of superficial translation work which could replicate dominant oppressive languaging practices and remove learner agency. As we demonstrated in the following section, with this adoption, we saw a shift from peripheral engagement to agentic, centered engagement of children. Alternatively, we designed transdisciplinary experiences where translanguaging was visible, heard, agentic, and embodied—where they engaged on their own terms. Embodied experiences such as a Blackfoot medicine and MTH meeting walk led by a Blackfoot knowledge-holder and educator offered a transformational space for embodied repertoire use.

The aforementioned concretized design elements were balanced with the spontaneous child-led moments of co-fostering in the translanguaging space. The greatest learning from Year One was done by listening to the children — not to their responses to our questions, but rather listening to how they responded to one another and to the space through agentic and embodied experiences. Attention paid to informal spaces, and micro-interactions were most insightful in understanding the children and their relationships to language as an avenue for (re)connection. We intentionally concretized the lead of our children as a central design element, as co-fostering such a space would not be possible without this work being done *with* the children.

Collaging

Through the aforementioned intentionally concretized design elements Soil Camp and the iterative design reflections, translanguaging had a commonplace during the planned and unplanned activities. Specifically, during a collaging activity that took place over two days, children were prompted to create collages of their collective and individual networks of community. This experience took place in an event tent on the land, while children came in to find the tables covered with a variety of print materials spread out for them to cut and paste from local cultural, event, and business magazines. All children in the identity collaging activity were Yazidi-identifying from Iraq working alongside Sophia and co-facilitator Layelle, an educator of Syrian descent. Notable translanguaging that went beyond named languages including the Kurdish dialect of Kurmanji, Arabic and English occurred in modes of verbal communication and child-led music selection which played in real-time in the co-fostered space. Through the intentional design and deep caring relationships developed among facilitators and the children over the course of two summers, these interactions broke down the hierarchy between "teachers" and "students" and actively countered the macro geopolitical, and linguistic matrix of power tied to identities in the space. While the designed experience encouraged learner agency and embodied expression through the medium of collage, the activity became a site where children, unrestricted by the design of the activity, took the opportunity to showcase parts of their shared identity on their own terms. Through an initial discussion of unpacking what community meant to them, the children articulated their complex, layered, and emerging relationships with languages, places, people and more-than-humans (MTH). The topic of discussion included what community is and how children located themselves within networks of community—geographically, locally and abroad, as ecosystems, culturally, linguistically, spatially, and through interest-based networks. We also discussed how Soil Camp was a meeting point that transcends boundaries and divides. As Dila (all the participants' names are pseudonyms), a girl-identified Yazidi participant expressed:

> I am still connected to Iraq, my language, I feel connected to Indigenous ways, it shows us many things, like Canada, like Calgary, and Arabic—it is kind of a language of ours but it's a little different. I connect to everything.

This quotation captures how Dila connected to core pieces of her identity, that are lived, and transcend borders and divides, including complex historical dynamics embedded in the fabric of her linguistic repertoire tied to the Arabic language. Arabic is the national language of the dominant majority in her country of origin and the officially adopted language of ISIL who were responsible for the unjust genocide and forced displacement of the Yazidi people (as brought up by children during the activity). Evident forms of redefining such relations through the new spatial repertoires formed in translanguaging spaces have surfaced across both years. We can see that for these racialized multilingual children language is seen as alive, embodied, and is employed as an act of sustaining relationality (Henne–Ochoa et al., 2020)—which is further unpacked explicitly in the subsequent section. The children collaboratively created the networks of community collage, with a significant inclusion of images and words related to environmental sustainability and more-than-humans that the children were in community with at Soil Camp. Some children used the scrapbook letter stickers to create words of the places in which they connected with—including countries of origin (Iraq, Syria) as well as Canada. Images of Treaty 7 territory were also focal to the collective piece including both natural features and man-made monuments—taken from the local magazines. Images of peoples donned in Indigenous cultural regalia, and other images of cultural celebrations were also featured on the poster. Following the completion of the collaborative poster, all were given a piece of scrapbook paper that they used as a base for their identity collage.

Embodied translanguaging and interactional presencing of dîlana kurdî

The following interaction highlights the equitable participatory design in action through the child-led moment of moving beyond the designed learning experience and into a space they co-fostered relationally in the moment. This assemblage exemplifies the dynamic exchange and the ways in which the children draw upon their lived-experiences, collective practice and other available spatial resources to co-create child-led artifacts that were embodied tools for storytelling, (re)connection, and collective remembering. This episode occurred during the individual collaging experience. As the children alongside the facilitators engaged in the artistic process, rich conversations emerged around MTH relationality among the group leading to one child to begin singing about her connection to MTHs that she described as "being a part of [me]." Sophia asked the group if they would like to play Kurdish songs on Sophia's iPhone and they were quickly met with a wave of excitement. The girls passed around the iPhone, taking turns playing Kurdish children's songs that they were fond of and listen(ed) to pre-migration in Iraq and after resettlement in Canada. An eruption of collective remembering, singing along and sharing connected to the songs emerged from this addition to the space. It was not until the introduction of music that the planned experience of collaging began to shift into a child-led employment of linguistic and non-linguistic resources for expression and collective remembering through music. This was the start of a powerful exchange with Sophia and the children about family traditions and customs of the ethnoreligious community around their celebration of Eid and weddings—touching upon food, clothing and celebratory practices including dance. Embedded and integral to this interaction was the ways in which this engagement was approached, the participants explained many pieces of this through a comparative lens—employing their knowledge of Sophia and the co-facilitators' religious and cultural identities (Muslim Arab women). They shared their knowledge of both common and differing experiences. Episode 1 began as the children were in the final stages of their pieces. Kurdish music filled the tent, and the co-facilitator suggested an Arabic song that her students enjoyed and asked if the children knew the song as well. The children immediately suggested the song be played and as the song began the majority of children began to sing along. Dila joins in dancing from her seat, rolling her shoulders forward to the beat.

#12:22:56-7#	Sophia	Can you show me?

Figure 1

Excerpt 1 in action

After this invitation by Sophia, there was an immediate response by the group. Lilan stopped her cutting and pasting and joined pinkies with Sophia and both Dila and Alal came from around the table to link pinkies. The girl-identified children began guiding Sophia through the motions of the dance. They took the opportunity to teach facilitators the isolated steps as their arms rowed forward synchronously, continuously linked by their pinkies. The children gently guided Sophia and took the time to explain the many variations in the dance known as Dîlana Kurdî, a Kurdish folk circle dance. Sophia paid close attention and asked clarifying questions related to the movements—following the children's lead. Dila invited and guided the group to move outside of the tent to continue the dance. A noteworthy use of language showcased the democratization of power occurring through this child-led interaction.

#12:24:01-5#	Dila	We can go outside and dance like this /holds pinky out/
#12:24:03-0#	Sophia	Should we ↑
#12:24:03-4#	Dila	Yeah, let's go

Prior to the re-interlacing of the pinkies and the circle dance commencing, a moment of joy was exhibited while moving-on-land, the children were dancing, jumping, clapping and hugging (see centered image in Figure 2). The Arabic song continued playing and the Dîlana Kurdî began again. The girls modeled with their bodily movements supplemented with counting and verbal feedback. The repurposed Arabic music became the soundtrack of this interaction. The girls verbally shared how much fun they were having, and the co-facilitator asked if they would like to learn Debka, a similar-styled Levant folk dance. The co-facilitator was met with enthusiastic responses and Sophia made explicit the commonality she found in both dances and explained the steps in a parallel manner to Dîlana Kurdî. The Arabic Debka music plays, and the girls recognized the song. The girls held hands and followed the lead of the facilitators. The Debka dance ends and Lilan shared her knowledge of how circle dances are common across cultures. The group found commonality as they discussed the importance of these dances in celebratory times including weddings and holidays such as Yazidi New Year. Dîlana Kurdî began again as Kurdish wedding music played, the co-facilitator heard a familiar word حياتي, hayati, a term of endearment meaning 'my life' in Arabic. The co-facilitator was met by the children sharing that this is a common word in Kurdish—an additional shared dimension of their semiotic repertoires.

Notable in these interactions are how all the participants started to become "co-learners" through embodied translanguaging—the ways that transcended borders between facilitators, who are Arabic speakers carrying Muslim diasporic practices and Yazidi children. We see a shift in conversation and moments of collective remembering emerge on a collective and individual level. Silenced personal experiences and the sharing of the collective story of the ethnoreligious group from the perspective of Lilan began. Layered sharing filled the hollow middle of the circle and was assembled in situ as all agentically shared. Lilan talked about the lived, pre-migratory and current oppressive histories of her peoples as she danced:

> For Êzidîans (Yazidis) back in the olden days, they had to do what adults had to do like at the age of 6. They weren't really treated that goodly and they really didn't have that much money. So, they had to make their own stuff and farm. But it was so much fun though, I miss those days. Now it's harder...there is still people trapped by the Daiş (ISIL) [It's not really like a war] that's why we had to move from that place.

Figure 2
Dîlana kurdî in action: Visualizing the assemblage

Together there was a shared use of translanguaging as a tool for (re)connection to one another, MTH, shared linguistic and non-linguistic embodied resources as well as silenced histories and stories. The meaning of translanguaging to (re)connect for co-facilitators in this moment manifested into being a witness and listener as the flow of sharing occurred. Translanguaging to connect for the participants in this moment meant connecting to memories of joy, loss, nostalgia and hope that were layered, heard and alive in the recounts as Tela shared, "I love the place that's, just like, flat and it is all green with daisy and flowers."

Discussion

In this paper, we have demonstrated how iterative design of translanguaging space towards equity and justice facilitated the emergence of an assemblage where silenced languaging, cultural practices and lived realities coming from the peripheries became centered in the learning space of our designed Soil Camp program. While the design initially focused on linguistic translanguaging experiences, dance was employed by the children as an embodied nonlinguistic resource; a meaningful piece of their semiotic repertoire deeply tied to historicized sociocultural dimensions and embodied connections to the land. It is in such a moment that "embodied communication [comes] plainly into view" (Blackledge & Creese, 2017, p. 255). Both the Kurdish circle folk dance and Levantine Debka have origins connecting to story, land, soil regeneration, promotion of plant growth and agricultural fertility (Al-Awwad, 1983). Circle folk dance, a common and integral part of all co-learner's repertoires were brought out and made visible through this child-led moment. It is in such moments that new avenues, unimagined by facilitators, come alive. The children employed dance as a mode of translanguaging to communicate silenced stories and lived experiences of their community through dance, which can be seen as an act of *presencing* (Nxumalo, 2019). The performances spontaneously emerged in new geographical locations, allowing for (re)connection with living things across cultural, species, spatial, linguistic and temporal divides.

Through these evolving intentional and explicitly designed disruptive practices, not only were children's multilingual identities validated, but also the intergenerational knowledge systems and stories that are intrinsically embedded within their repertoires—resulting in the co-creation of "new social realities" for learning (García & Leiva, 2014, p. 204). This can be seen as an assemblage of silenced histories, stories and collective remembering as a result of the promotion of child-led, dynamic opportunities for (re)connection. Children were then able to see how their repertoires are resources in all spaces and offer tools for (re)connecting relationally. It was evident that to foster an agentic and embodied translanguaging space we had to follow the *corriente* (García et al., 2017, p. 21) and lead of our co-learners. Facilitators welcomed and encouraged the in-the-moment adaptation of the learning experiences and space by participants. We see active and reflective listening centered in the episode, and as such, facilitators were able to follow children's agentic movements and insight as a way of reorganizing "systems of activity in which participants becom[e] designers of their own futures" (Gutiérrez & Jurow, 2016, p. 566) in line with social design experiments. As demonstrated in this paper, Soil Camp's spatial and embodied semiotic repertoire could emplace the silenced displacement of peoples, knowledges, and histories that are inextricably connected to land and MTH networks of connection. The explicit design intention to concretize linguistic elements of design toward corporeal expansion of translanguaging, while balancing such elements with spontaneous child-led moments is what led the researchers to dance with the children—a literal embodied pathway toward equity and justice.

Examining Rights to Participate and Struggles to Belong in Science Classrooms through a Black Girl's Engagement in Argumentation

Jennifer Schellinger, Lama Z. Jaber, Sherry A. Southerland
Jls09h@fsu.edu, ljaber@fsu.edu, ssoutherland@fsu.edu
Florida State University

Abstract: If we are to support students to become epistemic agents in the ways envisioned in reforms, we must acknowledge that classrooms can be spaces of injustice, where instructional efforts can propagate inequitable systems of oppression. In this case study, we describe the epistemic efforts of one Black girl, Jessie, and the rights and privileges afforded or denied to her as she worked with a group of her peers to develop and negotiate a scientific claim. Through examination of video data, transcripts, and student work products, we characterized students' efforts as about epistemic, rhetorical, and pseudo-argumentation, and how we explored how such efforts invited or constrained Jessie's epistemic agency. Jessie's pattern of persistence, which we understand to be her fight to have her rights as a scientific sensemaker acknowledged, surfaced issues of inequity in which Jessie's ongoing efforts to engage in epistemic argumentation were rejected by her peers.

Introduction

Educational reforms have positioned the development of science proficiency as the end goal of science instruction—that is, students should be able to use the tools of science to construct explanations of phenomena (NGSS Lead States, 2013). This work requires that students are positioned as epistemic agents (Miller et al., 2018; Stroupe, 2014) who share, discuss, and refine their thinking (Berland & Reiser, 2009; McNeill, 2011).

To support students to be epistemic agents, classrooms need to be structured as equitable spaces where students feel their ideas are valued by themselves, their peers, and their teachers--that is, they must be viewed by others and themselves as entitled to and worthy of contributing to the classroom community's advancement of scientific knowledge (González-Howard & McNeill, 2020). Equity, however, is often framed around ideas of access and inclusion for *all* (Martin, 2019). This framing does not always acknowledge that classroom spaces are embedded in cultural systems of knowledge and practice grounded in whiteness and heteropatriarchy (Calabrese-Barton et al., 2022; Ladson-Billings, 2006) that position historically marginalized students as outsiders with minimal power and authority (Nasir & Vakil, 2017). Inviting students into these spaces and expecting them to participate in the dominant discourses and practices that manifest in systems of privilege and oppression (Milner, 2015) may limit their agency in the classroom. More importantly, it may also impact the value they place on engaging in similar future endeavors given the required effort and associated costs (e.g., emotional, epistemic) this engagement requires (Eccles et al., 1983; Wigfield & Cambria, 2010).

If we are to support students to become epistemic agents in the equitable ways envisioned in reforms and discussed among the science education community, we must acknowledge that classrooms are spaces of injustice where a singular approach does not work. We must understand how instructional reform efforts can propagate inequitable systems of oppression. As Calabrese-Barton and colleagues (2022) point out, we must renegotiate "what the rights to being and learning in science are or could be" (p. 54), especially for historically marginalized students. To engage in this renegotiation, we must attend to who has the rights and privileges to participate, and to understand the struggles to belong in science that arise in learning environments constructed to engage students in the epistemic work of science.

Accordingly, this research aims to understand rights and privileges viewed through the experience of one Black middle school girl, Jessie, and her efforts to participate in scientific argumentation in a science classroom. We build from the work of González-Howard and McNeill (2020) that points to engagement in argumentation as consequential for learners' sense of agency. Agency is shaped not only by one's own comfort and perceived capability to engage in the epistemic work and practices of scientific argumentation, such as construction and critique of ideas, but also by the rights and privileges that are afforded by one's community to participate in this work, that is how one's community takes up these efforts (Calabrese-Barton & Tan, 2020; González-Howard & McNeill, 2020).

When students engage in *epistemic ways of argumentation*, they participate in knowledge critique and refinement by using evidence and reasoning to support a claim, challenging the evidence and reasoning of others with competing claims, or examining evidence and reasoning against existing theories (Berland & Reiser, 2009; Duschl, 2008). When students engage in these ways, they come to see their ideas as valid for scientific sensemaking and consequential to the learning community (González-Howard & McNeill, 2020). However, non-scientific ways of argumentation present in science classrooms (Berland & Hammer, 2012) move away from these potentialities and may work to undermine learners' epistemic agency. These ways of argumentation include rhetorical and pseudo argumentation. When students engage in *rhetorical ways of argumentation*, they engage in persuasive aspects of argumentation in which they take a competitive stance stressing differences of opinions rather than working to understand those differences, or emphasizing the correctness of their claim with minimal regard for evidence, reasoning, or competing claims presented by others (Mercer, 2000; van Eemeren et al., 1996; Walton, 1998). When students engage in *pseudo-argumentation*, they engage in the ways of doing school, that is when they work to satisfy the teacher or focus on completing the task, without attention to sensemaking or to coming to a consensus understanding (Berland & Hammer, 2012).

The research presented here aims to better understand the epistemic efforts of Jessie and the rights and privileges afforded to her as she works with her peers to develop and negotiate a scientific claim. We use the theoretical lens of ways of argumentation and ask the following research questions: (1) What ways of argumentation do Jessie and her group members engage in during a small group argumentation activity? and (2) How do these ways of argumentation invite or discourage Jessie's epistemic agency?

Methods

Context and participants

In this research, we took a case study approach— an approach that allows for an in-depth examination of complex issues bounded by context (Creswell, 2007; Miles et al., 2014). In this case, we study the interactions of Jessie (all names are pseudonyms), and her group members during a small group argumentation episode bounded by a lesson. The group consisted of Jessie (a Black girl), Lee (an Asian boy), Chad (a white boy), and Kendall (a Black girl) as well as another student that interacted with the group named Joseph (a white boy). The lesson was led by Mr. Jerry, the white male teacher of this middle school biology class. Mr. Jerry was a teacher enrolled in a professional development (PD) opportunity, a larger project from which this research is drawn. The PD was centered on supporting teachers to develop instructional practices and knowledge to engage their students in epistemic discourse to learn science in ways that align with science education reforms (NGSS, 2013; NRC, 2012). As part of this PD, Mr. Jerry implemented a four-day lesson called *Cell Structure* (Sampson et al., 2014). This lesson was structured to engage students in scientific argumentation where students were involved in collecting data and using those data as evidence to support a claim that they negotiate with their peers.

For this research, we examined video data and corresponding transcripts from a small group episode and associated student work products. The episode was the main source of data and was analyzed to identify ways of argumentation, as described above. In this analysis, we attended to discourse and multimodal affective markers to understand how Jessie's peers' responses invited or discouraged her epistemic agency.

Analytical approach and stages of analysis

This work began when we, the three authors of this research, were examining small group interactions during argumentation activities to better understand how teachers support students to engage in productive epistemic discourse. As we were focusing in on different small group interactions, the interactions surrounding one student, Jessie, stood out, and we began to recognize that her epistemic efforts were taken up by her group members in different ways during their interactions. We were particularly interested in Jessie because she had a powerful presence in the classroom (e.g., often bringing her ideas forward during whole group discussions and being animated in these interactions) and because she was persistent in her attempts to have her ideas heard and taken up when working in the small group component of activities, work that far exceeded those exerted by others in the activities, and because of the affective frustrations that she exhibited in these interactions.

We began our analysis by examining the efforts that Jessie engaged in as she worked to bring her ideas forward in one argumentation activity, *Cell Structures*. In this analysis, we independently watched videos and examined transcripts of the activity and then met to discuss the dynamics we were observing, how Jessie's efforts were or were not taken up by her group members, the work that was required of Jessie in these efforts, and the salient affective moments that stood out. We recognize that these interactions may be influenced by existing relationships and power dynamics between individuals and within this classroom space. However, we focus on this one lesson, not to minimize the power of these histories but, instead, to closely examine manifestations of these dynamic within this learning context. After multiple views and discussions, we focused on one 24-minute episode that occurred on day three, when the group began developing their argument. This development included deciding on their claim and the evidence that they would use to support this claim. We chose this episode because it included students' idea negotiations, multiple claims, and evidence consideration in an effort to identify the claim that best accounted for the data.

To further understand the interaction dynamics of this episode, we watched and rewatched video recordings of the group as they made observations and discussed these observations at a microscope and as they worked to develop their claim, evidence, and reasoning (CER) poster at their lab table. The authors watched the video independently and came together to discuss what they were noticing. They noted particular moments that stood out to them from the episode, including moments of discourse and affect that they felt were particularly salient. The authors continued to engage in watching and then discussing the video and examining the transcript to gain a better understanding of the group dynamics and Jessie's efforts within this work.

After this initial analysis, the first author examined the episode and identified thirteen segments. Segments were a period of interactions when the group, or members of the group, held a common focus before shifting to another focus. Many of the segments occurred when the group moved between the microscope and lab table spaces or when one group member physically left the space. However, because of the recursive nature of the group's deliberations, multiple segments occurred within these spaces.

The first author coded each segment using the ways of argumentation framework described earlier. Further, she identified whether there were particular moments of affective expressions (e.g., gestures and voice intonation) of frustration associated with these utterances and interactions. She focused on these expressions because the authors had noticed in their examination of the data that Jessie's ways of argumentation were often marked by her visible frustration with her peer's ways of argumentation or engagement. While all group members exhibited affective markers, here we focus on Jessie because they were the most pronounced of all group members and because of our concentration on her. Screenshots of these affective moments were captured and added to a summary of each segment, which included an overview of the segment, a description of each student's interaction, and a description of affective dynamics at play.

Once all segments had been coded, the first author created a visualization of the segments showing the different ways of argumentation present within segments, the participants involved, and Jessie's affective markers associated around her frustration when they emerged. We used this visualization and segment summaries to examine the data and answer the research questions, paying particular attention to affective markers, shifts between segments, and ways of argumentation.

Researchers' positionalities

The three authors, two white women (the first and third author) and one immigrant Arab from Middle Eastern background (the second author), were intimately involved in the larger project from which this research is drawn. We began this project to understand group dynamics at play in students' sensemaking spaces, but as we examined the data from Jerry's classroom, particularly those videos from Jessie's small group, we were struck by Jessie's extensive efforts to be recognized as a contributing member of her group's ideas. As we engaged further in these data, we began to understand the racial and gender dynamics at play in these spaces. While we could understand some of the gender dynamics occurring in the space, given that all three of us have experienced forms of gender inequities as female science learners and scientists, we understand that we do not bring a history informed by racial marginalization, particularly around the lived experiences of blacks in the United States. To account for this positionality, the authors have worked to understand intersecting issues of race, social justice, and gender by examining literature and research around these issues and attending to these ideas in their examinations and discussion of this case. While the researchers acknowledge that these endeavors do not provide an insider view of Jessie's experience, they did provide groundings by which the researchers could work to attend to the intersectionality as outsiders of the community.

Relevant background to situate the episode

In the four day *Cell Structure* lesson, students were tasked with determining how an unknown microscopic organism should be classified (Sampson et al., 2014). On day 1 and 2 of the lesson, students examined plant and animal cells at microscope stations at the back of the classroom. They were tasked with drawing and describing what they saw on a worksheet with one column for the drawing and one column for the written characteristics of the cell. On day 2, a slide mount of an unknown organism was introduced and students were tasked with making observations of the slide before beginning to develop an argument answering the guiding question, "How should the unknown microscopic organism be classified?" On day 3, students continued developing their argument and created a claim, evidence, and reasoning (CER) poster. This required the majority of the class session. During this time, students worked with their groups at their lab tables, while revisiting the microscope slides to check their ongoing sensemaking. Towards the end of the day, groups shared their posters with their peers in a round-robin format in which one member of the group stayed with and shared the results of the posters with students from other groups. On day 4, students individually wrote up their argument.

Findings

Jessie and her group engaged in multiple ways of argumentation during the episode examined here. The group, particularly Jessie, largely engaged in the epistemic ways of argumentation in which ideas or evidence brought forward by group members were attended to or pushed against, and evidence to support a claim were brought forward. These epistemic ways of argumentation occurred frequently across the episode. However, the ways of rhetorical and pseudo argumentation by particular group members, which occurred to a much lesser extent, worked to constrain Jessie's rights and privileges to have her ideas taken up. We saw evidence of Jessie's frustration as she was not being given full access to the learning space. This evidence manifested in her affective expressions which included gestures (e.g., eye rolls, downward eye gaze, and hand movements) and changes in voice intonation (e.g., raised or softened voice) as she brought forward evidence to support her claim ("The cell is a plant cell because *it has a cell wall*") or brought attention to the fact that group members were not attending to her ideas ("You guys are not listening."). These markers of frustration shifted from ones reflective of Jessie's exasperation to ones that indicated a sense of somberness at the end of the episode as Jessie's persistent attempts were not taken up in the group's argument and she was tasked to present an alternative claim, a claim that did not represent the ideas that she worked so hard to bring forward.

Ways of argumentation that Jessie and her group members engaged in

An overview of the ways of argumentation that the group engaged in are represented in Figure 1. In the figure, column headers indicate the different segments (1 to 13) of the episode. The width of each segment represents the proportion of time the segment took out of the 24-minute episode. Gaps in these segments represent moments when the group was not observed to be focused on argumentation. Rows are separated by each of the three ways of argumentation and their characteristic(s). Colored boxes in these rows indicate when something that a student said or did was coded in this way. Orange boxes indicate moments when one of the group engaged in the epistemic ways of argumentation. Green boxes denote when one of the group engaged in rhetorical argumentation including telling an answer or emphasizing the correctness of a claim with minimal or no regard for supporting that claim with evidence, reasoning, or considering the claims of others. Blue boxes denote pseudo argumentation indicating when students were focused on completing the poster. Figure 1 shows the broad distribution of students' engagement in the epistemic ways of argumentation, of which bringing forth evidence occurred most often. Rhetorical and pseudo argumentation occurred less frequently and are clumped within particular segments.

Figure 1

General Overview of Ways of Argumentation Identified Across Lesson Segments

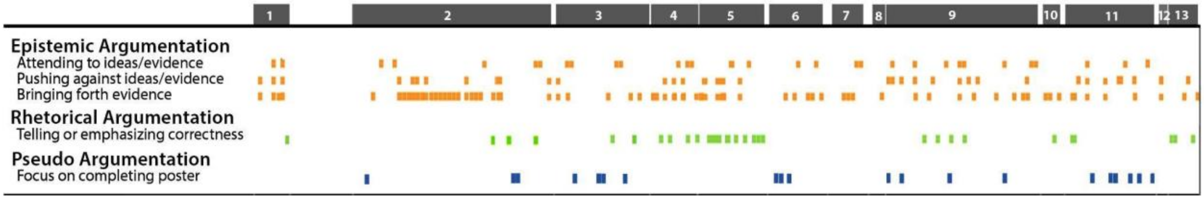

Figure 2 shows patterns in particular students' ways of argumentation. This figure is organized in a similar way to Figure 1 in which column headers represent segments and column rows represent ways of argumentation. However, here students' individual ways of argumentation are visible by the colored box within each row. Jessie is represented in red, Lee in blue, Kendall in green, Chad in light blue, and Joseph in purple.

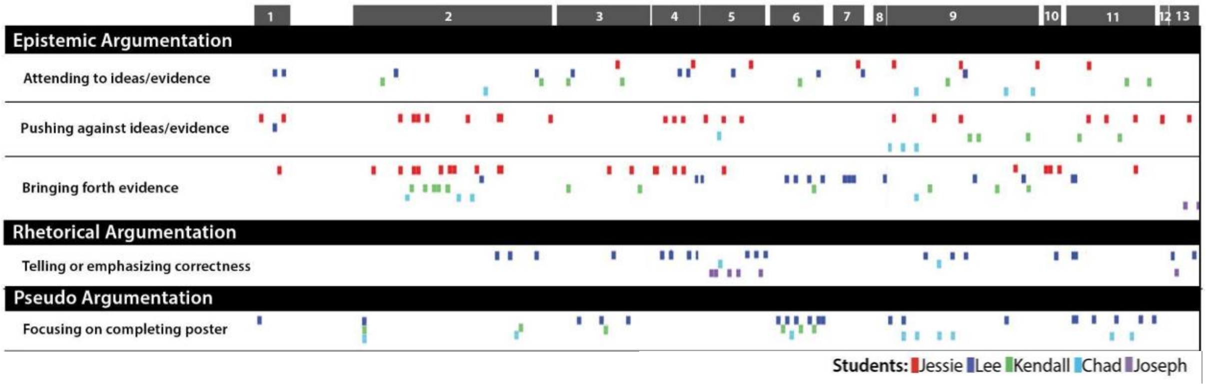
In this figure, we see that Jessie engaged in the epistemic ways of argumentation across the episode. She engaged in multiple epistemic ways including attending to her group's ideas and the evidence they present, pushing against their ideas and evidence, and bringing forth evidence in support of her claim. Bringing forth evidence and pushing against her peers' ideas occurred more frequently than attending to the ideas or evidence of her peers. In this work, she argued that the cell represents a plant because it had a cell wall, an argument that she made consistently across the episode drawing upon evidence in her notebook, the group's worksheet, and the microscope slide to support her claim. She attended to her notebook, a place where she has written down the underlying concepts of the lesson, to "research" her claim or for evidence to support her claim. She used the worksheet, an artifact that represents the observations that the group made when examining the cell slides under the microscope, as evidence to support her claim. And, she referred back to the microscope to push against Lee's ideas or as evidence to support her claim. Jessie did not engage in rhetorical or pseudo argumentation.

Figure 2
Ways of Argumentation by Enacted by Students Across Lesson Segments



Kendall interacted in epistemic ways as well by attending to ideas or evidence, pushing against the ideas or evidence of others, and bringing forth evidence herself. These interactions were largely with Jessie and Chad. While Kendall engaged in epistemic ways of argumentation, she also engaged in pseudo argumentation when she focused on constructing the poster for completion, a way of argumentation that Chad similarly engaged in. Chad, who was tasked by Lee with constructing the CER poster, engaged in all forms of argumentation. However, he remained largely focused on drawing the component parts of the poster and making sure the group presented a complete claim on the poster, as evidenced by the light blue marks in the pseudo argumentation category in Figure 2.

Lee similarly engaged in all ways of argumentation. He engaged across the episode in epistemic ways and also participated in rhetorical and pseudo argumentation. Lee's rhetorical argumentation occurred when he told the group the claim (i.e., the unknown slide represented an animal cell) providing minimal evidence to support the idea and when he pressed Jessie to convince him that her claim was correct. These rhetorical ways of argumentation are located around moments when Lee brought forth evidence in ways aligned with epistemic argumentation to support his claim as well as times when he also engaged in pseudo argumentation as he directed the poster construction. This mixture of argumentation resulted in rhetorical and pseudo argumentation being foregrounded in the interaction he has with his peers, a dynamic explored in more detail below.

Lastly, Joseph, a student from a nearby group, who is denoted in purple in Figure 2, engaged with the group in mostly rhetorical ways of argumentation when he told Jessie how the evidence should be interpreted in the middle of the lesson and again at the end of the lesson in support of Lee's argument.

Ways of argumentation that invited or discouraged jessie's epistemic agency

As noted in the introduction of this section and as shown by the density and distribution of Jessie's argumentation efforts, Jessie consistently engaged in epistemic ways. This portrait of engagement intertwined with her peers' ways of argumentation might suggest that Jessie had equal access to the sensemaking space. That is, from a cursory examination, one might assume that a student's engagement in the epistemic ways of argumentation or the interactions of one's peers around this argumentation, as visualized in Figure 2, means that students are collaboratively considering each other's ideas and negotiating these ideas towards a shared understanding. However, upon closer examination of these interactions and the affective markers surrounding them, mainly Jessie's exhibits of visible and verbal frustration, we came to understand that Jessie's persistent efforts were an ongoing attempt to gain access to the group's sensemaking efforts and to have her ideas heard and considered. All the while, the ways of rhetorical and pseudo argumentation Jessie's peers engaged in were powerful in acting against her epistemic agency, reducing her rights and privileges in the learning space.

In Figure 3, we overlay the affective markers of Jessie's expressions of frustration that we identified to assist in visualizing and animating these dynamics. These markers are presented as red squares in the first row of the figure and represent moments when Jessie was visibly and/or verbally frustrated in a segment. These moments were marked by Jessie cupping her face in her hands, putting her head up towards the ceiling, spreading her fingers and putting her hands out in front of her, shrugging her shoulders, hunching over, rolling her eyes, putting her hands on her hips, or making statements such as, "You guys aren't listening to me" or "If I'm wrong I'm going to feel like a failure." in raised or softened intonations. Figure 4 provides examples of some of these gestures.

Figure 3
Ways of Argumentation by Student

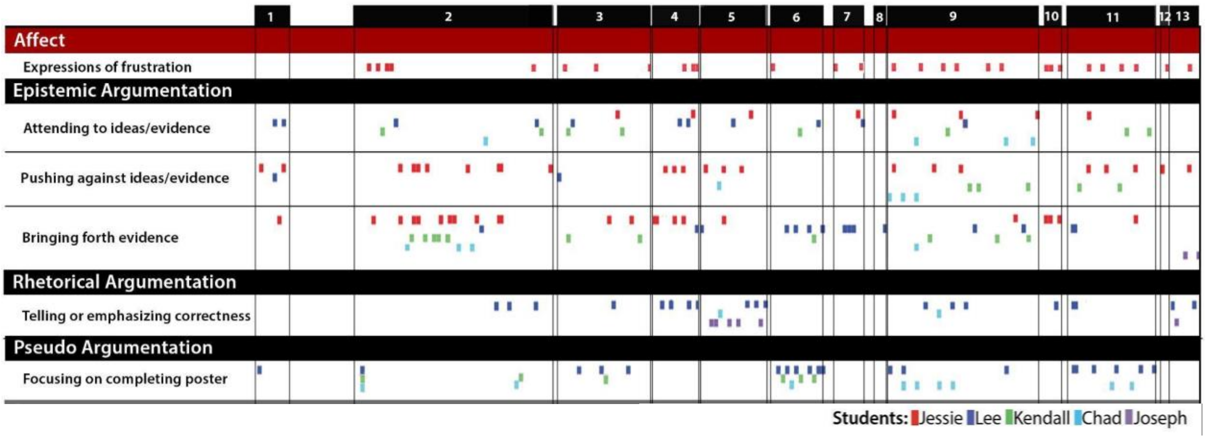


Figure 4
Examples of Jessie's Affective Gestures

These moments of frustration occurred at the bookends of many segments. Black column lines have been added to Figure 3 to help visualize the location of these markers in relationship to these segment boundaries. One example of such a frustration occurred in segment 2 when Lee was directing Chad and Kendall in constructing the structural elements on the poster (i.e., a section for the claim, evidence, and reasoning). In this interaction, Jessie was arguing that the unknown cell represented on the slide was a plant because it looked like the plant cell that the group had observed and drawn on their data sheet. Jessie pointed to the group's worksheet where they had recorded their observations of the plant cell and told the group "it looked like that because it [the unknown cell], it looked like it had lines." The group continued working on the poster without attending to Jessie's comment. Jessie then told the group to "Listen." to her and she continued to describe the slide saying "before, before somebody moved it [the slide mount under the microscope], it had, it didn't look like that [point to an animal cell on the worksheet]." She then questioned the group pointing to the unknown cell on the worksheet and saying in a raised tone, "This is the unknown right there, so why would it be this [an animal cell] when it looked like this [a plant cell]?" The group continued to focus on the poster and Jessie said "You guys are not listening. You are drawing on the piece of paper. Can you listen now?". In this interaction, Jessie is leaning on the table with her hands placed in front of her, she had an exasperated look on her face with her eyes wide open, and she asked for the group's attention in a raised tone. These efforts worked to shift Kendall and Chad's attention away from the poster to engage with Jessie's ideas, represented by the green and light blue marks in the ways of argumentation rows in the middle portion of segment 2 in Figure 3. Lee enters the conversion after these interactions saying "But, that's clumped up [the depiction of the unknown cell] and everything. It's clumped up." He then poses the question "So are we saying animal or are we saying plant?". This question is not answered by the group and instead results in Chad and Kendall moving back to focus on the poster (i.e., pseudo argumentation). Jessie remains focused on presenting evidence to support her claim and pushing against the evidence brought forward by the group saying,

> You guys are saying that this [the representation of the animal cell on the worksheet] is the same thing as this [the drawing of the unknown cell], but when you have these lines and you see these dots inside those lines [characteristics the unknown with matches a plant cell] that's not the same thing. That cannot be the same thing when it looks that different. It's not an animal cell!

In response, Lee tells Jessie that she might be right but that she needs to "give us evidence", "support the evidence", and "support your claim". Here, Lee's comments represent rhetorical ways of argumentation because he is requiring Jessie to convince him of her claim using the vocabulary of argumentation without using the conventions of the disciple (e.g., bringing forth evidence to support an alternative claim). In response to Lee's comment and his disregard for the epistemic work that she was doing, Jessie puts her hand behind her head in exasperation before saying "If I'm wrong…" in a frustrated tone before she moved to her notebook to do "research" before putting her it down slowly and turning back to the group to look at what they are doing.

The example just provided is an exemplar of the kinds of effort (cognitively and emotionally) required of Jessie to have her ideas heard by the group. She raised her voice and asked for the group's attention ("Can you listen now?") and while she obtained Chad and Kendall's attention, she lost this focus when Lee entered the conversation. In this space, Lee directed Chad and Kendall in the development of the poster and he pressed Jessie to justify her claim that the cell was a plant, justifications that she made (e.g., pointing to the group's representation of an animal cell that did not match the characteristics of the group's representation of the unknown cell) but were disregarded. In these presses, he provided minimal evidence to support his claim that the cell was an animal and, instead, took the stance that he needed to be convinced that his idea was not correct (i.e., rhetorical argumentation). The red marks in the row for ways of epistemic argumentation in segments 9, 10, and 11 in Figure 3 show that Jessie continuously engaged in the epistemic ways of argumentation across these segments. Also shown are the corresponding expressions of frustration that Jessie exhibited as she made these efforts for her ideas to be taken up.

Notable in this depiction are the marked increases of Jessie's expressions of frustration across segments 9 to 12. These related not only to Lee's requirement for Jessie to convince him that her argument was valid, but also to the group's uptake of Lee's claim, even when Chad acknowledged that it did not represent the group's ideas ("We think it's a plant but they [Lee] think it's an animal"). In this interchange, Chad asked Mr. Jerry what to do about this disconnect between Lee and the alternative claim. Mr. Jerry responded by telling the group to "roll" with what they had on their poster ("you wrote animal, so go with that") and then to give their "side of the story". Jessie exhibited exasperation that her ideas, again, are not being considered, asking if she had to argue for the alternative claim ("Do I have to argue this?) and stating "If I'm wrong, I'm going to feel like a failure." in segment 12. While Jessie continued to push against these ideas in segment 13, she ultimately shared the claim that the cell was an animal during the first round robin interchange. She stated, "The evidence is that there is no cell wall, the cell doesn't have a defined shape", both pieces of evidence that she argued against throughout the episode. As she described the claim on the poster, she said:

> Okay, so basically we looked. They looked for. Lee, Lee looked for everything that were in plants to see if it was in the cell that we are observing and he determined that they don't have any characteristics.

In this statement, Jessie is positioning herself as an outsider to the group, shifting from the use of the collective "we" to then distance herself from the action with the pronoun "they", referring to her group members, and ultimately calling out Lee in particular as the one in charge of this sensemaking effort. In this interaction, Jessie is somber and soft spoken as she leans up against the wall as she shares the claim, one that was counter to what she had continually argued for. These affective markers contrast those for which she exhibited during the episode when she was more energetically focused (e.g., animated hand gestures and raised intonation) as she worked to have her voice heard and ideas taken up by her group.

While we share these examples as evidence that Jessie engaged in considerable effort, in the epistemic ways of argumentation, to gain access to the scientific sensemaking of the group, privileges and rights were blocked Lee, Kendall, and Chad through their use of the tools of rhetorical and pseudo argumentation. We would also like to make note of Joseph, the fourth student that entered this group from time to time. We attend to Joseph's interaction with the group because they worked to bolster Lee's position and to further push against Jessie's epistemic agency as his efforts served to validate Lee's claim, often in the ways of rhetorical argumentation, in which he told Jessie that Lee's claim was correct (i.e., the cell represented an animal). We think that these interactions, while infrequent, were powerful in enforcing Lee's rhetorical efforts and Jessie's access to the learning space.

Conclusion

The case study presented here is an attempt to understand the rights and privileges to participate, and to understand the struggles to belong in science that arise in science learning environments through the lens of a young woman of color, Jessie, and her experiences. Our analysis as shown in Figures 2 and 3 provides an account of Jessie's efforts, detailing the extensive and continued work she engaged in to have her epistemic agency acknowledged by her peers. In many ways, Jessie's continued efforts to be seen as an active contributor to the construction and critique of knowledge claims are to be celebrated given the ways in which her peers (often boys) worked either actively or by omission to push her efforts as a Black girl toward the periphery. At the same time, further examination of these efforts highlights that Jessie's persistence is a reflection of her fight to have her rights as a scientific sensemaker acknowledged, and surface issues of inequity in which Jessie's efforts to exert her epistemic agency were eventually rejected by her peers. In this case, we see Jessie's continuous efforts to have her rightful presence acknowledged when the tools of argumentation were used to marginalize and subvert her privilege.

This analysis illustrates the interplay of the personal and communal in the performance of students' epistemic agency and the power that the community has in shaping this dynamic (Calabrese-Barton & Tan, 2020; González-Howard & McNeill, 2020). Recognizing and understanding this interplay and the power dynamics inherent in classroom spaces are essential if we are to push against systems of oppression inherent in classroom spaces towards more equitable and just science learning environments.

Abstract: The spread of misinformation regarding socioscientific issues necessitates that science teachers shift focus towards promoting students' use of reliable scientific reasoning strategies and practices (in addition to content knowledge) during instruction. Our goals in this study are twofold: 1) to develop a trustworthy survey instrument that can effectively measure students' experiences engaging in the epistemic practices (EPs) of scientists in the classroom, and 2) to better understand the mechanistic link between instructional approaches and student outcomes. We present a mixed-methods analysis of the variation in classroom experiences that emerged between two teachers with contrasting sets of student outcomes. This study represents one pathway to creating a novel, contextualized survey instrument that can effectively measure the extent to which learners might engage with aspects of EPs in their science classroom. It also further supports student-centered argumentation practices as an effective approach for shifting instruction towards promoting EPs.

Introduction

Given the rampant spread of misinformation regarding important scientific issues (e,g, vaccine safety, climate change), there is a pressing need to promote scientific literacy and, thus, an understanding of scientific practices in classrooms (Gorman & Gorman, 2021; NRC, 2012). This focus foregrounds the development of students' abilities to critically evaluate evidence and distinguish well-justified and accurate information from false and misleading claims (Chinn et al., 2020). It can be contrasted with traditional modes of teaching and evaluation, which have favored emphasizing science content instead of such scientific practices (Windschitl et al., 2012). The shift to bring scientific practices and reasoning skills to the forefront can be framed through research on developing learners' *epistemic cognition*—or the ways of thinking and practices used to establish, critique, and use knowledge within disciplines (Greene et al., 2016). An individual's epistemic cognition informs how they evaluate the reliability of scientific claims and how they come to understand how scientific knowledge is generated. Given this connection, we refer to a set of scientific practices and reasoning skills discussed in this study as examples of the *epistemic practices (EPs)* of scientists.

However, steep challenges exist in promoting EPs during science instruction. First, the link between instructional design and teaching practices that can help develop students' knowledge and use of EPs is not well understood (Muis et al., 2016). Further, little is currently known about how to effectively measure student outcomes in relation to EPs and how they might change over time (Hofer, 2016). As such, teacher educators have been grappling with how to optimize the design of professional development (PD) opportunities needed to help teachers further develop their own knowledge regarding the EPs of scientists, as well as the skills needed to facilitate students' understanding and use of EPs (e.g., Park et al., 2022). This includes, for example, knowing the reliable strategies scientists use for systematically evaluating evidence, justifying why scientific knowledge is reliable, and then engaging students in discussions around these topics to further their understanding.

In this study, we apply the Apt-AIR model of epistemic cognition, which outlines explicit goals for a successful epistemic education (Barzilai & Chinn, 2018), as a framework to inform the design of a curricular intervention in high school biology that we hypothesize, in turn will lead to improved classroom experiences for students. We focus specifically on EPs related to the domain of scientific modeling with complex systems (described in more detail below). Classrooms that incorporate learning environments like this can likely foster students' skill in understanding and enacting reliable EPs to accurately evaluate claims and evidence in their everyday lives (Chinn et al., 2020). We were guided by the following research questions:

1. How can we measure the extent to which students engage in the EPs of scientists during class?

2. What, if any, relationships can be drawn from student classroom experiences regarding their engagement in scientific EPs and what we know about how teachers implemented?

Measuring student experiences related to promoting apt EPs of modeling

Measuring student learning outcomes in science class as they relate to teachers' PD is both difficult and rare (Hofer, 2016). Within the field of epistemic cognition, there is a dearth of studies that use survey instruments with enough statistical rigor (e.g., they incorporate an analysis of model fit and/or the reliability of latent constructs) that reliably capture students' learning of this construct (Sandoval et al., 2016). These instruments are also difficult to validate given the contextualized natures of one's epistemic cognition and thus in the moment observations, as well as metacognitive reflections, are needed to help clarify relationships that might emerge in survey data (Bricker & Bell, 2016).

To address the need to focus on student learning outcomes using robust methodologies, we used elements of the Apt-AIR framework to inform the design of a survey instrument aimed at measuring students' experiences and opportunities in engaging in the EPs of scientific modeling. This framework integrates two models of epistemic thinking: the AIR model (Chinn et al., 2014) and the multifaceted framework of epistemic thinking (Barzilai & Zohar, 2014). The AIR model establishes aims, ideals, and reliable processes as the three main components of epistemic cognition. *Epistemic aims* are the specific goals related to an inquiry process. *Epistemic ideals* comprise the criteria that people use to evaluate whether their aims have been successful. *Reliable processes* denote the strategies that people use to achieve their aims and enact ideals. For the purposes of this study, we used the framing of ideals and reliable processes to help elucidate the specific set of EPs germane to the curricular intervention we were investigating. This is because preliminary coding analysis uncovered infrequent articulation of students' aims. For example, one of the ideals and its associated process relevant to this learning environment included *Rigorous fit with evidence that is systematic and conclusive* (Ideal) and *Considering multiple hypotheses* (Reliable Process used to enact that Ideal). These findings were then used as a basis for item design in the survey.

Furthermore, the multifaceted framework can be used to help design for the varying aspects that promote a comprehensive epistemic education. It states that education should include five key aspects of epistemic performance. These include (*with a survey item example to demonstrate how we attempted to capture each facet*):

i. Cognitive engagement in epistemic performance (e.g., engaging in an educational task in accordance with learning goals); *I often have opportunities to hypothesize and predict scientific results.*

ii. Adapting epistemic performance (e.g., adjusting learning strategies across environments to fit new contexts); *In my science class, my teacher points out how a focus on fitting models to evidence has parallels in science that I can see in the news*.

iii. Regulating and understanding epistemic performance (e.g., considering and reflecting on the purpose and processes of educational tasks); *In my science class, my teacher encourages me to discuss how to use reasoning practices in science out of school.*

iv. Caring about and enjoying epistemic performance (e.g., expressing curiosity, interest and enjoyment while engaged in educational tasks); *I learn science for my own interest.*

v. Participating in epistemic performance together with others (e.g., engaging in collaborative and collective discourse to achieve learning goals). *In my science class, I discuss or share my ideas with people using computer technologies.*

It is important to note that these aspects are not mutually exclusive (i.e., the same item can often fall within multiple aspects). However, using Apt-AIR is theorized to promote learners' abilities to achieve success through competence in epistemic activities (e.g., in the ability to reliably use data to formulate accurate inferences), as well as understanding how to regulate their use of EPs through metacompetence (e.g., in evaluating whether certain inferences can be made given the data available). Thus, we invoked the Apt-AIR model here to measure the wide-ranging aspects of students' experiences related to engaging in what we describe as the *apt EPs of modeling*, which comprise the ideals and processes situated within the context of this intervention. The goal is to demonstrate how this instrument might be used to detect any shifts in students' classroom experience in engaging in apt EPs. Ultimately, constructing a survey like this could be used to assess global classroom experiences, which is important when considering how to scale-up interventions and optimize student impacts. In addition, it would help researchers uncover the links between instructional approach and the degree to which students engage in EPs. To this end, we incorporated findings from qualitative data to elucidate how teachers' instructional approaches might be linked to any shifts that occurred. We now briefly turn to select research on how teachers' instructional approach might promote students' development of epistemic cognition.

Instructional approaches that can promote apt EPs in the science classroom

The call for science instruction to shift emphasis from content to the real practices and reasoning strategies of scientists has been well-established (Duschl, 2008; NRC, 2012), yet the exact approaches teachers can implement to enact this shift are difficult to identify and vary across contexts (Windschitl et al., 2012). One type of generalized approach identified as a critical area for teachers to focus instruction on involves immersing students in argumentative practices, especially in science classrooms as it is through these practices that knowledge advances in the field (Hand et al., 2016). Focusing on argumentative practices requires an emphasis on language through active dialogue, collaboration, and various forms of communication (Hand et al., 2021).

For example, science classroom dialogue should focus students' attention on interpreting data to make evidence-based claims, evaluating opposing claims, and communicating these ideas through verbal, written and graphical forms. To generate knowledge in this way, the classroom environment needs to be student-centered and deemphasize the need to "get" to the right answer (Hand et al., 2016; Muis et al., 2016). In this study, we used qualitative data to understand how teachers' instructional approach when engaging their students in scientific argumentation may have contributed to the quantitative differences in student outcomes that emerged from the survey data. Therefore, this study represents an attempt to draw clear links between the instructional approaches that can lead students to further developing their knowledge and use of EPs during class.

Methods

This study builds upon a larger project that engages high school science students in data collection and analysis through complex systems modeling curricula (Yoon et al., 2017). These curricula consist of five stand-alone units (covering topics spanning biochemistry to ecology and evolution). In this exploratory investigation, the research team collaborated with 8 teachers considered expert in implementing these modeling units to help further theirs (and their students') understanding of apt EPs as they relate to scientific modeling. We also engaged teachers in co-design work in partnering with them to revise the curricula to better promote apt EPs. We present a brief description of the PD below.

The summer workshop portion of the PD occurred over 10 days (with up to 4 hours of synchronous and asynchronous work each day) from August 3-17, 2021 and consisted of introducing teachers to the terms *epistemic cognition* and the AIR model. Next, we explored the differences between cognition and metacognition, the notion of aptness when engaging in EPs, and how to avoid cognitive biases when evaluating evidence. Finally, we discussed instructional strategies for promoting apt EPs and how to extend the EPs of scientific modeling to reasoning about socioscientific issues. In addition, we held four synchronous, 1h meetups with teachers during the school year to analyze the progression of teachers' implementation towards promoting apt EPs. In implementing this sustained PD with teachers, our goal was to improve teachers' understanding and skill in supporting student development of EPs and to increase the infusion of apt EPs into their instruction. In addition, we followed the eight teachers who participated in the PD into their classrooms to understand how their teaching practice might have changed and how that might impact their students. Half of the teachers taught at private, college preparatory schools and the other half taught at large suburban public schools in the north or southeastern U.S. The eight teachers were selected for this study as they represented teacher experts with respect to the modeling units being studied (i.e., they had implemented the curricula multiple times already and helped to facilitate other teachers' uptake of it). These teachers had, on average, 10 years of teaching experience, with a range of 5–18 years at the time the summer workshop occurred.

Participation in student surveys was voluntary, so this study includes survey data from 215 self-selecting students across teachers. Sample sizes of students per teacher ranged from 10 – 52 students and averaged 28 pre- and post-responses per teacher. Despite these sampling limitations teachers indicated that the participating students represented a broad range with respect to performance level. Of students who chose to report their demographics, 56% identified as female, 41% as male, and 3% as non-binary or gender conforming; 1% identified as American Indian Pacific Islander, 17% as Asian, 6% as Black or African American, 2% as Hispanic, 60% as White, non-Hispanic, and 14% as multiple races.

To address the first research question, we created a Likert-scale survey administered to students pre- and post-intervention to measure aspects of their science classroom experience. The survey consisted of 50 statements and was designed to measure latent constructs related to apt EPs of modeling (e.g., engaging in inquiry, problem solving, and scientific reasoning). Students responded to these statements using a five-point agreement rating scale (1=strongly disagree to 5=strongly agree). We employed an exploratory factor analysis (EFA) to reduce the survey dimensions to a lesser number of constructs based on patterns in the respondent data. Construct validity emerged by running the EFA on pre-survey data and retaining items only if they produced factor loadings greater than 0.40 and retaining factors only if 3 or more items clustered under it. We used visual inspection of the parallel analysis scree plot to determine that a solution of 4-6 factors was likely. We then ran three EFAs using a 4-, 5-

and 6-factor solution and compared the outputs. We determined that a 6-factor solution was the most reliable and simplest with Cronbach alpha scores for each factor ranging 0.81-0.92, no items identified as too ambiguous (i.e., clustering significantly under more than one factor), and fewer items clustering under each factor (ranging from 4 to 9) when compared to the other solutions. Eleven questions were identified as too indeterminate (i.e., correlated with none of the factors >0.40) and these were dropped from the item pool. The research team came to consensus on the construct names based on the pattern of items that clustered together (see Table 1). We averaged the responses for all students within a given factor and compared them pre- and post-intervention using paired t-tests. We then calculated Cohen's *d* (interpreted as small-0.2, medium-0.5, and large-0.8) if significant differences from pre- to post-survey emerged.

Table 1
Six Factors and Corresponding Latent Constructs from Student Survey Responses

Factor (Alpha)	**Construct**	**Example Items Comprising the Factor**
Factor 1 (0.81)	Engaging in empirical investigations in the science classroom	• I have opportunities to collect data to test and modify hypotheses. • I often hypothesize and predict scientific results. • I often have opportunities to find out answers on my own.
Factor 2 (0.82)	Engaging in problem-solving and communicating using multiple sources with others	• I discuss or share my ideas with people using computer technologies. • I often practice these skills…solving real world problems. • …communicating in multiple ways (e.g., through graphs, email, Internet, web-based tools, writing).
Factor 3 (0.83)	Connecting scientific reasoning in class to everyday life	• In my science class, my teacher encourages me…to discuss how to use reasoning practices in science outside of school. • …to point out how a focus on fitting models to evidence has parallels in science that I can see in the news.
Factor 4 (0.92)	Positive attitudes towards learning science	• I am motivated to learn more science in the future. • I learn science for my own interest.
Factor 5 (0.85)	Using modeling and modeling practices to learn about and do science	• I use computer models to conduct experiments and produce evidence to help me reason and understand scientific ideas. • I use computer simulations, images or animations to collect and analyze data and to draw conclusions.
Factor 6 (0.83)	Using and discussing criteria for good models	• In my science class, my teacher encourages me…to discuss the common characteristics of good complex systems models. • …to discuss why good models should fit all the evidence.

Next, we addressed the second research question by testing whether the overall shifts in students' classroom experience varied by teacher. We ran paired t-tests *by teacher* to investigate any changes pre to post for the factors that showed significant growth in the overall sample paired t-tests described above. Of the 8 teachers, we chose to highlight two for the purposes of this study, where one teacher's (Rachel) students showed negative average growth, whereas the other teacher's (Catherine) students showed significantly positive average growth. In focusing on two teachers with contrasting student outcomes, we aimed to elucidate the teacher implementation strategies that may have led to the differences in student reported outcomes. To do this, we turned to our qualitative data (i.e., video-recorded classroom observations, teacher debriefs and student focus group interviews) collected in each classroom to uncover what differences in instructional approaches may have existed. This in-depth qualitative approach would help us discern if the survey instrument was sensitive enough to detect variation across classroom experiences.

Results

Below we first present any changes in classroom experience regarding students' engagement in the 6 apt EPs measured. Second, we compare the student outcomes of two teachers, Rachel and Catherine, and then use their observational and interview data to better understand the links between teachers' implementation and the differences in students' classroom experience that emerged in the quantitative analysis.

Students show significant growth in three classroom experience factors

Overall, students across the 8 teachers' classrooms made significant gains in three of the six factors measured (see Table 2). Namely, students expressed having more opportunities to *Engage in Empirical Investigations in Science Class*, *Connect Scientific Reasoning in Class to Everyday Life*, and *Use Models and Modeling Practices to Learn* *about and Do Science* after the intervention. Effect sizes ranged from small to medium and suggest that the modeling units were at least partially successful in increasing students' engagement in apt EPs.

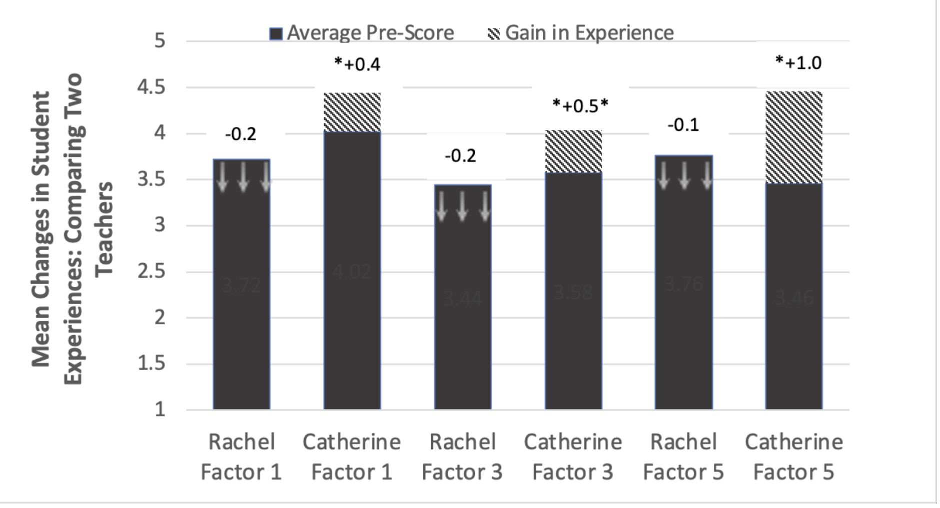
Table 2
Students' Overall Changes in Apt EP Experiences Before and After the Intervention

Factor	Pre Avg (SD)	Post Avg (SD)	Average Gain	Paired t-test results	Cohen's *d*
1-Engaging in empirical investigations in the science classroom	3.86 (0.96)	4.11 (0.90)	+0.24	t = -5.1, df = 214, p<0.0001*	**0.39**
2-Engaging in problem-solving and communicating using multiple sources with others	4.09 (0.88)	4.16 (0.83)	+0.07	t = -1.9, df = 214, p= 0.06	—
3-Connecting scientific reasoning in class to everyday life	3.64 (0.97)	3.85 (0.94)	+0.21	t = -4.0, df = 214, p<0.0001*	**0.28**
4-Positive attitudes towards learning science	3.90 (1.0)	3.91 (0.99)	+0.01	t = -0.13, df = 214, p= 0.89	—
5-Using modeling and modeling practices to learn about and do science	3.68 (0.99)	4.11 (0.86)	+0.43	t = -7.6, df = 214, p<0.0001*	**0.62**
6-Using and discussing criteria for good models	4.16 (0.84)	4.13 (0.81)	-0.03	t = 0.67, df = 214, p=0.50	—

Student classroom experiences vary by teacher

We next evaluated the three significantly different factors from above *by teacher* to uncover what, if any, variation in student outcomes existed across teachers' classrooms. For this smaller study, we present only the results from Rachel's and Catherine's implementation, as analysis at the teacher level showed these teachers' students demonstrated opposing trends in the survey data (see Figure 1 with * denoting the change from pre to post was significantly different). Paired t-test results showed that Rachel's students (n= 24) exhibited no significant measurable change across the three factors (Factor 1 t=1.3, p=0.2; Factor 2 t=1.7, p=0.1; Factor 5 t=0.8, p=0.5); however, Catherine's students (n=21) reported significant growth in all three (Factor 1 t=-2.3, p=0.03; Factor 2 t=-3.6, p=0.002; Factor 5 t=-7.0, p<0.0001). We now turn to qualitative data sources to better understand how teachers' instructional approach may have contributed to the differences in student outcomes that emerged.

Figure 1
Comparison of Student Experience Outcomes for Teachers with Opposing Trends



Selected differences in the instructional approaches of Rachel and Catherine

Here we present select details regarding the differences in how the two teachers implemented the project units to better understand how their instructional approach may have resulted in differing student experiences. However, we want to note that this study is in its early stage, and more complete coding of the full dataset is forthcoming.

The first noteworthy difference between Rachel and Catherine was in the number of units implemented. Rachel implemented only two of five units, and these were clustered towards the beginning of the school year (November and December). She had indicated her intention of implementing a third at the end of the school year

(June) but ultimately ran out of time. In contrast, Catherine implemented all five units and these were spread out over the course of the year (October, November, February, March, and May). This shows that the instructional time spent on curricula designed to emphasize the apt EPs of modeling (i.e., the "dosage" of the intervention) was much greater in Catherine's classroom.

Next, we compared how the two teachers facilitated the same group discussion, which was a Claim-Evidence-Reasoning (CER) prompt embedded within the Sugar Transport model. This model allows students to visualize the processes by which nutrients are transported from the intestines and into the bloodstream. In Rachel's class, students had worked in their groups for about 20 minutes to make observations about how the molecules were moving through the simulation. When facilitating the large group discussion about what mechanism was responsible for the spreading out of molecules, she called on each group in turn, asking "What did [your group] pick?" One student from each group would respond simply with the letter of the claim they chose without providing any evidence or reasoning behind their choice. Group 1 had chosen Claim B, while the other 7 groups called on after them had chosen Claim A. Rachel then exclaimed, "A! It is claim A. The random motion of the molecules is responsible for it spreading out. What evidence do we have of that?" A student from Group 1 discussed their reasoning behind choosing Claim B (i.e., the molecules repel because they "would spin a bit and then fling off"). Rachel seemed to avoid trying to unpack why Claim B did not fit the evidence in that moment when responding, "I guess you can say [that], but what evidence do we have of their random motion?" and shifted students' attention to justifying Claim A instead. She then called on 3 different students, solicited their ideas, listened to their responses, and then summarized back to them the take home message,

> We should have seen that the molecules moved in all different directions, which is random motion…so no particular pattern, it was random, they were moving in different directions. They may have bumped into each other and changed direction, and eventually they spread out evenly. Any questions? [Then Rachel moves on with the next activity in the packet].

In this episode, Rachel encouraged students to articulate the evidence they collected in the model from their various observations and confirmed that Claim A was correct. She geared the discussion towards primarily justifying the correct claim. In total she spent 2 minutes and 25 seconds on the class discussion of the CER.

Catherine, on the other hand, had tried out a new approach to facilitating this CER discussion with her students. In a debrief with her after the class, she mentioned how the PD workshop had impacted her decision to "do things a little a differently" this time.

> I was thinking about what we had talked [at the workshop] when I was planning for this. And just really leaning in to more like…I really feel like I'm guilty of…being like okay we need to get to the right answer. And then once we're there we need to immediately pick back up, or we're not going to finish. Because we're always just stressed for time...So that was me trying to kind of, let's actually take some time on this group discussion. And I modified the student handout so it only had this one group discussion so we could take the time. And I wanted them to think about alternate hypotheses and not just read it and be like, which is most right, and then not even consider the validity of the other two.

In her planning, Catherine anticipated that if she asked the students "what's right? [They're] gonna all say similar things", so she wanted to "explore" the validity of the other two claims a little bit. To do this, she assigned two groups each to Claim A, B and C and posed the question that if the claim they were assigned was correct, what evidence would students see in the simulation to prove that it is correct? She then had students talk in groups for about 5 minutes and told them to come to the board when they were ready to write and share the ideas they discussed. Going through the evidence on the board for each claim, she posed questions to students about whether they saw the evidence described. Students engaged in lively discussions, with one articulating in regard to Claim C (blood flow causes the molecules to spread out) that they "did not have enough evidence yet" from the simulation to determine if it plays a role, but they suspect that it did. Catherine replied, "That's totally fine to say" and validated this student's thinking even though Claim C was technically incorrect. This student was so engaged in the discussion that he stayed after class to work with the model to gather the evidence he needed to be sure.

After various students had the chance to articulate their ideas, she then ultimately asked them to rate each claim as to whether they thought it was the correct one via thumbs up (agree), thumbs side (partially agree), or thumbs down (disagree). She summarized her take home message,

> You always want to be looking for the *why* in biology. It's kind of lazy if we just say, "They just do!" We need to figure out why… It's like pool balls on an empty table in one area, if we shake it, they're going to bounce and spread out into the empty space. And I liked how we talked about cycle, tying back to our complex systems idea, this is not beginning or end, right? There is no end point. It's a cycle, and there would be more bouncing and more spreading out. That's what diffusion is. That's how things move out randomly without energy, it's a very interesting scientific concept we don't think about a lot…So take a moment with your partner, pick what claim you are most convinced by…And then talk about how you want to articulate your reasoning. *Why* does that evidence prove your claim is correct? [Then Catherine has students continue working on the packet]

In this episode, Catherine encourages students to predict what they would see, think about the reasoning behind it, and then decide which claim was correct, without indicating there was only one correct answer. She geared the discussion towards careful evaluation of each claim, making sure she engaged different students in articulating their thinking out loud. In total she spent 28 minutes and 28 seconds on the class discussion of the CER.

In comparing these instructional episodes across the two teachers, we can see elements of Factor 1 (*Engaging in Empirical Investigations)* emphasized in Catherine's practice, where she actively encouraged students to make predictions and find out the information on their own. Catherine's students also exhibited their largest gain in Factor 5 (*Using Modeling and Modeling Practices to Learn About and Do Science)*, and we can see clear demonstrations of this in her emphasis on using models to understand scientific ideas and to engage in scientific reasoning and inferencing. While Factor 3 (*Connecting Scientific Reasoning to Everyday Life)* was not necessarily on display in either episode, Catherine did later describe a fad diet project she implements with students in conjunction with this Sugar Transport model. She gives students a choice of researching 1 of 4 fad diets, all which make claims about how they increase athletic performance and energy. It is possible the connection to fad diets is something students found useful in their everyday lives, and similar to the episode presented here, Catherine tasks students with systematically evaluating whether these claims can be substantiated.

In contrast, Rachel mentioned in the debrief after her class that she's "usually pretty 'notes heavy' with biology just because [she] still feels like [she's] a new bio teacher." Her training was in chemistry-education and her course shift to biology occurred three years prior to this episode (compared to Catherine who was trained in biology and had six years of teaching experience). Rachel's students further elaborated on her practice in their focus group interview that in her biology class they would "write everything down, and that would be the entire class. It was just memorizing facts and definitions." From the comparison of these two episodes and approaches, we see that Catherine displayed a shift towards emphasizing apt EPs whereas Rachel's practice seemed largely focused on emphasizing content; furthermore, these differences were detected in the survey instrument.

Discussion

In this study, we used the Apt-AIR framework to inform the design of PD with high school biology teachers and administered a Likert-scale survey to the students in their classrooms to measure the extent to which teachers enacted shifts towards promoting apt EPs in their instruction. The survey was sensitive enough to detect significant shifts from pre to post in three constructs related to students' classroom experiences (*Engaging in Empirical Investigations, Connecting Scientific Reasoning to Everyday Life,* and *Using Modeling and Modeling Practices to Learn About and Do Science*). This study represents one pathway to creating a novel, contextualized survey instrument that can effectively measure the extent to which learners might engage with at least some aspects of apt EPs in their science classroom. In addition, we lend support to the findings from the survey data with observational and interview data that focused on the instructional approach of two teachers with contrasting student experience trends. This underscores the value in engaging with multiple assessment methods when measuring outcomes related to epistemic cognition (Bricker & Bell, 2016). Ultimately this research can help address the need to examine broad-level student impacts that extend beyond individualized case studies (Hand et al., 2016). Our future work building from this study will include a more systematic analysis of teacher variation and the qualitative data associated with it. For example, more analysis is needed to determine if the survey instrument is sensitive enough to detect differences among the other teachers in the cohort.

This study addresses another gap in the literature in that we aimed to draw relationships from student classroom experiences regarding their engagement in apt EPs and what we know about how teachers implemented. This can help uncover the connections between the instructional approaches that led students to further develop their knowledge and use of EPs (Muis et al., 2016). We can attribute at least some of this shift towards foregrounding EPs in Catherine's instruction to participation in the PD, as she cited it as part of her planning of the CER discussion that engaged her students in many apt EPs (e.g., engaging in multiple hypotheses, systematically evaluating evidence). She also facilitated a rich discussion with her students that prompted them to articulate their reasoning and evaluate opposing claims through various forms of communication (verbal and written), which has previously been identified as an effective approach in promoting EPs (Hand et al., 2021). However, Catherine admitted feeling “guilty” of focusing too much on performance goals (i.e., getting to the ”right” answer) due to time pressure in the past. We saw this focus emerge in Rachel’s approach, where she emphasized discussing the evidence for the correct claim only in her relatively brief CER discussion example. It is thus important for PD developers to focus more attention on developing teachers’ instructional approaches while also considering the intense time constraints that teachers face in their everyday practice (Hand et al., 2021). Overall, this work is important in developing informed citizens that can transfer their use and understanding of EPs to their everyday decision-making regarding current socioscientific issues (Chinn et al., 2020).

Epistemic Systems: A Knowledge-Level Characterization of Epistemic Games

Hillary Swanson, Utah State University, hillary.swanson@usu.edu

Abstract: Engaging students in epistemic practices, including explanation, modeling, and sense-making more generally, has become an important focus of science education. This paper draws from two theoretical frameworks: *epistemic forms and games* and *knowledge in pieces*, to create a framework for building fine-grained models of the knowledge involved in scientist and student engagement in epistemic games. The *epistemic systems framework* (ESF) features two main components: one perceptual and one cognitive. The perceptual component includes the perceptual strategies the individual uses to extract raw information from the world. The cognitive component includes the network of knowledge the individual uses to make sense of that raw information and turn it into an epistemic artifact (e.g., an explanation or model). The paper presents two case studies to demonstrate how the ESF can be used to model student engagement in both informal and formal epistemic games.

Introduction

Engaging students in epistemic practices has become a central focus of science education (Duschl, 2008). Epistemic practices are knowledge-building practices of science. They include theory-building practices, such as modeling and explanation. They include empirical practices, such as representing, analyzing, and interpreting data. They include practices that bridge theory and data, such as argumentation. In general, these practices engage students in sense-making and support their construction of knowledge through the same practices that scientists use in their construction of formal knowledge (Schwarz et al., 2017). Engagement in epistemic practices can help students develop understanding of scientific phenomena, as well as skills for engaging in scientific practices. Importantly, constructing knowledge through epistemic practices challenges students' beliefs about who has the authority to generate and evaluate scientific knowledge (Ford & Foreman, 2006; Manz, 2015).

A number of research programs have sought to characterize students' engagement in epistemic practices in the context of classroom activities (Lehrer & Schauble, 2000). Some of this work has characterized the nature of student participation in computational modeling (Wilensky & Reisman, 2006). Another strand of work has examined elements of students' mechanistic reasoning in the context of modeling and explanation activities (Krist et al., 2019; Russ et al., 2008). Yet other work has examined the knowledge students have about the nature of scientific products and practices, including their epistemic considerations when constructing and critiquing explanatory models (Berland et al.; 2016), their meta-modeling knowledge (Schwarz & White, 2005), and their criteria for scientific models (Pluta et al., 2011).

These characterizations provide a good foundation for understanding student engagement in epistemic practices. diSessa has articulated a need for building knowledge-level characterizations of student engagement in knowledge-construction activities (diSessa, 2014). Such characterizations would include fine-grained models of cognitive processes underlying students' participation in and learning through epistemic practices. Such models can help us understand the knowledge and cognitive dynamics involved in the construction of new knowledge. This, in turn, can inform the design of instruction that effectively helps students learn scientific material through participation in epistemic practices. This paper introduces a framework for modeling the knowledge leveraged by individuals engaged in epistemic practices, including informal sense-making and more formalized scientific knowledge-building processes.

Theoretical foundations

The theoretical framework introduced in this paper integrates ideas from two existing theoretical frameworks. The first, *epistemic forms and games* (Collins & Ferguson, 1993), is concerned with characterizing scientific knowledge-building practices. The second, *knowledge in pieces* (KiP; diSessa, 1993), is concerned with modeling, at a fine grain size, the structure and dynamics of both naive and expert knowledge. Synthesizing the two frameworks enables the construction of fine-grained models of the structure and dynamics of knowledge involved in both informal and formal knowledge-building processes.

Epistemic forms and games

Collins and Ferguson (1993) introduced *epistemic games*, to characterize the knowledge-construction activities of scientists and other scholars. Example epistemic games include building temporal models of processes, hierarchical lists of related entities, and computational models. Each epistemic game is played to produce a particular epistemic artifact, which is a specific instantiation of a general epistemic form. For example, in the case of the "temporal decomposition" game, the target form is a timeline of events in a larger process and a resulting artifact might be a stage model of cognitive development. In the case of the "hierarchical list" game, the target form is a list organized by a hierarchy of categories and a resulting artifact might be a taxonomy of mammals in the animal kingdom. In the case of the "computational modeling" game, the target form might be an agent-based computational model and the resulting artifact might be a model of predator/prey dynamics.

The epistemic form can be thought of as a template with slots that, when filled, answer the question driving an inquiry. The form constrains the game played to fill the slots. Collins and Ferguson unpack the example of an inquiry inspired by the question "What is the nature of X?" The answer to this question may take the form of a list of characteristics of X. A *list* is a template with slots for distinct characteristics of X. The corresponding *list* game is played to fill out this template. The game is characterized by moves such as adding, removing, merging, and splitting list items. For example, a scientist might ask the question: "What is the nature of the Zebrafish?" They might list characteristics such as "lives in freshwater," "belongs to the minnow family," "originates in both tropical and subtropical climates."

Collins and Ferguson present a list of epistemic forms and games. They divide games into structural, functional, and process games, and illustrate each kind of game with examples. For each example, they describe the form and the basic moves by which the game is played. The theoretical framework introduced in the present paper is designed to characterize the knowledge an individual draws on in their enactment of an epistemic game.

Knowledge in pieces

Knowledge in pieces (KiP; diSessa, 1993) is a cognitive theory of knowledge and learning. In contrast with cognitive perspectives that view the knowledge of an individual as a unitary structure consistently used across contexts (Wiser & Carey, 2014), KiP views the knowledge of an individual as a complex system of elements that are drawn into networks in response to the sense-making demands of a given context.

From a KiP perspective, the naive knowledge system consists of elements that are activated inconsistently across contexts, while the expert system has more consistent connections between elements and contexts. In the naive system, elements may be activated in contexts where they are productive as well as in contexts where they are not productive. In the expert system, elements are activated reliably in contexts where they are productive. The transition from novice to expert (i.e., learning) is viewed as a gradual tuning to expertise through which the individual's knowledge system is reorganized and refined. Elements of prior knowledge that were unproductive in one context may be repurposed and used productively in a new context. For this reason, KiP views a learner's prior knowledge as rich with potentially productive *resources* for the construction of more formal knowledge. This sets KiP apart from "misconceptions" perspectives, which view learners' commonsense conceptions as obstacles to learning (McClosky, 1983). While "misconceptions" perspectives view students through a deficit lens, KiP views students through an asset-based anti-deficit lens (Adiredja, 2019).

A primary goal of KiP is to build theoretical machinery for modeling the structure, dynamics, and development of an individual's knowledge system. Towards this aim, a number of scholars working within the KiP paradigm have developed ontologies of knowledge elements and knowledge structures, which bring knowledge elements together synergistically to accomplish particular goals.

Knowledge elements

KiP researchers have proposed elements belonging to a number of different knowledge ontologies. *Conceptual knowledge elements* have been proposed to account for individuals' intuitive sense of mechanism and their sense of satisfaction with explanations or predictions of phenomena. This kind of knowledge includes phenomenological primitives (p-prims; diSessa, 1993). A well-documented p-prim called "Ohm's p-prim" captures the intuition that "greater effort leads to greater result." An individual might draw on this intuition when asked to provide an explanation for why they are able to push a couch across the room with greater speed, saying: "Because I pushed harder." *Epistemological resources* have been proposed to explain how individuals understand the nature of knowledge. This kind of knowledge includes ideas about the origins of knowledge and the nature of its validity, as well as epistemic forms and their associated entry conditions and constraints (Hammer & Elby, 2002). Epistemological resources for understanding the nature of knowledge include ideas such as "knowledge must be transferred from one person to another" and "anyone can make up a new idea." In addition to conceptual and epistemological resources, a category of knowledge has been proposed, which facilitates the enactment of *epistemic game moves* (Swanson, 2023). This includes knowledge facilitating an individual's division of a larger process into smaller pieces during a temporal decomposition game, or their identification of similarities and differences in a move to merge items during a list game.

Knowledge structures

An important knowledge structure developed within the KiP paradigm is the coordination class. Coordination classes were invented to model knowledge systems used by individuals when obtaining measurable information from the world, such as force or velocity (diSessa & Sherin, 1996). Coordination classes are knowledge systems that feature two components, one perceptual and one cognitive. The perceptual component consists of the sensory machinery used by an individual to attend to objects and events and extract raw data from the world. This component has been called *readout strategies*, because it consists of the perceptual strategies the individual uses to "read out" data from the world. The cognitive component consists of the knowledge used by an individual to direct their attention to particular objects and events, and the knowledge they use to infer the desired information from the extracted data. Because it includes knowledge supporting an individual's ability to infer information from the world, the cognitive component has been called the *inferential net*. The combination of readout strategies and inferential net used by an individual to obtain a particular kind of measurable information from a particular context is called a *concept projection* (diSessa & Wagner, 2005). An individual may have multiple concept projections for obtaining the same information from different contexts. The greater number of contexts for which an individual has productive concept projections, the greater their expertise regarding that information.

A concrete example may be helpful for illustrating the different components of a coordination class. Imagine an individual trying to determine which of two vehicles travels with greater speed around a track. The individual's inferential net includes knowledge that directs their attention to the relative positions of the vehicles, because their knowledge contains ideas about the connection between position and speed, as well as the knowledge that the vehicles began to move at the same moment from the same initial position. Their readout strategies extract data that Vehicle A is further away from the initial position than Vehicle B. Their inferential net then draws on knowledge relating speed to change in position with respect to change in time, helping the individual infer that Vehicle A must be traveling faster. The particular readout strategies and inferential net used by the individual in this situation would be the concept projection they used to determine which vehicle moved with greater speed.

The knowledge structure introduced in the present paper is similar to the coordination class in that it features both perceptual and cognitive components. While coordination classes are knowledge structures used to obtain measurable information from the world, the knowledge structure proposed below is activated when an individual engages in an epistemic game, whether it be informal sense-making or a more formalized process such as scientific theory building. I present this knowledge structure, which I call an *epistemic system*, next.

Epistemic systems

The *epistemic systems framework* (ESF) incorporates elements from both epistemic forms and games and KiP. Drawing on epistemic forms and games, it aims to characterize individuals' informal sense-making and formal knowledge construction as engagement in epistemic games. It draws on elements of KiP to characterize both the informal and formal knowledge involved in the enactment of epistemic games at a fine grain size. It uses coordination class theory as a reference model and likewise has two components: one perceptual and one cognitive. The perceptual component is the same as in the coordination class model: it consists of the perceptual strategies (e.g., sense of hearing and sight) which mediate an individual's perception of particular objects and events in the world, allowing them to extract raw data about those objects and events. The cognitive component is similar to that of the coordination class model and is referred to as the *epistemic net*. The epistemic net is the knowledge network drawn on by an individual during an epistemic game.

The epistemic net can be further decomposed into different kinds of knowledge resources, each serving different functions in the enactment of the epistemic game. This includes *epistemological*, *conceptual*, and *epistemic game move resources*. The individual's epistemological knowledge orients their attention to relevant raw data. This is because their epistemological knowledge includes knowledge of both informal epistemic forms (e.g., intuitive expectations for what comprises a satisfactory explanation) and formal epistemic forms (e.g., a stage model), which motivates their inquiry and guides it towards a particular end goal. The individual's conceptual knowledge is used as raw material for generating explanations, and as a benchmark for comparison and assessment of the reasonableness of given explanations or phenomena. The individual's epistemic game move resources are used to fill out the epistemic form by connecting conceptual knowledge elements and evaluating and refining the epistemic artifact. As in the case of the coordination class, an individual may draw on different combinations of perceptual and cognitive components when enacting the same basic epistemic game in different contexts. Each unique combination is considered a different *epistemic projection*.

How system elements might work together in the case of informal epistemic games

In the case of informal epistemic games, the system elements work together to support the individual's sense-making activity. For example, imagine that one morning, an individual walks barefoot across a lawn towards a building. As they approach the building, they notice their feet becoming wet. They wonder why their feet have become wet, while just a moment before their feet were dry. Let us examine the activity of their epistemic system from this moment forward. Epistemological resources within their epistemic net make them feel there must be a plausible explanation for this phenomenon. This drives them to seek a causal explanation (an intuitive epistemic form), which directs their senses to aspects of their environment where they anticipate they might find clues. Through their sense of touch, they extract information that the grass closest to the building is quite wet and coldest in temperature. Through their sense of sight, they determine that this grass is in the shade produced by the building. The grass just beside the shaded region is in the sun, it is still damp but not as cold or wet. Just a few steps further out the grass is dry and warm. The individual enlists epistemic game move resources to compare the wet and dry regions. They determine that the shaded regions are wettest and coldest, regions nearest to the shade but in the sun are damp and slightly warm, and regions far from the shade and in broad daylight are dry and warm. The individual draws on conceptual knowledge, including ideas about sunlight causing water to evaporate and about the rising sun shrinking the shaded region around the building. By synergistically drawing on their perceptual and cognitive components, the individual takes in the phenomenon and makes sense of it. They produce the explanation that as the sun has been rising, the shaded region of grass beside the building has been shrinking, leaving the grass driest in spots furthest from the building, wettest closest to the building where it is still covered in shade, and somewhere on a gradient between wet and dry between these two zones.

How system elements might work together in the case of formal epistemic games

A formal epistemic game can also be modeled using the ESF. In this case, the individual's epistemological resources would also include a formal epistemic form, which would orient the individual to their knowledge construction task. For example, the individual may be interested in creating a computational agent-based model to explain the dry-to-wet gradient of the grass on their morning walk to work. The agent-based model would act as a template with slots to be filled, guiding their epistemic game. Specifically, these slots would prompt the individual to name the agents in the model (e.g., photons and water droplets), to specify their initial conditions (e.g., photons leave the sun with some range of energy values, water droplets are randomly distributed across grass blades and have some range of initial energy values), and to specify their behaviors (e.g., photons leave the sun and travel in a straight line, water droplets absorb photons, gain energy, and fly away from the grass in random directions with varying probabilities). Needing these particular pieces of information might cause the individual to look for and extract particular data, drawing perhaps on their memory of the different entities in their morning stroll, and the warmth of the sun and the cold wet grass under their feet. They might use epistemic game moves to compare the relative temperatures and moisture levels of the grass in the sun with the grass in the shade, and their conceptual knowledge might allow them to make decisions about assigning initial energy levels to the photons and water droplets in the model, based on their temperatures. By orchestrating the perceptual and cognitive components of their epistemic system, the individual engages in a formal epistemic game of building a computational agent-based model, which simulates and validates their informal sense-making.

Methodology

Data featured in the following section were taken from a larger study, which investigated students' engagement in an 8th grade science elective course that focused on the generation, evaluation, and refinement of pattern theories (Swanson, 2019). The kinds of patterns featured in the course were patterns in behaviors or processes that led systems to change over time, including threshold and equilibration. These kinds of patterns can be found in phenomena across domains, from physical to psychosocial. For example, a pattern of threshold can be recognized in a tipping point of a tower of blocks, as well as the limit of a person's patience.

The course, called the Patterns class, was implemented and refined across four iterations. Data from the final implementation are reported in this paper. This implementation occurred in a middle school located in an economically depressed neighborhood of the U.S. West Coast. It was the primary curriculum of an 8th grade science elective course, which had traditionally been used as an enrichment period for students who had scored above average on tests of basic math and the English language. The course met for 40 minutes, 3 times a week over the entire school year, for a total of 52 hours. Twenty-one students participated in the course (11 girls, 10 boys). The majority of the students spoke English as a second language and had immigrated to the U.S. from Central America and Mexico. The author was the primary teacher of the course.

The Patterns class engaged students in an epistemic theory-building game, in which students generated, evaluated, and refined pattern theories. Their theories were simply descriptions and/or explanations of the patterns they found in multiple phenomena. For example, for the pattern of threshold, one student's pattern theory read:

"Adding more until you get a reaction." The course guided students' exploration and articulation of four patterns: threshold, equilibration, exponential growth, and oscillation. Data from the equilibration unit are presented in this paper. For each pattern, students explored two example phenomena and then wrote their first theory draft. They then evaluated their theory against a third example and wrote a second draft. They then generated examples of phenomena from their own lives that followed the pattern, evaluated their second drafts against these, and wrote third draft theories. Through cycles of generation, evaluation, and refinement, the students iteratively revised their pattern theories and their thinking.

Data were collected in the form of video footage, student work, and teacher/researcher reflections. Two video cameras captured each session. One was positioned at the front of the room and captured the students working at their tables or participating in class discussions. The other camera was positioned at the back of the room and captured presentations made at the front of the room by the students or teacher, and what was written on the white board. Student work was collected at the end of each class session and scanned or photographed and then returned to the students at the start of the next class period. The teacher wrote reflections at the end of each period, noting anything that stood out from that day in terms of student thinking, activity design, and classroom management.

Data were analyzed using knowledge analysis (KA), a suite of techniques developed for analyzing data through a knowledge in pieces lens (diSessa et al., 2016). Reflecting its KiP orientation, KA views data through a cognitive lens, with a goal of modeling the structure, dynamics, or development of individuals' knowledge systems. Analyses typically focus on characterizing these phenomena at a fine-grain size. Knowledge structures are therefore described in terms of the smaller elements of which they are composed, and the systems' dynamics and development are described in terms of smaller moves in an individual's reasoning or the piecemeal shifts in thinking occurring at fine time-scales. Knowledge analysis often moves in a bottom-up direction, with a goal of inventing new models to characterize data. Below, Patterns class data are analyzed through a fine-grained lens to model the structure of the epistemic system students draw on when engaging in informal and formal epistemic games. For the informal epistemic game, video footage of a whole-class discussion is analyzed. For the formal epistemic game, student work is analyzed. Pseudonyms are used in the place of student names.

Findings

I present examples of both informal and formal epistemic games enacted by students in the Patterns class. For each example, I present data and then use the ESF to characterize the epistemic projection of one student.

Informal epistemic game

The example of student engagement in an informal epistemic game is drawn from a whole-class discussion, which occurred near the beginning of the equilibration unit. The discussion followed an activity in which the students investigated a glass of cold milk warming to room temperature. The graph of the milk's temperature over time showed that the milk warmed fast at first, and then slowed down as the milk reached room temperature. The class discussion focused the students on generating a causal explanation for the "fast-then-slow" warming phenomenon. Just prior to the discussion, the teacher had asked the students to write down their initial explanations.

The teacher seeded the discussion by reading aloud each of the students' explanations, leaving them anonymous. She then asked them to consider one idea in particular: "Because it was getting to room temperature at the end, so it was slowing down. It's like a race, when you're getting to the destination you start to slow down." The students debated the idea, pushing the student who had written it to unpack his thinking and explain why approaching room temperature would cause the milk to slow down. This student was Alvaro, though, due to the anonymity of the activity, no one knew this but he and the teacher.

> Leo: Why would you slow down when you're about to finish a race? It doesn't make sense.
> Teacher: Does anyone want to try and make a guess why?
> Alvaro: Say there's a wall. Are you going to run straight into it Leo?
> Leo: Well, I'm not gonna go slower though, because then I'll lose.
> Alvaro: Like no-no-no-no-no! Like, say you're winning 'cause you're going as fast as you can, then when you're gonna reach the wall, don't you start to like kinda? <stomps feet on ground>

Michelle then challenged Alvaro's race-to-a-wall analogy on the basis of its fit with the milk scenario.

> Michelle: Is there a wall?
> Alvaro: Yes, there's a wall.
> Michelle: There is no wall.

> Alvaro: There is a wall.
> Michelle: Where?
> Teacher: Alvaro, what would the wall be in the case of the milk warming up?
> Alvaro: The room temperature.

Because the debate had interrupted his explanation, the teacher asked Alvaro to summarize it.

> Alvaro: You're like running, like fast as you can, 'cause like just straight, and then you're like gonna run into the wall, you're not going to keep going the same speed <turns to Leo> dude, you're just going to […] You have to slow down to stop.

Alvaro's epistemic projection

Epistemological resources. Alvaro's epistemological resources frame the task at hand, orienting his attention and motivating his activity. In this segment of transcript, Alvaro hears Leo and Michelle challenge his explanation for the fast-then-slow warming. He is motivated to defend his ideas and craft a satisfactory causal explanation for his classmates. This intuitive epistemic form drives Alvaro to understand the problems his classmates have with his original explanation and to modify it accordingly.

Perceptual strategies. Alvaro's goal of crafting a causal explanation orients his attention to both his original explanation and the phenomenon he is trying to explain. He may be attending to the explanation that is written on the board, or he may be attending to his memory of it, which may include details that he has not publicly articulated. As for the phenomenon he is trying to explain, he may be focused on the graph or data table representing the temperature over time, both of which are drawn on the board. It is also possible his attention is focused on a memory of his participation in an activity where he demonstrated the temperature change of the milk by walking along a thermometer drawn horizontally on the board (Swanson & Trninic, 2021). From the objects of his attention, Alvaro's perceptual strategies enable his extraction of the information his explanation must account for: the milk is warming quickly at the start and then slows down as it approaches room temperature.

Epistemic game move resources. Alvaro employs a number of epistemic game moves in his attempt to make his explanation sensible to his classmates. His initial hypothesis had explained the slowing of the milk's warming in terms of a race analogy. Leo challenged his analogy on the basis of its logic, questioning why a runner would slow down at the end of a race. Alvaro recognized the problem with his logic and modified the analogy so that it was logical, by making the race end at a wall. Alvaro's moves suggest that he had knowledge facilitating their enactment, specifically knowledge enabling his evaluation of the logic behind his original explanation and recognition of its shortcoming, and knowledge enabling his evaluation of his proposed modification to the analogy. When Michelle challenged the analogy by pointing out a missing mapping (asking Alvaro what the wall was in the case of the milk), Alvaro clarified the mapping, stating that the wall in the case of the milk was room temperature. Again, Alvaro's moves suggest underlying knowledge, specifically knowledge facilitating his evaluation of the mappings between the race analogy and milk scenario and his identification and evaluation of the mapping implicit in his explanation.

Conceptual resources. Alvaro draws on several conceptual resources in attempting to make his explanation sensible to his classmates. These likely include knowledge of what it is like to run a race both in the open (where you wouldn't need to slow down to stop) and what it is like to run a race to a wall (where you would hurt yourself if you didn't slow down to stop), and an intuition which may be a p-prim: "you have to slow down to stop." This logic is at the heart of his explanation for why the milk is warming more slowly as it approaches room temperature and it is the key behavior illustrated by the race analogy. He draws on these conceptual resources in constructing his original explanation, and in modifying and more clearly articulating his explanation in response to his classmates' criticisms.

This example shows how the perceptual and cognitive elements of Alvaro's epistemic projection worked together to help him clarify the sensibility of his explanation for why the milk warms fast-then-slow.

Formal epistemic game

The example of a formal epistemic game is drawn from students' second draft equilibration theories, written towards the middle of the unit. Construction of pattern theories is considered a formal epistemic game, as it is guided by a formal epistemic form. The drafts were written following exploration of the examples: cold milk warming, hot tea cooling, and particle diffusion. For his second draft theory, Emre wrote:

> Fast then slow, fastest, faster, fast, slow, slower, slows, stop, slows down b/c reaching equilibrium goes fast in the beginning because it has more room to cover.

Emre’s epistemic projection

Epistemological resources. Emre’s epistemological resources frame his task, orienting his attention and motivating his activity. In this case, his epistemological resources include a formal epistemic form given to him by his teacher: the form of a pattern theory. This form is a template for a description of a behavior common to the behavior he had explored thus far (including the cold milk warming, hot tea cooling, and particle diffusion).

Perceptual strategies. The pattern form orients Emre’s engagement in an epistemic game of pattern-theory building and brings his attention to the three phenomena he has observed. It directs his attention to the behavior demonstrated by each phenomenon, as opposed to their surface features.

Epistemic game move resources. Emre employs epistemic game move resources in his attempt to find a behavior that is common to the three examples. The moves likely involve knowledge facilitating his comparison of the three example phenomena, and his identification of similarities in their behavior.

Conceptual resources. Emre draws on several conceptual resources in articulating his pattern theory. The idea that the milk “slows down b/c reaching equilibrium” suggests a conceptual resource like Alvaro’s, that one has to slow down to stop. “Goes fast in the beginning because it has more room to cover” may be another intuition, that one will move faster the further one is from one’s destination.

This example shows how the perceptual and cognitive elements of Emre’s epistemic projection worked together to help him write his second draft pattern theory. A notable difference between Emre’s epistemic projection and Alvaro’s is the nature of the epistemic forms employed by the students (Emre is using a formal epistemic form and Alvaro is using an informal epistemic form).

Discussion

The paper presented a theoretical framework for characterizing student engagement in epistemic games. The framework synthesized ideas from two existing theoretical frameworks: *epistemic forms and games* and *knowledge in pieces*. Like epistemic forms and games, the framework is meant to characterize an individual’s knowledge-construction process. Like KiP, the framework is meant to characterize the structure and dynamics of the individual’s informal and formal knowledge at a fine grain size. The resulting *epistemic systems framework* features two basic components: one perceptual and one cognitive. The perceptual component consists of the *perceptual strategies* the individual uses to extract raw data from the world. The cognitive component consists of the individual’s *epistemic net*, which is a network of knowledge resources including *epistemological*, *conceptual*, and *epistemic game move resources*. These resources orient and motivate the individual’s attention to their task, and facilitate their enactment of the epistemic game. The ESF is introduced and used to produce fine-grained models of instances of both informal and formal epistemic games.

The paper makes a theoretical contribution to literature concerned with characterizing the nature of scientist and student engagement in epistemic practices. As well, it extends the theoretical machinery of knowledge in pieces, producing a framework that researchers can use for modeling individuals’ engagement in epistemic games ranging from formal modeling to informal explanation and sense-making. The ESF is still in its infancy. Future directions include further investigation of both scientist and student engagement in epistemic games, with the aim of refining the framework. Of specific interest is investigation of the dynamic interplay between the different kinds of knowledge elements belonging to the epistemic net, to understand more clearly how the different kinds of knowledge elements interact in individuals’ knowledge-construction processes. Finally, it is well known that many epistemic games are not played by individuals in a vacuum, but rather, are distributed among individuals and materials (Dunbar, 1997). Therefore, understanding how epistemic systems can be used to model distributed epistemic games would be beneficial.

Youth as Pattern Makers for Racial Justice: How Speculative Design Pedagogy in Science Can Promote Restorative Futures

Kathleen Arada, Anastasia Sanchez, Philip Bell
karada@uw.edu, sapient@uw.edu, pbell@uw.edu
University of Washington

Abstract: In this article, we examine the development of youth sociopolitical consciousness and agency in an eighth-grade science classroom as students explore the multi-scalar, racial realities and possibilities of the science and engineering of pervasive digital technologies. Through case studies of two girls of color (ES and GS), we analyze the youths' cultural learning pathways. Our analyses show how youth use their felt, cultural, and community knowledges, and their developing physics knowledge, to confront and analyze manifestations of racial bias in technologies. The findings highlight the significance of teachers' pedagogical support and providing opportunities for meaningful transdisciplinary science investigations and speculative designing for more just and thriving futures. The Critical Speculative Design Pedagogy framework suggests how teachers can cultivate equitable, expansive, and consequential science learning. Please review the full journal article to see design principles relating pedagogical commitments to the instructional flow of the unit (Arada, Sanchez & Bell, 2023).

Introduction

In historical and ongoing ways, American education has been an institution committed to securing white settler futurities. We explore the pedagogical possibilities of *critical speculative design* to construct futures of STEM education which propel youth's development of sociopolitical consciousness and agency through an arc of science instruction, towards "community futurity work" that manifests collective power, love, care, and ancestral thriving (Harjo, 2019). Through our research, we explore the following questions:

1. How can school-based science learning environments support the critical speculative design pursuits of middle school Black, Brown, and Indigenous youth?
2. What socio-technical patterning processes do Black, Brown, and Indigenous youth develop and engage in as they imagine critical futures of light and computer vision technologies in society (e.g., for facial recognition, medical diagnosis, and more)?

Theoretical framework for critical speculative design involving science

We leverage, apply, and extend established theoretical frameworks for cultural learning pathways that attend to sociomaterial, relational, affective, and power laden dimensions of learning processes (Bell et al., 2012; Nasir et al., 2020). As a social practice theory of learning (Lave & Wenger, 1991), we elaborate cultural learning pathways to center specific sociopolitical edges of the learning environment that are salient to this work: (a) desettling the image of science and science education (Bang et al., 2012), (b) centering multiple ways of knowing and expression (Warren et al., 2020), and (c) supporting learning focused on the cultural thriving and joy of Black, Brown, and Indigenous youth and communities through sustaining and resurgent pedagogies (Paris & Alim, 2017). Focusing on learning pathways allows us to build knowledge about "chains of personally consequential activity and sense-making – that are temporally extended, spatially variable, and culturally diverse with respect to value systems and social practices" (Bell et al., 2012, p. 270). They reveal how engagement and cultural learning connect with identities of learners, with a focus on relational, affective, and motivational elements (Nasir et al., 2020). From a designed learning environment perspective, we conceptualize learning pathways to involve instructional phases of: *threading practices* as learners engage in sociopolitical interpretation; *weaving practices* as they coordinate multiple ways of knowing and being in relation to their interpretation; and *patternmaking practices* as they conceive of more just patterns, practices, and politics through speculative design (Benjamin, 2020).

Threading: Cultivating sociopolitical consciousness and interpretive practices

We develop *threading practices* as a felt, agentic, and collaborative process of historicized, embodied sense-making of generative themes, "iconic representations that have a powerful emotional impact in the daily lives of learners" (Freire, 1970). Learner inquiry into generative themes must involve political clarity of the connected ethical and political commitments, "being grounded not only in personal experience and consciousness but also in a continually evolving assemblage of ethical and political commitments towards engaging in rigorous and human research" (McKinney de Royston, Sengupta-Irving, & Cosby, in press). Discerning and mobilizing *political clarity* in STEM learning environments is a vital strategy for lifting up the relevant *threads* within generative themes—for analysis, commentary, and response practices. The subject matter and practices of science itself is inherently political and entangled with racialization processes and racist endeavors historically and scientifically (Marks, 2017). The felt, emotional dimensions of learning should also be situated as both an influence on learning and an intentional focus of what is to be learned (Vea, 2020). *Threading* asserts felt knowledges (Harjo, 2019; Million, 2009), disrupting the gatekeeping and gaslighting logics of white supremacy (McKittrick, 2021). Learning to apply critical consciousness and emotion to generative themes through *threading practices* involves the coordination and mobilization of context-dependent knowledge resources that produce emotionally and socially just ethical meanings. *Threading practices* set the stage for *weaving* multiple ways of knowing as part of further analyzing and contextualizing the topic from a racialized, sociopolitical perspective.

Weaving: Principled coordination of multiple ways of knowing

Weaving practices guide youth in the stitching of their learning and sensemaking resources with sociopolitical consciousness and purpose across their life pathways (Nasir et al., 2020), to see the systemicity of bias. Through the threading of their critical consciousness with unit learning content, students navigate ethical and moral sensemaking through *weaving* connections of (un)just, critical science phenomena across academic disciplines and real life, "a collaboration between sparking synapses and political struggle" (McKittrick, 2021, p. 70), thus recontextualizing learning in more consequential terms. Taking a horizontal learning approach (Warren et al., 2020) allows students to thread their critical consciousness and *weave* their axio-onto-epistemic heterogeneities, contextualizing science with living, to "engage in the imaginative, ethical, and political dimensions of knowing and being" (Bang, 2020). *Weaving* supports *patternmaking,* which present "conceptual openings" and opportunities for youth imagining and agentic constructing of collective alternatives.

Patternmaking: Imagining new patterns of liberation through speculative design

Through the *patternmaking practices* in speculative design, youth can challenge and refuse the racialized assumptions, preconceptions, and givens coded onto them (Benjamin, 2020; Nxumalo, 2021)—to then *make patterns* for generational flourishing. Speculative design pushes students to transcend settled disciplinary silos (Warren, et al., 2020) and braid the threads of felt, cultural, scientific, media, relational, and artistic knowledges. These principles act as a guide for teachers to design for and decipher manifestations of youth learning beyond normative science. When thoughtfully integrated with unit content, they center youth knowledge and voice, and provide them with multiple openings for reexamining, reimagining, and rebuilding worlds within and beyond the classroom. We pose the following elements of a Critical Speculative Design Pedagogy:

- **Consequential Concern**: Shifting learning purposes from individual to collective well-being, catalyzes youth to think broadly about justice matters of consequential concern impacting their communities and to design more just futures (Sanchez, in press). By situating learning within the entanglements of society and justice, young people are essential change-makers and stakeholders, which fosters community and cooperation to provide a legitimate sense of knowing and responsibility beyond themselves.
- **Kindred Relationality:** Building bonding relationships of reciprocal respect, love, and care through thick solidarity, while collectively mobilizing to reject oppressive and damage-centered narratives, nurtures learning and multiracial responsibility and thriving (Harjo, 2019; Liu & Shange, 2018).
- **Critical and Liberatory Presencing:** Leveraging ways to engage with the work of people who look like them, have similar histories and experiences as them, and do science in expansive ways can support youth's consequential learning in juxtaposition to problematic political projects (Sanchez, in press).
- **Constellar Youth Knowledges:** Youth dexterously traverse the cultural ecologies across their lives, grasping onto what speaks to them, to then develop a unique, connected repertoire of practices and transdisciplinary expertise. The constellation of resources comes from: (a) their specialized interests, relationships, and school engagements (Ito et al., 2013), (b) the familial capital from kin and cultural connections rooted across histories and lands (Kimmerer, 2013; Nxumalo, 2021; Moll, et al. 1992; Yosso, 2005), and (c) their intuitional felt resonances (Harjo, 2019). This learning occurs as movement across time, space, and activity as they span their expertise over the bounds of home, school, digital, and other learning environments focused on sustaining their cultural lifeways (Gutiérrez et al., 2017).
- **Futurity Play:** Rejecting the adultification of Black, Brown, and Indigenous youth, "social dreaming," through imagining and tinkering, can bring youth to make sense of and build worlds, and center play as a leading activity in social change (Espinoza, 2009; Gutiérrez, et al., 2017; Mitchell & Chadhury, 2020).

Methods

Context: Research-practice partnership & curriculum co-design

This social design research project (Gutiérrez, et al., 2020) partnered with two ethnically and linguistically diverse public middle schools in the Northwest United States during the height of the COVID-19 pandemic. The class demographics consisted of 65% self-identifying Black, Brown, and Indigenous youth and relatively even among those who self-identify male and female. We wove themes of community, anti-racism, liberatory expression, and civic engagement into the co-designed physics unit, pulling in principles of CSDP (see Theoretical Framework):

- **Consequential Concern:** Our designed science and social focused unit storyline traced the role of light in our lives, specifically centering the experiences and impacts Black, Brown, and Indigenous communities, with the driving question: "How can and does light serve some communities and not other communities?" The readings examined phenomena from a critical sociopolitical stance: (a) on light energy and technologies highlighting environmental and racial injustice through workplace inequities, (b) on melanin and medical racism with technologies using UV light detection, and (c) on racial bias in dermatology and in AI algorithms used to detect skin cancer.
- **Kindred Relationality:** As a teacher-researcher team composed of white and Brown women, we sought to refuse the white domination and racial neutralization and invisibilization forced upon students, while also fostering collective solidarity and agency with students. Especially in COVID-19 when closeness among classes is difficult to develop given a 28-minute weekly time period together, this unit occurred amidst highly publicized racial reckonings—communicating about emotional and political action brought them together to begin recognizing aspects of shared struggle and individual racialized struggle.
- **Critical and Liberatory Presencing:** Countering absent, misrepresented and/or abstract narratives of non-settler communities in curricular design, we prioritized the voices, experiences, and work from transdisciplinarians of color, like Ruha Benjamin, Joy Buolamwini, and Movement for Black Lives.
- **Constellar Youth Knowledges:** We developed lessons for students to engage with content related to justice topics (technology, environment, health), in various forms (readings, discussions, class lessons, videos), and pertaining to ranging interests (maps, graphs, technology, arts, pop culture). Rather than adhere to a strict standard of annotation, we encouraged students to express sensemaking with emotion and personal experience, which granted us insight into the heterogeneity of their conceptions of justice. Embedding the unit with cross-disciplinary learning engagements like the Visioning Board signaled a valuing of the intellectual and cultural epistemologies and ontologies of youth, which was oppositional to the domain specificity that situates knowledge as settled, zero-point epistemologies that perpetuate onto-epistemic supremacy (Warren et.al, 2020).
- **Futurity Play:** In the guidelines for the culminating activity of the unit, the Visioning Board, we aimed to center student innovation and experience, avoiding work that could be telegraphed by the teacher or constrained by curricular standards. The media and text would be tools for understanding expressions of their reflections, inquiries, fears, and introspections, where they could "grapple with their interiority through images and creating artwork" (Harjo, 2019, p. 206) and tinker with possible configurations of resistance and transformation (Gutiérrez et al., 2017).

Data collection

Over the course of two months of science classes, the duration of the lightwaves unit, we made ethnographic observations, recorded field notes, collected chat logs, and took screenshots of class presentations. We also conducted semi-structured interviews with the teachers to understand their backgrounds and contextualize their interactions with students over time. Given that this research study occurred in the midst of a global pandemic, our core data came from student work: annotations of reading assignments, online chat and discussion posts, and Visioning Boards. Students emphasized key concepts and paragraph summaries (PS) through highlighting, drawing, reinterpreting, and adding personal connections, questions, and emotional reactions. We also administered an exit ticket after the lesson on AI-driven dermatology, and a reflection form at the end of the unit to learn more about their process, inspiration, and more specific speculations regarding their Visioning Board.

We studied 158 students' learning pathways ethnographically, first identifying students whose Visioning Boards indicated a pointed interest in light/computer vision technologies, and then tracking their resonances throughout the unit across our field notes and their reading annotation assignments, online message board discussion posts, in-class participation logs, exit tickets, reflection forms, and interviews. For our analysis, we mainly concentrated on the students' Visioning Boards and their annotations of the readings as the most semiotically rich data types in the corpus. With COVID-19 significantly impacting attendance and synchronous class time, we found that their annotated readings afforded them more time to question, critique, and imagine with the critical data on. Thirteen students were identified with data representative of the learning pathway analysis.

Thematic analysis of pathways & ethnographic analysis of learner cases

We used *threading*, *weaving*, and *patternmaking* dimensions in our analysis for the 13 students to inductively identify thematic dimensions within and across those phases, categorizing students' work and noticings chronologically (Wolcott, 1994) in their (a) *threading*: making initial observations and beginning to form critical consciousness (expressing an emotional or other relational connection to the topic, highlighting the importance of a particular concept), (b) *weaving*: grappling with sensemaking around race through the application of their multiple ways of knowing (recognizing systemic rather than individual inequities, navigating ethics or morality, advocating for justice, perceiving white as a standard, noting racial invisibility), and (c) *patternmaking*: sharing their desired futures focused on collective thriving (racial justice in various industries; health in intellectual, physical, social, or spiritual ways). To analyze emotion, we examined students' syntactical choice (use of particular words, organization of words), punctuation (use of exclamation points, question marks, or ellipses), stylistic formatting (bolded, italicized, underlined, capitalized, or highlighted), and personal examples that may have revealed or suggested a particular emotional state. Taking a sociocultural lens, we followed the students' guided emotion participation, examining their representations of emotion in relation to their other enactments and interactions (Vea, 2020). We then synthesized the three phases across the 13 students. With the Visioning Boards, which represented their patternmaking phase, we took a critical media ethnographic approach, using interactions and prior writings from the threading and weaving phases to help interpret students' creations (Jocson, 2014).

We wanted to center and explore the brilliance of Black, Brown, and Indigenous youth to document liberatory possibilities of the approach through this analysis. This led us to interpret the unfolding learning pathways of two girls of color whose expressions of learning differed from western normative expectations of science and from one another. Developing ethnographic cases for these two girls allowed us to more closely understand the cultural pathway of their individual learning (Bell et al., 2012).

Findings

We share two ethnographic case studies of girls who engaged in this instructional unit. After setting the context around each main case, the accounts are organized as a chronological unfolding of threading, weaving, and patternmaking phases, highlighting how the elements of CSDP impact their learning journeys. We name students based on a synonym of their name's meaning and refer to them by those initials (ES and GS).

Case study of the Enlightened Student (ES)

Case context

The Enlightened Student (ES), who is part of the school's East African student community, fluidly makes connections between school and the real world, incorporating her multiple forms of knowledge and expression in science. According to her teacher, ES possesses an "innate drive with school" and a "hunger for knowledge." The relationship she built with ES and her family over the school year, through COVID-19 circumstances, surfaces in ES's openness in her annotations as well as her desire to discuss content outside of class time.

Threading

In the reading on solar energy, ES writes, "Having diversity is very good for an industry like this. Because there will be more buyers from different communities if they see diversity and their own people. ES indicates that diversifying a predominantly white industry would be beneficial because communities can buy from "their own people," suggesting that she places significance in cultural capital, in supporting the economic and professional gain of her "own people" (Yosso, 2005). As a form of political clarity (McKinney de Royston et al., in press), we take this as ES beginning to infuse personal experience and consciousness with her working understanding of bias in the solar industry, that the industry should be diverse not just for diversity's sake, but because this shift in the racial makeup of a workforce can potentially lead to a light technology benefiting more communities.

In ES's annotation on the melanin and medical racism article, she writes, "*LaToya's husband believes our black people are dying because … doctors practice and perfected healing whites skin and other skin that's like it, not the skin that's darker.*" We observe ES's felt resonance with the perspectives of Black people in the readings as she starts to develop awareness of injustices in healthcare and technology, and the overall well-being of their communities. Her comment expresses relationality and solidarity with the highly melanated people's experiences and voices. These emotional and familial resonances, as part of her *constellar knowledges*, serves as the initial catalyst that moves the readings from a detached assignment to a more personal, felt social alignment

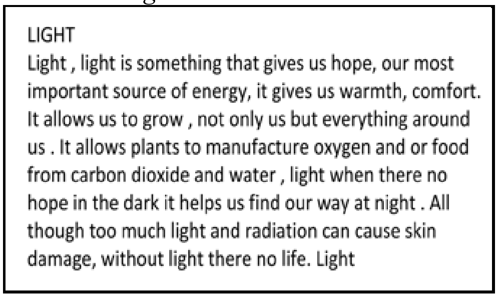
(Harjo, 2019). We see her perspective-taking through LaToya to make sense of the data. ES problematizes medical technology as unethical in its white prototypical design centering whiteness and white life (Browne, 2015). In referring to them as "*our* black people," she speaks as a student analyzing data and as a kin member, upset at how doctors prioritize the health and "perfected healing" of white and lighter skin people. Her feelings appear to be drivers of her sensemaking and move towards critical consciousness, setting up emotional configurations related to her histories, and motivating her to more clearly see the ethical wrongs in LaToya's situation in relation to herself (Vea, 2020). Her thinking-feeling response is based on the racial violence built into the algorithm, that the healthcare system is not built to support Black humanity as it is for white patients (Harjo, 2019; McKittrick, 2021).

Weaving

In her reflection after the lesson on racism in AI-driven dermatology, ES's Exit Ticket further demonstrates felt relationality with the highly melanated people referenced across the lessons. She writes*, "I have darker skin … I wonder if my skin is dark enough for the facial recognition to not identify me. I felt a little disappointing, simply because black people are always looked down upon in the system, and its hard when society's future in technology does not fit our features and our skin tone. Its literally 2022."* ES shows disappointment, impatience, and incredulity (e.g. "Its literally 2022") at the continued unjust treatment of people with darker skin through the use of "the system" and "always." In acknowledging the importance of racial equity in persistent technologies and the need to wrestle with associated systemic inequities, we perceive her to be questioning if and how people with her "features and skin tone" fit into that future. With mentionings of the lesson on AI-driven dermatology, ES advances emotional configurations she used for sensemaking in her prior annotation to give social meaning to her emotions, correlating skin color with her own potential racial invisibility and of others in the larger Black community (Vea, 2020). We see strong evidence of her new learning about environmental and medical imaging technologies and melanin entwining with her personal knowledge and emotional awareness of inequitable treatments towards people of color. ES sees that it is not the technology but rather people who perpetuate a white-dominated system of racism and reinscribe biased practices and technologies that ignore a more melanated humanity, and are violent to "Black livingness" (McKittrick, 2021). The statistics and stories of people who look like her bring her to confirm her own felt knowledge and see how racial inequities are built into society. ES makes vital scientific arguments by expressing political clarity around her racial equity concerns about technological functionality as a systemic issue involving a stance that dehumanizes Black people. In her thinking, we see these related strands of knowledge and purpose starting to coalesce—setting the stage for her speculative designs.

Patternmaking

Figure 1
ES's Visioning Board



LIGHT
Light , light is something that gives us hope, our most important source of energy, it gives us warmth, comfort. It allows us to grow , not only us but everything around us . It allows plants to manufacture oxygen and or food from carbon dioxide and water , light when there no hope in the dark it helps us find our way at night . All though too much light and radiation can cause skin damage, without light there no life. Light

Standard culminating knowledge forms for classroom science education—causal explanations, conceptual models, evidence-based arguments—cannot easily accommodate the radical speculative dreaming of students. Using her *constellar knowledges* as a guide, ES gravitates towards poetry in her Visioning Board (see Figure 1) and particular resonances from the readings to synthesize her interpretation and analysis of a more socially just future. Through a mix of repetition, metaphor, and science knowledge, she highlights *light* as a necessary tool for health and survivance for humans and nonhumans, while also cautioning against its misuse and excess.

ES's poem also acts as a declaration for racial recognition and mattering: with light, there is "warmth, comfort … without light there [is] no life." Her genre flexibility leverages her expertise in poetic expression as *futurity play*. Through this medium, ES freely communicates her stance on racial justice and tests out her theoried future, artfully remixing her learning with her own *constellar knowledges* (Gutiérrez et al., 2017). ES's poetry are speech acts of refusal of racism, piecing together the different woven strands that she has gathered from the readings and her own *constellar knowledges*, to understand racism as systemic and action as collective, and to claim bold movement and responsibility towards justice. ES surfaces her purpose in her speculative dreaming, in seeing her role in her community's care and thriving, while also recognizing that to fight against the wider systemicity of injustice, "everything" and everyone must work together. We take this poetic approach to social dreaming as a strong example of liberatory classroom science instruction.

Case study of the Gifted Student (GS)

Case context

For Black, Brown, and Indigenous youth, individualism and myths of meritocracy often falter and wane as motivation for academic engagement, as these ideologies and privileges are not aligned with their cultural and racial values and ways of being and mattering. This change did not go unnoticed by GS's teacher, who shared that her "best practice" is "building relationships with them and as a class, everything is different now, for all of us but especially my kids of color." GS had completed only one unit prior to our focal unit on lightwaves. Her teacher explained, GS "started the year off strong, then dropped off the face of the planet. Then, I called home and said some very motivational and genuine things and boom, she was back in the game...to the extent that I gave her the science award [for demonstrated excellence]." GS's teacher shared about her matriarchal team (including GS's mother and grandmother) as a trio of "badass" and "magical" women. As shown below, this powerhouse of intergenerational, Black expertise was core to the learning artifacts GS generated.

Threading

Analysis of GS's early learning artifacts showed that threading began as very one-dimensional, with complexity and vibrancy increasing as the learning moved through the increased CSDP into the unit. On solar energy, GS summarizes, *"Organisms that include our bodies and plants need energy to live."* Though she demonstrates competency in conceptual knowledge, we take this as a sign of disengagement and disconnect from the content. With the next reading on AI-driven dermatology, there was a marked shift in the elaborations and affective engagement in GS's annotations. In her paragraph summaries, GS mentions bias and an example of dehumanization through African American and Asian populations not being recognized by technology but rather being mistaken as gorillas. Her choice to include this specific experience in her notes over other broader concepts implies its influence on her understanding of algorithmic technology, and potentially leading to *kindred relationality*, and also feeding into GS's progression of political clarity through the reading. GS's visceral pulling from constellar, felt knowledges was evident with the calling out of *"Early technology adopters"* as lacking awareness of the consequences of using biased technologies and her refusal to maintain white dominance in the field of medicine, stating that *"research should include diverse samples across multiple populations"* and *"...there is not enough medical professionals of color nor enough medical information on marginalized communities."* Through her questions and colored highlighting of wonderings and key concepts, and her opinions of what "should" change, we see GS beginning to form critical consciousness, wading through sensemaking and displaying a desire to know more about the ethics and morality of biased and novel technologies (McKinney de Royston et al., in press). In her responses, we see acts of refusal, means of working to secure futurity (Nxumalo, 2021, p. 6), opening up space for Black, Brown, and Indigenous youth livingness in the next phase of their inquiry.

Weaving

This flow of activities and GS's annotations are necessary for the weaving of epistemic heterogeneity needed in STEM endeavors (Bang & Medin, 2010). GS grapples with illuminated diffractions of *dark matters* as seen through the aperture between the science of light and the politics of lightness, bolding her words to bring attention to her demands and suggest an urgency. As part of her paragraph summary, she writes, *"Melanoma and its mortality rates affect different classes of people at different levels. ...* ***The messages I have seen regarding sunscreen promotes its use by light-skinned people but not those of African descent. Public health groups should do a better job at promoting the dangers.****"* GS weaves in information from a reading about melanin as a defense against UV rays, with information from a separate reading about the risk of skin cancer for communities of color. GS uses facts to demand that public health groups do a better job at advertise, bring awareness, and protect dark skinned people. We believe the combination of statistics, felt knowledge, and personal experience in seeing advertising not designed for her likely leads GS to make this statement. GS's emotional configurations draws from her own life, attaching social meaning. We argue that this critical sociotechnical interpretation and commitments provides a humanizing stance for their speculative design engagement during patternmaking.

Patternmaking

An interview with GS's teacher revealed the essential living story taking place at GS's kitchen table with her grandmother related to her Visioning Board: "she seemed a bit nervous at first to tell me [that she and her grandmother worked together], probably because some teachers might see that as cheating … when I told her it was awesome that she made the board with her grandma, she beamed." Together, GS and her grandmother engaged in animated threading, weaving, and patternmaking as they spoke to and from their relational knowledge together. Contextualizing GS's previous work and her increased in-class participation with her Visioning Board, the shift in how bias is articulated illustrates the melding of GS and her grandmother's perspectives—a form of collaboration likely to have involved a coordination of intergenerational knowledges.

Figure 2
GS's Visioning Board

AI projects a false sense of a secure, holistic and fair search process while validating and deepening bias further in its algorithms.

Diminishing Bias in Artificial Intelligence

The current biased artificial intelligence(AI) systems have become a significant problem throughout the world and in multiple industries such as healthcare/medicine. In vulnerable populations, people have been hurt or suffered the impingement of their rights due to biased AI. Furthermore, in healthcare, racial minorities and those living in poverty often get substandard healthcare quality than non-Hispanic Whites and people with higher income and wealth. Algorithms trained on inaccurate, insufficient quality data will produce the wrong results, leading to inadequate care delivery.

Just as humans have to admit bias/racism to defeat it, so do machines, algorithms, and AI.

The Visioning Board (see Figure 2) maps her just future by providing a grounding text titled "Diminishing Bias in Artificial Intelligence," as a synthesis of content knowledge and onto-epistemologies curated between GS and her grandmother. This centering of *constellar knowledges* through intergenerational relations reinforces the importance of distributed expertise and collaborative sensemaking. Moving from left-to-right through the images of the Visioning Board, GS tells a proleptic narration of the weaponization of technoscientific innovations, calling out specific forms of bias and claims of universality in algorithms. There are refusals of bias in STEM fields "ranging from computer science to genetics." GS offers up contextual representation of Black medical and science professionals for the *critical and liberatory presencing* of diverse backgrounds reflective of their own identity. Through her textual explanations and curation of images, GS's Visioning Board indicates *futurity play*, re-creating what the future of AI could and should look like. GS's work provides a counter design to the normative physics unit, weaving in threads of ontological and intergenerational knowledges through their articulation of racial injustice and emphasis on eliminating bias, while proposing refusals as methodologies for patterning thriving Black futurities in our ever-increasing technoscientific society. This transdisciplinary form—with intergenerational collaboration—supported her speculative dreaming of a more just future with technology.

Conclusions & implications

This research focuses on informing how science learning environments can desettle traditional western science education and create spaces for liberatory dreaming and designing for Black, Brown, and Indigenous youth and their co-conspirators (Bang, et al., 2012). Returning to the unit's original question (How can and does light serve some communities and not other communities?), building capacity for thick solidarity towards collective thriving will continue to be a timely generative theme. The work we engaged with students signals a crucial opportunity for education in opening up possibilities for future generations to critique and reject racist sociotechnical systems, examine teaching practices, and enact agency for centering multiracial justice and the felt and relational implications of design. The materials, instruction, and student positioning that supported critically conscious inquiry and speculative design in this project-has broad implications to how science learning environments should be constituted for all youth—and specifically for Black, Brown, and Indigenous youth. Culturally expansive learning means accepting the multiple contexts and spaces that students engaged in threading, weaving, and patternmaking, and consciously distancing ourselves away from the westernized approach with science, with technology, and with one another. Speculative design science instruction shows promise for supporting youth in critical analysis and liberatory dreaming and realizing of more just and thriving futures.

How Computational Thinking Can Become a Sensemaking Practice for Preservice Teachers in an Engineering Course

Gözde Tosun, Pennsylvania State University, gjt5160@psu.edu
Amy Voss Farris, Pennsylvania State University, amy@psu.edu

Abstract: The role of computational thinking (CT) in science education presents an important challenge for teacher preparation, as CT and closely related concepts now appear in science standards in many regions. There is broad agreement that computation is an epistemic practice in science and engineering (e.g., Nersessian, 2008). However, supporting preservice teachers' (PSTs) understanding of CT as sensemaking practices in engineering design remains underexplored. We present a qualitative exploratory study in which we aim to support PSTs' participation in and recognition of CT practices in engineering design contexts within a semester-long science and engineering course. We present two themes that inform how CT became a sensemaking practice in engineering: (1) the design of learning environments in which CT is reflexive (Harel & Papert, 1990) with PSTs' own experiences in engineering design and (2) the central role of contextualization and addressivity (Bahktin, 1986; Sengupta et al., 2021) in CT in engineering education.

Introduction

During the past 15 years, many geopolitical areas have included CT and closely related ideas in the science curriculum (Braun & Huwer, 2022; NRC, 2012). However, prior research investigating science teachers' preparedness and motivation to implement computational thinking shows that teachers do not feel ready to integrate CT into their classes (Kang et al., 2018). To address this problem, researchers have integrated CT into university-level teacher preparation classes. This integration takes multiple forms, from integrating a CT module that takes a couple of hours (Walton et al., 2020; Yadav et al., 2011) to re-designing an undergraduate class to incorporate CT (Mouza et al., 2017). These approaches suggest moderate success in supporting pre-service teachers' understanding that CT can be taught in different disciplinary contexts, even without using computers (Yadav et al., 2011). However, results also demonstrate that PSTs usually made relatively superficial connections (i.e., based on keywords) between components of CT and science curricula (Walton et al., 2020) and they were largely unable to develop lesson plans that meaningfully incorporated CT with disciplinary content (Mouza et al., 2017). The PSTs' understanding of CT fell short of showing how CT supports science learning (Walton et al., 2020).

We propose several reasons for these challenges. One of the most common ways of integrating CT into science classrooms is for students to re-represent explanations of what they have already "figured out,"—an approach that masks the generative potential of CT as a *means* for sensemaking. Another common approach to integrating CT is to provide general experiences in introductory computer science in order to create new points of entry for more students, thus, broadening the computing "pipeline." It is not surprising then, that expressing how CT mediates disciplinary learning is challenging for educators, since common rationales for integrating CT with science and engineering do not offer any insight into how computational thinking practices are epistemic practices in the natural sciences and engineering (Sengupta et al., 2021). Additionally, many teacher learning experiences are compressed in methods classes and last only a couple of sessions. As a result, participants do not have prolonged and disciplinarily contextualized participation in CT practices, therefore, do not experience for themselves how disciplinary learning happens through CT. We describe an approach that advances PSTs' participation in prolonged and contextualized CT activities to support their understanding of how CT mediates disciplinary learning in science and engineering.

Theoretical and conceptual framework

Previous literature shows that computing is often a legitimate sensemaking practice in science and engineering. This is consistent with constructionist views that learning computing makes learning disciplinary concepts easier, known as *reflexivity* (Harel & Papert, 1990). For example, as argued by Farris et al. (2019), elementary science students learned to critically interpret their own data about motion through creating agent-based models of that motion, moving back and forth between the phenomena, their data, and their models. Following Odden and Russ' (2019) definition, participation in sensemaking requires "building or revising an explanation in order to "figure something out"... to resolve a gap or inconsistency in one's understanding." (pp. 191- 192). Our sensemaking stance has its roots in the epistemological frames (e-frames) theoretical construct and refers to the approaches learners take to an educational activity (Hammer et al., 2005). A sensemaking frame positions learners to participate in an activity in order to build a new explanation (Kapon, 2016). Furthermore, computational thinking provides a means of managing complexity (NRC, 2010). It is apt that CT can be leveraged in engineering design from complex problems towards solutions. However, little research has considered supporting PSTs to learn to use and recognize affordances of CT practices in the context of engineering design using physical science concepts.

Currently, enactments of CT in STEM classrooms often do not take up a sensemaking frame. It is common that programming environments are introduced so that students can reproduce or "posterize" (Windschtil & Thompson, 2013) what is already known about the phenomenon (e.g., creating a literal representation of some features of the solar system in Scratch (https://scratch.mit.edu/) at the conclusion of an inquiry about the solar system). In addition to side stepping sensemaking goals, educational computing frequently stays in the realm of a technocentric stance (Farris & Sengupta, 2016; Sengupta et al., 2021). Technocentric views typically fail to conceptualize children's computing in a broader context that goes beyond device-level engagement (Papert, 1980; Sengupta et al., 2021; Silvis et al., 2022). However, a more situated approach, rooted in Bakhtin's framing of language (including computer languages) as heteroglossic (i.e., multivoiced), invites us to think about the socio-material and dialogic work through which sensemaking occurs. Bakhtin (1986) proposed that utterances are shaped by real and imagined listeners, a phenomenon he termed *addressivity*. In this sense, the design of a computational artifact becomes a dialogue with potential users and the use contexts of that object. Learners' considerations of the user in the design process, including writing guidelines for them and interacting with them, can shape their computational design by making the designer better understand the relation between user action, elements of the code, and the output (Sengupta et al., 2021). We propose that a focus on how CT can support disciplinary learning goals in engineering must consider how computing is framed in broader contexts and positions learners as being responsible and answerable to real or imagined users and use cases (Bakhtin, 1986; Sengupta et al., 2021).

In this study, our central hypothesis is that development of CT in K-12 curricula can be synergistically supported by physical science and engineering design curriculum. In our study, PSTs engaged in epistemic engineering practices that are reflexive with CT across different modules throughout the semester. We regularly prompted PSTs to reflect on how CT practices were evident in their work as they explored a scientific phenomenon or iteratively improved design solutions. Our inquiry is guided by the following research questions: How does their understanding of CT's role in science and engineering evolve across the semester? What aspects of the learning environment mediated these changes?

Design

Our study took place in an introductory engineering course for elementary educators taught during Spring 2022 at a large research university in the northeastern United States. In this qualitative exploratory study, we take a microgenetic approach (Saxe, 2012) as our goal was to investigate how PSTs come to understand CT's role in science and engineering across the course of the semester. Twenty-three of the 25 enrolled students consented to participate in this study. These 23 students consist of one graduate student (Science Education) and 22 undergraduates (17 pre-major College of Education students, Elementary and Early Childhood majors). Twenty-one of 23 expressed a career goal to become an elementary school teacher. Most students were in the first half of their undergraduate career: five first year students, 11 second year students, five third year students, and one fourth year student). The graduate student was a former kindergarten teacher.

The class met twice a week for 15 weeks, each class meeting was 75 minutes long. This introductory and interdisciplinary course focused on physical science concepts, pure and applied science and scientific processes, engineering design principles, and associated technologies. The course is designed in four modules: structures, simple machines, electricity, and making and modeling with code. Based on previous literature (e.g., Nersessian, 2008), we conjectured that (1) engaging in course material and epistemic engineering practices throughout the course will authentically necessitate learners' engagement in computational thinking and (2) this engagement will support PSTs to express examples of CT that contribute to goals in engineering design. Each module involved multiple aspects of CT as a means to accomplish scientific and engineering sensemaking.

We, as the instructors of the course, intentionally highlighted and named the following components of CT: abstraction, decomposition, pattern recognition, debugging, and automation, and related these to the following CT practices (Weintrop et al., 2016): data practices, modeling and simulation practices, computational problem-solving practices, and systems thinking practices. These were overviewed during a presentation about CT during Week 1. When we observed students participating in these components, we named them in class discussions to help build a common language of CT practices and components in our collective engineering work. For example, in the structures module, preservice teachers *recognized patterns* in the number of diagonal braces needed to stabilize a polygon. Later, PSTs *used simulation* to help them build and improve their physical bridges. When they were building bridges, they drew on *abstraction* and *systems thinking* as they were focusing on individual members and joints and figuring out how they work together and how those affect the structure as a whole. In each module, students were asked to write about or reflect on how CT components and practices were evident in their engineering design or in elementary-aged learners' engineering design. Data includes preservice teachers' course assignments and instructor fieldnotes and communications. For this study, we selected five focal assignments (Table 1) from the data corpus. These assignments are ones in which pre-service teachers were explicitly asked to write about CT and are distributed across the course of the semester.

Table 1
Focal Assignments and Prompts

Assignment	**Prompt**
CT Response 1	Create an image that depicts elementary-aged students engaged in CT in science or engineering design activity. Write two or three sentences explaining how the activity in your drawing involves CT and supports learning.
Applications to Teaching	Consider whether you see examples of CT practices present in the lesson design. What examples do you see?
Quiz 1, Item 6	Identify two components or practices of CT that you have used in the structures unit. For each example, please briefly explain your thinking. How do you think using those CT components or engaging in those CT practices was helpful for what you were doing?
Micro:bit Design Project	Please give a visual and verbal description of the tool and the context you imagine it being used in. Describe any relevant components of CT that you have used and how they were evident in your project or the design process. In what ways are these components relevant for the (imagined) learners?
CT Response 2	The same as CT Response 1.

Analysis and findings

We first analyzed how participants wrote about the role of CT in science and engineering at the beginning and end of the semester. Participants' CT Response 1 and CT Response 2 were coded using open and axial coding (Strauss & Corbin, 1990). This process generated three top level codes: technocentric, disciplinary contextualization, and practical contextualization.

Figure 1
Counts for Each Code at CT Response 1 and 2 and Illustrative Examples for Each Code

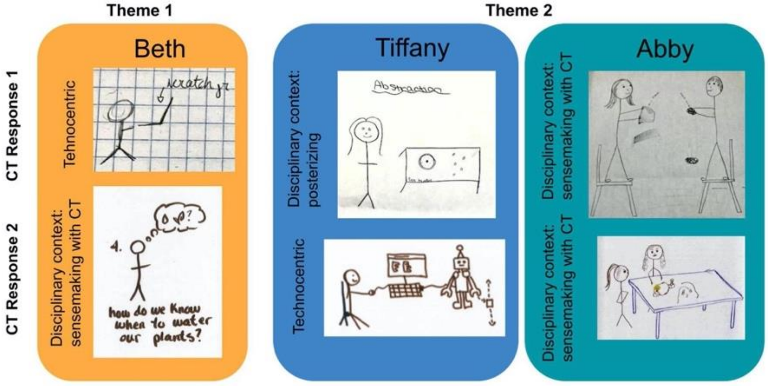
	Code	Example Student Response
Techno-centric	Technocentric	"Student [will]...make [the] sprite do something...by coding on Scratch...The learning goal would be to understand coding." (CT Response 1, Abby)
Disciplinary Context	Following Instructions	"Using legos and following directions that are provided are an example of Algorihms." (CT Response 1, S22)
	General Problem Solving	"Students are thinking about how they are going to get [a] marble to the other side [of the roller coaster]." (CT Response 1, S6)
	Sensemaking with CT	"engage[ing] in debugging...students will have to find why [the LED] is not working...For instance, are [the] alligator clips connected correctly?" (CT Response 2, S9)
	Posterizing	"...using abstraction by making a model [of an animal cell]...hav[ing] a good representation of what a cell looks like" (CT Response 1, Tiffany)
Practical Context	Sensemaking with CT	"...Students [will] pick shapes to finish the pattern...Students must use pattern recognition." (CT Response 1, S11)
	Following Instructions	"Algorithmic thinking...gives the children a step-by-step explanation of how to complete their gingerbread man." (CT Response 1, S23)

Technocentric responses indicate that the response focused on learners gaining familiarity with coding without contextualizing it into any context. Second, disciplinary contextualization indicates that the response incorporates CT into a disciplinary context in science or in engineering. This code also contains four sub-codes: sensemaking with CT, general problem solving, posterizing, and following instructions. We note that activities coded for "general problem solving" were too broad to be coded as sensemaking. The examples that received the code for "general problem solving" did not elucidate how any particular aspect of CT was used to solve the problem. The third top-level code is practical contextualization. Although the prompt specifically asked about a

CT integrated activity in science or engineering, some of the participants shared examples from everyday life which were not connected to science or engineering contexts, and these responses were coded using one of two sub-codes: sensemaking with CT or following instructions. See the quotations in Figure 1 for illustrative examples.

As shown in Figure 1, our analysis of CT Responses revealed a decline in technocentric framings of CT and CT for non-sensemaking means such as posterizing what is already known. We observed an increase in activities in which CT is used towards sensemaking goals in STEM contexts. Pre- and post- measures do not describe what mediated this change, nor the process of increasingly positioning CT as a sensemaking practice. We therefore conducted a microgenetic analysis (e.g., Saxe, 2012) to try to understand how students' positioning of CT evolved across the course of the semester, focusing on the data points shown in Table 1 and our field notes. From this analysis, we identified two themes. Each theme, following Braun and Clarke (2005), "captures something important about the data in relation to the research question and represents some level of *patterned* response or meaning within the data set" (p. 82). Theme 1 illustrated how learning about CT in elementary science and engineering became reflexive (Harel & Papert, 1990) with PSTs' own undergraduate-level experiences in engineering design, and we present Beth's work as a representative case (Yin, 2009). Theme 2 is concerned with addressivity (Bahktin, 1986). We use contrasting cases (Yin, 2009) from two additional students, Tiffany and Abby to illustrate how addressivity is essential for learners' positioning CT as sensemaking practices. Together, these two themes help to explain how the learning environment—firmly rooted in the disciplinary learning goals in engineering design and physical science concepts (Figuiredo, 2008) support the PSTs to recognize CT practices as sensemaking practices.

Figure 2
Participants' Drawings in CT Response 1 and 2



Theme 1: Learning about CT becomes reflexive with engineering design

To explain the Theme 1, we present examples from Beth's coursework as representative and explanatory case of the theme. Beth was in the fourth semester of her studies and expressed a desire to be an early childhood/elementary teacher. Before the course, Beth had no prior experiences with coding or physical computing.

Drawings analysis: Beth

At CT Response 1, Beth drew a figure of a student working on a laptop, with a "Scratch Jr." label on the screen (see Figure 2). In her written explanation, Beth wrote an example of how elementary-aged students would engage in CT "to make [the] sprite do something automatically by coding on Scratch." Beth wrote that this activity supports learning because "students are learning to code" and the main goal of the activity is "to understand coding." Beth did not mention a purpose of coding other than to learn to code.

At the end of the semester, Beth's CT Response 2 involved multiple drawings of students working on different design problems, including building simple machines to "make our lives easier" or making a potato circuit. For example, one of these drawings depicted a student imagining a raindrop and a plant and asking, "How do we know when to water our plants?" (see Figure 2). In her explanation, Beth wrote that the forms of activity in her drawings support learning because "students gain an understanding of the world around them" through participating in engineering to solve problems. Across CT Responses 1 and 2, Beth moved from a technocentric framing of CT to a framing in which CT is used in disciplinary science and engineering contexts to tackle problems. Beth's initial drawing illustrated a typical technocentric view (e.g., "learning to code", however, her final response illustrated how she is situating CT in disciplinary learning goals (simple machines make "work…easier").

Developmental analysis: Beth

What mediated Beth's movement from a technocentric perspective about CT to a sensemaking perspective? In Quiz 1, Beth reflected on how certain CT practices were helpful in the structures module. She wrote, for example, how modeling and simulation practices helped her to "visualize how structure[s] worked and how they can be improved." Beth reflected on how she used a CT practice in the context of engineering design to iteratively solve a problem.

In her Micro:bit design project, Beth re-mixed code to command the Micro:bit to measure the ambient temperature and report the output on the LED display. She shared different uses of the engineered tool from how to manage the water temperature in a fish tank to investigating how certain weather conditions impact temperature. Throughout the design process, Beth considered potential uses of the tool and what would be feasible for children. She wrote in the design report: "[I] searched for a project that seemed interesting and doable for young children." In the video included in her design report, Beth explained the relation between input devices (i.e., the temperature sensor) and output. She wrote that debugging and algorithmic thinking were salient CT components she engaged in as she was building the thermometer. Beth's Micro:bit design project illustrated how she engaged in coding, algorithmic thinking, and debugging to create a tool that can be used in solving problems, such as managing the water temperature in a fish tank.

We propose that Beth's experiences across the semester drove her shift from thinking about stand-alone coding activity "to make [a] sprite do something" (CT Response 1) to using a micro controller to solve an everyday problem such as knowing when to water the plants, via engineering a soil humidity sensor (CT Response 2). Our analysis of Beth's case suggests that through her first-hand experiences in engineering design, she recognized that CT can be helpful in solving engineering problems people face such as designing a stable truss bridge or building a device to manage the water temperature in a fish tank. In other words, Beth began to position CT and engineering practices as mutually reflexive. Beth's rationale for CT shifted from "learning to code" to "exploring the world around us" and she was able to contextualize instances of CT into problems and solutions in science and engineering contexts, with imagined users and human implications.

Theme 2: Fostering sensemaking requires contextualization and consideration of uses

Theme 2 concerns contrasting cases of Tiffany and Abby, both of whom planned to become early childhood/elementary educators. Tiffany was in the third semester of her studies, and Abby was in her second semester. Neither student had any prior experience with coding or physical computing. We contrast their work to illustrate the importance of designing for imagined uses and users.

Drawings analysis: Tiffany and Abby

Tiffany's responses in the CT drawing tasks stayed in the realms of posterizing (Windshitl & Thompson, 2013) a scientific concept and a technocentric framing of CT (Sengupta et al., 2021). In CT Response 1 (Figure 2), Tiffany drew an image of a student creating a model of an animal cell. She explained that this activity involves CT since the student uses *abstraction* to minimize "the complexity of the cell to show the key elements of what she is learning." Tiffany wrote that this activity supports students to have "a good representation of what a cell looks like" by making the model of the cell "bigger and more simple." The model does not offer any further exploration of the cell but rather a bigger and simpler representation of it. In CT Response 2 (Figure 2), Tiffany drew an image of a student working on a block-based coding software to program a robot and wrote that activity involves *automation* because students are "programming a robot to pick up and put down a block on its own." Tiffany's emphasis on programming became the primary goal of the learning activity, emphasizing "inviting [kids] to explore coding" and students' opportunities to "program many different codes..." Tiffany's CT Response 2 was therefore representative of a technocentric framing of CT since programming is at the center of the activity as she emphasized the learning goal is "exploring coding".

In contrast to Tiffany's drawings, Abby's drawings increased in their connectedness among CT and epistemic goals in engineering. In CT Response 1, Abby drew an image of two students testing if/how surface area and mass impact travel duration during free fall (see Figure 2). To Abby this activity involved *pattern recognition*—a component of the CT—since students "compare different types of materials and guess which will fall at a slower speed." In CT Response 2, Abby drew an image of "two students working on trying to figure out why this circuit is not lighting both of the light bulbs" (see Figure 2). To Abby, this activity involved debugging; she stated students will "not only need to figure out how to light the bulb but in the process, they need to figure out why." Abby wrote that the activity supports learning since "debugging pushed students to a deeper understanding of a [electricity] concept."

Abby's CT Response 1 and 2 were similar in the sense that both activities pursue disciplinary learning goals. However, we observe an important nuance between these two: In Abby's first response, CT was used towards gaining declarative knowledge about the relationships among mass, surface area and duration of travel. In the second response, CT was used to solve a problem in engineering design and explore electricity concepts (e.g., conductivity and polarity). In this sense, we identify an epistemically richer use of CT in the second response.

Developmental analysis: Tiffany and Abby

In order to better understand Tiffany's experiences across the semester, we examined her other assignments. In the Micro:bit design project, Tiffany found online instructions for an air guitar and selected this project. In the original project, the Micro:bit air guitar would play a different melody when different buttons on the Micro:bit were pressed. The code—freely downloadable as part of the project —specified the light level variable to control the pitch of the melody when pin 1 (P1) is pressed (see Figure 3 for the code). In her written work, Tiffany barely explained how the air guitar works. While she did specify have a use case (a music class), her explanation failed to demonstrate a worked-out relationship between the functionality of her project and the contexts in which it could be used: "My project was supposed to play different songs depending on the amount of light it receives" and she added that it "can be used to teach students in a music class about different notes and how to play songs."

Figure 3

Abby's code for her guitar and the physical design

As Tiffany worked on her project, we observed that she did not attend to the ways that inputs (e.g., when a button or pin is pressed) and outputs (e.g., playing music) were associated within the code. As she wrote, "When I first tested my project, it didn't play the songs it was supposed to play, unless I pressed one of the buttons on the Micro:bit." The Micro:bit code could have been slightly altered to meet her desired goal, that is, playing something without pressing any button or pin. Instead, Tiffany made changes to the physical guitar by permanently connecting P1 to the GND pin so that the circuit is closed, and as a result P1 is continuously stimulated without any input (see Figure 3). In the design report she wrote, "After trying a couple of different things, I was able to improve my project a little bit so that it would play a song without a button being pressed." She did not report that she tried adjusting the code in any way toward meeting her desired design goals. We observe that the code was isolated from the design process and stood by itself as a "received" and immutable object, and therefore, it was an end in itself, rather than a means for meeting disciplinary goals. We propose that Tiffany's experience of the code for the air guitar contributed to her technocentric stance, and her perception of the code blocks as a received and unchangeable object, rather than an understanding of code as language to accomplish desired design goals. Rather than working on her physical design in tandem with the code, she hacked the physical mechanism of the guitar to overcome the challenges in her code.

We contrast Tiffany's work with Abby. In the Micro:bit design project, similar to Tiffany, Abby also designed a Micro:bit guitar. Abby's guitar was coded and set up to play a different melody depending on the pin pressed (see Figure 3). She faced challenges knowing when her code had been sent to the microcontroller, so she adapted the code to show an icon on the Micro:bit display as a means of confirming it was running the code (Figure 3). In the project report, Abby explained how the user can use the guitar: "When placing a finger on 1 piece of foil connected with either pin 1 or 2 and then another finger on the foil connected to the GND pin, you complete an electrical circuit by letting a small electric current pass through you." She continued her guidelines by explaining the interplay between the circuitry and the code: "This triggers the code on the Micro:bit and starts playing a song." Abby also shared a detailed explanation of the context of use: "This touch sensitive project can teach students about external inputs and how to complete an electrical circuit by using touch inputs and [the] GND pin."

How could teacher educators help Tiffany and others in similar positions? Although both Abby and Tiffany were asked for a detailed description of the engineered tool and the context they imagined it being used, the ways they answer the question were quite different. Tiffany broadly wrote about how the designed tool works without addressing how the parts (code, pins, circuitry) interact with each other and wrote that the project could have been used in a music class. In contrast, Abby gave an elaborate description, intended for a user, explaining what kind of user input creates a desired output and why. Abby also explained the imagined context for the tool thoroughly. We propose that the difference between these cases is partially explained through considering the degree to which Tiffany and Abby were able to contextualize the engineering goals in meaningful contexts, and the role of engineering design as addressive (Bahktin, 1986) for whom the designs are for. Abby's detailed description of the tool for the user, and her addition of features may shape her understanding of the interplay between input, the code, circuitry, and the output. Knowing the relationship among these components, Abby recognized how her production and modification of code, as well as the physical inputs can be altered to meet her design goals. In other words, she recognized how CT can be leveraged to solve an engineering problem. Overall, Abby's case illustrated how CT (for example, debugging a circuit in her CT Response 2) can become a sensemaking practice to generate a solution to an engineering design problem with attention to users' experience of the tool, unlike Tiffany, who took the code's role to be immutable in her own work and the ultimate end goal of the activity in CT Response 2.

Discussion and contributions

We have demonstrated how PSTs learned to participate in CT as practices *in service of* science and engineering goals. Our analysis indicated an important shift in the way in which participants talk about CT in contexts of teaching and learning. Their initial foci were on technocentric learning activities and "posterizing" (Windshitl & Thompson, 2013) what is already learned, and their end-of-semester responses described activities in which CT is positioned as a sensemaking practice in science learning and engineering design. For 16 students, their final CT responses revealed enactments of CT that serve epistemic goals in contexts of engineering design and scientific inquiry. Our findings contribute to a more worked out understanding of how teachers frame disciplinary learning in relation to CT, a need noted by existing research (e.g., Mouza et al., 2017; Walton et al., 2020). We argue that moving to a more contextualized and reflexive understanding of CT as a sensemaking practice at the university level can support teachers to integrate CT into their future pedagogy, rather than perpetuating technocentric goals. This framing of CT is complementary to a pedagogical emphasis on scientific and engineering practices and ameliorates perceptions of CT as an extra teaching burden on top of science and engineering content.

When CT practices are routinely positioned as ways that PSTs figure things out in an undergraduate course, the PSTs adopted a more epistemically oriented view of CT practices in their pedagogy. Our microgenetic approach focused on how the learning environment mediated the shift from technocentric and isolated framings of CT to more contextualized and epistemically embedded framings: Beth's case illustrated how one PST's learning about CT became reflexive with her own undergraduate-level experiences in engineering design over the course of the semester. This is important since even though scholars have long acknowledged the overlap between CT and engineering design (e.g., Nersessian, 2008; NRC, 2010), supporting PSTs' understanding of CT in engineering design is largely underexplored. The second theme illustrated how contextualization, especially addressivity in engineering design, supported sensemaking. Tiffany and Abby's contrasting cases showed that the PSTs' imaginings of a user and a use context of their designs are intricately connected to their understanding of the relationships among components of computational artifacts.

Our study illustrated the deeply intertwined relationships between sensemaking practices and addressivity in contexts of CT and engineering. We extended prior arguments about dialogism in design (Sengupta et al., 2021) to demonstrate the affordances of learners' attention to real or imagined users in the context of pre-service teacher education. This process of contextualization generates a more dialogic approach to engineering, overcoming the tendency of technocentrism in CT-engineering design activities, such as the Micro:bit work we share here. We illustrated how the epistemic work of making sense of the relationships among code, microcontrollers, and the physical inputs and outputs was supported by imagining *how* the tools would be used. We argue that recognizing the interrelation among computing and other components of design, including physical inputs and outputs through the addressivity in design processes supports a more nuanced understanding of how CT can be leveraged in engineering design. This shift results in a deeper conceptualization of CT as a sensemaking practice of engineering, as evidenced in CT Responses 1 and 2. Our paper is a step toward understanding how to make the connections between computing and engineering design meaningfully present in the lived experience of PSTs, thereby positioning CT practices as closely connected to disciplinary learning goals in engineering and science, and helping to re-orient conceptions of preservice teachers' computing work towards a more humanistic stance focused on the users of technological artifacts.

Designing for Equity: Moving Project-Based Learning From Equity Adjacent to Equity Infused

Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu
Rochelle Urban, Digital Promise, rochelle.urban@gmail.com
Gina Olabuenaga, ginaolabuenaga@gmail.com

Abstract: Project-based learning (PBL) is an inquiry-based approach that aims to engage students in challenging, active, and meaningful experiences connected to the world outside the classroom. However, PBL's student-centered approach has not always explicitly focused on educational equity. The goal of this paper is to provide a PBL curriculum design framework that goes beyond creating engaging curriculum to providing experiences that are equitable, relevant, and meaningful to each and every student, while supporting students' learning and identity development. To do so, we examined recent PBL curricula and related literature to identify the PBL design features leading to impactful and equitable year-long K-12 curriculum. We present cross-cutting PBL curriculum design principles and lenses to interpret design principles.

Major issues addressed

Given the learner-centered focus of Project-based Learning (PBL), it has always been uniquely positioned to advance educational equity; however, PBL has not always been explicitly part of the pedagogical approach in schools (Tierney, Urban, Olabuenaga, & Paulger, 2022). This paper presents a design framework for designing equitable PBL curricula that engages each and every student in meaningful learning experiences that are relevant to the world beyond the classroom, affirm and sustain all students' identities, and focus on the development of the whole child.

PBL is an inquiry-based approach that aims to engage students in challenging, active, and meaningful experiences connected to the world outside the classroom (Barron & Darling-Hammond, 2008; Krajcik & Blumenfeld, 2006; Tierney et al., 2020). The goal of education is not solely to prepare students to pass a test but to foster learning in a way that is transferable to their personal, cultural, academic, professional, and civic lives. PBL encourages students to develop the skills and understanding needed for the long-term retention and application of what they have learned (Strobel & van Barneveld, 2009). Importantly, this goal of deeper learning attends to the application of content knowledge and problem solving as well as the inter- and intrapersonal domains – which include communication and collaboration skills – and metacognition and learning to learn (National Research Council, 2012). Further, focusing on deeper learning means challenging students to take ownership of their work, engage in rigorous content, and develop skills and ideas that will have a positive impact on many areas of their future lives (National Research Council, 2012).

Project-based learning can improve student performance on traditional measures of academic achievement, build social and emotional learning skills, and engage students in deeper learning. This form of engagement focuses on higher-order thinking and skills that will help students succeed in college, their future careers, and their lives as active members of their communities. The alignment of PBL and deeper learning is supported by a growing body of evidence that PBL has a significant positive impact on student learning and other outcomes associated with deeper learning (Boardman et al., 2021; Deutscher et al., 2021; Duke et al., 2021; Krajcik & Schneider, 2021; Saavedra et al., 2022; Tierney et al., 2020). Further, this paper also seeks to more closely examine the link between the design of PBL curriculum and educational equity.

The persistent achievement gap between groups of students in the U.S. shines a light on the need to create deeper-learning experiences for all students. Ladson-Billings (2006) reframes the achievement gap, focusing instead on the educational debt that has accumulated from decades of inequitable education for those in historically marginalized groups, such as students of color, economically disadvantaged students, and multilingual learners. In her call to action, which is all the more relevant today, Ladson-Billings argues that the societal disparities, both historic and current, require that we, as part of the education system, use our expertise to alleviate these inequities. To truly address the educational debt, equity must be an explicit priority in the design of classroom experiences and throughout the education system (Paris & Alim, 2017).

The goals of PBL, therefore, go beyond deeper learning to providing experiences that are equitable, relevant, and meaningful to each and every student while supporting the development of not only students' academic learning, but also their social, emotional, and identity development. For this paper, we refer to this as a whole-child approach, acknowledges that supporting learning is dependent on the multidimensionality of a student's life. This means teaching and learning must focus on academic and cognitive development alongside social, emotional, and identity development. Given the learner-centered focus of PBL, it has always been uniquely positioned to advance whole-child development and educational equity; however, PBL curriculum has varied in how explicit, in design, the focus on equity has been and who has had access to PBL curriculum in public education (Deutscher et al, 2021).

In developing equitable PBL curricula, it is important to understand the principles that guide the design of PBL curriculum. A number of frameworks that define PBL (Condliffe et al., 2017) have informed the design of PBL curricula over the years. One of the challenges of designing PBL curriculum is the many choices that need to be made, not just about curricular content, but also the roles of students and the connections to the world outside of the classroom. These choices necessitate curricular design principles to guide the many choices that need to be made. Design principles have long been used in curriculum design to help guide curriculum designers as they make choices on the structure, content, assessments, and the roles of learners within the curriculum (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013; Reiser, Novak, McGill, & Penuel, 2021; Tierney et al., 2020).

While there exists previous valuable work that has documented PBL curriculum design, and specifically PBL design principles (Krajcik & Blumenfeld, 2006), this work is often targeted to individual teachers who are designing their own projects, tends to focus on the principles of designing a single project, and predates recent PBL research on rigorous PBL positively impacting student outcomes and learning, specifically focused on year-long K-12 PBL curriculum (Boardman et al., 2021; Duke et al., 2021; Deutscher et al., 2021; Krajcik & Schneider, 2021; Saavedra et al., 2022; Tierney et al., 2020). This paper seeks to examine this recent body of literature to identify the PBL design principles leading to such impactful year-long K-12 curriculum. In order to bring clarity and coherence to the important work of developing high quality PBL curricula and increase their prevalence, this paper seeks to define a set of features and criteria to aid in the development of and analysis of yearlong PBL curricula.

We write this paper with the perspective that PBL, in its design and implementation, is at an inflection point. Here we can simultaneously recognize the impressive learner-centered work that has occurred thus far in PBL writ large and specifically PBL curriculum work, while also elevating learner's cultures and educational equity as a more explicit feature of PBL moving forward. High-quality PBL curricula, alongside sustained professional learning, supports larger-scale shifts in educational systems (Condliffe et al., 2017). Carefully designed curriculum materials that embody PBL with equity at its core can support teachers in providing students with deep and equitable learning experiences. In this paper we explore the following research questions: 1) What educational commitments and theoretical lenses can support the creation of equitable PBL curricula? 2) What PBL design principles lead to positive student outcomes and learning?

Potential significance

This paper describes the key Design Principles and Critical Lenses required to develop project-based learning curricula. These principles, divided into three categories, describe PBL curricula that have (1) learner-centered approaches to support purposeful, authentic learning that values students' voices and encourages collaboration and reflection; (2) course structures that deeply integrate coherent and authentically assessed content in projects; and (3) curriculum supports for students and teachers to enable the deep learning and practice shifts needed.

While Design Principles provide guidance for curriculum design, developers can often interpret and enact the Design Principles in a variety of ways. Therefore, the Critical Lenses align the pedagogical commitments needed to interpret the principles in a way that promotes the goal of equitable, deeper learning that attends to the development of the whole child. Designers should consider the perspectives they use as they design a curriculum for deeper learning and equitable development of the whole child. The perspectives designers use become operationalized in the developed curriculum, influencing the ways teachers implement the curriculum and, therefore, what students will experience in the classroom. To help illustrate this idea, imagine a photojournalist tasked with capturing an event. The intended audience, the photojournalist's personal style and perspective, and the context of the event all shape both the content and composition of the end results. This is similar to the work of curriculum designers, whose experiences, values, and pedagogical knowledge all influence – intentionally or not – the curriculum they create. In this paper, we present the Critical Lenses to support designers as they interrogate their process and approach in PBL design, helping designers become more purposeful in designing for educational equity.

Creating a PBL curriculum that perfectly captures all aspects of each Design Principle and Critical Lens is challenging, especially when developers must also take into account specific priorities and contexts for their curriculum. For example, while the principles as described here have strong evidence that they are effective in science, English language arts, and social studies classrooms, it may be that PBL in a mathematics classroom would require somewhat different interpretations of the principles. However, regardless of its contexts, a curriculum that prioritizes deeper learning and equity must draw on all the principles and lenses as they encompass pedagogical best practices and draw on evidence of how students learn.

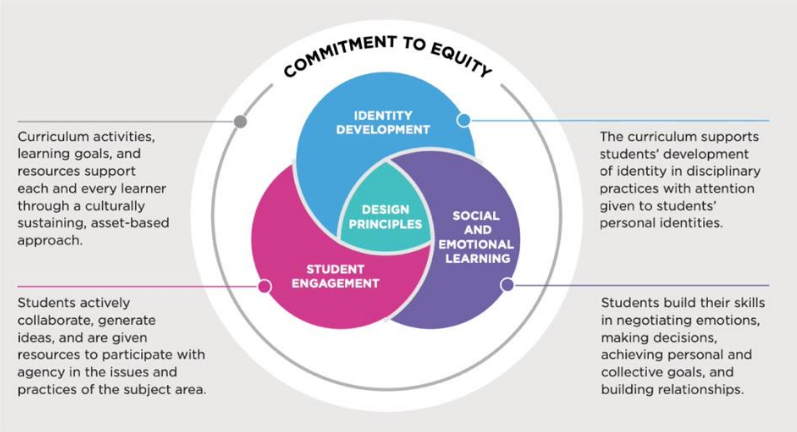
Designing a curriculum that embodies equity and deeper learning requires designers to push on the traditional structures of education. Indeed, one motivator for designing PBL curricula is large-scale systems change. For example, while curriculum designers may not have the power to change required content standards, they may push beyond standards by prioritizing deeper learning and whole-child development and by deemphasizing standards that are problematic and perpetuate historic inequities. We hope this paper ensures that regardless of who the curriculum designers are or their specific context for writing, there will be a shared understanding about the goals of creating PBL curricula that supports the development of all students and provides equitable experiences in deeper learning.

Theoretical perspectives

Creating a PBL curriculum that allows for deep and equitable learning is a complex and challenging task. Our theoretical framework for this paper acts both as lenses from which we identified and examined PBL design principles, but also, we believe, lenses for researchers, designers, and practitioners to enact PBL design principles. Regarding the latter use, while design principles embody values, they can still be interpreted in numerous ways. This matters deeply when seeking educational equity. The intent that is applied to design principles makes or breaks the extent to which the principles work in the service of educational equity or not. For example, a design principle focused on student agency (broadly, students' ownership of and engagement in their learning – a more specific definition is offered later in the paper) can be interpreted and used to promote student-centered curriculum but may not support the creation of equity-centered curriculum. In this way we name the theoretical framework of this paper as critical lenses to be used to interpret PBL design principles, ensuring that all students are valued, engaged, and included. These commitments provide a frame through which curriculum developers can interpret the Design Principles to ensure they are not producing or reinforcing inequities. We name these pedagogical commitments as Critical Lenses both for their essential place in design and to denote the role of critique in curriculum design.

The four Critical Lenses that make up our theoretical framework for this paper are: Commitment to Equity, Identity Development, Student Engagement, and Social and Emotional Learning (Figure 1).

Figure 1
Relationship of Four Critical Lenses for PBL Design



Curriculum activities, learning goals, and resources support each and every learner through a culturally sustaining, asset-based approach.

The curriculum supports students' development of identity in disciplinary practices with attention given to students' personal identities.

Students actively collaborate, generate ideas, and are given resources to participate with agency in the issues and practices of the subject area.

Students build their skills in negotiating emotions, making decisions, achieving personal and collective goals, and building relationships.

These interconnected concepts and pedagogies support the development of the whole child, and we present them as a set of pedagogical commitments curriculum developers should use to create a PBL curriculum that represents the valued outcomes of the PBL approach. As illustrated in Figure 1, all of these lenses overlap and come together to define how to enact the Design Principles in curricula, while Commitment to Equity also encompasses the other three, representing the constant eye toward equity that should occur in PBL design.

Identity development refers to the process of people understanding who they are as they participate in the world. This process, which is ongoing as an individual changes over time, is not solely internal but also embedded in social interactions that are influenced by societal norms, stereotypes, and power relationships (Holland et al., 1998). *Student Engagement* refers to the multifaceted way in which students interact with their learning environment, including how they participate, react emotionally, and invest in their learning and school community (Fredricks et al., 2004). Engagement can be defined at multiple levels, from moment-to-moment interactions with ideas and peers to involvement with school and subject areas across classes and academic years. *Social and emotional learning (SEL)* is the process of negotiating emotions, making decisions, navigating challenges, expressing empathy, achieving personal and collective goals, and establishing and maintaining relationships (Jagers et al., 2019). Finally, *Equity-committed design* calls upon curriculum designers, as well as teachers and the broader educational system, to embrace and enact a series of anti-oppressive, culturally sustaining, and asset-based approaches that center on students, their identities, and their experience (Gay, 2018; González et al., 2005; Paris & Alim, 2017). These equity-committed approaches in PBL design include but are not limited to: instructional approaches supported through curriculum, curricular content, and the selection of valued skills and dispositions embodied in the curriculum.

Within the broader scope of equity-committed design, we include a number of approaches: culturally sustaining/revitalizing pedagogy (Paris & Alim, 2017), culturally responsive pedagogy (Ladson-Billings, 1994), funds of knowledge (González et al., 2005), historically responsive framework (Muhammad, 2020), culturally responsive teaching (Gay, 2018; Hammond, 2015), Indigenous and land-based perspectives (Bang et al., 2014; Barajas-López & Bang, 2018), and culturally and linguistically relevant pedagogy (Hollie, 2011). Valuing, amplifying, and celebrating students' identities and backgrounds are central to all these approaches. These include, but are not limited to, students' racial, cultural, historical, linguistic, gender, ability/disability, community, and family identities and backgrounds.

Methodological approaches & data sources

This paper is a mixture of curriculum review and a review of related literature and theory. We first analyzed a subset of PBL curricula focused on year-long K-12 curricula that showed positive impacts on student outcomes and learning, then turned to the educational theories and literature that informed the relevant design principles. We then iterated on this process to identify design principles, critical lenses, and approaches to design. For the purposes of this paper, which is focused on design of course-long K-12 curricula, we pulled data as well as design principles and frameworks from five courses where the entire course was built around PBL (Table 1). These courses have a strong body of evidence demonstrating significant outcomes on both student learning as well as other positive student measures across income (Boardman et al., 2021; Duke et al., 2021; Deutscher et al., 2021; Krajcik & Schneider, 2021; Saavedra et al., 2022; Tierney et al., 2020).

Table 1
Design Principles Course-long K-12 PBL Curriculum

Knowledge in Action	*AP U.S. Government and Politics and AP Environmental Science courses—Two Advanced Placement courses for high schoolers co-designed by researchers at the University of Washington and high school teachers (Lo & Tierney, 2017; Nolen, Wetzstein, & Goodell, 2020; Parker et al., 2011, 2013; Saavedra et al., 2022; Tierney et al., 2020).*

Project PLACE	*A Project Approach to Literacy and Civic Engagement—Second-grade curriculum integrating social studies and literacy developed by researchers at the University of Michigan and Michigan State University (Duke et al., 2021; Halvorsen et al., 2012).*
Learning Through Performance	*A yearlong science course for sixth graders developed by researchers at Stanford University (Deutscher et al., 2021; Holthuis et al., 2018).*

To identify the collection of principles for this paper, we looked at these aforementioned year-long K-12 PBL curricula and identified principles that repeatedly occurred or were particularly important to aligning fully with the theoretical framework/ critical lenses described earlier in the paper and achieving equitable learning for each and every student. From there, we explored related literature referenced by the PBL curriculum projects as central to the design principles used in the curriculum design. In the curriculum review, we explored the nuanced differences of how the common features of PBL were represented in each curricula creating a set of the design principles that applied writ large. An example of this is Content Coherence, a design feature of all the curricula we examined and one of our design principles. To further refine our collection of design principles and their definitions, we reviewed literature from both project-based practices and cognitive psychology as it relates to how people learn. This allowed us to both strengthen the case for principles identified in the curriculum review and raise up minor or yet-to-be included aspects of the principles. Oftentimes, principles were identified and their definitions refined because of their important role in advancing educational equity. An example of this type of design principle includes the authenticity of projects. While authenticity exists in all of the reviewed PBL curriculum, the implementation of it with the expressed purpose of lifting up students' context, identities, and communities changes the definition of the principle. For each of the design principles, we will define the characteristics, describe related seminal publications, and highlight the ways that the design principle supports this type of learning and engagement across multiple disciplines and grades.

Major findings

Design principles are often used as a tool to help curriculum designers organize and center qualities they would like the developed curriculum to embody. In PBL, design principles have been used to emphasize aspects such as student agency, authenticity, and collaboration (Tierney et al., 2020; Tierney, Urban, Olabuenaga, Paulger, 2022). We describe a set of Design Principles that can support the creation of content-rich, student-centered experiences. The Design Principles presented in this paper fall into three categories: 1) Learner-Centered Approaches, 2) Course Structures, and 3) Curriculum Supports (Table 2). The order in which we present these categories does not imply a sequence to the design process, nor does it suggest levels of priority. In addition, while we present each principle as a distinct idea, there is a significant amount of overlap between them.

We begin with the *Learner-Centered Approaches*, which focus on how students experience the curriculum. Project-based learning that attends to the development of the whole child and deeper learning places students at the center of learning in ways that value and build upon what students know, the skills they have, and what they care about. The principles in this first category answer these questions: "How do students engage with the project and their learning?" and "How do learners experience the project and course?" The Design Principles in this category support the development of PBL curricula that are authentic to students and integrate the Critical Lenses. These principles attend to engagement, connect to students' lives, value student voice, allow students to develop fundamental cognitive skills, generate understanding collaboratively, promote independence, and support success in college, career, and life.

The second category, *Course Structures*, contains principles concerning the scope and sequence of the content and supporting a coherent learning experience. While the previous category applies to how students experience individual projects, here we address what happens at the course level. This category of PBL Design Principles answers the question, "How are the course content and skills chosen, designed, and organized?" The principles outlined in this section are essential for a tightly designed PBL curricula that attends to how content is approached and organized across projects in the course (i.e., the scope and sequence of content, as well as the structure of each project) and integrates the ideas of the Critical Lenses.

The last category, *Curriculum Supports*, includes principles that help students and teachers navigate the course and their learning. Teaching PBL is complex. It involves deep content-area expertise, pedagogical knowledge, and a commitment to equity, which requires supportive curriculum materials. Similarly, students need supports and structures embedded in curriculum materials. This final category of PBL Design Principles answers the question, "How do the materials support teachers and students?" While the other principles can describe the experience of PBL in the classroom more broadly and independently of curriculum materials, these final two principles are unique to curriculum design.

Table 2
Design Principles for PBL Curriculum

Principle	**Short Description**	**Key Literature**
Learner-Centered	**How do students engage with the project and their learning? How do learners experience the project and course?**	
Purpose for Learning	Projects provide students with a reason for learning by engaging them in experiences that connect their own ideas to the project's problem or question before deeply exploring the content.	Parker et al., 2011; Schwartz & Bransford, 1998
Authenticity	Projects are relevant to students' lives, families, and communities and connect to the world outside the classroom, especially to tasks, roles, and practices of the discipline.	Krajcik & Blumenfeld, 2006; Parker et al., 2013; Polman et al., 2018

Student Agency	The course design allows students to make substantive and consequential choices in their projects as well as to apply the work and learning to their daily lives.	Calabrese Barton & Tan, 2010; Nasir & Hand, 2008; Tierney et al., 2020
Collaboration	Throughout projects, students work together on problems in purposeful and supported ways and create a community of active learners that includes students and their teacher.	Barron & Darling-Hammond, 2008; Blumenfeld, et al, 1996
Metacognition	Students have opportunities to build and use metacognitive skills to reflect on what and how they have learned, including disciplinary ideas as well as other skills and practices.	Fusco & Fountain, 1992; McCormick, et al. 2012
Course Structures	**How are the course content and skills chosen, designed, and organized?**	
Centrality of Projects	The projects are integral to learning by framing the entire process of and purpose for learning. A PBL course embeds all content in projects.	Condliffe et al., 2017; Parker et al., 2011
Integration of Rigorous Content	The curriculum integrates projects with core disciplinary ideas and practices. It also specifies learning goals aligned with standards as well as other essential content, such as literacy, social and emotional learning, and equity.	Krajcik & Shin, 2014 Parker et al., 2013
Coherent and Purposeful Content	The content of a PBL course is strategically sequenced to deepen understanding as students' progress through the course, revisiting and connecting ideas across projects.	Parker et al., 2013; Schwartz & Bransford, 1998
Assessment	The curriculum provides ongoing opportunities for assessing learning of disciplinary, social and emotional, and other essential skills and ideas that are performance based and authentically embedded in the work students are doing.	Parker et al., 2013; Taylor & Nolan, 2008
Curricular Supports	**How do the materials support the teachers and students?**	
Curricular Supports for Student Learning	The curriculum provides appropriate scaffolds and tools to support learning, with access points for all students, including explicit framing for lessons, scaffolds for disciplinary and social and emotional learning, and multimodal content.	Engle, 2006; Engle et al., 2012; Puntambekar & Hubscher, 2005
Curricular Supports for Teacher Learning	The curriculum materials support teachers in deepening their disciplinary, pedagogical, and equity understanding in ways that embed the resources in a teacher's daily practice and allow teachers to effectively adapt to their own contexts and students.	Davis et al., 2017; Nolen, Wetzstein, & Goodell, 2020

In order to move PBL from equity adjacent to equity infused, we argue that it is not enough to simply add equity as another design principle. Instead, we highlight pedagogical commitments, or Critical Lenses, for designers to consider to ensure that all students are valued, engaged, and included. These commitments provide a frame through which curriculum developers can interpret the Design Principles to ensure they are not producing or reinforcing inequities. The four Critical Lenses presented in this paper include: Commitment to Equity, Identity Development, Student Engagement, and Social and Emotional Learning. All of these lenses overlap and come together to define how to enact the Design Principles in curricula, while Commitment to Equity also encompasses the other three, representing the constant eye toward equity that should occur in PBL design.
