Professional Development of Teachers in Online Contexts: Differences in Learning Engagement and Relevance of Achievement Goals

Martin Daumiller, Raven Rinas, Markus Dresel
Martin.Daumiller@uni-a.de, Raven.Rinas@uni-a.de, Markus.Dresel@uni-a.de
University of Augsburg, Germany

Abstract: University teachers are required to learn and improve their teaching competencies for their own development and to facilitate successful learning experiences for students. Online professional development courses represent an important learning opportunity for this, yet teachers differ in how well they learn from them. We investigated whether teachers' motivations and engagement explain these differences. Using an achievement goal approach, we assessed mastery goals (task and learning goals), as well as performance approach and avoidance goals. We developed an online course on pedagogical-psychological informed teaching and 67 university teachers completed assessments of their goals before the course, a knowledge test at the beginning and end of the course, and their implementation intentions after the course. Through learning analytics, we modelled learning engagement based on 8 indicators concerning usage of different course elements. Structural equation modelling showed that task goals were beneficial for learning engagement, and consequently, implementation intentions.

Introduction

University teachers are required to continuously learn and improve their teaching competencies to meet evolving educational demands and equip students with knowledge and skills needed to compete in today's job market. Professional learning opportunities play a crucial role in facilitating effective teaching; however, they also require persistent motivation (Shulman & Shulman, 2009). In terms of delivery formats, online professional learning courses have gained prominence as a central means of university teachers' professional development (Castro & Tumibay, 2021; Wynants & Dennis, 2018). Research indicates challenges in online learning, including lower completion and participation rates (Ng, 2016; Simpson, 2013; Wynants & Dennis, 2018). Thus, gaining a better understanding of the factors that contribute to university teachers' engagement and learning in online courses represents an important research direction (see also Liu et al., 2009).

Online professional development courses differ from face-to-face formats in terms of the nature of interactions, supplementary information availability, and non-linear design of the learning experience (Dettori et al., 2006). Moreover, participants often have more autonomy in online contexts, and as such, require increased self-regulation for effective learning (Azevedo & Cromley, 2004). Participants can therefore be expected to differ in how they learn in online courses, where personal characteristics, such as their motivations in the form of their achievement goals, might play an important role (Daumiller et al., 2022). Due to systematic differences, previous findings on face-to-face learning contexts cannot be readily transferred to online contexts, warranting further investigation. Exploring online learning contexts offers the opportunity to objectively analyze participants' engagement, as opposed to relying solely on self-report measures (see Daumiller et al., 2021). Specifically, using learning analytics, the medium of learning in online courses can be leveraged to objectively assess differences in learning engagement and associations with initial motivations and post-course learning gains. This can shed light on the relationship between teachers' engagement in online professional development, its impact on learning outcomes, and how teachers' motivations can enhance effective online learning.

Teachers' professional learning and relevance of their achievement goals

Teachers' professional learning encompasses continuous educational experiences tailored to enhance their teaching practices and outcomes. This process spans diverse forms, methods, and structures (Desimone, 2011), with professional learning courses emerging as a pivotal avenue. While limited research has addressed the topic of learning in online courses among university teachers, the significance of teacher professional learning for teaching engagement, practices, and student learning outcomes is well-established (Shulman & Shulman, 2009). Notably, increased financial investments and regulatory changes fail to consistently yield anticipated benefits for teacher practice and student learning (Hill et al., 2013). Consequently, it is necessary to identify ways to support teachers in their professional development.

Fullan and Hargreaves (2012) emphasize that professional learning is about aiding teachers in self-directed growth; it respects individual goals, not external demands. Teachers enter professional learning courses as self-directed learners, bringing with them individual goals and learning expectations (Tannehill, 2016). Furthermore, professional learning opportunities, especially in online course formats, are characterized by high autonomy and self-initiative. Thus, focusing on teachers' motivations represents a meaningful approach to understanding what drives them to engage in professional learning.

We draw on Achievement Goal Theory to characterize teachers' motivations and explain interindividual learning differences. Achievement goals constitute cognitive representations of end-states that individuals seek to approach or avoid in achievement settings (Elliot & Hulleman, 2017). This theory has been successfully used to describe teacher motivation, linking different goals to affective, cognitive, and behavioral patterns. Although achievement goals have been associated with differences in teachers' professional learning, this research is limited, with learning having been operationalized by loosely-connected aspects, such as attitudes towards helps-seeking (e.g., Butler, 2007), number of attended trainings (e.g., Fritzsche & Daumiller, 2018), number of magazines read (e.g., Nitsche et al., 2013), time spent on professional learning (Hein et al., 2020), and use of feedback (Hein et al., 2021; Kunst et al., 2017). However, few studies have considered differences in learning engagement, which are important for understanding differences in professional development (Daumiller et al., 2021).

Learning engagement in online courses and its relevance for learning gains and implementation intentions

Engagement denotes time and energy invested in purposeful learning activities (Kuh et al., 2005). Higher engagement has been associated with improved learning for students and teachers (Daumiller et al., 2021; Froiland & Worrell, 2016), which can help foster knowledge gains and intentions for knowledge transfer. Online courses offer an opportunity to capture a more reliable understanding of learning engagement and its linkages with motivations and outcomes by use of learning analytics and log data (e.g., views, clicks, posts, scrolls). These objective indicators can measure learners' actions in a more direct, minimally disruptive way, mitigating limitations and biases associated with self-report measures conventional for motivation research.

Numerous studies highlight the value of objective engagement indicators in research on student learning in online courses (Bonafini et al., 2017; de Barba et al., 2016; Pursel et al., 2016). These objective forms of engagement have been linked to diverse learning outcomes, including learning gains (for a summary see Daumiller et al., 2022). This research highlights the benefit of considering engagement as a latent variable to capture the overall psychological engagement construct rather than just individual indicators.

A clear consensus on the usefulness of different objective learning engagement indicators has yet to be reached (Agudo-Peregrina et al., 2014). To obtain comprehensive and reliable insights, simultaneous examination of multiple indicators is essential. Thus, based on the indicators that are commonly reported within studies investigating objective learning engagement in online courses (see Daumiller et al., 2022, for an overview), we measured learning engagement using page and lesson views, clicks on buttons and links, access of supplementary materials, and use of questions and answers.

Achievement goals and learning in online courses

Encompassing "different ways of approaching, engaging in, and responding to achievement situations" (Ames, 1992), achievement goals energize and direct competence-relevant behavior. As such, they should matter for university teachers' learning experiences and behaviors in online courses. Given the dynamic and context-specific nature of motivation, it is important to consider the motivations that teachers hold regarding upcoming courses as opposed to broad motivational characteristics. Instead of studying *why* teachers decide to participate in professional development, we were primarily interested in differences in *how* they are motivated for this learning context.

More specifically, achievement goals are defined as cognitive representations of competence-related end states in achievement contexts that individuals are committed to approach or avoid (Elliot & Hulleman, 2017). Different types of achievement goals with which participants approach an online course can be distinguished (de Barba et al., 2016). These goals are directed at what individuals want to reach at the end of their learning and act as a motivational basis for the interpretation of learning situations and self-regulation therein. Thus, close links with learning engagement and learning outcomes are plausible and have been empirically documented, including linkages with self-regulated learning (e.g., Adesope et al., 2015), learning engagement (Daumiller et al., 2022; Froiland & Worrell, 2016), and academic achievement (Church et al., 2001).

Following Achievement Goal Theory, different types of goals are posited to be relevant in achievement contexts. While further distinctions have been discussed (see Daumiller et al., 2019), at least three fundamental types of goals should be distinguished: mastery, performance approach, and performance avoidance goals (Elliot & Hulleman, 2017), which have been meaningfully linked to differences in learning engagement. Although these linkages are largely based on student populations and may not transfer to online learning, they can still meaningfully inform our expectations regarding how these goals should matter for teachers' engagement in professional training online courses.

Mastery goals are characterized by a focus on task mastery and improvement. They can also be further distinguished (see Daumiller & Zarrinabadi, 2021; Elliot et al., 2011; Hulleman et al., 2010; Korn et al., 2019) depending on whether an individual is oriented towards conducting tasks right (labelled *task goals*) or improving competencies (*learning goals*). Teachers have been found to distinguish between these two goal types (Daumiller et al., 2019; Mascret et al., 2015), where both are proposed to be functional for engaged learning and learning gains, given their focus on increasing competence by acquiring knowledge or skills (Daumiller et al., 2021; Murayama et al., 2012; Payne et al., 2007; Wolters, 2004). Nevertheless, emerging evidence indicates that task and learning goals might operate differently, with task goals enfolding particularly adaptive effects for learning engagement (Daumiller et al., 2022). Task goals might be superior to learning goals, as learning goals might distract learners from covering the full breadth of content to be learned. As the research and practical implications drawn from these findings can differ substantially, further investigations into the different facets of mastery goals are necessary.

Aside from mastery goals, *performance approach goals (1)* entail strivings aimed at wanting to be better than others, while *performance avoidance goals* are focused on avoiding doing worse than others. Combining a favorable approach-orientation with a focus on performance that serves to keep performance efforts channeled toward normative standards, performance approach goals are often linked to high levels of performance (Murayama & Elliot, 2019). However, this might distract from deep learning, as reflected in a meta-analysis by Payne et al. (2007), where no associations with learning gains were found despite increased (adaptive as well as maladaptive) learning processes (e.g., Harackiewicz et al., 2000; Senko & Dawson, 2016). Combining two negative aspects (focus and valence), performance avoidance goals render clearly negative effects, as reflected in increased anxiety, task distraction, and helpless engagement patterns (e.g., Elliot & Church, 1997), reduced learning gains (e.g., Payne et al., 2007), as well as more procrastination, surface processing, and disorganization (e.g., Diseth, 2011; Wolters, 2004). Performance-based goals are still little understood in online learning contexts, where studies have either omitted them altogether (e.g., de Barba et al., 2016), or have not considered them relevant in remote learning contexts due to a lack of contact with peers (Sachs, 2001). More research is needed to determine their significance, especially as concerns about what others do may still be prevalent despite others not actually being present.

The present research

Our study aimed to better understand how teachers differ in their motivations and learning engagement in online courses, and how these differences matter for learning outcomes. Overcoming limitations of past research, we considered university teachers' learning engagement in an online professional learning course using a broad array of objective learning indicators concerning how they interacted with the online course.

Based on this, we aimed to identify differences in participants' learning engagement, analyze how these differences matter for learning outcomes, and study their relationships with achievement goals. To this end, we considered achievement goals by distinguishing task and learning facets of mastery goals and including performance approach and avoidance goals. Based on the presented theoretical notions and prior empirical research, we formulated the following hypotheses:

Hypothesis 1: Learning engagement positively predicts knowledge gains and transfer intentions.

Hypothesis 2: Task and learning goals are positively associated with learning engagement.

Hypothesis 3: Performance avoidance goals are negatively associated with learning engagement.

Given the unclear nature of performance approach goals, we did not formulate a directed hypothesis for this type of goal. Further, we presumed both task and learning goals would result in positive effects but tested for potential differences on an explorative level.

Method

To answer our research questions, we constructed an online course on pedagogical-psychological issues underlying effective teaching (including motivating lessons, feedback from students, different types of learning activities). We offered this course as a professional learning course within the professional development in teaching framework offered by the respective university. Answers of all participants were anonymized using a self-generated codeword. We provide the online course used as an open educational resource and provide all data and code underlying this research in an open repository: https://osf.io/wmb37/.

Participants and procedure

Participants included 67 university teachers (M_{age} = 40), of which 42 were women; 11 had less than 1 year of teaching experience, 13 between one and two years, 13 between two and five years, 12 between five and 10 years, and 16 more than ten years. The most prominently taught subjects included education (12%), psychology (10%), science and engineering (10%), sports (9%), math and statistics (9%), and languages (7%).

The online course contained 3 lessons (including 10, 3, and 9 pages of learning content, respectively), 3 videos, 7 pages of additional information, 16 quizzes, and 3 end-of-lesson assessments. It was constructed based on an earlier online course that we piloted regarding understandability, content relevance, and ease of use. The average time spent on the online course was 71 minutes (*SD* = 34). When accessing the online course for the first time, participants completed a survey assessing their achievement goals and baseline knowledge. During the online course, we measured their learning engagement in the form of log data corresponding to eight different indicators based on views, clicks, and interaction with course materials. Directly after completing the course, participants were required to complete another knowledge test covering the topics within the course to gauge their learning gains, and subsequently rated their intentions to transfer learned content into teaching practice.

Measures

Following the item stem "In this online course…", we measured task approach (4 items; e.g., "my goal is to fulfill the different requirements very well"; internal consistency: McDonalds Omega ω = .94), learning approach (4 items; e.g., "my goal is to expand my knowledge as much as possible."; ω = .89), performance approach (4 items; e.g., "my goal is to be better than the other students."; ω = .88), and performance avoidance (4 items; e.g., "my goal is not to be worse than the other students"; ω = .97) goals using the university teacher motivation achievement goal scale by Daumiller et al. (2019) answered on a scale from 1 (*do not agree at all*) to 8 (*agree completely*).

As indicators of participants' engagement during the course, we used log data concerning (1) total pages viewed, (2) total buttons clicked, (3) total links clicked, (4) amount of clicks within course pages, (5) amount of clicks within supplementary course materials, (6) amount of core lessons accessed, (7) number of answers submitted in quizzes, and (8) amount of additional information accessed. We modeled residual correlations between closely corresponding and partly dependent indicators (e.g., link views with lesson clicks). A CFA confirmed the presumed one-dimensional structure and supported modelling engagement as a latent factor (CFI = .973, TLI = .950, SRMR = .089).

Participants' content knowledge in the course was measured using a self-created multiple-choice test containing 5 questions with 4 answer options each before the start of the course, as well as the same questions along with 9 further, more difficult questions after finishing the course. We subsequently computed the residual change scores between these two knowledge test scores to describe participants' learning gains. Given that the post-test was more difficult than the pre-test, it should be noted that the change scores do not reflect the absolute amount of learning gains for each participant, but rather differences between the participating teachers regarding their learning gains.

Finally, transfer intentions were measured with 5 items slightly adapted from Daumiller et al. (2021), for example, "I will try to integrate the content of this course into my own teaching" (ω = .91). All items were answered to on an 8-point Likert-type scale ranging from 1 (*do not agree at all*) to 5 (*agree completely*).

Analyses

We used structural equation modelling to investigate our research aims: Learning engagement was modelled as a latent variable based on the eight indicators, learning gains and transfer intentions were included as dependent variables, and achievement goals were included as predictors. We estimated the direct effects as standardized partial regression coefficients and obtained indirect effects by combining the specified coefficients for direct effects; their statistical significance was tested with *z*-tests. The model was estimated in R version 4.2.2 (R Core Team, 2022) using the lavaan package version 0.6-12 and MLR as an estimator.

Results

Descriptive statistics and bivariate correlations are presented in Table 1. In line with prior research, we found high levels of task and learning goals and lower levels of performance goals. All goals contained substantial intra-individual variability, indicating that participants started the course with different goal compositions.

Table 1

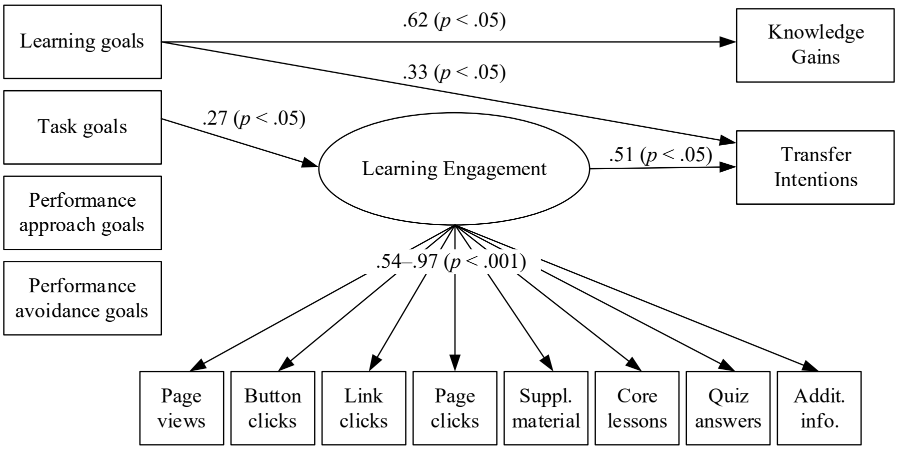
Figure 1
Results of Analyzing the Associations Between Achievement Goals, Learning Engagement, and Learning Outcomes; Note. Only statistically significant effects are visualized. Residuals and their correlations are not presented.



The results of the structural equation model (CFI = .96, TLI = .93, SRMR = .08) are visualized in Figure 1. Task approach goals had a positive, statistically significant effect on learning engagement, while learning approach goals and the two performance goals did not. Engagement had a positive, statistically significant effect on transfer intentions, however, not on learning gains. According to Acock (2014) both effects can be considered moderate in size. Further, there was a small, statistically significant indirect effect from task goals via engagement on transfer intentions ($\beta = .14$). While learning goals were not statistically significantly related to learning engagement, they had direct associations with knowledge gains and transfer intentions that were not mediated through learning engagement. As such, this illustrates differences in how learning and task goals matter for the teachers' learning processes and outcomes in the online professional development course.

Discussion

As professional development of university teachers is paramount for successful educational process, and online courses represent an important, yet little understood, form of educational delivery, we aimed to investigate differences in university teachers' engagement in an online course and how they were related to achievement goals and learning outcomes. Following an achievement goal approach, we distinguished between two mastery goals, namely task and learning goals, and also included performance approach and avoidance goals. Besides offering a detailed view on potential differences between goals, we expanded prior motivation research that primarily relied on self-reports by combining traditional data collection methods and novel learning analytics techniques, measuring learning engagement based on a broad variety of objective indicators. Our finding that especially task goals are beneficial for learning engagement, and in turn, learning gains, extends prior literature on differences between these two types of mastery goals and paints a more nuanced picture of how mastery goals matter and form a relevant premise for successful online learning.

Contrasting prior findings (e.g., Bonafini et al., 2017; de Barba et al., 2016), we did not find that learning engagement measured via objective indicators within the online course mattered for learning gains. However, learning engagement was significantly linked to transfer intentions (Hypothesis 1). It should be acknowledged that our measure primarily focused on behavioral aspects of engagement; an increased relevance of engagement for knowledge gains might have been found had we also considered cognitive and affective aspects. This highlights the importance of designing online courses in ways that spur engagement, as well as considering the role of personal learner characteristics that might impact learning engagement.

One such personal learner characteristic is university teachers' achievement goal pursuit. In terms of linkages with engagement, like other studies conducted within online contexts (Daumiller et al., 2022), task goals were found to matter more for engagement than learning goals (partial support for Hypothesis 2). Aside from replicating prior findings and lending support towards the relevance of task goals, this provides insights into learning goals: We found learning goals to directly matter for knowledge gains and transfer intentions instead of through engagement. This implies that learning goals may not necessarily go along with greater quantity of learning engagement (as assessed in the present study via the objective indicators), but rather greater quality (see Daumiller et al., 2020). For example, teachers with stronger learning goals may not have visited many pages within the course but may instead have deeply focused on pages that were relevant for their specific learning needs. Teachers with task goals, however, might have been particularly concentrated on interacting with all aspects of the course to thoroughly complete it and do a good job. Our findings therefore lend support to both task and learning goals being adaptive in terms of learning but enfolding different mechanisms. Our findings render first indications to this end; however, further research is required. Specifically, research that disentangles different forms of learning engagement by including more qualitative aspects of cognitive and affective engagement processes is needed (see Ben-Eliyahu et al., 2018).

Aside from this, we did not find support for Hypothesis 3 regarding performance avoidance goals being negatively linked with engagement; the same was true for performance approach goals. This may signify that the online course did not include enough opportunities for normative comparisons between participants. As such, performance goals may not have been a relevant motivational driver in the context of the present study. While this could be followed up on by designing course features in a way that provides more opportunity for comparisons between the participants (e.g., leaderboards), it should be considered that our course was designed in a similar manner to most other professional development courses for teachers (see Daumiller et al., 2021). Opposed to course settings where normative elements cannot be fully avoided (e.g., students requiring grades to pass a course), the point that normative comparisons matter less for university teachers within professional development courses can be deemed helpful in terms of being able to focus more on the mastery orientation of these settings (Karabenick & Noda, 2004) and fully profit from the potential that strengthening participants' task and learning goals may have.

Overall, our study entailed several strengths including the implementation of a micro-longitudinal design, the use of a knowledge test to assess learning gains, as well as the integration of objective indicators of learning engagement. Nevertheless, several limitations should be considered when interpreting our findings. First, we assessed the present relationships with respect to a single online course, limiting generalizability of findings. Future research should incorporate different online courses with different designs. Second, our study only focused on objective indicators of engagement. Thus, assessing other forms of engagement that have been identified within the literature would offer a more holistic approach and the opportunity to further validate the present findings. Despite these limitations, first practical implications can be drawn from our study: Course instructors and designers should be made aware of the importance of task goals for online learning experiences in university teachers and focus on encouraging participants towards these goal strivings, as well as designing courses in a corresponding manner. This may be facilitated through (1) directly influencing these goals by scaffolding and stressing the importance of task mastery and putting the goals into writing (reminding participants of their goals and aspirations); and (2) supporting the respective goal pursuit by an arrangement of contextual features emphasized in the online course (stressing mastery goal structures, see Lüftenegger et al., 2014).

Endnotes

(1) Similar to mastery goals, performance goals can be further distinguished based on whether they are directed at normative comparisons regarding performance (normative goals), or at competence demonstration (appearance goals). For theoretical and conceptual clarity, we focus exclusively on normative comparisons (in line with Elliot & Murayama, 2008; Elliot et al., 2011).

Abstract: The learning sciences community is currently exploring new ways to enact productive and equitable co-design research-practice partnerships that are sensitive to all the concerns and needs of stakeholders. The paper contributes to that still-growing literature through an interaction analysis of a co-design discussion involving school district partners that unfolded about cultural relevance and sensitivity in relation to the use of a specific image in an elementary school coding lesson. The episode involved looking moment-by-moment at how district educators recognized and acknowledged that a specific design decision could be harmful for a minoritized population of students enrolled in the district. However, once a key change was made to be more culturally responsive and considerate, new and unexpected pedagogical challenges appeared. This case serves to illustrate some of the unexpected tensions that can appear in real-time when unanticipated questions about cultural relevance are foregrounded during lesson and materials co-design.

Introduction

Given already full curricula and numerous standards, a set of design strategies are emerging that move away from introducing computer science ideas to students as a standalone topic in schools. This appears heavily in what is sometimes referred to as "STEM+C" (STEM plus Computing") approaches, whereby computer science and computational thinking are used pedagogically to support other expected content and practice learning goals, while also helping students develop in their computational thinking proficiencies. For example, computational thinking has been introduced as a way to understand natural selection in high school biology classes through algorithmic explanations (Peel et al., 2019). While some generative new frameworks (e.g., ibid, Weintrop et al., 2016) are appearing on how to integrate computational thinking with STEM content, there are still a number of other practice-based considerations and decisions that need to be made to support STEM+C integration in schools, many of which are still only partially known to learning scientists. Thus, learning scientists have been embracing research-practice partnership and collaborative design ("co-design") with classroom teachers and other school-system partners (e.g., school district coordinators, students, school librarians) (see Severance et al., 2016 for an example) in order to develop and refine STEM+C integration approaches.

This current paper originates from a research-practice partnership that involves co-design of STEM-C integrative lessons and resources with district and school educators. The goal of this larger project has been to design activities and materials (in the form of lesson plans, computer programs, and artifacts for teachers and other school educators) that could integrate specific elementary mathematics topics as they are treated in the district's adopted mathematics curriculum with district-required computer science instruction for elementary students. The paper focuses on an event that occurred during co-design activities in which an important conversation unfolded about culture and a minoritized group of students enrolled in the partnering school district. This episode was recorded on video and noted immediately by one of the researchers as a notable and extended (i.e., lasting several minutes and reappearing a second time on the same day) explicit conversation about cultural awareness and sensitivity. The purpose of this paper is to illustrate how that conversation about culture was laced with multiple underlying tensions. As will be illustrated below, the tensions relate to how different stakeholders responded to an explicit call for cultural sensitivity; some individuals were immediately concerned, and others needed more time. Another tension in this episode related to how the decision to make changes in the design of instruction to be more sensitive culturally were complicated by how the mathematics content and computational thinking were to be integrated as well.

Literature review: Cultural relevance and computing education

Above, we situated the work of this research-practice partnership co-design project as orienting toward integration of mathematics and computational thinking in elementary school and designing supports for paraprofessional educators who lead instruction in the computer lab. The district schedule allows for one computer lab lesson per week. However, through an approach informed by the theory of expansive framing (Engle et al., 2012), our co-design and partnership is organized to create and link multiple contexts of mathematics and computing and the classroom and the computer lab. For now, we turn to a body of literature that pertains to this analyzed episode is the intersection of cultural relevance and computing.

First, we assert that culture is already omnipresent despite it not often explicitly foregrounded in conversations about computer science, computing, or computing education. We follow Rogoff (2003) and others (Nasir et al., 2020) in asserting that all human activities are inherently cultural in nature. Current models of professional computer science and computing professions are already inherently cultural, but they center the experiences, preferences, and values of specific populations who tend to be more heavily represented in computing professions and computing coursework; often, it is the group that is racialized as White and (cis)gendered as male (National Academies of Science, Engineering, and Medicine, 2021). Observations of how computer science and computing education have been highly gendered have been made repeatedly over the years. Turkle and Papert (1992) made a call for epistemological pluralism in how students learn to do computer programming and relied on (White) feminist critiques of epistemological styles that are often associated with gender (e.g., planning vs bricolage). Kafai, Richards, and Tynes (2017) have also explored issues of computing and gender, noting ways in which women, across races, are not always provided the same forms of access to computational communities. One approach to change that has been to emphasize different practices and artifacts that can integrate computing that are not necessarily associated with masculinized norms of computing (such as robotics). One notable example in learning sciences research is electronic textiles (Buechley et al., 2013), through which computing and computational thinking take place in the context of creating and enhancing fabric crafts. Others include recognizing gendered craft activities such as weaving or knitting as already using computational thinking (Keune, 2022; Lee & Vincent, 2019).

In addition to gender, computing education can also be reimagined along ethnic and racial axes. First, computing education experiences can be designed so that they take reside in online and physical spaces that are designed specifically to welcome and empower historically minoritized racialized groups. *Digital Divas* (Pinkard et al., 2017) and *COMPUGIRLS* (Scott et al., 2013), along with nonprofit organizations such as *Black Girls Code*, are all compelling examples that are intersectional and speak to both gender and race. Race and ethnicity can also be made an explicit part of computer science education by helping minoritized youth to recognize and critique inequitable social structures that tend to align with race and ethnicity. This approach can create opportunities for students to raise their critiques and develop counternarratives (Vakil, 2018). Another way that race and ethnicity have been considered, especially in US-based work, has been in the intentional linking of computing with heritage practices. For example, Searle and Kafai (2015) have embarked on work with indigenous communities in the United States to combine Native craftwork with computing. Similarly, Eglash and colleagues (2006) have sought to elevate ethnocomputing by recognizing the rich computational reasoning that resides in practices such as cornrow hair braiding and beadwork.

These aforementioned projects provide aspirational models of what could be culturally relevant and responsive designs for computer science learning environments and learning tools. Our current paper is slightly different in emphasis in that we ask: what tensions arise within a research practice partnership when working together to resolve an issue of culturally relevancy within the context of a co-design session? Where we add to this literature is from the perspective of co-design and from the real-time encounters and engagements with cultural relevance and responsiveness as they appear during design conversations. The phenomena we analyze and share here provides a vivid image of what actual conversations about cultural relevance and sensitivity looked like and what were some of the underlying tensions related to both cultural sensitivity and the integration of math and computing content.

Theoretical framework

The interpretive and theoretical framework informing this paper is situated in what Philip et al., (2016) has called racial-ideological micro-contestations. Racial-ideological microcontestations (heretofore shortened to 'microcontestations') are an ontological innovation (diSessa & Cobb, 2004) from design-based research that names a class of interactional phenomenon during which the learning of disciplinary content knowledge is an overarching concern, but issues of race are invoked such that there are multiple simultaneous stances invoked including those that are epistemic, affective, and moral. They are moments when fluency on matters of race and matters of disciplinary content are simultaneously and prominently raised. Microcontestations have been presented in the context of a data literacy activity in a high school classroom that directly involved students of multiple racial identities and discussions of how data and their referents accord with racial dynamics related to geographies and media preferences. Specifically, in the source example, a high school class discussed a geographic data visualization and a conversation ensued about why there was a difference and how it was associated with a neighborhood that consisted heavily of one historically-marginalized racial group. At various times, students tried to provide explanatory stories around the data visualization on the basis of what they knew from their own racial membership and express solidarity. The teacher intervened and made attempts to redirect conversation to respond to some emergent tensions. In that source case, the lens of microcontestations revealed some missed opportunities that could have shifted the interactional dynamics between students and between teacher and student were noted. By making issues of race and content prominent in interaction, this lens serves to spotlight some tensions and complexities that learning scientists must consider and respond to in the design of learning experiences.

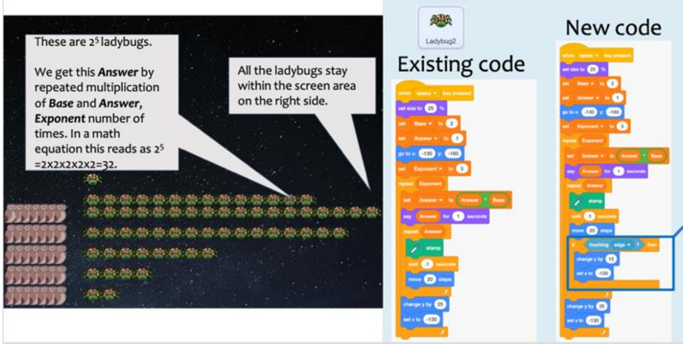
Methods and data sources

The co-design research-practice partnership

The larger project is a multi-year research-practice partnership in which a university-based team is working with a rural-serving school district to develop supports for paraprofessional educators who are tasked with teaching computer science as part of their computer lab responsibilities. The computer lab specialists (their official title) had historically been responsible for overseeing instruction on matters like basic computer literacy, internet safety, keyboarding, and search. With the adoption of statewide computer science standards for K-12, districts throughout the state have explored a range of approaches to address those standards while recognizing that instructional time was already full and that budgets could not be expected change to allow for new permanent full-time teaching staff to be hired.

As a partnership, this project is of the co-design variety. In preparing for and enacting co-design, a number of discoveries are being made about optimal design arrangements. Of specific note is that “design” was a loaded term that needed to be re-examined when district partners saw this as more comfortably viewed as “adaptation” (Lee et al., 202). Design is a valued and highly-involved practice, especially in learning sciences. A tacit ideal of co-design is that the collaborative aspects of design work occur under the presumption of simultaneity and equal participation. That is, co-design is thought to be a time for all parties to meet and invest equal amounts of time to develop common vision and mutually worthwhile solutions. District partners, while enthusiastic about the project, were very limited on time given so many other responsibilities for their schools and classrooms. This was especially true for the classroom teachers and computer lab specialists who were part of the co-design team. Given that, joint sessions were done as periodic meetings with all parties present, sometimes via zoom and sometimes in person depending on circumstances (note: this project began in the remote work portions of the COVID-19 pandemic). A sequence had been developed and agreed upon that the university and district participants would generate together ideas for where there were the most content needs and what were the existing constraints (schedules, pre-requisites, availability of technical resources) and ideate on what could be intersections of computational thinking and the identified mathematics topic. For example, the topic of interest to the episode below is exponents. Teachers noted that students regularly mixed exponents with multiplication, and that this was a challenging topic for their students. Through co-design conversations, the decision was made to address this by working with Scratch-based visualizations of exponents as repeated multiplication and that multiplication can be thought of as repeated addition, with these having very different effects (see Figure 1 below).

Figure 1
Depictions of Scratch elements that show repeated addition and repeated multiplication.



Once this was identified, the university team would work separately with the involvement of district personnel providing intermittent feedback on the creation of the materials and artifacts. In this example, it was Scratch programs, slides, posters for the classroom and computer lab, and lesson plans. When another simultaneous design meeting was held when the classroom teachers and computer lab specialists could also attend, the material drafts were provided and discussed. One important activity to help evaluate this was role-play by which classroom teachers and computer lab specialists taught the lessons to each other during the sessions and offered commentary or suggestions. It was during this role-play that the analyzed episode appeared.

The region where this project is set is, according to 2020 Census records, about 85% non-Hispanic White. Hispanic/Latinx individuals (White and non-White identifying) make up about 11% of the local population. Less than 2% is of Asian ancestry and all other Census-tracked racial groups were less than 1% each of the local population. All of the district personnel and teachers on the co-design team are White. The local research team was predominantly White, with two of four graduate research assistants present who were international students of South Asian origin. Political preferences were not discussed, but the region had historically voted for conservative candidates in local and national elections by a 2:1 ratio (e.g., in the 2020 US presidential election, the region voted about 65% for Donald Trump and 28% for Joseph Biden). Two other research personnel from a different institution and region were present as well for the observed design activity. These other individuals (East) Asian and Black respectively.

Interaction analysis

Interaction analysis is a methodological approach that appeared early in the learning sciences literature (Jordan & Henderson, 1995). Basically, it leverages the availability of interactional records such as video and audio recordings and focuses on short time-scale moments (often on the scale of a few minutes). These interactions typically involved speech between multiple individuals and the use of various artifacts and nonlinguistic modes of interaction (e.g., gesture, body position, etc.). The aim of it was to understand social meanings as they were expressed and negotiated in real time. Because of the complexity of human interaction, the standard techniques for conducting interaction analysis as a form of inquiry involved reliance on various forms of transcription and multiple iterative group reviews of the original video footage. Techniques such as competitive argumentation and progressive hypothesis refinement have been offered for supporting the interpretive work. While it is more involved, these will all involve many iterations of review, applying and challenging interpretive lenses, and identifying observable evidence or warrants for interpretations that persist. The validity of an interaction analysis is based on its reporting with transparency provided on the interactional episode, the interpretation, and the justifications for those.

Consistent with that approach, we iteratively reviewed, transcribed, re-transcribed, and intensively discussed the episode and video footage in several ways (watching it without sound, watching it focusing on a single person, etc.) over a period of multiple months with multiple trained analysts to generate the interpretations offered below. Of note for this reporting, we are being intentionally vague about the individuals' specific roles within their schools, district, or universities to further reduce risk of reidentification.

Results

The analyzed episode took place during a design meeting that involved district personnel, classroom teachers from multiple participating schools in the district, computer lab specialists from multiple schools, and researchers. The entire group of participants were split into two with one half congregating at one table and the other congregating at another. A stationary video camera was placed at one end but not controlled by a researcher. Given that, the angle and audio quality was not ideal – some speakers could only be seen from behind or leaned in and out of camera view - but the quality was sufficient for this analysis. At the table were multiple classroom teachers and computer lab specialists, one central district office employee, and members of the research team hailing from two universities. For ease of reading, the episode is broken into three sequential "scenes".

Identifying the concern

Prior to this meeting, a set of materials including lessons, slide decks, and a *Scratch* program had been prepared by a member of the local the university team. The local university team had not been aware of the specific potential cultural insensitivities prior to this meeting with the teachers, specialists, and district personnel. The concern is that the choice of Sprite in the Scratch program could cause discomfort for a group of students.

The episode took place in the midst of one of the school district team members, Lisa, role-playing instruction using the Scratch program that had been developed to represent repeated addition and repeated multiplication. She had been asking others at the table who were role-playing as students to open the pre-developed Scratch program (see Figure 1, above) and to begin making specific edits to explore multiplication and exponents when another school team member, Daphne, interjected. Her register and posture changed to indicate she was not role playing as a student but speaking as a colleague. Eleanor also worked in the school district. Alex and Taylor were members of the university team.

1. Daphne: You know the problem with the owls, is we have Navajo students, and owls in the Navajo-
2. Eleanor: yes
3. Daphne: -are like really bad luck, and like, like it's intense, it's a like a big thing.
4. Lisa: (turns to the left where university team members are sitting, sighs) Did you hear that?
5. Alex: Yeah?
6. Lisa: (to Daphne, hands raised, palms up): wait but you can't-
7. Daphne: -Like they freak out over it
8. Lisa: -you, can't (raises pitch and punctuates words with beat motions) you find something wrong with every kind of creature? (drops hands on desk)
9. Daphne: -Yeah
10. Lisa (laughs, looking left towards university team members): I don't know
11. Taylor: Oh, we probably should change that.

In this transaction, Daphne changed the interaction to be one of educators and designers. She expressed immediately that in the student population at the school district, there were indigenous students who were part of the Diné/Navajo nation. In line 3, Daphne stresses this is something for the group to be aware of, stating three times ("really bad luck", "it's intense", and "big thing"). This was apparently new to Lisa who was surprised and turned to the university team members. The reason for this could be that this was a correction to note for revision of the materials. However, after, she does express an initial objection (line 6) to Daphne ("wait but you can't"). Daphne was still continuing to stress the seriousness of the use of the owl sprite (line 7).

This was the first known instance in which race or ethnicity had appeared as a topic of discussion during the day. While this was the first mention of a topic explicitly related to a racially minoritized population, the initial response was surprise from Lisa. Her initial responses (lines 5 and 7) were to suggest that this might be something that need not be modified ("you can't..."). She then added in a slightly higher linguistic register as if channeling an exaggerated voice that it would be possible to "find something wrong with every kind of creature". This was not stated with any markers of anger but more of disbelief. The higher linguistic register, accompanied a slightly exaggerated slapping of hands on the desk, making this statement appear as ambiguous regarding whether it was mock frustration for humor or an invitation for solidarity from others who might feel similarly.

Again, the political preferences of individuals were not known. However, the initial response from Lisa bore resemblance to what some of the interaction analysts noted was common in political discourse in the United States about matters of inclusion and equity in the country – that one observation related to race be immediately generalized ("something wrong with every kind of creature"). Specifically, the sensitivities that are urged in order to be more inclusive of historically marginalized communities are seen as unnecessary additional asks for others to accommodate or anticipate. It is also possible that Lisa was expressing frustration on shifting topics to the sprite selection when she was trying to role-play teaching, and this was an interruption.

Seen as a contestation, what was at odds here was whether the racial and cultural concerns that were raised and marked by Daphne were important enough to merit changes. There was a tension with respect to whether this was a concern, but it was expressed in a partially exaggerated way, allowing for this to be dismissed as a comment or as an entry for someone else to express their solidarity in thinking this was not a matter requiring a response. It was mock generalized to "every kind of creature". If sprite selection was indeed a problem for everyone, then it may seem like responding to this instance was prioritizing one group over another. For members of the university team, however, this was seen as something that required response and correction (Line 11).

Elevating the concern

Shortly after, Lisa was seeking clarification on the implications of what would need to happen next. The role play had been halted, and she leaned toward Daphne to ask the following before Daphne interrupted again.

12. Lisa: So, does that mean we have to-
13. Daphne: Yeah, no, like I had t- take um, I had one in my class this year that was Navajo. Um…[student name]
14. Lisa: Ohh (tilts head to the side)

15. Taylor: I guess one suggestion is that-
16. Daphne: And then remember when I had-
17. Daphne: maybe you weren't here when I had [another student] and she was like Navajo.
18. Taylor: What do you guys think of about a [alternative] sprite. What animal do you think would be good?
19. Eleanor: (turns to educator on her left) Because in their tradition owls are bad omens, and it's like a curse if I understand it correctly.
20. Daphne: (looking towards Eleanor and then back to computer): Yeah, it's - I don't know all the details on it, I just know it's like a big thing.

In line 13, Daphne then expresses a personal connection. She adds that she had a Diné/Navajo student in her "class this year". Lisa seemed to recognize the name of the student and change tone with "Ohh" (line 14). At that moment, her arm that is upright then bends at the wrist as if any tension being held with the erect arm just dissipated, and Lisa tilted her head sideways in what appeared to be an expression of understanding and empathy.

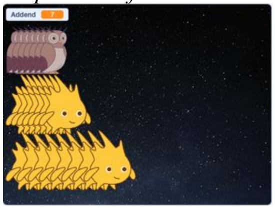
Some side conversation also took place from a university team member who is trying to find another sprite to use (line 15 and 18). During this time, Daphne has some overlapping speech (line 16) and also adds another point of personal connection when she "had [another student] and she was Navajo." At this point, Lisa looks down and appears to accept this is a matter that can be addressed. At the other end of the table, Eleanor overheard this and turned to the educator sitting to her left to explain that "owls are bad omens". Daphne, who was not being addressed but could hear Eleanor speak, turned and added that she did not know much about it. What she did know it was important ("a bi:::g thing", line 20).

This portion of the exchange suggested that once a specific individual was identified (line 13), Lisa had been engaged and stopped remarking. This was a marked change from the earlier response to the caution that this was potentially problematic for a group of people. Also, what was revealed was that the need for sensitivity was shared, but the exact reason for *why* it was a sensitive matter was not widely shared. Eleanor seemed to know some, but no one knew immediately why it was potentially harmful.

Discovering unexpected ramifications

Several minutes (not included here for space) were then spent with different individuals at the table suggesting alternative sprites and offering opinions (such as whether they liked them, if it was cute in appearance). Eventually, a sprite ("Gobo") was selected to replace the owl in the Scratch program and the lesson role-play continued. However, the next interruption that involved stepping out of the role play was initiated by Lisa.

Figure 2
Depiction of the Owl and Gobo sprites



21. Lisa: So far on this sheet, if we go with this one, can we have it move 20 steps versus 10 steps because they're just kind of so close together. So, I just changed mine to 20 just to see what it would look like it
22. Alex: The problem with that could be is they are going to change to a number to [inaudible]
23. Lisa: That's right
24. Daphne: you could change it later, after, like for this particular one, you could do 20 and then
25. Lisa: But see I would do this then..I'd tell them [inaudible] it gets erased
26. Daphne: I get what you're saying

The concern that Lisa raised was that the Gobo sprite (see Figure 2) was wider. When it was stamped, the Gobo overlapped whereas ("they're just kind of so close together") when it was the owl, there was no occlusion on sprite stamps. Lisa suggested that the number of steps to move laterally should change from 10 to 20 so that there would be no overlaps when stamps were made. However, Alex then observed that this was going to be a problem for later parts of the lesson. When there were larger values for the number of stamps, they would not fit on the stage in Scratch. Lisa (line 23) realizes what Alex was saying would be a problem if this was a permanent change. Daphne suggested it be done temporarily, "you could change it later..." (line 24). However, Lisa expressed that this could be counter to what they intend for students as the change could be made for the one example, but then "it gets erased" so that they could complete the other examples. Daphne acknowledges that this is a problem (line 26).

As far as the contestation goes, a change had been made once it was agreed that this change in sprite was appropriate. However, this created the new tension of how the pedagogical strategy and Scratch program were designed to link the mathematical idea of exponents as repeated multiplication as demonstrated by Scratch code would be represented. While the change to the Gobo sprite responded to the need for cultural sensitivity, it ended up challenging the pedagogical and integration strategy as represented in the curriculum material being developed and tested.

Discussion

The entire episode is longer and has more discussion of sprites and sharing what was discovered about the meanings of owls in Diné/Navajo communities, which will need to be reserved for a longer paper. However, this microcontestation episode as presented spotlighted some concerns that learning scientists and research practice partnerships involving design should consider for future work.

First, is that it is very possible for designer ignorance and general assumptions that given tools were sufficiently appropriate factored into this. No members of the university team had been a priori aware of the importance of owls as a bad omen, and there was also little awareness of how many students of Diné/Navajo background would be in the school serving a predominantly White student body. As demonstrated by Taylor in her response, it is something that, once discovered, is a matter that would be taken up immediately and seriously. However, why did this situation come about? Because this was in Scratch, a well-known tool for introducing computer programming, a blanket assumption seemed to have been that the tool was already vetted enough. The added responsibility to think about tools meant to increase issues of exclusion as having potential shortcomings was not in immediate awareness. The research community is still recognizing how educational technologies that are meant to be neutral or safe to use can still end up embodying mechanisms of exclusion (Litts et al., 2021). It is a caution worth keeping in mind.

Second, this did not appear to be a concern that produced a uniform response across design team members. Daphne had seen this as a point of immediate concern whereas Lisa needed some more time to see that this was a pressing concern. We caution the reader to exercise restraint in how different actors are viewed in this episode. We firsthand had seen how Lisa is generous and helpful in a range of interactions and in this project. Her initial response was compelling not because it was her that had expressed it, but it is very likely the same one that large segments of people in the broader geographic region and nation would have. This is not to be accepted as how we may wish things should be, but it is how things are currently. If partnerships and collaboration are a priority for our work, we have the opportunity to recognize this and find productive ways forward. In this case, it appeared a key turning point was when Daphne connected the impact of the owl symbol with a specific student that both she and Lisa knew. Once it was a specific person for whom all were invested in educating and supporting, the seeming reluctance to making changes in the sprite eased.

Third, while it was known as a cause for concern and should be acknowledged, the reasons for why it was a concern were not fully known. Daphne could confidently assert that the owl was problematic, but Eleanor needed to introduce why it was problematic. This was a key learning moment for all to understand the owl's meaning to the Diné/Navajo. The question this raises is what level of knowledge we want educators to have that equips them to be inclusive and sensitive to matters of cultural diversity, exclusion, and harm. We are not equipped to know the long-term impact of this incident for the actors involved. We can assert that the sprite has been changed, but it is unknown if how work around issues of culture and historically marginalized communities will be understood or centered. It could be possible that simply new behaviors are put in place to respond to immediate concerns, but the underlying matters and thoughts about race and racism that limit progress are not being addressed. Rather, they are just becoming harder to see in public in some settings.

Finally, there was an entanglement here that the math and computing integration had with the owl. While the sprite selection may have seemed arbitrary and interchangeable, it turned out that its precise size on the screen supported specific uses in line with pedagogical intent. The owl was small enough to appear a certain number of times in the space given and help to illustrate repeating processes represented computationally. What the owl selection serves to illustrate here is that whether or not the harm or risks are known, the infrastructure in which something as simple as a screen sprite is placed and which it supports quickly become intertwined. It is not simply a matter of cosmetic change in response to cultural concerns. Rather, it implicated many other changes that had to be made.

Thus, in a brief moment when a Scratch program was being built in service of a co-design, a seemingly neutral owl was selected as a sprite to help realize a model of computation and mathematics. However, an interaction analysis of a computer science co-design conversation about how it would be problematic showed us that the selection of an owl had far more below the surface than had been anticipated.

Using the Adaptive Cycles Framework to Conceptualize the Temporal Dimension of Teacher Learning

Nadav Ehrenfeld, Barbara Stengel
Nadav.Ehrenfeld@vanderbilt.edu, Barbara.Stengel@vanderbilt.edu
Vanderbilt University

Abstract: Attending to when and where teachers are with respect to change and learning—the temporal aspects of teacher learning—can yield more effective, timely, and responsive professional development (PD) efforts. Toward this end, we conceptualize phases of learning in a PD program, and how these phases are shaped by different resources and levels within teacher learning ecologies. Conceptually, we build on the Adaptive Cycles framework (Gunderson & Holling, 2002) and empirically, on video-based teacher conversation from a partnership with a PD-organization (PDO). We describe the learning of two school-based teams in the PD through the four phases of the Adaptive Cycles: problematization, reorganization, growth, and conservation. Findings show how the teams differed in their starting point, learning trajectories, and external resources invoked by participants. These findings strengthen our call for centering temporality and provide conceptual tools for doing so in research and practice, towards greater responsiveness to teacher learning ecologies.

לַכֹּל, זְמָן; וְעֵת לְכָל-חֵפֶץ, תַּחַת הַשָּׁמָיִם (קהלת ג' א')
To everything there is a season, and a time to every purpose under the heaven (Ecclesiastes 3:1)

Objective

For more than two decades now, sociocultural research on teacher learning highlighted its social and contextual nature, and as a result, portrayed quality PD as collaborative and situated in teachers' instructional contexts (Ball & Cohen, 1999; Horn & Garner, 2022; Kazemi & Hubbard, 2008). At the same time, empirical findings from such PD designs also point out several impediments to learning within teacher conversations (Borko et al., 2008; Horn et al., 2017; Vedder-Weiss et al., 2018), underscoring the need for ever more nuanced theories of teacher learning to inform teacher educators' responsive work (Cochran-Smith et al., 2014; Ehrenfeld, 2022; Horn & Garner, 2022; Opfer & Pedder, 2011; Stengel, in press). In this paper, we contribute this line of research by arguing that responsive PD efforts require a conceptualization of the temporal dimension of teacher learning.

We show why and how temporality matters by framing teacher learning as a *phased affair* with teachers open to various sorts of resources and interventions depending on where they are in their learning cycles. Theoretically, we take inspiration from sociocultural, ecological, and complexity theories and their guidance to (respectively) understand (1) teachers as agentic sensemakers; (2) within the context of their learning ecologies; (3) through phases of change and learning. Conceptually, we adapt and use the adaptive cycles framework (Gunderson & Holling, 2002). Empirically, we use data from Project SIGMa (Horn & Garner, 2022) to illustrate these temporal aspects of teacher learning. Project SIGMa was a research-practice partnership with a PD organization, and, as a central part of our joint work, we used video-based conversations to support secondary mathematics teacher teams in improving their practice. Here, we look at two school-based teams and ask: *How do different resources within teachers' learning ecologies interact in different phases of their learning?*

Theoretical and conceptual frameworks

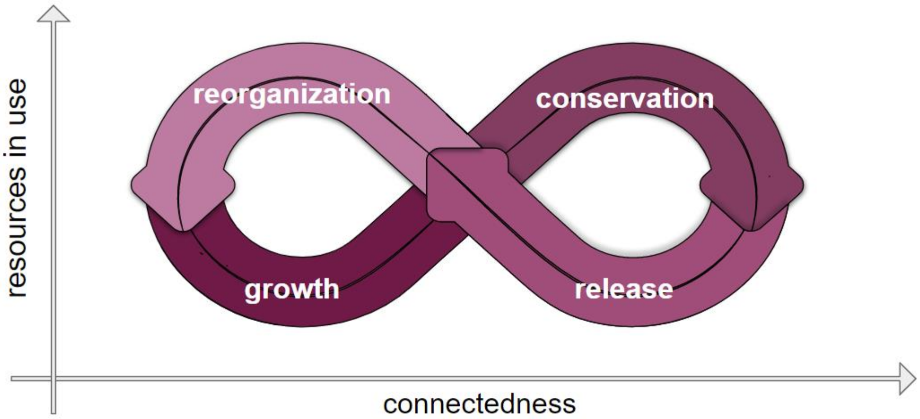
This work is rooted in a sociocultural, ecological, and complexity perspectives on teaching and teacher learning. *Sociocultural research* on teacher learning informs our approach of privileging contexts and conversations, and positioning teachers as agentic learners and sensemakers (Horn & Garner, 2022; Lefstein & Snell, 2013). *Ecological theories* foreground the fact that learners are simultaneously involved in many settings and ask questions about the ways learning emerges from the interactions between these settings, as well as other resources and levels of teachers' learning ecologies (Bronfenbrenner, 1979; Cobb et al., 2003; Ehrenfeld, 2022). Finally, in line with ecological theories, a *complexity theory orientation* seeks to identify systems that interact towards the emergence of teacher professional learning (Cochran-Smith et al., 2014; Opfer & Pedder, 2011). In addition, models rooted in complexity theories also guide us to look at phases of change in ways that, we argue here, are useful for understanding teacher learning trajectories. An example is Gunderson and Holling's (2002) adaptive cycles framework.

The adaptive cycles framework

In traditional environmental ecology, processes of change within ecosystems (such as forests) were described as linear with two phases: growth towards an end point or climax, and conservation, the state the system would reach if not disturbed. However, in adaptive cycles, the climax, or the conservation phase, becomes a transition phase in a continuous cycle, proceeding through phases of release (later in this paper described as problematization), reorganization, and then again growth and conservation. In the forest example, the phase of release can be thought of as triggered by forest fires or drought. Then, in the reorganization phase, nutrients become available for new pioneer species to capture opportunities towards the following phase of growth. Finally, the framework also describes differences between the phases in terms of the level of resources in use, and the connectedness of components in the system (see Figure 1).

Figure 1

The four phases of the adaptive cycles



Note. The cycle reflects changes in two properties: (1) The y-axis represents accumulated resources in use (originally described by Gunderson and Holling as *potential*); (2) The x-axis represents connectedness of elements within the system. The behavior of loosely connected elements is largely influenced by external variability. The behavior of highly connected elements is mostly influenced by their inward relations, which strongly mediate external variability.

Adaptive cycles in the case of teacher learning

In the case of teacher PD, a focus on temporality helps us think about different phases in the teachers' learning trajectories and how they are supported by different resources (see Table 1).

Table 1

Four Phases of Adaptive Cycles in Forests and Teacher PD

Phase	Forest Analogy	Teacher PD
Growth	Competitive processes lead to a few species becoming dominant, potentially previously suppressed vegetation.	**Experimenting** with the new professional arrangement.
Conservation	Nutrient and biomass resources become bound with existing vegetation preventing others from utilizing them.	New practices are **consolidated,** and teachers are proficient with a new professional arrangement.
Release	Forest fires, drought, or intense pulses of grazing.	**Problematization** of institutional practices and teaching norms.
Reorganization	Nutrients become available for new pioneer species to capture opportunities.	**Navigating** tensions between institutional logics and teachers' pedagogical goals. Renewal, **planning**, and **recruitment** of new arrangements and practices

Growth is the longest and slowest phase and represents what Gunderson and Holling called *incremental learning*, where, in our case, teachers are experimenting with new teaching arrangements, adapting or rejecting practices according to their needs and sense of agency, until the arrangement becomes relatively stable. *Conservation* represents the phase when practices are consolidated, and teachers become more proficient with their professional arrangement. *Release* represents the *problematization* of current institutional logic and teaching practices, and often involve external agents as PD facilitators, or a new policy introduced to school (note that we renamed the release phase in the context of teacher learning as problematization). In the case of video-based PD, video-based reflection can also disrupt existing teaching and learning arrangements. Then, *reorganization* can represent navigating tensions between institutional logics and teachers' pedagogical goals, inherent conditions of teacher learning (Horn & Garner, 2022). Just as the reorganization phase in the forest is where nutrients become available for new pioneer species, teachers' reorganization phase is about renewal, planning, and recruitment of new arrangements and practices. Gunderson and Holling (2002) describe this phase as "the engine of variety and the generator of new experiments" (p. 74). At this point, transition to *growth* (experimenting with the new professional arrangements) and back to *conservation* may represent what Gunderson and Holling called *transformational learning*. Importantly, adaptive cycles also guide teacher educators' responsiveness to different phases of teacher learning. In the case of teacher learning, the x-axis in Figure 1 (and later with more elaboration in Figure 2) represents connectedness of resources and teaching arrangements within the system. Within the reorganization and growth phases, when resources and teaching arrangements are loosely connected, new invoked external resources are expected to be more salient in promoting change. In contrast, within the conservation and release phases, internal processes such as video-based reflection are more likely to be salient in promoting change. This distinction in central to our analysis and discussion of how different phases of teacher learning calls for different support.

Methods

Research context

This study is part of a larger research-practice partnership where the research team collaborated with a Professional Development Organization (PDO) to support the participating teachers' development of ambitious and equitable mathematics instruction. Through this partnership, we worked with teachers from six schools. All participating teachers had five or more years of experience and were affiliated with the PDO. Together, we co-developed a video-based formative feedback (VFF) intervention to provide teachers with timely information about their classroom instruction and help them make sense of problems of practice.

Data collection

During the 2017–2018 and 2018-2019 school years (Year 1 and Year 2 of our partnership), we worked with six school-based teacher teams, each ranging from two to five people. We visited and filmed teachers in each team one to six times over the course of the year. To film lessons, we used two cameras. Camera 1, a tablet camera on a robot tripod (Swivl), captured the whole class with a focus on the teachers' movements. Camera 1 also captured conversations from four student groups through four separate microphones placed at their tables. Camera 2, a point-of-view camera (GoPro), was mounted on the focal teacher's head, shoulder, or chest to approximate what they saw as they moved through the classroom interacting with students. In addition to these recordings, our classroom data included fieldnotes, lesson artifacts, photos of whiteboards and student work. The data also included fieldnotes about or recordings of conversations with the teachers before and after instruction, as well as texts and email exchanges with the teachers about the classroom activities. To film debrief conversations, we used the same wide-lens tablet camera and a recording of the researchers' laptop screen to document what teachers and researchers watched at any given time. In addition, debrief data included fieldnotes, photos of whiteboards when used, and fieldnotes about or recordings of informal conversations with the teachers before and after the formal debrief. All 32 debrief conversations were initially transcribed by an external transcription service and then finalized by Project SIGMa team members.

Focal cases

Within this larger group of well-supported and experienced secondary math teachers, we focus here on the Rees Middle-School team (Ezio and Veronica) and the Noether High-School team (Brad, Marisa, Abigail, and Greg). These two school-based teams had a similar leading concern, which remained relatively stable across our partnership. Both teams had the explicit goal of promoting student collaboration. This goal typically included a focus on teaching conceptual math content and supporting social inclusion. Notwithstanding their similarities, the two teams perceived their institutional contexts in significantly different ways. At Rees, tensions between the teachers' personal commitments and school practices were significantly more contradictory. In contrast, at Noether, between Year 1 and Year 2 of our partnership, one focal teacher (Brad) was appointed as department chair. This shift implied that he had greater agency around issues like curriculum design and even purchasing classroom furniture to better support student collaboration. Another difference between the two teams was the length of our partnership. By the end of Year 1, one of the two teachers from Rees moved schools and our partnership ended. However, our work with Noether continued to Year 2, with a one-time Member Check visit in Year 3. Year 1 with the Rees team included three VFF cycles. Year 1 and Year 2 with the Noether team included six VFF cycles. Secondary data include interviews with the participating teachers.

Data analysis

The overarching goal of this data analysis was to understand the teachers' learning was in different phases of the PD, how their "phasing" impacted what resources they are bringing to bear, and what they accounted for because of where they are. We looked at learning trajectories across all meetings we had and described the teams' learning at the PD through the lens of the adaptive cycles. For each of the phases of *problematization*, *reorganization*, *growth*, and *conservation*, we asked whether and where do we recognize conversations that are associated with this phase. First, for the phase of problematization, we searched for and analyzed instances where teachers problematize either institutional practices and norms, or aspects of their own instruction. Second, for reorganization, we focused on instances where teachers discussed planning and recruitment of new ideas, including the tensions between institutional context and their own pedagogical goals. Third, for growth, we focused on instances where teachers tried out relatively new ideas and professional arrangements (in and out of classroom.) Finally, for the phase of conservation, we focused on evidence that teachers became proficient with new professional arrangements, to the extent that these arrangements were consolidated and stable within teachers' routine practices.

Notably, we quickly learned that instances that represent the four phases were usually mixed across the data, that many episodes can be seen as representing multiple phases, and that phases were never really "done" but more or less salient at different points of the conversations. In other words, while these categories are analytically distinct, real life is messier. We tried to consider this messiness in our analysis and be explicit about it. This nuance in and of itself led to some interesting findings. For example, when the Rees team mostly coordinated resources in light of institutional contexts, we considered it *reorganization*. When the Rees team mostly tried out these new resources, we considered it *growth*. However, we noticed that while the main focus of the formal video-based conversations became the growth, our informal conversations with the teachers were still a space for teachers' sensemaking about their reorganization, highlighting how formal and informal dimensions of the PD were interrelated.

Finally, we explored the guidance provided by adaptive cycles to consider the influence of external variability on different phases of learning. Adaptive cycles suggests that within the reorganization and growth phases, invoked external resources will be more salient. In contrast, in the conservation and release/ problematization phases, internal processes such as video-based reflection will be more salient. The temporal analysis is reported in the following section.

Findings

In this section, we describe our partnership with the two teams through the lens of the four phases. First, we show that our work with the Rees team centered on the *reorganization* and *growth* phases. Then, in contrast to Rees, we briefly describe how our work with the Noether team can be seen as a *full adaptive cycle* across all four phases. We conclude by considering implications to designers' and facilitators' responsiveness to teacher learning by using the lens of temporality.

Rees: The PD focused on the reorganization and growth phases

Several years before our partnership began, Ezio and Veronica moved to Rees High-school from the same previous school. Veronica moved first. She was displaced from their old school as the youngest teacher in the department, with less than 5 years of teaching experience at the time. Ezio joined her shortly after, with more than 15 years of experience. When they re-joined forces at Rees, Ezio and Veronica had a strong collegial relationship and collaborated as much as their schedules allowed. This collaboration strengthened when they joined the PDO as a team, which bought them an official shared planning time during their school day. As a team, Ezio and Veronica shared two main goals. First, they wanted to change their lessons to support more student collaboration. In an interview in Fall 2017, they described supporting student collaboration as a topic they tried to grow the most that year. Ezio described not having a lot of experience with student small groups and mentioned he was working on leading students to the answers instead of simply giving answers. Veronica described groupwork as being "outside her comfort zone," and yet she was willing to take "big risks" and try new practices in her classroom. Second, Ezio and Veronica felt a commitment to work towards making their school more equitable. Both teachers were frustrated by the distribution of resources within school, which they felt was favoring affluent families. These families were either newcomers to the school's gentrified neighborhood, or students who were recruited to school's magnet program from other neighborhoods.

Problematization of school routines happened before the PD

Using the terminology of the adaptive cycles, the phase of *release* — the *problematization* of their school routines and of their own teaching — mostly happened before our intervention. Specifically, Ezio and Veronica had grown concerned about the unofficial tracking in their department. For them, tracking was not just about differentiating levels of math classrooms but extended to other activities (such as electives) and created what Ezio called a "sharp divide" between different groups of students. In other words, Ezio and Veronica started our partnership with relatively clear articulations of issues that bothered them in their classrooms as well as in their school. The phase of *reorganization* represents the generating of ideas to address these problems, navigating tensions between institutional practices and their personal commitments.

Reorganization and growth phases

The phase of *growth* involves experimenting with new ideas and instructional practices. Our work with Rees across three VFFs focused on these two phases. Rees VFF 1 illustrated their preliminary reasoning with regards to groupwork facilitation, and the recruitment of ideas towards supporting more equitable student collaboration (i.e., *reorganization* phase). For instance, in Rees VFF 1, Ezio and Veronica made a strong connection between their grouping strategies and their institutional concerns about stigmatizing groups of students. When it came to grouping strategies, they noticed that purposeful grouping amplified the consequences of tracking in the shape of labeling kids as "dumb" or "awesome" — even if teachers did not explicitly state their grouping scheme — while random grouping disrupted it. Then, the following two VFFs were mostly focused on experimenting with and consolidating instructional practices such as random grouping, re-grouping, and rotating groups (i.e., *growth* phase). For example, Veronica started incorporating the aforementioned random grouping into her teaching routine. In this case (Rees VFF 2), Veronica implemented it by the book, with limited flexibility and discretionary judgment. Trying out these new practices constituted experimenting. The debrief offered her an opportunity to hone her flexibility and consider overriding the randomness to attend to the specific teaching situation, which allowed her to consolidate some of her understandings of her experiment. For another example (Rees VFF 3), Ezio incorporated the instructional practices of rotating-groups, another experiment. This new practice introduced to Ezio and Veronica by their PDO coach. The debrief offered teachers several opportunities to consolidate the practice. The idea was that when groups were rotating, they left (by design) their whiteboard scribes to the following groups to reflect on. However, in watching the clips of his classroom, Ezio realized that when he addressed the groups, he talked to the students as if they wrote the scribes next to them, which resulted in some type of miscommunication.

Notwithstanding the analytic distinction between the two phases, the reorganization challenges in light of the school context were never fully resolved. Even though the formal video-based conversations shifted to focus on experimenting with new instructional practices, Ezio and Veronica continued to mention their concerns about school in interviews and informal conversations, and our team used these opportunities to support them on this end. For example, one of our team members described to Ezio Rochelle Gutiérrez's argument of why teachers need political knowledge and creative insubordination (Gutiérrez, 2016). This example calls attention to seeing the VFF cycle — and PD in general — as an activity that happened both on the formal "front stage" (the video-based conversation) and on the informal "backstage" (Goffman, 1959).

Conservation: No evidence for a stable phase

Throughout our partnership, Ezio and Veronica demonstrated instructional growth, however, we cannot describe these new instructional arrangements as stable. Using the terminology of the adaptive cycles, Ezio and Veronica did not reach the phase of *conservation* with their new practices. Rather, our work with the Rees team was centered on reorganization and growth. In contrast, the case of the Noether team illustrates a full adaptive cycle.

Noether: The PD entailed full adaptive cycle toward stable changes

The Noether team included four teachers: Brad, Marisa, Greg, and Abigail. The four teachers had different backgrounds and years of experience. For Brad, Noether was his first teaching job. He was there for over five years, and at the end of the first year of our partnership, he was appointed department chair. Marisa was new to the school and was Brad's collaborative planning partner. This section mostly focuses on them as a subgroup within the Noether team. Abigail arrived at Noether the same year as Brad, after teaching at another school for two years. She had a close relationship with Brad and Greg, who both described her as someone who helped them become better teachers. Greg was the most experienced teacher on the team with more than 20 years experience, all at Noether. Brad himself was inspired by Greg's commitments, as a veteran teacher, to shift his teaching and focus more on students' thinking and discussions. In sum, the team was supportive and collaborative, committed to improvement, and included a variety of backgrounds and experiences.

Problematization: Seeing where instruction falls short through video-based reflection

Notwithstanding the team's collaborative and committed nature, the Noether team did not show signs of arriving at our partnership with a sense of urgency, neither with regards to their institution nor their teaching. in contrast to the Rees team, *problematization* of some aspects of their instruction, and of institutional norms, emerged within the PD as a result of the video-based reflection. The three VFFs in Noether Year 1 often included problematization of the teachers' practices. By problematization in this case, we mean that we discussed central aspects of instruction aligned with the teachers' stated goals, and yet, were still not recognized by them as possible avenues of growth in their teaching. These aspects included, for example, refraining from providing students with answers and instead directing students to each other as resources of mathematical knowledge.

Reorganization: Planning new teaching arrangements

Toward the end of Year 1, it became evident that Marisa and Brad were not only reflecting on and problematizing their practice, but also considering ways to *reorganize* their teaching arrangements. Noether VFF 3 signaled this shift. After watching a video clip of Brad's groupwork facilitation, the research team pointed out the gap and possibility of further directing students' questions to each other within the group. Marisa then invoked her experiences teaching a problem-based curriculum in her previous school to suggest that the constraints of supporting student collaboration are stemming from the culture of their classrooms and school. In later interviews, we found further evidence that these discussions pushed Brad and Marisa to reorganize their classroom and units. Indeed, in the following year, Brad and Marisa used their common planning time to restructure their curriculum and to experiment with new lesson structures.

Growth: Experimenting with groupwork

During Year 2, Brad and Marisa restructured their classrooms to have students work in small groups daily over a five-week unit on statistics. This was the context for Noether VFF 6. At this point, Brad had become department chair and therefore had greater agency in curriculum design. Brad and Marisa took advantage of the new design to "dive in full" into groupwork experimentation in the way Marisa pushed to in the previous year. Brad's classroom design and interaction with student groups in Noether VFF 6 included changes that echoed Marisa's previous experiences with the problem-based curriculum that she invoked frequently. Their experiments with these ideas (e.g., directing students to each other when asking questions) represented a phase of *growth* towards the following phase of consolidating the new arrangements into relatively stable practices

Conservation: New teaching arrangements consolidated into a stable practice

Until now, we described how Brad and Marisa's learning trajectory spanned across the three phases of problematization, reorganization, and growth. Our argument in this last section is that Year 3 illustrated a full adaptive cycle towards a new stable practice. The new stable practices were supported by a variety of resources and levels in the teachers' learning ecology: VFF video resources, together with their shared analysis, external resources like curricula and conferences, and institutional resources such as Brad becoming the department chair. All of these supported Brad and Marisa in the adoption of new structures and practices around the notion of groupwork. In February 2020 of Year 3, our team members visited Brad's classroom for a Member Check. (At this point, Marisa had moved to a new school for family reasons.) Coincidentally, they arrived a day after Brad received new group tables to replace his individual desks with obstructive arm trays that made groupwork difficult. He had completely built the lessons they observed around student collaboration, and our team members noted in their fieldnotes that students seemed used to it (which Brad confirmed in the interview). Importantly, our team also noticed several instructional moves we had discussed during past VFFs: (1) quiet circulation in the classroom listening to groups; (2) asking what students were talking about; (3) directing students to each other rather than giving them answers; (4) using student roles. In the interview after the Member Check observations, Brad recalled this learning process:

> I remember you guys came and observed somebody and it was like we had been very new into doing groupwork. [...] And I just felt like the kids needed to talk more and needed to work together more and that I just needed to change things up [...] So, I did all year group work, fall

> to spring and then Geometry. I only started last spring. So they're used to working in groups […] highest level kids that are used to just being A students and don't need the other three end up valuing group work by the end of the year. So... so I've just dove in full on to having all my classes work in groups.

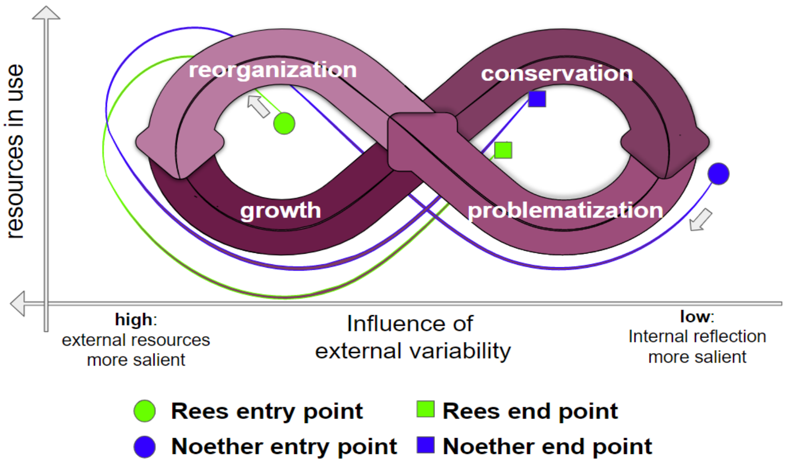
Overall, there was a lot of evidence in Brad's classrooms that he has developed more strategies, structures, and awareness about setting up and supporting effective groupwork. Even more, Brad recalled how these arrangements started with *problematization*/*release*, when he "remember you guys came and observed… I just needed to change things up." They then shifted to *reorganization* and *experimentations*, during which he and the kids got used to work in groups, and side by side with their frustrations, students are seeing the affordances. Eventually they seemed to arrive at a stable phase, which we argue is a new *conservation* phase.

Summary and comparison of the two cases

In this analysis we used temporality as an analytic tool to view teacher learning as a phased affair, with teachers open to different support depending on where they are in the adaptive cycles (see x-axis in Figure 2). Ezio and Veronica from the Rees High School were mainly concerned with establishing new professional arrangements, experimenting with them, and coordinating their work with school norms and policies. In other words, our work with them centered on the reorganization and growth phases (see green line in Figure 2). In addition, there is evidence that at the end of our partnership their new teaching arrangements did not yet stabilize and reached another phase of conservation. In contrast to Rees, we described our work with the teachers at Noether as spanning almost across all four phases (see blue line in Figure 2). For Noether, we used the metaphor of release to describe the phase of acknowledging and reflecting on the gap between the teachers' pedagogical goals, and the ways their teaching often played out in the classroom and fell short with regards to student learning. Then, transitions from problematization to reorganization represents navigating tensions between institutional norms and teachers' pedagogical goals towards renewal. A main institutional resource in this phase was Brad becoming the department chair. At this point, the transition from reorganization to growth included experiments with the new visions of collaborative learning, towards a well-established new arrangement we found in a Member Check in Year 3, that can be described as nearing conservation.

Figure 2

Revisiting the adaptive cycles in the cases of Rees and Noether



Discussion: Responsiveness to different phases of teacher learning

Responsiveness to different phases of teacher learning calls for different support. As a general guidance, this example suggested that in the conservation and problematization phases, internal reflection has more potential to promote change. This was particularly evident in the case of Noether VFFs in Year 1, where problematization mainly stemmed from reflection on video representations of teaching. In addition, these examples suggest that in the reorganization and growth phases, acknowledging and providing a variety of external resources has more potential to promote change. Within the reorganization phase, the focus should be on reconciling these resources with school context, and in the growth phases on experimenting and consolidating them into practice.

Temporal analysis and comparison between the Rees and Noether VFF cycles resulted in several more insights. First, while the phases in Figure 2 are analytically distinct, in real life, they are interrelated. For example, while Ezio and Veronica were experimenting in the growth phase, they kept making sense of their school contexts and coordinating external resources (reorganization phase). Relatedly, this analysis also highlighted how formal and informal dimensions of the VFF cycles were interrelated, as when the informal conversations with Ezio and Veronica provided additional opportunities to provide resources and support. This insight extends the meaning of responsiveness in PD, from facilitation of the formal video-based conversation to the ongoing formal and informal communication and relationship building.

As we work towards more nuanced theories of teacher learning, we call to centering responsivity for teacher learning trajectories and their temporality in the sense of time that Erickson (2004) referred to as *kairos*, which in modern Greek means *opportunity*, or "a brief strip of the right time." (Erickson, 2004, p. 7). It is the qualitative aspect of time as humanly experiences. It is not simply duration (as often time is discussed in literature of teacher learning) or the sequential *chronos* from point A to point B, but rather a lens for supporting teachers with responsibility and attention (Stengel, in press), providing them the right resources at the right moment.

Abstract: This paper explores how MoDa, an integrated computational modeling and data environment, enabled students to express their ideas about diffusion and shift them toward canonical ideas. Drawing on data from an 8-day unit with two 6th-grade science classes, we analyze students' utterances in presentations, drawings, and written responses to document their diverse ideas about diffusion We present three case studies to illustrate how engaging with computational modeling in MoDa and the unit around it enabled students to shift from non-canonical ideas towards more canonical explanations of diffusion. In particular, we identify three factors that helped in shifting students' ideas: the availability of code blocks to represent a diverse range of ideas including non-canonical ones, consistent access to video data of the phenomenon, and model presentations to the whole class. The paper illustrates how a computational modeling tool and curriculum can make students' diverse ideas visible and shift them toward canonical explanations.

Introduction

Scientists tightly integrate computational modeling and real-world data analysis; they develop and evaluate multiple theories to explain a phenomenon before converging on a single explanatory account (Chandrasekharan & Nersessian, 2002; MacLeod & Nersessian, 2013; Nersessian, 2002). Similarly, in science education, students come to the classroom with diverse ideas to account for how the world works (Rosebery et al., 2005; Smith III et al., 1994). Computational modeling tools can surface students' diverse ideas and make them available for exploration and critique (Linn and Hsi, 2000; Wilkerson, Gravel and Macrander, 2013; Sengupta, Dickes and Farris, 2021). However, computational modeling environments have largely been used in science education to confirm canonical ideas rather than for students to explore multiple, possibly non-canonical theories. Hence, little time is spent allowing them to design explanatory models or showing them the evidence for the model. Moreover, integrating real-world data into the modeling process provides learning opportunities that do not arise when students focus on models alone (Bumbacher et al., 2018). However, opportunities for students to explore and analyze real-world data and to design computational models based on evidence remain largely disconnected. Existing work that integrates computational modeling and data analysis relies on curricular activities outside the modeling environment to link the two (Blikstein et al., 2014; Blikstein et al., 2016; Fuhrmann et al., 2014).

This paper investigates how MoDa (Eloy et al., 2022; Fuhrmann et al., 2022; Wagh et al., 2022), a computational, block- and agent-based modeling environment that integrates model design and real-world data analysis, enabled students to express and refine their thinking about diffusion. Drawing on an 8-day computational agent-based modeling unit on diffusion with two 6th grade science classes, we analyze students' utterances in presentations, their drawings, and their written responses. We illustrate three different non-canonical ideas that students expressed while designing a MoDa model for diffusion and trace how these ideas shift over time. In particular, we identify three features of the MoDa unit - the availability of code blocks to represent a diverse range of ideas including non-canonical ones, consistent access to data through the modeling activity, and whole class model presentations - as contributing to shifts in students' thinking toward canonical explanations of diffusion. Our findings suggest the value of integrated modeling and data analysis activities for both surfacing students' diverse ideas and shifting them towards scientifically accurate explanations.

Theoretical background

We first briefly review the literature on computational modeling, focusing on domain-specific block-based modeling in particular and how it has been incorporated into science classrooms. We then contextualize this study within work that emphasizes the link between data use and scientific model construction.

Block-based, computational, agent-based modeling

Designing computer models combines the advantages of traditional modeling with computational literacy, opening new possibilities for inquiry-based learning (White & Frederiksen, 1998). Agent-based computational modeling environments, in particular, simulate the actions and interactions of autonomous agents (e.g., individual organisms, particles, molecules) in order to understand the behavior of a system. Domain-specific block-based programming environments provide students with a limited library of blocks related to the target phenomenon (Wilkerson et al., 2015) and significantly lower the threshold for students to program and test their theories about scientific phenomena (Hutchins et al., 2020; Repenning, 2017). The domain-specific nature of programming can align with students' existing ways of thinking and provide a language to articulate their scientific ideas (e.g., Aslan et al., 2020). It also supports students' developing conceptual understanding and mechanistic reasoning (Wagh & Wilensky, 2018). In the last two decades, innovations in agent-based, and domain-specific, block-based computational modeling technologies have enabled learners to create their own models using visual and block-based (as opposed to script-based) programming in environments such as NetTango (Horn et al., 2014), Deltatick (Wilkerson-Jerde et al., 2015), ViMap (Sengupta et al., 2021), and Much.Matter.in.Motion (Saba et al., 2021).

One design tradeoff of relatively small block libraries is the more limited opportunities for students to explore non-canonical ideas. In some cases, students are asked to use or manipulate a model from existing blocks that only present "canonical" scientific explanations of phenomena. Students miss the opportunity to engage in iterative model building: to articulate and test out an initial idea, identify its limitations, and try out different ideas and explanations. We study the intentional inclusion of non-canonical blocks in MoDa's block library to study the implications surfacing and understanding students' ideas about scientific phenomena.

Using data to design models

Modeling and data practices are tightly intertwined in professional scientific work (Nersessian, 2002). Scientists use data from real world phenomena to both design and validate computational models to build explanatory theories about those phenomena. However, model-based learning approaches in the science classroom predominantly focus on model-based and data-based practices separately (Bumbacher et al., 2018). The Bifocal Modeling framework (Blikstein et al. 2016; Fuhrmann et al., 2014) suggests integrating real-world data collection with computational modeling to enable real-time comparisons of simulated and real data. Juxtaposing data and modeling enables students to notice and attend to discrepancies between models and data, bringing noise, uncertainty, and intrinsic differences between them (Blikstein et al., 2016; Gouvea & Wagh, 2018). Such comparisons create new learning opportunities, enabling students to develop conceptual understanding and meta-modeling competences (Blikstein, 2014; Fuhrmann et al., 2018), deeply explore the underlying features of a phenomenon (Schwarz et al., 2013), and make decisions based on data to think critically and evaluate models (Holmes et al., 2015). Besides designing classroom activities that enable and emphasize this integration, learning environments can also highlight for students the links between real-world data and computational modeling (e.g., Bumbacher et al., 2018). Without available tools, it is difficult to engage students in the explicit coordination of computational models and real-world data for theory building and to study the types and conditions of learning that arise from comparing real-world data and computational models.

Building on these research traditions of integrating data and modeling, we explore two research questions: (1) How do students use a block- and agent-based computational modeling environment to express their initial ideas about diffusion? (2) How do students' ideas about diffusion shift over the course of the unit?

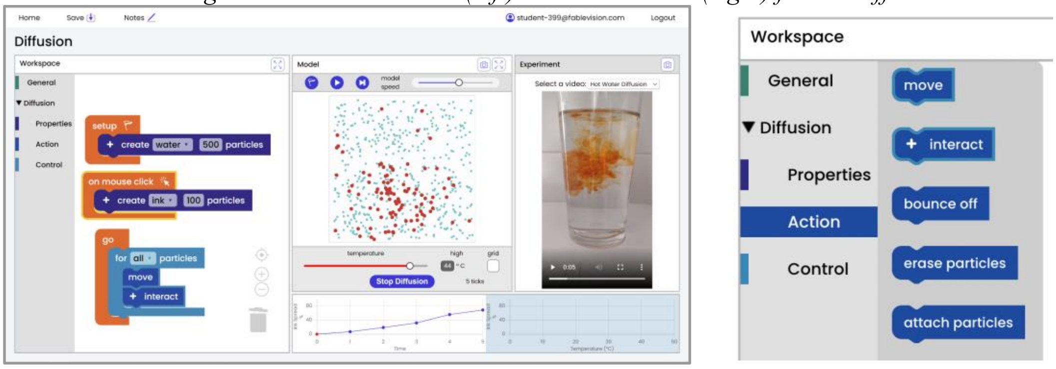
Materials & methods

MoDa: The modeling and data environment

The block- and agent-based, domain-specific computational modeling environment used in this study is MoDa (Eloy et al., 2022; Fuhrmann et al., 2022; Wagh et al., 2022), which was designed for middle school students and teachers to use in science classrooms. MoDa combines computational models using domain-specific code blocks (Wilkerson-Jerde et al., 2015) with the Bifocal Modeling framework, in which learners compare their computational models with real-world data (Blikstein, 2014; Fuhrmann et al., 2018). MoDa consists of a modeling area (built using Google's Blockly library), in which students can drag and drop blocks to program agent-based models that run on the NetLogo engine (Wilensky, 1999). It also includes a real-world data area with videos serving as visual data. In the unit described in this paper, this area includes two videos of ink spreading in hot and in cold water (Figure 1, left). The simulation area includes phenomenon-relevant parameters (e.g., temperature) that students can adjust to evaluate their models. The code library includes blocks for the canonical explanation (i.e., the "bounce off" block that changes heading on collision) of diffusion and typical non-canonical student explanations such as “attach” that makes two particles stick together and “erase” that deletes a particle (Figure 1, right).

Figure 1

The MoDa modeling and data environment (left) and code blocks (right) for ink diffusion in water

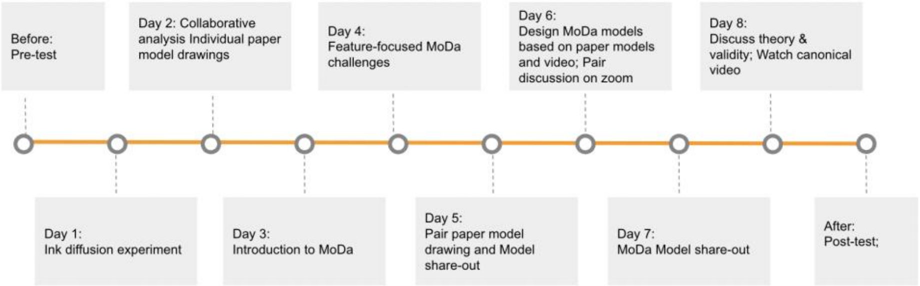


Participants, settings, and instructional sequence

Participants were 6th grade students in a private school in California. Across two classes with the same teacher, 16 students consented to participate (8 girls, 6 boys, and 2 non-binary students). They conducted a diffusion experiment to compare the rate of ink spread in hot and cold water and drew paper models to explain the difference in the rate of spread across the two conditions. Students used MoDa to program computational models to explain their observations and shared both their models with the class for feedback. On the last day, students discussed the validity of their models and watched a video of the canonical explanation for diffusion. All names are pseudonyms. The science teacher has been part of this project for 2 years and participated in professional development and co-design sessions with the project team. The unit occurred over eight class periods and included activities to explore ink diffusing in hot and cold water (Figure 2). Although diffusion is an important concept in science curricula (NGSS, 2013), it can be challenging for students to learn. Diffusion is the net movement of any substance from a region of higher concentration to a region of lower concentration as the result of individual molecules bouncing off one another during the course of Brownian motion. Diffusion occurs faster at higher temperatures because temperature is expressed, molecularly, through an increase in Brownian motion. The science classes did not meet every day of the week, so a few days passed between days of the instructional sequence.

Figure 2

The diffusion unit’s instructional sequence



Data sources and analysis

To identify students’ different explanations for diffusion, we analyze videos of students designing MoDa models (Day 6) and of students presenting their models to their classmates (Day 7). We then trace these explanations back to their origins in earlier data sources (pre-test responses and drawings on Days 2 and 5, respectively) and to their conclusions in students’ post-test responses to construct progressions of students’ explanations through the unit. We marked moments in which students either changed or articulated having changed their explanations and we identified what factors contributed to the shift. This analysis was done independently by the first author and two other co-authors. The above data sources were coded using grounded coding (Corbin & Strauss, 2014) to identify factors that led to students’ shifts. We construct three cases that typify both the non-canonical ideas that students shared and their trajectory toward a shift to a canonical understanding of diffusion.

Results

Our analysis revealed that students were able to express a range of ideas to explain how diffusion works through their computational models. In total, we identified nine kinds of explanations about diffusion expressed in code. We identified three factors that played a key role in shifting student thinking towards more canonical explanations: the availability of domain-specific blocks to model non-canonical ideas, consistent access to the phenomenon through the video data within MoDa, and model presentations to the whole class. Below, we illustrate three initial non-canonical ideas that students expressed while designing a MoDa model for diffusion: the barrier model, the attach model, and the density model. For each idea, we present examples of how students stated, drew, and coded it in MoDa, and how their ideas shifted towards the canonical explanation.

The barrier model

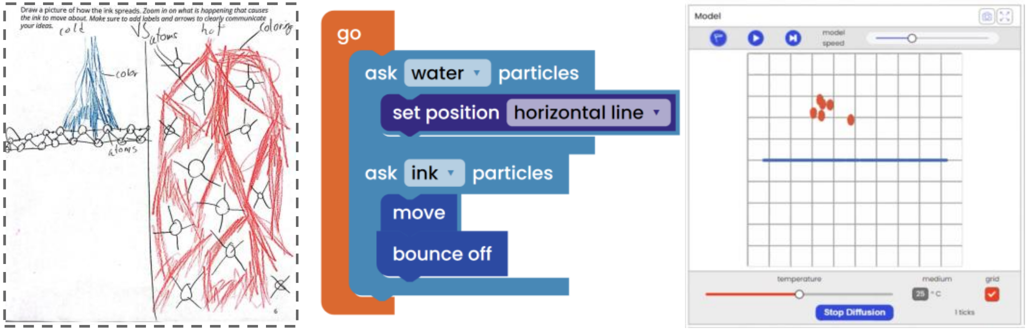
In their first non-canonical model, Johana and Ted had cold water particles create a barrier or border that blocks the ink particles from spreading throughout the glass (Figure 3, left). By the time they created the pair drawing on Day 5, Johana and Ted had expressed the canonical effect of temperature on ink and water particles ("When the water or ink molecules are warm, they move/spread faster. When they are cold, they move/spread slower.") but maintained a non-canonical explanation of particle interaction. While creating their MoDa model on Day 6, Johana and Ted coded the barrier model.

> *Ted: We need to fix that horizontal line thing.*
> *Johana: Is it supposed to be like a barrier or something?*
> *Ted: Yes, I bet it can still pass it through.*
> *Johana: If we make it so they have to bounce off, then it won't be able to pass through it.*

In creating their barrier model, Johana and Ted included the canonical "bounce off" particle interaction to prevent the ink particles from passing through their water barrier (Figure 3, middle). By adding drops of ink above this water "barrier," the students kept the ink at the top of the simulated beaker (Figure 3, right).

Figure 3

The barrier model: Johna and Ted's model drawing (left), the code (middle) and simulation (right).



Draw a picture of how the ink spreads. Zoom in on what is happening that causes the ink to move about. Make sure to add labels and arrows to clearly communicate your ideas.

```
go
  ask water particles
    set position horizontal line
  ask ink particles
    move
    bounce off
```

After a few more revisions to their code, primarily focused on the ink particles' movement, Johana recognized an important discrepancy between their simulation and the video data.

> *Johana: Even if we get this to work, if the border is on the top, it won't let the ink go to the bottom, right? And doesn't, every time when we see it [in the video], it comes down towards the bottom? Maybe here, let me try something. [...] So, our initial idea was to create a border at the middle, then we realized that even if we programmed that, we would have to program them to bounce off, right?*
> *Instructor: Yes*
> *Johana: So they would be staying at the top, and that is not what it looks like in the actual thing [the video].*
> *Instructor: Oh so you revised your model.*
> *Johana: So now I am more, leaning towards the bounce off model.*

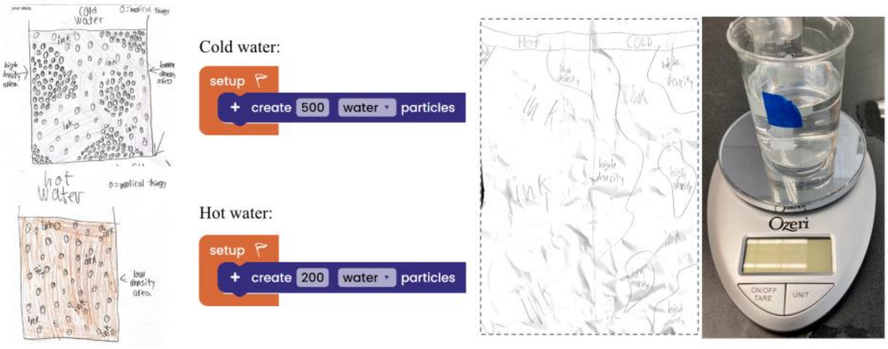
In the whole classroom model presentation on Day 7, Johana and Ted had not yet finalized their code but emphasized that *"we had a border [barrier] and we are going to take that away. So it's just they are bouncing off* *of each other and, again, if something is moving quickly and it bounces off, it is going to travel further. If something is moving slowly, and even if it bounces off, it is not going to travel as far."* They explained the reduced spread in cold water solely as a result of temperature, in line with canonical science.

The density model

Introducing the variable of weight to the system, Miguel expressed the idea that hot water particles were lighter than cold water particles. As early as his Day 2 drawing, he explained that *"The ink in the cold just sank to the bottom of the glass. It might have lower density, so there is more space for the ink. It might have been the only place it could move into."* In his drawings (Figure 4, left), Miguel's "density theory" implies pockets of heavier, more densely packed cold water particles, where ink has minimal open paths ("places") to spread. In contrast, he understood hot water to be uniformly less dense, allowing the ink to diffuse everywhere throughout the glass.

Figure 4

The density model: Miguel and Wade's model drawing (left), code (middle) and experiment (right).



Cold water:

setup
+ create 500 water particles

Hot water:

setup
+ create 200 water particles

On Day 5, when Miguel and Wade coded their density model, they created more water particles for the cold water condition and fewer particles for the hot water condition (Figure 4, middle). In Day 6 pair drawing, they created a density model, but after a discussion with the teacher, Miguel decided to test his dense theory by using the scale in the classroom (Figure 4, right). When he learned that the hot and cold water beakers weighed the same, Miguel balled up his paper model and threw it in the trash (note the wrinkle lines in Figure 4). Still, he maintained the density theory going into the Day 6 computational model presentations.

> *Miguel: First set it to 203 [particles]… this right now is hot water … I basically modeled density by the amount of water particles on the grid… I know hot water has a lower density than cold water, so there are less particles to model a lower density.*
> *Instructor: (plays simulation and video; class notes discrepancies) How can we model the cold water diffusion?*
> *Miguel: Set water particles to 500.*
> *Instructor: (plays simulation and video; class compares) … What are you thinking about density based on what we just saw? (7 second pause) Did you notice a huge difference between hot and cold when you changed the density?*
> *Miguel: Uhh, yeah, it… one seemed… I don't know, not really.*
> *Instructor: I didn't either! I didn't notice too much of a difference, and I think that's really important information. What about anyone else? (solicits individual students for reactions)*

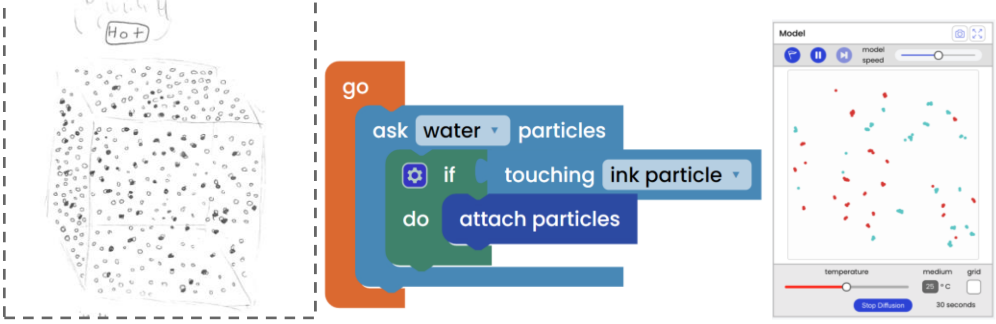
After the whole-class presentation comparing the fit between his hot and cold models with the other students' presentations and the corresponding videos, Miguel started to doubt his density theory ("I don't know, not really."). By the post-test, Miguel expressed the canonical theory for diffusion that *"since particles move faster in hot water, they will bounce off more things in a certain amount of time."* Wade, Miguel's partner who joined class remotely for the Day 6 model presentations, maintained the density theory through the post-test, explaining the difference between cold and hot water diffusion as "*cold has density, hot has air bubbles*."

The attach model

Qahira expressed the attach theory, the idea that the ink spreads in water because the particles "pick up" or stick to one another. Though Qahira didn't articulate the attach model on her pre-test or Day 2 drawing, she clearly expressed it in her Day 5 pair drawing with Rachel (Figure 5, left), which she captioned *"In the hot water the water particles move faster, as they move they pick up the ink particles around them spreading the ink faster. In the cold water the water particles move much slower than in the hot water so they pick up the ink and spread them much slower."* She then coded this model on Day 6 using the "attach particles" block (Figure 5, middle), which made the particles clump together (Figure 5, right).

Figure 5

The attach model: Qahira and Rachel's model drawing (left), code (middle) and simulation (right)



```
go
  ask water particles
    if touching ink particle
    do attach particles
```

As Qahira and Rachel stated while presenting their model on Day 7, they eventually changed their minds about the attach model.

> *Qahira: We realized that ink particles attached more than one ink particle to the water particles and making clumps and moving around like that. That wasn't really what we saw at all in the video. And, therefore, comparing real life with the model, we were able to figure out that one was not the right one.*
> *Instructor: Explain your thinking about this bounce off.*
> *Qahira: Well, our thinking was, if the particles of water are moving slowly in the cold water, they're not gonna hit the ink particles as fast. Therefore the ink particles have time to fall to the bottom and then, like, so, yeah. It will kind of look good, I guess, in the model, similar to what the water does in hot water and cold water [in the video].*

By coding their non-canonical attach theory and comparing the simulation to the video data, the students realized their theory wasn't accurately capturing the diffusion phenomenon. Qahira noticed a better fit between her simulation and the video when using the bounce off model. She maintained this canonical understanding through the post-survey, where she explained *"the hotter the water, the faster the water particles move. When the ink and water particles collide, they bounce off of each other."*

Discussion

Our findings highlight three key points. First, students brought a diverse range of ideas about the mechanisms underlying ink diffusion in water, some of them canonical and some of them not. Although limited in number, *the collection of domain-specific blocks available in MoDa* enabled students to express these diverse theories and test them by creating a diverse set of models. In contrast to the drawn paper models, which students completed before modeling their theories in MoDa, the dynamism of computer models seemed to prompt students to refine their non-canonical models in ways not afforded by drawing static models. Consistent with the literature on model-based learning, students began to shift away from non-canonical theories once they saw how those theories played out in action. Also consistent with conceptual change research (Smith III et al., 1994), students may have been more willing to change their ideas away from non-canonical explanations after seeing why those ideas don't function in the way they expect, in contrast to simply seeing why a canonical theory works. Second, *students' consistent access to video data* of the ink-in-water experiment within the modeling environment seemed crucial to their evolving theories of diffusion. Aligned with our previous work (Fuhrmann et al., 2018), comparing their models with experimental data highlighted discrepancies between the data and models, leading students to shift towards other, canonical explanations. For all students presented in this paper, the lack of alignment between the video data and their coded model (e.g., the simulated barrier blocking ink in ways that did not occur in the video, particles clumping in the attach simulation and not in the video data) led to a shift in student explanations towards canonical ideas.

Finally, *computationally representing their theories in code to the whole class* turned students' ideas into concrete artifacts available for consideration and critique by the class community. Computational models can serve as critical artifacts for sense making at the level of the classroom (Wilkerson et al., 2017). In presenting to the whole class, students shared their own ideas and listened to other students' ideas. The models presented by students in these whole class presentations led to students shifting their explanations and revising their models to reflect canonical ideas. Though not a focus of this analysis, we suspect the concrete yet dynamic representation of students' thinking afforded by MoDa also enabled the teacher to guide both individual and whole-class instruction toward disciplinary norms. Further work is needed to validate this assumption.

Conclusions

To conclude, MoDa and the unit described in this paper was used by these classes as an inquiry tool that enabled students to express, explore, and develop their ideas about a scientific phenomenon. Acknowledging students' existing ideas early on in the unit through the design of blocks in MoDa and accompanying activities supported students in developing a range of models including non-canonical models. Having access to real-world data to notice discrepancies through comparison with the model as well as presenting their ideas and computational models to the whole class supported students in iteratively refining their models to represent a more canonical explanation of diffusion.

Abstract: Systemic oppression impacts access to equitable opportunities and leads to barriers in learning from each other through meaningful communication. A recent scoping review of peer reviewed texts on how the field of Communication Sciences and Disorders (CSD) is identifying and challenging systemic oppression was conducted through the application of a critical analysis. The following paper aims to discuss the nine recommendation categories informed by the final 39 articles included in the review.

Introduction

Communication is powerful as it connects people to each other (Abrahams et al., 2022). However, communication binaries in terms of what is considered normal and pathological in the context of systemic oppression have led to a division between people. This has contributed to communication breakdowns, challenges in collaborative learning, and a crisis of connection (Way et al., 2018). The field of Communication Sciences and Disorders (CSD) has contributed to this systemic oppression. This is evidenced by the fact that our professional title has the world "pathologist" in it (i.e., speech language pathologist, SLP) and that our goal is effectively to simultaneously normalize and pathologize ways of communicating and learning. As a means to challenge this reality, CSD professionals can learn from literature recommendations that employ a critical analysis in order to subvert current power imbalances and work towards learning and communication equity.

Purpose

The purpose of this paper is to discuss the recommendations that resulted from a scoping review of peer reviewed literature using a critical analysis in the CSD field (Hussain et al., 2023). The goal of this paper is to discuss and learn from these recommendations to work towards communication equity.

Methods

A scoping review was conducted using the PRISMA Extension for Scoping Reviews (Tricco et al., 2018) to systematically map peer-reviewed literature from six electronic databases. The primary research question for the scoping review that gave rise to the recommendation categories discussed in this paper was as follows: what CSD literature applies a critical analysis? A critical analysis in the field is defined as work that: a) identifies and challenges systems of oppression, hierarchy, power relations (Collins, 2017; Sajnani, 2013), and "domains of power" (p. 27, Collins & Bilge, 2016). In turn, these power relations and domains of power re/produce inequity, exclusion, and dominant discourses within the field (Bianchi 2009; Dominelli, 2002); b) aims to understand marginalization as a function of social constructs (Pesco, 2014) rooted in systems like capitalism, colonialism, and cis-heteropatriarchy that perpetuate inequity. This includes "intersecting systems of power" (Collins & Bilge, 2016, p. 27) leading to a simultaneous culture of disabling and unjust institutions with systemic barriers and inequitable access to services, research opportunities, and professional training. This impacts those who are marginalized as a function of dis/ability, race/ethnicity/religion, age, gender, sexuality/sexual orientation(s), class/socioeconomic status, and/or intersecting systemic marginalization (Collins & Bilge, 2016; Crenshaw, 1989, 1990); c) provides recommendations to counter oppressive relationships and systems towards transformative change and social justice within the field (Asakura et al, 2020; Corneau & Stergiopoulos, 2012; Pesco, 2014; Rudman, 2018). This paper focuses on the latter, providing recommendations to counter systemic oppression towards transformative change and social justice. Recommendations are thematized into nine recommendation domains across the final 39 articles included in the review. While recommendation domains are identified and discussed separately, some domains overlap with each other and they are included in the quantitative portion of the analysis.

Results

Nine common related domains of recommendations were identified across the final 39 scoping review articles: 1) Identifying and countering colonialism (n = 22, 56% of 39 articles), 2) Indigenous epistemologies (n = 4, 10% of 39 articles), 3) advocating for the implementation of critical theories and critical conceptual frameworks (n = 17, 44% of 39 articles), 4) critically examining the construction of disability (n = 9, 23% of 39 articles), 5) trust and relationship building (n= 14, 36% of 39 articles), 6) changes to assessment intervention protocols (n= 10, 26% of 39 articles), 7) changes to the curriculum (n= 15, 38% of 39 articles), 8) awareness/changes in clinician's attitudes, values, and/or behavior (n= 18, 46% of 39 articles), 9) systemic and policy changes (n= 12, 31% of 39 articles). Identifying and countering colonialism is the highest-ranking recommendation domain.

Analysis and discussion

Identifying and countering colonialism

22 articles address colonialism. Some of these articles provide recommendations on decolonization, cultural safety, cultural responsiveness, countering the pathologization of Indigenous languages/Indigenous variations of English, and/or language policy in the context of the colonialism faced by Indigenous and/or Black people in Australia, Canada, Aotearoa/New Zealand, South Africa, and the U.S.A (Allison-Burbank, 2016; Brewer, 2017; Gillipsie, 2016; Gould, 2008; McLellan et al, 2014; Peltier, 2008; Pesco, 2014; Purdy, 2020; Zingelman et al. 2020). Several articles specifically discuss recommendations for clinical services for Indigenous people with acquired brain injury, including as a result of stroke (Penn et al., 2017; Armstrong et al., 2019; Brewer et al., 2016; Brewer et al., 2020; Penn & Armstrong, 2017), in the context of ongoing consequences of colonialism that inform health outcome disparities (Brewer et al., 2020). Other articles provide recommendations when addressing colonialism. They highlight the importance of acknowledging discrimination and racism as integral features of apartheid, western imperialism, and colonialism, which constructed/continue to construct the profession's whiteness, English language cultural imperialism, and the belief that white western cultures are superior to others (Khoza-Shangase & Mophosho, 2018; Kathard & Pillay, 2013; Pillay & Kathard, 2015; Pillay & Kathard, 2018; Pillay 1998; Pillay, 2003; Moonsamy et al., 2017; Pascoe, et al., 2020).

Applying indigenous epistemologies

Four articles assert the importance of incorporating (pan-) Indigenous perspectives, frameworks, research, and epistemologies (Brewer et al., 2016; Brewer 2017; Purdy, 2020; Zingelman et al., 2020) to facilitate SLPs' effective engagement with culturally responsive practices. Furthermore, studies highlight the importance of implementing Indigenist methodologies while collaborating with Indigenous peoples with the aim that the research will be decolonizing, transformative, and beneficial for Indigenous peoples (Brewer et al., 2016).

Advocating for the implementation of critical theories and critical conceptual frameworks

17 articles recommend that the CSD field implement specific critical theories and conceptual frameworks as a means to work towards social justice: a) active citizenship as a concept to counter dominant cultural narratives of disability and rehabilitation by focusing on relationships and community belonging (Pound, 2011); b) anti-racist, anti-oppressive, and social justice education as a way to go beyond cultural responsiveness when teaching CSD students to examine economic and social inequalities and respective manifestations of disparities at global and micro levels of daily interactions (Pesco, 2014); c) concepts associated with critical social theory to provide relevant and responsive services around the world (Hyter, 2014); d) critical science and decoloniality as a way to confront colonial and hegemonic global north practices which have shaped the field. More specifically, political consciousness and the relationship of laboring affinities (RoLA), whereby SLPs use equality and social justice as a lens for transforming practice (Karthard & Pillay, 2013) and shifting from dominant views of the global north with respect to health care delivery from individualized health care to transformative practices that are embedded in the communication context informed by social, relational, cultural, historical, linguistic, and political realities (Pillay & Kathard, 2018); e) critical paradigm and curriculum of practice in the context of cultural imperialism impacting training, policy and research practice particularly as it impacts Black South Africans (Pillay, 1998; Pillay & Kathard, 2015); f) critical speech language pathology to adopt contextually relevant methodologies (Penn 2004); g) epistemic disobedience by South African CSD professions to counter capitalist, colonial, and heteropatriarchal scripts and to re-imagine their own Afropolitan scripts (Khoza-Shangase & Mophosho, 2018); h) frameworks focusing on language and power such as critical social science for inciting change in problematic report writing and clinical practices in schools (Ng et al., 2014) and language ideology to describe the intersectionality of factors that lead to the exclusion of people in need of an AAC in multiple languages (Tönsing and Soto, 2020). Furthermore, Gould (2008) emphasizes the importance of understanding health policy as it

relates to language policy (versus the two being separate) in the context of the medicalization of non-standard language systems in existing power imbalances between Indigenous and non-Indigenous people; i) public health approach focusing on structural racism and inequities faced by Indigenous people in a colonized society, thereby addressing issues such as power, racism, and equity (Brewer et al, 2020); j) intersectionality as a lens to work with people's agency navigating sociolinguistic interactions in the context of macro-social structures leading to oppression based on social identities such as race, class, disability, and gender (e.g. Guerrero-Arias et al., 2020; Donaldson et al, 2017). Intersectionality is also recommended in tandem with the International Classification of Functioning, Disability and Health (ICF), gender-affirming services to ensure that family and social support systems can provide a holistic lens for the benefit of transgender individuals and their health (Jacob & Cox, 2017). It is important to note, however, that the ICF is critiqued because it does not address disabling conditions such as poverty and it is recommended to be combined with social and human rights models of disability (Kathard & Pillay, 2013); k) Universal Design for Learning to enhance speech language pathologists' practice with a strengths-based approach (Rappolt-Schlichtmann et al., 2018).

Critically examining the construction of disability

Nine articles specifically critique the field's approach to disability by recommending a shift from a deficit-based to a social model of disability and strengths-based approaches (Pound, 2011; Donaldson, 2017; Rappolt-Schlichtmann et al., 2018), critically examining the construction of disability such as stuttering (Watermeyer & Kathard, 2016), and reconstructing social roles after aphasia (Penn, 2004). Guerrero-Arias et al. (2020) specifically discuss the construction of disability identity at the intersection of other social constructs such as race, gender, and socio-economic status that have been borne from relations of power and power imbalances. Similarly, Gould (2008) challenges the disabling of Indigenous children who are second dialect/language learners. Meanwhile, Kathard and Pillay (2013) shift the concept of disability to the disabling contexts of poverty, exploitation, and oppression. They argue for the need to apply social and human rights models of disability. Ng et al. (2014) invite clinicians to critically examine language use in report writing with respect to disability and normality. They discuss how notions of normality, disability, failure, and success actively shape and impact a child's identity and opportunities. They assert the need to nuance how language is understood.

Trust and relationship building

14 articles recommend focusing on building trustworthy relationships between [non-Indigenous] clinicians and Indigenous clients, their families, and communities in order to decolonize and transform practice. This includes: listening to Indigenous clients' stories (Brewer, 2017), establishing and maintaining relationships with family and community members while being self-reflexive about the history of colonial intergenerational trauma experienced by Indigenous peoples (Gillispie, 2016; Brewer et al., 2020), addressing power differences (Brewer et al., 2016), building relationships with Indigenous health colleagues providing cultural support (Brewer et al., 2016), and building a strong and affirming therapeutic relationship shaped by the SLP's appreciation of the extended family, the person's worldview, the therapy setting, and resources used (McLellan et al., 2014). In some cases, the recommendations such as culturally responsive intervention are grounded in the needed recognition that mistrust towards colonial education and health systems exists among Indigenous peoples due to colonial trauma, including intergenerational trauma related to boarding/residential schools (Allison-Burbank, 2016; Gould, 2008). [Settler] clinicians and researchers are also recommended to decolonize attitudes and practice when working with Indigenous peoples, including recognizing that Indigenous peoples are best placed to work within their own communities (Penn et al., 2017). The term "settler" is added as a qualifier here to distinguish between settler and Indigenous clinicians/researchers. Pillay and Kathard (2015) highlight that traditional CSD curriculum typically entails disrupted and disconnected relationships with populations (e.g., site placements). They argue that longitudinal engagement with populations is important to facilitate a sense of belonging. Similarly, Pound (2011) discusses strong, reciprocal, and healthy relationships (including the importance of friendships), and community belonging while exploring the concept of active citizenship to support user-led projects and leadership of those who have a communication disability. This is echoed in Purdy's (2020) article about Māori culture focusing on lasting relationships, and therapeutic relationships being centered around co-constructing goals, as opposed to the healthcare provider having all the power. Jacob and Cox (2017) discuss the importance of familial and social support in the lives of Transgender people. They assert that healthcare professionals are key in disseminating accurate information to prevent family rejection of Transgender individuals. This recommendation is also classified under the importance of relationship and trust building. Meanwhile, Ng et al. (2014) recommend clinicians to be critically reflective in writing recommendations to school-based professionals. The authors assert the importance to phrase reports that facilitate collaborative dialogue versus directive language. Finally, Smith

(2020) asserts the importance of clinicians building trust with Transgender clients in tandem with cultural competence and empathy.

Changes to assessment and intervention protocols

Ten recommendations focus on making shifts in assessment and intervention approaches, including broad shifts from individual focused approaches to those that are contextualized within the given political, social, linguistic, cultural, relational, and historical realities (Pillay & Kathard, 2018). Pillard and Kathard (2015) assert that the most vulnerable and poorest populations will not be served within a healthcare model that only focuses on the individual. They argue that population-based interventions need to be implemented to address service inequities. Others recommend that clinicians use non-standardized assessment tools (e.g., dynamic assessment), protocols with the aim of effectively differentiating between language disorders and language/dialect differences, and questioning the validity of colonial languages being used as standards to evaluate speech-language proficiency for Indigenous people (Gillispie, 2016, Gould, 2008; Peltier, 2008). Others argue for cultural responsiveness (Pesco, 2014), and strategies such as considering population diversity related to immigrant generation status, age of exposure to English, specific types of bilingualism (Khamis-Dakwar & DiLollo, 2018), and strategies informed by an understanding of racial microaggressions and the impact of colonial trauma during assessment and intervention (Allison-Burbank, 2016). Gould (2008) asserts that the educational system must ensure that assessments for Indigenous children occur with full support and in collaboration with children's families. Pound (2011) uses the concept of active citizenship to argue for peer support to focus on personal development, social exchange, and community building for service users' "being, belonging, and becoming" (p. 201). Finally, Shefcik and Tsai (2021) make a specific recommendation with respect to assessing voice related experiences among non-binary individuals by using the Voice-related Experiences of Nonbinary Individuals (VENI) while recognizing that further psychometric evaluation is needed.

Changes to the curriculum

15 articles recommend changes to curriculum. A couple of articles recommend primary school curriculum changes (e.g., cultural concepts and native languages) so that they are relevant for Indigenous children and permissible by the child's family and community (Gillispie, 2016; Allison-Burbank, 2016). One article addresses demands for reviews of South African language policies within higher education and the need for these policies to be "Africanised" (Pascoe et al., 2020, p. 109). One article recommends adopting a neurodiversity lens and strengths-based approach to intervention with students with dyslexia by applying a Universal Design for Learning (Rappolt-Schlichtmann, et al., 2018). One article focuses on clinicians learning from service users. More specifically, Pound (2011) recommends the importance of creating opportunities and conditions for people to develop as active citizens and to see them as colleagues, providers, and role models. The author specifically discusses an example whereby people with aphasia were trained to have conversations to provide feedback to health care staff on ways the latter can improve their communication with the aim of making services more accessible. The other articles refer to changes in professional training for audiology and SLP students with a specific focus on coursework/modules on: a) case studies from research literature for SLP students or SLPs engaged in professional development as a way to reflect on how SLPs and Indigenous parents / educators can discuss what is deemed important in children's development and education (Pesco, 2014), b) critical thinking in cultural competency training of graduate students when working with Arab Americans (Khamis-Dakwar & DiLollo, 2018) and Transgender people (Jacob & Cox, 2017), c) ongoing critical self-reflection and learning culturally responsive intervention when working with Indigenous peoples in addition to understanding Indigenous demographics, region, and history (Allison-Burbank, 2016), d) going beyond English when teaching SLP students phonetic transcription in multilingual settings (Pascoe et al., 2020), e) and implementing Africa-centered courses and a postcolonial stance in a broader context of a decolonized South African curriculum (Khoza-Shangase & Mophosho, 2018; Moonsamy et al., 2017; Pillay & Kathard, 2015). More specifically, CSD professions are recommended to specifically introduce political consciousness and address imperialism, colonialism, and apartheid (Khoza-Shangase & Mophosho, 2018; Pillay & Kathard, 2015). In the author's argument for the application of curriculum of practice to the entire CSD field, Pillay (1998) states the importance of understanding *why* a given curriculum is taught, *to whom* the curriculum is being taught and *who* is teaching the profession. This way, CSD students can better understand underlying beliefs and values informing the dominant curriculum, including the ways in which time is not spent on building long-term relationships with a given population and that this needs to change (Pillay & Kathard, 2015). Pillay and Kathard (2015) also recommend the democratization of classrooms whereby future professionals are trained in dialogical models, whereby collective participation is valued. Lastly, Tönsing and Soto (2020) advocate for attracting students from diverse language and cultural

backgrounds to programs (including for AAC training) while encouraging them to be meaningfully collaborative, reflective and responsiveness practitioners.

Changes in clinicians’ attitudes, values, and/or behavior as this informs service delivery

18 articles recommend awareness of/changes to attitudes, values, and/or behavior. Several articles specifically focus on work with LGBTQ+ people, recommending affirming practice (Taylor et al., 2018), cultural competence, empathy, trust building (Smith, 2020), and the use of Voice-related Experiences of Nonbinary Individuals (VENI) as a questionnaire specifically designed to assess diverse voice-related experiences among non-binary people (Shefcik & Tsai, 2021). Khoza-Shangase and Mophosho (2018) recommend that institutions and service delivery in South Africa be Africanized. By advocating for curriculum of practice, Pillay (1998) questions clinicians’ fundamental beliefs about communication and its constructed disorders as informed by an English imperialist rooted framework of practice. Some authors recommend the importance of CSD students better understanding underlying beliefs, values, power, and the nature of the relationship between client and therapist while reflecting on principles of equity, accountability, and mutual engagement (Pillay & Kathard, 2015; Pound, 2011). Similarly, Purdy (2020) argues that [settler] clinicians shifting from a traditional western view of health to an Indigenous worldview may facilitate cultural responsiveness and safety in clinical and research practice. Pillay and Kathard (2018) assert that valued beliefs about communication, hearing, and swallowing disabilities will shift when applying a South African/postcolonial or Southern discourse to disrupt the global north’s colonial imposition of its values on communication. In order for service providers to interrogate inequity in intervention services in South Africa and the United States (U.S.), the use of political consciousness, population-based (vs individual only) concerns, professionals challenging their cultural assumptions, and responsive clinical approaches (Kathard & Pillay, 2013; Hyter, 2014; Tönsing & Soto, 2020) are recommended. This dovetails with similar recommendations embedded within a critical thinking cultural competency training whereby graduate students explicitly discuss anti-Arab and anti-immigrant attitudes in the United States and respective impacts on service delivery (Khamis-Dakwar & DiLollo, 2018). Similarly, Pascoe et al. (2020) discuss potential attitudinal changes in SLP students through phonetic transcription training in the languages of South Africa as a way to change SLP students’ attitudes so that they are better prepared to work in multilingual environments. Service delivery recommendations also include centering participants’ (e.g., people who stutter) knowledge through narrative therapy (Leahy et al., 2012). Self-awareness and the decolonization of attitudes, belief systems, and practices as part of colonial institutions is recommended (Allison-Burbank, 2016; Penn et al., 2017). Finally, a shift in attitudes that adopt a neurodiversity and strengths-focused approach for people with disabilities, including students with dyslexia, is recommended (Rappolt-Schlichtmann, et al., 2018).

Systemic and policy changes

12 articles make recommendations related to policy and systemic changes. Moonsamy et al. (2017) argue that SLPs and audiologists must advocate for systemic change with respect to accessibility to relevant resources and services for marginalized populations in both urban and rural areas in South Africa. Kathard and Pillay (2013) use the lens of political consciousness to discuss South African policy-driven opportunities, such as the National Health Insurance, for SLPs to promote public health equity. Penn et al. (2017) recommend advocating for Indigenous peoples with communication disorders across clinical, community, and policy contexts in tandem with trust building. Navsaria et al. (2011) argue that there is a need for SLPs in South Africa to expand their services in ordinary schools given that there is a large student population at risk of learning difficulties, including literacy. Pascoe et al. (2020) discuss the potential of phonetic transcription as a way for SLP students to engage with language diversity and multilingualism as a concrete way to facilitate institutional inclusivity and social cohesion as per the Revised Language Policy for Higher Education in South Africa. Simon-Cereijido (2017) argues that SLPs need to continue advocating for multilingualism and protecting clients from language policies that violate their communication rights. Similarly, Khoza-Shangase & Mophosho (2018) assert a transformation in language and clinical training policy in South Africa that respects people who speak several languages, not solely English or Afrikaans. There is also a recommendation that people within CSD adopt public health roles particularly when working with Indigenous people with aphasia to discuss issues of racism, power, and equity, and to work towards revised service delivery models that are sensitive to societal factors such as displacement, mobility, struggle, and socio-political history (Brewer et al., 2020; Penn & Armstrong, 2017). This includes the educational context whereby educational policy should not be based on assimilation and paternalistic practices towards Indigenous students, and instead culturally responsive models need to be adopted (Gillispie, 2016), including language testing (Gould, 2008). Pillay (1998) argues that the curriculum of practice promotes policy as practice in terms of understanding the relationship between policy and practice with respect to who is developing a given policy and the process of policy development itself in the given political context. More specifically, context-facilitated

learning, which demands a critical, political, social, and historical reading of the situation to inform policy changes towards equity and decolonization.

Conclusion

The current paper discussed recommendations provided by CSD literature based on a recent scoping review of literature applying a critical analysis. Nine recommendation domains were discussed: identifying and countering colonialism; using Indigenous epistemologies for the benefit of Indigenous Peoples; advocating for the implementation of critical theories and critical conceptual frameworks; critically examining the construction of disability; trust and relationship building; changes to assessment/intervention protocols; changes to curriculum and learning; awareness/changes in clinicians' attitudes, values, and behavior as this informs service delivery; systemic and policy changes. This paper aims to contribute to a flourishing landscape of criticality, learning, and moving towards deeper actions in confronting and dismantling unjust CSD practices as a way to work towards collaborative learning, human connection, equity, communication, and social justice for all.

Complex Dynamics of Epistemic Agency in a College Physics Lab Course

Ian Descamps, Tufts University, ian.descamps@tufts.edu
Sophia Jeon, Tufts University, sophia.jeon@tufts.edu
Rachel Scherr, University of Washington-Bothell, rescherr@uw.edu
Natasha Holmes, Cornell University, ngholmes@cornell.edu
David Hammer, Tufts University, David.hammer@tufts.edu

Abstract: We study students in a college physics lab course encountering a designed-for discrepancy between their data and the relevant physical model. We examine the moment-by-moment dynamics of the groups' efforts at problematizing and sensemaking, with a specific focus on *epistemic agency*. Drawing from prior studies of agency – as it relates to learning (Damşa et al., 2010), inquiry (Keifert et al., 2018), and scientific practice (Pickering 1995) – we study the complex ways in which epistemic agency manifests (and doesn't) in the students' work. Our analysis suggests several influences on the students' agency, including features of the social and material context as well as how the students frame what it is they are doing (Hammer et al., 2005), in the lab as a whole and in moments within it. The findings suggest implications and questions with respect to designing labs to support disciplinary practices.

Introduction

There are several efforts at reform in introductory physics labs to position students with greater epistemic agency, in line with many years of calls for reform in physics instruction (Otero & Meltzer 2017; Miller et. al. 2018). Rather than guide students toward "discovering" canonical results, curriculum developers have been designing activities to generate uncertainty (e.g., Phillips et al. 2021), often guiding students to experience particular empirical discrepancies. These labs aim to promote students' problematizing (Phillips et al., 2017) and sensemaking (Odden & Russ, 2019). Evidence to date shows that sometimes students take up these opportunities (Sundstrom et al., 2020), and sometimes they do not (Phillips et al. 2021) – more study is clearly needed.

We build on this previous work and draw as well on research in other contexts, including elementary school science (Manz, 2015; Louca et al. 2004) and college biology (Hayes & Gouvea, 2020), to study why, how, and when students in reformed undergraduate physics labs take up opportunities to act as epistemic agents. We adopt Miller et al. (2018)'s definition of epistemic agency as "students being positioned with, perceiving, and acting on opportunities to shape knowledge building" (p. 1058). In our case, lab is designed to provide students with opportunities to shape knowledge building. We attend to students' perception of these opportunities, which we see as part of their framing what is taking place.

Framing in the sense we adopt here refers to how an individual or a group understand what is taking place (Tannen, 1993). To frame a situation is to tacitly answer the question "what is it that's going on here" (Goffman, 1974) and how an individual or group frames a situation shapes their understanding of what could happen, what features of the event require attention, and what qualifies as appropriate action (Hammer et al., 2005). For example, Phillips et al. (2021) found that students who framed the learning activity as confirming a known result or as a series of hoops to jump through to complete the assignment did not problematize upon encountering a discrepancy between their data and the models they were testing. Hayes and Gouvea (2020) similarly found that students framing lab as "about demonstrating a target idea" and that destabilizing this framing helped students better see opportunities to construct knowledge.

Like Hayes & Gouvea (2020), we examine how students perceive and take up opportunities to engage in knowledge building. Through an analysis of the moment-to-moment evolution of these students' framing as they work in the lab we explore questions of why, how, and when they take up opportunities to act as epistemic agents.

Theoretical framework

We draw from Damşa et al. (2010) and Keifert et al. (2018) to identify evidence of epistemic agency. Damşa et al. (2010) outline *shared epistemic agency* as a descriptive construct to understand collaborative efforts to create knowledge objects. Damşa et al. (2010) focus on actions and outline two main dimensions of shared epistemic agency: actions that lead to the creation of a knowledge object (epistemic); actions that organize the process of knowledge creation (regulative). While Damşa et al. (2010) provide a way to identify when collaboration in learning environment involves epistemic agency, Keifert et al. (2018) develop a conceptualization of epistemic agency centered on the experience of participants engaged in inquiry; their lens "focuses our attention on what participants do that signals productive work *to them*" (p. 2). Specifically, Keifert et al (2018) examine the interactions in which participants negotiate the context of inquiry.

Additionally, we use Pickering's (1995) account of experimental science as a dance of agencies to connect the students' enactment of epistemic agency to disciplinary practices. In this view, scientists set up an experimental apparatus and then position it with a kind of agency: they see what it has to say, what it contributes to knowledge, in the data it produces. The dance is between scientists' agency and the materials' – "a dialectic of resistance and accommodation" (p. 22) – a complex and cyclic interaction that, hopefully, progresses toward alignment. This formulation provides a detailed account of meaningful activity in experimental science.

Course context and data collection

The data analyzed here comes from an introductory physics lab in a large, four-year research university in the northeastern United States. The data were produced as part of a project to study students' thinking in labs designed to promote student autonomy in devising experimental methods and drawing their own conclusions (Descamps et al., 2022; Philips et al., 2021). Graduate or undergraduate teaching assistants taught sections of up to 14 students. Instruction occurred in the Spring of 2021 when the course was operating in a hybrid format due to the COVID-19 pandemic. Students worked in groups of two or three, with some students in-person and others virtual. Students recorded their video calls, and we had a camera and audio recorder in the room.

The first author watched the videos, taking notes and logging activity in 5-minute intervals (Derry et al., 2010). He then selected candidate episodes for workshopping (Hammer et al., 2018), focusing on episodes of (potential) sensemaking and scientific inquiry (Odden & Russ, 2019; Watkins et al., 2018). He prepared analytic memos (Bailey, 2007) to present to the research team, constructing and revising based on discussion and feedback. Like in Hammer et al., (2018), the team considered a range of theoretical scales, from individuals' thinking (diSessa, 1993; Tannen, 1993) to social interactions and activities (e.g., Jordan & Henderson, 1995)

In this episode, two of the students, Peter and Holly, are in-person at the same lab table; their other lab partner, Judy, is virtual (all pseudonyms). The students are in the second week of the first lab activity of the semester: investigating Galileo's claims that the period of a pendulum does not depend on either the mass of the bob or on amplitude. In fact, the period does depend on amplitude, which careful measurement can show; the lab is designed for student to encounter and grapple with that discrepancy. The instructions for the lab ask students to provide an "unambiguous statement" of whether their data do or do not deviate from Galileo's claims. We turn now to our data and analysis of the students at work, as they work to analyze their data.

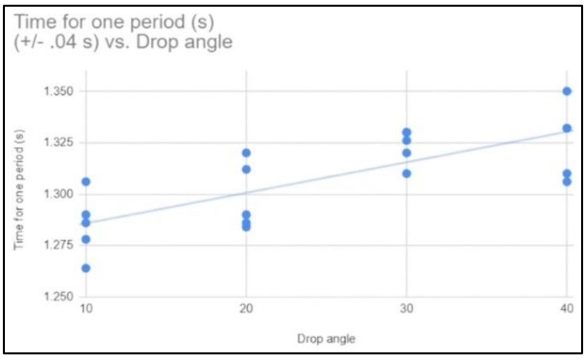
Data and analysis

We present the data and analysis in four sections, beginning with the students first noticing the discrepancy, continuing with their taking two different approaches to addressing it, and finally their arriving at their conclusion. Line numbers refer to the full transcript, which we excerpt here.

The students encounter a discrepancy

Holly, Judy, and Peter produced data for amplitudes of 10, 20, 30, and 40 by timing five swings of their pendulum and dividing by five to find the average period; they did five trials at each amplitude. They estimate their uncertainty in timing to be ±0.2 seconds, which makes the uncertainty in their period measurements ±0.04 seconds. To show their data, we provide as Fig. 1 a graph the students produce toward the end of the lab period.

Figure 1
Students' data



This episode begins immediately after they finish collecting data, a little over an hour into their lab period.

01 Peter:	I mean so we are clearly seeing like very slight changes. I know, I think we had the same thing last time that the amplitude seemed to change it just a tiny bit. I wonder what about like how we're doing it is making it change it consistently?
02 Holly:	Is it not supposed to change?
03 Peter:	Uh, it should be the same regardless of amplitude. But I guess there must be something else that we're doing that's making it change just a little bit. Although it's very insignificant.
04 Holly:	I wonder if it's, um, friction. Like, is it— does this move back and forth [reaches up to examine pendulum string]— No

Peter immediately sees the data as "clearly" showing "slight changes" in the period with amplitude, which he remembers their seeing in the first lab session as well. He locates the problem in their doing of the experiment: something they did made the data change in this way. With Holly's question about what is supposed to happen and her suggestions in line 4, we infer that both Peter and Holly are framing their lab activity as confirming a known, correct result. Judy, on the other hand, suggests a different interpretation of the data:

08 Judy:	But I feel like the correlation is too strong to ignore, like it— like it makes sense, like it's decreasing very slightly as you decrease the amplitude
09 Peter:	Yeah, I mean, I think looking at our data, it would seem that it is related, but just at a really small like ratio I guess, so like the amplitude has a really small effect. But like, I know, theoretically we shouldn't be seeing any effect. So I'm wondering what about what we're doing is making it look like that.
10 Holly:	I don't know. Like, yeah, like where is our error coming from?
11 Peter:	Uh… also, what parts could have error? The drop, the starting and ending of the timer

In line 8, Judy begins to argue that the amplitude does have an effect on the period. Her saying "but" suggests she distinguishes her interpretation from Peter's and Holly's; that the effect they see in their data could be a feature of the phenomenon. She does not seem to frame the goal of their work as confirming Galileo.

In line 9, Peter acknowledges the logic of this reasoning, that "it would seem" the period changes, based on their data. Still, he continues in line 9 to defend his articulation of the problem. He clearly vests epistemic authority in Galileo (or perhaps the instructor). At the same time, he readily admits that their data is saying something different; he and Holly frame the problem they need to solve as finding the source of their "error."

The problematizing evident in these first 11 lines is a clear demonstration of epistemic agency: the students identify a discrepancy between their data and the theoretical model and then, in dialogue with each other, they refine their understanding of what is the problem to solve. For both Damşa et al. (2010) and Keifert et al. (2018), students developing ideas that help regulate the direction of their intellectual work is fundamentally epistemically agentive (inter)actions. In addition to the social negotiation occurring here, the apparatus and phenomenon are central to the emergence of epistemic agency.

Peter and Holly troubleshoot their apparatus

Following Holly's comment in line 10, she and Peter begin to brainstorm ideas for where their error could come from. Judy does not participate. Instead, after Peter remarks "Although it's very consistent for some reason" (line 13) Judy suggests they graph their data and starts working on that. In other words, she decides to produce a new knowledge object. Meanwhile, Peter and Holly try to figure out their problem.

19 Holly:	I wonder if error could also be in the drop itself. Like if you don't just like [random noises] take your hand directly away, like if it's like cushioning it at all. But like, I don't know how that would
20 Peter:	Yeah and, I mean, would that have a larger effect at higher drop height? That's the question.

21 Holly: I don’t know. I mean actually it might
22 Peter: It might. Cause I think, like I’m doing my best to release the ball at once and obviously I’m not
23 Holly: Right. I see and there’s nothing you can do to make that better, unless you have like a literal like hard thing holding it up and you take that away immediately, like there’s no way to remedy that.
24 Peter: Yeah, so I mean, that could be it. Do we think, can we think of a reason why it would be a larger effect at a higher drop. I mean, say it’s staying exactly where it is for a little bit before it starts to fall.
25 Holly: Um, well I don’t know. Cause like if you only bring it out to here it has more velocity in the x direction than the y direction whereas up here [pendulum stand almost falls over] […] If you bring it up here, like it has like, past— well it’s not like we’re going passed 45 degrees, but like there’s more velocity in the y direction up, up at a higher point… maybe

Holly suggests a possible physical effect that might affect the pendulum’s motion, perhaps in releasing the bob; Peter asks if that effect would vary with amplitude. In this way both students are focused on possible physical mechanisms that might explain the trend in their data. It is possible Judy’s critique had an influence – Judy told them not to ignore the correlation. Their first ideas, that the error might come from timing or from the drop, are not sufficient explanations to them. Rather, they are the beginning of a search for a mechanism that would consistently increase the period length as they increase amplitude. We see this troubleshooting work as an aspect of disciplinary practice as they are holding possible explanations accountable to the data.

Indeed, the troubleshooting seen above embodies Pickering (1995)’s description of scientific practice as a dance of agencies: the students have constructed a combination of instruments and machinelike human practices (e.g., stopping the timer) to capture the phenomenon of pendulum motion. Their experiment produced data contrary to their intentions and now the students are actively and intentionally working to accommodate this "resistance” (Pickering 1995) on the part of the materials. Holly’s and Peter’s work here involves grappling with and deconstructing the production of their data, a sophisticated epistemological framing (e.g., Hardy et al., 2020) that is nested within, and we suggest supported by, their confirmation framing of the lab as a whole. That is, they expect to confirm the authoritative claim, but the apparatus resists with discrepant data, and this prompts them to troubleshoot. The clear material resistance drives Peter and Holly to enact epistemic agency.

New ideas for data interpretation

A few turns of talk after line 25, Judy returns to the conversation to share with them the spreadsheet she has made, and Peter works to plot this data.

40 Judy: Cause, yeah um, it looks like it’s really linear.
41 Holly: Yeah.
42 Judy: Do you see this? [laughs]
43 Peter: Yeah. Wha— uh…
44 Holly: Guys we just disproved Galileo’s theory
45 Judy: It’s a literal straight line!
46 Peter: No no no, it’s it, this is not a straight line for the reason you think this is a straight line, look at the axes flipped [laugh]
47 Judy: But like it’s so straight, like the line is like
48 Peter: I mean the reason it’s straight is because we’re, this isn’t an actual x-axis on the bottom, like look at what the units are on the bottom
49 Judy: Oh, I’m so silly [laughs]

Judy’s sharing her spreadsheet prompts Peter and Holly to shift their attention back to the data. Looking at the clear, “straight line” of the graph, Holly and Judy conclude that they have disproved Galileo, that amplitude affects period. Holly, who was previously invested in figuring out how their experimental procedure caused error, now exclaims “we just disproved Galileo” (line 45). From her tone, it is not clear how much she believes this statement; perhaps she was less than fully serious. Judy, on the other hand, is clearly happy about this development.

Peter, however, notices a mistake in the graph that is the reason for the straight line. We do not have direct evidence of the mistake, but we reproduced what we suspect it was: they included the word "seconds" in the cells with their raw data, and the period values are to the left of the amplitudes. This would have Excel ignore the period values and plot (1, 10), (2, 20), (3, 30), and (4, 40) – a straight line that does not reflect their data.

Judy recognizes the mistake Peter identifies – "I'm so silly" – and in the work that follows she steps aside, asking, "Can somebody else attempt this, I'm, maybe I'm just terrible at Excel but it's literally just not letting me" (line 59). For the rest of the lab session, Judy's participation is notably diminished.

We return to the students' work as they examine a new graph of their data. Holly leans towards her computer and says,

64 Holly: It almost looks like it dips down at 30
65 Judy: Yeah, it could just be from like error. But they're all like 1.3 something, {like they're very close—}
66 Peter: {Oh. That's, that's that's} the issue, it's cause this was, uh, was 1.28 here and 1.33 and [Unclear] uh cause we had it 30 20 10 40

Peter and Judy briefly discuss some spreadsheet logistics and Peter narrates some data reformatting for about a minute before Holly makes another observation about their data.

69 Holly: It's interesting how much closer the 40-degree and 30-degree values are compared to the 10-degree and 20-degree ones
70 Peter: Yeah
71 Holly: So I wonder if using a bigger amplitude would have us— or, a larger amplitude would allow us to have more accurate results in accordance with the theory
72 Peter: It's possible. Yeah I think it would probably be easier to measure for larger amplitude because we are, you know, it's a more extreme peak.
73 Holly: So then maybe it is a timing error for the smaller ones.
74 Peter It might be.

In addition to her comments in lines 64 and 68, Holly's body language – leaning in towards her computer – is evidence she is focused on interpreting the data. Her observation and conjecture in lines 69 and 71 reflect and support a return to sensemaking, as she considers another possibility for explaining the discrepancy. Peter joins this work, articulating this explanation in his own words and elaborating on the mechanism.

Judy, too, seems to shift in her approach to the data and to the activity. Even though her comment in line 65 is an evidence-backed explanation, she now seems to view the data as relatively consistent. That said, Peter's comment in line 66 suggests that, perhaps, the current plot has the amplitude data incorrectly ordered. As figure 1 makes clear, reordering the amplitude data would undercut the evidence for a linear relationship, perhaps informing Judy's new explanation. Recall the dispiriting exchange in line 40-50, which could also have contributed to her shift. Additionally, that she says "just" seems to indicate that the abstract notion of "error" is a now sufficient explanation for the data, which is certainly a shift in her thinking.

In between lines 66 and 69 Peter generates a new and (likely) accurate graphical representation of their data. In contrast with their first sensemaking conversation in which Holly and Peter deconstructed their experimental set up to think through the possibilities for error, here, their sensemaking is grounded in their plot and data interpretation. In lines 69-74 Holly and Peter position their data as a legitimate source of information that needs to be explained and/or reconciled with the theoretical model.

Furthermore, the central idea of their discussion – perhaps there are larger timing errors for the smaller amplitudes because those are harder to measure – exemplifies the complex, entangled relationship between human and material agency that Pickering (1995) envisioned: "disciplined human agency and captured material agency are, as I say, constitutively intertwined; they are *interactively stabilized*" (p. 17). Holly and Peter claim here that certain configurations of their apparatus – which involves both instruments and machinelike human actions – enables them to capture the phenomenon and produce data more accurately.

Starting in line 74, Peter returns to tweaking the formatting of their plots. First, he seeks to plot "exact" averages of their trials, then tries to include the extrema of trend lines. That is, he wants to plot the trend line from the shortest period of the smallest amplitude to the longest period of the largest amplitude and vice versa in order to compare them (this is a technique the TA mentioned at the beginning of the lab when talking about how uncertainty measurements influence the conclusions you can draw from data). Before she joins Peter in figuring out how to plot such trendlines, Holly continues to make observations about the data.

Although we do not include the transcript (mostly discussion of Excel), it is important to point that this discussion, too, treats their data as a legitimate source of information. To use the language of knowledge-creation, Peter and Holly are invested in generating knowledge-objects to concretize their ideas; this Excel reformatting is a demonstration of shared epistemic agency. Notably, they engage in this behavior while still framing the activity as confirming a known result. Their (epistemic) agency is disciplined by their (epistemic) framing of the activity.

The students reach a conclusion

The students have excel put in a generic trendline for their data, which spurs the following exchange

92 Holly:	Unfortunately, it's not super horizontal
93 Peter:	Yeah, I mean it, I think actually it is close enough to horizontal because of how small our axis is. Like if I zoom this out, uh, if I go from like 0 to 2, like it's extremely horizontal
94 Holly:	Do we want to like make another copy of this graph, show a zoomed in version versus a zoomed out version?
95 Peter:	We could do something like that.
96 Holly:	And be like, despite what it looks like this line is actually fairly horizontal.

Line 92 is a representative description of how Holly and Peter have been interpreting their data: "Unfortunately, it's not super horizontal." Holly is honest about what their graphical analysis demonstrates and understands it to be a problem. While Peter had previously shared in this interpretation of their data (see line 1), his response in line 93 seems to be a departure: it's close enough to horizontal, it's *actually* not a problem. On its face, Peter's explanation is not based in physical or mechanistic reasoning – that the graph looks horizontal is the evidence.

Still, rescaling plots to gauge the relative size of an effect is a reasonable, if novice, analytic technique. It does not seem to us that Peter means to manipulate their data to hide this problem. In fact, following the exchange above (line 97), he asks Judy directly about her thoughts on this new zoomed out graph, clearly a bid for her participation, and perhaps a bid for consensus. In line 94, Holly signals her agreement by suggesting that they show both graphs. Holly has her own conditions for being satisfied with this explanation and conclusion to their inquiry: intellectual honesty and epistemic accountability.

Part of what makes Peter's invitation for Judy to participate notable is that Judy is largely absent from the later discussions. Judy responds to Peter's question by letting him know that she can't even see the graph that they are referring to. They work it out for her to see the graph, but it is clear (and unsurprising) that Judy not being in the room with Holly and Peter generates different experiences. For example, in line 75, Holly makes another observation about the data Judy starts to respond, but Peter talks at the same time and neither he nor Holly seem to recognize that Judy was cut off. Furthermore, the general tone and pace of conversation between Holly and Peter is notably different than when Judy participates. By the end, despite Peter's invitation to participate, she mostly remains quiet. In essence, we both see how intersubjectivity drives their enactment of (shared) epistemic agency and we see how constraints on that sharedness distort or inhibit epistemic agency.

After Peter shows Judy the zoomed-out graph it appears that Judy agrees with Peter's explanation. Less than a minute later, the TA enters their video call, which changes the activity and ends the episode.

Discussion

Trends in education research and contemporary national curricular standards have shifted toward objectives of students' *doing science*, seeking to "engage students in knowledge construction—to position them as doers of science, rather than receivers of facts" (Miller et. al. 2018, p. 1056). Yet, designing for doing science and effectively supporting students enacting epistemic agency is not simple (e.g., Manz, 2015, Sundstrom et al., 2020 Phillips et al., 2021). As more undergraduate science labs seek to promote disciplinary practices and epistemic agency, it is crucial to examine the dynamics underpinning the emergence of productive behavior.

Holly, Judy, and Peter's encounter with anomalous data – more specifically, the inconsistency between their results and their expectations – leads them to problematize, troubleshoot their apparatus, and produce various plots to analyze their data. They primarily work to build an explanation for their discrepant data and ultimately conclude that the effect they are seeing is insignificant. In this episode, Holly, Judy, and Peter are epistemically agentive: they take their data seriously as a meaningful reflection of the phenomenon they have constructed and, upon encountering unexpected results, enact various (epistemic) actions.

That they position themselves as epistemic agents while simultaneously framing the activity as confirming a known result is surprising. In previous studies examining student framing in instructional labs designed to support student agency (Smith et al., 2018; Smith et al., 2020; Phillips et al., 2021), researchers observed that students framing the activity as confirming known result did not take up epistemic agency. These students focused on producing or aligning their data with what they presumed to be the "correct" answer. As Philips et al. (2021) point out: "if a group of student expects to reproduce known results in the lab, they regard knowledge as something that will be given to them by the instructor or written resources rather than constructed by them" (p. 2). Indeed, as we see in line 9, Peter admits that just looking at their data would indicate amplitude has an effect, but the authoritative claim they have been given by the instructor paints a different picture; much of their intellectual work is driven by their commitment to an external epistemic authority.

Consider also the perspective of Reiser, Novak, and McGill (2017) who state that if students do not have a hand in articulating the overarching question driving their experimental work, then they cannot be "truly engaging in scientific and engineering practices" (p. 4). Once again, Holly, Judy, and Peter's commitment to an external epistemic authority drives their work – they frame the activity as confirming Galileo. Still, their framing shifts in subtle and complex ways throughout this episode. Nested within an overarching confirmation framing, the students engage in troubleshooting and data interpretation. They are not simply going through the motions of science, but agentively engaging in disciplinary practices.

Holly, Judy, and Peter view their data as a genuine problem and work to resolve it. In the beginning, all three participants signal, negotiate, and experience their efforts as productive inquiry. The material resistances they encounter motivate their intentional, disciplinary accommodations (Pickering, 1995). That they frame the activity as confirming a known result is a key reason that they seek out such accommodations. They attend to the production of their data and create, refine, and make sense of concretized conceptual artifacts; throughout, they wrestle with the entanglement of human and material agencies that facilitated the capture of this phenomenon. Through both conceptual and procedural actions, the students show epistemic agency.

We have identified several aspects of this learning environment that affected this agency: supportive social interactions and access to them, values of intellectual honesty and epistemic accountability, material resistances that are clear to the students, the freedom to create knowledge-objects, as well as their framing the activity as confirming a known result. The last may be surprising, as confirmation framing is generally associated with limited epistemic agency (Philips et al., 2021; Smith et al., 2020). Here, as in other cases (e.g., Jeon et al., 2023; Sundstrom et al., in prep), much seems to depend on the particular dynamics of the group. Idiosyncrasy is a general feature of complex dynamics, and it suggests limits on what curriculum and course designs can accomplish in themselves to support students' epistemic agency.

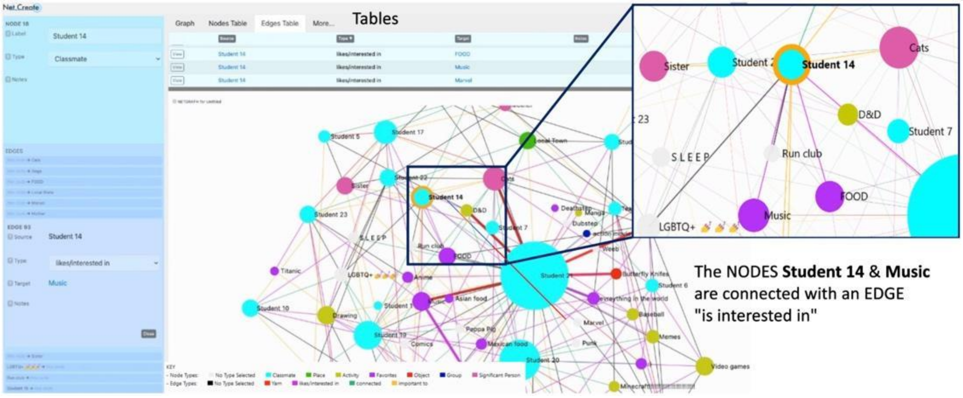
Abstract: This study aims to understand how elementary students can reason about data and data visualization through participation in thematic network visualization activities that integrate locally relevant, personally meaningful data. Young students constantly struggle to focus beyond individual data points to comprehend the overall trend for a complete dataset (Rubin, 2020). This study describes the design of a curriculum unit that incorporates a series of network visualization activities as building blocks to develop students' reasoning skills on aggregate patterns of the entire dataset. Our analysis draws on Cultural Historical Activity Theory (Engeström, 1999) to identify mediators within four network visualization activities and explicate how they transformed students' progressive understanding of the aggregate dataset they were exploring to make inferences.

Introduction

In an era of data deluge, the general public has more access to a massive amount of data and more opportunities to engage in data reasoning activities than ever before. Therefore, learning scientists have intensified efforts to prepare students for working with this kind of data in personally meaningful contexts (Rubin, 2020) and advocated for further strengthening young students' data reasoning abilities to support future learning (Jiang et al., 2022).

Fundamental data literacy activities include data collection, management, analysis, and interpretation using data visualization tools (Rubin, 2020). The expert's viewpoint on data exhibits a fluid and flexible switching between local and global observations (Ben-Zvi & Arcavi, 2001). Local data observation refers to a focus on individual data points, whereas global observations include summarizing the overall pattern of the entire dataset and making inferences from the patterns. This global observation serves as the foundation for the identification of broad patterns within the data. For example, to recognize specific data points as outliers, it is necessary to consider how they relate to other data values from a distributed perspective. However, young students frequently struggle to move beyond individual data points and find it difficult to reason about the overall dataset patterns, leading this to be a perennial barrier in data literacy education efforts (Rubin, 2020).

Figure 1
Students' identity network in Net.Create (left) with an expanded view of sample nodes (right)



The NODES **Student 14** & **Music** are connected with an EDGE "is interested in"

Visualization tools can be vital to support students' reasoning with data; for example, CODAP (Hardy et al., 2020) and TinkerPlots (Rubin & Morkros, 2018) support learners in viewing different data graphs and answering relevant data questions. The present study utilizes Net.Create (Craig et al., 2021), an open-source network visualization tool that enables multiple users to intuitively co-construct and co-revise network datasets. It has previously been successfully implemented in undergraduate-level humanities classrooms to engage students in sensemaking about historical figures, events, and their relationships with each other (Craig et al., 2021). Net.Create allows students to work on a collective network simultaneously by creating nodes of various types and linking each node via different kinds of edges. A node is a circle typically representing a person, place, thing, or event. Figure 1 depicts one Net.Create network used in the present study, illustrating students’ collective identity in the form of interests, experiences, and connections to each other. The nodes represent individual students, hobbies, or locations, and the edges (lines between them) represent relationships such as “likes/interested in.” Net.Create, like other network visualizations, can automatically adjust the size and positions of each node and edge based on how many connections a node has to other nodes. Node size is determined by the number of connections to other nodes, a value often labeled as degree centrality. By visualizing this as the size of the node, network visualizations show the relative importance of the influence of the individual nodes in the network. Users can further explore the influence of a node by manipulating the network physically, as larger nodes have more “gravity” and thus pull smaller nodes along. An edge’s thickness also communicates the number of connections between two specific nodes and may therefore indicate the impact of these relationships. In addition to the network representation, Net.Create includes other interconnected data displays (e.g., tables) to support students’ data reasoning across those displays (see Figure 1, top middle). Although the affordances of visualization tools support data exploration and interpretation, students need an entry point to engage productively with visualizations (Roberts & Lyons, 2020). Therefore, we designed a series of network visualization activities to mediate students’ data reasoning and interpretation as part of the present study. The present paper includes an analysis of this sequence to better understand how learners engage with the range of tasks and networks. We specifically aim to answer: how do different ways of mediating students’ exploration of network visualizations affect their reasoning about network datasets?

Theoretical framework

Our work is grounded in Cultural Historical Activity Theory, or CHAT (Engeström, 1999), and particularly takes up the notion of mediation to examine how different network activities transform students’ emergent understanding. Mediation (Vygotsky, 1978) is the idea that activities, including learning, are transformed by other elements of the social and cultural environment (Danish, 2014). These elements or mediators include tools, community, rules, and the division of labor that shape learners’ activity as they pursue a shared goal, often referred to as the object of activity (Engeström, 1999). The present study examines four network activities (Table 1) with objects ranging from creating/modifying networks to making inferences from pre-built networks. In each activity, our analysis focuses on how individual students (subjects) participate in the creation, modification, or analysis of network visualizations (tools) in different group settings (a division of labor). Their participation is also regulated by the classroom *norms and rules* of each activity.

Design

This study is housed within a larger project called Visualizing Funds of Identity (VFOI), which intends to leverage network visualization tools to help students understand more about themselves and their community as well as to hone their fundamental data literacy skills (Stiso et al., 2023). The entire curriculum spanned six forty-minute class sessions designed to engage students in a cycle of creating, modifying, and exploring network visualizations of different topics. Those topics were co-designed with one classroom teacher and utilized class-based projects and a board game format in order to display network values in locally and personally meaningful ways. The present study focuses on the ways that two physical networks and three digital networks mediated elementary students’ progressive data literacy skills. See Table 1 for a summary of the four network activities.

Table 1
A Summary of the four network activities

Topic	Format	Summary
Collective identity	Yarn network	Icebreaker to explore how a network represents people and relationships
Collective identity	Net.Create	Use Net.Create to learn basic network terms, how to create a network, and the value of network visualization compared to the yarn network
Chicken industry	Net.Create	Explore the meaning of sizes (node & edge) in a network visualization for a real-world context
Social media marketing	Net.Create and board game	Apply meanings of sizes and types of nodes and edges to a real-world context

Data sources and analysis

Twenty-three fifth and sixth-grade students from the Midwestern United States participated in this study, and seventeen of them completed both the pre-and post-tests. This analysis examined what students learned from their performance on the pre/post-test and their in-situ understanding that emerged through classroom activity mediation. The pre/post-test contains seventeen open-ended questions aimed at evaluating students' grasp of a range of practices of network visualization and data literacy. The authors iteratively developed and refined qualitative characterizations of students' understanding of the key concepts explored in their answers during the pre/posttests with a focus on data literacy concepts that were used to identify patterns in students' understanding. The classroom video data analysis began with reviewing and content logging students' recaps and debriefs of each activity across the six days of implementation. The present analysis focuses on four network activities, selected to provide a rich contrast regarding how the different modalities support a wide range of network utilization and, thus, aim to represent the potential of these kinds of activities rather than every single moment from the present study. Finally, all authors performed Interaction Analysis (Jordan & Henderson, 1995) to determine how students' understanding arises across those network activities and mediators that supported their emergent understanding through iterations of collaborative data sessions.

Findings

Pre/post tests

Analysis of these tests shows that students improved their understanding of what a network is, particularly how networks are made up of nodes and edges and their ability to interpret network visualization as a means of making sense of the underlying data represented within it. Findings also indicate that students began to recognize the practical uses of networks in real-world contexts. Students' explanations about networks shifted from vague references to a network as "a thing on the internet" to more robust technical definitions such as "a network is usually something online that shows how people might be connected to certain things." Students' interpretations of the network moved from initially describing details depicted in individual nodes (e.g., video games, Minecraft) to indicating a rich appreciation of the relationships between multiple nodes within the network. For example, ten students indicated their awareness of connections within the network in the post-test, while one student did in the pre-test. In addition, nine students appreciated the utility of networks as a way "to get to know each other better/ people's like and dislike." While not all students completed the post-test worksheet due to the number of questions, we view these results as quite promising, especially given how the network activities also helped students to explore key ideas of interest to the classroom and teachers, such as how the chicken farming industry works (see below).

Three cases

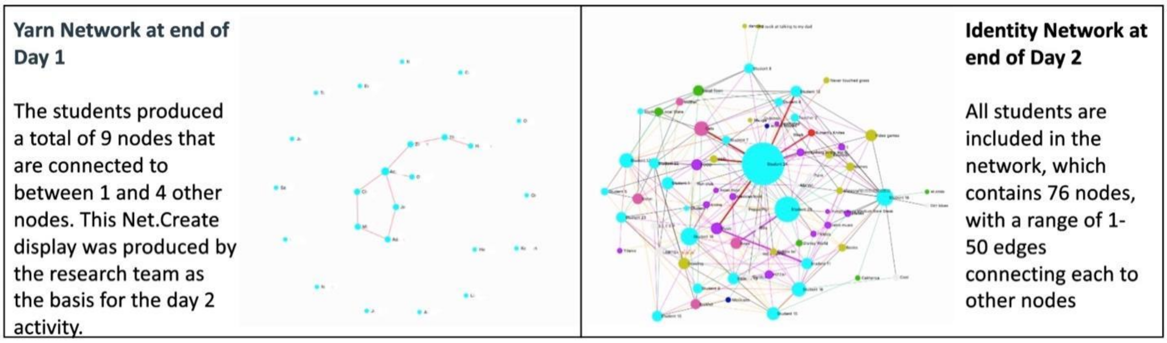
The three cases below were chosen from the four network visualization activities in which students participated in the exploration, comprehension, and utilization of network datasets. Select deidentified example networks can be seen at: http://theraptlab.org/projects/netcreate_examples. For each activity, we iteratively reviewed the classroom video data, discussing as a team what we felt was the most salient mediator within each episode. We then conducted Interaction Analysis (Jordan & Henderson, 1995) to explore how the salient mediators appeared to influence the students' activity. Case one depicts two network activities from the first two days of the intervention in which students first built a physical yarn network of their interests and then expanded that network within the Net.Create software. Here, we examined how the community and network tools in the activity functioned to enhance students' awareness of their connections. In case two, students' prior knowledge and the teacher's facilitation mediated their exploration of a pre-made network visualization of how the chicken farming industry works, a topic chosen to complement a semester-long cross-curriculum project the teachers had previously planned, which will involve the students in researching various locally relevant farming industries. Case three depicts an activity from day 5 where students' explorations of how marketing may work in social media websites were mediated by their emergent understanding of networks, the activity rules, and the facilitators.

Case1: Starting to explore the classroom as a network

Students constructed a physical yarn network as the opening activity of the implementation. In this activity, each student acted as a node (representing themselves) and was connected to peers who had overlapping interests or experiences using yarn (tool) that was strung between them on the floor. To create the network, we developed eight questions (tools) based on the Funds of Identity literature (Esteban-Guitart & Moll, 2014) to prompt students to share their own experiences and stories (rule). Sample questions included "name a place that is important to you?" and "what is an activity or hobby you enjoy?" Initially, none of the students were connected. The first student then selected a question from the list and shared an answer as well as an elaboration (rule). Next, any peers who felt they had a similar experience would raise their hand (a division of labor), and the first student would pick one to "connect" to, passing them the ball of yarn. This next student often explained their connection to the student who passed them the yarn, they would then select a new question, and the process continued.

Figure 2

Students' yarn activity on day 1 (Left). A complete identity network (Right)



Yarn Network at end of Day 1

The students produced a total of 9 nodes that are connected to between 1 and 4 other nodes. This Net.Create display was produced by the research team as the basis for the day 2 activity.

Identity Network at end of Day 2

All students are included in the network, which contains 76 nodes, with a range of 1-50 edges connecting each to other nodes

This yarn activity led students to tell elaborated stories about themselves and their families, many of which were previously unknown to the teachers and the class. We see this in class debriefs in which many of them indicated that they had learned something new about one another. For example, one student shared that her mother was from Ireland, which surprised the teacher, who exclaimed, "I cannot wait to hear the story." The teacher (community) asked follow-up questions which served to mediate the students' description, leading them to share an anecdote about how the mother's Irish accent perplexed family members. In addition to prompting students' story sharing, we observed that teachers (community) rephrased key details in the stories in a more general way or identified other stories to help mediate the process of students identifying connections. For example, in this instance, the teacher shifted the initial focus from the mother's Irish family roots, which did not lead to anyone claiming a connection, to the student's father, who is from San Francisco, and asked if anyone connected to California, which inspired many students to speak aloud about their connections in various ways. While creating a physical yarn network allowed students to get to know one another better, they also complained that many of them were unable to connect due to the time constraints and the activity rules that only one new student receives the yarn after each prompt.

To help students see further connections amongst themselves and appreciate the value of computerized network visualizations over physical constructions, one researcher created a digital replica of the yarn network using Net.Create to model students as individual nodes that were connected to other nodes of classmates, significant people, and objects through edges of three categories (like/interested in, connected, important to) (Figure 2 Left). This digital yarn network was used as a starting point for the day 2 activity, in which students worked in pairs (the division of labor) to add more content to the network. Each dyad created new nodes and edges that they felt described their individual interests. While they were asked to enter their individual interests, they worked in pairs so that they could discuss the process, and our intention was that the completed network (Figure 2 Right) represents the class as a whole (rule & division of labor).

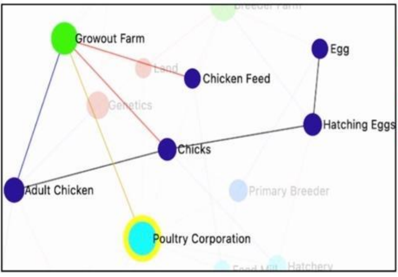
Students' comments during the post-activity debrief indicated they had begun to pay attention to the content of the nodes rather than just stating that they knew more about each other. Upon being asked, "What did you learn about your classmates?", many students looked back at the network before responding. They then responded with content that was in the nodes, such as cats (Figure 1 Right), the name of the town, and the state where they lived. The fact that students oriented towards the network visualization and then focused on the specific nodes and edges indicates that they were relying upon the visualization to mediate their response in ways that the yarn network could not, potentially supporting early appreciation for the power of network visualization tools.

Case 2: Understanding the importance of degrees (edge counts)

The activity for day 4 features a pre-built network modeling vertical integration in the poultry industry that was integrated as a part of a teacher-designed project that involved students designing and managing a fictional farm. The teachers had developed this cross-curricular activity because the school is located in a small suburban community adjacent to many rural farm areas, with an active locally sourced food community. Students worked in pairs (the division of labor) and were asked to vote for the top three nodes in the pre-built network that they felt were most crucial for operating a successful chicken farm (rules). There is no "correct" answer to this question, but it was intended to motivate learners to make sense of the network in order to vote. Information contained in the network visualization, including the characterized categorization (indicated by different colors), different numbers of edges, and nodes' sizes, was intended to mediate students' noticing and interpretation.

Figure 3
Left: A subset of the nodes that students attended to. Right: A re-creation of the information in the table view, which showed students' votes juxtaposed with the degrees of centrality (connections).

Left is a subset of the nodes, highlighting the ones students discussed.



Node	Degrees	Votes
Poultry Corp.	11	2
Breeder Farm	8	3
Growout Farm	8	2
Genetics	6	1
Chicks	4	4
Adult Chicken	5	4
Chicken Feed	3	4

Right is a table indicating connections and votes that students had (re-sorted by votes).

Students initially voted for chicken feed (degree=3; vote=4) and chicks (degree=4, vote=4) as the top two important elements in the network. Students' explanations indicated that their awareness of individual node's content and out-of-school knowledge/experiences mediated their interpretations rather than network features, "I voted for chicks because they are cute, and they are chickens. You need to have chickens to have chicken farms" and "you can feed chicken pretty much anything, … like you can feed chicken chickens." However, when asked whether connections of the network influenced their voting, one student mentioned the importance of connections, "I feel like if the circle node has more connections, then you can tell it is very important." They explained the importance of these connections by stating that "all of (the) things connected to [the node], probably make it happen." This suggests that they recognized the value of degrees of centrality but were not yet aware of how to articulate these ideas. Researchers also asked the two students who voted for the most connected node, poultry corporation (degree=11), why they had selected it. Unfortunately, the students were not able to articulate a reason for this choice.

The next round of exploration prompted students explicitly to consider if the number and types of connections revealed something crucial to a successful farm operation, "let's take two mins to go back to the network and explore this. Tinker with what has a lot of connections and not a lot, and see if you think it matters. … So, you look at and see, do the number of connections or types of connections help you understand." During the discussion, H claimed that the network did not visualize the statement "everything comes from the egg." However, when asked how to redesign the network to emphasize the connection, her response indicated the connection string of egg-hatching egg-chicks (tool, Figure 3 left) may be valuable to her recognizing the developmental process starts from eggs, "eggs went to hatching eggs which went to chicks, so I thought, which went to, so, which was very important, so I was thinking about now, egg is where the chicken is born from." We read H's responses as showing that network connections made some relationships more salient to them, although they may still struggle to articulate the significance of connections in the network fully.

Figure 4
Each node's brief introduction

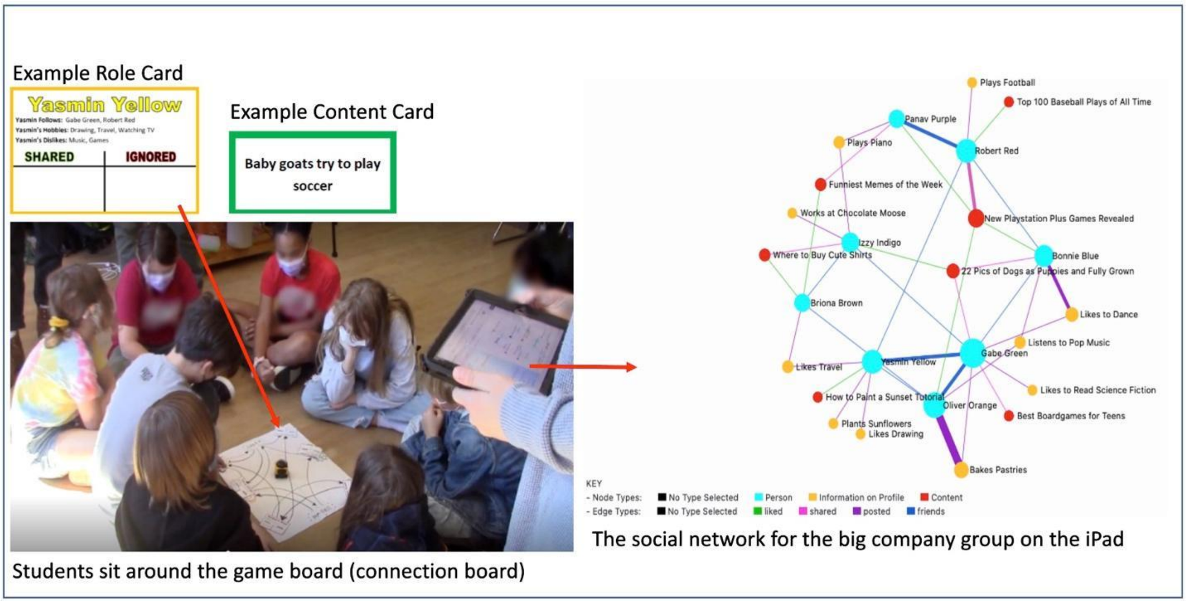
	Degrees ▲	Label	Type	Votes	Notes
View	11	Poultry Corporation	Corporate Owned Facility	2	Major poultry corporations (like Tyson)
View	8	Breeder Farm	Contracted Facility	3	Hatches eggs and sorts the chicks
View	8	Growout Farm	Contracted Facility	2	Takes chicks and raises them to adulthood
View	6	Genetics	Issue	1	Modern chickens have many specialized genetic traits that make them much better as livestock. However, some of these have unintended side effects for the chicken's health.
View	6	Transportation Company	Corporate Affiliate	0	Ships products between different facilities
View	5	Adult Chicken	Product	4	Broiler chickens (special chickens bred to make meat) reach adult weight in just 6 weeks,

Students' tendency to focus on familiar individual data points is also evident in their small group conversations. In one group, despite the teacher's efforts to re-mediate students' attention toward nodes' connection numbers by navigating students in that group to identify nodes with the most and the second most connections, they remained focused on a node, adult chicken, "yes, but me and M voted adult chicken three times because you need adult chicken to get chicks.” In the whole-class discussion, we observed the teacher’s continued mediation of orienting students’ attention to the nodes’ connection numbers by rationalizing their votes, “when we see what the second most important thing, we found this growout farm. and this connected directly to you H because this growout farm takes chicks and raises them to adulthood.” The teacher’s explanation of the growout farm was based on a brief introduction (Figure 4) of that node that we incorporated into the Net.Create design (tool). Thus, the interface further mediated the teachers’ and students’ exploration of the chicken industry. The teacher also aimed (a division of labor) to help re-orient the students’ attention toward the number of connections and node details as the students explored the network. While not all of the students shifted their activity, they did all have the opportunity to participate in the resulting whole-class discussions that built on these interactions, giving them a chance to notice the same connections their peers did, which may have helped in later activities.

Case 3: Make inferences based on a combination of connections numbers and edges types

Case 3 involves students playing a board game designed by the research team in which they were divided into two groups (a division of labor), with one representing big companies (e.g., TikTok) and another representing fictional social media users. A Net.Create social network (tool) was made available to the big company group allowing them to gain information about the social media users’ profiles, the content they shared/liked, and people whom they are friends with (Figure 5). Students in this group were given a series of content cards that represented social media memes (e.g., sports videos, or cute puppy videos) and were tasked with leveraging network information to identify the best user who would see a content card first and then disseminate the content through the network to more users (a division of labor). For example, students might give the “cat video” card to a user whose media personality indicates loving cats. The media users group has a connection board (a tool) (Figure 5) with information about who follows whom on social media so as to determine how to distribute the content card once they receive it (a division of labor). In addition, each user receives a role card (a tool, Figure 5) summarizing their likes and dislikes as a reference to choose whether or not to share the content card chosen by the big company group (rule). As part of this activity *rule*, the social network visualizes users’ partial interests. Therefore, to develop an effective marketing tactic of distributing a content card to a bigger audience (object), it becomes essential for the big company group to use the social network to infer influencers and their interests.

Figure 5
Social media marketing context



Example Role Card

Yasmin Yellow
Yasmin Follows: Gabe Green, Robert Red
Yasmin's Hobbies: Drawing, Travel, Watching TV
Yasmin's Dislikes: Music, Games

SHARED	IGNORED

Example Content Card

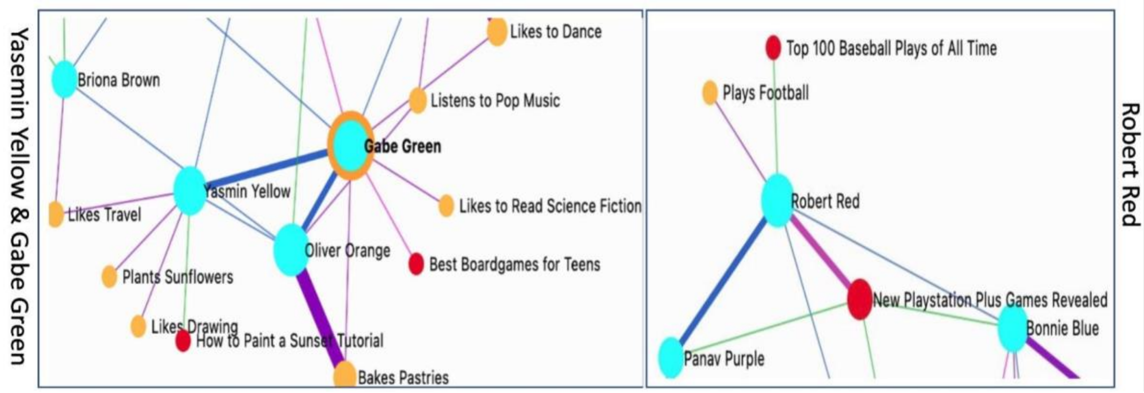
Baby goats try to play soccer

Students sit around the game board (connection board)

The social network for the big company group on the iPad

The initial conversation on marketing strategy demonstrated that students’ network visualization reasoning is mediated by their emergent understanding of how networks work. O shared her marketing strategy of passing a content card to those with the most connections, and her game-playing aligns with the strategy. Her first marketing attempt was to choose Gabe Green (Figure 6 Left), who has the greatest connections (degree=11), to receive the content card “Best Sports Bloopers of the Week." However, this content card was ignored because of Green’s distaste for sports. O’s second trial chose Yasmin Yellow (Figure 6 Left), who has the third-highest number of connections (degree = 8); however, the chosen content card concerning music (Playlist: Music to paint to!) is what Yasmin Yellow finds objectionable. Thus, neither content card spread to the second player since the card content did not match the person's interests and was disregarded. Here, we interpret O's strategy as mediated by the idea of using the connection number of a node to assess its significance, which may be learned from the chicken industry network; however, this strategy failed to completely utilize the social network as a mediational means to make inferences, as O only attends to connection numbers of nodes and ignores edge types and connected nodes. This was a great opportunity to help students re-orient toward the specific node and edge content.

Figure 6
Yasemin Yellow & Gabe Green (Left) Robert Red (Right) connections



The next player was H, whose marketing strategy was more successful as the content card she chose spread to many of the other peers. In the final discussion, O summed up H's marketing strategy as choosing the first person "based on what was being liked, instead of giving it (content card) to somebody randomly." Here, how H played the game (a division of labor) functions as a mediational means for O to identify the best marketing strategy. We reviewed H's gameplay to see if this was indeed her strategy. H role-played the big company and picked a content card of "Highlights of local sports games." She talked out loud about the card content to the teacher (community) who participated in this group as a social media user. Then, the teacher (community) began to look at the role cards of the users sitting next to him to determine who likes/dislikes sports. However, this violates the game *rule*, in which the company group is supposed to rely only on the social network. A researcher halted this infraction by reminding them of the rule, which prompted H to turn to the social network on the iPad. While zooming in on the social network, H murmured, "Who likes, ok, Robert really likes Sports." She continued to zoom in and out of the social network silently before finally handing Robert Red the content card. It was unclear what other factors H was considering before choosing Robert Red; however, H's marketing strategy turned out very effective. This is because Robert Red is the third most connected node (degree = 8) and enjoys sports, as indicated by his sharing of sports content (Figure 6 Right). Although we do not have a full picture of H's reasoning, her pick of Robert Red and the accompanying murmuring indicate her attention to what was being connected to the Red's node (e.g., interests). H's successful marketing plan of identifying the right person to promote a content card matching the person's interest is mediated by the teacher's guidance in getting her to find whose interests match the content card within the network visualization (tool). Thus, it appears that H's successful marketing strategy mediated O to notice the importance of what and how nodes are connected in addition to the connection numbers (a division of labor).

Discussion

This study demonstrated that elementary students are able to use network visualizations productively to make sense of a wide range of topics related to both their classroom pursuits and data literacy. We reported how different mediators present across the three activities supported students' data reasoning in the network visualization. Case one explicates different mediations of the physical network and the virtual network in supporting students' exploration and comprehension of connections. Case two showed explicit conversations about connections and Net.Create's built-in features mediated a discussion of a more interconnected view. Case three illustrates that students' understanding built on their emerging understanding of networks and different roles-taking attuned them to connection numbers and information flows in the network. Attending to students' participation in four network visualization activities provides insights for activity designers and classroom teachers into how mediation in activities and discussion was necessary to support students in exploring network visualizations as aggregate representations as opposed to focusing solely on specific nodes they are familiar with. While not all students appeared to display a nuanced articulation of network visualizations, many developed an appreciation for the affordances of network visualizations for exploring patterns in data. Like with other data representations and previous research (e.g., Ben-Zvi & Arcavi, 2001), familiarity with individual ideas continued to distract some students from aggregate patterns, but we view the results as promising given that many students did begin to exhibit emergent attention to those aggregate patterns. In addition to developing students' data literacy skills, this project highlighted the potential of network visualizations as a vehicle for leveraging locally relevant content (e.g., students' interests and the classroom focus on the poultry industry) and incorporating physical activities (e.g., yarn activity and board game) to help students make some of the relationship relevant to them. In the future, we will further explore how we can re-mediate learners' activities to help even more students attend to these network features and explore how network visualizations might support other dimensions of data literacy.

Supporting the Appropriation of Historical Practices in a Game-Based Undergraduate History Classroom

Zach Ryan, Christina Stiso, Joshua Danish, Eric Robinson

Abstract: This study took a cultural-historical activity theoretical lens to a game-based history learning environment. Situated in an undergraduate history course titled *Greek History through Games*, students participated in a semester-long bespoke strategy-board game known as *Cities on the Edge of War*. This study examined how designed elements of the game and course mediated students in appropriating five historical practices, which are difficult to teach in lecture-style courses and noted as important learning goals by the professor of the course and Author 4 of this paper. Alongside designed elements, we considered historical practices to be key mediators of students' interactions. We analyze where in interaction these historical practices emerged and unpack the most common mediators within the learning environment that co-occurred alongside these historical practices.

Introduction

A persistent challenge in teaching history is imparting the practices that historians use to overcome and account for these biases of the present (Wineberg, 2001). Historians understand that the people of the past had their own culture, histories, and values that influenced their actions and decisions. One way to address this challenge is to design active learning environments to support students in engaging in these historical practices, such as *game-based learning* (GBL) environments. The present study looked at an undergraduate history GBL course designed by authors 3 and 4 titled *Greek History through Games*. Through a combination of strategy-board game elements and role playing, students in an upper-level history course took on the social and political realities of historical actors in a game called *Cities on the Edge of War* to foster historical practices that are a necessary component in the study of history (van Hover & Yeager, 2004; Craig, 2017).

This work is grounded in *cultural historical activity theory* (CHAT; Engestrom, 1999) which centers the importance of context (i.e., the places, languages, tools, cultures, and histories) in learning. Within this epistemology, learning is defined as *an appropriation of mediators which supports a shift in one's participation to be in line with the community they are interacting with*. Specifically, how appropriating designed mediators of the GBL environment alongside historical practices transforms students' participation aligned with how historians interact and interpret the past. Toward this end, we ask the question: *Within a history based GBL environment, what mediators support students' appropriation of historical practices?*

Literature review

Learning through a game-based history classroom

At the undergraduate level, lectures are typically how students are presented with historical content. While lectures are useful at conveying a large swath of information to many students, they tend to fall short at fostering the types of skills which are valued in a given field (Bransford et al., 2000). To foster these kinds of historical practices in students, more active learning designs for classrooms, such as the GBL context of this study, provide ways to deeply engage students in taking up these kinds of practices through creative activities (Birdwell & Uttamchandani, 2019). In this study, we focus on analyzing where students take up the historical practices of *perspective-taking*, *evidence use*, *reflection*, *argument construction*, and *articulations of context* in interaction. These were practices that the professor of the course noted they had trouble fostering in their students in their typical lecture-style classes, and the GBL environment was a way for students to better engage in them.

We define a game and gameplay as a form of playful activity focused on winning as an end condition for activity with a set of well-structured rules (DeLiema et al., 2019). GBL environments typically take the form of a set of activities within a curriculum unit, designed with the intention of engaging students in cycles of inquiry around a gamified problem, where a particular problem is framed as an activity that needs to be solved, with a set of rules and conditions to win guiding participation (Fields & Kafai, 2018). For example, the Reacting to the Past game setting allows for students to play alongside others and engage with the social and political conditions of a certain period (Hagood et al., 2018). In Cities on the Edge of War, this type of roleplay was a core mechanic which allowed for students to think at various levels of the factions they were a part of, as they might be simultaneously working with and against each other depending on their unique characteristics.

The design of a semester-long game-based course was intended for students to continuously engage with various historical perspectives over a long stretch of time, creating opportunities for reflection and articulations of the actions and decisions they made as a historical actor (Stiso et al., 2020; Ryan et al., 2021). This was grounded in the idea that extended engagement with the complexities of the historical context might create opportunities for students to reflect on and better appreciate the situated tensions felt by historical actors of the period. At its core, our design was intended to structure a system of activity which mediated students' engagement with historical practices which are necessary for historians to develop.

Mediating learning through the appropriation of historical practices

Activity as a unit of analysis through a CHAT lens allows for an in depth look at students' interactions within the course with attention paid to what in the environment is mediating students' fostering of historical practices. *Practices* in this context refer to the patterned forms of participation within activity that evoke shared assumptions, rules, and values that mediate interactions of a group participating in the game (Danish & Phelps, 2011). This goes beyond simply "doing" in a context, but doing in specific historical and cultural ways that are relevant to a specific context.

For example, historians assert that to effectively learn about the past, certain practices are needed such as articulating context, reflection, argument construction, and perspective-taking (Craig, 2017; Monte-Sano, 2011; Shopkow et al. 2012). These practices are more than simply recollecting names and dates, but rather allow for students of history to "go beyond the written word and examine the intention, motive, plan, and purpose" of historical actors (van Hover & Yeager, 2004, p.9). For instance, historical *perspective-taking* is the action of taking on the situated perspective of historical actors during a given socio-political period in history (Wineberg, 2001), and is considered to be a key historical practice as a way to combat what Wineberg (2001) calls presentist thinking by preventing historians from slipping into misconceptions of the past by viewing it through a contemporary lens, inserting values and beliefs which are situated in our world into a completely novel context where they do not readily transfer into. Through a CHAT lens, these practices are key mediators which help to orient students' participation towards their activity goals in ways that align with how historians interpret the past.

Students' appropriation of historical practices involved taking them up within in-game interactions, which created opportunities for transforming students' participation in activity in specific ways which align with how historians' appropriate discourse, tools, and actions which mediate their studying history. Grounding both the design of the course as well as the present study in CHAT allowed us to think explicitly about how our GBL activities shaped learners' abilities to interpret the past in line with how historians do. Here, a practice such as perspective-taking can be thought of as a tool which is shaped by the goals of the game as well as mediators such as course readings that helped students to take on a historically situated perspective (Stiso et al., 2020). The present study unpacks the most common co-occurring designed mediators which supported the appropriation of these practices, which in turn became key mediators within interaction to transform how students oriented themselves in interpreting history.

Design

Within the course *Greek History through Games,* students played the bespoke board game *Cities on the Edge of War*, originally designed by the 3rd and 4th authors of this paper, and later revised by the entire team (Ryan et al., 2021). Set prior to the Peloponnesian War in ancient Greece, students took on the roles of leaders of various Greek City- States (e.g., Sparta, Athens, and Argos), and navigated the material, social, and political conditions of the war-time period in their City-State teams. At the start of each game, students were given a character to roleplay, either a named character in history (e.g., Lysander of Sparta) or an unnamed archetype leader (e.g., oligarchic leader of Corinth). Students were given a character sheet with information regarding their characters and explicit goals that they should prioritize as they played the game. Roleplaying as these characters provided students to think about their game decisions on multiple levels, as they had competing goals and tensions to consider. For example, students certainly needed to work as a team for their City-State to prosper, but students also had individual goals that might make them work to defeat a political rival within their own City-State to usurp power for themselves (e.g., Lysander of Sparta seeks an elevated position in Sparta, and should aim to overthrow the kings if they are able).

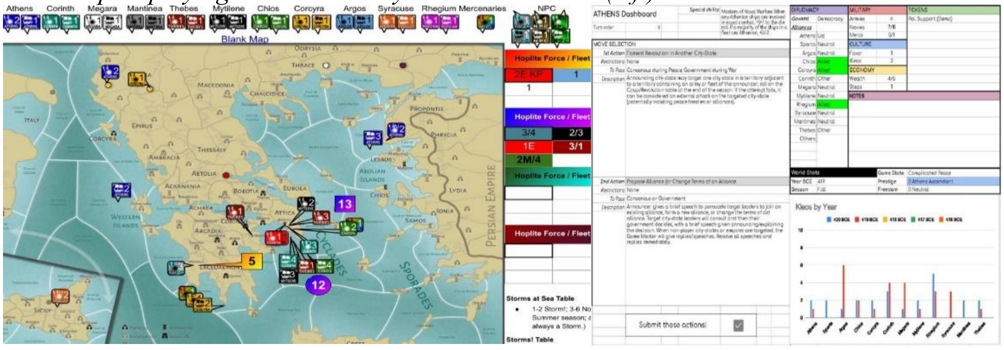
The design of Cities on the Edge of War centered most of the synchronous class time on students playing the game as a whole class, with 2 hours of the 2.5-hour block dedicated to playing the game. There were 12 City-State teams, with Athens and Sparta both having 5 student players, and the other City-States having 2 players. The game was broken into three phases consisting of planning, diplomacy, and action phases. Planning phases consisted of private breakout sessions in Zoom where teams planned their actions and moves. Diplomacy sessions were designated planning sessions where teams could talk and plan actions with their allies, or negotiate with enemies without conflict (i.e. in-game war and battling army units via strategy board-game). Action phases were the main turn-taking portion of the game where various actions were taken by teams in a single season of the game (e.g., late summer or spring). The available actions were pre-specified by game cards and included things such as moving a military force, seeking the favor of the Gods, or dispatching a secret envoy.

While students had the freedom to carry out special actions that were not listed on the available action cards, the game cards were meant to structure accurate historical choices and conditions of the time, such as realistic distance a large army would be able to move in a single season, or leaders of the Greek world seeking favor from their patron God of their pantheon for in-game bonuses. The bespoke nature of *Cities on the Edge of War* meant that we could link explicit game elements to the core learning objectives set out in an undergraduate history course.

Along with the action cards students could select from, we also incorporated several other strategy board game features to help structure students' choices. This included a virtual game map tracking all City-State teams military units and colonies and dashboards tracking their in-game stats (see Figure 1), including Kleos, which is Greek for "glory" or "renown" and served to keep track of various cultural achievements made by City-States (e.g., Megara makes a grand philosophical discovery). Kleos and favor from the Gods gained City-State teams in-game bonuses which could help them to compete with the other teams along military, cultural, and economic dimensions.

Figure 1

Game map displaying various military units and colonies(left) and Athen's Virtual Dashboard (right)



Cities on the Edge of War was designed explicitly as a sustained GBL environment to allow for students to continuously engage with various historical practices and decision-making over the course of a semester-long course. The game elements described above all had distinct design purposes that were meant to support different aspects of students' engagement in the historical period. Like the current study, the design of *Cities on the Edge of War* was also theoretically grounded at the crossroads of GBL (Fields & Kafai, 2018) and activity theory (Engestrom, 1999). We were particularly interested in how these game elements could support learners' pursuit of in-game goals, and we had certain design conjectures for game elements that we thought would help to support students' learning and ensure that their in-game decisions were grounded in relative historical accuracy of diplomacy and warfare of the ancient period.

Methods

Data sources

This study took place during the spring 2021 semester in an undergraduate history course at a large university in the midwestern United States. As a result of the covid-19 pandemic, the course was held virtually over Zoom. There were 27 students enrolled in the course. Data consisted of Zoom video recordings of two City-State teams', Sparta and Argos, planning and diplomacy sessions to analyze interactions. Note that the team membership changed between the first and second game session, so this represents 4 different total groups of students. Each session consisted of between 25-40 minutes of interaction data, with approximately 750 minutes of total analyzed video data. These teams were identified as potential cases because they were filmed across both game sessions, whereas other teams were only filmed for one of the two games. These two teams were selected for the focal analysis because they represent both the small (Argos) and large (Sparta) team dynamics present within the game, leading to unique forms of interaction within each team. Even though the team membership changed between games, following the same City-State allowed us to see how different students pursued similar goals across the two games, and analyze 14 of the 27 students.

Data analysis

Analysis began with students' final exams, confirming that historical practices were present at the end of the course. A brief interview with the professor verified how similar style final exam scoes differed from past lecture-based courses they taught on the same topic. Knowing that these historical practices were present within students' final summative assessments, the goal of the analysis was to identify where these practices emerged in interaction and how the mediators present within the game-based activity system supported the appropriation of these practices. After selecting the focal City-State teams, reviewed the video data in two passes where we content logged and coded for historical practices, followed by a pass of interaction analysis (IA; Jordan & Henderson, 1995).

The first pass we content logged events and noted when player talk shifted from one topic to another. These consisted of either planning, conflict, or negotiation, with conflict and negotiation being either internal within the City-State or *external* between multiple City-State teams. Within each logged interaction, we then open coded for any of the five historical practices noted as learning goals by the professor of the course: a) *argument construction,* b) *articulations of context,* c) *reflection,* d) *perspective-taking,* and e) *evidence use* that emerged within interaction was marked as well. *Evidence use* was split into three distinct forms of referencing prior knowledge, prior gameplay, or primary sources read in the course.

The second pass of the video data we used IA on specific episodes of video of the teams' planning and diplomacy sessions. To select episodes, we looked for co-occurrences of historical practices and mediators that were present in the interactions. These mediators consisted of aspects of a system of activity and included the *subjects*, *objects* (i.e., goal pursuit), *tools, rules, community,* and *divisions of labor* (Engestrom, 1999). Here, goal pursuit was broken down into three forms that were structured into player's character sheets within the game which included *City- State, Greek world,* or *individual-based* goals being pursued. Episodes were selected to serve as exemplars of trends where multiple historical practices and interactional mediators tended to co-occur alongside each other.

Results

The professor stated at the end of the course that the final exams were "collectively impressive". Over half of students writing in the exams were "remarkably good", with overall student performance being "notably better than my students generally manage on finals". Students' performances on their final exams demonstrated not only an understanding of the course content, but that a grasp on the historical practices laid out as learning goals by the professor and designers of the course supported the learning outcomes present within the final exams (see Table 1). We chose to omit the practice of *argument construction* from analysis of these final exams, as the prompts for the exam explicitly asked for students to produce a historical argument. This meant that it would be present in all the exams that received a passing grade, as opposed to the practice naturally emerging in students' interactions.

Table 1
Historical practices and frequencies in students' final exams.

Historical Practice	Example	Distributions Across Finals
Articulating Context: Unpacking the social, political, and/or details surrounding a historical context or event.	*"While most city states depended on the yields of their own lands to support them, by maintaining access to the sea Athens could now utilize the massive fortune they had accrued via tribute from their Delian league members to keep the inflated population of Athens fed for the foreseeable future."*	**188**
Evidence Use – Gameplay Events*: Direct reference to events that occurred in gameplay.	*"For example, in the second game round, a round wherein fairly little warring occurred for the majority of the time, Sparta had the goal of dismantling the Argive alliance."*	**68**
Evidence Use – Primary Source: Direct reference to a primary source using a formatted citation.	*"In Sparta, this issue also arose, despite the Spartan virtue of caution, as King Archidamnus struggled to contain Spartan calls for war against Athens, calling for caution and vigilance even as troops departed (Thuc. 2.11)"*	**182**
Perspective-taking*: The action of taking on the situated perspective of historical actors during a given socio-political period.	*"In Athens, the pretenses with which they propelled their empire were recognized by even themselves, admitting that the only true justification for their conquests was the desire for power over Greece."*	**51**

Reflection*: Deliberately thinking about a specific action or event outside of when it occurs.	*"In our historically based game, justifications for war and conquest were rarely so eloquent, or based on honor or spirituality; more often, they were contingent on who threw the first stone."*	**76**

(*= Only emerged on certain questions on the final exam)

One important note is that the final exam was structured so that students had a choice of 2 questions from a 6-question bank. Not all these questions were directly asked about their gameplay, which might explain the lower counts of Evidence use - Gameplay Events, Perspective-taking, and reflection if students were not directly referencing their gameplay in their writing. Students who did answer questions asking about their gameplay tended to use each of these practices an average of 4-5 times in their exams, whereas students who did not answer questions related to gameplay used these between 1-2 times in their exams. The results below highlight the most common interactional trends of what mediators co-occurred and supported the historical practices that emerged within students' gameplay (see Table 2).

Table 2

Summary of common co-occurrences between mediators and historical practices

		<u>**Historical Practices**</u>				
		Argument Construction (16)	Articulating Context (61)	Evidence Use (110)	Perspective-taking (68)	Reflection (41)

	Roleplay (73)	**12**	22	48	**63**	5

Bold #s = Co -occurrences where mediators were present more than 50% of a given historical practice

Perspective-taking and roleplaying

Within this analysis, perspective-taking in interaction nearly always co-occurred alongside students' engaging in roleplay as their game characters within their planning or diplomacy sessions (63 of 68 instances). For example, during one diplomacy session midway through the first game, a Spartan player, Sam, gave a rousing speech condemning Athens in the game, who had just attacked Sparta (see Figure 2). As they give their speech, Sam role-plays in the perspective of their character, a Spartan King whose people were just attacked in neutral territory. This isn't Sam simply referring to themselves in character, but rather through their speech they evoke culturally and historically rooted notions of piety and honor. For example, Sam condemns Athens claiming, "Athens believes that they are beyond reproach, they believe that neither the laws of man *nor Gods* apply to them" (Lines 12-13). Sam also denounces Athens not simply for violating a sacred treaty, but for the dishonorable act of "[propping] up a false pretender to Macedonia's throne…and now they have killed our men, breaking a sacred truce signed to keep the peace" (Lines 15- 16). This perspective that Sam took on was made salient through multiple mediators. Sam's unique character goals explicitly laid out in their goal sheet for the game helped to mediate what goals they might pursue for themselves, their City-State, and the Greek world. The course readings described actions their character made in history to mediate how they might respond to certain events. Their sustained gameplay allowed Sam to continually engage with and develop their character across multiple game sessions, allowing for opportunities to experience the consequences of their decisions as in-game events.

	16	*false pretender to Macedonia's throne, threatening civil war and ruin, and now*	
	17	*they have killed our men, breaking a sacred truce signed to keep the peace.*	

As students roleplayed, they utilized the perspectives of the historical characters they embodied in pursuit of their in-game goals. In the example above, Sam utilizes the perspectives of a Spartan king, a leader of a City-State, and member of the Greek world to better appeal to their peers during negotiations and planning. This directly mediated not only the student taking on the perspectives, but the students role playing alongside them as they situated themselves in the social and political realities of the period in their negotiations. Additional mediators that supported this co- occurrence pattern were the structure of the game which supported multiple players to participate in interactions, such as in the five-person team of Sparta or in external negotiation types of gameplays. In fact, perspective-taking and roleplaying emerged in most moments of negotiation across the game (39 of 67 instances), lending merit to students' arguments or articulations to their peers when discussing events of the game.

Argument construction and negotiation

Primarily, students engaged in *argument construction* in interactions of in-game negotiation, both internal and external (12 of 16 instances). These negotiations were directly mediated by the game design of larger teams leading to more internal negotiation, and diplomacy periods as one of the phases of the game allowing for interactions across teams. For instance, in an internal negotiation of whether Sparta should declare war (a structured game action which worked to mediate students' discussion of options to include debates) three students, Helen, Leo, and Jack developed competing arguments in pursuit of their common team goals of building up their City-State (see Figure 3). While there was agreement on the need to declare war, the game structure of needing to choose the temporal sequence of actions mediated the discussion of how and when to engage, leading students to construct arguments for their perspective.

Students' arguments were often bolstered by additional mediators and even other historical practices, such as the game rules and *articulations of context* (i.e., the unpacking of the social and political details surrounding historical context), to support students' argumentation. For example, in the above exchange Leo articulates that "at the end of the day half of our opponents are just City-State islands with 2 hoplites and triremes a piece, if that" (lines 8-9), so it really does not matter what their reaction would be to Sparta declaring war. Additionally, Leo frames his argument by referencing explicit game rules, noting that "the advantage of going first would be purchasing a mercenary army in one action since we're going to war regardless" (Lines 14-15), noting the game rule that a team cannot purchase an additional mercenary army *unless* they were already at war. In these interactions, mediators such as the structure of the 5-person Spartan team, the explicit game rules, and other practices such as *articulations of context* or *perspective-taking* mediated students' formulating their arguments in pursuit of their in-game goals.

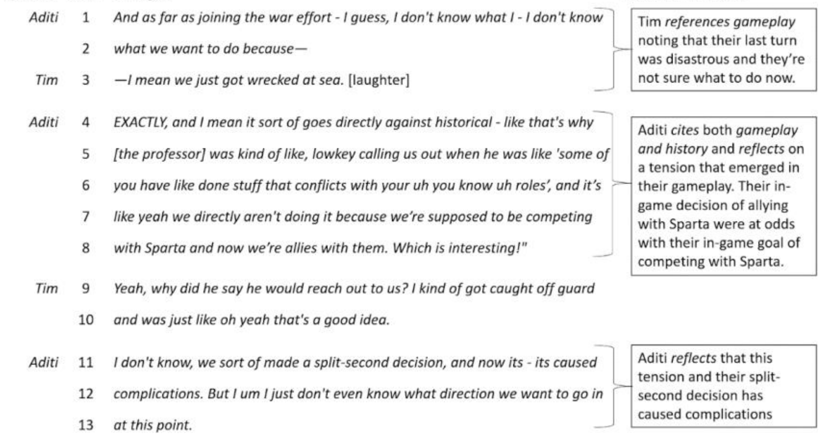
	8	*states will actually do. Because at the end of the day half of our opponents*	
	9	*are just city-state islands with two hoplites and 2 triremes a piece, if that.*	
	10	*Like half of you were playing that situation last round. You know how much*	Leo takes on the *perspective* of the leader of a smaller City-State to emphasize his point
	11	*you don't want to get into a fight. So the optics are just kind of something to...*	
Jack	12	*...Yeah but what is the advantage of going first? Just so we could attack them*	
	13	*before they could potentially move a force?*	
Leo	14	*The advantage of going first would be purchasing a mercenary army in one*	Leo references the in-game rules to further support his argument
	15	*action since we're going to war regardless.*	

Reflection and planning

When thinking about students' reflections as a historical practice, we take up the definition of Schon's (1983) idea of *reflection on action*, or deliberately thinking about a specific action or event outside of when it occurs, to define how we searched for students participating in reflection on both the game events and their course readings. For example, in one interaction between the players in Argos, Aditi and Tim, reflect on the turn that just took place prior to the planning session they are currently in (see Figure 4). The episode emerged from a co-occurrence trend wherein *reflection* within students' interactions primarily occurred within the 2-person City-State team Argos (30 of 41 instances). Additionally, students' reflections primarily occurred in the planning sessions explicitly designed within the game (32 of 41 instances), where interactions were limited to only a player's City-State team.

Figure 4

Transcript of Argos players reflecting on the game.



Speaker	Line	Dialogue	Historical Practices
Aditi	1	*And as far as joining the war effort - I guess, I don't know what I - I don't know*	Tim *references gameplay* noting that their last turn was disastrous and they're not sure what to do now.
	2	*what we want to do because—*	
Tim	3	*—I mean we just got wrecked at sea.* [laughter]	
Aditi	4	*EXACTLY, and I mean it sort of goes directly against historical - like that's why*	Aditi *cites* both *gameplay and history* and *reflects* on a tension that emerged in their gameplay. Their in-game decision of allying with Sparta were at odds with their in-game goal of competing with Sparta.
	5	*[the professor] was kind of like, lowkey calling us out when he was like 'some of*	
	6	*you have like done stuff that conflicts with your uh you know uh roles', and it's*	
	7	*like yeah we directly aren't doing it because we're supposed to be competing*	
	8	*with Sparta and now we're allies with them. Which is interesting!"*	
Tim	9	*Yeah, why did he say he would reach out to us? I kind of got caught off guard*	
	10	*and was just like oh yeah that's a good idea.*	
Aditi	11	*I don't know, we sort of made a split-second decision, and now its - its caused*	Aditi *reflects* that this tension and their split-second decision has caused complications
	12	*complications. But I um I just don't even know what direction we want to go in*	
	13	*at this point.*	

These two co-occurrence trends indicate that reflection in the context of the game was best supported in small group interactions. For example, in the exchange above Aditi reflects that "that's why [the professor] was lowkey calling us out…it's like yeah, we directly aren't doing it, we're supposed to be competing with Sparta, but right now we're allies. Which is interesting!" (Lines 4-8). Here, they reflect on an event that occurred where the professor mentioned that they were currently going *against* their designed City-State goals, which are rooted in the historical context, by not directly competing against Sparta. However, in the context of the game Argos and Sparta politically aligned as allies with each other, which Aditi noted came from "a split-second decision, and now it's - it's caused complications" (Lines 11-12) for their historically rooted goals. The game design allowed students to collectively create their own narrative of the history, which inevitably created incongruences between the in-game and historical reality. These tensions that emerged mediated students' reflection on their in-game actions and the historical reality, such as deciding which of their in-game goals were most important to them as City-State leaders.

Discussion

The primary goal of this study was to closely examine the context of *Cities on the Edge of War* and understand how mediators in the learning environment supported students in taking up historical practices. In the results section above, episodes detailed some of the most common co-occurring mediators alongside a historical practice in interaction, such as the designed game elements helped to structure students' interactions in these moments. Notably, when historical practices co-occurred with each other, they became additional mediators which supported each other within interaction. It would be worthwhile to carry out further work to study the relationship between historical practices, and how they mediated each other within interaction to support students' appropriation of these practices.

The field of the learning sciences has long valued studying the full complexity of learning and the complex environments which support it. Yet, when it comes to researching the types of interactions and mediators which foster disciplinary practices the field has primarily pursued contexts within STEM fields. We hope that this study has demonstrated that it is worth expanding our analytical lenses towards new disciplinary horizons. We believe the field has a lot to offer how we might structure history learning environments to be more playful and aim to foster intricate practices that enculturate students into being doers of historical research rather than passive observers of historical events. In designing game-based activity towards humanities-based learning objectives, the field can come to better understand what kinds of norms, roles, and tools better support students engaging in this type of sustained playful activity.

Contextual Dynamics in a College Student's Reasoning about Natural Selection

Julia Gouvea, Tufts University, julia.gouvea@tufts.edu
Scott Benjamin, Bunker Hill Community College, sbenjamin@bhcc.edu
Sukanya Chakraborty, Vidyanjali International School, sukanyachakraborty079@gmail.com

Abstract: Empirical studies of students' reasoning about natural selection show evidence of context-sensitivity, yet prior work has not been able to explain why certain contexts evoke different reasoning patterns. Applying a knowledge-in-pieces perspective, we present a moment-by-moment analysis of a student's shifting understanding of context in an interview about natural selection. We describe how different contexts activated different locally coherent sets of conceptual resources. This work builds theory that can account for previously unexplained empirical patterns in the domain of natural selection. More generally, by demonstrating how coherence changes with the scale of context, this work contributes to general understandings of the role of context in students' reasoning.

Introduction

An enduring concern of research in science learning is how conceptual understandings develop. A knowledge-in-pieces (KiP) perspective posits that novices construct understandings out of fine-grained knowledge elements or "resources" and that a central mechanism of conceptual development involves gradual refinement in patterns of resource activation within and across contexts (diSessa, 1988, 2014; Hammer *et al*., 2005). An important area of research within the KiP program is to build theoretical knowledge of how and why different contexts function to activate, stabilize, or destabilize resource activation and coordination (Chao *et al*., 2018; Sherin *et al*., 2012). We contribute to this aim by investigating the moment-by-moment contextual dynamics of a student's reasoning in the domain of natural selection.

Natural selection is an especially promising domain in which to investigate how context influences patterns of resource activation because students' reasoning in this domain varies with many features of task context (e.g., Nehm & Ha, 2011). Interview studies have also described within-subject shifts in reasoning (e.g., Southerland *et al*., 2001). Despite the empirical evidence of context-dependence and within-subject variability, little research has been done to attempt to model the underlying contextual dynamics from a KiP perspective. Much of the prior work on students' reasoning in natural selection has been focused on explaining the prevalence of misconceptions in terms of deeply held cognitive biases or naive theories (Ferrari & Chi, 1998; Kelemen, 2011) or mixed models in which normative and non-normative ideas co-exist (Opfer *et al.,* 2012). Neither of these types of models can explain why students would sometimes construct correct explanations and construct incorrect explanations at other times.

In this paper, we examine the role of context in activating different conceptual resources for reasoning about natural selection. We present a moment-by-moment analysis of an interview with one college student, describing her changing interpretations of context across the interview and how these shifts help explain different patterns of resource activation and the tentativeness of her responses. We claim that while her reasoning could be described as inconsistent or mixed when viewed at a global level, in local contexts her reasoning is much more consistent and sensible. This consistency holds for explanations that she has prepared ahead of time as well as those that she appears to construct in moments in the interview.

Theoretical framework

A "knowledge-in-pieces" (KiP) perspective models learners' knowledge in terms of fine-grained knowledge elements that are dynamically activated and coordinated in moments of reasoning (diSessa, 1988). Working in the domain of physics, diSessa (1993) described phenomenological primitives (p-prims) as one type of knowledge element. Subsequent work has used the more expansive term "resources" to describe a range of conceptual, contextual, and epistemological elements that can be coordinated together to form *dynamic mental constructs* (DMCs)—temporary, local assemblies of resources (Sherin *et al*., 2012).

A core tenet of the KiP perspective is that resources cannot be described as correct or incorrect independent of their use in contexts (Hammer, 1996; Smith *et al*., 1994). Rather it is the activation and coordination of resources into DMCs in particular contexts that may be considered more or less aligned with correct conceptions. For example, the application of the p-prim *closer means stronger* can be correctly applied to explain the change in temperature with distance to a heat source like a flame, but incorrectly applied to explain the seasons in terms of closeness to the sun (Sherin *et al*., 2012). Given the potential application of resources to generate both correct and incorrect explanations, an important mechanism of conceptual development involves changes in how resources are activated and coordinated in different contexts rather than the eradication or replacement of those resources. Understanding the role of contexts in activating, stabilizing, and triggering shifts in reasoning is therefore central to understandings the mechanisms of conceptual development (Chao *et al*., 2018; diSessa, 2014; Hammer *et al*., 2005; Sherin *et al*., 2012).

Both perceptual and conceptual features of tasks function as contexts that can lead to differential patterns of resource activation (diSessa, 2014; Hammer, 1996; Sherin *et al*., 2012). Task features can prime the activation of contextual resources that make the activation of different sets of linked resources more or less likely (Chao *et al*., 2018). In addition, shifting framings during an interview can create different contexts for resource activation. For example, when students perceive themselves in the situation of an *oral examination*, they tend to offer school-sanctioned ideas, whereas when students perceive an interview as an opportunity to engage in *inquiry*, they are more likely to show evidence of tentativeness and offer informal or everyday ideas (Russ *et al*., 2012). Thus, from a KiP perspective context is constructed dynamically as interpretations of tasks and situations are coordinated to prime different sets of resources. In this work, we model a student's shifting interpretations of context and associated shifts in resource activation in an interview about natural selection.

Candidate resources and contexts in the domain of natural selection

In this section we briefly review prior work in the domain of natural selection that suggests candidates for relevant conceptual resources and aspects of contexts that could influence resource activation.

Conceptual resources for reasoning about natural selection

To our knowledge there is only one example of a knowledge element being described explicitly from a KiP perspective in the natural selection literature. Southerland *et al*. (2001) described *need as a rationale for change* as a "biological p-prim" that captures the idea that organisms will evolve when they experience some challenge that cannot be met in their current form. For example, organisms that are visible to their predators experience a "need" to adapt to camouflage themselves. Notice that this idea is neither intrinsically correct nor incorrect. Need can be applied correctly to describe the gap between a current state and a better adapted state, or incorrectly if used to describe intentional change by the organism to meet this need.

While not described in terms of resources, other conceptions described in the literature on students' reasoning about natural selection can be "reconceived" as resources (c.f. Smith *et al*., 1994). These include conceptions about *variation*, *inheritance*, and *differential success* that are considered to be the core components of scientifically normative Darwinian explanations of natural selection. Also included are ideas such as *need as a rationale for change*, *change due to use*, or *environmental pressure*, each of which has been described as incorrect or "naïve" (Nehm & Ha, 2011; Opfer *et al*., 2012). Each of these ideas can theoretically function appropriately in evolutionary explanations or as part of incorrect explanations. However, because these resources can be used ambiguously or metaphorically, it can be challenging to interpret their intended meaning in data, particularly in written responses in which students have no ability to clarify or elaborate (Rector *et al*., 2012). For example, the statement "environmental pressures cause species to evolve" could be considered incorrect if the student is thinking that the pressure itself is the direct cause of the change. However, a metaphorical use of "pressures" to explain that environmental factors that have an impact on differential survival could be considered correct. From a KiP perspective, these ambiguities call for caution in interpreting the correctness or incorrectness of students' explanations. For this reason, we refrain from evaluating individual resources as correct or incorrect and use caution in making inferences about their correctness or incorrectness.

Contexts that influence reasoning about natural selection

Analyses of students' written explanation have revealed significant differences in how students respond with varying features of natural selection tasks, including taxonomic group (e.g., plants or animals), trait type (e.g., morphological or behavioral), direction of trait change (gain or loss of function), unit of analysis (population or species), and students' familiarity with the organisms. For example, students tend to include more statements that are considered canonically incorrect when reasoning about the evolution of a loss of trait function as opposed to a gain of function (Nehm & Ha, 2011).

While analyses of written responses have demonstrated that features of tasks can influence response patterns, such methods are not able to explain how or why these features activate different resources for students. Such explanations must attend to the moment-to-moment dynamics of how students are interpreting contexts. In an interview study of middle school students, Southerland *et al*. (2001) found that students' explanations included different knowledge resources when they interpreted interview questions as asking them to explain *why* a trait evolved as opposed to *how* it evolved. Building on this work, we examined how a student constructed different understandings of context and the resources she activated in these different contexts.

Methods

Study context and participant selection

This case study interview was selected from a study of 8 community college students enrolled in a tropical biology course taught in Costa Rica. As part of a course activity, each student participated in a brief interview during which they were asked to define natural selection as well as provide an explanation for how a trait that they had observed in their field excursions could have evolved from an ancestor that did not have that trait. Students were allowed to choose the trait that they wanted to explain.

We chose one interview with a student named Anna for the focus of this analysis. While we saw shifting patterns of resource activation in all 8 interviews to some degree, the clarity of shifts among clusters of resources in Anna's interview make it a useful illustrative case. At the time of the interview, Anna was in her first year as a biology major at a community college. For her interview, Anna chose to explain the gain of "jumping ability" in a tropical mudskipper (*Periophthalmus spp*.) or "skipping fish" that can use its front fins to guide the fish to jump from one tidepool to the next. The interview lasted 7 minutes and was captured on video. Anna is bilingual, and the interview was conducted in English, which was not her first language. In our transcription of the interview, we left Anna's expressions unedited. As part of our analysis, we divided the interview into 8 segments, each of which corresponded to shifts in the context (see Figure 2).

Characterizing contexts

We characterized contexts by analyzing the question posed by the interviewer and evidence of how Anna interpreted the question in the moment. For example, when the interviewer asked Anna, "What, in your mind, is natural selection?" Anna responded with "Natural selections [sic]. It is…." Together the request (*What is*) and her response (*It is*) suggest a mutual understanding of the context as *defining of natural selection*. Overall, we identified 5 contexts: *defining of natural selection*, *explaining why an organism evolved*, *explaining how a trait evolved, attending to variation*, and *making analogies to humans*.

Identifying conceptual resources and characterizing DMCs

Descriptions of conceptual resources were constructed through iterative rounds of coding and discussion of the interview video as a research team. We began by describing candidate resources in each of the 8 interview segments using the following three heuristics: Candidate resources were components of explanations that were (1) propositional (2) general enough to apply beyond the specific mudskipper question, and (3) neither correct nor incorrect. We then cross-referenced our descriptions with descriptions of conceptions from the natural selection literature.

In some cases, we agreed that our descriptions straightforwardly captured Anna's intended meaning. For example, when Anna described offspring as "not all identical" we agreed that her meaning was well captured by the resource *variation*. In other cases, Anna's meaning was more difficult to interpret. In these cases, we made tentative resource assignments and articulated alternative possibilities. For example, at one point we encountered uncertainty in assigning the resource *differential success*. When Anna was describing how jumping could have evolved, she described a transition from fins balancing to fins that can jump. In her description Anna said, "eventually the fins become stronger so like over time they survive." In this example, it is unclear what Anna means by "they." Anna could be using "they" to refer to only those fish that have stronger fins, a reference to *differential success*. Alternatively, "they" could mean all the fish, in which case the success is not differential. While later in the interview, Anna does say that she doesn't think all the fish will evolve the new abilities, we cannot tell what she intends in this moment.

Another ambiguity concerned whether Anna intends the idea *use enhances a trait.* As she was describing how mudskippers' fins could have evolved from fish, she began to talk about how a fish out of water wobbles around and "maybe like, like over time they have like, they create more muscle or more energies like to do the wobbly thingy." One interpretation of what Anna is saying here is that muscles get stronger through use. However, her use of the term "over time" makes this interpretation ambiguous. It could be that Anna is talking about muscle changing at the scale of evolutionary time. In examples like these, we maintained uncertainty in our assignment of resources, which we denote with parentheses in our results (see Table 1).

Analysis of interview framing dynamics

Russ *et al*., (2012) used verbal (e.g., hedging language), paraverbal (e.g., pauses) and nonverbal (e.g., gaze) behaviors to make inferences about how interviewees were framing interview interactions. They noted that shifts in clusters of behaviors could be evidence of shifts in framing.

To conduct gaze analysis, we first viewed the video in its entirety and identified four distinct observable gaze patterns: looking forward at the interviewer, looking down at her paper, looking to the right, or looking to the left (Figure 1). Using NVivo, we coded the entire 7-minute clip using these four categories. We also identified moments of pause and calculated their duration and coded all instances of hedging language. Finally, we coordinated these patterns across the different interview segments to make inferences about how Anna might be interpreting or experiencing the interview in those moments.

Figure 1
Categories of gaze: forward, down, right, left

Findings

Contextual activation of resources

We found two patterns in how Anna activated resources across the interview. As summarized in Table 1, we found distinct patterns of resource activation across contexts. We also found that in each context the resources were linked in coherent and sensible DMCs.

Table 1
Presence/absence of resources in different contexts (parentheses indicate tentativeness in resource assignment)

	Define natural selection	Why organism evolved	How trait evolved	Attend to variation	Analogy to humans
variation	x			x	
inheritance	x		x		
differential success	x		(x)		
change takes time	x		x		
genetic basis				x	
need as rationale		x			
environ. pressure		x			
trait function		x	x		
use changes trait		(x)	(x)		
transitional forms		x			
change via learning					x

Defining natural selection activates darwinian DMC

When Anna understands the context to be asking her to *define natural selection* she activates a DMC that includes conceptual resources considered to be in line with canonical Darwinian explanations.

> Anna: Natural selections it's like when, um, one or- organisms, like over generations, like parents, they have babies, but they have like similar babies, but they're not identical, like colors and everything, and whichever's strongest and fit with the natures, they can survive but the weak one dies.

While this would not be considered a completely correct Darwinian explanation, we characterize this DMC as Darwinian because it includes the core concepts of *variation*, *inheritance*, and *differential success* to describe *change over time* occurring within a population. Anna activates this same set of ideas a second time later in the interview when asked to connect her response to "what she said earlier about natural selection" (see Figure 2).

Explaining why organisms evolve activates evolutionary rationale DMC

The interviewer asks Anna to explain how the skipping fish could have evolved the ability to jump from "ancestors who could not do that." Anna begins by describing possible ancestral forms (fish- or salamander-like) and then describes challenges posed by the environment that provide a rationale for why those ancestors would evolve.

> Anna: At first I thought that maybe because they always like, got wash away to the beach, like nearby the beach and then like, if they couldn't jump, they eventually die.… Or just like another reasons, like, it's possible, like when they wash in the tide pool and then they start living there, there's like a lot of predators like crabs chasing them and they get cornered so if they can't jump, then they'll die.

In this context, Anna links *environmental challenges* (waves and predators) to *differential success* by noting that those individuals who could not jump, would die. In doing so she is providing a rationale for why functional fish-like ancestors would evolve into the "skipping-fish" form. Given these environmental challenges, adapting a jumping ability could be seen as a clear advantage.

Explaining how trait evolved activates pathway of transitional forms DMC

In the next section the interviewer attempts to clarify that he is looking for an explanation of how the trait evolved via natural selection. However, it appears that Anna understands him to be asking for a proximate physiological explanation of how a fish-like form could be transformed into a jumping form. Anna describes how jumping could have evolved from a "wobbling" behavior of an ancestral fish.

> Anna: Maybe (0.5s) at first, you know how fish, usually they do that when there's no waters, like wobbling around, maybe like (0.5s) like over time they have (0.5s) like they create more muscle or more energies like to do the wobbly thingy. And then like eventually they can jump and then like maybe the fins- because they're like supporting the ground, like they're trying to support the ground when they jump. So eventually the fins become stronger so like over time they survive and then their offsprings have a really good jumping skills and stronger fins so it feels like they can walk.

In explaining how a complex trait like jumping could evolve, Anna provides a series of *transitional forms.* Each transitional form has its own *function*, that could plausibly define a pathway from the evolution of an ancestral fish to a jumping mudskipper. She begins with the wobble in an ancestral fish and then posits that this form evolved into a form that used its fins to support the ground. Eventually, the fins got stronger allowing the fish to jump. Note that in describing how the fish could "create more muscle" and fins becoming stronger as the fish tries to "support the ground", it appears that Anna is activating the resource *use enhances a trait*. In addition, she connects this trait development to *inheritance* by offspring. Thus, her description of transitional forms includes elements of "Lamarckian" explanations (Ferrari & Chi, 1998).

Attending to variation activates ideas about the genetic basis for traits

Anna's reasoning shifts when she is asked to attend to variation in the population. This shift happens twice when the interviewer asks Anna to explain if all the fish are "born with" the ability to jump (see Fig 2). In each instance, Anna begins by establishing that she understands that individuals are not all identical—a *variation* resource. In the second instance, Anna also activates ideas about the *genetic basis* for this variation for the first time in the interview.

> Interviewer: Okay. So do they all—let's say you have a population of them can, they're born, can they all develop that ability?
>
> Anna: (1s) Not all of them, like only some of them. And then like (1s) so this fittest one survives and then they reproduce with another fittest one and their generations become—they have a good gene for that.

Anna later clarifies that the “good gene” she is describing is for “jumping abilities and strong fins.” It is difficult to interpret from this utterance exactly what role the gene plays in her explanation. One interpretation is that Anna is saying that phenotypic variation in the population for jumping ability corresponds to a gene and that over time those who have this ability, and this gene, will be more successful and increase in frequency (*differential success*). Another possibility is that Anna is somehow imagining that the gene changes along with or because of the phenotypic change.

Analogies to humans activates learning as a mechanism of change

Towards the end of the interview, the interviewer shifts from asking Anna to provide an explanation to asking her to reflect on her “thought processes” and any “past experiences” that she is using in answering this question. The reference to her own prior experiences appears to be understood by Anna as asking for *analogies to humans.*

> Interviewer: Are there things from your past that you've learned or know, or, or have heard that you're using like tools? You know what I mean?

Anna: I think so like (0.5s) humans experiences maybe <rising intonation> Like (0.5s) just like a kids, for example, like, um, if a human, like, for example like maybe at first they don't know that snikes [sic] are snakes are poisonous and like one person get bitten and then like they (0.5s) and then the next person they tell another person not to touch it so it's like nowadays humans don't touch snakes anymore, but maybe like in the old times-something like that I don't know

In this segment Anna is describing a process whereby humans change their behavior by learning to avoid snakes. Learning has not previously come up in this interview in Anna’s explanations for the skipping fish.

A blend of learning and genetics contexts reveals a contradiction

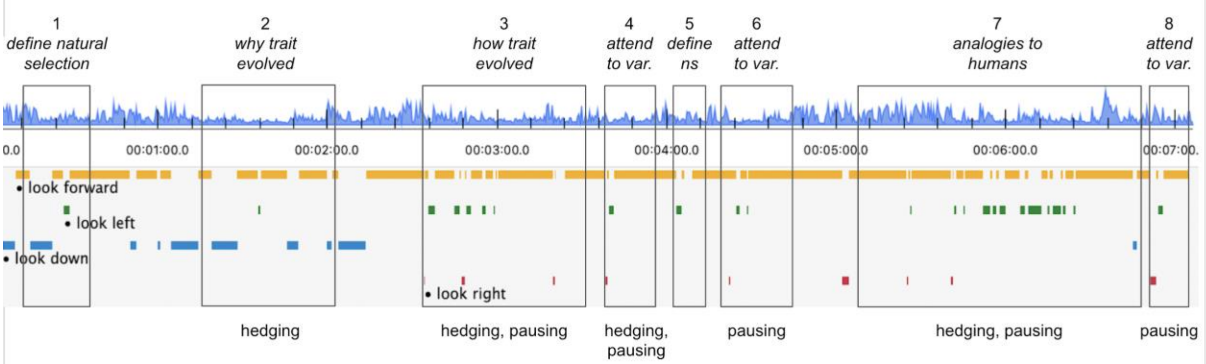
When following up on what Anna is saying about learning, the interviewer asks if Anna thinks the skipping fish learns. Anna agrees, despite having said earlier that the jumping trait has a genetic basis. This contradiction prompts the interviewer to clarify.

> Interviewer: Okay so the skipping fish learns
>
> Anna: Yea
>
> Interviewer: to put its muscles like that
>
> Anna: Mm hmm
>
> Interviewer: But it’s genetic
>
> Anna: (.5s) Well, when they'll learn, sometimes (1s) I believe in mutations, like, although like you're learning some things yeah so it's passed down the traits.

It appears that when these two contexts come together Anna is unsure how to reconcile her ideas. She does not seem to want to reject learning as a mechanism, yet at the same time she affirms her belief that traits have a genetic basis. The interview ends here with these two sets of ideas left in play.

Figure 2

Gaze, hedging, and pausing across the interview segments



Shifts in framing behaviors across contexts

Anna's gaze, use of hedging language, and speech cadence vary over the course of the interview (Figure 2) suggesting she is engaging in different types of explanation in different segments. In segment 1, when Anna is defining natural selection, she alternates between looking down at her paper and looking up at the interviewer. While Anna does not appear to be reading, her gaze suggests that she is referencing a prepared response. She uses no hedging language, and her speech is steady without pause. This cluster of behaviors suggests Anna is reciting her prepared response. In the next segment, Anna continues to look down as if referencing her writing, and while her speech is still clear, she now includes hedges such as, "I think" and "maybe." These inclusions make sense because Anna is explicit about offering her "hypotheses" here. Thus, while she is signaling that these ideas are tentative, she again appears to be reporting of a prepared response.

In segment 3, Anna's behaviors shift. She looks to the right and then repeatedly to the left as she begins to answer. Looking left overlaps with hedging language ("maybe") and pauses. A similar cluster of behaviors is evident in segment 7 as Anna is offering an example of how humans learn to avoid snakes. These behaviors suggest Anna is actively constructing her responses in these moments.

Finally, each time Anna is asked explicitly to attend to variation (4, 6, 8), she briefly flickers her gaze. During these shorter responses it appears Anna is pausing to think, indicating that she is perhaps initially unsure how to respond, but then settles on a response without extensive construction—each time affirming that she would expect variation in the population.

Discussion: Global incoherence and local coherences in context

Anna does not draw from a singular, globally coherent mental model of natural selection in her explanations. Over the course of the interview Anna's responses vary in terms of their alignment with each other and with scientifically accepted explanations. When asked simply to define natural selection, Anna's explanation included the appropriate use of the core concepts of variation, inheritance, and differential success. In contrast, Anna's explanations of *why* and *how* the jumping trait could have evolved included resources that have been described as "naïve" (Nehm & Ha, 2011; Opfer *et al*., 2012). Yet, when viewed in relation to the contexts of their activation, these resources appear both locally coherent and sensible.

Anna applies ideas about *need as a rationale for change* when she identifies features of the environment that would favor jumping ability. These sorts of explanations, because of their focus on trait function, have been explained in terms of underlying teleological biases (Kelemen, 2011). Anna uses the environmental problems to provide a reason why a fish would need to evolve into a mudskipper. Her explanation does not appear to suggest that Anna thinks that the need itself caused the change. In the segment prior, Anna has already explained change in terms of the differential success of variants and the inheritance of traits over time. In line with Southerland *et al.* (2001), we argue that Anna's use of the "need" resource is sensible in the context of the "why" question she understands herself to be answering.

Similarly, Anna's description of a *series of transitional forms* that get "stronger" and are inherited by offspring could be described as evidence of an underlying "Lamarckian" theory of evolution. While it does seem like Anna is suggesting that changes within an individual can be inherited by offspring, mechanisms of inheritance are not the focus of her explanation. Anna is focused on describing a plausible series of transitional forms connecting an ancestral fish to a jumping fish and explaining the physiological mechanisms, such as changes in muscle and energy, that could underlie the transformation of one into the other. Given that this is her focus, it is not clear whether she intended to communicate that the change happens through *inherited use*. Moreover, throughout this response Anna makes several references to the idea that *change takes time* (e.g., "eventually they get stronger"), possibly intending to communicate change over a longer evolutionary time.

Finally, when Anna interprets the interviewer as asking her for analogies to humans, Anna activates ideas about *learning as a mechanism for change*. This idea makes sense applied to how humans might have learned to avoid snakes. When the interviewer switches the context back to the skipping fish, Anna continues to affirm the use of this resource. This moment is evidence of the strength of context effects. Anna has not previously mentioned learning, but once the idea has been activated it seems to stay active. When challenged to consider the genetic basis of the trait, an idea that Anna had offered previously, Anna appears to attempt to combine the two ideas together seemingly indicating that both mechanisms have a role to play.

Our interpretations are limited by the fact that Anna is a bilingual English language learner and the fact that the interview was time limited. Open questions remain about Anna's meaning in various moments. Nevertheless, Anna's interview suggests that different constructions of context played a strong role in explaining the patterns of resource activation in Anna's reasoning. Anna's thinking was sensibly related to context whether she was recalling a prepared response or constructing an explanation in the moment. Overall, these patterns in Anna's thinking align with a KiP model comprised of interconnected sets of resources that are temporarily assembled in interaction with contexts.

Significance and implications

Researchers continue to advocate for the need to directly address students' misconceptions about natural selection during instruction (e.g., Nehm *et al.*, 2022). Without consideration of the role of context in influencing reasoning patterns, these interventions are unlikely to result in lasting conceptual change. Our work suggests that ideas that are considered misconceptions play a functional role in context-specific explanations, making eradication an untenable and undesirable goal. Additional work is needed to understand the mechanisms by which students develop the fluidity to activate resources in appropriate contexts as well as to reconcile seeming contradictions across contexts. In addition, work may also be required to help instructors understand how students are constructing contexts so that they can more appropriately interpret and respond to students' thinking.

Mathematics Curricula that Center Black Brilliance and Joy: Design Principles and a Task Analysis

Lara Jasien, CPM Educational Program, larajasien@cpm.org
Michael Lolkus, CPM Educational Program, mikelolkus@cpm.org
Marlena A. Eanes, Vanderbilt University, marlena.a.eanes@vanderbilt.edu

Abstract: Building on *Black Feminist Mathematics Pedagogies* (BlackFMP; Joseph, 2021), we examine how discipline-specific features of curricula can support antiracist teaching. BlackFMP builds on scholarship that attends to (a) individual Black girls' mathematics experiences, (b) the historical context that situates those individual experiences, and (c) the brilliance of Black girls and women. Based on the contents of the BlackFMP framework, we synthesized four guiding questions and developed a codebook to further articulate how each of the questions might manifest in a mathematics curriculum. Our findings indicate that the process of coding mathematics curricula using the BlackFMP framework can create learning opportunities for curriculum writers as they explore ways to create textbooks that have increasingly equitable opportunities for Black girls and for all students.

Overview

Mathematics curricula are saturated in whiteness (Battey, 2013; Martin, 2010; Stinson, 2011). Mathematical spaces, including curricula, align with white ideals and culture and thus constrain the ways learners are allowed to exercise their agency (Battey & Leyva, 2016; Gutiérrez, 2017). Even more, schools function as a vehicle for social reproduction, preparing students of color to exercise less agency in society than their white peers (Anyon, 2013). In fact, racism has profound effects on the educational opportunities of marginalized students. For example, when Berliner (2006) disaggregated the results of the PISA of 2000 by race, they found that:

> If the educational opportunities available to White students in our public schools were made available to all our students, the United States would have been the 7th highest scoring nation in mathematics, 2nd highest scoring nation in reading, and the 4th highest scoring nation in science. Schooling for millions of US White children is clearly working quite well. On the other hand, were our minority students 'nations,' they would score almost last among the industrialized countries of the world. (pp. 963-964)

Though these results are from over two decades ago, the inequitable distribution of opportunities to learn has not changed much (Carnoy & Rothstein, 2013). Although it is important to tell this story of oppression, many Black scholars today are arguing that if white teachers and scholars understood what Black Joy looks like, schools would be a more humanizing place for students of color (Math Learning Center, 2022).

As scholars who create mathematics curricula that affect over 700,000 students each year, we have a responsibility to hear this call to action. Because evidence suggests that mathematics curriculum substantially impacts instruction and students' experiences in the classroom (Kloosterman & Walcott, 2010), we wonder how frameworks centering Black brilliance and joy from an intersectional perspective can be leveraged to influence the work of curriculum designers. We also recognize the limitations of reimagining mathematics curricula in alignment with reform-oriented mathematics education given the enduring differential learning outcomes for Black students even after over three decades of current reform efforts (Berry et al., 2014; Bullock, 2019; Martin, 2010). Yet, for now, teachers and students do continue to work and learn within the existing system. Our work aims to disrupt the status quo to make a difference for those with immediate needs.

To do so, we take up Dr. Nicole Joseph's (2021) *Black Feminist Mathematics Pedagogies* (BlackFMP) framework and use it to analyze a reform-based secondary mathematics curriculum designed to support ambitious mathematics instruction (Lampert et al., 2010) and culturally responsive teaching (Gay, 2018; Hammond, 2014) to find ways curricula can support an antiracist stance. This pedagogical framework supports us in identifying elements in the written curriculum that can foster instruction that features pedagogical actions that benefit Black girls (see Stein et al., 2007 for connections between the intended and enacted curriculum). Taking up BlackFMP to guide us, we ask: How can frameworks centering Black girls' mathematical experiences help us understand how mathematics curricula do and do not support humanizing and just teaching in ways that are actionable for curriculum designers?

Conceptual framework: Why center black girls?

Black girls experience intersectional forms of oppression (Crenshaw, 1989), including sexism and the US's ongoing history of antiblack racism and violence against Black people. We take up BlackFMP for our analyses because it builds on scholarship that attends to (a) individual Black girls' mathematics experiences, opinions and perspectives, and ways of relating to the broader collective of Black woman/girlhood (Black Feminist Thought; Collins, 2000; Dillard, 2000; Smith, 1989), (b) the historical context that situates those individual experiences (Critical Race Feminism; Evans-Winters & Love, 2015; hooks, 2000), and (c) the brilliance of Black people in general and Black girls and women in particular (both theories, Joseph et al., 2016). The critical theories that BlackFMP is built upon argue that a commitment to human solidarity and justice more broadly is required for justice for Black women and girls in particular, making scholarship from this intellectual tradition ideal for considering educational justice for a diverse student body (West, 2019).

Another essential reason for centering Black girls in our analyses is the violent ways that antiblack racism manifests for Black girls in schools. Black girls experience antiblack racism in schools through (a) the adultification of Black girls (i.e., the belief that Black girls need less nurturing, protection, and support than white girls); (b) the characterization of Black girls as too social, loud, and disruptive; and (c) disproportionate discipline, resistance to naming Black girls' intellect even when they excel, to name a few (Epstein et al., 2017; Joseph, 2021). Centering Black girls' experiences in the pursuit of justice can motivate, for example, making mathematics learning environments increasingly nurturing places where students are invited to bring their full selves and demonstrate their brilliance (i.e., humanizing mathematics; decentering whiteness; Collins, 2002).

This focus on Black girls' experiences does not negate the experiences of other groups who experience oppression and violence by white people and largely white governments (e.g., Native/Indigenous peoples, Asian Americans, Jews). Because antiblackness is the most predominant and visceral form of racism in America, attending to the experiences of Black girls should benefit all students and teachers, and perhaps extend internationally as racism in the US may be an exceptionally informative "extreme case" (Flyvbjerg, 2006). Centering the design of curricular materials in ways that benefit and build on the brilliance of Black girls will benefit all due to the considerable impact of curriculum on what students learn (Kloosterman & Walcot, 2010) and providing supports necessary for healing for the nuanced and varied ways students experience and internalize antiblack racism (Case, 2019) (1).

We center the BlackFMP framework because it builds on scholarship that attends to the experiences of individual Black girls in US schools (Joseph et al., 2016) while also situating those experiences within a historical context with an eye toward the brilliance of Black people in general, and of Black girls and women in particular. BlackFMP builds on ambitious reform efforts but argues that they are not enough, and in some sense have had a colorblind impact as they still create inequitable opportunities for Black girls. Thus, BlackFMP says that ambitious mathematics instruction is not enough.

Research design

Based on the contents of the BlackFMP framework (Joseph, 2021), we synthesized the following four guiding questions: (1) Ambitious Mathematics Instruction: How does the curriculum engage students in argumentation, reasoning, modeling, and problem-solving? (2) Academic and Social Integration: How does the curriculum allow humor and socializing to promote healing from intellectual trauma and violence in math spaces? (3) Critical Consciousness and Reclamation: How does the curriculum create opportunities for alternative, transgressive, hybrid spaces generated and occupied by students' conscious spirits? (4) Robust Mathematics Identities: How does the curriculum support students to view themselves positively as math learners and doers, as well as having strength, agency, and resistance to oppressive mathematical experiences?

We then developed a codebook (see Table 1) to further articulate how these questions might manifest in a mathematics curriculum. This codebook was based on the BlackFMP framework and revised to reduce overlap across and within the four categories and to ensure the codes and our conversations centered Black girls. We also expanded what was in the codebook based on how the curriculum we coded "answered" the questions.

In addition, BlackFMP distinguished between procedural fluency and conceptual understanding, but to resolve coding disagreements, we found we needed a more nuanced approach to cognitive demand and so took up Stein et al.'s (2000) framework of high cognitive demand (i.e., *doing mathematics* and *procedures with connections*) and low cognitive demand (i.e., *procedures without connections* and *memorization*). The cognitive demand framework supports our analysis because we aim to discover how rich curricular tasks are rather than assuming their richness ("groupworthy tasks," Lotan, 2003) or looking at whether they spur rich interactions (e.g., sociocultural studies of learning; Engle & Conant, 2002; Sengupta-Irving & Enyedy, 2015).

After coding several lessons, discussing the results, resolving dilemmas, and modifying the codebook further, we developed sub-codes for each of the four guiding questions. We share the sub-codes in Table 1 to support a fuller understanding of how we understand each guiding question based on the BlackFMP framework and our attempts to use it to code curricula. Because we conjecture that this framework centering Black girls will benefit all students, we use "students" in our codes rather than "Black girls."

Table 1
Working codebook

Guiding Principle	Codes
Ambitious Mathematics Instruction	High cognitive demand, Low cognitive demand, Status and equitable participation, Access and productive struggle, Make sense of student thinking and build on student ideas
Academic and Social Integration	Humanizing, Responsiveness
Robust Mathematics Identities	Mathematical dispositions, Representation of mathematics[a], Expansive definition of achievement[a], Disrupting dominant narratives[a]
Critical Consciousness and Reclamation	Read the world with mathematics, Write the world with mathematics, Power and solidarity[a], Author positionality[a], Teacher positionality[a]

[a] Codes not yet used in our analysis.

To further refine our working codebook, we honed our agreements of coding practices and identified areas of tension to outline our ongoing analysis through coding an additional two lessons that immediately preceded our focal lessons. The focal lessons on wage inequities foreground the curriculum developers' (i.e., CPM Educational Program, 2022) explicit efforts toward centering culturally responsive materials and intersectional discrimination based on race and gender.

Secondary mathematics curriculum

The CPM Educational Program (CPM) has demonstrated commitments to equity-oriented instructional practices since its inception in 1989, specifically through its three pillars of collaborative learning, problem-based learning, and mixed-spaced practice (CPM, 2022). Over the years, CPM, specifically, and the mathematics education field broadly, has continued to develop nuanced understandings of how mathematics curriculum can better support students from more diverse backgrounds. As such, CPM began developing the Inspiring Connections curriculum for 6th- through 8th-grade mathematics (Inspiring Connections 1, Inspiring Connections 2, Inspiring Connections 3). Currently, the Inspiring Connections series is under various stages of development and field testing, with Inspiring Connections 1 undergoing the second round of year-long field testing in 20 classrooms across 14 US cities.

We selected CPM's Inspiring Connections series for our proximity to the development of the curriculum. Jasien began supporting CPM's development through the organization's research arm in 2019, synthesizing research to inform the curriculum writing process and engaging in critical evaluations of CPM deliverables to foster more equitable mathematical experiences for students in CPM classrooms across the country. Informed by his experiences partnering with Black and Latinx high school students in Newark, NJ, Lolkus joined the CPM writing team in 2022 to develop culturally relevant and social justice-focused mathematics curricula. Our commitment to supporting CPM's mission of bringing more mathematics to more students encourages us to question who is and can be served by our most recent efforts to develop mathematics curricula centered around tenets of culturally relevant teaching. We detail findings from two lessons in Inspiring Connections 1, *The Job Offer* and *Weekly Earnings*, which have students write, interpret, and simplify expressions in contexts related to wage discrimination in the United States.

Findings

Though BlackFMP centers Black girls, we found that this framework helped us consider dimensions of the curriculum that are important for all students. In our findings, we share the actionable ideas we developed through the coding process. Notably, we found more value in the process of coding and in the rich conversations the coding sparked than in producing reliability amongst the research team. This outcome aligns with our aim to find ways that the BlackFMP pedagogical framework can support meaningful learning for curriculum designers: as we iteratively coded and refined the codebook, our conversations led us to redefine each code in ways that made the pedagogical framework of BlackFMP increasingly more particular to curriculum design.

In addition, our coding differences led us to conversations in which we imagined new curricular possibilities. For example, when we expanded BlackFMP's attention to procedural fluency versus conceptual understanding to account for levels of cognitive demand (Stein et al., 2000), we had disagreements over whether many problems should be coded as high cognitive demand ("procedures with connections") or low cognitive demand ("procedures without connections"). Through our conversations about the most meaningful ways to code, we recognized that most tasks had lower-level procedural scaffolding (e.g., part (a) and part (b)) that led to a more conceptual ending (e.g., part (c); see Figure 1).

July 10, 2021

Emily Miller
2718 E Street
Golden, CA 90452
916.281.8284

Dear Emily Miller,

I am pleased to offer you full-time employment at Stats and Health Inc. A detailed job description is attached to this letter for your reference. This position will begin on Monday, July 23, 2021. The hours of work are 7:00 a.m. to 4:00 p.m. Monday through Friday, with a one-hour lunch break each day, for a total of 40 hours per week. Pay will be at a rate of $10.75 per hour.

If you accept this offer of employment, please sign and return the attached contract.

I look forward to working with you.

Sincerely,
Camila Rodriguez
President, Stats and Health Inc.

6-21. Emily gets a job offer at Stats & Health Inc. Her job offer is shown in the letter.

a. What would Emily's annual salary be if she accepts this position? Assume that she works 50 weeks a year.

b. How does the salary you calculated in part (a) compare with the salaries listed in the table in problem 6-20?

c. Do you think this offer is fair? Why or why not? If not, what do you think is a fair offer?

Our disagreement lay in whether the scaffolds in the problem reduced the cognitive demand of the richer, more conceptual parts of the problem. Without resolving this completely, we concluded that we could increase the cognitive demand of each lesson and have students do mathematics (the highest level of cognitive demand) by flipping the parts of each task, putting what was at the end first, and providing students with the resources that are currently scattered throughout the current lesson at the beginning of the lesson. This was true in both the scale of the lesson and of the task: the task in Figure 1 would be richer if it started with part (c). The scaffolding questions could be included in the teacher edition of the textbook for just-in-time support as students solve the non-routine tasks. In this way, there are multiple options for curriculum designers to iterate on their designs, either at the scale of the lesson or at the scale of tasks.

There is an endemic challenge to designing mathematics lessons that foster students' engagement with social issues: too often, lessons foreground mathematics or social content instead of meaningfully interweaving each due to constraints, such as time (Gregson, 2013), the instructor's sociopolitical or mathematical knowledge (Kokka, 2015), or even challenges to aligning the mathematics and sociopolitical goals (Brantlinger, 2011). In the case of the CPM curriculum, we found that the scaffolds that we interpret as the curriculum designers' attempts to avoid de-elevating the mathematics actually reduced the cognitive demand across the questions. Thus, the intent and the impact of the design are mismatched. Figure 2 and Figure 3 showcase one example of this tension.

Figure 2
Mathematical prompts for investigating the fairness of Emily's job offer

6-22. Emily wants to make sure the job offer is fair, so she decides to keep investigating.

First, she talks with some of her older friends who already work at Stats & Health Inc. None of her friends have worked for the company for more than two years. She asks them what their salaries are and writes them in a list.

$25,600, $26,500, $28,750, $29,100, $29,950, $30,075, $35,250, $36,300, $37,050, $38,275

Next, Emily does an Internet search for information about salaries at Stats & Health Inc. and she finds the following infographic.

a. Calculate the mean and median of Emily's friends' salaries.
b. What does "salary range" mean?
c. What is the maximum salary at Stats & Health Inc.?
d. What information does the bar graph provide?

Figure 3
Mathematical Prompts for Investigating the Fairness of Emily's Job Offer

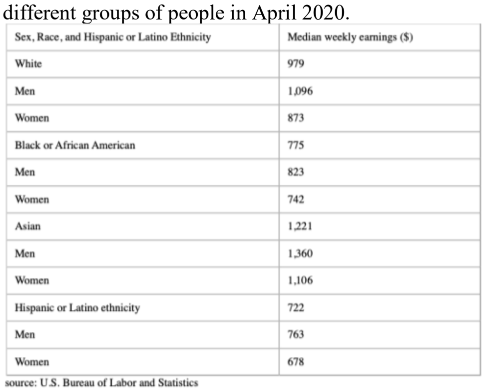
6-23. Emily needs your advice about the job offer.
   a. Should she accept the job offer? Why or why not? Use the information in problem 6-14 to support your answer.
   b. Suppose Emily decides to negotiate for a higher salary. What salary do you think she should ask for? Provide at least two data points to justify this salary.

Students begin investigating scaffolded mathematical questions (i.e., Figure 2) that build to more cognitive demand (i.e., Figure 3) throughout the lesson. If the questions were flipped, with the current initial task instead provided as just-in-time scaffolds, then the curriculum would better support both high cognitive demand mathematics learning as well as more meaningfully support students to develop their critical consciousness with connections to their lived experiences.

We also note that many of the social issues and higher cognitive demand features of the Inspiring Connections 1 lessons were located in the teacher edition of the curriculum (see Figure 4 and Figure 5). In relation to the student edition's push for social analysis, we see a table that includes gender and race/ethnicity. This may support students in grappling with gender discrimination and wage inequality. Yet, the questions in the student text do not prompt students to notice or explore these issues, making it possible that such issues remain unexamined in the public space of classroom discussion. Instead, the social issues are explicitly mentioned in the teacher edition of the text as a caution to ensure that, if students use the data to affirm racist and sexist ideas, teachers know to facilitate a discussion about that use of the data as unacceptable.

Figure 4
Student Version of Problem 6-33

6-33. Bailey finds data from the U.S. Bureau of Labor Statistics. The table shows the median weekly earnings for different groups of people in April 2020.



Sex, Race, and Hispanic or Latino Ethnicity	Median weekly earnings ($)
White	979
Men	1,096
Women	873
Black or African American	775
Men	823
Women	742
Asian	1,221
Men	1,360
Women	1,106
Hispanic or Latino ethnicity	722
Men	763
Women	678

source: U.S. Bureau of Labor and Statistics

Bailey writes the three expressions shown in parts (a) through (c). For each expression, complete the following:

i. What question might Bailey be answering by writing this expression?
ii. Justify your answer by explaining what each term in the expression means.
iii. Perform the calculation to answer the question you wrote in the first bullet.

a. 52(678 + 678)
b. 5 x 52 x (1,096 + 823)
c. (1,360 + 1,106) - (763 + 678)

Figure 5
Teacher Version of Problem 6-33

Move teams to problem 6-33. the expressions in this problem require using the Order of Operations to evaluate. Students need to complete the addition within the parenthesis before completing the other operations. Students have been evaluating expressions like this since 3rd grade (3.OA.B.5), so this problem should serve as a reminder. However, continue to monitor their work as you circulate and provide support as needed.

The context of problem 6-33 (median weekly earnings for men and women of different races and ethnicities) lends itself to a conversation about income inequality. After teams complete this problem, lead a class discussion. Start by reminding students of the class's agreed-upon expectations for respect and collaboration. Then ask the class questions, such as:

- *What do you notice? What do you wonder? Was anything surprising to you? What questions do you have?*
- *Why were these data collected? Where did they come from?*
- *Who is affected by these data? Who could be hurt by them? Who could be misled by them?*
- *What are the benefits and challenges of living in a diverse society?*

These data highlight issues of income inequality in the U.S. based on sex, race, and ethnicity. The data highlighted in this problem could cause some people to create confirmations of racism or sexism. For example, they might argue that Black people should make less money because they do not work as hard. This racist argument is unacceptable. Instead, the data and the subsequent discussion should be used to challenge the system that has created the inequities. Consider collaborating with your colleagues in the Social Studies or History departments to continue the discussion beyond this lesson.

If you do not feel a class discussion would be appropriate or productive for your class, conduct another Dyad instead so that students can express their thoughts about the data. Students will likely start asking about up-to-date information about income. Move them to problem 6-34, which gives them an opportunity to research this information.

Relating to cognitive demand, the student-facing version of Problem 6-33 (i.e., Figure 4) has students engage in procedures without connections because there is little ambiguity about what they need to do and how to do it. The teacher-facing instructions (i.e., Figure 5) provide opportunities to further increase the cognitive demand of the problem by prompting students to ask follow-on questions that support students to make connections between the sociopolitical contexts and the procedures they investigated. This makes it more likely that overworked and underpaid teachers are less likely to encounter these elements and more likely that students experience less ambitious instruction and teacher responses that are less sensitive to the social issues within the curriculum. We know that teachers often plan lessons using the student versions of their textbooks (e.g., Superfine, 2008), so this finding has prompted discussions about how to strengthen the content in student materials.

Discussion

Joseph's (2021) BlackFMP framework supported our sensemaking about both the rigor of the curriculum from a perspective of ambitious mathematics instruction and opportunities for curriculum writers to engage with essential dimensions of mathematics learning: bringing students' full selves to the mathematics classroom (i.e., Academic and Social Integration), generating in transgressive spaces (i.e., Critical Consciousness and Reclamation), and developing mathematical identities that center their own strength, agency, and resistance to oppressive experiences (i.e., Robust Math Identities). Through this interrogation of Inspiring Connections 1, we are working toward a reimagined mathematics education that can provide equitable opportunities to Black girls to correct for the historic and ongoing harm of low expectations and limited opportunities provided through our nation's education system. Though beyond the scope of this analysis, we note that a professional learning session we hosted for Inspiring Connections curriculum designers resulted in changes to the lessons presented here and, suggesting the session will shape future lessons.

While this critical analysis of a secondary mathematics curriculum demonstrates promise for supporting curriculum designers to attend to students who have historically been marginalized in mathematics classrooms, more is needed. We note that many of the codes we did not use in our analysis (because they were not present in the lessons analyzed) are essential to taking an antiracist stance in curriculum design. For example, under Robust Mathematics Identities, we did not use the codes Representation of mathematics, Expansive definition of achievement, or Disrupting dominant narratives. We argue that these codes may not be a good fit for a lesson on gender discrimination and wage inequity, but nevertheless are essential to designs for curricula that seek to dismantle the status quo. Likewise, curricula must explicitly support teachers to understand that mathematics lessons are appropriate places for students to be playful and goofy (i.e., humanizing) and that support students to see and embody their full brilliance (i.e., Robust Mathematics Identities).

Noting that we were not able to code for author positionality within these social inequality lessons (or the textbook as a whole), we call on curriculum designers and researchers (including ourselves), both within and beyond CPM, to (a) engage in critical reflections on their own positionality and (b) complicity in developing classroom materials that harm, rather than celebrate, Black girls; and (c) identify individual areas of growth, such as commitments to engage students in problems that foreground BIPOC characters and mathematicians that break multiple, intersecting, social stereotypes and use mathematics as a tool for developing students' and teachers' critical consciousness.

Endnotes

(1) Students from dominant, oppressive social groups are also harmed by antiblack racism, for instance, by internalizing negative stereotypes and distorted representations of Blackness that they perpetuate into adulthood (Baines et al., 2018; Wynter-Hoyte & Smith, 2020).

Abstract: Engaging students in computational modeling (CM) to explain natural scientific processes can help prepare pre-college students for STEM careers and lower boundaries to teaching computer science in pre-college schools. This study addresses the need for concise CM experiences that typical teachers can feasibly integrate into science instruction and are accessible to students from historically excluded STEM groups who have no programming experience. We describe the design and enactment of a one-week CM unit and report on its classroom feasibility, students' learning outcomes, and students' CM activities. We observed significant pretest/posttest gains indicating that the unit benefited students even after completing a typical course of study on kinematics. Two student vignettes illustrate how students' CM activities provided learning opportunities in physics and computational thinking.

Introduction

This study responds to recent efforts to integrate the teaching and learning of science and computational thinking (CT) in pre-college classrooms. The emergence of computation as the third pillar (alongside theory and experiment) of science and engineering compels schools to incorporate CT into the existing pre-college science courses and address disciplinary intersections highlighted in contemporary education standards in science (e.g., Next Generation Science Standards) (NGSS Lead States, 2013) and computer science (K-12 Computer Science Framework, 2016). To prepare for STEM careers, pre-college students must engage in authentic STEM practices that increasingly rely on CT. Computation-based STEM practices are needed for students to explore natural scientific processes and apply scientific knowledge to design solutions for real-world STEM problems. Incorporating CT into science also lowers boundaries to teaching of computer science (CS) in pre-college schools, as not all schools have the necessary programs or expertise to teach CS. Including it in core subjects (such as science) has the potential to broaden global participation in CS.

Engaging students in developing computational models (CMs) offers promise for supporting coherent integration of science and CT experiences for pre-college students (Sengupta et al., 2013; Basu et al., 2016; Weintrop et al., 2016). CMs provide representations that support modeling of dynamic phenomena that can be simulated by a computer (Weintrop, 2016). Teachers face numerous challenges with implementing CMs as part of science instruction. Developing CMs requires some programming expertise, which students must acquire and teachers must support in the classroom. However, many science teachers do not have experience with programming and are unable or unwilling to set aside the instructional time needed first to teach requisite CT concepts, then engage students in applying these concepts to modeling science phenomena. Many teachers and students would benefit from the availability of short, integrated experiences that can be implemented feasibly into their science instruction. In response to this need, we describe the design and implementation of a one-week kinematics computational modeling (KCM) unit, report on its classroom feasibility and students' learning outcomes in physics and CT, and examine relationships between students' learning and the nature of students' CM activities as logged by the environment. In this design-based study, we investigate the following research questions: (1) What are students' learning outcomes in physics and CT from using the KCM unit? and (2) How is students' physics and CT learning associated with their CM activities?

Perspectives and rationale

We build on affordances of CM building for pre-college students. Developing a CM of a scientific phenomenon leverages constructionist learning perspectives (Papert, 1980) and involves key aspects of CT, such as identifying mathematical rules that govern system behavior, comparing generated representations with observations of target phenomena, and refining models to achieve increasingly sophisticated explanations of the phenomenon. Integrating CT and scientific modeling can benefit learners in numerous ways (Sengupta et al., 2013), such as emphasizing CMs as a core scientific practice (Soloway, 1993) and providing a contextualized representation to support the teaching of programming (Hambrusch et al., 2009). Prominent examples of environments that support integration of science and CMs include Boxer (e.g., diSessa, 1991), NetLogo (e.g., Wilensky & Rand, 2015), DeltaTick (Wilkerson-Jerde et al., 2015), and CTSiM (Basu et al., 2016).

While studies on these environments provide evidence for design principles and learning mechanisms for integrated science-CT learning in pre-college students, many use only descriptive case studies, engage students only in advanced science classes or at schools with selective admissions criteria, or engage researchers as teachers instead of students' classroom teachers. As such, these studies often do not demonstrate the classroom feasibility of these environments or examine learning in typical instructional conditions. Relatively few studies provide evidence of promise of integrated science and CT that (1) include a large proportion of students from historically excluded STEM groups, (2) are short enough to be practical for typical teachers, (3) engage students' own teachers in teaching the units, and (4) demonstrate pre/posttest learning gains in science and CT for hundreds of students.

In this study, we address salient challenges to the practical implementation of integrated science and CT instruction that use CMs. For students, challenges include the time required to learn programming constructs and model building practices. For teachers, challenges include the length of the instructional interventions and the need for programming expertise to support students with CM building. One way we address these challenges is by scaffolding students' CM building and problem-solving through the creation of a domain specific modeling language (DSML) (Jackson & Sztipanovitz, 2009) implemented using visual, block-structured constructs. Our DSML uses computational blocks that are directly linked to concepts in the kinematics domain, facilitating students' conceptualization and development of CMs (Hutchins et al., 2020). The use of a block-structured format provides not only relief from the burden of learning the syntax of general-purpose programming languages, but also a level of abstraction that exploits the synergies between CT constructs and CM building practices in the domain. This study examines how combining a DSML with a visual programming language can help make short CM experiences in science feasible and beneficial for both teachers and students.

Design

Domain specific modeling language and computational modeling environment

The C2STEM (Hutchins et al., 2020) CM representation (Figure 1) uses custom kinematics DSML blocks developed on top of NetsBlox (Broll et al., 2018), a block-based extension of Snap! (http://snap.berkeley.edu/). We have developed a physics DSML for our high school physics curriculum targeting the key domain concepts and practices in kinematics. In the context of integrating physics modeling and CT practices, our DSML is designed to support a temporal step-by-step approach to modeling the motion of an object. This approach, in contrast to equation-based modeling, aims to help students apply kinematics principles to decompose the motion of the object into components by updating the velocity and then updating position of an object at each time point, improving students' understanding of how the motion occurs over time. Similarly, other constructs, such as the use of domain-relevant variables (e.g., acceleration, velocity, and time), and explicit constructs (blocks) for initializing and updating the variable values helps students discern how chosen initial values and functions for updating variable values together affect the system behavior. In addition, students also learn to use traditional computational constructs (variables, expressions, conditionals, and loops) in a physics context, thus facilitating their understanding of these constructs and their use in programming.

Figure 1 illustrates the C2STEM system modeling interface and includes example code for modeling the motion of a truck moving with constant acceleration. The left panel depicts the DSML, which includes physics-specific blocks, computational control flow blocks, and custom blocks that define the initialization and the simulation steps of the students' CMs. In order to program, students drag appropriate blocks from the left panel to the center model building space. When students run the simulation, they can observe the motion of the object on the stage located on the right side of the interface.

In C2STEM, a computational kinematics model consists of three parts (labeled in red in Figure 1). (1) When the green flag is clicked, the model sets the initial conditions of the motion (e.g., position, velocity, and acceleration of the object and the duration of the time step), then executes the simulation step. The simulation step then specifies (2) how the motion variables are updated with each time step iteration and (3) a stopping condition that determines when the simulation ends (e.g., when the position crosses a particular threshold).

Instructional design

The week-long unit used for this study was based on a longer unit designed to integrate physics and computational thinking practices and concepts across a semester of physics instruction on force and motion (Hutchins et al., 2020). The unit's design approach involved (1) unpacking the science and computational thinking disciplines to identify the key physics and CS constructs to be addressed in the instruction (2) developing integrated learning goals and corresponding evidence statements (describing students' proficiency with the learning goals) to establish coherent connections between physics and CT disciplines, and (3) developed curricular activities aligned with these evidence statements.

    stop simulation
```

Sprite time in s 12.65
Sprite x position in m 20.16375
Sprite x velocity in m/s 6.325

Because the length of the original unit precludes practical implementation for many high school physics teachers, we developed the single-week version (based on the original) used for the current study. We examine the KCM unit's feasibility and affordances for typical physics teachers who could devote a single week of instruction to integrating CT and participate in a modest amount of professional development prior to enactment. The unit sequence consisted of the following six activities:

- **Create a flipbook (Day 1).** Students create a paper flipbook animation and reflect on the experience to support their understanding of how the computational simulation represents motion.
- **Code comprehension (Day 1).** Students explore and manipulate the code of a simple CM of an object moving at constant velocity, with the goal of explaining the function of each coding block. Motion values are hard-coded rather than being expressed in terms of kinematics variables.
- **Model horizontal constant velocity (Day 2)**. Students develop a generalized CM of a truck moving at constant velocity, test the model, and use it to solve a series of simple kinematics problems.
- **Model horizontal constant acceleration (Day 3)**. Students augment the constant velocity model to model constant (non-zero) acceleration and use it to solve a series of horizontal constant acceleration problems.
- **Model vertical constant acceleration (freefall) (Day 4)**. Based on the previous model, students develop a model of a medical drone delivering a package to a target (vertical motion using acceleration due to gravity), then use the model to solve a series of freefall problems.
- **Model projectile (2-dimensional) motion (Day 5)**. Based on the previous models, students develop a model of 2-dimensional projectile motion and use it to solve a series of projectile problems.

Each modeling scenario was designed to build on code students developed previously. Each student worked in a paper and pencil packet that guided the modeling tasks using C2STEM. Each student worked at their own computer but was encouraged to collaborate with an elbow partner. Students worked through the activities at their own pace. We did not expect all students to complete all activities. We expected most students to complete the horizontal motion activities and many students to complete the freefall activity. In the Results section, we report on students' variation in their completion of the activities.

Methods

Participants and context

We conducted the study at a large public high school (approximately 3500 students) in the western United States. Most students were 16-18 years of age. More than 80% of the student population belongs to STEM underrepresented racial groups (Black, Latine) and 71% are reduced-price lunch eligible. All four of the school's physics teachers used the unit with all 16 of their mixed-ability physics classes, so each teacher taught 3-5 classes. One teacher had previous professional experience in programming and more than 5 years of science teaching experience. Another teacher (having more than 10 years of science teaching experience) advised the school's robotics club and had enacted a prior version of the KCM unit at their previous school. The other two teachers each had less than five years of teaching experience and no prior programming experience.

Teachers described the science and math achievement level of the students in these classes as wide ranging, remarking that some students struggled with mathematics required for physics problem solving, while other students chose not to enroll in the advanced physics class only because of scheduling conflicts. Teachers had high interest in using the unit because they wanted students to experience an innovative method for learning physics and to raise awareness of the role of computing in STEM careers. Prior to engaging in the unit, the teachers and students had already completed a standards-aligned course of study in kinematics addressing problem solving about motion with constant velocity and constant acceleration in one dimension (but not two dimensions). As such, this study examines the value added of the unit relative to typical kinematics instruction.

Teacher supports for implementation

We used four approaches to support teachers' classroom enactment of the KCM unit. (1) We developed daily lesson plans that guided teachers with a timeline for the activity, suggested discussion and reflection prompts, and ways to address anticipated student challenges. (2) We developed an annotated version of the student packet, including answers and descriptions of specific anticipated challenges or incorrect answers, to help teachers rapidly gauge their students' progress on the activities and inform subsequent classroom discussions. (3) Prior to implementation, we conducted a two-hour training session where we introduced the student materials and demonstrated the C2STEM environment, then supported teachers as they developed the kinematics CMs for each of the modeling activities. The teacher who had prior programming experience was not able to attend the training session, but worked independently on the CM tasks before classroom enactment. (4) During classroom enactment, a member of the research team modeled the teaching of each activity for the first one or two classes of the day, while the teacher observed and assumed a supportive role. For the remaining classes in each day, the teacher and researcher switched roles, with the teacher leading the activity with support from the researcher. Between classes, teachers and researchers had opportunities to debrief the activities, and in some cases teachers made adjustments to increase their comfort with pedagogy, leverage students' prior knowledge, or attend to classroom norms. Classroom enactment lasted five days for about one hour per day. Two of the teachers used the unit during the first week and the other two used it the following week.

Data sources

Pre/post assessment. We developed a pre/posttest with a physics subtest (max score = 16) and a CT subtest (max score = 13). Both subtests were based on the test used in a prior study (Hutchins et al., 2020). The physics subtest consisted of 5 task scenarios and 12 total items and addressed kinematics concepts involving constant velocity and constant acceleration in one and two dimensions. To measure learning resulting from CMs (which involves a discrete, rather than continuous, representation of motion corresponding to the time step), the tasks were designed to be able to be solved by using discrete motion representations (they did not require the use of kinematics equations typically taught in high school physics). The CT subtest consisted of 3 task scenarios and 9 total items and addressed the key programming concepts of variables, expressions, conditionals, and loops that needed to be used for students' CM development. Seven of the items were based in everyday contexts not related to motion. The remaining two items asked students to comprehend a simple block-based computational motion model. All CT tasks used either pseudocode or block-based programs using everyday language (and not Snap! Code) so that pre/post gains would not merely measure students' improved facility with Snap!. We administered the pretest and posttest to students the week prior and the week following the unit enactment, respectively. Pretest and posttests were identical except for changes in item order and superficial differences such as numeric values or names.

Student background questionnaire. Immediately following the pretest, students responded to a short questionnaire about their programming experience and mathematics coursework.

C2STEM process data. The C2STEM environment logged students' actions during the CM activities. We retrieved logs from 271 participating students. Our analysis focused on (1) the total number of actions students performed; (2) the number of play actions, which indicates the number of times students ran their models; and (3) the number of non-play actions performed, which includes model building actions such as assigning values to variables, adding coding blocks, and moving coding blocks.

Student artifacts. We collected the paper and pencil packets that students completed individually.

Classroom observations. We developed a classroom observation protocol documenting shifts in classroom activities, the quality of student participation and engagement, and episodes of teacher questioning. At least one researcher who was not leading or supporting classroom instruction documented observations in each class for each teacher. We documented whether each class was led by a researcher or the classroom teacher.

Teacher interviews. After teachers finished enacting the KCM unit, we conducted semi-structured interviews with three of the four participating teachers. The interview focused on teachers' perceptions of student engagement, successes and challenges, and what the teachers learned from the experience.

Scoring and analyses

Three researchers collectively scored 280 students' pretests and posttests. The researchers were trained using responses from 20 students' pre-and posttests. Then, more than 20% of responses were scored by two researchers each and interrater agreement computed. Once 80% agreement was achieved on 20% of the responses, the remaining responses were each scored by one of the three researchers. Scoring discrepancies were resolved by discussion. To examine learning gains, we conducted paired t-tests on the physics and CT tests separately. We conducted multiple regression analyses predicting posttest scores and pre/post gains to identify predictive factors for learning. We analyzed students' actions for each CM activity they completed, computing total actions, play actions, non-play actions, and the ratio of non-play to play actions for each student for each activity. Finally, we illustrate our conjectures about students' learning processes and their posttest performance using descriptive vignettes based on two students' pre/posttest responses and logs of their CM activities.

Results

Unit feasibility and student engagement

The unit was enacted as intended, without any technology issues. Students exhibited variation in their completion of the activities. Based on the C2STEM logs, 264 students engaged in the horizontal constant acceleration modeling activity, 149 students engaged in the freefall modeling activity, and just 33 students engaged in the projectiles modeling activity. The variation in activity completion was consistent with expectations, based on teachers' descriptions of student variation in ability level. During the unit, we generally observed students to be highly engaged with the activities, and their engagement increased as they progressed and gained familiarity with the nature of CMs and features of C2STEM. Teachers noted that students' engagement was high, relative to their typical instructional activities. One teacher described a student who "never did anything" during typical classes but was highly engaged throughout the unit enactment. Another student told us that they were highly motivated to complete the tasks because they believed the experience would support their future university studies in STEM.

Pretest-posttest performance

Overall, students exhibited small but significant pretest to posttest gains on both the physics [M(pre)=7.0, SD=2.2; M(post)=7.3, SD=2.3; t=2.7, df=279, $p<0.01$; d=0.13] and the CT tests [M(pre)=4.8, SD=2.1; M(post)=5.5, SD=2.4; t=5.7, df=279, $p<0.001$; d=0.31]. Further, performing a median split and comparing gains of low pretest students with high pretest students shows that the gains were considerably higher for low-pretest students (effect sizes of 0.6 and 0.8 for physics and CT respectively). These gains indicate that the unit had added value for students, especially for those with low prior knowledge in physics and CT, even after completing a typical course of study on kinematics based on algebraic problem-solving methods and hands-on lab activities. This finding is consistent with the idea that low prior knowledge students had more room for improvement, especially on CT concepts, which would have been more familiar to students with prior programming experience.

We conducted t-tests comparing outcomes of students in researcher-led classes to teacher-led classes. These analyses did not reveal significant differences in pre/post gains between these groups, indicating that the participating teachers were able to feasibly enact the unit after participating in the training session and observing researchers teaching earlier in the day. We also conducted a multiple regression analysis to relate students' posttest scores to the extent of their unit completion (based on students' completion of the paper packets). We found significant, positive relationships between students' unit completion and their physics ($p<.01$) and CT ($p<.05$) posttest scores, controlling for students' pretest scores. This finding indicates that students' posttest performance and unit completion were not mediated only by students' prior knowledge level, providing evidence that students' engagement in the CM tasks had impacts on their learning in both physics and CT.

To further illustrate learning approaches that might have resulted in these gains, we describe two illustrative student vignettes: "Chris", who scored above median on both the physics and CT pre-tests but made modest pre/post gains on each subtest, and "Sam", who scored below median on both the physics and CT pre-tests and made relatively large gains on each subtest.

Illustrative vignette 1: Chris (high pretest scores, high posttest scores)

Over the course of the KCM unit, Chris developed CMs for all four modeling activities in the unit. On the background questionnaire, Chris reported "a little" prior experience with programming and a relatively strong background in mathematics, having enrolled in pre-calculus and statistics. Chris made a modest improvement on the physics subtest, from 9.5 to 11. Most of the gain was a result of improved performance on the item asking students to compare the motion of two projectiles moving in two dimensions. This improvement is consistent with

Chris being one of just 33 students who engaged in the projectile modeling activity. The students in this study did not learn about 2-dimensional motion in their previous instruction because the topic is not included in the state standards, so Chris' improvement is likely a result of their engagement with the modeling task.

Chris also improved from 8 to 11 on the CT subtest. All of their CT pre/post improvement was from improvement on items assessing the CT concept of conditionals (students had to write expressions representing conditions for ending and for winning a computer game). Chris earned zero points on these pretest items and three points on these posttest items. The improvement on these items is consistent with Chris' CM activity (as illustrated in more detail below).

Our analysis of Chris' modeling activities based on the log files reveal that their non-play to play ratio for the final modeling activity was 5.89, much higher than their non-play to play ratios for the constant acceleration activity (3.96) and the freefall activity (2.85). This trend illustrates how Chris made a smaller number of changes to the code between tests for most of the activities, but made more changes to the code between tests in the final activity, reflecting increased comfort with C2STEM and CMs.

Figure 2 shows Chris' CMs for the constant velocity and constant acceleration activities. Both models correctly simulate the motion specified for the respective tasks, including appropriate initial values, kinematics relations, and stopping conditions. The constant acceleration model (Figure 2b) includes unused programming blocks (outlined in red) that illustrate how Chris attended specifically to the stopping condition reflecting the change in direction relative to the previous motion scenario. Specifically, the value of "5" in the unused block illustrates how Chris previously tested the model using the incorrect conditional expression, then replaced the incorrect condition (position > 5) with the correct one (position < 5). This episode of debugging the model is consistent with Chris' pretest to posttest improvement on the CT items related to conditionals.

Figure 2

Chris' (a) constant velocity model and (b) constant acceleration model. Note: A non-numerical value of Δt (which appears in the model on the right) is assigned by the environment to a default numerical value.

  stop simulation

<[ ] > [5]>
if < >
```

(b)

Illustrative vignette 2: Sam (low pretest scores, high posttest scores)

Over the course of the KCM unit, Sam developed CMs for only two of the four modeling activities, both addressing horizontal one-dimensional motion. On the background questionnaire, Sam reported no prior experience with programming and a modest background in mathematics, having enrolled in coursework up to only advanced algebra. Sam made a large pre/post improvement on the physics subtest, from 5.5 to 9.5. Two of Sam's four point pre/post gain was a result of their improvement on an item asking students to solve a kinematics problem involving velocity, acceleration, and time; Sam was unable to solve it on the pretest, then solved it correctly on the posttest. The assessment task reflected the same type of motion (one-dimensional, constant acceleration) that Sam engaged with for most of their time studying the KCM unit. Sam also made a large improvement on the CT subtest, from 4 to 7.5. The entire 3.5 point gain was a result of improvement on assessment items addressing the concept of iteration. (Students were asked to predict the output of block-based programs containing a "repeat" block.) Sam's large improvements on both the physics and CT subtests is promising, illustrating that engaging with the KCM unit appears to promote learning in both disciplines for students with low prior knowledge, even if they were not able to complete all the curricular activities.

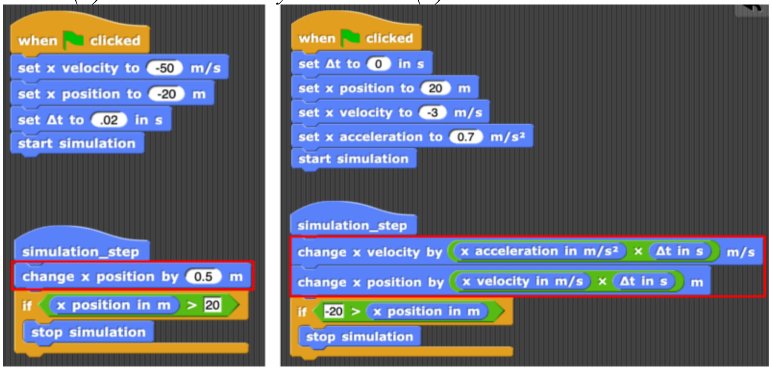
Our analysis of Sam's modeling activities reveal that they worked deliberately on the one-dimensional accelerated modeling scenarios. Sam conducted a high number of total actions on the constant acceleration task

(313 actions, 82nd percentile). Sam also performed just 2.26 non-play actions per play action (10th percentile), indicating an approach involving frequent testing. The mean ratio of non-play actions to play actions on this modeling task was 5.04, so Sam tested their model with more than double the frequency of the typical student.

Figure 3 shows Sam's CMs for the constant velocity and constant acceleration tasks. In Figure 3(a), Sam has "hard coded" a specific value of position change in the simulation step (outlined in red), rather than specifying a kinematic expression involving the velocity variable. As a result, Sam would have observed through testing that changing the velocity value would have no impact on the truck's simulated velocity, and this model could not be used to solve a different problem involving a different initial velocity. We observed this error to be relatively common among students in the initial stages of modeling. In Figure 3(b), Sam subsequently improved the coding of the simulation step by expressing the velocity and position changes in terms of the acceleration and velocity values, respectively, so these variables are updated with each iteration of the simulation step (outlined in red). This improvement of the model is consistent with the nature of Sam's pre/post improvements on both the CT test (iteration) and the physics test (accelerated motion in one dimension). Although Sam was not able to achieve a completely correct model for this particular modeling scenario, we conjecture that these modeling experiences—involving model development, testing, and debugging—contributed to the corresponding improvements on the physics and CT pre/post assessments.

Figure 3

Sam's (a) constant velocity model and (b) constant acceleration model.



```
when clicked
set x velocity to -50 m/s
set x position to -20 m
set Δt to .02 in s
start simulation

simulation_step
change x position by 0.5 m
if x position in m > 20
  stop simulation
```

```
when clicked
set Δt to 0 in s
set x position to 20 m
set x velocity to -3 m/s
set x acceleration to 0.7 m/s²
start simulation

simulation_step
change x velocity by x acceleration in m/s² × Δt in s m/s
change x position by x velocity in m/s × Δt in s m
if -20 > x position in m
  stop simulation
```

(a) (b)

Note. A zero value of Δt (which appears in the model on the right) is assigned by the environment to a default non-zero value.

Discussion and implications

Our study provides evidence of the promise of effectiveness and classroom feasibility of the KCM unit. Four teachers (only one of whom had a programming background) implemented the unit effectively in a single week after receiving a modest amount of training. Our study population included many students from historically excluded STEM groups and with no prior experience in programming, but students were still able to demonstrate significant pre/post gains in both physics and CT, with low prior knowledge students demonstrating the highest gains. The study addresses gaps in the research literature related to the effectiveness of integrated science and CM instruction in typical instructional contexts and with typical teachers.

We offer several conjectures for the successful outcomes we observed. First, implementing the unit following students' typical kinematics instruction likely facilitated their learning of the programming concepts because students did not have to contend with new science and programming concepts simultaneously. Second, we designed the unit to minimize the amount of time students would need to spend learning and implementing programming constructs by employing the DSML and by designing a sequence of modeling activities that each builds on code from the previous activity. Our study adds to the existing body of research that illustrate the benefits of domain-specific modeling constructs for science learning (e.g., Hutchins et al., 2020; Basu et al., 2016; Wilkerson et al., 2015) and testing and debugging computational models (Shin et al., 2021). Third, the KCM unit included two distinctive features that might have uniquely supported students with understanding the nature of the CMs. The flipbook activity provided a tangible representation of the motion simulation and the Δt variable, which was observed as a challenge in previous studies with C2STEM (e.g., Hutchins et al., 2020). In addition, the code comprehension activity, which was anchored to a kinematics context, replaced a previous programming activity intended to introduce programming constructs in a familiar geometrical context for students lacking prior knowledge of kinematics. Because our students had already received some instruction in kinematics, our activity might have more efficiently helped students develop an understanding of the domain specific blocks and further clarified the nature of the Δt variable.

Finally, we discuss implications for classroom enactment. Our participating teachers uniformly found observing researchers enacting instructional approaches to be helpful, consistent with established teacher professional learning models in computer science (e.g., Goode et al., 2014). Teachers were even able (and eager) to make in-the-moment pedagogical adjustments to researchers' teaching practices based on their shared prior experiences with students. In interviews, teachers pointed to numerous benefits of CMs relative to their typical instruction. These benefits included the ability to engage students who were unengaged by typical instructional approaches, the authenticity of students creating their own artifacts, and the autonomy students had in working through the modeling tasks. Teachers also noted that there would have been a greater return on their investment in teaching CMs if they were to teach a subsequent CM unit on another topic, because students would have already gained familiarity with C2STEM and the nature of CMs. Despite initially being willing to use C2STEM for only a single week, the teachers were open to the idea of implementing another unit later in the year once they had implemented the KCM unit. These insights illustrate the potential for short CM units to constitute a low risk, high reward opportunity for science teachers to try out computational approaches.

Expanding What Counts as Scientific Investigations in the Era of the Next Generation Science Standards

Abstract: Science education reforms advance an epistemology of investigation as hypothesis-driven tests of theory. We argue that this is a narrowly drawn image of investigation that leads to lost opportunities for learning and teaching science. These include opportunities to develop an investigator's skills and conceptual understandings and situate investigatory practices within a broader scientific epistemology. This study portrays examples of the day-to-day investigations involved in a non-laboratory, scientific workplace: a neighborhood coffee roastery. Through microethnographic analyses we show that professional coffee roasters accomplish the same goals that science education reforms seek to achieve, and that these goals take different forms. We argue that coffee roasters' uses of investigatory practices toward non-laboratory, everyday ends expand our views of what counts as scientific investigations in the current era of reform.

Introduction

Science education reforms advance an epistemology of investigation as hypothesis-driven tests of theory (National Research Council, 2012). We will argue that this is a narrowly drawn image of investigation that leads to lost opportunities for learning and teaching science. First, an emphasis of investigation (in the NRC's terms, encompassing what is conventionally called experimentation) as theory testing minimizes the role of human agency in scientific knowledge production (Gooding, 1990), implying a view that theories, not humans, motivate scientific action (Radder, 2009). Second, investigations allow for the co-development of embodied investigatory skill and conceptual development (Maslen & Hayes, 2022) which are erased by theory-testing perspectives. Lastly, researchers have paid less attention to the interdependence of investigation and related scientific practices (e.g., modeling) in the practice turn era (Ford & Forman, 2006; Manz et al., 2020). Rather than a central driver within a broader scientific epistemology, reform documents treat investigation as a process to *confirm* existing theories and demonstrate content understanding (Hodson, 2014). There is thus a need to better understand *in situ* practices of investigation and their relevance to the current era of science education reform.

Our choice of "in situ" practices requires elaboration. First, ethnographers of science have long argued that leading images of scientific activity are partial and distorted. These images "have been culled from interviews with eminent ex-scientists or from other public pronouncements about the nature of science" (Woolgar, 1988, p. 86) and advance reconstructions of science as methodical, systematic and the logical outcome of linear scientific procedures. Ethnographic field studies of science involving the *in situ* observation of scientific activity reveal less linear and logical and far more social ways of scientific knowledge production (e.g., Latour & Woolgar, 1987). Such ethnographies make visible the embodied, material, and social ways of working ("practices") which are often written out of publications (Gooding, 1990). Second, we argue that scientific practices are not limited to the actions of professional scientists (Conner, 2005; Secord, 1998; Shapin, 2012) and that a broader view of investigation from other settings can recover the rich diversity of science in our lives. To expand our imagery, we advance findings from a multisite, ongoing project that examines the people, practices, and cultures of *non-laboratory, scientific workplaces*. We argue that this approach, and similar examinations of scientific activity outside of the laboratory, can reshape our views of how and why science is conducted, and ultimately can and should impact the ways that science is taught and learned in schools. Our objective in this paper is to portray examples of the day-to-day investigations involved in a non-laboratory, scientific workplace. Our program of work begins here with the practices of investigation enacted by professional coffee roasters.

This paper's theoretical frame for investigation comes from the National Research Council's *A Framework for K-12 Science Education* (2012). The consensus report reads, "Scientists and engineers investigate and observe the world with essentially two goals: (1) to systematically describe the world and (2) to develop and test theories and explanations of how the world works" (p. 59). Ethnographies of science, on the other hand, show that scientists investigate for goals beyond these two (cf. Knorr-Cetina, 1981; Lynch, 1985; Woolgar, 1988) and some philosophers of science view theory-testing as actually hindering scientific advancements (e.g., Feyerabend, 1975). Additional goals of investigation include scientists' attempts to simply "make things work" (Knorr-Cetina, 1984) and develop their own experimental skill (Gooding, 1992). However, and because we wish to locate our work inside ongoing reform conversations, we adopt the NRC's language.

In the following sections we will view coffee roasters' practices through a lens of Planning and Carrying Out Investigations, the third of eight Science and Engineering Practices offered by the *Framework* (NGSS Lead States, 2013). All K-12 learners, according to the *Framework*, should be able to do these seven things as part of investigations by graduation: (1) formulate questions (2) and theory-based hypotheses, decide on (3) tools, the (4) type of data, and (5) amount of data, and plan a procedure that (6) identifies variables and (7) controls (NRC, 2012, p. 60).

There are strong competing images of *what* science *is*, and we do not seek to add fuel to those ongoing debates. As such, in this paper, we do not argue that coffee roasting *is* science. Rather, we argue that *all* of the NRC's goals of investigation are involved in coffee roasting. The former is an intractable philosophical debate that distracts from the broader aims of our project: to expand our scientific imagery toward re-imaginations of science education. The latter is not a question of philosophy primarily, but one of empirical evidence.

In this paper we empirically demonstrate one roaster’s application of the goals as he develops a new coffee product. Through our analyses we will show that the science *in* coffee roasting has implications which extend beyond new perspectives of investigatory practices. For example, the scientific practices in roasting demonstrate the real-world value of scientific knowledge and know-how—answering questions teachers routinely get and often dread, such as, “When will I ever need to know this?” More broadly, presenting cases of scientific knowledge and practices of *non-laboratory work* connects with the *Framework’s* "goals [that] are for all students, not just those who pursue careers in science, engineering, or technology or those who continue on to higher education" (p. 9). The practices involved in coffee roasting thus speak to a vision of science education for *all* learners, and especially those roughly 90% of American K-12 students (NSF, 2022) who do not pursue normatively recognized science careers.

Methods: Research context

The principal roastery in this paper is in a small Midwestern college town. Sam and Mimi operate an 800-square-foot roastery as a “community-oriented coffee company.” This sentiment is reflected in the roastery’s neighborhood location and literal opened doors, through which customers often visit to fill their reusable coffee bean containers, or to join weekend “sensory evaluation” education experiences. Sam contrasts this community feeling with prior employment as a “production roaster” at large-scale, “soulless,” industrial coffee roastery. Sam roasts 180 pounds of coffee three days a week (MWF) and Mimi handles the business’ logistics to serve its coffee houses, numerous wholesale accounts, and online orders. On the weekends they attend farmers’ markets to interact with the public and teach various beginning-to-advanced coffee tasting and roasting courses. On Tuesdays and Thursdays, Sam and Mimi travel to establish new accounts and experiment with new coffee products and services, such as the day's sample roasting of a new coffee from Peru.

Methods: Data collection and analysis

We began participant observation (Becker & Geer, 1957) with Sam and Mimi in May, 2022. We have since participated alongside and observed Sam and Mimi during roasting sessions, sensory evaluations, barista trainings, and coffee classes. This paper draws from a broader data corpus that consists of audiovisual data (Erickson, 2006), semi-structured and photo-/video-elicitation interviews (Harper, 2002), as well as field notes, jottings, memos, and annotated photographs (Emerson et al., 2011). In combination with participant observations at additional roasteries, these sources represent roughly 200 hours and 250 pages of data. In this paper we present microethnographic analyses (Streeck & Mehus, 2005; Stevens & Hall, 1998; Hall & Stevens, 2015) of Sam’s investigatory practices recorded on video over the course of an afternoon. What was captured during this afternoon is representative of what we see in the broader data corpus. These analyses include Sam’s non-verbal actions, verbal explanations of his actions, and our interpretations of how these actions allow for the completion of his work. Lastly, Sam reviewed our findings and incorporated his insights when possible.

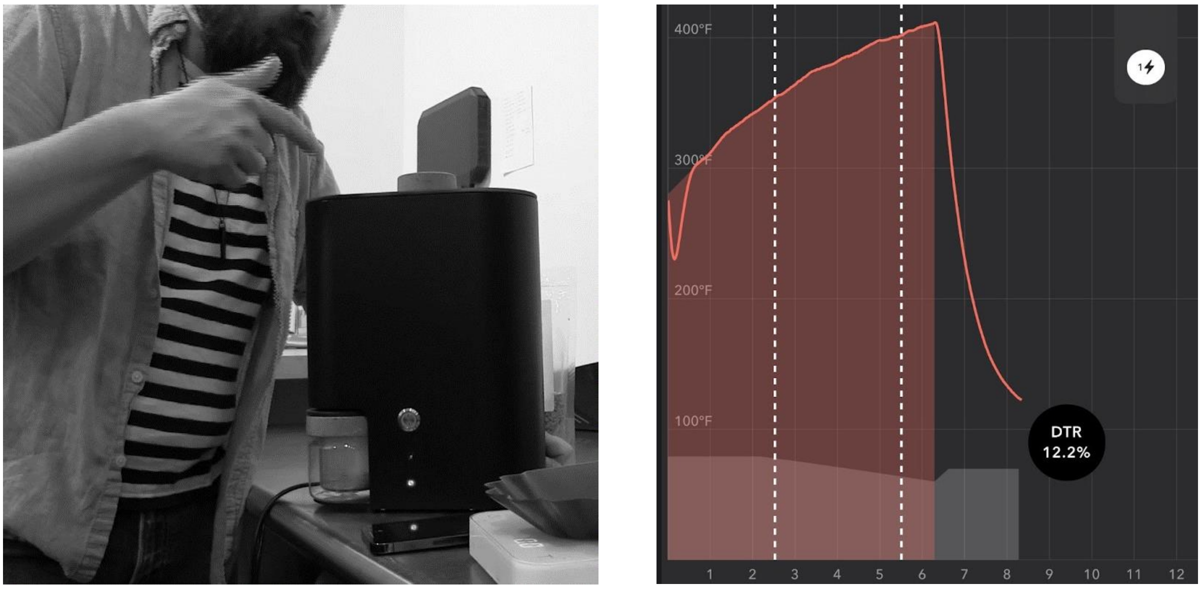
Findings: Sample roasting

The investigation we explore is a sample roasting session, and a brief introduction is needed. Sam’s raw, green coffee ranges from $4 to $7 per pound and he buys beans in thousand-pound shipments. The unknown quality and characteristics of the raw coffee makes each purchase something of a gamble. To minimize risks, Sam sources 300-gram samples from coffee importers, develops various "roasting profiles," performs sensory evaluations by smelling and tasting the coffee, and ultimately decides to purchase it in bulk or not. Sam invited us to observe sample roasting so that we could understand the entire scope of his workflow: from sample roasting and purchasing, to fine-tuning “retail roasts,” educating the company’s baristas, and selling the coffee. The data below are drawn from a sample roasting session which Sam described as “literally the very first step” in his process. The machine that Sam uses in his daily operations is a 26-pound capacity IR-12 Diedrich and is thus too large for sample roasting. Instead, Sam uses a 50-gram PRO50 Ikawa sample roaster (Figure 1, left). Sam's down-scaling of tools resembles microscale investigations in laboratories:

> Which is why it's nice using the Ikawa. You can try multiple things and you're using only 50 grams per batch. Where if I wanted to have that experimentation on the Diedrich I'd have to use 60 pounds for three different sample roasts. And that's expensive for me, and importers, and farmers.

Figure 1

Sam's Ikawa Roasting Machine (left) and "Roasting Profile" (right).



The sample roasting session (hereafter "investigation") is motivated by Sam's concern that his existing "lineup is really small compared to most roasters." The roastery's four coffees don't meet consumers' wide-ranging expectations. To fix this, Sam wants to create a rotating blend. "My goal is...a roaster's blend...like a rotating blend that we just come up with here. We probably won't even put the origin on the bag...So people always know it's a rotating blend." Expectations has two meanings here. The first is what a roastery is expected to offer in terms of coffee varieties; the second is an alignment between consumers' and roasters' sensory expectations. The latter informs many of Sam's practices:

> This is a coffee, that, if I do like it, I'll probably buy it to create a new blend for [current company]. It'll be a mixture of this Peru and a, hopefully, Burundi. I'm starting with a Peru and a Burundi, something that I did with [previous company] back in the day. I was just spitballing, and I was bored, and I blended these two coffees together and it was just ((gestures with hands)) delightful. It was so good. You know. You get the nuttiness and caramels of a Peru, and you get those higher acids, little bit of a tea and herbal thing from the Burundi. It was so nice. I called it Perundi ((laughter)). Yeah, it worked out pretty well.

With a *question* to guide his work (SEP3 goal 1), "What's the best way to roast this Peru?", Sam plans a *procedure* (SEP3 goals 6 and 7). A procedure in coffee roasting takes the form of a "roasting profile" (Figure 1, right). Profiles are sets of time and temperature values that roasters design for each individual coffee. As another roaster in our study has said, "Each coffee demands something different. It's like they have their own personality." For Sam, roasting profiles are graphical representations of these time and temperature values (Figure 1) and he annotates these graphs with crucial decisions made while roasting. Sam's annotations allow for an iterative process with the ideal procedure becoming the final "standard profile" (see Gloess et al., 2014 for laboratory investigations of roasting profiles). Sam begins by selecting a procedure from Ikawa's online repository. To refine his search, Sam looks for a profile for Peruvian coffees, "I know we've had a Peru before.

I'll do a couple roasts of this. The first one I'll do [is] a standard, ‘oh if you don't know anything about this coffee, this is a good starting point.’” Sam is unable to find a profile for Peruvian coffees in Ikawa’s database. Instead, he selects one from a trusted source, coffee consultant Rob Hoos, who has uploaded his procedures to Ikawa. “The point of this roast, according to Rob, is...to emulate...a real time roast that would have all your sets of drying, browning, and development.”

Sam has chosen his *tools* for this initial investigation (SEP3 goal 3). Moreover, we view his decisions to use the smaller-scale Ikawa and a roasting profile from coffee consultant Rob Hoos as framing a *theory-based hypothesis* (SEP3 goal 2) in ways that move beyond the NRC’s goals. Sam does not simply think about what kind and how much data to collect. Rather, his first strategy, selecting a profile and roasting a coffee based on its origin, requires discipline-specific knowledge of coffees that originate from the same country. This is what historians and philosophers of science term *theoretical presuppositions*: “Such commitments cannot *all* be optional, nor can they be treated as if they were distorting ‘biases.’ Rather they are the sine qua non of beginning an experiment—as well as ending it” (emphasis in original, Galison, 1987, p. 4). Sam’s second strategy, selecting a profile based on someone else's expertise, indicates trust in the broader organization of shared disciplinary knowledge—a phenomenon some ethnographers of science call “epistemic cultures” (Knorr-Cetina, 1999). Both decisions display a continuum of knowledge and trust of competence that pervade the discipline of coffee roasting. Sam’s reliance on prior knowledge and a community of practitioners as entry points into his investigation underscore reasons for investigation beyond theory testing (Radder, 2009). For instance, Sam’s work highlights the role of human agency in experimentation (Gooding, 1992) as a way to “make things work” (Knorr-Cetina, 1984). To summarize Sam’s investigation so far: he is driven to re-create the Peru’s “nuttiness and caramels”; has chosen appropriate materials (the Ikawa rather than the Diedrich; SEP3 goal 3); and decided on a procedure (Rob Hoos’ roasting profile). Sam’s choice of profile reveals the relevant types of data (SEP3 goal 4) he requires in this investigation, such as quantitative time and temperature data, as well as qualitative data of the Peru’s “drying, browning, and development” (Folmer et al., 2017).

Sam not only *identifies relevant data* (SEP3 goal 4) but integrates these into a broader investigatory repertoire involving his senses. Roughly six minutes into the nine-minute roast, he leans into the Ikawa, places his left ear above the machine's roasting chamber, and says, “I'm gonna try to listen for first crack.” As the liquid water inside the Peruvian beans begins to boil, transition into gas and expand, the beans become visibly larger and crack open like popcorn. The relationship between temperature and “first crack”, as detected by Sam's sense of sound, is important to future roasts with the Peru: “You want to be able to taste all the nuance of the coffee. That will give you an idea of, [should I] take this a little darker and give it more body?” First crack is thus a reference point that Sam must establish in his aim to highlight the Peru’s characteristics. Sam does not want to roast beyond first crack as that would impart smells and tastes from the roasting process, thereby masking the qualities inherent only in the beans. Once he knows the Peru’s first crack temperature, he can adjust parameters to optimize different characteristics in the coffee. Discerning first crack is not easy: “I heard one little pop. That's what I call a ghost pop. I'm gonna wait until we hear a really consistent ((interrupts statement to listen in silence)).” Seconds later, Sam annotates the graph with what he believes to be first crack (white lines in Figure 2), thereby producing a piece of knowledge in the multi-step process of developing a new rotating blend. The ambiguity of first crack is not a result of Sam’s senses, but rather chemical reactions’ stochasticity. All roasters in our study note that few roasts behave identically, even those with seemingly identical beans. In this episode Sam identifies sound as *data type relevant* to his investigation (SEP3 goal 4) and his pausing for more sounds identifies a *relevant amount of data* required in his investigation (SEP3 goal 5).

Sam’s sensory discernment (Goodwin, 1994) of first crack resembles many scientific practices in the face of nature’s recalcitrance (Gooding, 1992). For example, these practices are found in Goodwin’s case study of geochemists (Goodwin, 1997) who use their senses to determine when a chemical reaction should be terminated. For Sam, the variability in roasts causes ambiguity in first crack and leads to abundant evidence that he is exercising his human agency: hesitation, uncertainty, finer discernment, and subsequent identification. Sam’s practices so far seem to challenge images of scientific activity that advance accounts of objective, meticulous adherence to rigidly followed procedures. However, this “is another artifact of the disembodied, reconstructed character of retrospective accounts [of scientific activity]” (Gooding, 1992, p. 68).

Sam revises his procedure in light of new data. To do this, he inspects the roast’s time and temperature data and analyzes what roasters call the rate of rise: the average rate of change in temperature computed over 30 second intervals. Sam notices that the rate of rise headed toward a negative value. On a previous day he said, “When we're getting close to the end ((points at computer monitor)) you don't want this number, your rate of rise, to drop below 0.” A negative rate of rise, according to Sam, means that “essentially nothing is happening. There's no activity going on...there's less reactions happening because of the low energy.” In this sample roast, Sam interprets the negative rate of rise to mean that the profile was probably not meant for a Peru: “That's one thing I noticed about Rob's profile is that the rate of rise dipped into the negatives there ((points at graph; Figure 2, left)). So I think that could have potentially stalled this coffee and maybe on a different coffee that rate of rise wouldn't have dipped...Maybe an Ethiopian?" Sam interprets data (time, temperature, sound, rate of rise; SEP3 goal 4) and creates new knowledge: the Peru requires a changed profile for a positive rate of rise.

Revising investigations in light of new evidence is notably missing from the NRC's seven goals. We suggested that too narrowly drawn images of investigation lead to lost opportunities for teaching and learning science. This is one such opportunity. Revising investigations based on new evidence is a hallmark of scientific practice (e.g., Gooding, 1990) and is argued to be a causal mechanism underpinning revolutions in scientific theories (Kuhn, 1970). However, Sam demonstrates that revising investigations has utility and meanings in addition to theory testing. For instance, Sam's revisions are made possible by his investigatory skill—in particular, his sense of hearing and identification of first crack. Second, Sam ties his revisions to conceptual understandings, exhibited by his analyses of the roast's rate of rise ("There's no activity going on...there's less reactions happening because of the low energy"). Related, Sam's revisions are dependent on his analyses, showcasing an interdependence of practices that is underdeveloped in the NGSS era (Manz et al., 2020).

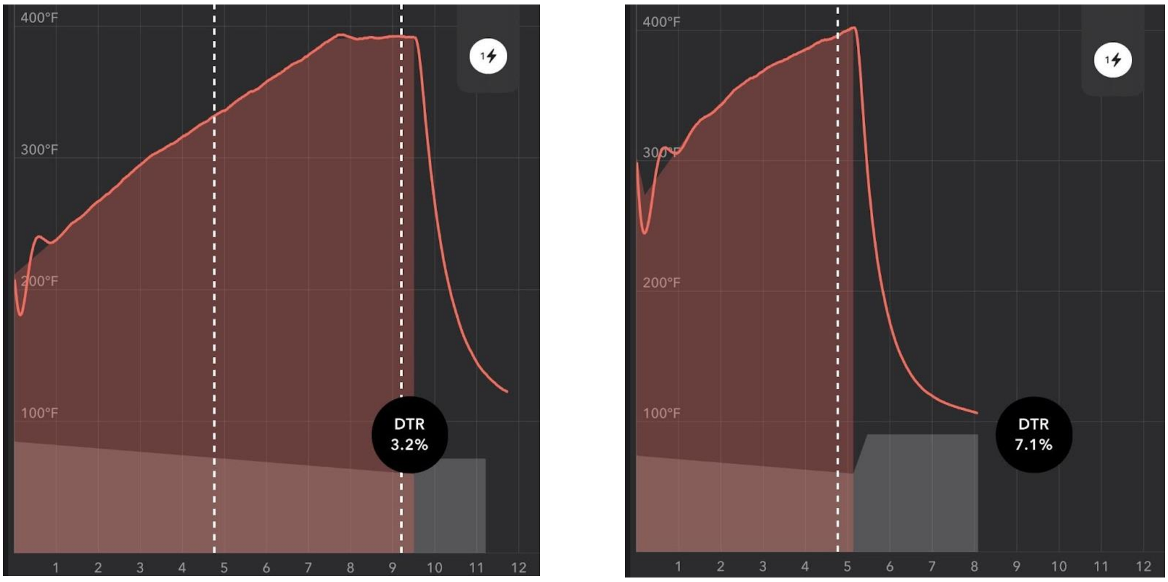
Sam's "Maybe an Ethiopian?" displays the tacit knowledge he has developed from years of roasting. This knowledge "is as much an art of doing as it is an art of knowing" and has long "remained unspecifiable at the very heart of science" (Polanyi, 1962, p. 56). While not a goal of SEP3, Sam's sensory discernment between "ghost pops" and "consistent" first cracks, analysis of rate of rise, and ability to integrate these toward revisions to his procedures underscore the role of knowledge and skill in investigations. One wonders how the disembodied goals of SEP3 (asking questions, identifying data and variables, and so on) are differentially achieved by an investigator's ability *and* desire to answer those questions and identify those data. More broadly, Sam's investigatory practices cause us to re-ask the question of how human skill impacts the quality and quantity of data that can be collected, and how human skill impacts subsequent revisions to investigations. Further, these data and revisions are made possible by Sam's skills *and* interest and promote conceptual development that are core outcomes of school science investigations (Hodson, 2014).

We observed interdependence between Sam's investigatory skills and his conceptual understandings. During his post-roast analyses Sam pauses and says, "...honestly, before I started doing this I should have…tested the density of this coffee and the moisture content…I'll do that on another day. I'll test everything first and really hone in on what I think will be a good profile for it [the Peru]." These data (SEP3 goal 3), according to Sam's theory of roasting, impact a roast's "charge temperature" (SEP3 goal 6: identification of variables). Sam says that "the more dense something is, the higher temperature it can withstand." Thus, if this Peru is more dense than the coffee Rob Hoos developed his profile for, then Sam has to adjust the initial temperature of the roast: "If this was a tiny little peaberry [a type of coffee bean], that's super tightly densely packed, it's gonna need more heat, more energy, to penetrate the bean. So, yeah. It will tell me the starting point of the coffee." Laboratory studies confirm Sam's comments about density and moisture content affecting a roast's heat distribution, and likewise recommend changes to charge temperatures to maintain consistency (Ogunjirin et al., 2020). Sam did not measure the density or moisture content of this Peruvian coffee, despite articulating that he should have and will in the future. This once again highlights the methodological necessity to observe scientific activity as it unfolds and restore what is often written out of narrative reconstructions (Gooding, 1990) and other influential images of science.

Sam produced new knowledge about how to roast Peruvian coffees, learned from his post-roast analysis, and revised his procedure in response. "My goal is to add more temp on there" to "get a nice rolling crack for this coffee." Sam's revisions allow him to compare roast #1 with roast #2 (SEP3 goal 5) and experience all of the Peru's nuance in a tasting session that will follow (SEP3 goal 4). To add more temperature to the roast, Sam literally clicks and drags the end point of the time-temperature graph in the Ikawa app (Figure 2). A higher temperature means that oils and related organic molecules in the beans will undergo additional chemical reactions and produce a wider range of flavors, and that already-ongoing reactions will occur at a greater rate and over a longer period of time (for an overview of the organic chemistry of roasting see Folmer et al., 2017). Sam makes his new knowledge and revisions explicit:

> So what I want to do with that info is…I want...a profile now that goes a little bit deeper into the roast. Shorter, but higher end temp. The end temp on this one was only 394[°F]. So, I don't think it really had enough energy to really get a nice first crack going…I think it will still give me a good idea of the potential that this coffee has. So, I'm gonna go edit ((clicks edit)) and I can adjust the curve here ((drags curve on Ikawa app)). My goal is to add more temp on there. So I'm just gonna [drag it up]. There we go...And now we're gonna try this one out ((laughs)) and see.

Figure 2
Sam's first profile from Rob Hoos (left) and the revised profile (right). Sam shortened the roast time from 9:31 to 5:08, increased the charge temperature from 210°F to 302°F, and raised the target end temperature from 392°F to 403°F. The revisions resulted in greater development time ratio (DTR) by 3.9% (from 3.2 to 7.1).



Sam's revisions provide a snapshot of investigation in a longer arc of work, revealing interdependencies between practices of investigation and interpretation (Manz et al., 2020). Here, he analyzes data from roast #1 to make sense of roast #2: "...we started getting ghost pops on that last round around 392[°F]. Right now we're at 391. ((leans in and listens)). And we have a lot more energy right now than we had in the last roast." Sam demonstrates this arc as the Ikawa reaches its target end temperature and begins to cool down: "There we go. So it was subtle, but it was definitely ((gestures with hands)), I could hear a little bit more activity going on. It [rate of rise] definitely didn't go negative, so, I'm expecting more vibrancy out of this roast." Sam's next steps involve the integration of sensory data with time and temperature data. These analyzes will allow Sam to confirm his claim that the second roast will be more "vibrant" than the first. Sam will do this by smelling and tasting the coffee: "I'm saving the remainder of the green for after cupping [tasting] these so I can make some adjustments as needed." With the information from a sensory evaluation, Sam will carry out more sample roasts and ultimately decide if this Peru fits his vision for the roastery's first rotating blend.

We next demonstrate how Sam *uses controls* in his investigations (SEP3 goal 7). Roughly 30 minutes after the episode above, Sam and the first author carried out a sensory evaluation by tasting coffees. During that tasting, the first author asked Sam, "How does cupping impact your roasting practices?" He responded:

> So, I think, you know, especially with this Guatemala [a coffee Sam has been experimenting with for two months], I think it's a great example. You know, I would say, only changing one thing at a time. Having controls. And, you know, not changing too much. I really want to make this ((points at graph)) basically the exact same except for bringing up my energy here ((moves finger to right)). So that's the one change I'm making, just so I can ensure that change is accurate. You know. I don't want to make too many changes and say, 'Well, what was the real cause for this?' So, just having those controls there. Yeah, I think that's the big thing.

Table 1
Summary of Sam's Demonstration of the Seven SEP3 Goals

SEP3 Goal	Selected Evidence
1: Questions	"What's the best way to roast this Peru?"
2: Hypotheses	"Oh if you don't know anything about this coffee, this is a good starting point."

3: Tools	"Which is why it's nice using the Ikawa. You can try multiple things and you're using only 50 grams per batch. Where if I wanted to have that experimentation on the Diedrich I'd have to use 60 pounds for three different sample roasts."
4: Data Types	"I should have…tested the density of this coffee and the moisture content"
5: Data Amounts	"I'm saving the remainder of the green for after cupping these so I can make some adjustments as needed."
6: Variables	"If this was a tiny little peaberry, that's super tightly densely packed, it's gonna need more heat, more energy, to penetrate the bean. So, yeah. It will tell me the starting point of the coffee."
7: Controls	"You know, I would say, only changing one thing at a time. Having controls."

Discussion

Our objective in this paper has been to portray examples of the day-to-day investigations involved in a *non-laboratory, scientific workplace*. We began with the practices of investigation enacted by Sam, a professional coffee roaster. We have been careful to avoid the pitfalls of discussing whether Sam's work *is* science or not, an unhelpful, unanswerable ontological question or an effectively political one. Asking the "what science really is" question distracts us from our broader purpose: to *expand* our imagery of scientific practices toward re-imaginations of science education. Toward this end, we showed how Sam's practices met all seven of the NRC's goals for investigation.

We have shown Sam's practices for two reasons. First, science education reforms advance an epistemology of investigation as hypothesis-driven tests of theory. We argue, and Sam demonstrates, that investigations have utility and meanings beyond the testing of theories. These include opportunities to develop an investigator's skills, conceptual understandings, and situate investigatory practices within a broader repertoire of scientific practices. Second, we argue that scientific practices are not limited to the actions of professional scientists and that images narrowly drawn *only* from these sources fail to capture the rich diversity of science in our lives. Sam demonstrates the importance of investigatory practices in his work.

Our demonstration of Sam's use of scientific practices toward real-world, everyday ends is perhaps our most significant contribution. The *Framework's* "overarching goal…for K-12 science education is to ensure that by the end of 12th grade, all students have some appreciation of the beauty and wonder of science" (p. 1). A central argument in the *Framework* is that K-12 science education fails to achieve this outcome, because it is not organized systematically across the grades, focuses on breadth over depth, and does not provide opportunities to "experience how science is actually done" (p. 1). To this list we add that K-12 science education fails to recognize the beauty and wonder of science that exists outside of the laboratory, and that this failure represents tragic, lost opportunities to connect with the roughly 90% of K-12 students (NSF, 2022) who do not pursue normatively recognized science careers.

Continued conversations about how science is conducted are needed, as these will influence how we teach and learn science (NRC, 2012), will influence what images of scientific practice are elevated, effaced, and ignored. Our study, the first of many planned investigations of *everyday scientific practice*, leverages the practice turn (Ford & Forman, 2006; Knorr Cetina et al., 2001) to step outside of the lab into the wider world of scientific work. Sam's diverse forms of investigatory practice, as inextricably tied up with personal and commercial concerns, are suggestive for new directions in understanding how and where science happens, and why science can be meaningful and relevant in the pursuit of *non-laboratory, everyday concerns*. We are inspired by Sam's work to imagine potential transformations of science education in the era where the practice turn guides us to continuously renew and expand our images of science (Davey & Stevens, 2023; Stevens et al., in preparation).

Explanatory Refutation Texts Increase Epistemic Trust in Climate Scientists and Anthropogenic Global Warming Acceptance

Abhirami Senthilkumaran, Leela Velautham, Michael Andrew Ranney
abhirami_s@berkeley.edu, leela.velautham@berkeley.edu, ranney@berkeley.edu
University of California, Berkeley

Abstract: Trust is fundamental to the non-experiential learning of complex scientific knowledge that informs societal decision-making (e.g., about climate change). Global warming (GW) beliefs and attitudes often reflect one's trust in climate scientists as reliable information sources, so fostering GW knowledge includes addressing misconceptions that can inhibit such trust. Using a pretest-posttest control group design (with an extra posttest-only treatment group that eliminated experimenter-demand concerns), we herein showed that two (long/short) brief explanatory, persuasive, refutation texts addressing climatologists' research practices increased learners' (a) trust in climate scientists (and scientists overall) and (b) acceptance that anthropogenic GW is occurring and concerning. Our experiment's results support prior findings that people revise their GW beliefs—without polarization—upon encountering crucial, valid, and germane, information. These findings expand empirical evidence demonstrating the utility of directly confronting epistemic misconceptions (e.g., about scientists'—especially climatologists'—reward structures) using explanatory, persuasive, refutation texts.

Introduction

Confidence in scientists among the US public is typically high and on par with their confidence in their military (Funk et al., 2019): 86% of residents have "a great deal" (35%) or "a fair amount" (51%) of confidence that scientists act in the public's best interests. However, trust in scientists varies by scientific field, and this variability is prominent for socio-scientific issues (SSIs), such as pandemics (Evans & Hargittai, 2020), evolution, and global climate change (e.g., Ranney, 2012; Ranney & Clark, 2016). About 25% of Americans "somewhat" or "strongly" distrust scientists as sources of global warming (GW) information (Leiserowitz et al., 2011). Given this landscape and the need for well-informed citizens/consumers, communicators have analyzed the factors—in a message, a messenger, and a recipient—that influence trust. Various strategies improve the effectiveness of climate change communication (Nisbet, 2009), including increasing people's trust in scientists (e.g., Goodwin & Dahlstrom, 2014). The following two subsections briefly survey literatures that informed the current experiment's design, especially those involving (a) epistemic trust and (b) kinds of texts that change minds and counter misinformation.

Elements of trust and epistemic trust

Mayer et al. (1995) define trust as "a function of the trustee's perceived ability, benevolence, and integrity, and of the trustor's propensity to trust," with (a) *ability* being the trustee's domain competence/expertise, (b) *benevolence* being the extent to which a trustee is seen to act in the trustor's best interest (beyond the trustee's personal benefit), and (c) *integrity* referring to the trustor's sense that the trustee follows principles acceptable to the trustor. Origgi (2004) describes *epistemic trust* as trust in a source's knowledge-reliability in a specific domain (vs. trusting someone to keep a secret or watch your laptop). Extending epistemic trust to science/scientists, Hendriks et al. (2016) characterize it as "trust in the knowledge that has been produced or provided by scientists." Epistemic trust permeates the acquisition of vicarious knowledge because it is difficult for non-experts to gain a first-principles understanding of many scientific phenomena. To make well-informed decisions about SSIs, laypeople should establish the trustworthiness of various knowledge sources (scientists, journalists, etc.); thus, their scientific beliefs about a field are often closely tied to their trust in that field's science/scientists.

Trust in scientists' competence, integrity, methods, and motives crucially shapes public opinions on climate action (MacInnis & Krosnick, 2016). Anthropogenic global warming (AGW) *acceptance* (a) significantly correlates with *trust in climate scientists* (Hmielowski et al., 2014) and (b) is causally related to *awareness of AGW's scientific consensus* (van der Linden et al., 2015). Indeed, one's trust in scientists moderates the relationship between knowledge of, and concern about, GW: Malka et al. (2009) report that knowledge is positively associated with concern among people who at least moderately trust scientists, yet knowledge is *uncorrelated* with concern about GW among those who are distrustful of what scientists say about the environment. Climate change skeptics—and many groups with vested fossil fuel industry interests—often claim that climate scientists push AGW narratives to get funding (Boussalis & Coan, 2016; Mann & Toles, 2016). Further, Funk and Kennedy (2016) note that 31% of US adults believe that climate scientists understand global climate change's causes "not too well" or "not at all." More saliently for the present study, they also note that only 23% of US adults—and only a tiny 7% of conservative Republicans—believe that climate change research findings are influenced by *concern for the public's best interests* "most of the time." These data show Americans' nontrivial distrust of climate scientists over all three aspects of epistemic trust: expertise, integrity, and benevolence. Therefore, items comprising our experiment's trust instruments cover all three aspects.

Using texts for conceptual/epistemic/attitude change and countering misinformation

Enhancing public understanding of, and engagement with, SSIs often entails (a) conceptual change in understanding a scientific phenomenon, (b) attitude change about the emotion or valence an SSI evokes, and (c) epistemic change about the nature of science knowledge and practice (Sinatra et al., 2014). Consider how different kinds of texts can shift knowledge and attitudes. *Refutation texts* are a text-genre in *misconceptions-based learning* that are designed to spur conceptual change. These texts state the learner's (presumed or actual) incorrect belief about a concept to make them cognizant of that belief—and then contrast it with more plausible, scientific alternatives (Tippett, 2010). Refutation texts can artfully counter readers' prior beliefs non-threateningly and invite attentive processing: in a meta-analysis of text-based, instructional strategies, Guzzetti et al. (1992) found refutational expository texts to be more effective than traditional expository tests (with a mean effect size of 0.22). *Persuasive texts* are designed to alter readers' *attitudes* about an issue (often emphasizing such alterations over knowledge changes), typically having a claim, then evidence supporting the claim, and a warrant linking the claim to the evidence. Persuasive texts tend to be effective if they counter readers' initial beliefs, promote mindful processing, and motivate readers to revise their beliefs (Chambliss & Garner, 1996).

This experiment also draws on work on communication strategies designed to combat misinformation. Such *agnotology-based learning* involves teaching techniques to examine and critique misinformation (Cook, 2019). Lewandowsky et al. (2012) showed that disconfirming misinformation alone may not end its influence: it is crucial to fill the coherence gap left by the disconfirmed beliefs with a plausible, alternative narrative. As noted, many who deny GW cast doubt on climate scientists' motives and findings (Oreskes & Conway, 2011). Cook (2019) classified such "attacks on the integrity of climate scientists" as a climate misinformation rhetorical strategy. Our experiment's texts directly counter flaws in claims about climatologists' purported over-devotion to financial or social-acceptance goals—which, among other things, helps readers empathize with climate scientists.

Inoculation-messages can also counter misinformation (Cook et al., 2017). When shown flawed logic or specific misinformation instances (e.g., *fake experts* feigning a lack of scientific consensus on GW), people are cognitively inoculated against similar deceptive tactics they may see in the future. Explicitly debunking misinformation (e.g., countering misleading claims based on cherry-picked information) is effective when designed aptly and repeated often. If misused or poorly constructed, trying to debunk may worsen matters (Farmer & Cook, 2013)—for instance, it may cause a *backfire effect* (i.e., should a false idea become more accepted than the facts that counter it). Beyond correcting the money-libel and clan-appeasing aspersions, our intervention text may also inoculate against other forms of misinformation that target climate scientists' integrity.

Refutation texts and persuasive texts have shifted climate change attitudes (Thacker et al., 2020) and aided climate change conceptual changes (Nussbaum et al., 2017). Other explanatory texts have increased both GW knowledge and concern (e.g., Velautham et al., 2019; Ranney & Velautham, 2021). Refutation-based interventions (Chang et al., 2018) have focused on climate change's causes and misconceptions, but intervention texts targeting misconceptions that contribute to climate change denial have not directly addressed scientific research's reward system. Individual scientists have tried to dispel the mere-greed myth by detailing their funding (Mandia, 2010). Others have emphasized science's incentive for proving one's peers wrong (Mann & Toles, 2016), which our intervention subsumes (among other elements). In full, our experiment's intervention text is designed to persuade readers that GW is real and man-made—mostly by refuting the (largely false) idea that climate scientists exaggerate AGW for personal gain (Boussalis & Coan, 2016; Oreskes & Conway, 2011).

Experiment

We herein assessed the utility of two brief intervention texts (long and short) in yielding (a) conceptual-and-attitudinal changes (as measured by readers' anthropogenic Global Warming Acceptance [GWA]), and (b) epistemic change (as measured by readers' Trust in Scientists [TiS] and Trust in Climate Scientists [TiCS]). Our three primary hypotheses (H1-H3) were: that the (a) long and (b) short texts would increase readers' TiS (H1), TiCS (H2), and GWA (H3). H1 and H2 reflect predictions that trust in (general and climate) scientists will increase due to crucial new epistemic information refuting misconceptions about climatologists' motivations. H3 reflects the idea that GWA and TiCS increases ought to co-occur, because trusting climatologists means that their AGW claims gain credence. A secondary hypothesis (H4) is that our texts succeed with liberal *and conservative* participants (i.e., with no polarization—as Ranney et al., 2019, etc., have found for other brief GW interventions).

Participants

A diverse set of 419 online (*Qualtrics Panels)* adult US participants were pre-selected to roughly reflect three US distributions that were counterbalanced across all conditions: age, education, and political affiliation. It was thus a more balanced/diverse sample than is typical of most studies (e.g., those using Mechanical Turk, whose samples tend to be younger, more liberal, and more educated than US adults). Our median participant was middle-aged with some college credit (but no post-high-school degree). Political affiliations reflected the US's (somewhat labile) proportions, with 36.3% Democrats, 35.6% Independents, 27.4% Republicans, and 0.7% Green/Libertarian/Other participants. Our campus's institutional review board approved this study. Qualtrics received $4.50 per not-excluded participant, half of which went to individuals—with the actual value (whether cash, gift card, or other cash-substitute) being proprietarily determined by Qualtrics and its panel provider(s).

Design

Participants were randomly assigned to one of four conditions: (a) a Pretest, Long intervention-text, plus Posttest (PLP) group, (b) a Pretest, Short intervention-text, plus Posttest (PSP) group, (c) a No-Pretest, Long intervention, plus Posttest (NPLP) group, or (d) a control-text group. We hypothesized (H1-H3 above) that PLP (H1a-H3a) and PSP (H1b-H3b) groups would show pretest-to-posttest gains for all outcome variables (TiS, TiCS, and GWA), relative to the control group. The PSP group effectively assesses a dosage hypothesis regarding whether roughly halving the text's words (vs. PLP) would still yield such gains. The NPLP group served to detect any pretest sensitization suggesting (in the PLP or PSP groups) either an experimenter demand or a consistency bias. Such a pretest-treatment interaction would mean that a pretest increased or decreased participants' sensitivity to an experimental text (i.e., people getting pretests sometimes show more or less gain compared to a no-pretest group). Spurious gains to please experimenters were greater threats to our experiment's validity than reduced gains, so we hypothesized (H5) that the NPLP posttest scores would not be significantly below the PLP posttest scores, indicating no experimenter demand effect. The NPLP condition also allowed replication of a longer-text treatment effect beyond the PLP group: we hypothesized (H6) that the NPLP posttest scores would exceed the other groups' pretest scores, which would indicate yet another treatment main effect for the (long) intervention text.

Procedure

Participants gave informed consent before receiving material for their randomly assigned group from a Qualtrics link. Each pretest and posttest included 30 items over four online presentation-pages. Participants failing to complete the experiment or pass quality checks were replaced from the panel pool. Those who responded correctly to at least one out of two items in each of these were retained: a) two attention-check items mingled into pretest items, b) two attention-check items mingled into posttest items, and c) two comprehension check queries right after the (control or intervention) text. Speeding checks on the total time spent were also enforced: those spending less than half the median time for their assigned condition were excluded. Finally, anomalous indicators—such as (1) page latencies (i.e., local speeding), (2) very low within-participant variance, and (3) internal incoherence among responses to similarly-worded or negatively-phrased items—were examined to remove random, *straightliner*, and inattentive responders. Demographic information was solicited after the posttest.

Materials (texts and instruments)

Two intervention-text versions with the same brief, core, message were used: the PSP group's Short (i.e., roughly condensed) 253-word version—and the PLP and NPLP groups' Long 483-word version. (The control text was a similarly engaging 500-word summary of the film *Mary Poppins*.) The intervention texts countered hoax-ideas that are common in some subpopulations—such as that climatologists bolster their field's status quo to get grants/accolades—by highlighting that *real* scientists' fame reflects the field-altering shock of their findings. A part of the short version highlights this: "Scientists also don't just accept global warming because they want to get along with other scientists. That's mostly the opposite of how scientific rewards work. Scientists treasure any chance to show that the vast majority of their peers are incorrect: that's how Einstein-types achieve fame. [...] About 98% of climate scientists accept human-caused global warming even while wishing it were false—and having incentives to disprove it. This reflects the very high probability that climate change is truly happening."

A scientist can earn trust and engage doubtful audiences by showing vulnerability and highlighting a willingness to sacrifice (Goodwin & Dahlstrom, 2014)—for instance, through a commitment that clearly shows that the scientist has something to lose. Our texts do so by (beyond their other features) describing a scientist (this piece's third author) who often publicly pledges to quit all climate-related activities and return all climate-related funds he has received if "someone could please" disabuse him of his beliefs that GW is occurring and human-caused; he developed the texts' prose over dozens of lectures with sometimes-dubious audiences (e.g., one in a bar in Texas, USA). The texts quote him, including: "Indeed, virtually all climate scientists absolutely wish that global warming were not happening—especially if they're parents!" He elaborates that anyone who *can* disconfirm GW *would*, as the person would win a Nobel prize, become the "most famous scientist ever," and get "wildly rich" (from fossil-fuel companies, etc.). The texts are available on our group's academic site (at https://convinceme.com/downloads/papers/SenthilkumaranVelauthamRanney2023-ICLS-ExtraMaterial.pdf) and our group's public-outreach site (at https://www.howglobalwarmingworks.org/trust-in-scientists.html—along with some of our other brief materials that have been shown to increase global warming acceptance/concern).

An eight-item TiS instrument and an eight-item TiCS instrument were developed (with items adapted from Nadelson et al., 2014) and validated prior to this study. Both were highly reliable (Cronbach's $\alpha = 0.75$ and 0.90, respectively), and their sum-scores correlated (r = 0.69 and 0.87, respectively) with those from an eight-item GW Acceptance instrument from our prior experiments (e.g., Velautham et al., 2019), further supporting their validity. The GWA instrument measures how much people believe that (a) GW is occurring and largely human-caused, (b) GW's effects are a serious threat, and (c) GW's effects are concerning. All items were rated on a 1-9 scale from "extremely disagree" to "extremely agree" (with verbal labels at each number). An example of a TiS item is: "Scientists honestly look for flaws in the methods and findings of other scientists." A *negatively*-phrased example of a TiCS item is: "Climate scientists do not accurately convey their findings." An example of a GWA item is: "I am confident that human-caused global warming is taking place."

Statistical-analysis rationale

Because univariate effects were of central interest in comparing changes among experimental groups for our pretest-posttest design, we bypassed a MANOVA to directly use univariate ANOVAs on each outcome variable. Intercorrelations among the outcome variables on the pre-tests (covering Control, PLP, and PSP groups' data) ranged from .65 to .82 and on the *post*-tests (covering all four groups' data) from .69 to .84. We used (per Smolkowski, 2019) a change (posttest minus pretest) score approach over an ANCOVA on posttest scores or a repeated-measures ANOVA. We used the Holm-Bonferroni correction, given multiple-comparisons and Type 1 error, such that the experiment-wise α was .05. We first performed one-way ANOVAs on each outcome variable; for ANOVAs revealing a statistically significant between-groups difference, we performed post-hoc Dunnett's tests. For the NPLP group, we compared its posttest scores to (i) the PLP group's posttest scores (to rule out experimenter demand), and (ii) the other groups' (PLP+PSP+Control combined) pretest scores (for replication).

Results

Gains for both trust-text treatments for all within-participant measures

Table 1 shows pretest (if applicable) and posttest group means (out of 72) for GWA, TiS, and TiCS. (Each group's data for all outcome variables were reasonably symmetrically distributed—with few outliers on one or both tails.) As hypothesized, the PLP (H1a-H3a) and PSP (H1b-H3b) groups showed posttest gains for all three outcome variables. Focusing on Table 1's *changes*, Table 2 shows means and *SDs* of the change scores for the three GW and trust measures from groups who had a pretest (control, PLP, PSP). The PLP group, with its longer-than-PSP text, tended to yield the largest gains on the measures, and the control group showed basically no changes.

Table 1

Pretest and Posttest Means and (italicized) Standard Deviations of Outcome Variables by Condition

Group	n	GWA Pre		GWA Post		TiS Pre		TiS Post		TiCS Pre		TiCS Post	
		M	*SD*	M	*SD*	M	*SD*	M	*SD*	M	*SD*	M	*SD*
Control	113	52.4	*14.7*	51.7	*15.1*	49.7	*9.3*	49.8	*8.8*	49.1	*11.5*	49.6	*12.6*
NPLP	91	-	-	56.5	*12.8*	-	-	53.0	*9.2*	-	-	53.7	*10.7*
PLP	104	47.5	*16.0*	50.5	*16.2*	48.9	*10.1*	51.0	*10.4*	46.0	*13.5*	50.7	*13.5*
PSP	111	49.7	*17.1*	51.6	*16.6*	49.2	*9.3*	51.7	*10.3*	47.1	*14.0*	51.3	*13.8*

Note: Max. possible score on each of these measures was 72 (i.e., 8 items each on 1-9 scales); - = no pretest

Dunnett's test (df = 325) showed that the PLP (p < 0.00001, Cohen's d = 0.77) *and* PSP groups' GWA gains (p = 0.00013, Cohen's d = 0.54) were significantly greater than the control group's change (by 3.7 and 2.6 points, respectively). This test builds on a significant difference among those three groups in a one-way, between-subjects ANOVA on *GWA-change-score*: F(2,325) = 17.16, p < 0.00001. The same pattern was obtained for the TiS gains: Dunnett's test (df = 325) showed that the PLP (p = 0.00958, Cohen's d = 0.38) *and* PSP groups' gains (p = 0.0018, Cohen's d = 0.45) were significantly greater than that of the control group (by 2.1 and 2.4 points, respectively). The one-way between-subjects ANOVA of the *TiS gains* warranting the test showed a statistically significant difference among groups: F(2,325) = 6.53, p = 0.00166. As with GWA and TiS, a one-way between-subjects ANOVA of the TiCS gains showed a statistically significant difference among groups: F(2,325) = 15.93,

$p < 0.00001$. The follow-up Dunnett's test ($df = 325$) showed that the TiCS gain of the PLP group (4.2 points) differed significantly from that of the control group ($p < 0.00001$, Cohen's $d = 0.69$), and the TiCS gain of the PSP group (3.7 points) showed a significant difference from the control group ($p = 0.00001$, Cohen's $d = 0.61$). These results show that both the intervention-text's longer (H1a-H3a) and shorter (H1b-H3b) versions successfully increased readers' global warming acceptance and trust in climate (and generic) scientists; in other words, even the smaller, 253-word, "dose" of our intervention was successful.

Table 2

Change Scores by Condition (Posttest minus Pretest, rounded to nearest 0.1)

Group	N	GWA Gain		TiS Gain		TiCS Gain	
		M	***SD***	**M**	***SD***	**M**	***SD***
Control	113	-0.7	*4.1*	0.0	*4.4*	0.5	*5.1*
PLP	104	3.0	*5.6*	2.1	*5.8*	4.7	*6.3*
PSP	111	1.9	*4.5*	2.4	*5.9*	4.2	*6.5*

Note: The NPLP condition did not have a pretest.

Replicative gains for all NPLP measures (and no experimenter demand)

Table 3 shows the NPLP posttest scores' means and standard deviations (presented earlier in Table 1), along with the means and standard deviations of the pretest scores of the other three conditions combined, and (broken out of that combination) the PLP posttest scores. We performed two main comparisons with the NPLP condition's data: one assessing experimenter demand (H5), and another assessing coherence with the PLP data (H6).

Table 3

Relevant Between-Group Summary Statistics for NPLP Posttest, PLP Posttest, and Combined Pretest Scores

Group	n	GWA Pre		GWA Post		TiS Pre		TiS Post		TiCS Pre		TiCS Post	
		M	***SD***	**M**	***SD***	**M**	***SD***	**M**	***SD***	**M**	***SD***	**M**	***SD***
Combined	328	50.0	*16.0*	n/a	*n/a*	49.3	*9.5*	n/a	*n/a*	47.4	*13.0*	n/a	*n/a*
NPLP	91	-	-	56.5	*12.8*	-	-	53.0	*9.2*	-	-	53.7	*10.7*
PLP	104	n/a	*n/a*	50.5	*16.2*	n/a	*n/a*	51.0	*10.4*	n/a	*n/a*	50.7	*13.5*

Note. "Combined" = groups with pretests (PLP, PSP, & Control). Mean maximums = 72; n/a = not-applicable; - = no pretest.

We found no evidence of experimenter demand: NPLP and PLP posttest scores were compared with a one-sided equivalence test (i.e., a noninferiority test), with a decrease (PLP minus NPLP) of less than 1 point (of a possible 72-point sum) per measure considered negligible. The null hypothesis was that (*PLP-post – NPLP-post*) > 1 (i.e., experimenter demand exists), and the alternate hypothesis (H5) was that (*PLP-post – NPLP-post*) <= 1 (i.e., no experimenter demand). Our results showed no experimenter demand effect for any of the measures. For example, the 95% CI [-6.39, 0.46] for the TiCS PLP-NPLP posttest score difference does not contain 1, indicating *no* experimenter demand effect ($p=0.0117$, Cohen's $d= 0.32$). Similarly, *no* experimenter demand effect was found for either the TiS scores ($p=0.0196$, Cohen's $d = 0.30$, 95% CI [-4.73,0.85]), or the GWA scores ($p=0.0005$, Cohen's $d=0.47$, 95% CI [-10.07, -1.87]). If anything, the data indicate that taking the pretest and becoming sensitized to the variables under study reduces the text's effectiveness, demonstrating *lower* gains than would otherwise be obtained without pretest sensitization. This is the *opposite* of what one would expect had participants induced the hypotheses and tried to please the experimenters with biased ratings on the posttest.

Supporting hypothesis H6, the NPLP group's long text replicated significant gains (of moderate effect size) for all three measures—GWA, TiS, and TiCS (~6.5, ~3.7, and ~6.2 points, respectively): NPLP showed such significant gains for GWA ($t(176.7)=4.07$, $p=0.00007$, Cohen' $d=0.42$), TiS scores ($t(417)=3.26$, $p=0.00119$, Cohen's $d=0.39$), and TiCS ($t(417)=4.19$, $p=0.00003$, Cohen's $d=0.50$) relative to the combined groups' pretest scores. (NPLP posttest scores were compared to the pretest scores of the other three groups [combined] using an independent-samples t-test [two-tailed] for each gain variable. The GWA scores were compared assuming unequal variances, and the TiCS and TiS scores were compared assuming equal variances, as per Levene's test.)

No polarization, either regarding belief level or political affiliation

Supporting hypothesis H4, we found *no* evidence of our texts causing polarization (cf. Lord et al., 1979)—using three lenses: initial belief level, political affiliation, or conservatism. Neither those with low initial belief /attitude levels—nor those identifying as Republican or conservative—showed polarization or a backfire effect.

Regarding beliefs and attitudes, participants scoring 24 or lower (33% of 72) summed points on the GWA or TiCS *pre*tests numerically *increased* their mean post-intervention scores. Such "bottom-thirders" did *not* show the losses that polarization would predict. Indeed, PLP and PSP bottom-thirders yielded +8.0 and +3.4 respective

TiCS point-gains above pretest levels (and +1.2 and +3.3 respective GWA point-gains). (No PSP/PLP participant scored 24-or-under on the TiS pretest, so we report no TiS changes; likewise, NPLP had no pretest, so that group could show no polarization.) Turning to political affiliation, Republicans (a separate AGW denial correlate) did *not* exhibit the losses that would indicate polarization—indeed, they yielded *gains* on *all three* measures for both relevant groups: PLP (+3.1, +2.3, and +4.9, respectively, for GWA, TiS, and TiCS) and PSP (+3.1, +3.6, and 7.0, respectively, for GWA, TiS, and TiCS). Similar gains were found for Democrats and Independents, yet gains for Republicans (who had the lowest mean *pretest* scores) were generally the highest.

We can assess (the lack of) polarization more directly than with bottom-thirders and political party: The correlations between GWA/TiS/TiCS changes and (separately, economic and social) conservatism were all close to zero (with r's ranging from -0.06 to +0.18). The largest of these six correlations, between GWA-change and social-conservatism, was still weak (ρ=0.184, with a 99% CI of [0.01,0.35]). However, it—like most of the other (weaker) change-conservatism correlations—was *positive*, and thus (as above) in the opposite direction that polarization would predict. Likewise, for all nine levels of self-rated economic conservatism among PLP and PSP participants, mean changes (on TiCS, TiS, and GWA) were positive for 52 of the 54 (9x6) sub-cells—and the remaining two sub-cells showed losses of less than 0.5 points. (Results for *social* conservatism, which we have found are typically less linked to AGW denial, were similar.) Indeed, our *extreme* conservatives (with self-ratings of 9 of 9), exhibited gains for all three (GWA, TiS, and TiCS) measures for both PLP and PSP conditions.

Discussion

Political discourse often focuses on one's finances or affiliations, so it is not shocking that some people criticize climate scientists by suggesting that they largely follow greedy or tribal motivations. This libel (i.e., when knowingly false) is spread by special-interest groups (Oreskes & Conway, 2011)—and their agents/lobbyists—who oppose climate-friendly reductions in greenhouse gas emissions (and deny AGW's reality or huge scale). It is further intensified by some political influencers who portray climate scientists as enemies—heightening in/out-group separations that social-media algorithms tend to amplify. What our Trust-texts cultivate, though, is a humanizing empathy about being in a climate scientist's shoes (e.g., "Were I a climatologist, I'd want to aid society by providing veridical, actionable, information—even if I got pushback."). The interventions herein help people both cognitively and emotionally understand that virtually all climate scientists: (1) fervently wish global warming were false and (2) would gladly disconfirm GW if they could—due to the almost-unimaginable rewards they would reap. Our data show that readers are changed by this narrative, and in 253 words (let alone the longer, 483-word text) our experiment successfully increased (a) the more proximal construct of Trust in Climate Scientists *and* the more distal constructs of (b) Trust in Scientists overall and (c) Global Warming Acceptance.

In addition to our findings that both of this experiment's brief texts increased belief ratings for the TiCS, TiS, and GWA measures, the no-pretest group (NPLP) showed that the gains in normative beliefs were (a) not due to experimenter demand and (b) further replicable (i.e., the NPLP results replicate the PLP—and implicitly, the PSP—results). In sum, all six of our hypotheses (H1-H6) found support in the data. The findings both bolster extant research on evidence-based strategies to combat misinformation and support our (and Hmielowski et al.'s, 2014) strong link between trusting climate scientists and accepting their AGW findings. The results also show that explanatory persuasive-refutation texts can succeed without yielding polarization or backfire effects: most participants across each of several relevant spectra showed *gains* for all dependent variables (TiCS, TiS, and GWA). The gains are even robustly found across participant sub-spectra that are, *a priori*, most indicative of potential GW deniers—namely participants who had up to three indicators of strong content-skepticism (i.e., high conservatism, Republican [and Independent] affiliation, and low trust or GWA pretest scores).

Although we used common techniques to improve data reliability, they are not without external validity concerns. Attention and comprehension checks aid in reducing statistical noise, but they modify the inferential target to a subset of the population: people who complete the experiment and pass all screeners may differ from those who do not—especially in public-attitude studies (Aronow et al., 2019). Dropouts and inattentiveness in online studies may often be due to extraneous reasons, but a would-be-participant who exits upon viewing the pretest questions or an intervention text—or fails the quality checks—may denote (a) a difficulty in understanding the text and instructions, or (b) a reluctance to engage with the topics of GW and/or climate scientists.

Beyond addressing a common misconception among deniers, our texts also communicated science's incentive structure. SSIs make an excellent context for nature-of-science learning (e.g., Eastwood et al., 2012), and knowledge about the nature of science increases public acceptance of science regardless of identity factors (Weisberg et al., 2021). Our results indicate that explaining *science's motivations and methods* to the public can increase learners' trust in scientists, their expert findings—and hopefully their wisest recommendations.

Conclusions

This experiment supported six hypotheses (H1-H6) that advance climate change cognition. Its trust-text genre brings to 12 (detailed in Ranney & Velautham, 2021, and Velautham, 2022) the ways in which our lab's brief materials have been shown to boost AGW acceptance/concern. Other ways include statistics about climate change (even marbled with misleading statistics), related statistics (on energy efficiency, electrification, and reducing meat), graphs of Earth's warming (vs. the US stock market rise), statistics reducing nationalism, texts about high CO_2's cognitive harms, information about GW's physical and economic effects (e.g., sea-level rise), activities involving selecting climate change solutions, and texts and videos about global warming's mechanism or effects.

This experiment cannot escape the context of US subgroups who struggle to understand and access diagnostic information. From public health guidelines (e.g., slowing COVID-19's spread with masks) and US election-results denial to climate change mitigation and adaptation, people vary in how much they trust experts (Evans & Hargittai, 2020; Leiserowitz et al., 2011). Given the proliferation of misinformation in mass media and its effect in undermining trust in domain experts, it is crucial to make accurate, relevant, and non-polarizing information (such as those used in our texts) widely available—and repeated through multiple sources—to bolster trust and improve public science understanding. Not *all* scientists (whether they work on climate *or* fossil-fuels) are beyond reproach. Some are tempted to overstate or obscure in reporting, and some even fall from grace; legal and peer-review systems are imperfect. But history—and science-driven technologies—have shown that science largely, if not fully monotonically, eventually gets it right. Our findings demonstrate that reading even 60 seconds' worth of the shorter (PSP) text significantly changes minds about some of the most important elements of our era: scientific veracity—and its role in informing humanity about a potentially cataclysmic future.

Abstract: Helping teachers move beyond the pedagogical practices they experienced as students represents an enduring problem in teacher education. Even when they experience more creative alternatives during preparatory coursework, they often have trouble transferring these approaches to their clinical practice. This paper systematically reviews scholarship on two constructs from the situative tradition, *productive disciplinary engagement* (PDE) and *expansive framing*, that hold potential for promoting instructional transformation and transfer. We find that both constructs illuminate core issues in teacher learning, but that, as pedagogical tools in themselves, expansive framing is more easily taken up by teachers than PDE is. We conclude by advancing a view of theoretical synergy between the two frameworks that could hold promise for future efforts towards encouraging instructional transformation and transfer.

Introduction

In recent years, learning scientists have increasingly acknowledged the importance of teacher education, learning, and development for bridging learning research and educational practice (e.g. Chen et al., 2020; Superfine et al., 2022). One key challenge scholars have identified relates to instructional change: Teachers who as students experienced an "apprenticeship of observation" (Lortie, 1975) that consisted mostly of rote instruction have difficulty envisioning a more stimulating alternative. A second, related problem has to do with transfer: Reform-based strategies learned in teacher education programs (TEPs) or professional development (PD) courses often are not taken up in classroom practice (Dreer et al., 2017; Fishman et al., 2022). In short, so-called traditional instruction proves stubbornly resistant to change.

Teacher education scholarship offers no shortage of responses to these twin challenges of instructional change and transfer—for example, engaging with teachers' epistemic beliefs, providing clearer modeling, or staging rehearsals within TEP coursework (see, e.g., Grossman, 2018; McDonald et al., 2013; Monte-Sano & Budano, 2013). This paper offers a "conceptual contribution" (ISLS 2023 CFP) to learning sciences scholarship by examining the affordances of two constructs developed by the late Randi Engle and colleagues: *productive disciplinary engagement* (PDE; Engle & Conant, 2002) and *expansive framing* (Engle, 2006; Engle et al., 2012). Through a systematic review of literature applying these frameworks to teacher education, we find significant potential for promoting instructional change and transfer in creative new ways.

Theoretical framework

Drawing on theories of situated cognition (e.g., Greeno, 1998), Engle and Conant (2002) advanced the term *PDE* to refer to impassioned and productive engagement in disciplinary activity. They proposed four design principles for prompting such engagement: (a) *problematize* disciplinary content from students' own perspectives and experiences, (b) confer them *authority* to pursue these problems, (c) hold them *accountable* to their peers and to disciplinary norms, and (d) provide access to relevant *resources* needed to accomplish these goals. Examples of PDE include student design of a robot (Verma et al., 2015), impassioned whole-class discussions of historical events (Freedman, 2020), and debating the proper classification of the species *orca* (Engle & Conant, 2002). These sorts of productive, student-driven inquiries starkly contrast with the instruction most teachers experienced as students. A key question guiding our review then, is, "What learning outcomes result from teachers experiencing PDE during pre-service or on-the-job training?" For instance, does this lead them to employ PDE principles in their own classrooms?

Engle (2006; Engle et al., 2012) later offered *expansive framing* as a situative means of promoting the transfer of learning across settings. To frame a learning context expansively means to forge links between the activity occurring there and the activity that occurs (or has occurred) in other meaningful contexts, thereby creating what Engle called "intercontextuality." For example, rather than reminding students that material covered will be useful for an upcoming test, a teacher might help them connect that material to prior outside experience and reflect on potential uses in community, career, civic, or other settings. Intercontextuality is also thought to emerge when students are positioned as *authors*, capable of applying their ideas broadly across contexts. Our review, then, searched for evidence that expansively framing the work undertaken in a teacher education setting might promote more robust transfer to a classroom instructional setting. As with PDE, we also asked how teachers might learn to utilize expansive framing in their own practice.

While the frameworks for PDE and expansive framing are distinct—the former focusing on engagement and the latter on transfer—they do connect in important ways. As already noted, building students' authority or capacity for authorship is central to both frameworks. Further, problematizing a topic entails *transferring in* conflictual knowledge (e.g., noticing that a zookeeper's classification of orcas conflicts with a classroom reading; Engle & Conant, 2002). Problematizing often also entails recognizing a topic's import beyond school. In this sense, expansive framing may enhance PDE and vice versa. The close connection between the two frameworks is why we consider them in tandem in this review, even though scholarship has tended to pursue each separately.

To briefly summarize, our review found that: 1) both PDE and expansive framing can support teacher learning, 2) as an instructional approach, expansive framing lends itself for teacher use more easily than does PDE, and 3) use of expansive framing could help teachers better transfer use of PDE principles to clinical practice.

Method

As part of a larger systematic review, we used Google Scholar to identify 2714 publications (as of June 2022) containing the terms "productive disciplinary engagement" or "expansive framing" or citing Engle's scholarship. Two team members independently coded each publication as unpublished/irrelevant/inaccessible (450), not in English (287), passing reference to Engle's work (800), supporting reference (803), or include (374), with an interrater agreement of 78% (Cohen's kappa = .72; disagreements were resolved by the more experienced reviewer). Passing references were those that cited Engle without incorporating her ideas, while supporting references were those that drew on her ideas only peripherally. Publications marked for inclusion engaged substantively with PDE, expansive framing, or both. For the current paper, we flagged the included publications that dealt specifically with teacher education or teacher learning: 12 journal articles, two book chapters, one conference proceeding, and one monograph. Nine of these publications focused on PDE, while five focused on expansive framing, and one addressed both frameworks.

Findings

Engle's work has been taken up both in teacher education programs and in PD opportunities for practicing teachers. Generally speaking, the causal mechanisms implied by each theory—that the four guiding principles promote PDE, and that expansive framing promotes transfer—appear to hold for pre- and in-service teachers, as prior research has shown with K-12 students (see Engle, 2012). The literature illustrates the PDE principles' potential for engaging emerging teachers in case analysis, scientific modeling, and collaborative inquiry—and it shows how expansive framing can promote transfer of content knowledge and pedagogical practices from coursework to the field. Some studies went so far as to promote teachers' use of PDE and expansive framing *themselves* as pedagogical practices, though none did so explicitly (an issue we return to in the Discussion). We begin with studies that employed the frameworks as vehicles for teacher learning, followed by studies that treated the frameworks as pedagogical tools for teachers to use in their own right.

PDE and expansive framing as vehicles for teacher learning

In the first application of the PDE framework to teacher education, Engle and Faux (2006) compared two instantiations of case-based instruction in an educational psychology course. One instructor (Engle) focused on getting her students to use psychological constructs to illuminate the cases—which presented managerial, curricular, and other dilemmas drawn from real classrooms. By contrast, the other instructor (Faux) placed greater emphasis on the students exploring the cases from their own perspectives as practitioners. In this sense, Engle's class section fostered greater disciplinary accountability but diminished students' opportunities to problematize the case material or establish a sense of authority, whereas Faux's section showed the opposite pattern. As an instructional method, case analysis holds high potential for helping prospective teachers connect theory to practice, yet Engle and Faux's study illustrates how the strategy can often fall short of that goal—either by devolving into an academic exercise of matching theories to cases (as occurred in Engle's section), or by sparking discussion of personal experiences unilluminated by learning theory (as in Faux's section). In this way, the PDE framework proved a fruitful tool for analyzing a pedagogical practice within teacher education, with an eye towards improvement. Based on the study's findings, the authors began exploring ways to first establish students' authority before later adding in elements of disciplinary accountability.

Lipponen and Kumpulainen (2011) took up this issue of building PSTs' sense of agency. To do so, they engaged the PSTs in a collaborative inquiry into Middle East conflicts during an 8-week TEP course. The PSTs were to construct, negotiate, re-negotiate, and contest accountability and agency within their inquiry groups—among peers and with their teacher educator. Analysis of classroom discourse confirmed that as the teacher educators stepped back from their traditional authoritative roles, the PTSs came to share authority and act as "accountable authors" (p. 816), in line with the PDE principles. Similarly, Juutilainen et al. (2018) used "home groups" to build PSTs' sense of agency. The home groups created a space for the PSTs to acquire emotional safety, learn to function as a team, and renegotiate power dynamics between students and the teacher. Well-functioning home groups proved a fertile ground for active knowledge construction and the negotiation of power and authority within the group, though some reported negative features such as inequality among group members. Overall, participants reported that the home groups successfully built their sense of agency. As with Lipponen and Kumpulainen's study, however, it remains unclear whether the participants went on to enact similarly collaborative and authentic learning experiences in their own classroom practice.

The aforementioned studies illustrate the PDE framework's potential for enhancing teacher preparation coursework. By promoting problematizing, distributed authority, and disciplinary accountability, teacher educators can engage their students in the kind of authentic inquiry the latter might seldom have experienced in their own schooling—thus expanding their view of what is possible. Such inquiry can also have discrete learning outcomes, such as more adeptly applying learning theory to illuminate problems of practice (Engle & Faux, 2006).

Our review found expansive framing also to carry potential for promoting teacher learning, although here the emphasis was on transferring concepts learned in coursework to the field. Van Duzor (2011) described a PD course that used expansive framing to encourage K-8 teachers to transfer chemistry concepts and inquiry methods to their professional practice. The authors drew on Engle (2006) to characterize the course's framing of time and participation as creating intercontextuality between the PD and its context of use. For example, in a weekly journal, the participants reflected on how they could apply ideas from the course in their clinical settings. Analysis of the journals illustrated broad success of the program: The participants discussed incorporating content and teaching strategies from the PD into their current and future practice, even extending and adapting them to fit their students' needs. As a single case design, however, the study offers limited evidence that it was expansive framing *per se* that yielded these results, nor could the authors say with confidence that the participants actually did in practice what they said they would in their journals.

Extending the concept of transfer, Dohn and Hachman (2020) focused on PSTs' transformation of knowledge between educational and professional settings. The authors sought for PSTs to transfer content knowledge, an associated teaching strategy, and underlying educational theory to a clinical setting. Using a design inspired by expansive framing, the teacher educators pursued these goals in two ways: 1) they explicitly told PSTs that knowledge from the TEP could be applied in their practicum teaching, and that reflections on their practicum teaching would in turn be discussed in their TEP, and 2) they had PSTs engage in and design activities that they would then use in their practicum. In the TEP course, PSTs engaged in a storytelling activity designed to teach about dramatic arc; they then used the same activity in a lesson with 5th graders at their clinical site. Immediately after, they reflected on the similarities and differences between the lesson as planned and enacted in the TEP and as implemented with 5th graders. The authors found that the PSTs transferred knowledge about dramatic arc and one strategy for teaching about it. Beyond that, PSTs adapted the lesson for the perceived situational demands of the classroom context, as they incorporated some of the underlying learning theory into their lesson. They did not seem to fully connect the theory to their instructional choices, however. The researchers speculated that doing even more to expansively frame the course might help students better see this connection between learning theories and instructional choices. In this study, then, certain types of knowledge (i.e., of disciplinary content and learning activities) were transferred, while other types of knowledge (conscious application of learning theory) were not.

Finally, Andrews et al. (2019) described an online, asynchronous course designed to extend expansive framing from something instructors do for their students to something students do among themselves. Given the scaffold of social annotation prompts that supported intercontextuality between course concepts (theories of learning) and future clinical practice, PSTs did take up expansive framing in their own discourse. Further, those who expansively framed more in their annotations tended to perform better on a final exam which was used as a proxy for transfer, leading the researchers to conclude that the PSTs' expansive framing did promote transfer of course concepts to their future practice.

The research described so far employed PDE and expansive framing as vehicles for teacher learning. Most did so quite successfully, suggesting that these frameworks can serve as powerful strategies for helping teachers learn disciplinary and pedagogical knowledge—and in some cases, transfer that knowledge to the field. Exploration into the extent to which the teachers used the frameworks as pedagogical tools *in themselves* was beyond these studies' scope—for none of them sought to *teach about* the use of PDE and expansive framing to promote student learning. In the following section, we summarize studies that did take this latter approach.

PDE and expansive framing as pedagogical tools for teachers' practice

Nine studies examined teacher educators engaging their students in PDE or expansive framing with the (implicit) expectation of similar approaches being used with *their own* students in their future classrooms. Generally speaking, attempts to encourage pre- and in-service teachers to adopt PDE principles in their practice were met with more limited success than attempts to get them to adopt expansive framing.

Ford and Wargo (2007) aimed for PSTs to engage in what the authors called "authentic disciplinary engagement" (essentially, PDE) in a science methods course. To facilitate that, the authors altered the "routines, roles, and responsibilities" (p. 134) governing the class to conform more closely with authentic science and asked the PSTs to negotiate the "nitty-gritty" details (p. 142) of designing, carrying out, and interpreting the results of an experiment. In terms of Engle and Conant's schema, the course sought to redistribute epistemic authority from the teacher to the community as a whole, thus promoting the scientific practices of peer review and critique. (Other PDE principles, including problematizing and accountability, clearly influenced the course design but did not factor into the authors' analysis.) The findings hold important implications for teacher education: While the PSTs proved capable of themselves adopting the scientific routines, roles, and responsibilities, they tended to view these as inappropriate for K-12 classrooms. Ford and Wargo's study points to the difficulty of transforming PSTs' views of what good teaching entails, even after participating in activities that uphold PDE principles.

Kawasaki and Sandoval's (2019) study represents another attempt to encourage prospective teachers to adopt PDE principles in their own professional practice—also with limited success. The authors designed a PD program aimed at aligning instruction with the Next Generation Science Standards (NGSS) and promoting accountability and authority among students. They argued specifically that teachers need to hold students accountable to their own and their peers' claims, as well as to disciplinary norms, to foster epistemic agency. Drawing on a single case study, Kawasaki and Sandoval found that the teacher struggled to cede epistemic authority and accountability to her students. The authors attribute this to the structure of many of the teacher's class lessons—rather than encouraging students to voice their own ideas about specific physics phenomena, the teacher introduced course concepts in the abstract and had students answer discreet, isolated questions related to their classroom lab activity. This lesson design positioned the teacher as the authority figure and the students as consumers of course content rather than as authors. Kawasaki and Sandoval concluded that their PD program failed to give the teacher the resources necessary to help her pursue PDE as an instructional strategy.

Windschitl and Thompson (2006) offered another less successful example of designing with and for PDE. In this case, the authors sought to build PSTs' appreciation for the epistemic roles that models, theory, and argument play in scientific inquiry. They aimed specifically for PSTs to devise their own models, which would then guide the design of experiments and interpretation of results. The authors linked these aims to PDE principles: in the science methods course they designed, PSTs would need to problematize phenomena and author ideas while remaining accountable to disciplinary norms. The findings were mixed. As learners, the PSTs showed they could use models to appreciate scientific complexity. When planning a unit of instruction at the end of the course, however, most PSTs did not use models as the underlying basis for designing and carrying out an investigation. Windschitl and Thompson conceded that, in its original form, their PDE-based methods course fell short of enabling teachers to integrate scientific modeling into their future instruction.

Based on these results, Windschitl et al. (2008) added two design principles to the PDE framework, calling their augmented system *heuristics for progressive disciplinary discourse* (HPDD). First, PSTs should see modeling of prototypical cases of disciplinary activity early on; and second, they should be given opportunities to take on discursive roles that allow them to practice this activity. To enact the first new principle, the revised course made explicit to students scientific knowledge's epistemic characteristics of being testable, revisable, conjectural, explanatory, and generative. To enact the second new principle, the course asked learners to inquire into the reasoning of their peers in various ways. After experiencing the newly revised course, 15 of 17 participants refined their preconceived notions of models, theory, evidence, and argument, in the desired direction. The following school year, 15 former participants (now student-teachers) were evaluated on applying the methods course concepts to their own teaching: Only 2 consistently used models in the desired fashion, while the rest made various degrees of progress in this direction. However, Windschitl et al. concluded that it was not the HPDD framework that was ineffective, but rather its application in the methods course that compromised transfer to the clinical setting.

Antink-Meyer and Parker (2021) also drew on the PDE design principles to inform PST instruction. In this case, the authors described their re-design of an Inquiry and Design course (IDC) taken prior to a science methods course. They developed three curricular features that each corresponded to at least one PDE design principle. At the end of the course, the PSTs were to design an engineering or science learning activity, which was evaluated on the extent to which it encouraged problematizing, giving students authority, and holding them accountable. The authors found that PSTs who took the IDC alongside a standard methods course designed activities that the authors deemed "student-centered" based on the rubric they used. They also found evidence that the IDC was successful in improving the PSTs' self-efficacy for teaching engineering. Based on these findings, the authors concluded that the IDC's curricular features were valuable for promoting engagement among the PSTs, and that those who took a prior or concurrent methods course were especially prepared to design student-centered learning activities that may promote PDE. The study shows promise for encouraging PSTs to foster PDE in future professional contexts by first having them experience PDE themselves in their TEP coursework.

Finally, Haverly et al. (2020) used the PDE framework to explore how novice teachers (in this case, two interns and one first-year teacher) can make space for students' sense-making. They suggested that equitable science classrooms are characterized by teachers distributing authority through shared ideas and treating these as *epistemic resources*. Through a comparison across the three classrooms, the authors concluded that newer teachers need better support to recognize idea-sharing moments as useful instances of sense-making, as opposed to ones of confusion or misunderstanding.

Compared to these mixed results in promoting PDE, attempts at getting pre- and in-service teachers to adopt expansive framing proved more successful. Stephens et al. (2022) reported on how an expansively framed PD program helped teachers make sense of new computer science (CS) concepts, while also fostering the teachers' own use of expansive framing in their practice. Over a 7-week course, teachers met with researchers weekly to collaboratively plan lessons from a computer science curriculum, *Expansively Framed Unplugged* (EfU). In a creative use of expansive framing, the curriculum leveraged learners' familiarity with board game play to introduce CS concepts that the learners would then transfer to coding activities. Researchers first established the curriculum's success in helping the teachers learn more about coding. They then tracked how the teachers incorporated the course's pedagogical practices in their own teaching. Analysis of teacher discourse with students showed that teachers enlisted the same expansive framing techniques they had learned and benefited from in their PD.

Benichou et al. (2022) studied teacher learning through an extended DBIR partnership for school-based citizen science. Citizen science involves framing settings and roles expansively such that participants become emerging authorities whose work adds to the knowledge of a broader scientific community. In a first iteration, teachers did not identify strongly with the practice and goals of citizen science, instead seeing the partnership as deepening their content knowledge and inquiry teaching practices. In a subsequent iteration, teachers worked more closely with scientists and had the opportunity to act as authorities in ongoing conversations among stakeholders across settings. They subsequently saw their work in the partnership as meaningful, not only to their own professional development, but also to outside scientific and educational communities. In addition, illustrative quotations from teachers showed that they expansively framed their own learning *and* teaching as they planned new school-based citizen science projects for students.

Finally, Hoidn's (2017) book on student-centered college classrooms voiced optimism about how expansively framed TEP contexts can promote teacher learning and transfer. Hoidn described several ethnographic case studies in which instructors drew on elements of both PDE and expansive framing. For example, teacher educators invited outside community members (experienced teachers, high school students, and young children) into their classes to share their own experiences in K-12 schools and to share insight on salient educational problems. Hoidn argued that this framing helped TEP students visualize how they might apply what they were learning to real-world classroom settings. The book also emphasized the extent to which learning is driven by students' questions and solutions that emerge as they struggle to make sense of course concepts, practice taking on authority, and defend their ideas in public discourse. Hoidn's case studies, then, suggest that PDE has significant learning benefits among TEP students, and that using expansive framing can encourage them to think about how they might use experiences from their TEP—especially those aligning with PDE—in future clinical settings.

Discussion

Several key trends emerged from this systematic review of studies applying the PDE framework and expansive framing to teacher education. First, the studies demonstrate positive effects of having pre- and in-service teachers experience PDE in their coursework, such as helping them apply learning theory to problems of practice (Engle & Faux, 2006). That said, experiencing PDE does not necessarily lead them to implement similar forms of instruction in their own classrooms. Studies that did encourage teachers to transfer the use of PDE into clinical settings were met with limited success (e.g., Ford & Wargo, 2007; Kawasaki & Sandoval, 2019; Windschitl & Thompson, 2006). Second, the available evidence suggests that expansive framing does appear to facilitate transfer of other disciplinary and pedagogical concepts from TEP or PD coursework to clinical practice (e.g., Stephens et al., 2022; Benichou et al., 2022). Future research could build on this potential, perhaps as one strategy for helping teachers more readily transfer their use of the PDE principles *themselves* into practice. Taken together, PDE and expansive framing offer promise for addressing longstanding challenges in teacher learning and transfer (e.g., Dreer et al., 2017; Fishman et al., 2022).

One question these findings raise is: Why were expansive framing principles more readily taken up in clinical practice than PDE principles were? It may be that implementing PDE requires more substantial shifts in teachers' epistemic orientations, whereas expansive framing can be practiced on some level simply by adjusting discourse—even while maintaining other, more traditional instructional approaches. Given the two frameworks' substantial overlap, we wonder if a strategy for facilitating the use of PDE in classrooms might be to first introduce teachers to expansive framing. If teachers develop the habit of encouraging their students to relate academic content to outside contexts and experiences, they are already fostering problematizing and authorship of ideas—two key elements of PDE. Other aspects of PDE might follow from there. Future research could look further into ways that PDE and expansive framing might be used together to support teacher learning and transfer.

Another explanation for the lack of teacher uptake concerns the ways the two frameworks were introduced in these studies. While the researchers based their interventions on PDE or expansive framing principles, most did not explicitly outline these principles for their teacher participants. Stephens et al.'s (2022) PD program encouraged teachers to use elements of expansive framing in their own instructional contexts and was ultimately successful. The authors, though, stopped short of demonstrating that the teachers formally used expansive framing as a cohesive instructional strategy. In this sense, the teachers experienced a specific kind of learning without fully appreciating the epistemological shifts required to foster such learning. This and other interventions fell short of helping the teachers understand PDE or expansive framing on a paradigmatic level and as a set of principled teaching strategies for future application in their classrooms.

That said, it is hard to tell just how well the teachers in these studies could apply these frameworks since almost none followed the teachers from the TEP or PD course into the field. Future research could prioritize longitudinal designs of this sort.

Conclusion

Based on our systematic review, we conclude that a nested approach to teacher education is worth exploring more rigorously: Designing teacher learning experiences as expansively framed applications of PDE, explicitly engaging teachers in understanding the design principles on an epistemic level, and directly encouraging them to apply PDE and expansive framing as pedagogical strategies when they plan for instruction themselves.

Framing teacher education expansively and with PDE's guiding principles clearly supports teachers' own learning. However, it is not in itself a guarantee that they appreciate the guiding principles explicitly, know how to design instruction in accordance with them, or that they should automatically want to do that. More research on if and how teachers transfer Engle's tenets into their own practice is needed to understand what is being done in the learning settings these educators create for their students—and why that is. Linking clinical observations to teacher learning that was originally designed for PDE and expansive framing could provide much needed insight. Until then, existing scholarship points to the immense potential of Engle's ideas for illuminating persistent challenges in teacher education.

Infrastructuring Multilevel Connected Learning and the Agility for STEM Curriculum Innovation

Pakon Ko, The University of Hong Kong, kopakon@hku.hk
Nancy Law, The University of Hong Kong, nlaw@hku.hk

Abstract: Would teachers be able to respond with agility and remain on track in their education innovation initiatives in the face of unanticipated external disruptions? This study aims to understand whether and how teachers persist with the innovation efforts they have embarked on when macro-level crisis conditions hit, such as the emergency online teaching that was instituted for extended periods of time due to the COVID pandemic. This study uses the MultiLevel MultiScale (MLMS) model to analyze the infrastructuring efforts made by two schools that had engaged in the same school-university partnership innovation network before the COVID pandemic disruptions started but responded rather differently at the school level in the ensuing 1.5 years. The study finds that the infrastructuring work affected the scope within which teachers can stay on track with their innovation plans, and hence the resultant education innovation agility of a school.

Introduction

In an increasingly complex world, there are bound to be times when teachers and educators encounter fresh challenges and adverse situations that disrupt their plans as what we have experienced during the COVID-19 pandemic. For those schools that have been on track for developing innovative practices, how could they continue to steer education innovations when facing unanticipated threats and unstable situations? Education innovations such as the implementation of self-directed learning pedagogy entails changes in the practices of teaching and learning (Hew, et al., 2016). New practices might be lost easily if these are not accompanied by a continuous history of learning (Wenger, 1998). The capability to sustain education innovations in times of unanticipated crisis is necessary to persist in the strive for realizing significant advances in educational vision and values. This study explores how schools can be agile to stay on track with their educational innovation initiatives even in times of high uncertainties. This could contribute to building knowledge for educators and school leaders to think about how to sustain education innovations in times of crisis.

The call for steering education innovations in unstable situations resonates with the need for agility in the high-tech industries in order to make appropriate innovative responses as the industry exposes itself to unpredictable market volatility and change (Nissim & Simon, 2020). Agility entails flexibility in managing uncertainty (Stigler, 1939) for sustainable organizational change (Worley, et al., 2014), with the capacity to manage its resources in changing contexts to be able to innovate and secure valuable outcomes (Teece et al., 2016). In education, agility requires teachers to approach teaching and learning with a flexible attitude to develop new mindsets for implementing innovations and making change (Nissim & Simon, 2020). The agility also calls for the generation of innovative practices based on existing educational values and visions (Kidd & Murray, 2020). Thus, education agility can be conceptualized as the capability of spearheading change to realize the desired educational visions and education outcomes despite unanticipated obstacles in times of high uncertainties.

Research on agility in education has been focused on individual attributes such as agile leadership (Nissim & Simon, 2020) or individual learning agility (Lombardo & Eichinger, 2000; Özgenel & Yazıcı, 2021). While these studies show us the importance of individual capacity to spearhead education innovations in difficult times, we lack knowledge about the conditions for individuals to learn in sustaining education innovations under challenging circumstances. As teachers are key agents in changing practices, we are particularly concerned about conditions for their learning in times of stress. Wenger's (1998) communities of practice construct highlights the situatedness of learning in the workplace. Thus, conditions in the workplace are also learning conditions which could affect how teachers learn to achieve education agility. The conditions for situated learning (Lave & Wenger, 1991) through the negotiation of meaning in communities of practices are conceptualized as architectures for learning (Wenger, 1998). Teachers could be in multiple communities of practices and their learning interactions can be in different settings such as within the boundary of a community or crossing boundaries of communities for achieving aligned outcomes of education innovations (Stein & Coburn, 2008). Their learning can be affected by architectures for learning across different settings. A systems view is thus needed for understanding how to support teacher learning for changing their practices through changes in their situated environments.

Curriculum and pedagogical innovations introduce changes to the goals and practice of education, as well as the roles of teachers, students and other stakeholders that require changes in terms of organizational routines, support services, and technology infrastructure for them to become sustainable and scalable (Law, et al., 2021). The implementation of innovations is a dynamic process that requires continuous efforts on (re)designing infrastructures such as reform-related policies, allocation and management of human and technological resources, curriculum materials and school routines, etc. to ensure that the innovation stays on track. Such efforts are referred to as infrastructuring (Penuel, 2019). Within a systems view, the infrastructuring work could also be conceptualized as a process of *learning*—a process of evolving changes at different levels and parts of the system in the process of adapting to the broader environmental context. Law, et al. (2015) identified four key components within the context of educational innovations that are crucial to the scalability of such innovations—the organizational structure, interaction mechanisms, reification artifacts and technology—which they refer to as the architectures for learning (AfL). Infrastructuring work is about intentional adjustments in the architectures for learning. It is contextual and needs to respond to changes at different levels of the system.

While there cannot be a one-size-fits-all set of architectures for learning for any kind of innovation context, there could be principles to guide infrastructuring work for teacher learning to achieve aligned changes at different levels. Law, et al. (2015) put forward a Multilevel MultiScale (MLMS) model that can be used to analyze the architectures for learning within a research-practice partnership (RPP, Coburn & Penuel, 2016). The MLMS model also provides a set of guidelines for evaluating whether the architectures for learning contain weaknesses that might cause the infrastructuring efforts to fail in achieving scalability.

The purpose of our study is to explore the relationship between the efforts of infrastructuring on architectures for learning and education agility in terms of teachers' ability to persist on their course of educational innovation in situations of high uncertainties and volatility. The study was conducted within the context of a School-University partnership innovation Network for advancing self-directed learning in STEM subjects in Hong Kong (to be referred to as the SDL-STEM Network). When the COVID-19 pandemic first struck the city, these Network schools responded differently but most of them were able to get back on track for their set innovation goals at the end of a 1.5 years of disruption (Ko, et al., 2022). Two schools (X and Y) were selected from among those schools that got back on-track to resume their SDL-STEM innovation commitment for the purpose of this study. Both schools were similar in having engaged in the Network for years and showed demonstrable progress on their innovation trajectory before the pandemic. Teachers in School X developed high confidence in the face of uncertainties and had developed a larger scale of innovation implementation for SDL-STEM during the 1.5 years tracked by this study. On the other hand, the SDL-STEM initiatives were stalled in School Y initially, but teachers were able to implement a new SDL-STEM curriculum unit in the end and the school was prepared for scaling up related educational innovation with the introduction of a new subject in the new school year (2021-22). We analyzed the features of the infrastructuring work undertaken by both schools using the MLMS framework, as well as the motivations and goals underpinning their infrastructuring efforts, to explore whether and in what ways the infrastructuring features influenced the schools' agility in staying on track in the SDL-STEM innovation. We use the following two research questions to guide the investigation.

RQ1: What changes in the architectures for learning (i.e., the infrastructuring work) took place in the two schools from the start of face-to-face class suspension to the end of the study period?

RQ2: Is there a relationship between a school's infrastructuring work and associated teacher learning as well as the innovation outcomes in terms of the initial innovation goals?

Conceptual framework

Education innovations invoke changes in infrastructures as well as practices of learning and teaching. A change in infrastructures is needed to support changes in practice as learning is affected by the changing socio-historical contexts (Wenger, 1998) as well as the changing sociocultural and technical aspects of their situated environments in the system (Law, et al., 2016). With an ecological perspective, the adaptation and sustainability of changing practices require *changes as learning* at multiple levels such as policy, school, teacher and student levels in a system, and changes at one level could affect learning conditions at other levels (Davis, et al, 2013; Law, et al., 2016). While teacher learning is needed for developing new practices to shape learning conditions at the student level, their learning is also shaped by the changing infrastructures around them as informed by the situated learning theory (Lave & Wenger, 1991). Infrastructuring work is about the design of the conditions for the development of new practices in a system through changing the infrastructures. Infrastructures, for example assessment materials, school schedules, teacher professional development support, organizational routines (Penuel, 2019), are hidden substrates to ensure the smooth running of certain practices and standards within a community (Bell, 2019). They are taken for granted until they must be re-designed for building the appropriate capacity or conditions for the accommodation of new practices. The aim of infrastructuring work is not merely to sustain a single innovation but about building the capacity of people and systems for the changing practices (Penuel, 2019). Capacity building entails learning processes among different change agents and requires conditions for learning to align with the goals of the changing practices. The re-design of infrastructures cannot be a top-down process but should engage teachers in the inquiry and co-design process for it to contribute to capacity building (Penuel, et al., 2023). Positioning teachers and school leaders as learners for advancing education innovations, their agency and decision-making power are of great importance in the infrastructuring work.

We connect infrastructuring work (Penuel, 2019) with the concept of architectures for learning (Stein & Coburn, 2008; Wenger, 1998) as both are concerned about the design of learning conditions for capacity building and underpinned by sociocultural learning theories. The concept of architectures for learning focuses on supporting learning through the negotiation of meaning achieved via participative interactions and reification in communities of practice (Wenger, 1998). Law, et al. (2015) identified four key components of architectures of learning that shape participation and reification in learning interactions: organizational structures, interaction mechanisms, reification artifacts, and technology. Organizational structures such as subject departments determine who participates in decision making for specific levels of issues and who would take responsibility for effecting the action. Interaction mechanisms formalized through routines, such as co-planning meetings, facilitates people to get together and interact with regard to specific foci. Reification artifacts hold outcomes of prior negotiated meaning, propagate meanings, and create focal points for communication and negotiation (Wenger, 1998). Technology as a component of architectures for learning has its potential role as reification artifacts and as a platform for creating interaction mechanisms. These components could constitute categories of infrastructures for supporting learning in relation to specific work practices. We hypothesize that effective infrastructuring work should foster architectures for learning to give impetus to three building blocks for learning in practice as proposed by Wenger (1998): engagement, imagination, and alignment. Engagement means learners' contribution to the community they are in and their collaboration with others to achieve shared objectives. Imagination allows learners to explore and know where they are and to which direction they are moving. This relates to the sharing of visions in the community. Alignment allows learning communities to expand their horizons and cross boundaries to make contributions to broader objectives on a larger scale.

We use the MLMS model (Law, et al., 2015) as an analytical framework to examine how the infrastructuring work was carried out via the architectures for learning and how it affected teacher learning and education agility. The MLMS model with an ecological perspective gives a structure to examine infrastructuring work in terms of changing components of architectures for learning at multiple levels with a systems view. Cross-level interactions are necessary to ensure the alignment of reform goals (Stein & Coburn, 2008). The learning outcomes at one level could become or affect learning conditions at other levels (Law, et al., 2016). Hence successful alignment implies a series of connected changes at multiple levels. The MLMS model differentiates scales of learning interactions through defining the richness of idea diversity in the process grounded by the theory of knowledge building (Scardamarlia, 2002). The "scale" of learning interactions within the MLMS model refers to the diversity of interacting organizational units within the same level. The idea diversity becomes much richer with more members from diverse backgrounds co-participating in the design process. Members from the same community of practice share a similar history of learning for the continuation of within-unit practices but they have opportunities to learn new ideas for practices when they cross the boundary unit to interact with members from other units (Wenger, 1998). Cross-unit (i.e., cross-school/organization in this study) interactions thus increase the "scale" of the professional exchanges, facilitating more democratic sharing of diverse ideas and negotiations of meaning. However, schools are autonomous, self-governing entities regarding their own architectures for learning and cross-unit interactions cannot directly make decisions regarding within-school changes. To arrive at infrastructuring decisions that address the tensions experienced by teachers and school leaders at different levels, the innovation process requires the availability of within-unit mechanisms for co-participation and appropriate reification. Thus, the MLMS model provides a framework for analyzing infrastructuring work of schools with attention to teachers' and school leaders' agency in learning and making change.

Research method and design

Research context

The investigation reported here is situated in a larger design-based implementation research (DBIR) study in a 2.5-year charity-funded university-school partnership programme to advance integrated STEM education with pedagogical approaches informed by self-directed learning (Hew, et al., 2016; Knowles, 1975). The programme involved a network of 32 government-funded primary and secondary schools when the pandemic started, which was about a year after the project was launched. The design of the Network was informed by the MLMS model that architectures for learning at network, school (leadership) and teacher levels are necessary to support teachers' curriculum and pedagogical innovations to deliver self-directed learning (SDL) experiences for their students through curriculum units that span more than one STEM discipline (referred to as integrated STEM). At the start of the COVID-19 crisis, the Network re-designed its own infrastructures, including setting up emergency online meetings as *interaction mechanisms* for school leaders and teachers in the Network to share experiences of the challenges encountered and strategies that were successful in addressing them. The sharing and co-inquiry covered issues at various levels, such as school policy and routines, technology arrangements and support for teachers and students, including strategies to detect cases of hardship and stress among students during school suspension, and ways to provide socioemotional support within the school community. The Network collated the shared situated knowledge under thematic headings and set up a dedicated website for open dissemination of *reification artifacts*. Shortly after addressing the most pressing crisis management issues, the pre-pandemic monthly Network teacher professional development events resumed, but took place using both synchronous and asynchronous online *technologies.* By refocusing the Network activities on the SDL-STEM project goals via alternative channels of communications and interactions, the University partner also wanted to model how the use of technology could be designed to support online STEM learning. Each Network school was originally committed to the development of STEM curriculum units with dedicated support from a Network consultant assigned by the university team. However, schools had full autonomy in determining their innovation pathway. During the pandemic, the Network schools could re-design their own new strategies, and the mode and frequency of school-based co-planning meetings, lesson observations and open classrooms. Among the 30 schools participating in the two innovation networks supported by the same university team throughout the 1.5 years from the onset of the COVID-19 pandemic, 26 schools were able to resume the design and implementation of SDL-STEM innovations by the end of that period (Ko, et al., 2022). The selected two case study schools, X and Y, were among these 26 schools for in-depth examination of their infrastructuring work during this period.

Methodology, sampling, data sources and analysis

The investigation adopted a qualitative case study methodology (Yin, 2003) with comparative analysis of teacher learning in two different schools. A comparative case study method is suitable for investigating cases with common relevant characteristics or interests through comparing commonalities and differences in actions through time (Miles, et al., 2020) to find out the "predictable reasons (a theoretical replication)" (Yin, 2003, p.47). A two-case comparative analysis is a heuristic design that identifies features more responsible for the generation of specific outcomes. The two schools in this study, X and Y, were purposefully selected as they were among the successful schools in staying on track for the innovation during the crisis. Both are primary schools that had been collaborating with the university team for 3 and 4 years respectively, which include collaborations in prior funded Networks for self-directed learning before joining the current SDL-STEM innovation Network. Multiple data sources were used for examining these schools' infrastructuring work as well as their teachers' engagement in STEM curriculum innovation during the study period of 1.5 years from the pandemic outbreak. Data used in this study include transcriptions of interviews with principals and teachers held at the end of each academic year, transcriptions of teacher sharing during Network meetings, fieldnotes, audio-recordings of co-planning meetings, video-recordings of lesson observations, and transcriptions of debriefings in the two schools.

We investigated changes in infrastructures during the study period in two phases based on the academic school year as it was a common practice for schools to revise their yearly plan in preparation for a new academic year. The first phase was from the end of January to August 2020, starting from the first school suspension due to COVID-19 until the end of that school year. The second phase was from September 2020 to July 2021. We took several steps to analyze schools' efforts on infrastructuring work for teachers to have learning opportunities to face unanticipated challenges. As learning brings changes (Law, et al., 2016), we first coded the data of interviews, debriefings and teachers' sharing collected in the two phases to identify (i) the learning conditions and outcomes and (ii) challenges at different levels in each of these two phases, which allowed us to identify changes, if any. Aligning with our focus on infrastructuring, we categorized the changes under the four architectures for learning components: organizational structures, interaction mechanisms, artifacts, and technology (Law, et al., 2015). Adopting an ecological perspective, we also investigated the relationship between learning conditions and the changes effected (learning outcomes) to meet the challenges encountered at different levels. Importantly, we analyze the schools' infrastructuring strategies within the context of their modified innovation visions and goals in the face of mega-scale disruptions due to the extended periods of pandemic-induced school suspension.

Findings

Right before the pandemic hit, both schools X and Y targeted to build teacher capacity for STEM curriculum development with self-directed learning as a pedagogical approach of choice, but they had different strategies and major concerns. The principal in school X emphasized on making progress in the development of STEM education with hands-on and technology-facilitated STEM activities. Teachers from different subject departments engaged in and shared the responsibility of developing these curriculum innovations. The innovation focus of Principal Y was on building teacher capacity to scaffold inquiry learning and to foster an innovative mindset among students. In past years, different novice teachers in School Y were assigned to work with experienced teachers in the school-based project team as an innovation diffusion strategy to build teacher capacity beyond the STEM subjects. When the COVID-19 pandemic struck, both schools maintained their engagement in the scheduled Network meetings. However, both schools were unable to continue their original plan to design and implement STEM innovation curriculum units during the first phase of class suspension. On the other hand, teachers in both schools were able to innovate, develop and implement new STEM curriculum units in the second phase. School X teachers developed the capacity and confidence to implement STEM curricula with hands-on activities despite the having to teach fully online. School Y embarked on a school-based curriculum reform by spearheading the creation of a new school subject to foster students' 21st century skills throughout the six primary grades, and involving the efforts of the entire school in scaling-up the concept of curriculum integration based on their experience with STEM integration. Figure 1 provides an overview of the infrastructuring work across the two phases in schools X and Y respectively, showing only key changes in the architectures for learning components at school (leadership), teacher and student levels in relation to the SDL-STEM innovation focus in the Network. In the following part, we will answer the two research questions by first highlighting changes in the architectures for learning and challenges faced by teachers in the two schools, and then relate their infrastructuring work to teacher learning and innovation outcomes in times of uncertainties.

Infrastructuring work in school x

In the first phase, team teachers in school X faced the challenge of designing distance learning as they had no experience in conducting online lessons. The initial infrastructuring work featured in school X was a change in organizational structures to enable some teachers in the school to focus on re-designing the learning tasks to make use of technology so that they can be conducted at a distance. The cross-subject teacher team reverted to work in subject-based teams to focus on the exploration of how to facilitate students' self-directed learning at a distance during school suspension. The second feature was the use of an existing reification artifact facilitate imagination. Instead of moving on with the development of the new curriculum unit, teachers used a previous STEM curriculum unit and imagined how that could be adapted for implementation in the home-based learning conditions. They then engaged in the experimentation of home-based hands-on learning. Some students were able to conduct home-based investigations and uploaded videos for teachers to examine. Engaging in the exploration process made teachers affirm the plausibility of home-based hands-on learning while feeling discontented about how students' engagement had been limited by the materials students had access to. Teachers' discontent in the exploration stage contributed to changes in school level infrastructures for student learning such as delivering hands-on materials to students in later implementations. The initial infrastructuring process of the School in the second phase was the revitalization of a nested organizational structure for the innovation with a cross-subject team to spur more teachers to be involved in the curriculum innovation process at three different grade levels. This was followed by a re-emphasis of the school-level goal of self-directed learning (a school-level reification) which became a common language among leaders and teachers. The third infrastructuring move was the enhancement of multidirectional cross-unit interactions for building teachers' innovation capacity. The vice-principal and curriculum leaders created more beyond-unit interactions between teachers and the University-based Network consultant to facilitate the generation of new solutions in the face of uncertainties in the resumption of face-to-face classes. The teacher team enhanced their ability to use technology to manage and negotiate meanings through reification artifacts such as lesson designs among team members and with the Network consultant. With improved competence in conducting online lessons, teachers further experimented with ways of conducting hands-on synchronous lessons. At the school-level, learning outcomes were evidenced by the generation of guidelines for online lessons and the increase in funding for home-based hands-on learning materials. These developments provided opportunities for students to demonstrate their abilities in using technology for interactive learning. The teachers' enhanced competence was reflected through their sharing during online Network events.

> "After we made preparations for a physical classroom, we would think about what can be implemented online that we can do the same, and what can be replaced with some virtual means… so we will prepare a little more, and we can solve problems in the face of different situations" (Teacher X5, project team teacher, in Jul 2021 year-end interview)

Infrastructuring work in school y

At the start, similar to school X, team teachers in school Y lacked experience in conducting online lessons during the first phase. A new STEM curriculum unit scheduled to be implemented was halted in response to the first period of stipulated school suspension. Cross-school and within-school interaction mechanisms for STEM curriculum innovation diminished in the first half year. When the face-to-face classes resumed during the first phase, teachers found difficulties in re-arranging the provision of materials to individual students when students could not work in groups due to the need for social distancing within physical classroom settings. There was also a growing tension between time for catching up with the planned teaching schedule in the subject curriculum and time for the innovation implementation. Teachers decided not to continue the implementation despite feeling disappointed by the inability to realize the designed self-directed STEM learning opportunities for their students.

In the second phase, the original project team was replaced by two parallel strands of infrastructuring. First, the school set up a subject-based team with novice and experienced project teachers to take responsibility for the development of a new SDL-STEM curriculum unit, the scope of which was confined within a single school subject for one grade level. In parallel, the school established a cross-disciplinary task force to focus on the imagination and preparation of a new school subject to foster the development of 21st century skills (such as critical thinking, communication, collaboration, and creativity) to be delivered to students at all grade levels. This initiative was embarked upon to realize the implementation of curriculum integration with self-directed learning beyond STEM subjects. The principal engaged some existing and former project team teachers with experience of curriculum integration gained through the Network project to contribute to this new initiative.

The two initiatives described above were in fact connected. The new STEM curriculum unit which was underway in the second phase constituted one component in the new subject on 21st century skills. Co-planning meetings were resumed for the design of the new STEM curriculum unit. The project coordinator was able to arrange an online co-planning meeting with the Network consultant. When there was a change in the territory-wide policy about giving schools discretion to run a limited proportion of half-day face-to-face classes, the school decided to allocate some regular face-to-face class time for the STEM curriculum unit, indicating the priority given to removing the obstacles in conducting hands-on learning activities in the innovation implementation. After that, teachers were able to implement the newly designed curriculum unit and later to conduct an open class for learning together with other Network schools. Throughout the implementation experience, teachers felt discontented with the time constraint to implement STEM education within a conventional subject in the pandemic as they understood the provision of self-directed learning opportunities in STEM required time. Unlike school X, teachers in school Y did not learn how to run online hands-on STEM lessons. However, the instructional time constraint felt by teachers when innovating STEM education in the pandemic became a support for the school's infrastructuring work of a new subject in which more lesson periods would be allocated for STEM learning. Teachers felt optimistic with the new subject and were prepared to re-design curriculum units to extend self-directed learning opportunities for students with the concept of curriculum integration for the year ahead.

Comparison between schools x and y

A comparison between schools X and Y illustrates how infrastructuring work could influence teachers' learning trajectory and hence their agility in staying on track in curriculum innovation under crisis situations. Their agility is supported by a determined intention to scale up innovation despite being in difficult situations. The infrastructuring work in the two schools were respectively driven by different educational priorities. According to the principal in School X, their innovation was driven by a focus on enhancement of self-directed learning with hands-on STEM learning through pedagogically appropriate integration with e-learning as a visible outcome or "end-product". The work in school Y was driven by a focus on curriculum integration and self-directed learning by building on their experiences in STEM innovation. To achieve their respective focal visions and goals, infrastructures were instituted to support imagination, engagement, and alignment (Wenger, 1998). School X set up a renewed organizational structure in the first phase for teachers to focus on technology-enhanced pedagogical innovations. Teachers imagined home-based hands-on learning with existing STEM lesson design and engaged in experimenting new ways for students to engage in STEM inquiry. Their design principle aligned with the goal of self-directed learning at both school and network levels. School Y set up a task force to imagine and plan for a new subject which was aligned with the overall educational goal of the original project but their ambition went beyond STEM education. Previous designed curriculum units were used to facilitate imagination. Previous and new project teachers engaged in the innovation process despite the mega-scale pandemic disruptions.

Infrastructures at different levels necessarily change through multilevel multiscale connected learning. For example, the change in organizational structure in school X at the school level facilitated the exploration of home-based hands-on learning at the teacher level in the first phase. Responses from students and teachers' discontent led to school-level funding support increase for hands-on materials in the second phase. Guidelines for online lessons at the school level facilitated learning interactions during the synchronous hands-on lessons at student and teacher levels in the second phase. While school Y teachers faced severe instructional time constraints in designing STEM curriculum units within a subject-based team during the pandemic, a new task force at the school level was in place for developing a new subject as a new infrastructure to enrich self-directed learning opportunities and curriculum integration for the development of students' 21st century skills. When learning across levels is connected, teachers' discontent could stimulate or support emerging changes in infrastructures.

Conclusion and implications

Guided by the MLMS model, we examined the infrastructuring work of two schools in terms of changes in architectures for learning at school leadership, teacher, and student levels. The differences between schools X and Y in (re)designing components of architectures for learning illustrates how the educational goals and foci underpinning infrastructuring work could affect how teachers learn and the ensuing innovation outcomes in times of crisis. Infrastructuring work in both schools are characterized by the provision of opportunities for imagination, engagement, and alignment (Wenger, 1998) for learning and achieving innovation agility. While infrastructuring cannot be prescribed, it can be guided by design principles for multilevel multiscale connected learning to achieve dynamic alignment for innovation advancement. This study was limited to the exploration of infrastructuring work in two schools with substantial experience of engaging in education innovations in the same Network. Analysis of the infrastructuring work using the MLMS framework shed light on how these two schools were able to stay on track with connected learning at multiple levels and within/across units but with different developmental foci. Further research is needed to explore the value and limitations of this framework in its application to the analysis of infrastructuring among a wider spectrum of schools with different responses to crisis situations. More research is needed to understand the agility of schools and teachers in responding to crisis situations and its relationship to infrastructuring design to enrich the literature on the scalability of education innovations.

Abstract: Understanding why and how to support claims with data is a key challenge in scientific inquiry. We propose that arts-integrated approaches to data literacy have potential to increase engagement in data reasoning and support students in making data-based arguments. We co-designed a data storytelling unit, which aimed to engage 8th-grade students with their neighborhoods through photography and data. We asked: (1) How did students reason about data in their artist statements? (2) How did students use artistic strategies to communicate a message in their photo-essays? and (3) In which ways do data reasoning and artistic strategies co-occur in photo-essays? Based on qualitative analysis of 20 photo-essays, we found that students operationalized socio-scientific concepts through use of *variety*, highlighted differences within or between neighborhoods through *contrast*, and synthesized quantitative and qualitative data through *pattern*. Findings suggest that connecting artistic strategies and data reasoning practices generates opportunities for critical data literacy.

Introduction

The ability to ask questions, analyze and interpret data, construct evidence-based explanations, and engage in argument from evidence is essential to scientific literacy (National Research Council, 2013) and for societal engagement more broadly. Creating and interpreting data visualizations are key practices in making evidence-based claims that relate one or more variables to an outcome variable (i.e., scientific explanations). In middle school, students might construct a scatterplot to investigate whether the relationship between two variables is linear/non-linear and strong/weak; consider and interpret data represented in maps and histograms; or collect their own data. Yet students commonly struggle to support claims with evidence. They may fail to justify conclusions, consider the limitations of data, or support arguments with specific data (Hug & McNeill, 2008; Sandoval, 2003). Students may also approach "data as something to be explained but not as a necessary component of an argument" (p.41; Sandoval, 2003). More research is needed to explore how integrating data reasoning and artistic practices might support students in constructing data-based arguments.

Data storytelling is an interdisciplinary practice that supports *data literacy*, or "the ability to read, work with, analyze, and argue with data as part of a larger inquiry process" (p.84; D'Ignazio & Bhargava, 2018). Data stories integrate visual and narrative elements to engage an audience with data. Stories often elaborate on graphs, explaining what choices were made during data analysis, why a question is worth investigating, or the results of data analysis (Wilkerson et al., 2021). These visual narratives or arguments often highlight the people behind the data (e.g., the data storyteller or communities represented by the data) and aim to connect data to lived experiences (Lupi & Posavec, 2016). Data storytelling, therefore, has potential to challenge neutral, objective conceptions of data and support students in building *critical data literacy*, or using or producing data in ways that consider, highlight, or challenge inequities in social or environmental contexts (Philip, 2013; Bhargava et al., 2015; Tygel & Kirsch, 2016; Pangrazio & Selwyn, 2019; D'Ignazio & Klein, 2020). We suggest that data storytelling is particularly relevant for engaging students with data in non-math contexts and that more research is needed to investigate the role of artistic practices and materials in making sense of data.

In this study, we investigated how middle school students connected data reasoning with artistic strategies through the construction of photo-essays. Photography has been used in education to critically engage students with their community (e.g., photo-voice) as well as help students see mathematical relationships in everyday contexts (Meier et al., 2018; Rizzo et al., 2019). Yet in these studies, participants do not engage with quantitative data nor attempt to connect data reasoning to artistic strategies (i.e., principles of design, composition strategies, and elements of art). Photographs are used as a tool for elicitation rather than argumentation. To support argumentation, we build on documentary photography, which has a history of bringing attention to hidden stories and social issues by highlighting the lived experiences of people. Dorothea Lange brought public attention to the lives of poor, migrant workers during the Great Depression (e.g., *Migrant Mother, 1936*), Henri Cartier-Bresson captured “decisive moments” to elevate everyday street life, and Eugene Smith chronicled the everyday lives of individuals through a series of photos (e.g., *Country Doctor, 1948*). In more recent years, Wendy Ewald and Tony Diefell collaborated with students, who are frequently subjects of images, to represent themselves and their needs through photography (Klingensmith, 2016). However, the increasingly personal ways that data impact our everyday social interactions presents new challenges for documentary photography and data storytelling. We explore how integrating these practices might support critical perspectives about data.

Background

Data stories are syncretic texts; they create potential for new forms of action by connecting practices that are often in tension, such as everyday and formal practices or practices in art and STEM disciplines (Gutierrez & Jurow, 2016). Data storytelling activities implemented in non-math contexts can lead to sense-making, critical questions about how data are produced and used, and data wrangling (Wilkerson & Laina, 2018; Stornaiuolo, 2020; Kahn, 2020). For example, 7th grade students in a science classroom drew on their lived experiences to generate new lines of inquiry and ask critical questions about how data were produced (Wilkerson & Laina, 2018). High school students in a media arts maker space integrated data inquiry and visualization with design and storytelling to investigate how they spend their time (Stornaiuolo, 2020). Researchers found that students expanded their ideas about what counts as data (e.g., narratives, art, social interactions), seeing everyday experiences as opportunities for data collection. Students also widened their conceptions of how data can be used, for example, to know something, to learn about themselves, or learn about issues that matter to them (Stornaiuolo, 2020). A third study, which engaged youth in connecting family stories of migration to U.S. census data, found that data storytelling prompted students to engage in data wrangling (Kahn & Jiang, 2021). We build on these findings by designing opportunities to engage students in explicitly connecting data with artistic techniques and strategies used in photography.

Visual artists draw on an understanding of elements of art, principles of design, and composition strategies to construct meaning in their artworks (National Coalition for Core Arts Standards, 2014). Principles of design like variety, contrast, and pattern emerge through the organization of elements of art and use of composition strategies (J. Paul Getty Museum Education Staff, 2023a). Data storytellers who build on photography often find ways to connect quantitative data to photos that highlight everyday places, events, and routes; potential social and environmental consequences; or physical experiences and emotion (Segal, 2015; Field, 2021). These strategies mirror critical approaches to data visualization, such as those described by Data Feminism. Data Feminism is an approach to data “informed by direct experience, by a commitment to action, and by intersectional feminist thought” (p.10; D'Ignazio & Klein, 2020). The seven principles of data feminism include: (1) examine power, (2) challenge power, (3) elevate emotion and embodiment, (4) consider context, (5) challenge binaries and hierarchies, (6) embrace pluralism, and (7) make labor visible. We build on the principles of Data Feminism as a framework for critical data literacy, because they offer concrete design challenges and criteria that are relevant to visualizing data.

We designed opportunities to engage students with principles of Data Feminism by integrating data analysis into an art classroom, engaging students in telling data stories about their neighborhoods, and using photography as a tool for data collection, inquiry, and visualization. In their review of data literacy curricula, Lee and colleagues (2022) identified similar design characteristics that supported engagement with various principles of Data Feminism. Researchers also suggested designing for critical engagement by creating opportunities for students to reflect on how data are produced and measured, identify disparities within or between neighborhoods, and make arguments for change. In this study, we ask: (1) How did students reason about data in their artist statements? (2) How did students use artistic strategies to communicate a message in their photo-essays? and (3) In which ways do data reasoning and artistic strategies co-occur in photo-essays? This study offers insights into how arts-integrated data literacy units might engage students in constructing data-based arguments that use or produce data in ways that consider, highlight, or challenge inequities in social or environmental contexts.

Methods

Participants and context

In this study, we discuss findings from Year 2 of co-designing an arts-integrated data literacy unit investigating the question, “What contributes to a healthy neighborhood?” Participants included 20 eighth graders from a private middle school in a large urban area with a predominantly Latine and Black or African American population (85%). About 70% of students who attend the school are eligible for a free-or-reduced-price lunch. The initial curriculum was co-designed by two teachers, one who taught art and PE and one who taught math and ELA, during Year 1 (Amato, 2022). Teachers aimed to engage students in creating and interpreting scatterplots from community data, constructing stories inspired by data, and recognizing how art can be used for multiple purposes (e.g., to advocate for change or engage in inquiry). The second iteration, led by the art teacher, had a greater focus on artistic practices: (1) Students had three structured photography activities (vs. one photo walk), (2) lessons discussing elements of art, principles of design, and composition strategies were added, and (3) student writing was framed as an artist statement (vs. a letter) and supported with professional models and guidelines for introducing an artwork through description, reflection, and analysis (J. Paul Getty Museum Education Staff, 2023b).

Unit description

In this 13-day arts-integrated data literacy unit, which ran for 5 weeks, students were asked to create photo-essays in response to the prompt, "What contributes to a healthy neighborhood and why should people care?" Students engaged in the unit primarily in art/PE classes (8 classes total, one to two 45-minute classes/week). Individual lessons which focused on data analysis and writing were further supplemented with class time in math (3 classes) and ELA (2 classes). The unit included the following key activities:

1. **Introduction to data storytelling:** Students are introduced to the driving question and to the practice of data storytelling through the discussion of model photo-essays.
2. **Photo-walk 1:** "Tell a story about your neighborhood in three photos." This activity included in-class reflection: identifying key themes in photos, explaining how photos connect to the driving question, and constructing statistical questions to explore in their photo-essays.
3. **Analysis of neighborhood data:** (1) Create neighborhood maps that show places or routes that contribute to or symbolize a healthy neighborhood. (2) Investigate and analyze data from *data2go.nyc* (e.g., make a scatterplot, compare neighborhood statistics).
4. **Photo-walk 2:** Construct a data story that responds to the question, "What contributes to a healthy place and why should people care?" This activity included an introduction to elements of art and composition strategies, creation of a shot list (i.e., outlining a sequence of images and describing how each image connected to statistics they had investigated), and photo-captioning.
5. **Analysis of neighborhood data:** Reflect on emerging themes or trends in photo-essays and revisit *data2go.nyc* or other data source to refine data-based arguments.
6. **Photo-walk 3:** A whole-class photo walk in a well-known regional park. Students practiced composition strategies (e.g., leading lines, framing, point of view) and explored their topic in a different context. Students decided whether to integrate images into their final photo-essay.
7. **Construction of artist statements:** Students were prompted to introduce their work of art to an audience by engaging in description, reflection, and analysis of photo-essays.
8. **Presentation:** Students presented their photo-essays to peers, teachers, and researchers and finalized their work for a collective presentation in a well-known photography festival.

During the implementation, the curriculum was adapted in response to the following events: the art teacher received approval for a field trip to a well-known regional park, which shifted the order of photo-walks, centralized an investigation of greenspaces, and offered an opportunity to photograph a contrasting neighborhood. In addition, midway through the unit, the teacher was notified that her students would be able to participate in a well-known photography festival, which shifted the deadline for final photo-essays a week earlier than anticipated.

Data sources and analysis

Our data consist of 20 student photo-series, artist statements, data journals, and one 45-minute semi-structured interview with three students. We also triangulated findings with data from a one hour-long post-implementation interview with the art teacher in which we asked her to reflect on a selection of student photo-essays. We first read through students' photos and artist statements and described their main message. To answer RQ1 we used a constant comparison approach (Strauss & Corbin, 1998) to open code 20 data journals and artist statements for instances of data reasoning, ways in which students read data, read between data, or read beyond and behind data (Shaughnessy, 2007). Data reasoning codes included: describes a data point, makes a quantitative comparison, describes a bivariate relationship, and asks a statistical question. In a second pass, artist statements were then read in relation to principles of Data Feminism to characterize critical ways in which students read beyond and behind data (D'Ignazio & Klein, 2020). We then summarized data reasoning and critical data reasoning codes for each student. Table 1 shows the final set of codes for *critical data reasoning*, which are based on principles of Data Feminism.

Table 1
Critical data reasoning codebook

Critical Data Reasoning Code	Description & Student Examples
Embrace Pluralism	Makes a claim based on 2+ data types or sources. (e.g., personally-collected and public data.) Example: "Places with higher amounts of pre-schools had a higher percentage of children enrolled in the schools."
Elevate Emotion & Embodiment	Connects to lived experiences or emotion while (1) personally collecting data, or (2) reasoning about a statistic or graph. Example: "I see so many cigarettes everyday just on my walk to school. One day, I ended up counting 57 cigarettes on just one block."
Examine Power	Reasons about social or environmental implications or how data supports a claim about equity. Example: "There is a lower percent of white people who have diabetes in the Bronx area. I guess white people have access to better foods and proper medication to treat the start of diabetes."
Challenge Power	Generates new lines of data inquiry or ways to address issues of equity using data. Example: "The higher the white percent of people the more the health insurance coverage. The pattern could be shown because in most neighborhoods they are grouped by ethnicity. This could be important to show where more health insurance coverage could be put."
Rethink Binaries & Hierarchies	Reasons about how big ideas are operationalized or measured. Example: "... Life expectancy is a good way to measure the health of places because it shows how long people live in a certain neighborhood."
Consider Context	Represents details about social and environmental context to frame interpretations of data. Example: "*Downtown commercial area:* This is an area where all residents come together to shop. I love the cozy cottage, village vibe…"

To investigate how students used artistic strategies to communicate a message in their photo-essays (RQ2), two researchers independently coded photo-essays, looking at both the photo series and artist statement to identify artistic strategies related to their main message. We used a constant comparison approach to identify the following characteristics (Way, 2006; J. Paul Getty Museum Education Staff, 2023a): (1) principles of design: e.g., variety, contrast, pattern, (2) elements of art: e.g., line, color, value; and (3) composition strategies: e.g., leading lines, background/foreground. For each photo-essay, we discussed discrepancies in codes and came to a consensus. We then summarized frequencies for each principle of design and used codes for elements of art and composition strategies to help describe how design principles were constructed in students' work. Finally, to identify trends in how students connected critical claims and evidence to design principles (RQ3), we analyzed photo-essays for co-presence of critical data reasoning, data reasoning, and principles of design codes.

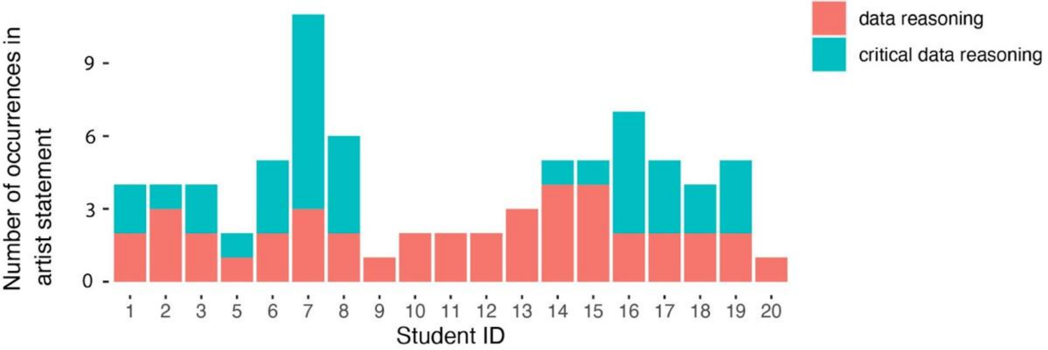
Findings

Participants constructed photo-essays that reflected on the health of their neighborhoods from various perspectives. Some students highlighted common, potentially overlooked, problems that affect their everyday life, such as litter on the streets, exposure to construction or highway traffic, access to nature, safety, poverty, access to healthy food, and unhealthy behaviors such as smoking. Others highlighted community resources using data such as neighborhood helpfulness, access to transportation, planned tree plantings, rates of recycling, and how small businesses support community members. To investigate these themes, students demonstrated both data reasoning and critical data reasoning in their artist statements and attention to principles of design in their photo series.

RQ1: Students reasoned critically about data in their artist statements

Students reasoned about data in their artist statements by asking statistical questions, citing relevant data points, describing bivariate relationships, and/or making quantitative comparisons. 13 students went further, also demonstrating critical data reasoning (see Figure 1): examining power (N=8), embracing pluralism (N=5), challenging power (N=5), elevating emotion and embodiment (N=3), and rethinking binaries and hierarchies (N=3). In their interview, three students reflected on how they not only read data but selected relevant data, considered how different variables were connected, and thought about how data "comes into play with society."

Figure 1
Number of occurrences of data reasoning and critical data reasoning in students' artist statements



RQ2: Students used variety, contrast, and pattern in their photo-essays

Students drew on principles of design to communicate a message in their photo series. There were 12 students who submitted complete photo-essays that expressed one or more principles of design. Three design principles (i.e., variety, contrast, and pattern) emerged as key strategies for connecting their main message to data. Below, we outline how the three primary principles of design emerged in students' photo-essays and offer an example of each.

Variety

Variety is the use of multiple elements of art or compositions in the photo series (N=5). One student application of variety transformed places into symbols of both community resources and expressions of beauty. The content of the series suggested that commercial areas, walkability, parks, nature, and housing contribute to a *healthy neighborhood* (e.g., see Figure 2). Whereas, the use variety connected these symbols by highlighting the peacefulness and beauty of living in a healthy neighborhood. A second application of variety, used in combination with pattern or contrast, supported a narrative arc in photo-essays (e.g., setting the scene, highlighting people, representing conflict, and symbolizing impact).

Figure 2
The Beauty Within defined a healthy neighborhood by connecting symbols of community resources to emotion.

"I wanted to depict something that represents how the resources and overall health of my neighborhood… impacts the way me and many other residents view it…In my photo series, the three most important elements that are depicted throughout the whole series are color, line, and space…"

Contrast

Contrast is a juxtaposition of visual elements or ideas (N=6). Photo-essays used value, space, color, and texture to create visual contrast. Contrast was used to visually distinguish images taken in different neighborhoods, whereas conceptual contrast (e.g., absence and presence; nature and trash) established the conflict or tension. The photo-essay *Trees*, which used conceptual contrast in conjunction with pattern reinterpreted the artist's initial observation of absence and presence by categorizing trees as the number of planned trees, newly planted trees, and grown trees (see Figure 3). Counting absences in this context helped the students predict a future increase in trees and thus neighborhood health.

Figure 3

The photo-essay Trees investigated the number of neighborhood trees from multiple perspectives by combining contrast and pattern.

"I wanted to depict something that represents how the resources and overall health of my neighborhood… impacts the way me and many other residents view it…In my photo series, the three most important elements that are depicted throughout the whole series are color, line, and space…"

Pattern

Pattern is a repetition of elements or repetition of a combination of elements (*N*=4). Photo-essays constructed patterns within a single image or across images (e.g., use of line to divide nature and the built environment). Pattern was fundamental in photo-essays that synthesized qualitative and quantitative data to construct an argument (see Figure 4). For example, in *Building the Bronx*, the artist represents construction as a norm in her community and part of everyday life by using repetition. She suggests that the everyday occurrence of construction in her neighborhood contributes to lower air quality by connecting her photo series to data on air quality.

Figure 4

Building the Bronx highlights everyday exposure to construction as a potential health problem.

"Construction isn't deemed to be important to many people, yet causes decreased air quality that is capable of damaging lungs and increased harsh sounds that contribute to noise pollution. My goal for this photo series was to shine light on these neglected endangerments…"

RQ3: Students used principles of design to express evidence-based arguments

Artist statements and photography worked together to form evidence-based arguments. Students who expressed pattern, contrast, and/or variety in their photo-essays frequently reasoned critically about data in their artist statements compared to those who did not express principles of design (83% vs. 25%). Photo-essays showed evidence of examining power across all combinations of design principles, whereas rethinking binaries did not occur in photo-essays that expressed only contrast. To support critical claims with evidence, students who used a principle of design made quantitative comparisons or described bivariate relationships more frequently than those who did not express a principle of design (75% vs. 33%). Students who did not express a principle of design were thus more likely to just cite a statistic and less likely to make data-based inferences.

Discussion

In this study we asked how integrating photography and data inquiry practices might support critical data storytelling in non-math contexts. We found that constructing photo-essays offered multiple ways for students to enter into data inquiry and that students frequently expressed principles of design in critical data stories.

Photography prompted students to shuttle between local and global perspectives

Data storytelling through photography offered students multiple entry points into data reasoning. "Stepping into the world of photography," according to the art teacher, helped students ask statistical investigative questions and explore their neighborhoods. For example, writing a statistical question that reflected observations in their photos challenged students to construct questions that were not only answerable with data but also relevant to their everyday lived experiences. Several students also reflected in their artist statements that photography helped them begin to make sense of data. They identified community issues by noticing emerging patterns in their photographs (e.g., plastic bottles in every photo) and used photos to quantify their environments (e.g., summing up the number of trees on each block). Others drew on artistic values and themes, such as beauty, to help them identify community resources. For those who had a clear investigation in mind, photography challenged them to translate quantitative findings into a story by representing potential implications for people and environments. These findings reflect prior research showing that students often shuttle between local and global perspectives to construct data stories (Wilkerson & Laina, 2018; Kahn, 2020). However, photography offered students a tool to collect and organize lived experiences as data and enabled them to draw on artistic strategies to help them construct evidence-based arguments.

Engaging students with principles of design can prompt critical data reasoning

Engaging students with elements of art, composition strategies, and principles of design generated opportunities for students to visually narrate data in different ways. The art teacher noted that her students' greatest challenge was making their photo-essays a complete story, not just highlighting a problem visually but also connecting it to data. Findings showed that those who were successful, typically drew on three principles of design: variety, contrast, and pattern. In traditional data visualization, the application of contrast might support a quantitative comparison, whereas pattern can show associations and variety can represent the distribution of a variable or identify multiple variables (Bach et al., 2018). However, students drew on photography not just as a data visualization tool but also as a secondary form of data and as a storytelling medium. Findings show that students connected artistic strategies and data reasoning practices in unique ways that were responsive to both their environments and investigative questions. For example, using contrast and pattern in *Trees* helped one student rethink how trees are counted and what counting absences might tell us about the future health of her neighborhood. In *Building the Bronx*, the student not only identified construction as a possible contributor to the lower air quality in her neighborhood but also constructed a pattern to justify her reasoning. Her photos, taken over multiple trips to school, framed construction as visible in her everyday routine and as a norm in her community. These findings reflect prior research showing how data storytelling challenges neutral, objective interpretations of data and can connect data to lived experiences (Stornaiuolo 2020; Kahn 2020). However, prioritizing engagement with artistic strategies in a data storytelling unit enabled students to draw on the tools of multiple disciplines to advocate for their neighborhoods, rethinking observed absences, highlighting overlooked variables, and representing the emotional impact of community resources.

Conclusion

Data storytelling is particularly relevant for engaging students with data in non-math contexts. However, students still need support to recognize and express principles of critical data literacy. This study suggests that prioritizing both artistic strategies and data reasoning practices in a data storytelling unit offers potential to support students in making data-based arguments and expressing critical data literacies. Findings in this study, however, are limited by a focus on a single classroom and on photographic arts. Future research might investigate how drawing on the artistic strategies characteristic of other forms of narrative-based art might support critical data storytelling.

Using Computational Thinking as a Metacognitive Tool in the Context of Plugged Vs. Unplugged Computational Activities

Ceren Ocak, Georgia Southern University, cocak@georgiasouthern.edu
Aman Yadav, Michigan State University, ayadav@msu.edu
Victoria Macann, Michigan State University, macannvi@msu.edu

Abstract: This paper explored how K-5 teachers incorporated computational thinking (CT) to support young children's development of metacognitive knowledge and abilities. Two 4th-grade mathematics teachers' lesson videos were analyzed to understand how K-5 teachers used CT as a metacognitive tool. One teacher incorporated CT ideas and practices into her teaching without using any computational device (i.e., unplugged), whereas the other used Dash & Dot robots to engage his students in CT (i.e., plugged). Within those activities, teachers used CT to engage students in a variety of metacognitive strategies, such as attending to critical features of a problem, creating a mental model of a problem, and monitoring solution paths. Our findings provided insight into how K-5 teachers can leverage CT to enhance their students' metacognitive knowledge and abilities.

Introduction

In recent years, computational thinking and computer science (CS) education researchers have shown a growing interest in metacognition (Prather et al., 2022). Metacognition is one's awareness of own cognitive processes, and it is critical to learning per se for enabling students to control and monitor their cognitive processes (Flavell, 1976). Similarly, CT—a systematic approach to solving and formulating problems—involves processes where one must constantly reflect on one's own thinking and actions, such as finding and fixing own errors (e.g., debugging) (Yadav et al., 2016). Given these overlaps, scholars have called for investigating the connection between CT and metacognition for their students' academic benefit (Yadav et al., 2022).

Some scholars have proposed that students' metacognitive awareness can be developed by engaging them in a systematic problem-solving process during programming (Loksa et al., 2022). Others have claimed that CT through unplugged activities (i.e., without any computational device) could also help develop students' metacognitive abilities. For example, Yadav et al. (2022) suggested that CT potentially enables and overlaps with several metacognitive processes (e.g., identification of steps to solve a problem, execution of the steps serially or in parallel, and solution-monitoring); therefore, CT could be one way to teach metacognition in classrooms explicitly. In this context, our purpose was to explore how elementary teachers can leverage CT to support young children's development of metacognitive strategies. To explore that premise, we asked:

1. In what ways do elementary teachers use CT to support students' metacognition?
2. How does teachers' use of CT as an approach to engaging their students in metacognitive strategies differ between a plugged and an unplugged CT approach?

To address this desideratum, we video-recorded two 4th-grade teachers' CT-integrated mathematics lessons. One teacher used Dash and Dot robots to teach the concepts of area and perimeter, while the other teacher implemented CT ideas into the arrays lesson without using any computational device. Treating each case separately, we elicited the metacognitive strategies that teachers taught during computational problem-solving. Our purpose was to expand the list of metacognitive strategies that teachers use to bring metacognitive experiences to elementary mathematics classrooms through unplugged and plugged CT activities. Our question is relevant and timely and contributes meaningfully to ongoing and current questions about using CT as a metacognitive tool to enhance learning and instruction.

Computational thinking and metacognition

Computational thinking

In 2006, Jeanette Wing defined CT as "solving problems, designing systems, and understanding human behavior by drawing on the concepts fundamental to computer science" (p.33) and proposed that CT is not only for computer scientists but for every child. Since then, the efforts to bring CT into elementary education have only grown stronger. Built on the momentum generated by Wing's (2006) article, several educational initiatives and reforms have focused on developing children's CT knowledge and skills by integrating computing into K-12 classrooms (e.g., International Society for Technology in Education [ISTE], American Computer Science

Teachers Association [CSTA], and Next Generation Science Standards [NGSS]). Those initiatives are critical in that they reflect the growing presence of computing in K-12 education. At the same time, education scholars have also called for meaningful CT integration practices as CT has made its way through standards and K-12 curricula. To date, CT has been incorporated across disciples for a wide range of purposes, including but not limited to its use to support problem-solving skills, modeling, analyzing and representing data, and, more recently, helping students understand how computing impacts society. The most common perspective around CT integration conceives it as a problem-solving approach (Kafai et al., 2020) that includes several practices, such as decomposing problems into manageable parts (i.e., problem decomposition), using a set of steps to solve a problem (i.e., algorithmic thinking), seeing whether the solution could be transferred to similar problems (i.e., abstraction). Yadav et al. (2022) have also argued that these sub-practices overlap with several metacognitive strategies that have been shown to support students' academic outcomes.

Metacognition

Metacognition has been extensively studied for over fifty years. In 1976, Flavell pioneered the notion of metacognition and framed it as a phenomenon associated with one's awareness of own cognitive processes, such as memory and problem-solving. Flavell (1976) proposed that metacognition had two major components: metacognitive knowledge (MK) and metacognitive experiences (ME). MK refers to knowledge of one's own strengths and weaknesses when dealing with a task, while experiences emerge when MK is called on during problem-solving (Efklides, 2002). The scope of metacognition, however, is over and beyond what one declares about their own cognitive states; it extends to how one takes action in controlling one's own cognitive processes, which overall entail "thinking about the learning process, planning for learning, monitoring of comprehension or production while it is taking place, and self-evaluation of learning" (O'Malley et al., 1985, p. 560).

Computational thinking and metacognition

Similar to metacognition, CT involves processes where one must constantly reflect on own thinking and actions. A growing literature suggests that CT naturally enables and offers mechanisms to engage learners in self-reflective practices through debugging, iterations, and abstraction (Allsop, 2019). Those processes naturally engage learners in retrospective and prospective decision-making to help reach an equilibrium between their current actions and future goals. In this way, students '*debug [their] own thinking*' retrospectively while engaging in processes help them move closer to achieving their final goal (Kafai & Burke, 2016, p. 321). Considering these connections between CT and metacognition, young children, who are taught CT, have a better chance of mastering their own learning and cognitive processes, which could also benefit their long-term academic success. However, still little is known about the shape and degree of how CT overlaps with metacognition. In this paper, we aim to fill this gap by examining metacognitive strategies that in-service teachers employ during CT tasks in plugged and unplugged contexts—which can provide insight into how CT could be used as a pedagogical tool to teach metacognitive strategies explicitly.

Method

The study employed Bezemer's (2015) analytical framework for video-based multimodal analysis for social interaction to analyze 45-minute length videos collected from two classrooms. Multiple channels of communication (e.g., spoken dialogue, body-based gestures) are translated into a multimodal transcript through a set of steps—such as choosing a methodological framework, designing a transcript, and defining transcription conventions—where images and text are combined for fine-grained analysis. This approach helped us elicit metacognitive strategies (e.g., gestures) that are multimodal, going beyond teachers' discourse or dialogue only.

Context

The videos were collected as part of a research project, CT4EDU, that focused on supporting elementary teachers in integrating CT into their science and mathematics teaching. Elementary teachers incorporated CT practices in their mathematics lessons, and we video-recorded their lessons and the interactions with the students using Swivl—a robotic mount for a camera that helped record the actions of a moving teacher. We used these videos to form a preliminary understanding of how teachers use CT practices as a metacognitive tool within their instruction. We randomly selected two 4th-grade mathematics lessons from two teachers who volunteered to participate in our study. We chose mathematics as a subject because it naturally enables CT integration and the development of metacognitive skills for being at the heart of problem-solving. All data were kept confidential, and the participants were given pseudonyms, as displayed in Table 1.

Participants

Participants included two elementary teachers from two schools in the Midwestern United States, as displayed in Table 1. The teachers had participated in a professional learning experience that focused on preparing elementary teachers to integrate CT into their mathematics and science instruction. The focus of this study was CT-integrated mathematics lessons that the two teachers facilitated. The first teacher, Michael, used dash and dot robots to teach the concepts of area and perimeter, while the second teacher, Jill, taught simple arrays without using any digital computational tools.

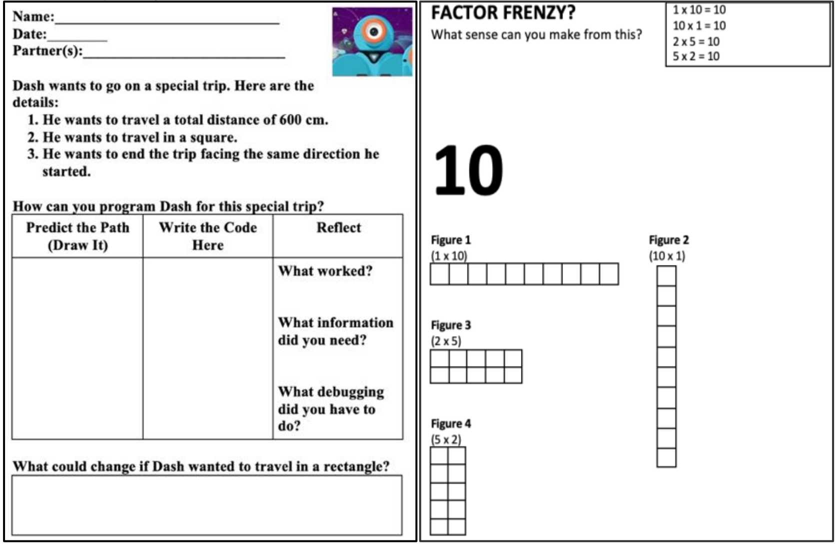
Table 1
Teacher Demographics and Recorded Lessons

Pseudonym	Gender	Grade	Class Size	Activity
Michael	Male	4	23	Dash & Dot Robot Plugged CT
Jill	Female	4	23	Factor Frenzy Unplugged CT

Research context

Dash and Dot plugged CT activity: In this activity, CT ideas and practices were used to teach basic mathematical concepts (e.g., perimeter and directions) when programming Dash robots. The major idea was to program the robot Dash to travel in a square. Therefore, our first teacher, Michael, instructed students to program the robot Dash for a special trip following the preset rules, such as traveling a total distance of 600 centimeters and ending the trip facing the same direction he started (see Figure 1, left column).

Figure 1
Dash & Dot Robot Plugged CT Activity (left) And Factor Frenzy Unplugged CT Activity (right)



Name:_________________________
Date:________
Partner(s):_______________________

Dash wants to go on a special trip. Here are the details:

1. **He wants to travel a total distance of 600 cm.**
2. **He wants to travel in a square.**
3. **He wants to end the trip facing the same direction he started.**

How can you program Dash for this special trip?

Predict the Path (Draw It)	Write the Code Here	Reflect
		What worked? What information did you need? What debugging did you have to do?

What could change if Dash wanted to travel in a rectangle?

FACTOR FRENZY?
What sense can you make from this?

1 x 10 = 10
10 x 1 = 10
2 x 5 = 10
5 x 2 = 10

10

Factor frenzy unplugged CT activity: The second teacher, Jill, used factor frenzy to teach factors in mathematics. At the same time, the activity largely drew on the use of debugging, abstraction, and decomposition to teach arrays, factors, and products. The students first used base ten blocks to write different multiplication equations for 10 in the form of arrays (see Figure 1, right column).

This activity was also scaffolded by giving a lower or higher number other than 10; an example for the number 54 might be as follows:

1. Students were reminded to begin with one row for the number 54 (i.e., 1 x 54).
2. Students then found different ways to create the factors of 54 (e.g., 2 x 27, 3 x 18, 6 x 9).
3. Students were asked to find the array's vertical and horizontal orientation (i.e., all the factor pairs).
4. Students then recorded their arrays on a construction paper, using the grid paper and correctly labeling their arrays (see Figure 2 for a sample construction paper)

Figure 2

A Sample Construction Paper

Data analysis

The video data was first transcribed verbatim and analyzed by three raters in segments according to where we identified both CT practices and metacognitive strategies. First, we identified CT practices such as *decomposing* large tasks into smaller sub-goals, using *patterns*, and thinking *algorithmically* to develop efficient solutions. Then, we explored the emergent metacognitive strategies associated with each CT practice. This approach allowed us to figure out overlapping elements of CT and metacognition. We then collated the information into overarching themes. The themes were identified through consensus building in recursive meetings with the raters (Baxter & Jack, 2008).

Results

Our video-based multimodal analysis in the context of plugged and unplugged computational activities revealed a set of strategies on how CT could help enhance young learners' metacognition in mathematics classrooms. The metacognitive processes and associated strategies used by the teachers are detailed in the following, and their connection to CT ideas, sub-skills, and practices are explained in a narrative form within the cases. Our focus was on the ways in which teachers' used CT as a metacognitive strategy rather than how the students reacted to the teachers' strategies.

Case 1

The analysis of the data from plugged computational activity (i.e., Dash & Dot) revealed three major themes of how CT could be used as metacognitive strategies: (1) developing an understanding of the critical features of a problem, (2) feeling for the constraints of the problem, and (3) monitoring solution paths.

(1) Developing an understanding of the critical features of a problem: The first metacognitive strategy that the students engaged in during CT was the critical analysis of a task. Our first teacher, Michael, first began by prompting the students to develop an understanding of the critical features of a problem (see Table 2). For example, after introducing the Dash & Dot activity, he asked his students: "What are some things that you need to think about with these preset rules, and what is important to know about Dash's trip". These questions helped students assess the problem's existing condition and better understand its critical features to attend to in the later stages of problem-solving. This is also a critical process of computational problem-solving, where students engage in abstraction as a CT practice (i.e., focusing on the most relevant and essential details of the problem).

Table 2

A Moment of Abstraction Through Developing An Understanding of The Critical Features of a Problem

Dialogue	Interaction	Transduction
Michael: So, with the people sitting next to you, I want you to turn and talk about what are some things that you need to think about with these directions [e.g., the total distance and shape of the path that robot must follow] **Michael:** … do some early thinking now. Ready, set, turn …	 [prompts the students to think about the critical features of a problem]	→ [metacognitive strategy: critical analysis of a task] Michael engages the students in **abstraction**, which involves focusing on the most relevant and essential details of the problem.

(2) Feeling for the constraints of the problem: The second metacognitive strategy that the students were taught during CT was feeling for the problem's constraints. Michael combined verbal prompts with perspective-taking to teach students how to set goals that are sensitive to problem constraints, which is a significant metacognitive activity (Paulson & Bauer, 2011). Table 3 displays how Michael first mentioned the limitations of the robot's movement. He said: "Dash can only walk forward, backward, turn right, and turn left." And then, following the verbal prompt, he visually executed those movements algorithmically as if he was the Dash robot. This interaction is significant for showcasing how algorithmic thinking and perspective-taking emerged as strategies to support students' goal-setting process—that is, a critical element of one's metacognition.

Table 3
A Moment of Algorithmic Thinking Through Verbal Prompts and Perspective-taking

Dialogue	Interaction	Transduction
Michael: Some of the groups are finding out that they made a plan that involves their robot traveling in certain directions. And then what they found out is that there are some limits that …Dash can only walk forward, backward …	 [prompts questions to feel for the constraints of a problem]	→ [metacognitive strategy: planning ahead] Michael prompts students to become cognizant about the problem constraints, executing a sequence of the robot's movements (i.e., CT practice of **algorithmic thinking**).
Michael: … turn left …	[Michael turns right, imitating the robot] 	
Michael: … or turn right … **Michael:** …So, there are really some things that you need to think about … that are a little bit different … So, if your planning involved just moving and sliding around, you might have to add in different things and try that out.	[He prompts the students to think about the critical features of a problem] 	→ [metacognitive strategy: planning ahead]

(3) Monitoring solution paths: The third metacognitive strategy that the students engaged in during CT was metacognitive monitoring. Metacognitive monitoring is "evaluating the process of learning or current state of knowledge" (Rivers et al., 2017, p. 549), and controlling that process is the ability to make changes to the original plan when it does not work as planned. Throughout the process, one asks oneself introspective questions, such as "am I following my plan? Is this strategy working?" (Martinez, 2006, p.698).

The following exchange between Michael and the students suggested that as students engaged in debugging (i.e., finding and fixing problems), they were given an opportunity to enhance their strategies associated with metacognitive monitoring and control. The following excerpt from Michael's instruction is strong evidence of how those initial strategies were later used by the students as part of their metacognitive monitoring at the end of the lesson, as appears in a set of brackets:

> What was nice is that they [i.e., small groups] kind of made a plan, and when they weren't sure [when the plan worked out well], they went back [monitored the solution], and they found some of the important information that was in these three things here [revisited the preset rules]. So, they said, well, I don't know, maybe I can do this, this, and this … [thought algorithmically &

> envisioned possible solutions]. And then when they were like, well, I'm not sure if I forgot an important part [checking task information to validate comprehension]. They went back, and they were looking at the three important rules here because the big idea is that he wants to go on a trip.

Case 2

The analysis of the data from unplugged computational activity (i.e., Factor Frenzy) revealed three major themes of how CT could be used as metacognitive strategies: (1) discovering patterns, (2) activating students' relevant background knowledge, (3) creating a mental map of a problem.

(1) Discovering a pattern: Our second teacher, Jill, first displayed the pair of numbers on a whiteboard, which gives a 10 when multiplied (aka factor pairs of 10), such as 1 x 10 = 10; 2 x 5 = 10. Like Michael's case, Jill began the lesson by encouraging the students to analyze a problem critically. She asked: "What sense can you make from this slide?" This exchange suggests that assessing the problem's initial condition is critical and common to CT and metacognition.

Jill: Take a look at the board. It says factor frenzy. *What sense can you make from this slide?*
Student: If that's factors frenzy, then the factors are like the multiplication numbers.
Jill: So, she remembers from last year. Good! That a factor is our multiplication numbers.
Jill: Tell me more. What does that mean?

(2) Activating students' relevant background knowledge: Next, Jill activated students' relevant background knowledge, which is an important metacognitive strategy (Lai, 2011). She asked, "Do you remember the name of these 10s? What were they called from last year?" (see Table 4).

In this case, activating students' relevant background knowledge went hand in hand with the CT practice of pattern recognition. Jill enabled her students to explore patterns based on the types of problems they had solved in the past. She used a variety of questions that engaged students in pattern recognition. She then used those patterns to help her students to understand the characteristics of a problem and figure out the kind of operations needed to solve a problem. As displayed in Table 4, she prompted her students to remember the nature of the problems that sum can be used: "Because remember … If we look over there [points at the CT posters in the classroom], sum goes with what kind of problems …"

Table 4
Teacher prompts

Dialogue	Interaction	Transduction
Jill: Anything else you notice? Somebody else? **Student:** … in the equation … All of them have 10s in. **Jill:** Do you remember the name of these 10s? What were they called from last year? Student: … Sum? **Jill:** Not the sum! Because remember … If we look over there [points at a poster in the classroom], sum goes with what kind of problems?	 [prompts the students to think about the givens of a problem]	→ [metacognitive strategy: activating relevant background knowledge] Jill prompts them to recall previous knowledge, using patterns to detect the inherent characteristics of a problem.

(3) Creating a mental map of a problem: The last metacognitive strategy Jill facilitated was when she mapped out "givens, a goal, and obstacles" (Davidson et al., 1994) of a problem for the students by posing several inquiry questions and suggesting strategies as appear in a set of brackets. For example, she said:

> I'm modeling (i.e., the problem) right now because you're going to be doing this. Today, you're going to be finding as many factors as you can for a number [setting a goal]. This is our target number [pointing at the givens of a problem]. And we were trying to find all the factors we could. We use the arrays to help us find the factors [cueing about reaching the goal]. And we

use the arrays to represent the equations. That's what computer scientists do. That's called abstraction [cueing about when to use what CT skill].

Being able to establish a relationship between *givens, a goal, and obstacles* of a problem is helpful in decomposing a problem and abstracting the essentials of that problem, and those are also critical skills of CT. The exchange above is, therefore, strong evidence of the connection between CT and metacognition.

Discussion

This study presented how two elementary teachers used CT to support students' metacognition in the context of plugged and unplugged CT activities as a part of their mathematics instruction. The findings suggested that CT could be used as a pedagogical tool to explicitly teach metacognitive strategies to young children in elementary mathematics classrooms. In both CT activities, with or without a computational device, our teachers brought in diverse metacognitive strategies that helped strengthen their students' metacognition during the different stages of CT; those strategies and processes are listed in Table 5.

Table 5
Metacognitive Strategies Emerged During Plugged & Unplugged Computational Activities

Name of the CT Practice (Yadav et al., 2022)	**Associated Metacognitive Strategy**	**How Our Teachers Used CT As a Metacognitive Strategy**
Abstraction: "Focusing on the most relevant and essential details of the problem that needs to be solved." (p. 409)	• Critical analysis of a task • Paying attention to important ideas • Creating a mental model of a problem	Asking students questions to develop intuition about critical features of a problem: 1. "What's going to be important?" 2. "What's important to know about this trip?"
Pattern recognition: "Finding the similarities and differences between problems." (p. 409)	• Activating students' relevant background knowledge through recognizing patterns • Understanding the inherent characteristics of a problem through those patterns	Asking students questions to encourage them to discover a pattern in the problem: 1. "What sense can you make from this?" 2. "What kind of problems does this pattern go with?"
Algorithmic thinking: "Designing a step-by-step solution to a problem." (p. 409)	• Perspective-taking to design a step-by-step solution	Asking students to think of the robot as an embodied agent, thinking of Dash as a human: 1. "Dash wants to go on a special trip. How can you program dash for his special trip?"
Decomposition: "Simplifying complex tasks by breaking them down into smaller parts." (p. 409)	• Creating a mental model of possible solutions	Designing lessons in a way that they have a built-in prediction component (e.g., "you have to predict the solution and draw the path")
Debugging: "Finding and fixing errors." (p. 409)	• Monitoring solutions	Asking questions to encourage students to think about their solution paths (e.g., "what makes you say that").

Our teachers often strengthened the metacognitive elements of the CT-integrated mathematics units by asking questions that made the students constantly think about their own decisions during the entire problem-solving process. We also observed that both teachers designed CT-integrated mathematics lessons in a way that both had a built-in prediction component, which is also crucial for metacognition. This helped learners to predict several possible solutions without executing them and select the appropriate strategies based on the expected outcome. As shown in Table 5, strategies used by our teachers are naturally a part of CT (first column) and essential to metacognitive skill development (second column).

Conclusion

This study is an initial attempt at exploring how CT can be used as an approach to support teachers to teach metacognitive strategies in elementary classrooms explicitly. Our findings hold several implications for the future of CT in elementary education. While much of the focus on CT in K-12 classrooms has been as a pathway to introduce computer science, our findings suggest that elementary teachers can use CT to teach metacognitive strategies to support disciplinary learning. Introducing those strategies might help students assess the initial conditions of a problem, devise solution paths responsive to the problem's constraints, and predict multiple solutions that could be applied as the problem conditions change (Liu & Liu, 2020). It should also be noted that one teacher used CT practices as a metacognitive tool in the context of the plugged activity, while another used CT as a metacognitive tool in the context of an unplugged activity. Future work should expand on this line of research to examine how CT can support students' learning in the core disciplines while improving their problem-solving skills.

Designing for Justice-Oriented Critical Caring in Science Methods Courses

Enrique Suárez, University of Massachusetts, Amherst, easuarez@umass.edu
Christina Krist, University of Illinois, Urbana-Champaign, ckrist@illinois.edu

Abstract: Contemporary science education centers on the desired conceptual understandings and science practices students should develop. While positioning students as knowledge constructors by valuing a sensemaking stance and leveraging heterogeneous meaning-making repertoires are important for equitable learning, the moral and ethical dimensions that undergird this emphasis have been overlooked. Here, we study our efforts to support science pre-service teachers (PSTs) in our methods courses to develop pedagogies rooted in what we call *justice-oriented critical caring.* Our design-based research approach grounds PSTs' science futures pedagogical practices in an ethic of care and in broader sociopolitical systems, particularly in three key ethical and design commitments: *discursiveness*, *relationality*, and *reflectiveness*. Our findings show how intentionally designed learning experiences for PSTs supported learners in navigating complex trajectories toward enacting transformative forms of caring.

Rationale and framing

From research agendas to policy documents and standards in the US, the conversation on what students should learn in science classroom centers around the desired conceptual understandings and science practices students develop (NRC, 2012). Within this scholarship, the moral and ideological implications undergirding this emphasis have often been overlooked. While positioning students as knowledge constructors by valuing a sensemaking stance (Russ, 2014) and fostering heterogeneity of ideas (Warren et al., 2020) is important for promoting justice in science, scholars have also called for a relational ideology of schooling where teachers support students in developing as persons who care and are cared for within oppressive systems (e.g., Antrop-González & de Jesús, 2006). Teachers are key for creating opportunities for students to learn science through engaging in science practices (Berland et al., 2016; Krist & Suárez, 2018) and fostering a culture of critical caring (Antrop-González & de Jesús, 2006). However, a relational orientation is seldom the focus of science teacher education. In this paper, we study our efforts to support science pre-service teachers (PSTs) in our methods courses to develop pedagogies rooted in what we call *justice-oriented critical caring.* Our approach centers PSTs' pedagogical practices in an ethic of care and in the context of broader sociopolitical systems. To this end, we designed science methods courses for PK-8 PSTs that foregrounded relational dynamics within the epistemic work of science: (1) examining and engaging with students' science ideas; (2) developing meaningful relationships with students rooted in solidarity and high intellectual expectations; and (3) create transformative science learning environments that build on the meaning-making resources and potentials of individual students.

Theoretical framework: An ethic of critical care

Within educational scholarship, an attention to care comes from philosophical considerations about the goals of schooling, as well as arguments about what kinds of ideological commitments should undergird teaching and learning. As originally formulated in the context of education by Nel Noddings (2013), teaching undergirded by an ethic of care is characterized by three important dimensions: (i) *Relatedness* – inextricably being present with others, knowing who they are as people and thinkers; (ii) *Receptivity* – listening intently and remaining open to others' ideas, rather than immediately judging them, as well as being attuned to the affective experiences of others, not as deterrents, but as modulators; and (iii) *Responsiveness* – attending to the meaning-making of others, with the intention of engaging with that thinking.

While this conceptualization of care attends to the roles adult teachers and students inhabit in classrooms, it does not directly account for the structural hierarchies that undergird these relationships. Critical education scholars have redefined the concept of care to explicitly illuminate and address issues of power in schools. For instance, Antrop-González and de Jesús (2006) introduced a caring framework that privileges "the cultural values and political economy of communities of color as a foundation for education" (p. 413). Specifically, the research from Antrop-González and de Jesús suggests that marginalized students benefit from relationships guided by *critical care*, where teachers offer friendship and mentorship in and out-of-the classroom, while maintaining high intellectual and academic expectations for their students. Similarly, Rivera-McCutchen (2021) calls on researchers and educators to leave behind what she calls limiting forms of care that are "characterized by pity and excuse-making made ostensibly in the service of children," and refuse to structural inequities such as racism (p. 3) –

Valenzuela (1999) characterized a similar form of care as *aesthetic care*, which privileged the grammar of schooling and denigrated youths' backgrounds. Rivera-McCutchen argues for a *radical care* that is rooted in anti-racist pedagogies, developing authentic relationships with and between children, creating and upholding high expectations for students, and creating nurturing and transformative schools. This scholarship contextualizes a notion of care, arguing that definitions of care that are not grounded in peoples' everyday perpetuate oppression.

In such versions of an ethic of care, caring is shaped by intersecting systems of privilege of oppression. Enacting care, then, also requires striving towards justice: reducing harm and promoting human flourishing via dismantling oppressive systems. Relatedly, feminist legal scholar Hudson (2006) rejects what she calls the "white, male character of justice in modern liberal societies" and describes a relational ethic of justice that comprises: (i) *Discursiveness* – bringing minoritized peoples into the discursive circle, rejecting the expectation that "claims to justice can only be acknowledged if they are voiced in the terms of the dominant group" (p. 34); (ii) *Relationality* – rights (and responsibility and culpability) are created and exercised in relation to other individuals and groups, including the recognition of connectedness between teachers and students, how each is understood in relation to social and historical context, and the interdependence upon one another; and (iii) *Reflectiveness* – considering individual claims of justice "in terms of all its subjectivities, harms, wrongs and contexts, and then measured against concepts such as oppression, freedom, dignity and equality" (p. 39), rejecting an abstract ethic of justice.

In our design, we bring into coordination these instantiations of an intersectional, justice-oriented interpretation of an ethic of care and propose a framework specific to science education that is grounded in the following ethical commitments: (1) Adopting a caring stance is a radical act in normative schooling that should *disrupt both meritocratic and technocratic* aspects of science teaching and learning; (2) Adopting a critical caring stance towards science teaching and learning must be *discursive* in nature, both because it emphasizes the need for examining and engaging with ideas, and because it pushes us to reconsider how minoritized students are often left out of the discursive circle; (3) Adopting a critical care stance towards science teaching and learning must be *relational*, accounting for authentic relationships between individuals, groups, and communities that are rooted both in solidarity and high intellectual expectations; and (4) Science educators who adopt a critical care stance must exercise *reflectiveness* around their own and their students' positionalities, particularly as they create transformative science learning environments that see the resources and potentials of individual students, rather than subsuming the unique circumstances of students under stereotypical generalities.

We are interested in how the commitments to discursiveness, relationality, and reflectiveness create opportunities for learners of all ages to engage in rich and meaningful science work. Specifically, we explore how to design learning opportunities for PSTs to develop a science pedagogy guided by justice-oriented critical caring. Here, we describe two iterations of science methods courses that aim to do so. In the context of these designed courses, we pose two research questions: (1) How do PSTs attend to relationality in science teaching and learning contexts?; and (2) How do PSTs attend to discursiveness in science teaching and learning contexts?

Designing for justice-oriented critical caring in science methods courses

This study comes from a collaboration between us – the two authors – following a design-based research approach (Cobb et al., 2003) to modify activities in the pre-service methods courses we taught at two public universities in Fall '21 and Fall '22. One course was designed for PK-5 PSTs (taught by Suárez), and the other one was for future middle school (MS) science teachers (taught by Krist); more details are provided below. Our designs aimed to attune PSTs to the ethical commitments of *discursiveness*, *relationality* and *reflectiveness*, particularly as they relate to contemporary science pedagogies. Given our own commitment to reflectivity, we defined these embodiments and how they should be implemented within the context of our individual courses.

We also note here the productive tension between the lofty ideological vision of our framework and the humbleness of design hypotheses and claims (Cobb et al., 2003). The two iterations we present are nowhere near the full implementation of our ideals. In alignment with DBR's goals and commitment to developing humble theories that are both domain-specific and are accountable to the design, we present the messy mangle of frameworks for care and justice, the tensions and challenges in learning to teach science through engaging in investigations of natural phenomena, and the bureaucratic realities of pre-service teacher education programs.

Course contexts and design features

The PK-5 methods course was taught by Suárez in a large public university in New England, USA. This course was part of undergraduate and teacher licensure programs within the institution, including both undergraduate students who planned on becoming PK-5 teachers and master students who were enrolled in the one-year teacher licensure program. Masters students also completed a full-day practicum in schools, while the undergrads did not. In Fall '21, the course enrolled 11 students: 5 undergrads and 6 grads (6 of whom consented to participate), and all identified as white women; in Fall '22, the course enrolled 7 undergrad students (6 of whom consented to participate): 5 of whom identified as white women, one as an AfroLatina, and one as an Asian woman. The course aimed to support PSTs in becoming enthusiastic, effective, and caring educators that design equitable science learning activities. Specifically, the course was guided by the following objectives: (i) Understand science as a collective process of meaning-making that leverages scientific practices (*discursiveness*); (ii) Develop a definition of "equitable science education" that attends to children's meaning-making repertoires (*discursiveness, relationality, and reflectiveness*); (iii) Develop a critical caring stance towards science teaching that humanizes students and supports their learning (*discursiveness, relationality, and reflectiveness*); and (iv) Develop strategies for eliciting students' ideas, prioritizing investigations, and developing collective explanations (*discursiveness*).

The course included three main activities where PSTs would reflect on, express, and leverage their ethical orientations as they developed an equitable science pedagogy. First, PSTs completed surveys that prompted them to reflect on their definitions of care and how they would center critical caring in their science teaching (e.g., "In the context of science investigations, what do you think "caring for students" could look like?"). These surveys were designed to promote *relationality*, as PSTs considered how to develop solidarity with and high intellectual expectations of their future students, and *reflectiveness*, encouraging them to identify how their positionalities guided their teaching and relationships with students. Secondly, three assignments asked PSTs to analyze videos from PK-5 science classrooms (e.g., "What evidence of Caring did you observe during these interactions in the classroom?") that depicted young bi-/multilingual students investigating and explaining physical phenomena. These video-based tasks required PSTs to attend to the *discursiveness* of critical caring, focusing on the substance of minoritized students' ideas and anticipating how meritocratic and technocratic ideals could hamper these ideas. These analyses also supported PSTs to consider *relationality* and *reflectiveness*, primarily through attending to the caring relationships between students and between students and teachers in those classrooms (or lack thereof). Finally, PSTs implemented a discussion-based lesson, in which PSTs described and enacted the pedagogical practices to emphasize the *relationality* and *discursiveness* aspects of critical caring towards their peers.

The Middle Grades (MG) methods course was taught by Krist in a large public university in the Midwest, USA. The MG course met the state's science subject-area endorsement requirement for students seeking a middle grades licensure; it also met the middle grades endorsement requirement for licensure in a specific high school science discipline. All students had a science placement in middle schools where they observed 1-6 hours per week. In Fall '21, the course enrolled 12 students: 11 undergrads and 1 grad (10 of whom consented to participate); and in Fall '22, the course enrolled 4 students: 3 undergrads and 1 grad (all of whom consented to participate). The course was designed to support PSTs to develop expertise on how to teach science in ways that were effective, transformative, and following a justice-oriented critical caring approach. The course had the following objectives: (i) Describe current theory and practices in teaching middle school science; (ii) Design science lessons that are consistent with current science education standards, guided by an ethic of critical care, and address the needs of middle school students; (iii) Critically analyze and reflect on the assets and inequalities at play in their placement community; and (iv) Critically analyze and reflect on one's own and others' teaching.

The course included three main activities that asked PSTs to enact and reflect upon their own ethical orientations with respect to students. Each of these activities was guided by Phillips' (2019) concept of *principled improvisation* for novice teacher learners, including asking students to both plan for and reflect upon their growth in the four key practices he identifies: (1) Learning to authentically listen to students; (2) Learning to follow students' lead in their learning; (3) Learning to facilitate students building on each others' ideas; and (4) Learning to craft critical questions that build on students' responses and move their analysis toward a deeper consideration of power and historical, social, political, and economic processes (ibid, p. 28).

The first assignment was a "get to know you" interview with students in their placement classroom about things *other* than science, such as what they liked to do for fun and what they thought about school. The goal of this assignment was to invite PSTs to engage with the students in their classroom and learn something about them that went beyond what they might see through their science learning. This assignment was quite open-ended and encouraged PSTs to ask questions that allowed middle grades students to be the "experts" teaching PSTs about themselves, their school, their families, and their community. My design hypothesis was that this orientation would promote *relationality* by beginning to re-position powered relations as more reciprocal. The second activity entailed reading responses to intentionally paired readings. I purposefully paired descriptions of pedagogical practices (e.g., eliciting and responding to student ideas) with first-person accounts from students about how they experienced schooling (e.g., what they wished their teachers knew about them during class discussions). The design hypothesis guiding these pairings is that the intentional contrasts would foster reflection around how various students might experience enactments of teacher-centered descriptions of pedagogical practices, imbuing *discursiveness* and *relationality* into practice-based teacher education. Finally, a third activity was a series of microteaching experiences that included modification, rehearsal, revision, and enactment of a lesson given to them by their placement teacher. They developed a written reflection about these processes, including a critical analysis of their final lesson as enacted using four frameworks for science and equity that we used throughout the term. These frameworks were intended to support their identification of how to "...move [students'] analysis toward deeper consideration of power and historical, social, political, and economic processes," Philip's (2019) 4th practice, which all students identified in self-evaluations as one in which they wished to improve.

Data collection and analysis

Qualitative data for this study comes from different streams, as each course had its own set of activities and assignments. For the PK-5 methods courses, data were collected from: (i) surveys; (ii) course assignments; and (iii) synchronous class activities, including analyzing videos of PK-5 classrooms and common science curricula that foregrounded investigations. For the MG methods course, course assignments were the primary data source, focusing on: (i) the get-to-know-you student interview reflection, (ii) reading response discussion posts for weeks with paired readings, and (iii) reflections and critical analysis of microteaching experiences.

We conducted thematic analysis (Braun & Clarke, 2006) from qualitative data across the iterations of our methods courses, guided by the analytic concepts of *discursiveness, relationality,* and *reflectiveness* to understand how PSTs conceptualized and enacted justice-oriented critical caring as part of their developing science teaching practices. For the PK-5 course, we analyzed two course surveys (administered in Week 2 and Week 7 of the semester) and the final video essay where PSTs analyzed how a group of 3rd bi-/multilingual students investigated how a string instrument produced sounds. For the MG methods course, we analyzed all of the assignments described above. For the purposes of this study, we focused our analyses on how PSTs attended to: (1) *relationality* in science teaching and learning contexts, particularly as it related to how PSTs attended to relationships and behaviors in the classroom and the power dynamics that shaped those interactions; and (2) *discursiveness* in science education, especially as it pertained to identifying and valuing students' varied conceptual and cultural resources and recognizing and disrupting the powered nature of participation. We coded these data separately and shared emerging findings to corroborate and refine analytical interpretations.

Findings

In this section, we discuss the main themes we identified in the data we collected from each course, particularly as they related to how PSTs attended to *relationality* and *discursiveness* in the related activities and assignments. We organized our findings according to the courses, rather than the research questions, in an attempt to highlight the complexities of developing a stance towards justice-oriented critical caring. First, we describe the group-level insights from the PSTs from Fall 2021 PK-5 science methods course, and then present the trajectories of three PSTs in the MG as they worked towards embracing justice-oriented critical caring.

Balancing politeness and meaning-making in the PK-5 science classroom

In Week 2 of the course, PSTs completed an initial care survey where they considered their own science learning experiences and generated a set of care-based features science learning environments should have. For instance, when thinking about how they would show care for their peers during the course's learning activities, PSTs emphasized the importance of listening "closely to what [peers] have to say and respect their views as individuals" and "always being respectful when others are sharing their ideas and by working collaboratively and respectfully with others." Similarly, when asked to describe how they would like others to express care towards them, PSTs described actions like "checking in to see if I'm feeling okay, checking in about confusing assignments," and "understanding that everyone makes mistakes and not to judge me based on not understanding a certain part of the classes lesson." Survey responses, which prompted PSTs to reflect on their experiences and positionalities, suggest that, at first, PSTs were attuned to how relationality shaped their interactions with peers. These reflections imply that PSTs were concerned with learning within a discursive space that would be respectful, free of judgment, and receptive – characterized by what we would call *politeness*. While this stance could be foundational for enacting justice-oriented critical caring, conspicuously absent from most of their insights is the need for relationships that would hold high intellectual expectations of each other, as well as be rooted in solidarity and comprehension. Moreover, these responses did not consider how school-based power hierarchies determine who is invited into the discursive circle (*discursiveness*) or whose ideas are valued and validated (*reflectiveness*). To move beyond this emphasis on politeness, I (Suárez) enacted learning activities for five weeks that pushed PSTs to expand their definitions of justice-oriented science education. Specifically, PSTs engaged with scholarship on students' heterogeneous meaning-making repertoires and analyzed four classroom videos, attending to: students' ideas, whose ideas were invited and engaged with, and how students and teachers enacted care towards each other.

When PSTs completed a follow-up survey in Week 7, their answers focused more on the role caring should play in science teaching and learning. When asked to reflect on how caring would shape their interactions with young students during an upcoming one-on-one science investigation, the PSTs were committed to caring " by really listening when they are discussing their answers and encourage them to explain and express their ideas," and "by not telling [students] they're wrong or that their thought processes are incorrect […] it would be key to ensure them that it is a low stakes environment." We interpret these statements as evidence of how the PSTs had reframed the construct of *relationality* towards wanting students to feel comfortable and respected and addressed elements of *discursiveness,* acknowledging that children come to science learning activities with a swath of valuable ideas that are essential for developing conceptual understanding, and wanting to develop the kinds of relationships with their students that would support their learning. At the same time, PSTs did not explicitly consider how their positionalities and/or those of their students could shape the enactment of care and their science learning (i.e., *reflectiveness*). Supported by these responses, I (Suárez) prioritized course activities where PSTs identified how the curricula explicitly connected science to children's lives and their communities' goals.

For their final assignment, PSTs in the course analyzed a video from a third classroom where a group of bi-/multilingual students problematized the mechanisms behind sound production. Students in the video explained their observations through connecting the physical features of the string instrument (e.g., length of the strings, tension on the strings) and the characteristics of the sound produced (e.g., low and high pitches), laminating multiple semiotic resources. In their essays, PSTs had to attend to the substance of students' ideas, the science practices students leveraged for investigating sound production, and how students and instructors expressed care for each other. As their responses to the surveys intimated, PSTs attention to relationality and discursiveness in the third-graders' caring reflected a wide range of themes. One prominent category in PSTs' insights pertained to how students and teachers created a discursive space driven by different forms of relationality. For instance, one PST highlighted how the teachers created a caring environment through making sure "that no other students were talking while another student was talking so they could really show respect for each other." We take this remark as evidence that some PSTs continued to focus on a form of relationality that valued *politeness*, where being respectful of their peers by not talking over them was essential for student learning. These analyses suggest that future iterations of the course ought to support PSTs in recognizing how justice-oriented critical caring must question cultural constructions of politeness and the teacher's normative expectations of behavior.

The majority of the PSTs attended to elements of *relationality*, *discursiveness*, and *reflectiveness* in their analyses, particularly as they reflected on the features of equitable science learning for bi-/multilingual students. Specifically, they focused on an exchange that involved G – a newcomer to the US who was learning English as an additional language – his peers and the teachers, where G explained how increasing the length of the string lowered the pitch of the sound produced. Independently focusing on this episode, these PSTs identified and analyzed the different forms of caring that supported G's rich meaning-making. First, PSTs identified how the other students gave G ample time to express his thinking through a combination of speech, onomatopoeia, and gestures, out of intellectual respect and not politeness. These PSTs were excited to see how G's ideas were taken up by other students as they explained the how/why of the sounds they heard. Second, PSTs focused on how the teachers enacted care and encouraged a caring learning space, highlighting the words of affirmation the teachers gave G to remind him that his thinking mattered. For instance, one PST wrote that "G seemed nervous when he was sharing his ideas, so [teachers] telling him that he did a good job affirmed that his ideas added something important to the discussion." Based on these excerpts, we argue that the PSTs' analyses of the exchange displayed their understanding of justice-oriented critical caring, articulating how students and teachers had developed strong relationships that supported their humanity and ideas (*relationality*), and leveraged the key conceptual resources G brought to the investigation (*discursiveness*). Moreover, these PSTs exercised *reflectiveness* through rejecting educational paradigms that would construe G's communication as insufficient and/or deficient, and instead highlighted the richness of his languaging and creativity for expressing a scientifically complex idea.

Science and caring in the middle grades: Navigating school norms and assumptions

We now present examinations of three students' individual trajectories of considering dimensions of caring through the course, as traced in their written course assignments that were largely about their own instructional enactments. These trajectories illustrate the range of possibilities for growth we saw in our courses, as well as offer areas for design refinement (i.e., are there ways we want to intentionally bound to support more focused growth?). The first trajectory follows "Carly" and represents her shifting from an ethic of relationality centering *politeness* to one centering *meaning-making.* The second trajectory follows "Gabby" and "Rob" who each entered with initial stances that revealed some elements of *reflectiveness* and *relationality*, yet as they brought these stances into contact with the standard pedagogies of science and cultures of schooling, tensions surfaced.

Carly's trajectory: From politeness to meaning-making

Carly typifies the students in the university's teacher education programs. She identified as a white woman from a wealthy suburb of a nearby large metro area, who was involved in her sorority. She was ambitious, working towards endorsements in math and science. During the Fall semester she TAed for a large math education course.

Carly's reflections about her "get to know you" interview focused around her surprise that a student she talked to was failing some of her classes. Carly wrote, "I can't tell if this is a common view of students, but personally when I was in middle school, I wouldn't be okay with my grades anything lower than an A." When discussing how these observations would inform her future teaching, she said, "I will try my best to have a positive attitude and energy in the classroom. I want my students to feel comfortable in the classroom and to have a connection with me. This way they will be more honest with me if they're struggling and will be more respectful in the classroom." This orientation towards respect continued to show up in Carly's reading response posts, which frequently mentioned boundaries, expectations, and reducing undesirable student behaviors.

Enacting a "microteaching" lesson where they were required to facilitate a sense-making discussion pushed Carly's comfort zone. Her co-designed lesson was more highly structured than I [the instructor] would have liked, but she insisted that her students needed the structure because she had never seen them do anything other than take lecture notes during her placement observations. I chose to respect her judgment, not knowing much about her placement classroom, and instead worked with her to select a few questions to make more open-ended and generate "back pocket questions" (Windschitl et al., 2020) to support elaboration of ideas.

Her reflections on this lesson were hesitant, but positive. She noted a high degree of student "stress" given the open-ended nature of the discussion, which they "weren't used to." Carly also reflected on how she had co-facilitated the discussion: "I think that I was good at following students' lead in their learning - if a student's response strayed from what we were looking for or brought up another topic, I wouldn't go right back to the next scripted question, but elaborated or asked further questions on where the student was leading the conversation [...] An area I could work on would be authentically listening - I think I was a little nervous as well so I could have had better responses to students' points and to have listened better than being nervous about all the possible scenarios during the discussion." In my comments back to her, I affirmed her decision to use follow-up questions and her goal of focusing on authentically listening (emphasizing *relationality*), and asked if she thought her nervousness would be diminished now that she had completed one teaching experience. Though she did not respond to my assignment comments, our next series of in-class activities involved small-group microteaching experiences. Carly was part of a small group with Rob (described in the case below), who wholeheartedly embraced the opportunity to try out a sensemaking discussion. He began by asking his "students" what they noticed about a photo of a sequoia seed vs. a sequoia forest and asking them how something so small could get so big. Although these microteaching experiences were meant to take 20 mins or less, this group discussed for about 45 minutes and then picked up the conversation again for another 10 minutes after class ended. Although Carly did not mention this particular experience in any of her artifacts, I remember noting that it was unusual for her to stay after class as she usually was one of the first ones out the door.

For her second teaching assignment, I saw resonances of the sequoia discussion experience coupled with her push to be more comfortable with "authentically listening" in her planning. Carly taught an engineering lesson in which students worked in small groups to design and test balloon rockets. In modifying this lesson, she carefully constructed how the groups would work together, including many back-and-forth emails with me, wordsmithing questions that would structure the interactions, but also be open-ended enough to facilitate conversation and not make students feel like there was "one right answer." In her final reflection, she was thrilled with how successful she felt this lesson was, noting, "Students were able to use this collaboration to identify patterns or commonalities with other groups' findings. I feel like socially, this lesson helped students come together and discuss the concepts. [...] Although they were following a set-up lesson, they had their own time to explore the things that happen with the balloon rocket and got to decide which areas/variables they wanted to explore within the rocket. Students also had a lot of discussion which had prompting questions, but was mainly student-led."

In terms of justice-oriented critical caring, there is still a long journey ahead for Carly. However, these small shifts – from "being comfortable as control," to recognizing in herself a goal to listen more divergently as well as valuing student interaction and discourse as supportive for learning – are important beginning steps, a foundation for moving towards the more ambitious ideals in our framework.

Gabby and Rob's journeys: Tensions between reflectiveness, relationality, and grammar of schooling

Gabby and Rob are two students who each came into the course with orientations to students that went beyond the discourse of politeness described above. They each encountered tensions throughout the course with various ideologies of schooling and how these conflicted with their stances towards students, though they navigated these tensions differently. At the end of the course, they collaborated on a final lesson modification that allowed them to leverage the strengths they had each developed in ways that stretched the other towards a fuller version of justice-oriented critical caring. Their two intersecting trajectories represent the complexities that students experience when enacting caring as a radical act. Here, we focus on the tensions they encountered as they navigated between an ethic of care and the structures of schooling, as they inform future design iterations.

Gabby and Rob both held multiply-minoritized identities within our teacher education program. Although neither of them directly connected their identities with their priorities to students, the orientations they held even early on reflected compassion and a sensitivity to individual's unique differences and needs. Gabby identified as a Black disabled woman who had shifted to education from engineering after growing weary of the constant (micro)aggressions she experienced. Rob identified as a white man who changed careers to become licensed as a teacher. Being an older student and a single father made him a non-traditional in our program student.

Neither Gabby nor Rob expressed ethics of care characterized by politeness. Instead, Gabby expressed an assumption of and value for heterogeneity in students' experiences, rather than "subsuming the unique circumstances of students under stereotypical generalities" – this reflects the component of *reflectiveness* in her ethic of care. For example, after conducting a "get to know you" interview with a few students during Week 2 of the course, Gabby reflected: "[T]his interview showed me I need to get to know all of them to see what they really want in science lessons. I need the whole picture, not just one case." She went on to describe how understanding that range of student desires and expectations would help her figure out how to strike a "balance" in her planning for instruction. In response to the same interview assignment, Rob expressed his surprise at how open students were in talking to him about their struggles and challenges. He wrote, "I think it's easy to forget how hard it is to be 14 [...] and especially after being online for the last two years and being thrust back into in-(person schooling. It is so important that we view our students as whole people, and give them time to adjust to new settings and new life situations. [...] I'm planning to informally check in with both of these students next week [...] to show that I was listening and care, so hopefully that at least shows them that someone is in their corner. I'm looking forward to seeing how all of these students grow as learners, and as people over the next few months." This aspect of *relationality* in his ethic of care demonstrates a commitment to forming "authentic relationships between individuals that are rooted in solidarity," at least around their experiences with COVID.

At various times throughout the semester, Gabby's and Rob's attention to reflectiveness and relationality resulted in tensions within their lesson planning and enactments, and within their observations at their placement schools. In weekly check-ins about their placements, Gabby often expressed frustration with how teachers in her placement school blamed students for not completing homework. She instead blamed boring lessons, including the school's required use of Cornell notes. When I pressed her about it, she saw the value of this structured note-taking strategy, but thought the school's policy on how students completed Cornell notes each week made them "busy work" and curtailed inquiry-oriented science. In her second microteaching assignment, Gabby used Manz's (2019) Investigations Framework to modify a flower anatomy lesson – a perfect candidate for Cornell notes! – to be a dissection activity. Students took Cornell notes as part of the "lab," but the notes were purposeful in helping students keep track of how their description of features mapped to the names and functions. She reflected on how the lesson was still more "vocab-heavy" than she would have liked, but was pleased with how engaged students were, asking a lot of questions and making connections to other plant and animal anatomical features. Notably, every student turned in their Cornell notes from the lesson, which we take as evidence of students' efforts to meet the high intellectual expectations that characterize *relationality* within a justice-oriented critical caring paradigm.

Rob similarly reflected on the implications of structures of schooling observed in his placement classroom for the kind of care-oriented teaching he hoped to enact, although his concerns throughout the course centered on how to set up class norms for discussion. For example, in a reading response post on the course's LMS about one set of paired readings, he wrote: "I still don't really have a great understanding of the norms in my placement classroom, or to what extent students even feel that there are explicit classroom norms. [...] While some engage deeply with the content, others get way off task, or will harass classmates, and I've not heard anyone reference any sort of classroom policy [...] While allowing [students] to explore [the norms] freely is critical for their emotional development, I think that setting up clear standards for science discussions is really a form of scaffolding for that practice." His commitment to students' development as whole people is clear, and his attention to collective norms as important aspects of *relationality*; however, he also describes it as "classroom policy," and mentions behavior management concerns as the ones driving his concern about norms. Unlike Gabby's articulation of trade-offs, Rob seems unaware of this tension between traditional schooling and justice-oriented critical caring. Later, this concern over classroom norms revealed a lack of trust in students to participate in small group discussions, as well as his own hesitancy to use meaning-making discussions as a regular part of his science instruction, potentially limiting opportunities for *discursiveness*. After enacting one such discussion for the first time, he wrote: "I also discovered that I 100% cannot do this every day. This lesson took a long time to put together and it took a huge amount of energy to get through! This type of lesson needs to be in my future instruction forever, but absolutely cannot be my everyday teaching style." Perhaps continuing to press on his doubts about students may be important for him to unpack this limitation, but we note that it represents an aspect of *reflectiveness* about himself – a productive move towards not operating out of an empty emotional tank.

Discussion & implications

We set out to study our efforts to support science pre-service teachers (PSTs) in our methods courses to develop pedagogies rooted in what we call *justice-oriented critical caring.* Through coordinating an intersectional, justice-oriented interpretation of an ethic of care, we proposed a framework specific to science education that is grounded in the following ethical commitments: *caring as a radical act*, *discursiveness*, *relationality*, and *reflectiveness.* Here we analyzed the activities and assignments from the pre-service methods courses we taught – one course for PK-5 PSTs and one course for future middle grades (MG) science teachers – and found evidence that our PSTs became attuned to various forms of *discursiveness*, *relationality* and *reflectiveness* in science classrooms. Specifically, PSTs in the PK-5 methods course strived to leave behind limiting forms of care that focused only on students' behaviors and, instead, embrace justice-oriented critical caring that attended to the substance of students' ideas and promoted their well-being. Moreover, the trajectories we outlined from the PSTs in the MG methods course described a much more complex process of how (future) teachers can be supported to work towards justice-oriented critical forms of care, especially when these steps are mediated by overarching structures, practices, and expectations of schooling that reinscribe oppression. Overall, our findings suggest that it is possible to design science learning experiences that reject the false dichotomy between content and ethical commitments, and doing so positions (future) science teachers to better support their students' science learning and humanities. However, our findings suggest that our PSTs encountered obstacles with reaching stable forms of *reflectiveness*, understanding how their positionality and that of their students shaped the caring relationships that supported meaning-making. For this reason, future iterations of our courses intentionally include frameworks and tools that encourage PSTs to readily engage with features of structural oppressions in science teaching and learning.

Comparative Design-Based Research: How Afterschool Programs Impact Learners' Engagement with a Video Game Codesign

Abstract: Community-based afterschool programs are valuable spaces for researchers to codesign technologies with direct relevance to local communities. However, afterschool programs differ in resources available, culture, and student demographics in ways that may impact the efficacy of the codesign process and outcome. We ran a series of multi-week educational game codesign workshops across five programs over twenty weeks and found notable differences, despite deploying the same protocol. Our findings characterize three types of programs: *Safe Havens, Recreation Centers,* and *Homework Helpers.* We note major differences in students' patterns of participation directly influenced by each program's culture and expectations for equitable partnerships and introduce Comparative Design-Based Research (cDBR) as a beneficial lens for codesign.

Introduction and background

Design-Based Research (DBR) is a methodology for producing generalizable knowledge about complex systems while also creating products that operate effectively within those systems (Barab, 2006). Borrowing the iterative logic of engineering design, DBR involves a cycle of building, testing, and improving prototypes in the context where they will be used. Due to the situated nature of the work, the products of DBR are influenced by the environments in which they are built. The interplay of context and creation allows DBR to not only facilitate the design of effective and engaging artifacts but also yield insights about situated environments, valuable to the Human-Computer Interaction (HCI) and Learning Science research communities.

However, a challenge remains in understanding specific constraints and unique strengths of these insights given they are derived from a highly contextualized process. When conducting DBR in settings where researchers are not members of the same social or cultural group as the intended users, participatory design methods, such as collaborative design (codesign) are often employed (Guha et al., 2013). Acknowledging that researchers' expertise does not extend to cultural and environmental norms in the settings where the products will be used, participatory design invites members of the community into the design process to provide insight into how products or programs could be designed for better cultural fit. However, it remains unclear how similar a new community would need to be for the insights to generalize, or perhaps how the design decisions could be manipulated for a differing community, given a lack of contextual information — i.e., more exact constraints, potentially limiting the findings.

Afterschool centers are a great environment to conduct adult-child DBR related to transformational games, as formal school schedules may be too rigid to allow for the unstructured play required to create highly engaging games. They cater to students' varied interests including sports, games, arts, STEM, etc. and routinely partner with external organizations to offer programs that students are highly interested in. Recently, afterschool STEM programs have been greatly promoted. Demand for such centers exponentially increased during the pandemic (Afterschool Alliance, 2022) and has remained strong even as schools have re-opened. Centers are expected to provide safe, supportive, adult-supervised environments, as well as academic, personal, social, and recreational development. Many providers are interested in expanding (or introducing) STEM program offerings, but not all STEM resources have proven successful in all environments. In fact, the multitude of virtues ascribed to afterschool centers creates an ever-growing list of expectations that partners are expected to meet, increasing pressure on providers to constantly change their programs to incorporate new, in-demand elements.

Codesign encapsulates multiple approaches, serving as a popular methodology to co-create experiences, products, and systems with users, stakeholders, and community members (Zamenopoulos & Alexiou, 2018). Codesign supports developing ideas, better designs for user and stakeholder needs, creating relationships between designers and groups of people, and quality results (Steen et al., 2011). Power sharing and shifting emerges from codesign, as stakeholders are given a pathway to provide insight and share needs (Westin & Salén, 2019). Often, codesign has been done with adult participants, however, as children utilize technology and are stakeholders in their own STEM educational experiences, it is necessary to include youth in codesign as well. Children's own insight is critical to designing effective experiences (McNally et al., 2016; Yip et al., 2013), since they are experts of their own interests. Their expertise is especially beneficial when the target goal is to create STEM educational products, such as transformational games (games developed with the intention of changing players in a specific way that transfers outside of and persists beyond the game) for diverse groups (Culyba, 2018).

Walsh et al., (2013) describe codesign as focusing on the design partners (their experience, needs for accommodations), design goal (design space, maturity of design), and design technique (cost, portability, physical interaction, and technology). However, when working with children, it is important that the techniques and framework for design fit the population and creativity is harnessed (Read et al., 2002). The needs for children from under-resourced or marginalized communities to become codesign partners may also be different and require a critical eye towards justice, diversity, and accessibility from codesigning researchers, e.g., drawing on critical race theory and intersectionality to better center diverse child codesigners (Ogbonnaya-Ogburu et al., 2020). Effectively involving diverse children in codesign can allow a range of participants to contribute valuable design insights. In particular, we aim to fill a gap in understanding how to effectively codesign with a range of children across different kinds of afterschool learning environments through a comparative approach.

In this study, we employ "comparative design-based research" (cDBR) to examine differences in barriers to implementation of STEM programs across five culturally and economically diverse afterschool centers. Our DBR program (the same program run across multiple sites) sought to create a robotics programming video game that would be engaging and practical within each cohort's environment. Each site's implementation spanned approximately 20 weeks and focused on codesigning a game that the youth in each cohort would like to – and be able to – play in their afterschool center. As expected, the codesign process produced inferences about the design of STEM games, however the cDBR approach also highlighted how different sites with communities of youth across different racial, age, and socioeconomic lines resulted in substantially different codesign experiences across populations. For the scope of this paper, we focus on the partnerships, codesign processes, and experiences to highlight methodology. Findings related to the game artifacts will be reported in a future publication.

In this paper, we argue that leveraging a cDBR approach provides insight and value to involving diverse youth in codesign work. We will demonstrate that beyond the conventional considerations that researchers take into account when designing research programs (such as racial and socioeconomic composition), additional critical factors to the conduct of participatory design-based research emerge from consideration of the internally aligned sets of goals, scheduling, and youth participation norms that follow from a program's structural character. The structural forms of different afterschool settings can be characterized by a common set of archetypal identities.

Context and method

Our program took place in a group of afterschool programs in and around a mid-sized city in the Mid-Atlantic region of the United States during the 2021-2022 academic year. Our goal was to collaboratively create video games with different afterschool sites where players program robot partners to accomplish goals together. The game was intended as an educational product, as well as a pedagogical exercise to foster students' identity as designers, increase their programming knowledge, and robotics domain knowledge.

We ran a 20-week program focusing on the codesign of game characters and narratives, block programming instruction, and game testing and iteration. In weeks 1-8, students were informed that they were partnering with our research team to create a video game where they collaborated with a robot by programming it to accomplish their in-game goals. Using different codesign instruments and activities, we explored different game narratives, co-created game characters and settings, negotiated game mechanics etc. The next 8 weeks were focused on block programming instruction to equip students with the skills needed to program their robots. This time also allowed our software development team to create a prototype version of the game. During the final 4 weeks, we iteratively tested the game with students. Students tested and critiqued prototype and beta versions of the game, often with us modifying the game elements, narratives, and mechanics between versions. Each codesign session was one hour long and consisted of snacking and icebreakers, scheduled codesign activities, and students playing diverse-genre video games from a curated selection. We obtained written consent from students' parents/guardians and our research was approved by our university's Institutional Review Board (IRB).

Each session was attended by 2-4 researchers (depending on the number of students), with one being a dedicated notetaker. One researcher (second author) was the main lead for most sessions at each site, while the others had supporting roles (taking notes, answering questions, passing out materials, etc.). Site staff members sometimes joined our sessions and assisted with the facilitation. The program was structured for 6-8 students but adjusted to accommodate much larger groups as necessary. After each session, the researchers met to discuss the data gathered and clarify any areas of confusion. These meetings were recorded and transcribed as well. All team members attended a weekly analysis meeting to review session interactions from the different network sites, design and refine planned session activities, and reflect on the types of program adjustments we needed to make to better serve each afterschool center. We recorded these analysis meetings and analyzed them as part of the data.

Table 1
Afterschool club information (collected from interviews) showing total students, age range, and demographics.

Club name	Total # students	Age range	Racial demographics description
Green Hill	30 (10 F, 20 M)	5-14	Mostly Black, some White, some Hispanic
Central Rise	12 (12 F)	11-14	Predominantly Black
Sunny Pond	19 (6 F, 13 M)	7-12	Predominantly White
Clear Bridge	15 (3 F, 12 M)	7-10	Predominantly White, some Hispanic, some multiracial
West Creek	48 (21 F, 27 M)	5-12	Diverse (including White, Black, Hispanic, Middle Eastern, multiracial)

We worked with 5 afterschool clubs (Table 1): Green Hill (former industrial low-income town with mostly Black families), Central Rise (low-income neighborhood in city center with mostly Black families), Clear Bridge (rural town with mostly White families), Sunny Pond (suburban town with mostly White families), and West Creek (diverse suburban town). Site names are pseudonyms. All programs took place in-person, except for at Sunny Pond, which was run mostly remotely due to COVID regulations with the help of a staff member onsite.

We have several sources of data: Staff interviews, observation notes, researcher reflection meetings, student surveys about technology and programming experience, and codesign data (including design artifacts, playtesting session observations, etc.). Staff interviews (N =10; 5 F, 5 M; 5 White, 3 Black, 1 South Asian, and 1 Hispanic) consisted of 8 who were dedicated to their individual centers, while 2 were administrators who served as STEM coordinators for all afterschool centers in the network. Each interview, focused on the culture of the programs, their available resources, and values, lasted one hour and was recorded for analysis. Participants were not financially compensated but were informed that participation would allow us to better cater to their students.

We conducted a thematic analysis on the different data sources (Braun & Clarke, 2012) to understand and characterize how organizational goals, resources, activity provision norms, and student participation criteria impacted the effectiveness of our codesign program and required different adaptations. We reviewed the interviews first, then session observations, and meeting notes for data that provided evidence for each identified theme. Given the focus of the interviews, preliminary themes highlighted aspects of program culture. These themes were then corroborated and iterated based on analysis of the other data sources. After this process was completed, the entire team discussed each theme extensively to clarify areas of confusion. Where necessary, the team watched session videos as a group where multiple perspectives were needed to unpack the interactions. We triangulated our findings with student-generated artifacts to ensure that all evidence was mutually supportive. Our team consisted of a range of researchers coming from computing, learning science, robotics, and game design academic backgrounds, as well as a variety of economic, racial, and cultural backgrounds (including East Asian, Black, and White, with American and African cultural backgrounds). Researchers often had multiple roles on the teams, including being facilitators, programming and building the games, and designing the games.

Findings

We identified three "program archetypes" across the five sites with characteristically different goals, schedules, and activity participation norms, which in combination had a dramatic impact on the conduct of afterschool programs (including our DBR activity, which was shaped as a STEM program). These categories are not meant to be exhaustive, or comprehensive for describing all kinds of afterschool program partners. Researchers may encounter partners who do not have any of the factors described, or more likely, partners who have characteristics that span across these archetypes. These characterizations provide insight into how different communities can be contrasted using one design program protocol. We find differences across sites by using a comparative approach.

Program archetypes: Safe havens, homework helpers, and recreation centers

Safe Havens

We categorized Green Hill and Central Rise as *Safe Havens*. We interviewed three directors from both programs (2 Black men, and 1 Black woman). These afterschool programs are located in high-poverty neighborhoods with mostly Black and Brown students attending low-performing schools. The primary purpose of these sites was to provide a safe space for children to stay after school. Unlike our other sites, all the students in these clubs qualified for financial assistance and therefore attended the program for free. They have strong partnerships with local schools – Green Hill is physically located in the local elementary school, and Central Rise has liaisons who work in the schools they serve. The Central Rise program director mentioned, *"We help with education… education by far, because not only are we on them when they get here or just when they're not here, we keep in contact with 'em. We have a liaison up at the school. Okay? Who's also checking on them, their mannerism …"*

Staff members in Safe Havens did not only serve as enrichment coordinators but also as parent and guardian figures. For example, the program director at Green Hill shared that he regularly raised funds from different organizations to ensure the students had clothes and school supplies – on several occasions he invited hair braiders and barbers to the afterschool programs to ensure students had presentable hairstyles. In both programs, members sometimes transported students in their personal vehicles, cooked meals for them, and advocated for them in schools and with their families. Taking on this parental role came easier for all three directors as they could personally identify with the students – they all shared that they grew up in similar neighborhoods, faced similar struggles, and attended afterschool programs with adults that made a difference.

In addition to providing a safe space and serving as parental figures to students, these administrators shared that exposing their students to more opportunities regardless of their interests was important to them. Central Rise had organized international trips to Ghana and Jamaica in the past to expose their students to people from other cultures, and Green Hill was constantly looking for more exposure opportunities.

> *"It's just like abilities to see things. Whether it be resources or supplies or whatever it may be … So, for me, the idea is like the exposure. I remember like going to a tennis camp… I didn't care about that tennis camp, not one bit, but now that I'm 31 years old, I can see someone playing tennis on TV, and I can appreciate that because at a young age, I was kind of exposed. I don't think that the exposure was so much about me like becoming Serena's [Williams] little homie. It wasn't about that. It was about me experiencing it … We're going on a walking trail tomorrow … these city kids have no idea what a walking trail looks like."* — Green Hill program director

Although Green Hill is part of a larger afterschool program network, they are physically located at least 30 minutes from the city center and are largely inaccessible by bus. Therefore, they do not benefit from the STEM programming and staff available to the other flagship afterschool sites located in the city. They also have very limited computing infrastructure; when we first started working with them, there were only three computers available to both students and staff. Due to limited opportunities for STEM programming, administrators welcome lasting external programs to accommodate many students with minimal infrastructure and staffing requirements.

Central Rise is in the city downtown and has better access to STEM programs and researchers from local universities, non-profit organizations, and technology companies. However, they also struggle with maintaining consistent STEM programming, as they didn't have the staff to provide instruction in house. Throughout the COVID-19 pandemic lockdown, our research was the only external program available to them. Although they had some donated computers, they were all severely outdated, and we had to provide technical support while working with them including replacing missing peripherals, operating system updates, upgrading memory, etc.

Homework Helpers

We categorized Clear Bridge and Sunny Pond as *Homework Helpers*. We interviewed three directors from both programs (one white woman, one white man, and one Indian-descent man). Clear Bridge is located in a rural town where white working-middle class families make up 95% of the population. Sunny Pond, on the other hand, is in a small town in close proximity to other afterschool programs in the network. Working class white families make up the majority of the population. Families in both clubs primarily signed up their children to get homework help from the coordinators. The program director of Clear Bridge described, *"We are homework help. That's a main one… Parents come for the after-school homework help. They like that. They like that we have structure here that we do the academic things… It's the ability because [parents] don't understand the math … So, when they get home, they're not having to worry about rushing around, getting homework done. They can actually spend time with their kids."* Focusing on academics makes *Homework Helper*s conducive to running structured programs.

> *"Students [at* Homework Helper *programs] will buy in enough to do what they're told, because someone told them to do it, whether or not they [fully] buy in … Most of the students are like, 'Okay, I will do what I'm told. I will sit here. We may not be passionate about it.' So, like when I picture [other programs in the area], we have the crazy, like, nothing goes smoothly, ever. All the kids are all over the place, but there's a lot of kids that are passionate and like excited about*

> *it… [At Sunny Pond and Clear Bridge], there's a little bit of crazy, but a lot more kids with less passion."* — Network-level STEM director

Since parents entrusted the administrators at the *Homework Helper* sites with the responsibility of overseeing all afterschool academic activities, they did not get involved in what activities their children participated in. Administrators had the responsibility of pre-selecting students who attended different programs based on their perceptions of student ability and interest. At Clear Bridge, administers gave us a list of students whom they felt were best suited for our program. While most of the selected students had prior programming experience and game design interests, several other students who could have benefited from the program were left out. On one occasion, we had the opportunity to share our program information with all students who attended the club on a particular day, and seven new students came to us informing us that they were interested in joining. Sunny Pond had a more flexible signup structure. Like Clear Bridge, the administrator pre-selected the students who they felt were best suited for our program, but they often reevaluated other students who visited the club.

Both afterschool sites had adequate technology infrastructure. Clear Bridge had a computer lab with touchscreen desktop computers. There was a general space for homework, and a makerspace with more computers and programmable robots. Sunny Pond did not have a dedicated computer lab, but they had laptops available for each student and several classroom-style spaces that were used for different programs. Both sites had an in-house STEM champion. The program director at Clear Bridge had taught several STEM programs in the past and was regularly soliciting partnerships for opportunities. Sunny Pond had a dedicated STEM programming staff member.

Recreation Centers

We categorized West Creek as a *Recreation Center* and interviewed two program directors (one Black man, and one Hispanic man) for this study. Prior to their serving as directors at West Creek, they worked as program directors at Green Hill and another local center not in this study, so they could reflect on their experiences working in the different settings. One program director mentioned, *"Your role might have to shift depending on the neighborhood and the kids that you're working with. [The other director] and I have a bunch of cartoon stuff around our office, and I think that exemplifies the vibe that we have here as kind of a, 'Hey, let's hang out buddy' type of thing ... I don't think they look at us as father figure sort of thing ... [We're] one of the, one of the homies."*

When describing the purpose of their club, the program director of West Creek explained the culture of the club centering fun and entertainment: "Kids either come here for sports, or they come here to do the fun kind of hangout things that are happening… The idea of the club is fun. … You know, like when you're in school … if they make a game out of learning, that's exciting. If you go to the club, and they make a game out of learning, and [the children may think] 'Whoa, whoa, what is this? Oh, we don't want to do this.'"

In addition to a dedicated computer lab, West Creek has a dedicated gaming room with several video game consoles, board games, and billiards for teenagers. They have an open lobby space with arcade style video games and consoles, billiards, and table tennis. They also have two dedicated gyms where multiple sports programs were conducted, an outdoor playground, an art room, and a dedicated maker space. While administrators recommended and encouraged students to join certain activities, the students have the agency to leave and join any other activities in the building at will. We observed several incidents where students joined the one activity but were informed by their friends that something cooler was happening elsewhere encouraging them to leave.

Norms around participation in codesign program

To illustrate the utility of our cDRB approach, we describe one main theme from the data, characterized by differences between archetypes touching on culture, values, resources, and demographics. In particular, we saw that the norms around and barriers to consistent participation dictated the types of data that could be collected and mediated how learners could engage with our program. Table 2 shows the attendance patterns at different clubs.

Attendance patterns at Sunny Pond and Clear Bridge were most consistent with our prior expectations for our program's participation. Most students who signed up attended most sessions as long as they were in the building. Although Sunny Pond and Clear Bridge had students attend less than 40% of all sessions on the average, the main reason for this was that these clubs were most sensitive to set of fee increases implemented by afterschool network partway through our program, as most children came from working to middle class families and did not qualify for financial assistance. There was a program wide-fee increase from $90 to $110 per week which caused some parents to pull their children from the club. For students who remained, attendance was higher. We made the fewest modifications to our original program design with *Homework Helpers*. Students attended consistently enough, provided codesign input, and were invested in the game output. There was less opportunity for identity transformation and learning gains compared to *Safe Havens*, and less diversity in game feedback compared to *Recreation Centers*, but their predictability was most beneficial for the original codesign process and product.

Table 2

*Participation information and archetype. Clear Bridge and Sunny Pond experienced a tuition hike that impacted the number of families that attended the afterschool program. *The second numbers listed for these afterschool clubs are the average for students who remained in the program despite the tuition increase.*

Club name	Archetype	Avg. % of total sessions each student completed	Avg. # of repeat students per session
Green Hill	*Safe Haven*	43%	11.45
Central Rise	*Safe Haven*	71%	7.45
Sunny Pond	*Homework Helper*	31% (*53%)	5.16
Clear Bridge	*Homework Helper*	39% (*50%)	4.8
West Creek	*Recreation center*	13%	3.95

Although they provided the most consistent student attendance, conducting research in *Safe Havens* was quite challenging. Despite having only 12 students, attendance was highly consistent at Central Rise. Most students at Green Hill attended 43% of all sessions — however, this was further reduced by months of including some students and excluding others, as we tried to maintain a maximum of 10 students in our program to avoid crowding in small spaces and support meaningful codesign interactions. Attendance was more consistent when we could provide enough research staff to accommodate all students. Staff members insisted that equitable provision of programs to their students involved mandatory participation. We tried different approaches to account for the number of students including taking half of the students on one day and coming the next day to repeat the program for the other half. That too, was not sufficient as staff members could not guarantee student attendance, so we had to cater to all students without additional time available. We also needed to spend more time teaching prerequisite skills. Students at Green Hill had mastered fewer arithmetic, reading, and STEM competencies compared to their middle- and upper-class counterparts. The mandatory participation requirement also meant that we had varied student interest in our program and had to work with students who did not want to be there. Given the low prior STEM knowledge and mandatory attendance requirements, students in *Safe Havens* showed the highest potential for STEM identity transformations and learning gains. Long term programs that make strong connections between STEM and other domains provide consistent attendance by research partners and expose students to different kinds of professionals seemed especially useful for this archetype of afterschool program.

In *Recreation Centers*, we had the most inconsistent attendance of all our programs. West Creek students attended an average of 13% of all sessions, and approximately 4 students were repeats compared to the 48 students we encountered in totality. Students in *Recreation Centers* shuffled between multiple spaces within the same time block looking for activities that seemed the most exciting. When students opted to play outside, play video games, or play sports in the gym, it was unlikely that they would stop by our program. When we had students in the room, there was high interest, but the attitude was all about play. One potential strategy to increase student participation was to communicate our program goals, milestones, and output directly to parents so they could encourage their students to attend. However, we did not have direct access to parents and lacked the consistency in output materials per child to make that strategy feasible during our time there. Given these attendance patterns, it was impossible to conduct pre- and post-testing, observe long term identity transformations, or conduct programs not centered around play or fun. Students in *Recreation Centers* provided inconsistent input in the codesign process, but their input was particularly valuable when testing new iterations of our video games. Because they did not have the same emotional ties and investments as groups who consistently informed the design of the game, their feedback was critical for understanding how each game might be understood by fresh students from other demographics.

Discussion

The outcomes of Design-Based Research are typically twofold: contextually appropriate products, and reflections on the context-product interactions that make them so. Typically, these insights are powerful and authentic but also inherently specific to a single context. In this paper, we presented findings from our effort to deploy a STEM codesign program across multiple settings. True to its DBR roots, this work produced data and analytic leverage from which to reason about the context (afterschool programs) in which the work was taking place, surfacing characteristics of afterschool programs that affect such programs. In particular, because our STEM codesign program served as a data collection instrument, we were able to identify numerous factors relevant to the conduct of design-based research in these settings. For instance, inconsistent student attendance at programs could result from several different forces – in programs with high levels of free choice, it could be the result of our activities being unappealing; in other programs attendance was constrained by level of trust; in others, it was beyond our control entirely. In other cases, the ways in which norms affected codesign participation could be quite subtle. For example, *Recreation Centers* maintained a culture of play and value of fun, making it trickier to direct youths' attention toward creation of more serious artifacts, especially when other activities like sports were offered at the same time. Vitally, it is the fact that we were able to observe the same STEM codesign offering playing out in these different ways between sites that allow us to be confident of the different mechanisms by which this occurred. Our findings corroborate prior literature characterizing types of out-of-school programs, relating to e.g., homework assistance (Cosden et al., 2001) and its benefits to learners. We extend such work by noting that programs in fact organize themselves quite substantially around core services they offer, such as homework help, creating differences across the culture of the organization, impacting many activities, including codesign.

Educational and methodological implications

Regarding implications for informal education research, by focusing on the differences between common patterns of program structure we found that codesign-critical program participation norms and routines could be highlighted using archetypes based on administrators' characterizations of programs. Comparing the alignment of administrator characterization to observed program routines across sites allowed us to see if that administrators' visions seemed to be the genesis of scheduling and attendance norms across sites, or at least that administrators were reliably aware of such alignments. While racial, socioeconomic, and broader structural factors are likely at play and cannot be separated from our findings given the nature of our specific sites, the archetypal descriptors provided micro-level insight into the site routines that determine whether a codesign session will be productive.

This work also yields methodological implications. The findings we present here are primarily triangulated from observed *differences* between *sites*. However, between-sites comparisons are not the only analytic leverage provided by cDBR. We have also seen promising results emerging from exploration of *commonalities* between the *products* resulting from codesign at each site (Higashi et al., 2022). We may thus hypothesize that, at a minimum, a cDBR approach could produce inference based on something akin to a 2x2 matrix of either *similarities* or *differences,* between *sites* or the *products* they generate – the present study, for instance, focused on *differences between sites*. Yet the matrix-cell approach ignores the inextricable link between contexts, processes, and products in DBR. Indeed, some of cDBR's greatest inferential power may come from examining combinations of these factors. We can readily imagine, for instance, a situation where certain product design features emerge across multiple different sites for different, yet independently sensible reasons. *Product similarities* despite *site differences* in design rationale would provide provocative evidence of *convergence*, supporting the existence of important invariants around DBR. Such insights remain notional now but point to a powerful potential for comparative methods in design-based research, which we will pursue in our future work.

We recommend that researchers who intend to use cDBR keep a few points in mind. A diverse range of programs will provide the greatest leverage for triangulation. Differences and therefore findings across sites may be more robust with greater diversity across multiple axes. Larger differences in site context will entail a wider array of needs across teams and communities, impacting the overall nature of the work and increasing the need for flexibility in the codesign protocol. Preparation for this may include, for example, ensuring the ability to call in extra research team members to support facilitation onsite for certain collaborations.

Limitations

There are some threats to validity. First, our evidence is drawn from a single codesign effort conducted across 5 sites in a single, geographically contiguous network of afterschool programs. Therefore, while our argument establishes an existence proof of the value of cDBR, determining the full extent and scalability of cDBR methods is left for future research. Similarly, we acknowledge that while we intentionally employed a diverse team of researchers and took an iterative process in our analyses, there are inescapable possibilities of bias when analyzing data and the inherent advantages and disadvantages of researcher-as-instrument in qualitative work. Additionally, a programming-based co-robotic game may result in prior knowledge highly influencing participation, and different insights might be uncovered for different types of products in other domains. Finally, by nature, some of our findings about suitability and responsive adaptation of DBR instruments to different contexts emerged from failure. Thus, while analyses of these breakdowns allow us to observe the failure mode, conditions under which issues occurred, and immediate causes, it is impossible to directly observe the counterfactual, i.e., what the program would have looked like had we incorporated needed adaptations in advance. We intentionally scope this work around the methods, showing the potential of this deployment of cDBR across sites. Broader results, including additional themes related to the design artifacts, including the games, will be reported in the future.

Conclusion

A cDBR approach, employing the same codesign protocol and processes in intentionally different settings, yields important insights about interactions between protocols and settings, and therefore serves to highlight particular strengths or limitations in the codesign findings. Without the comparative multi-site aspect, we would have not had a point of comparison from which to argue that interesting codesign process decisions stemmed from an interaction with systemic local conditions. While the focus of this paper has been to highlight the potential for cDBR through emphasizing differences between sites, future work will explore the *persistent* or *convergent* design findings that can also be made apparent by the approach.

Abstract: This study examines how the purposes and values Mexican immigrant families bring into a community garden space can serve as cultural strengths and facilitate opportunities for rich STEM learning. Taking place at a school-based community garden in the western US within the context of a long-term community-university partnership, researchers in this study engaged in qualitative ethnographic data collection with 20 gardeners and families over the course of nine months. Utilizing sociocultural perspectives, chiefly CHAT and the notion of a "third space," researchers analyzed semi-structured interviews, field notes of garden walks and community events, and self-documentation materials submitted by participants. Findings include (1) the identification of the concepts *distraer* ("to distract") and *conectar* ("to connect") as cultural strengths and the drivers of valued activity in the garden and (2) the effectiveness of these concepts in fostering families' engagement with natural phenomena and STEM practices.

Introduction

Deficit thinking in schooling is a seemingly intractable issue for students and families from non-dominant communities. Deficit thinking attributes failings to an individual's perceived abilities or cultural background and indexes the historical and structural inequities largely responsible for the opportunity gap in the United States (US) (Valencia, 2010). Whether through a students' experience in the classroom, or a family member's experience in a school meeting, students and families from non-dominant communities often confront pervasive and implicit assumptions that they lack knowledge or skills. Yet, non-dominant communities hold a wealth of knowledge (e.g., Yosso, 2005). Scholars in the learning sciences have long argued that to improve learning outcomes for students from non-dominant communities, learning environments must privilege the knowledge systems and learning practices of these learners and their families (Ishimaru, 2019). Within STEM education, learners from non-dominant communities rarely have the chance to meaningfully bring cultural strengths from their lives and communities into their learning (c.f., Bang et al., 2012; Calabrese Barton & Tan, 2019).

The inequitable outcomes learners from non-dominant communities continue to experience in STEM brings into relief the urgent need to explore how cultural strengths may intersect with STEM learning. This paper serves as an exploratory analysis of this aim, specifically the ways cultural strengths common to Mexican immigrant members of a school-based community garden mediate STEM learning opportunities. Prior work seeking to understand how culture may shape learning in Latiné communities revealed how complex coordination within families and groups during seemingly routine activity can provide a powerful learning space (Rogoff, 2014). Research has also noted the need in learning to attend to the regularity of a cultural value system within non-dominant communities where the well-being of the group or community is paramount (Severance, 2021). This shared sense of purpose and collective identity motivate joint activity wherein rich learning can occur (Rogoff, 2014). Work in "culturally responsive" (Gay, 2002) and "culturally sustaining" (Paris, 2012) design has demonstrated the validity of making cultural strengths – whether practices, values, or knowledge – of non-dominant communities central to learning. Within STEM education, researchers have demonstrated the power of making cultural strengths central for learners from non-dominant groups, including indigenous communities (e.g., Bang & Medin., 2010), Black communities (e.g., Brown, 2021), and Latiné communities (e.g., Eglash et al., 2013). More exploration of the nature of cultural strengths and their potential in STEM learning is needed, particularly those of an axiological nature which can promote particularly meaningful forms of STEM learning (Bang et al., 2016).

This study takes place within the context of a long-term community-university partnership in the western US, with university researchers and students having closely worked alongside local Mexican immigrant families for several years to support and sustain activity within a 0.5 hectare community garden. Located at a semi-rural primary school where 97% of students identify as Latiné and 100% receive free and reduced lunch (a marker of poverty) the garden is a hub of activity. Throughout the garden's existence, university and community members have sought to privilege community knowledges by design and to promote an anti-oppressive arrangement, where

Latiné immigrant families are the garden stewards and experts. A heterogeneous group of over forty Mexican Immigrant families cultivate not only their own food security, but also their own agency, identity, leadership, and knowledge, including STEM-related (agri)cultural knowledge (e.g., understanding of plants, water systems, etc.).

We are studying the garden as an activity system with a focus on codifying and understanding the cultural strengths Mexican immigrant gardeners and their families bring into the garden space and how these strengths may open up possibilities for STEM learning. Specifically, following work suggesting the centrality of shared purposes and values in STEM learning (Bang et al., 2016; Severance, 2021), we explore how the purposes and values of gardeners and their families can both motivate activity and mediate learning. Our research questions ask: (1) *How do the purposes and values of Mexican immigrant gardeners and their families shape their activity in the garden?* And (2) *How might activities motivated by shared purposes and values serve as rich opportunities to engage in STEM?*

Theoretical framework

To help analyze and explain learning phenomena encountered within the community garden, we draw on sociocultural perspectives, chiefly cultural-historical activity theory (CHAT; Engeström & Sannino, 2010) and heterogeneity or a "third space" (Gutiérrez, 2008). According to sociocultural theory, learning occurs as people engage in activity with one another through the use of cultural tools (e.g., language, symbols, systems of thinking, etc.), with learning having to occur on a social level between people or their proxies (e.g., writings, representations) before being internalized on an individual level (Vygotsky, 1978). Relatedly, learning within CHAT is defined broadly as an expansion of existing activity (i.e., something that did not exist previously; Engeström, 2001). These notions of learning and how learning occurs frame our examination of activity in the community garden. Within the community garden, we seek to understand whether and how learning as a 'co-construction of knowledge' and 'new social arrangement' of peoples "transforms and creates culture" in the garden (Engeström & Sannino, 2010, p. 4), particularly in relation to STEM (agri)cultural knowledge and practices.

CHAT also offers useful framings for understanding the organization of activity wherein learning occurs, namely what serves to drive and sustain collective activity. A bounded activity, such as the community garden, constitutes an 'activity system' (Engeström & Sannino, 2010). When members of an activity system engage in activity, their actions ideally support achieving a common object or goal. The notion of an 'object' equates to the purpose(s) that drives the individual and collective activity in a space. Engaging in goal or object-driven activity requires attending to other aspects of an activity system. CHAT posits that as individuals engage in activity with others in a community, their interactions are influenced by explicit and implicit rules. Moreover, for a community to engage in activity towards a shared object, a division of labor must occur. CHAT also theorizes the central role of cultural tools in increasing the capacity of individuals and community to engage in activity towards an object. We envision this project as a starting point to analyze the garden as an activity system. We seek to leverage the notion of an activity system to better identify and codify purposes and values that drive activity and better explain how aspects of the garden space, such as relationships among family members and the use of certain tools, shape activity.

In addition to CHAT, we draw on heterogeneous perspectives, chiefly the notion of a "third space," to better understand how horizontal arrangements of expertise, which have shown promise in promoting motivation and collective ownership over activity (Gutiérrez, 2008), can lead to potentially transformative learning opportunities. Often associated with formal education settings, achieving a "third space" requires the traditionally dominant practices of a space to come into dialogue with traditionally marginalized practices, resulting in a hybrid space offering previously unavailable access and agency to learners. Although the garden is not a carefully designed learning environment, we seek to leverage the notion of heterogeneity to examine whether and how the garden and the learning occurring in the garden may be developing and transforming "the individual, the individual's relation to the social environment and the environment itself" (Gutiérrez, 2008, p. 152). Possibilities may emerge in which the activity in the garden can confront ethnic and racial hierarchies and create new systems of relations that can provide opportunities for Latiné learners' empowerment, particularly regarding STEM learning.

Methodology

This study is a qualitative case study composed of multiple embedded cases (Creswell, 2007; Yin, 2009). Learning occurring in the context of activity in the community garden as a whole serves as the phenomenon of interest. The nature of this phenomenon results from the interaction of smaller subunits within the activity system, that is, the activity of individual gardeners and their families. In a tangible, physical way, the 0.5 hectare space of the garden reflects the parts-to-whole organization of the activity we seek to understand with the garden subdivided into 48

4.5x4.5 meter plots for which families take the lead on caring for and serve as the primary locus of their activity. The garden also has a large milpa (corn, beans, and squash) field, one large plot of pumpkin and squash varieties, a nopal garden, herb garden, and communal seating and cooking areas. All community members volunteer three hours a month to maintain communal areas under the direction of a garden manager (also a community member).

Data collection followed ethnographic qualitative approaches (Gonzáles et al., 2005), with researchers "following" the activity of gardeners and families over the course of a growing season from March to November. 8 gardeners and 12 families volunteered to serve as focal participants in this research study. The makeup of families in the community garden typically consisted of intergenerational units (e.g., children, parents, and grandparents). All participants identified as Mexican immigrants with a sizable number revealing undocumented statuses and over 70% employed as farm workers. Data for this study consisted of over 200+ WhatsApp entries from community gardeners engaging in photo and video self-documentation of their activity (approximately 3-4 times a month), 30+ semi-structured interviews, three filmed garden walks with gardeners and their families each season where we acted as observers and asked about their activity in their plots and the garden in general, and field notes from regular events and other communal activities that occurred over the course of a year in the garden (e.g., fall harvest activities and celebrations). All data underwent transcription and translation into English by researchers fluent in Spanish.

Data analysis involved periodic analytic memos (Emerson et al., 2011; Saldaña, 2009), as well as rounds of inductive and deductive coding. As we collected data over time, research meetings became facilitated reflection sessions focused on using an emic stance to derive potential insights into gardeners' and families' activity up to that point and capturing these in-process claims as analytic memos. These insights (e.g., primacy of relationships, different purposes observed) led to potential codes for use in reducing the data during coding. The coding process followed rounds of inductive ("bottom-up") and deductive ("top down") analysis (Emerson et al., 2011). To derive an initial set of codes, we drew on ideas from CHAT (e.g., object/purpose, cultural tools, rules, division of labor) and the notion of a third space for STEM learning (e.g., participant practices, STEM practices) in conjunction with insights from the aforementioned analytic memos. We revised the codebook via successive rounds of coding data. Any disagreements in coding led to group discussions to resolve the disagreement. Coding pointed to potentially revealing patterns and excerpts thought to exemplify (or contradict) those patterns. These excerpts underwent further fine-grained analysis to identify evidence supporting (or contradicting) claims related to broader patterns found.

Findings

Data collected over the course of nine months in the community garden has provided preliminary evidence for what we believe to be commonly occurring cultural strengths of an axiological nature that Mexican immigrant gardeners and families orient towards in their activity and how these strengths may offer opportunities and productive contexts for youth and their families to engage in meaningful STEM learning.

Claim: *Distraer y conectar* as axiological cultural strengths to drive activity

A consistent pattern that has emerged from data across 10 of the 12 focal families indicates the primacy of valuing connection as a cultural strength and the integral role this plays in motivating purposeful activity in the garden. We have characterized this phenomenon in the garden as what we see as the mutually constitutive concepts of *distraer* and *conectar. Distraerse*, is a reflexive Spanish verb meaning "to distract (oneself)," but is used more broadly to describe getting out of the norm of everyday life and being distracted in a positive way. Conectar means "to connect" and in the garden, we have seen activity focused on connection while seeking distraction, including "to connect" with family, with the land, with their foodways, and with their community more broadly.

Gardeners have talked about *distrayendo* (being distracted) and *conectando* (connecting) in primarily two ways while explaining the purpose and rationale for their activity in the garden. For many, going to the garden provides a change of scenery from day-to-day work and family activities and allows them to disconnect from various aspects of daily life, and to *conectar* (to connect) to themselves, each other, plants, and the land. One gardener, Marta, who decided to participate in the garden to "desocupando un poco mi mente" or *empty my mind a little* but also reinvest in her relationship with her sister, exemplifies this emphasis. Marta reflects, "ella era más como figura mamá y exigía y yo pues obedecia pero últimamente se ha convertido como ese lazo de hermandad que hemos formado." *She was more like a mother figure and she ordered and then I obeyed but lately she has become like that bond of sisterhood that has formed.* Being together in the garden, distracted from the typical dynamics that guided their relationships, Marta and her sister found a way to connect and remediate their relationship.

Gardeners also talked about the importance of the garden as a means to *distraer* and *conectar* for their children, to distract them from the TV and spend time outdoors in the garden and also promote building deeper relationships with their parents and connections to nature and long held (agri)cultural knowledge associated with prior generations and family origins. Fully 20 out of 42 of all families demonstrated this emphasis over time. Enrique and his children serve as a prime example of families who sought out distracting activities that could also provide opportunities for intergenerational relationship building and connecting through growing plants. During his interview, Enrique's explanation for his family's activity points to the cultural strengths of *distraer y conectar*:

Researcher:	¿Cuáles son las razones por las que le gusta participar en el jardín aquí en Calabasas?	What are the reasons you like to participate in the garden here in Calabasas?
Enrique:	Una de las razones más grandes es que ellos vienen a distraerse, mis hijos. Y cómo se los dije, él es al que le interesan más las plantas y se siente a gusto estar aquí. Y cada vez que venimos siempre vemos algo nuevo. A veces ellos se ponen a agarrar los insectos. Entonces mi mayor razón es que ellos puedan disfrutar un momento de estar a gusto, y también que aprendan cómo es que se producen las frutas y las verduras. Hay muchas cosas que aprendo de él. El luego me dice "las frutas crecen de está manera" o "podemos plantarla así y van a estar mejor." El me sorprende porque sabe muchas cosas de las plantas. Y yo veo que ellos están contentos y alegres. Y cuando vienen y cortan las fresas o ven que está creciendo lo que ellos plantaron, la emoción en ellos es muy grande. Entonces la mayor razón por la que yo estoy aquí son mis hijos.	One of the biggest reasons is because they come to get distracted, my children. And as I told you, he is more interested in plants and he feels comfortable being here. And every time we come we always see something new. Sometimes they [my kids] start to catch the insects. So my main reason is that they can enjoy a moment of being comfortable, and also that they learn how fruits and vegetables are produced. There are many things I learn from him. He tells me "the fruits grow this way" or "we can plant them like this and they will be better." He surprises me because he knows many things about plants. And I see that they are happy and joyful. And when they come and harvest the strawberries or see that what they planted is growing, they get very excited. So the biggest reason I'm here is my children.

Enrique describes how when his children "get distracted" in the garden it provides them valued opportunities to connect in multiple ways. He notes that his son can "[feel] comfortable being there" and how his children "start to catch insects," denoting desires to connect to the land and to nature. Enrique also reveals – albeit implicitly – the value he places on connecting with his children through their garden activity. His description of how "every time *we* come *we* always see something new" (emphasis added) suggests a perception of activity in the garden as an opportunity to share experiences with one another. Not only are his children learning "how fruits and vegetables are produced," but Enrique notes the "many things [he] learn[s]" from his son, a relationship dynamic he enjoys for its novel dynamic ("He surprises me") and the enjoyment he sees it promotes in his children. The cultural strengths of *distraer y conectar* mediate an impressive array of activity for this family.

Claim: Meaningful STEM learning through cultural strengths distrayendo y conectando

While the cultural strengths of *distraer y conectar* drive broad activity valued by families, we also see evidence that these strengths in the context of the garden promote rich opportunities for STEM learning. Mexican immigrants and the broader Latiné community have long experienced inequitable opportunities for STEM learning in the US. And yet within the garden we routinely observed families essentially doing STEM through a "third space" wherein they productively integrated the cultural strengths of valuing connection and relationships into their engagement in STEM practices – the ways in which scientists figure out phenomena and solve problems (NRC, 2012). Our data provides some insights into the mechanism by which *distrayendo y conectando* may promote opportunities for STEM learning that families see as purposeful and meaningful. Across all families, the intergenerational nature of the activity (e.g., with children, parents, grandparents) provides a rich foundational relationship that when taken to the space of the community garden provides the *a gusto* or "comfort" we observed with Enrique's children earlier – there is a sense of belonging (Calabrese Barton & Tan, 2019) – that helps mediate a willingness to explore nature and solve problems in the garden.

How families engage in STEM practices in the garden within the context of *distraer y conectar* has taken many forms. Consistently, however, families' engagement in STEM practices always centers on local phenomena and problems within the garden. Within science education, major instructional models (see Krajcik & Blumenfeld, 2006) and science education reform efforts (e.g., *A Framework for K-12 Science Learning*; see NRC, 2012) all seek to have students engage in figuring out phenomena and problems over time, seeing this framing as an effective way to position students as scientists using science and engineering practices. Families in the garden, however, have created a more natural and perhaps more meaningful setting for learners to deeply engage with phenomenon buoyed by the cultural strengths of *distraer y conectar*. For example, for two families observed, the gardeners shared that their children started to love watching, observing and caring for the plants, so much so that in each case, the parents mentioned their children are now conducting plant experiments, exploring whether they can grow mango and peach seeds and other seeds they find in their food at home with the hope of transplanting these seeds into the garden.

In the following excerpt, we revisit Enrique and his children from earlier. Here, he again explicates on the purposes and values he sees as driving his family's activity in the garden. But notably he connects these cultural strengths to more recognizable and traditional notions of engaging in STEM:

Researcher:	¿Y porque crees que es importante que tus hijos sepan cómo crece la comida?	And for you why is it important that your children know how food grows?
Enrique:	Porque así ellos también aprenden a valorar la Tierra, nuestro planeta, y los recursos que tenemos. Y nosotros cómo padres podemos tener una conexión diferente con ellos. No nada más es tenerlos en la escuela o la casa. Muchas veces nosotros cómo padres no nos damos cuenta de que, aunque a lo mejor lleguemos cansados del trabajo, pero tener esos espacios y salir a convivir con ellos nos da una perspectiva muy diferente y creo que nos desestresamos al verlos que ellos andan corriendo y contentos. Es importante que ellos vean las cosas crecer porque valoran los recursos que tenemos y nos ayuda a desestresarnos al estar aquí. Y también para que vean que no es tan fácil el cosechar y cultivar. Nos encontramos con muchos obstáculos, cómo ahorita hay una parte donde no hemos podido hacer crecer los cucumbers. Entonces ellos me preguntas "por que se secan?" y "por qué no crecen?"	Because that way they also learn to value the Earth, our planet, and the resources we have. And we as parents can have a different connection with them. It's not just having them at school or home. Many times we as parents do not realize that, although we may arrive tired from work, having those spaces and going out to be with them gives us a very different perspective and I think we let ourselves de-stress when we see them running and happy. It's important that they see things grow because they value the resources we have and it helps us to de-stress being here. And also so that they see that harvesting and cultivating is not easy. We find ourselves with many obstacles, for example right now there is a part where we have not been able to grow cucumbers. So they ask me "why do they dry up?" and "why don't they grow?"

Enrique makes clear how he values the learning his children experience around how food grows as this activity not only enables them to connect with and "value the Earth, our planet, and the resources we have" but he sees it as important to his relationship with them as a parent. Specifically, he sees the activity as an opportunity for a "different connection with them." It is within this context that Enrique notes how the garden space seems to provide a "different perspective," one where his children are free to run around but also to ask questions about phenomena and related problems: "So they ask me, 'why do [the cucumbers] dry up?' and 'why don't they grow?' *Asking questions and defining problems* constitutes a central science and engineering practice (NRC, 2012), which serves to focus STEM activity on a tangible phenomenon or problem. We see Enrique's family's experience of engaging phenomena within the context of pursuing *distraer y conectar* as a new learning arrangement (i.e., "third space") that privileges the values of a community historically marginalized in STEM alongside deep engagement in widely recognized STEM practices like *asking questions and defining problems* or *analyzing and interpreting data*.

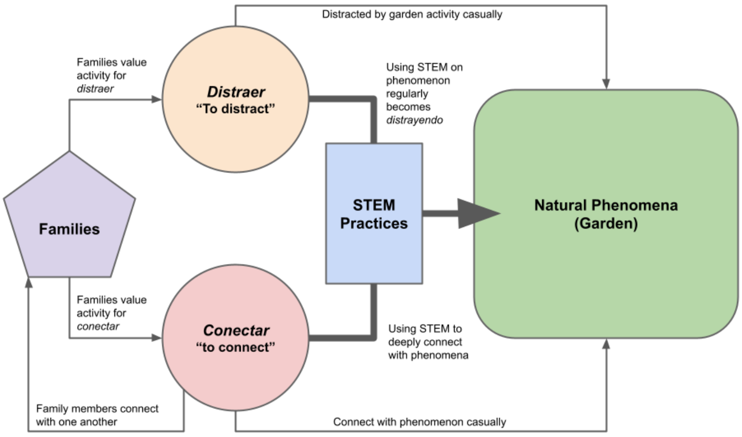
Families in the garden engaged in *distraer y conectar* over extended periods and opportunities for children and their families to connect to the phenomena of the garden and solve problems continued accordingly.

Families' prolonged engagement with phenomena echoes principles in science education (NRC, 2012; Krajcik & Blumenfeld, 2006), and sometimes became a primary focal activity in the garden. With Enrique and his sons Diego and Ronaldo, for example, the engagement with phenomena became synonymous with *distraer y conectar*. Enrique began to encourage and facilitate his son's exploration of natural phenomena in and out of the garden, even so much as providing his son Diego with resources to do "research" on plant growth. Here, during a self-documentation session, Enrique asks his son Diego to provide an explanation of their activity that day while in the garden:

Enrique: So what are you doing?
Diego: Planting the watermelon.
Enrique: Uh huh.
Diego: And each one, each time you plant one it always starts as a first little watermelon plant and it'll grow up to a bigger one and it'll have a flower and that flower will have a small little round thingy inside it and it'll grow and grow and grow bigger and bigger until it turns into a full-size watermelon.
Ronaldo: It'll grow bigger, bigger, bigger!
Diego: And ultimately if you find seeds in there you can replant them. And make sure you have great soil.
Enrique: Okay so this is the process in the plants to the watermelon. Correct?
Diego: Si. It's the lifecycle of the watermelon.
Enrique: Okay thank you.

Enrique's simple prompt belies the research and thinking his son has engaged in recently around the phenomenon of plant growth, specifically the development of fruit. Enrique expects his question to elicit an explanation – an act that very much resembles the science and engineering practices of *constructing an explanation* and *communicating information* (NRC, 2012). His utterance of "Uh huh" seems to act as a sort of science "talk move" (Michaels & O'Connor, 2012), similar to "say more" which is intended to draw deeper explanations of thinking from learners. Diego's extensive description of the phenomenon of plant growth and fruit development reflects *conectar,* with Diego connecting to nature (valued by Enrique), but also mediates a connection for younger Ronaldo with plant growth (in echoing "It'll grow bigger, bigger, bigger!). Similar to the previous vignette, we also see the family members connecting with one another in notable ways in the context of phenomena. Ronaldo interjects with his own mini-explanation to become part of the activity between Diego and Enrique. Enrique's prompts are purposeful, he is enjoying documenting their activity ("thank you"). Diego embraces his given role in this intergenerational activity, even correcting his father in providing a more accurate scientific term of "lifecycle" in wrapping up his explanation.

Figure 1
How cultural strengths distraer y conectar support (agri)cultural STEM learning in the community garden



Discussion and conclusion

This study examined how the purposes and values Mexican immigrant families bring into a community garden space can serve as cultural strengths and facilitate opportunities for rich STEM learning. Specifically, this study offers the mutually constitutive concepts of *distraer y conectar* as cultural strengths for learning. In the context of the abundant phenomena of the garden, pursuing *distraer y conectar* can lead children and families to explore the natural world through recognizable STEM practices while striving to *distraer*, to distract or disconnect from the everyday dynamics of life and to *conectar* or to connect with themselves, each other, and the land (see Figure 1). Broadly, this work follows previous STEM education research examining the axiological aspects of science learning (see Bang et al., 2016), and similarly finds that cultural values and purposes can serve as robust cultural strengths for STEM learning. Having a space to enact axiological cultural strengths can prove consequential, allowing for new activity, new relations to nature and each other, and a new relationship to STEM for youth and families, particularly those from historically marginalized populations in the US.

Relatedly, this study provides evidence for the transformative potential of allowing youth and families space to pursue and act on axiological cultural strengths like *distraer y conectar*. As gardeners purposefully engage in the garden to disconnect from the mundane routines of everyday life and to connect with themselves, each other, and the land, they place themselves in a different space both physically and otherwise. In line with the notion of "re-mediation" (Gutiérrez, et al. 2009), this study showed how the relationships people have with their external world can shift or transform into new relations and connections, changing themselves in the process. This study provides examples of how STEM learning can support such transformations. We offered evidence for how Diego's very being seemed to shift when in the phenomenon-rich space of the garden: he is happy in the garden, running around chasing bugs, exploring how the environment has changed and supported by his father in using STEM practices to deepen his explorations. As Enrique commented, Diego feels *a gusto* or at ease and comfortable in the garden. He feels a sense of belonging in this space, notable in that many students from Latiné and other marginalized communities do not feel welcome when engaging in science (Calabrese Barton & Tan, 2019). In a real sense, this study offers evidence for not only how STEM learning in the garden led to new understandings of STEM knowledge and phenomena, but people coming to new understandings of themselves and others.

Additionally, this study offers needed insights into how to achieve a heterogeneity of expertise or a "third space" (Gutiérrez, 2008) for STEM learning and its transformative potential. Beyond seeking a hybridization of dominant and non-dominant practices in learning (e.g., Gutiérrez et al., 1995), this study shows the potential of seeking to infuse values and purposes of marginalized groups with dominant practices (e.g., STEM practices). In this study, we saw evidence that the new arrangement – a valuing of *distraer y conectar* and exploration of the natural world via STEM practices – leads to new forms of value-laden STEM activity. The implications of this are potentially significant. It opens avenues for community members to both continue in valued cultural practices but simultaneously pursue explorations of phenomena in the natural world, solve relevant problems, and become essentially "culturally-sustaining" (Paris, 2012) STEM practitioners. Given time, this value-affirming activity may take root among families in the community garden, and children explaining phenomena and developing solutions to problems in the context *distraer y conectar* or other cultural strengths could become a regularity.

This study also contributes to research documenting knowledge and practices from non-dominant communities and provides unique ethnographic insights for understanding how shared community spaces like gardens function as rich sites for learning, including STEM learning. Learning in CHAT can be broadly understood as an expansion of existing activity (Engeström, 2001). This study provides evidence for how the garden is a new social arrangement where even the "experts" in the space who arrive with (agri)cultural knowledges are learning with others as they adapt to the climate and soil conditions, suggesting gardeners are "co-constructing knowledge together" (Engeström & Sannino, 2010). We continue to explore the full complexity of learning in the garden, but what is emerging in the data is how relationship building is embedded in the purposes of *distrayendo y conectando*. The importance of "learning with purpose" (Severance, 2021) in STEM and other settings in ways that attends to community and relationships has become increasingly clear. This study adds further evidence to these perspectives.

More research is urgently needed to understand how cultural strengths can support meaningful learning in STEM, particularly those of an axiological nature (Bang et al., 2016). Numerous important questions remain about how to properly engage learners' cultural strengths (e.g., *What counts as a cultural strength for learning? Under what settings and circumstances can cultural strengths be effective for learning?*) New insights that emerge from future work may provide the principles needed to support design work in other settings beyond community garden spaces (e.g., schools, museums, libraries). The implications are potentially vast in terms of addressing longstanding, seemingly intractable inequities in STEM learning and moving towards providing all learners, but particularly learners from non-dominant communities, opportunities to use and embrace cultural strengths in purposeful activity.

Abstract: Accumulating studies suggest including multiple feedback components such as evaluation and suggestion within one feedback unit is beneficial, yet how various feedback components are formulated and their learning effect remain understudied. This study examined the formulation pattern of different feedback components in the feedback given and received by groups with different levels of learning improvement. In social studies classrooms in Singapore, fourteen groups of secondary schoolers (n=61, female=61) participated in giving peer feedback during collaborative argumentation activities. Collaborative argumentation and feedback components of each group were collected and analyzed. The result reported that more-improvement groups tended to give and receive feedback that included an evaluation or position component before giving suggestions. No-improvement groups were more likely to give and receive feedback that started with a supportive standpoint of the reviewed content before opposing standpoints. The findings provide insights for the implementation of effective peer feedback in authentic classroom settings.

Introduction

Peer feedback is defined as a learner-centered educational activity in which students assess the quality of their peers' essays and provide feedback (Wu & Schunn, 2020) with the intention "to improve and accelerate learning" (Sadler, 1998, p. 77). From the socio-constructivist and socio-cognitive learning perspectives, peer feedback activities provide students the opportunity to close the gap between current and desired performance via discussion with peers, logical reasoning, and in-depth reflections (Noroozi et al., 2020; Sadler, 1998). Researchers conceptualized peer feedback as a communicative event based on the interpersonal communication model (Johnson & Johnson, 1991) that stressed the equal importance of feedback giving (producing feedback), feedback receiving (decoding the feedback), delivery of feedback (communication channel) and learning context (instruction and activity design) (Winstone et al., 2017). Despite the growing body of research highlighting the learning benefits of a feedback giver and receiver (e.g., Su & Huang, 2022), the delivery of peer feedback was less discussed. Delivery of feedback refers to how feedback is presented to receivers such as through feedback layout manipulation, level of detail, and presentation medium (Winstone et al., 2017). A failure in feedback delivery may result in not only feedback providers giving surface-level feedback but also feedback receivers facing difficulties in understanding the feedback, distrusting their peers as well as having negative emotions towards their peers (Carless, 2019). Such challenges were often identified in real-world K-12 classrooms, where students had limited time to construct and decode peer feedback (Winstone et al., 2017). Existing scholar surrounding the delivery of feedback message usually focuses on categorizing different feedback components in feedback content (e.g., Kusumaningrum et al., 2019). The different feedback components (Strijbos et al., 2010) commonly address the nature or purpose of the feedback content, which usually includes the evaluation of the work (identification of both strengths and weaknesses), seeking clarifications, and giving suggestions for improvements. For example, Hattie and Timperley's (2007) meta-analysis argued about three major components to be included in quality feedback: Where am I going?, How am I going?, and Where to next? (Hattie & Timperley, 2007). Another commonly applied model is Perkins (2003)'s ladder of feedback, consisting of clarity, value, question, and suggestion as the key content types. The recent studies by Wu et al., (2020, 2022) also discussed the different feedback components including identifying problems, providing solutions, and indicating the location of the problem and/or solution.

The different feedback components were found to mediate the impact of feedback on student learning in different ways. For instance, a positive evaluation that identifies strengths could boost the confidence of the feedback receivers and a negative evaluation that highlights learning gaps could discourage receivers (e.g., Eva et al., 2012). Suggestion for improvement was found to be an essential component for constructive feedback or feed-forward as it encourages critical and reflective thinking processes of the feedback receivers (e.g., Wu et al., 2022). In the context of collaborative argumentation activities in social studies classrooms, the types of standpoints students take on controversial topics and statements become feedback components such as supportive, opposing, or neutral positions (Jensen et al., 2021). To support more effective application of different feedback components, various scaffoldings were developed such as sentence openers or question prompts, scripts, and feedback exemplars (e.g., Peters et al., 2018; Latifi et al., 2021). These scaffolds often support different feedback components that evaluate the strength and weakness of work and give suggestions and solutions. Empirical studies have indicated the benefits of providing scaffolds to enable learners to give and receive constructive feedback in Computer Supported Collaborative Learning (CSCL) contexts (Winstone et al., 2017).

As accumulating studies suggest multiple feedback components within one feedback unit, researchers in recent years call for attention to the interplay of multiple components within one feedback (e.g., De Sixte et al., 2020), arguing the importance of a balanced proportion and meaningful formulation of different feedback components (e.g., Wu & Schunn, 2020). Instead of involving too complex and non-structured information that becomes overwhelming for the feedback receiver, feedback components are expected to be formulated with a stepwise presentation (Armengol-Asparó et al., 2022). Therefore, the sequence of feedback components becomes a key consideration of feedback formulation. Existing empirical studies surrounding the sequence of feedback components discussed the different ways students give positive evaluations such as simple praise versus mitigating praise (Patchan et al., 2016). Mitigating praise describes the formulation of positive evaluations given right before criticism, and existing studies reported mixed results in terms of its impact on students' learning (Patchan et al., 2016). The positive impact is that mitigating praise could soften the tone of negative evaluation but it might undermine the severity of the problem, resulting in recipients being less likely to act upon feedback (Wu & Schunn, 2022). In terms of giving feedback in the form of suggestions, researchers suggested providing elaboration on the problems before proposing suggestions was more beneficial than merely providing suggestions (Patchan et al., 2016).

The limited empirical evidence indicates that apart from what feedback components are given and received, further exploration of how feedback components are formulated and their role in learners' learning outcomes can add value to the existing understanding of effective peer feedback practices. An effective approach to identify good practices of peer feedback engagement is comparing the learning process of student groups with different learning performances or improvements (e.g., Noroozi et al., 2016). This study, therefore, will zoom into the groups with more improvement and no improvement in group learning before and after peer feedback activity.

Informed by the interpersonal communication model of peer feedback (Johnson & Johnson, 1991), this study aims to address the scarcity of study in the feedback delivery aspect to provide insights into supporting peer feedback practices in authentic classrooms. Thus, this study seeks to gain insights into formulation patterns of feedback components employed by student groups of different levels of learning improvements in a tech-rich social studies classroom. Fine-grained analysis of feedback content will be employed to reveal the sequential pattern of different feedback components within one feedback unit and a key research question will be explored: What was the formulation pattern of different feedback components in feedback given and received by more-improvement and no-improvement groups?

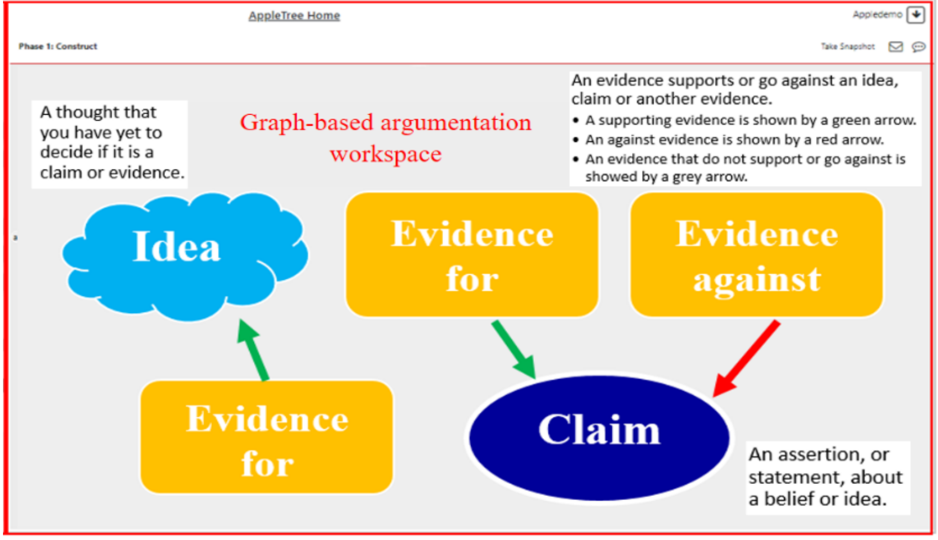
Method

Mixed-method analysis approach was employed to examine the peer feedback process and both qualitative and quantitative data analysis techniques were adopted to analyze the collected data.

Participant

A total of fourteen groups of students (n=61, female=61, average age=10) from two classes of a Singapore secondary school participated in the study and completed a series of collaborative argumentation activities on the AppleTree platform (appletree. sg), see Figure 1. This platform allows students to co-construct argumentation graphs in a shared workspace with claim bubbles, evidence bubbles, and structuring arrows. During peer feedback activity, the platform allows students to enter another group's workspace and leave comments. All participating students were familiar with their teacher and their group members before the commencement of this study.

Figure 1
AppleTree Platform Interface



A thought that you have yet to decide if it is a claim or evidence.

An evidence supports or go against an idea, claim or another evidence.

- A supporting evidence is shown by a green arrow.
- An against evidence is shown by a red arrow.
- An evidence that do not support or go against is showed by a grey arrow.

An assertion, or statement, about a belief or idea.

Procedure

Teachers and researchers co-designed 3 collaborative argumentation activities on controversial social issues of a similar level of difficulty. The collaborative argumentation activities were conducted in three classroom lessons (1-hour each) across three weeks. Each activity consisted of three phases: within-group ideation (20 mins), between-groups peer feedback (10 mins), and within-group refinement (20 mins), leaving 10 minutes for logistics and instructions. During within-group ideation (phase 1), each group co-constructed their group argumentation on the AppleTree platform. After ideation, the teachers briefly explained how to give constructive peer feedback by identifying strengths, identifying areas for improvement, seeking clarifications, and making suggestions. After the teacher's explanation, each group was invited to another group's AppleTree space to provide feedback on their group argumentation (phase 2). After providing peer feedback, they returned to their group workspace on the AppleTree platform and refined their group argumentation (phase 3). The group formation and teachers were consistent throughout the three argumentation activities.

Data collection

All groups' argumentation diagrams in both ideation (phase 1) and refinement phases (phase 3) across three weeks were exported from the AppleTree platform for further analysis. Similarly, all feedback given by groups (phase 2) was obtained from the AppleTree platform with every feedback tagged with the timestamp of feedback created, the creator's group identification, the receiver's group identification as well as feedback content details.

Coding of collaborative argumentation quality

To identify more-improvement and no-improvement groups, qualitative content analysis was conducted to code the collaborative argumentation quality before and after peer feedback activity. Each group's argumentations in the ideation phase and refinement phase were coded to identify their improvement in the collaboration outcome before and after peer feedback. The coding scheme of argumentation was adapted from Stapleton & Wu (2015) including four dimensions: clarity, multiple perspectives, selection of evidence, and elaboration and depth. Each dimension was coded on a scale of zero to three and the final quality score was the sum value of four dimensions for each group's argumentation. A total of 72 argumentation graphs were coded by two trained coders and inter-rater reliability was satisfying (Cronbach's alpha =0.844).

Based on the coding results of each group's collaborative argumentation quality, Hake's gain was calculated to identify each group's level of improvement before and after peer feedback in different argumentation activities. In this way, groups with Hake's gain higher than 15% were identified as more-improvement groups and groups with zero hake's gain were identified as no-improvement groups.

Coding of feedback components

To identify the formulation of feedback components in each feedback unit, we conducted content analysis guided by the segmentation procedure suggested by Strijbos et al., (2006) which stressed that "sentences or parts of compound sentences are more likely to contain a single concept, expression or statement" (Strijbos et al., 2006, p. 37). We used the syntactical unit or sentence level as the unit of analysis and every feedback unit was coded as a sequence of components. The coding scheme of the feedback component was adapted from the ladder model of feedback (Perkins, 2003), shown in Table 1, which was chosen for its good fit with the analysis of peer feedback activity conducted in the collaborative knowledge improvement context (Tan & Chen, 2022). Contextualized in collaborative argumentation activity in social studies classrooms, the components supportive position, opposing position, and neutral position were added to represent the content that focused on conveying assessors' standpoints on the argument topic. (Zhu & Carless, 2018). Positive, negative, and neutral evaluation components were also distinguished considering their different learning effects (De Sixte et al., 2020). A total of 316 feedback given and received by more-improvement groups and no-improvement groups were coded, 195 of which contained more than one feedback component and were coded as a component sequence. Here is an example of feedback that was coded as "Positive Evaluation (PE) with Clarification (C) and Positive Evaluation (PE) components": "It is good in the sense that the quote states clearly the obvious difference and that it really supports the claim (PE). But how many of the different races that they surveyed and is the number of people they surveyed the same for the different races? (C) A good source is chosen and it's a clear explanation (PE)." Two trained coders coded all feedback data independently and the inter-coder reliability was high (Cohen's Kappa= .891).

Table 1
Coding Scheme of Feedback Component

Component	Code	Description	Example feedback
Supportive position	SP	Statement indicating agreement or supportive standpoints on the argument	I agree with that you mentioned this because income really can't determine the number of problems people face.
Opposing position	OP	Statement indicating disagreement or opposing standpoints on the argument	I wouldn't agree that the government overlooks certain groups of people. This is because of the different financial aid and schemes given to different people of different economic statuses.
Neutral position	NP	Statement indicating neutral views on the argument	I personally feel like the application of the various schemes are extremely stringent and requires a lot of tedious tasks in order to get help from the government.
Positive evaluation	PE	Statement that identifies strengths	This is an excellent example to support this claim.
Negative evaluation	NE	Statement that identifies weakness	Your evidence is not appropriate to support your point.
Neutral evaluation	NEE	Neutral evaluation	This evidence is not linked back to your claim.
Clarity	C	Statement seeking clarifications or further explanations	How does Chinese giving up on their practices and privileges support and link to the fact that the efforts are not effective?
Suggestion	S	Statement that gives suggestions for improvement	Maybe you can elaborate on why people who are struggling refuse to get help.

Data analysis

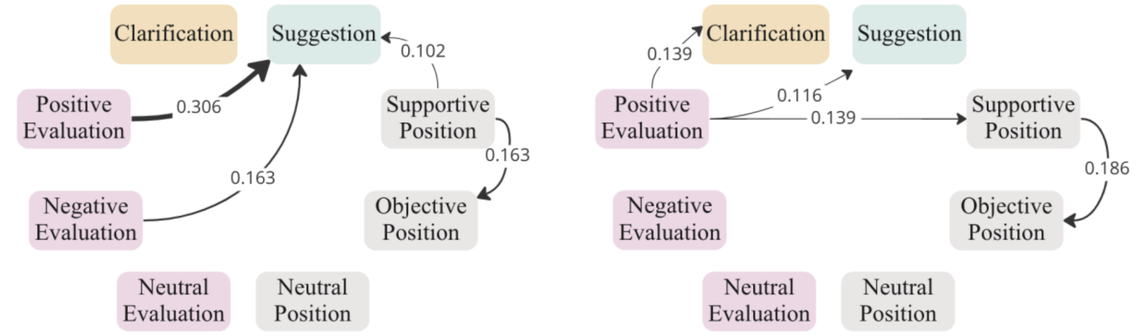
Mixed-method analysis approach was employed to examine the feedback formulation patterns in groups of more-improvement and no-improvement in collaborative argumentation quality. Based on the qualitative content analysis results of the peer feedback component, frequent sequence mining (Zaki, 2001) was implemented to reveal the sequential pattern among different components within one feedback. It is a powerful technique that was often used to reveal sequential patterns in CSCL context (e.g., Chen et al., 2017). The R package arulesSequence was adopted to the coded feedback components, which involved the SPADE algorithm, a well-known algorithm for sequential pattern identification (Zaki, 2001). To comply with the package's terminology, each feedback was treated as one component sequence and every component was treated as an event, such as the "suggestion (S) of positive evaluation (PE)". A total of 195 pieces of feedback given and received by both no-improvement and more-improvement groups were formatted and processed. The threshold of support value was set to 0.1 to identify the most frequent sequences in the output, meaning that only frequent sequences appearing for 10% or more in all feedbacks were considered. This value was chosen for its appropriateness considering the feedback dataset volume in this study.

Results

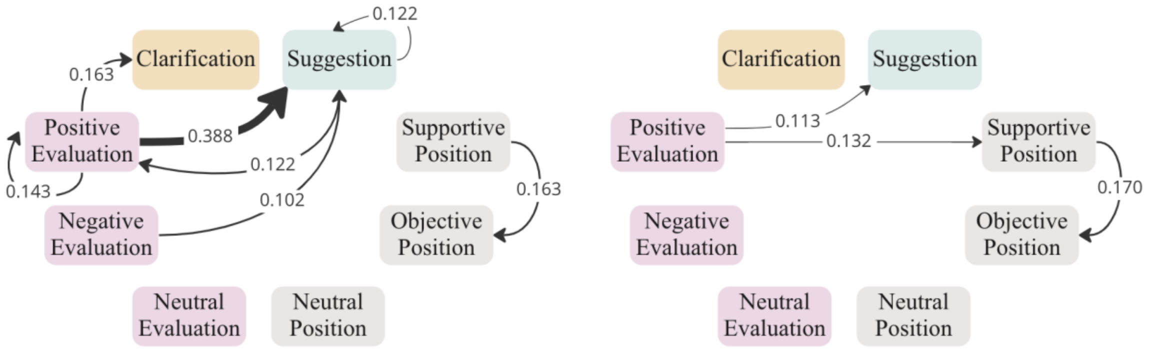
The frequent sequence mining output was reported in Figure 2. Each identified frequent sequence between two feedback components was represented with a weighted arrow line and its support value was attached. For example, the arrow line starting from positive evaluation pointing to suggestion indicates the frequent sequence of positive evaluation followed by suggestion within one feedback unit. The sequence with higher support value was presented with a thicker line, indicating its higher possibility to be identified in feedback provided and received by more-improvement groups and no-improvement groups.

Figure 2

Frequent Sequences Among Different Feedback Components in Feedback Given and Received by More-improvement Groups and No-improvement Groups



(a) Feedback given by more-improvement groups (b) Feedback given by no-improvement groups



(c) Feedback received by more-improvement groups (d) Feedback received by no-improvement groups

As feedback givers, more-improvement groups and no-improvement groups presented different feedback formulation patterns, see Figure 2 (a) and (b). More-improvement groups most frequently provided positive evaluation before suggestions for improvements, shown in Figure 2 (a). There was also a high chance that suggestions followed a negative evaluation. In comparison, non-improvement groups focused on sharing their standpoints instead of giving suggestions, reflected in the most frequent sequence of supportive position before an opposing position which stated the areas being agreed upon before articulating disagreements, see Figure 2 (b). Besides, non-improvement groups often gave a positive evaluation before a supportive position, identifying strengths and then sharing their agreements on the argumentation content. Another two sequences often applied are the clarification following a positive evaluation and suggestion. As feedback receivers, there were more diverse sequences identified for more-improvement groups than no-improvement groups, see Figure 2 (c) and (d). Most often, more-improvement groups received feedback that started with a positive evaluation and ended with a suggestion, shown in Figure 2 (c). Besides, they were also likely to receive feedback that include a supportive position before an opposing position. Some feedback sought clarification after positive evaluation. Interestingly, there was a frequent sequence that was positive evaluation followed by another positive evaluation, indicating the feedback continuously identifying strengths of the reviewed content. Another two sequences that were only spotted in more-improvement groups was the suggestion followed by a positive evaluation and suggestion after another suggestion. In the feedback received by non-improvement groups, shown in Figure 2 (d), the most frequent sequence was the supportive position and the opposing position. Other frequent sequences received by non-improvement groups were the positive evaluation followed by a supportive position or a suggestion.

To summarize, some key similarities, as well as differences in feedback formulation patterns, can be identified in the feedback given and received by the more-improvement and no-improvement groups. For both groups as feedback givers, students tended to put a positive evaluation or supportive position before introducing other components, especially before they gave suggestions or conveyed an opposing position. One noticeable difference was that the more-improvement groups focused more on giving suggestions along with giving evaluations and sharing positions, while non-improvement groups paid more effort into expressing their standpoints along with giving evaluations or seeking clarifications. Only more-improvement groups tended to point out weaknesses before providing suggestions. When receiving feedback, both groups shared the frequent sequence of supportive position followed by opposing position and the sequence of positive evaluation followed by suggestion. In addition, the feedback received by more-improvement groups showed a variation of sequences surrounding two components: positive evaluation and suggestion, reflected in the frequent sequences of suggestion followed by positive evaluation, a consecutive positive evaluation as well as consecutive suggestion. In comparison, the feedback received by no-improvement groups presented the highest frequency in the sequences supportive position before the opposing position. Besides, neutral evaluation and neutral position components were not identified in any frequent sequence.

Discussion and conclusion

As accumulating studies comparing the learning benefits for feedback providers and receivers (e.g., Wu et al., 2022), this study probed further on the feedback formulation patterns and their roles in mediating student groups' learning improvement before and after peer feedback. The results expand the existing understanding of the interpersonal communication model of peer feedback (Winstone et al., 2017), especially the *feedback delivery* aspect with a nuanced analysis of the sequential pattern of different feedback components. The finding reports that the key difference in the feedback formulation given by more-improvement and non-improvement groups lies in the ways suggestions and positions are formulated with other feedback components. More-improvement groups focused on identifying strengths or weaknesses before providing suggestions for the other groups' work. Non-improvement groups in comparison, were more likely to focus on expressing their supportive position before an opposing position, articulating the argumentation content they agreed with and disagree with. The different feedback formulation patterns between the two groups can be explained by the theoretical underpinning of cognitive and metacognitive natures of feedback when cognitive feedback focuses on the content of the work under review by summarizing, specifying, and explaining practices and metacognitive feedback is more evaluative or reflective, challenging the work being assessed (Lu & Law, 2012). From this viewpoint, the more-improvement groups may benefit from giving evaluative and reflective feedback practice when constructing suggestions for improvement along with evaluations. In comparison, the non-improvement groups may be limited to cognitive activities such as summarizing, specifying, and explaining practices as they focused more on sharing their standpoints about the argumentation content. This finding brings implications for future instructions for peer feedback activity in social studies classrooms when student learners should be encouraged to think via evaluative and reflective thinking instead of reasoning with the argument topic itself.

The finding also highlights the difference in feedback formulation between more-improvement and non-improvement groups as feedback receivers, when the more-improvement groups received feedback combined with positive evaluation and suggestions in various ways and the sequence of positive evaluation followed by suggestion stood out with the highest frequency. Different from the recommended warmly toned and elaborated suggestions in peer feedback (De sixte et al., 2021), two noteworthy sequences in feedback received by more-improvement groups were the negative evaluation before suggestion and the consecutive suggestions. Non-improvement groups received feedback that shared the feedback givers' standpoints surrounding the argumentation topic and the most frequent sequence consisted of a supportive position and an opposing position. This finding indicates that the feedback containing the givers' standpoints surrounding the argumentation topic seemed to be less effective for recipients than those seeking clarifications or offering suggestions for improvements, in the social studies classroom context. The beneficial effect of suggestion as a feedback component was also identified in previous empirical studies (e.g., Tan & Chen, 2022) as it helps recipients correct errors and offer strategies to tackle potential problems, making the feedback *feed-forward* (Wisniewski et al., 2020). Apart from suggestions, the sequence of positive evaluation followed by seeking clarification draw our attention to the feedback received by more-improvement groups. It is likely that the feedback seeking clarification has a higher level of *specificity* that made it easier for student groups to identify the missing explanations and therefore, benefit from the practice of *acting upon* feedback (Boud., 2015). Interestingly, the seeking clarification seemed to mainly benefit feedback recipients instead of feedback givers in this study.

A few shared frequent sequences across all groups deserve further discussion under the research body of *mitigating praise* and the *affective language used* in peer feedback studies (Wu & Schunn, 2022). Previous studies of mitigating praise stressed the use of positive evaluation before giving a negative evaluation (e.g., Wu & Schunn, 2020), while this study highlights the variations of mitigating praise when a positive evaluation was often provided before suggestions instead of a negative evaluation. Another variation of mitigating language use is the frequent sequence supportive position before the opposing position across all groups, indicating that in the social studies learning context, students tended to use not only *mitigating praise* but also *mitigating position* when expressing alternative standpoints surrounding the argumentation topic. In addition, although mitigating praise refers to the strategy of putting positive evaluation *before* criticism or suggestions, this study detected the sequence of positive evaluation *after* giving suggestions. Therefore, building on the existing studies that argued about the negative and positive effects of affective language use (Patchan et al., 2016; Wu & Schunn, 2020), this study suggests that apart from identifying *whether* an affective language is used, a close examination of *how* the affective language is used may contribute to a comprehensive understanding of its application and roles in peer feedback activities.

This study has its limitations. First, all participants were female secondary schoolers, which makes the finding less generalizable for male students. Besides, the existing analysis of frequent sequences of feedback components only indicates the overall formulation patterns without specifying the role of each sequence on students' learning improvement. Future studies are expected to realize a more fine-grained understanding of whether and how alternative feedback formulations may play a role in students' learning. Building on the existing studies reporting the benefits of peer feedback activity in the collaborative learning context, this study provided a close examination of the peer feedback formulation from the lens of the interpersonal communication model of peer feedback. The empirical evidence of feedback formation patterns in more-improvement groups and no-improvement groups shed light on the future effective implementation of peer feedback activities in real-world classrooms.

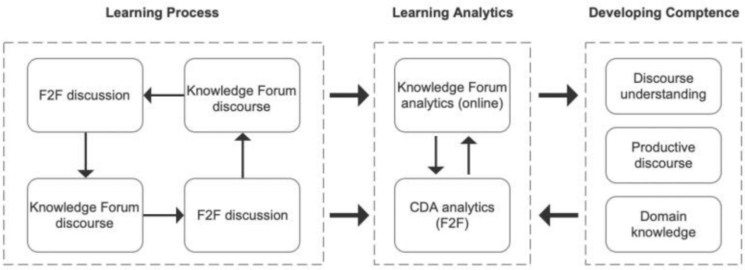
Abstract: This study investigates how secondary school students developed discourse understanding and engaged in productive discourse through a learning analytics-supported blended approach in a knowledge building environment. The study involved 15 10th-grade students studying visual arts in a Hong Kong secondary school. Students worked on collective inquiry in Art and Design through online Knowledge Forum® and classroom discussion. A key design involved the integration of online and classroom discussions through meta-discourse with the support of learning analytics. Results indicated that the students promoted discourse understanding and engaged in productive online discourse progressively. Qualitative analysis of classroom discourse and artifacts revealed students developed discourse understanding, relating to noticing of quantity and quality of discussion. The implications for the analytics-supported design to help students engage in productive discourse for knowledge building are discussed.

Introduction

Productive discourse is a dialogue that acts as a medium for helping students develop the learning processes, improve ideas, and create new knowledge (Mercer et al., 2019; Scardamalia & Bereiter, 2014). Helping students to develop productive discourse has been the focal point of research in learning sciences. However, Initiate-response-feedback (IRF), as a traditional structure that provides less opportunity for students to take responsibility and build on each other's ideas, is still the dominant discourse pattern in many classrooms (McNeill & Pimentel, 2010). Therefore, there has been a growing interest in investigating productive discourse and researchers have developed various concepts into discourse (e.g., academically productive talk, dialogic space, dialogic teaching; Alexander, 2017; Resnick et al., 2010; Wegerif, 2006). As an educational model, knowledge building focuses on the development of productive discourse and students adding value to community advances, supported by Knowledge Forum®, a multi-media discussion platform (Scardamalia & Bereiter, 2014). Knowledge Forum provides a communal space for knowledge development to support sustained productive discourse. Engaging in productive discourse is essential to knowledge building for community knowledge advancement. Previous research in knowledge building has been conducted to support students' engagement in creative processes, in particular developing productive discourse (see review, Chen & Hong, 2016). To engage students in knowledge building, classroom and online discourse are intertwined. Knowledge Building Talk (KB Talk) is commonplace as students reflect and talk about their Knowledge Forum work via classroom discussion. Research in the knowledge building field has primarily focused on using learning analytics to visualize online Knowledge Forum discourse that help students engage in a collective reflection process to improve ideas (Resendes et al., 2015; Yang et al., 2020), but limited study aligns students' reflection with online and classroom discussion analytics for knowledge building and how to integrate classroom discussion analytics into knowledge building circle is not well examined.

There has been intensive research on learning analytics to integrate big data and analytics to understand challenges in the educational area (Knight & Shum, 2017). In the context of knowledge building environment, increasing attention has been paid to the study of implementing learning analytics for supporting student collective reflection of progressive discourse (Chen & Zhang, 2016; Resendes et al., 2015). Since knowledge building emphasizes epistemic agency and collective responsibility, learning analytics need to move beyond providing feedback to teachers and be augmented with meta-talk for students to reflect on their own work to advance knowledge building process. As learning analytics use increases, it opens possibilities for visualizing the collaborative knowledge building discourse process and supporting the reflection from multiple layers, including individual and community levels. Although previous studies have considered the benefits of visualizing online Knowledge Forum discussions via learning analytics, few have looked closely at visualizing classroom KB talk. Another theme of the present study relates to students' understanding of the nature of discourse. Research in science education has examined students' understanding of the nature of science, but less research attention has been given to students' understanding of the nature of discourse. Students are not only expected to engage in productive discourse but also to understand the nature of discourse. Some preliminary evidence show that students' understanding of discourse could be fostered using reflective inquiry (Lei & Chan 2018). This study examines further how an analytics-supported knowledge building environment could help students to develop productive discourse because an analytics-supported approach may help students develop a deeper understanding of the nature of discourse, thus bringing about productive discourse. We proposed a framework integrating two modes of discussions analytics for developing knowledge building competencies (Figure 1). Guided by the framework, we designed a learning analytics-supported blended (LAB) approach that involved students integrating their online and face-to-face classroom discussions analytics for developing discourse understanding, productive discourse, and domain knowledge.

Figure 1
A design framework of analytics-supported discourse development for knowledge building.



A learning analytics tool - the Classroom Discourse Analyzer (CDA; Chen et al., 2020, 2022) - was implemented. CDA was originally developed to visualize classroom discourse for supporting teachers' reflection and analysis of classroom discourse (Chen et al., 2020). In this study, we provided the CDA to students for them to reflect on their KB talk in the classroom. Figure 2 shows an interface of the CDA visualizing various discourse moves, with corresponding videos and classroom discourse transcripts.

Figure 2
An example of the CDA interface (top left: classroom video; bottom left: discourse moves coding; right side: classroom discourse transcripts. Notes: Bubble size represents the number of words in a turn; the number on the right side of each line indicates the frequency of occurrences of the specific type of dialogue (identified in the list on the left side of each line); the corresponding percentage indicates the ratio to the total number of coded turns).

The purpose of the present study was to investigate how the designed approach was implemented to examine and help students develop discourse understanding and engage in productive discourse. Specifically, three research questions were addressed: (1) What characterizes students' understanding of discourse, and how do they change with the LAB approach? (2) How do students engage in productive Knowledge Forum discourse over time? And (3) How does the LAB approach scaffold students' discourse understanding and productive discourse?

Methods

Research context and participants

Fifteen Grade 10 students (aged 14 to 15; $n_{\text{female}} = 8$, $n_{\text{male}} = 7$), studying visual arts in a Hong Kong secondary school participated in the study. They studied the topic of Art and Design for three months. The teacher had employed knowledge building teaching for approximately 10 years.

Pedagogical design

The key design of the pedagogical cycle is to engage students in collective knowledge building through online and classroom meta-discourse processes in a designed LAB approach (Figure 3). In a regular knowledge building environment, students propose problems and build theories supported by Knowledge Forum. In this study, we enriched the design by emphasizing a blended approach by integrating online and classroom discourse, afforded by learning analytics. Primarily, students inquired on Knowledge Forum, augmented by classroom meta-discourse and learning analytics supported meta-discourse as reflecting on how their online and face-to-face discussions are developed. Students engaged in classroom meta-discourse and group work supported by analytics from Knowledge Forum and the CDA. Specifically, students were provided with the visualization of the ideas-building network (Figure 4a) and the CDA-generated discourse patterns (Figure 4b) with discussion content from the online Knowledge Forum and classroom discussion.

Figure 3
Pedagogical cycle of the LAB approach.

classification by speakers; bottom right: classification by types of discourse moves; bubble size represents the number of words in a turn

Data sources and analysis

Data were collected regarding students' (a) discourse understanding, using pre- and post-tests with open-ended questions; (b) domain knowledge of art and design, using pre- and post-tests with open-ended questions; (c) Knowledge Forum engagement using Knowledge Building Discourse Explorer (KBDeX) (Oshima et al., 2012) and content analysis through a theory- and data-driven coding scheme (Chuy et al., 2011; see Table 1); and (d) classroom discussion, interview, and artifacts.

Table 1

Coding scheme for analyzing discourse moves in Knowledge Forum inquiry.

Codes	Sub-codes	Description	Examples
Questioning	Explanation-seeking (C1)	Questions on seeking open-ended responses with the explanation.	How to design an artifact with the theme of traveling?
	Sustained inquiry (C2)	Asking further questions based on previous notes or ideas and making the discussion deeper.	How will you design an artifact that expresses the theme of traveling and technology with the purpose of helping people solve problems?
Theorizing	Proposing an explanation (T1)	Proposing an explanation that explains certain phenomena for the first time.	There are some steps in designing an artifact.
	Supporting an explanation (T2)	Supporting an already existing explanation proposed by another student and providing a justification.	It could be or not, but we can revise the steps during the progress of the design.
Community	Connection (C1)	Reference to their own or others' notes or quote extra sources to advance understanding.	We need to determine the theme for designing an artifact🟥("themes" S036) ...we also need to determine the purpose of this artifact.
	Synthesizing notes (C2)	Refer back to what has been discussed and ask a new question for monitoring the inquiry process and advancing the discussion or generating an explanation or evaluation to appraise their own or others' notes.	We discussed the idea of the purpose of design… 🟥 ("purpose" S015) and the purpose could be depended on the needs of the people 🟥("life" S011) What we need to inquire further is how to understand people's needs?

Results

RQ1. What characterizes students' understanding of discourse, and how do they change with the LAB approach?

The first research question examined the role of design and processes on students' understanding of the nature of discourse. We examined students' open-ended questions and interviews. Students' responses were analyzed to characterize their different levels of discourse understanding, aligned with knowledge building perspectives. We coded students' responses in the open-ended questionnaire into three levels. Students' views varied from knowledge-sharing to knowledge-construction and knowledge-building (van Aalst, 2009). At level 1, students are concerned with behavioral aspects of discussion or simple sharing, and at level 2, they referred to different views. However, at level 3, they viewed the role of community in knowledge construction. A significant change was obtained from pre- to post-test, $t(14) = 6.500$, $p < .001$. Students' responses on domain knowledge were coded using a three-point scale, ranging from simple to more complex and deeper layers. Significant pre- to post-test change was obtained, $t(14) = 4.785$, $p < .001$. The results suggested that students improved discourse understanding and domain knowledge after instruction. Qualitative analysis of student open-ended questions and interviews revealed interrelated themes about how students understand the nature of discourse. Table 2 shows the nine main themes representing students' understanding.

Table 2

Students' understanding of the nature of discourse captured in the open-ended questions and interviews.

	Themes	**Examples**
Theme 1	Share ideas (Goals).	"The goal of discourse is to express and exchange ideas."
Theme 2	Achieve correct answers, and solve problems (Goals).	"The goal of discourse is to get correct and fruitful answers." "The goal of discourse is to solve problems."
Theme 3	Advance community knowledge, create new knowledge (Goals).	"We combine diverse ideas and deepen the discussion to create new knowledge."
Theme 4	Active participation (Constituents).	"Many students participate in the discussion and express ideas."

Theme 5	Diverse topics and ideas (Constituents).	"Include different types of questions and diverse ideas."
Theme 6	Take collective responsibility and work as a community (Constituents).	"I think a good discourse needs collaborative work."
Theme 7	Build on others' ideas with examples and evidence, ask further questions (Strategies).	"Illustrate our ideas with examples and build-on others' ideas." "Ask further questions to extend and deepen the discussion."
Theme 8	Search relevant materials, and challenge each other for improving ideas (Strategies).	"Search materials and discuss them with others." "Refer back to the previous discussion and challenge others' ideas."
Theme 9	Reflect and synthesize ideas (Strategies).	"We need to synthesize ideas progressively." "Reflect on what we have discussed."

As shown in Table 2, themes 1-3 characterize student conceptions of the goal of discourse, including sharing ideas, solving problems, and advancing community knowledge. Students commented that discourse should "Combine diverse ideas and deepen the discussion to create new knowledge." So the students need to express their opinions and bring together the core ideas to deepen the discussion and advance collective knowledge. Themes 4-6 show student understanding of the constituents of productive discourse. Students regard active participation (theme 4), diverse ideas (theme 5), and collaborative work (theme 6) as essential constituents. As a student commented, "A good discourse needs collaborative work." Students should take collective responsibility to add value to their community. Themes 7-9 show students' ideas of the strategies for developing productive discourse. Students positioned that provide evidence and ask further questions as effective strategies for improving discourse (theme 7). To improve ideas, students further recognized the need to challenge others' ideas (theme 8) and reflect on the progress of the discussion (theme 9).

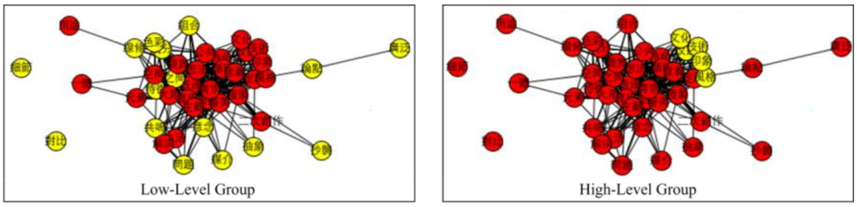
RQ2. How do students engage in productive Knowledge Forum discourse over time?

Differences in collective Knowledge Building inquiry

KBDeX analysis was conducted to understand how discourse understanding was related to students' collective knowledge building inquiry based on keywords usage and coherence (Oshima et al., 2012). First, students were divided into high- and low-level groups based on their post-test discourse understanding. Comparing the number of keywords used in the two groups (Figure 5, 30 versus 41 keywords used, respectively) suggested students with a higher extent of discourse understanding engaged more productively in knowledge building inquiry by using more keywords.

Figure 5

Visualization of keywords usage between low- and high-level discourse understanding groups in KF discourse.



Note. Yellow and Red Balls: words that were used by the whole community. Red ball: words that were used by the selected groups.

Changes in depth of productive Knowledge Forum discourse

Further to network analysis, content analysis was conducted to examine how students inquired in Knowledge Forum. Students' Knowledge Forum discussions were coded (see Table 1). The Knowledge Forum notes were analyzed into three phases, aligned with the time period based on the work of meta-discourse and visualization analytics-supported meta-discourse, to understand how students engaged in productive discourse progressively. In Phase 1, with the log data reflection (e.g., number of notes created, number of notes read), high- and low-level discourse understanding groups engaged in Knowledge Forum discourse moves, including sustained inquiry and proposing an explanation; In Phase 2, with the classroom meta-discourse, the high-level group conducted Knowledge Forum discourse moves, including sustained inquiry, proposing an explanation, supporting an explanation, and connection; while low-level group mostly engaged in surface discourse moves (explanation-seeking questions and proposing an explanation); In Phase 3, with the visual analytics-supported meta-discourse, the low-level group started to conduct higher-level discourse moves (e.g., supporting an explanation and connection) and the high-level group started to engage in more meta-discourse moves, including connection and rise-above. In sum, both low- and high-level discourse understanding groups showed engagement in progressive discourse over time. The findings suggested the role of the designed environment in supporting students' development of productive discourse.

Correlation and regression analysis

Correlation analysis was conducted to examine the relationships among different variables (Table 3). A common index of high-level discourse moves was created by combining high-level Questioning (sustained inquiry), high-level Theorizing (supporting an explanation), and Community (connection and synthesizing). Correlation analyses show that students with a deeper discourse understanding were more likely to engage in high-level discourse moves ($r = .645$) and had higher domain knowledge ($r = .553$).

Table 3
Correlation among domain knowledge, discourse understanding, and high-level Knowledge Forum discourse.

	1	2
1 Post-domain knowledge	-	
2 Post-discourse understanding	.553*	-
3 High-level Knowledge Forum discourse moves	.586*	.645**

Notes. **p* < .05; ***p* < .01.

Hierarchical regression was conducted to examine how prior domain knowledge, high-level KF discourse moves, and post-test discourse understanding predicted students' post-test domain knowledge (Table 4). Prior domain knowledge explained 46.9% of the variance, adding discourse moves explained an additional 11.8% variance, and adding post-test discourse understanding explained a further 4.3% variance, suggesting that high-level discourse moves and understanding contributed to students' post-test domain knowledge, over and above prior domain knowledge.

Table 4
Hierarchical regression on post-test domain knowledge.

	R	R^2	R^2 Change	F Change
Pre-domain knowledge	.685	.469	.469	11.471**
High-level Knowledge Forum discourse moves	.766	.587	.118	3.422**
Post-discourse understanding	.793	.629	.043	1.261*

Notes. **p* < .05; ***p* < .01.

RQ3. How does the LAB approach scaffold students' discourse understanding and productive discourse?

The following two examples illustrate students' reflection on their Knowledge Forum and classroom discussions with the help of visual analytics. Through qualitative analysis of the video recordings of classroom discussions, interviews and artifacts, these examples provided additional support illuminating how the visual analytics support meta-discourse. The examples are elaborated below.

Facilitating students' noticing of participation and engagement in discussion

Guided by the LAB approach, students used the visualizations from the CDA and Knowledge Forum to help them notice their participation and engagement in both classroom and online discussions (Figure 6). Students were aided to notice the amount and content of their classroom discussion. For example, students emphasized the importance of the length of the talk and the discussion content, "We can see the length of the talk based on the size of these bubbles. However, if the content is not good, it would not be a good discussion." "The bigger the bubble, the more explanation classmates provide." Moreover, when students continued their discussion in Knowledge Forum, they realized that "[We need to] express ideas and use evidence and explanations to support our ideas in online discussion." Taken together, supported by the LAB approach, students started to enrich their views on noticing the participation and engagement in the discussion.

1. Teacher (T): What did you notice from the visualization, video, and transcript?
2. S1: Discussion.
3. T: What do you think when you read these bubbles?

4. S2: We can see who has spoken [through the bubble] and what they have said [through the transcript]. **We can see the length of the talk based on the size of these bubbles**. However, **if the content is not good, it would not be a good discussion**.
5. T: Good point. Can anyone add more?
6. S3: The more lines, the more classmates speak. **The bigger the bubble, the more explanation classmates provide**. It will make the discussion become richer.
7. T: Anyone?
8. S4: **The teacher has many big bubbles and talks a lot in the discussion. Only three or four student lines here. It would be good if more classmates can join.**

標準5：有反駁/贊成

6. 請大家思考一下，我們應該如何分別改善提高課堂討論和知識建構平台討論呢？
勇敢点发表自己的观点和想法。在网上发言時可以引用更多論據和更多的解釋。

[We need to] express ideas and use evidence and explanations to support our ideas in online discussion

Increasing students' awareness and supporting reflection

Students also understand more about the use of discourse moves to enhance their awareness of the nature of discourse after the implementation of the LAB approach. Supported by the visualization of discourse types, S20 noticed the lack of higher-level moves in their discussion, "We do not have 'challenge', 'reasoning', 'connection', 'synthesis', and 'reflection' (the student points out the visualized bubble of classroom discussion). We need to have these discourse types, in particular the 'reflection'." Primarily, using discourse moves, particularly the higher-level moves, which are necessary for supporting idea development in progressive knowledge building discourse, is challenging for students and this approach could help students deepen discourse understanding and use different moves.

> "We need to join the discussion, ask questions, respond to others' questions, challenge each other, synthesize ideas, and reflect on the discussion. We also need to have evidence to support our ideas...Only three students joined the discussion. Also, **we only have the types of discourse** on one 'ask questions', seven 'propose ideas', one 'agree', and one 'build-on' in our discussion. We do not have 'challenge', 'reasoning', 'connection', 'synthesis', and 'reflection' (the student points out the visualized bubble of classroom discussion). **We need to have these discourse types, in particular the 'reflection'**."

Conclusion and implications

This study investigated the designs of a LAB approach to help students develop discourse understanding and engage in productive discourse for knowledge building. With a growing number of studies using analytics information to support teaching and learning processes, learning analytics becomes an essential approach to help students engage in productive learning (Lang et al., 2017). This study integrated two modes of discourse (online and classroom discussions) supported by learning analytics to address the issue of idea segmentation in knowledge building community. Results of the study using open-ended questions and interviews indicate that students promoted their understanding of discourse after the LAB approach. Content analysis of online discussions shows that students develop productive discourse over time. Analysis of classroom discussions and artifacts showed how learning analytics can support the noticing of participation and engagement in the discussion. This study contributes to the literature on knowledge building highlighting the role of an analytics-supported blended approach, with learner-generated information provided to participants for them to reflect on their ongoing work for promoting discourse understanding and developing productive discourse. The integration of online and classroom discussion through meta-discourse processes with learning analytics provides different possibilities. Many studies show the important role of learning analytics and this study also shows how the approach supports the development of discourse understanding. The significance of the study lies not only in its innovative combination of visual learning analytics to support both online and classroom learning practices, but more importantly, in its extension of the literature by examining how a LAB approach can be used to enhance the productivity of student discourse in a knowledge building environment, which carries implications for visual learning analytics related teaching and learning. Future research with more time would be undertaken to include multiple rounds of pedagogical cycles with visual analytics-supported reflections for knowledge building.

Abstract: Although students' self-regulated learning has been studied extensively, past research has not investigated students' fine-grained, self-regulated choice-making processes during learning with visual representations and strategies to support such processes. We conducted design and experimental studies with 148 students to develop and evaluate an intervention package for supporting students' self-regulated choice-making in using diagrammatic scaffolding in algebra tutoring software. A classroom experiment showed that students with the intervention learned greater conceptual and procedural knowledge in algebra than students in the control condition whose choices were not supported. Also, students with the intervention chose to use diagrams less frequently overall but showed distinctive use patterns that changed over time, indicating a form of self-regulated diagram use. This study demonstrates the importance of understanding and supporting choice behaviors that change over time during learning, going beyond simply measuring the frequency of choice behaviors and encouraging students to engage in these behaviors more frequently.

Introduction

In modern society, where we have access to abundant information and countless resources, learners need to proactively and strategically choose to use available resources so that they can handle tasks effectively and efficiently (Schwartz & Arena, 2013). Thus, one goal of education is to foster learners who can make strategic choices in using resources (Chin et al., 2019; Cutumisu et al., 2019).

One important choice for learners to make involves whether and how to use visual representations during learning activities. Visual representations are often used as instructional scaffold that can facilitate learners' sense-making processes during learning and problem solving. From a cognitive perspective, visual representations can help learning by, for example, reducing cognitive effort and making relevant information salient (Ainsworth, 2006). However, to use visual representations effectively, learners must (come to) understand when it is appropriate to proactively use visual representations, so that they can navigate problem solving effectively and efficiently (e.g., over-use of visual scaffolding might not help learning very much) (Schwonke et al., 2013). Acquiring such understanding is critical since learners will not always be presented with visual information in everyday problem-solving situations. Instead, they need to proactively choose to (or not to) use/create visual information to aid their problem solving when it is appropriate. Therefore, to use visual representations strategically, learners need to make self-regulated choices. In doing so, they need to judge if the use of visual scaffolding would help their problem solving or not, and make a choice accordingly. Such self-regulated choice behaviors could presumably lead to enhanced domain-level learning (Long & Aleven, 2016; Roll et al., 2011).

Despite the importance of understanding learner choices with visual representations, past research has rarely allowed for, and measured, these choices. Studies have mostly focused on learning *with* visual representations and student learning when students are *given* visual representations (e.g., Rau et al., 2015). A few studies investigated learners' spontaneous use of visual representations in problem solving (e.g., Uesaka et al., 2010). These studies found that, when the use of a visual representation is introduced as an option during problem solving, students generally tend not to choose to use it. Prompts can help learners use visual information more frequently (Wu et al., 2020), but these past studies use aggregated data in measuring choices (e.g., calculating the sum of choice behaviors) or post-hoc self-report data, making it unclear what specific choice behaviors students engaged in and how their choice patterns *changed over time* during their learning, a critical aspect of self-regulated learning (Greene et al., 2021; Roscoe et al., 2013). As learners develop skills and knowledge during learning, it is reasonable to expect that their use of certain strategies may change over time (Greene et al., 2021).

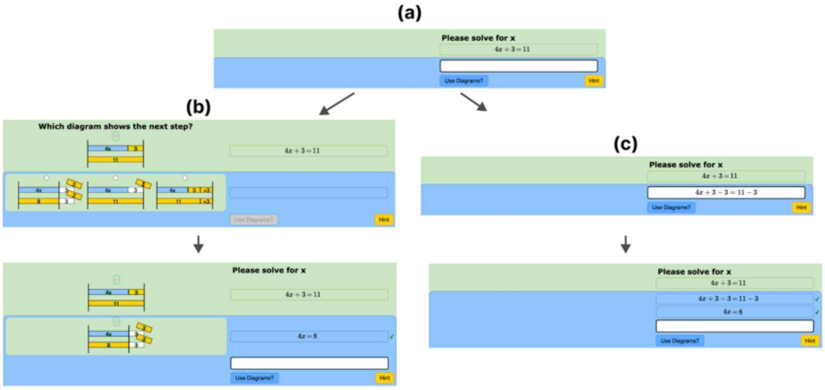
This paper reports on a design study and an experimental study we conducted with a total of 148 middle-school students in the U.S. to generate new scientific knowledge regarding learner's self-regulated choice behaviors during learning with visual representations, how these behaviors change over time, and how they might be supported with technology. We employed a user-centered design approach with eight students to create an intervention package for supporting students in self-regulated diagram use. This design phase was followed by an experimental study with 140 middle-school students in actual school classrooms in the U.S. that tests the learning that results from this intervention, when added to an intelligent tutoring system for algebra problem solving.

The diagram choice tutor

To investigate and appropriately measure students' choices in using visual representations, we designed and developed the *Diagram Choice Tutor*, an Intelligent Tutoring System for middle-school algebra in which students can choose, for each problem-solving step, whether or not to use a visual representation (called "tape diagrams," Murata, 2008) to help with their problem solving. As shown in Figure 1, when students opt to use diagrams, they need to select from three diagrams that depict what to do in the next step, one optimal diagram and two suboptimal or incorrect ones. This anticipative form of interactive visual scaffolding has been shown to support learning and problem-solving performance by having learners *self-explain* their problem-solving steps in a visual form, before they do these steps in the standard format (in this case, symbolic equations) (Nagashima et al., 2021).

The Diagram Choice Tutor presents an appropriate learning environment for learners to exercise self-regulated choice behaviors. Chin et al. (2019) argue that an ideal choice-based learning environment presents learners with options they would not select naturally (e.g., seeking negative feedback, Cutumisu et al., 2015). In the Diagram Choice Tutor, students (aged around 10-15) may naturally avoid using diagrams because doing so would require additional problem-solving steps, and tape diagrams introduce a new representation that students may not be familiar with (Murata, 2008). However, engaging with diagrammatic scaffolding during algebra learning has been shown beneficial for student learning, even with the expected cognitive effort required (Nagashima et al., 2021). Our Diagram Choice Tutor is also instrumented to collect students' learning process data to help overcome the lack of understanding regarding how students make choices.

Figure 1
In the Diagram Choice Tutor, (a) students start with an interface that shows a symbolic problem. They can choose to request a diagrammatic scaffold or not. (b) If they choose to use the scaffold for the given step, they then need to select, from three options, the diagram that shows the correct and optimal next step. After selecting the correct diagram option (e.g., the one on the left in the figure), students are prompted to do the step symbolically by referring to the diagrammatic scaffold that they have. (c) Students can also choose not to use diagrams to solve the step. This process repeats (i.e., students have the choice for every problem-solving step).



(a) Please solve for x

$4x+3=11$

(b) Which diagram shows the next step?

$4x+3=11$

Please solve for x

$4x+3=11$

$4x=8$

(c) Please solve for x

$4x+3=11$

$4x+3-3=11-3$

Please solve for x

$4x+3=11$

$4x+3-3=11-3$

$4x=8$

Designing support for self-regulated diagram use

Idea generation with students

Promoting self-regulated choices in the Diagram Choice Tutor presents a challenging design problem. It is difficult to define a criterion for when students should use diagrams (i.e., for when diagrams are most helpful for learning), as opposed to, for example, simply promoting more frequent use of diagrams. Drawing on the literature on help seeking in Intelligent Tutoring Systems, one might surmise that self-regulated learners would ideally neither over-use nor under-use the visual scaffolding but rather use it *when needed* (i.e., when the use might be most beneficial, Aleven et al., 2016). Although more frequent use of visual scaffolding means that students would get more exposure to the advantages that the visual representation has on learning (e.g., it might promote conceptual learning) (Uesaka et al., 2010), in the context of our tutor, students could overly rely on using the visual scaffolding in solving equations. Such over-use of diagrams in our tutor may lead to the acquisition of rather superficial “diagram-to-symbols translation knowledge” (i.e., copying what is shown in a diagram into the symbolic problem-solving step in the tutor, Nagashima et al., 2022, p. 1752). Because, in our Diagram Choice Tutor, tape diagrams as instructional scaffolding supplement the canonical representation (i.e., algebraic equations in symbolic notation), such superficial knowledge may not help learners when solving more advanced equation problems (for which tape diagrams are no longer useful, e.g., equations with negative numbers). On the other hand, self-regulated learners may use the visual scaffold to understand how to solve equations that they are not familiar with, but as they practice more, they might choose to practice their problem-solving/procedural skills without relying on the visual aid too much (Aleven et al., 2016). During this learning process, they may actively engage in key iterative stages of self-regulation (Zimmerman & Campillo, 2003), which are comprised of: self-assessment (“Can I solve this problem without help?”), self-monitoring (“Am I doing well with/without diagrams?”), and self-reflection activities (“How well did I do with/without diagrams?”).

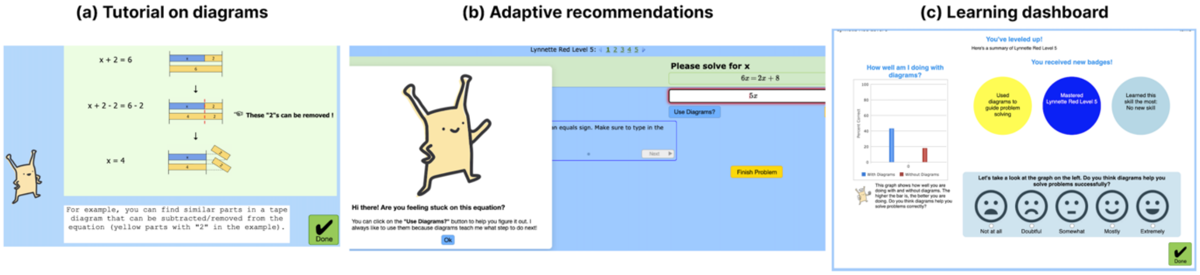
To approach this design challenge, we conducted one-on-one virtual idea-generation sessions with eight school students in the U.S. (one 4th grade, one 5th grade, one 6th grade, four 7th grade, and one 8th grade). In each session, the students first practiced a few problems with the Diagram Choice Tutor. Then, sharing a virtual whiteboard, the researcher and the student generated ideas in response to several prompting questions on self-regulated use of diagrams in the tutor (e.g., “What would be some features that would help you think carefully about whether or not to use diagrams for solving equations?”). A total of approximately eight hours of video recordings from the sessions were analyzed by three researchers using the Affinity Diagramming method. Affinity Diagramming is a standard technique used in the field of Human-Computer Interaction to analyze qualitative data to produce shared themes through multi-step synthesizing of codes and themes (Lucero, 2015). This process produced 117 codes, which we grouped into 13 themes. Then, of the 13 themes, those that share similar ideas were grouped together, resulting in five high-level ideas for promoting self-regulated diagram use in the tutor. Due to the page limit, we present just a short statement of four of the five main ideas that directly informed the design of our intervention: (Idea 1) *Tell me that diagrams are there to help, they are not there for no reason* (i.e., students want to understand how diagrams can be useful), (Idea 2) *I want to be prompted to consider using diagrams when they can be useful* (i.e., students want to know and be reminded when diagrams can be useful), (Idea 3) *Show me how diagrams are helping or not helping me* (i.e., students want to know if diagrams help their own problem solving and learning), and (Idea 4) *A diagram badge can help me think about using diagrams* (i.e., students want motivational features such as a badge for using diagrams).

Designing an intervention package for supporting self-regulated diagram use

Based on the four ideas generated by students, we (researchers) designed an intervention *package*, which consists of (a) an interactive tutorial that teaches students how diagrams can be useful (to address Idea 1), (b) an adaptive recommendation pop-up screen that prompts students to think about whether or not to use diagrams when they seem to have trouble solving problems (to address Idea 2), and (c) a student-facing learning analytics dashboard that shows how well students have been performing with and without using diagrams through visualization and badges (to address Ideas 3 and 4). See Figure 2 for more information.

Figure 2

(a) An interactive tutorial that explains how to use diagrams and research evidence on the benefits of diagrams on problem solving. (b) Adaptive recommendations, prompting students to think about diagram use, appear after any three consecutive problem-solving mistakes, after pausing for more than 90 seconds, and on the first problem in each problem set/level (more on problem levels described later). (c) A personalized learning dashboard that presents a graph showing the student’s problem-solving performance (i.e., percent correct) when they used diagrams (in blue) and when they did not use diagrams (in red) in the most recent problem level. Students are asked to answer a 5-scale “smiley” question on how they feel about the usefulness of diagrams. The dashboard also provides badges for students, based on their problem-solving performance and the use of diagrams.



(a) Tutorial on diagrams

For example, you can find similar parts in a tape diagram that can be subtracted/removed from the equation (yellow parts with "2" in the example).

(b) Adaptive recommendations

Lynnette Red Level 5: 1 2 3 4 5

Please solve for x

$6x = 2x + 8$

$5x$

Hi there! Are you feeling stuck on this equation?

You can click on the **"Use Diagrams?"** button to help you figure it out. I always like to use them because diagrams teach me what step to do next!

(c) Learning dashboard

You've leveled up!

Here's a summary of Lynnette Red Level 5

This graph shows how well you are doing with and without diagrams. The higher the bar is, the better you are doing. Do you think diagrams help you solve problems correctly?

Let's take a look at the graph on the left. Do you think diagrams help you solve problems successfully?

We designed these multiple intervention components and combined them as an intervention *package* to support the different stages of self-regulation mentioned earlier, rather than aiming to design one intervention. This decision was made because students expressed various needs and ideas for using diagrams during the idea-generation sessions. It is also suggested in the literature on self-regulated learning (Oppezzo & Schwartz, 2013). Specifically, (a) the tutorial is meant to help students think whether diagrams are useful for them (*self-assessment*), (b) the adaptive recommendations are to help students during the *self-monitoring*, and (c) the dashboard is designed to help students *self-reflect* on their choice behaviors of using or not using diagrams.

Method: Classroom study

We then conducted a controlled classroom experiment to test 1) whether the intervention package helps students gain better domain-level knowledge and skills in algebra and 2) whether and how the intervention package helps students demonstrate self-regulated use of diagrams. We compared two conditions in which students practiced algebra problem solving with the Diagram Choice Tutor (i.e., students in both conditions had control over whether to use diagrams for each problem-solving). The conditions differed in whether students had access to the intervention components (Supported Choice condition) or not (Unsupported Choice condition).

Participants

A total of 179 students participated in the study in their in-person classroom (38 5th graders, 37 6th graders, 86 7th graders, and 18 8th graders). Participants came from 11 classes in two schools in the U.S., taught by two teachers. Students in each class were randomly assigned to either the Supported Choice condition (n = 87) or the Unsupported Choice condition (n = 92). The participating teachers noted that their students' experience with tape diagrams was minimal (e.g., their instruction had never focused on tape diagrams).

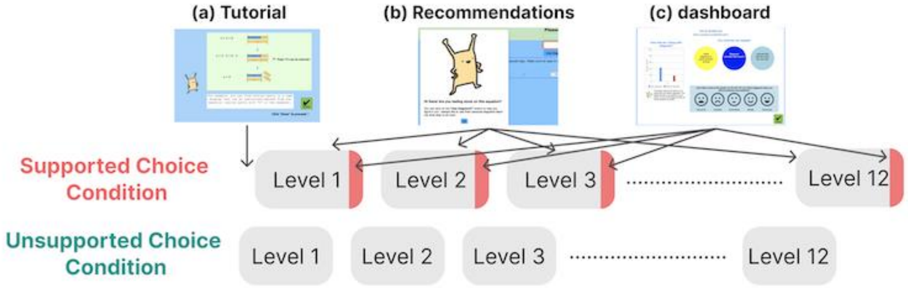
Materials

All students in both conditions in the study used the Diagram Choice Tutor (Figure 1) to practice equation solving during the study. Students in both conditions were assigned the same sets of problems (Table 1). Students in the Supported Choice condition additionally had access to the self-regulated learning (SRL) intervention components (Figure 2) embedded in the tutor. In both conditions, students had control over when to use diagrams. The only difference was whether or not students had the additional SRL components to support their choice making. Figure 3 illustrates how we integrated the intervention components into the Diagram Choice Tutor.

Table 1
Types of equation problems assigned in the tutor (in both conditions)

Problem level	Problem type	Problem level	Problem type
1	x + a = b	7	ax + b = cx + d
2	ax + b = c	8	ax + b = c (bonus content)
3	ax + b = c	9	ax = bx + c (bonus content)
4	ax = bx + c	10	ax + b = cx + d (bonus content)
5	ax = bx + c	11	ax = bx + c (bonus content)
6	ax + b = cx + d	12	ax + b = cx + d (bonus content)

Figure 3
Students in both conditions had the same practice problems from Level 1 to Level 12. Students in the Supported Choice condition additionally engaged with (a) the tutorial on diagrams before Level 1, and at the end of each Level, they were shown (c) the learning dashboard. (b) The adaptive recommendations were available from Level 1 to Level 12. Students in the Unsupported Choice condition solved algebra problems from Level 1 to Level 12 with no SRL intervention. Students in both conditions spent the same total time in the study.



We developed a web-based pretest and posttest on conceptual knowledge and procedural knowledge in early algebra based on items in the literature (e.g., Booth et al., 2013). Each test had 16 multiple-choice conceptual knowledge items and five open-ended procedural knowledge items. Two isomorphic versions of the test were developed and assigned in a counter-balanced way across pretest and posttest.

Procedure

The study was conducted during the schools' regular class periods across five consecutive days. Researchers joined the class through a video conferencing system to facilitate the study sessions. Students in both conditions first completed the web-based pretest. Then, they watched a brief video illustrating how to use the tutor. From the second day up to (and including) the fourth day, students solved algebra problems using the Diagram Choice Tutor. Students in both conditions spent the same total time in the study sessions; students in the Unsupported Choice condition spent the time exclusively on equation solving, while those in the Supported Choice condition spent it on equation solving *and* the SRL intervention components combined (Figure 3). On the final day, students completed the web-based posttest. After the posttest, all students were given access to both versions of the tutor so that they could experience the software that had been used in both conditions.

Results

Of the 179 students, 168 students completed all parts of the study. We excluded students who scored 100% on the pretest and those who did not complete more than 50% of the test items on the pretest and/or posttest, decided before testing treatment effects (Supported Choice condition: $n = 4$, Unsupported Choice condition: $n = 4$, Chan et al., 2022). Further, after a discussion with the participating teachers on students' exposure to equation solving prior to the study, all students from two advanced classes were excluded from the sample (Supported Choice: $n = 11$, Unsupported Choice: $n = 9$; these students were originally included in the study as the teachers wanted them to experience a research study, which they said they would not experience in the regular course of schoolwork). The final sample consisted of 140 students (Supported Choice: $n = 69$, Unsupported Choice: $n = 71$). No statistically significant difference was observed between the conditions in the dropout/exclusion rate, $\chi 2$ (1, N = 179) = .05, $p = .92$.

How did the intervention influence students' learning outcomes?

Table 2 shows students' mean pretest and posttest scores on conceptual knowledge and procedural knowledge in algebra. It also shows the average total number of algebra problems students solved in the tutor within the same time given to both conditions. To examine if the intervention package enhanced students' conceptual and procedural learning, we ran two separate linear regressions with condition as an independent variable, and conceptual and procedural knowledge as a dependent variable, respectively. In both models, students' pretest score (on conceptual and procedural knowledge, respectively) was added as a covariate to control for students' prior knowledge before the study. We found that students in the Supported Choice condition learned greater conceptual ($\beta = .95$, $t(137) = 2.52$, $p = .01$) and procedural knowledge ($\beta = .53$, $t(137) = 2.08$, $p = .04$) than those in the Unsupported Choice condition.

We also compared, between the conditions, the number of problems solved. We used a linear regression model with the same independent variable, and combined pretest score (conceptual and procedural) as a covariate, but with the average number of problems solved as the dependent variable. The model showed no statistically significant difference on the average number of problems solved in the tutor, $\beta = .67$, $t(137) = .32$, $p = .75$.

Table 2
Students' pretest and posttest scores (standard deviations in parentheses), and the number of problems solved

Condition	Conceptual Knowledge (*max* = 16)		Procedural knowledge (*max* = 5)		Number of problems solved
	pretest	posttest	pretest	posttest	
Supported	9.78 (2.72)	10.48 (2.49)	1.74 (1.74)	2.88 (2.03)	32.64 (13.52)
Unsupported	9.28 (2.22)	9.28 (2.15)	1.73 (1.74)	2.35 (1.88)	31.25 (13.10)

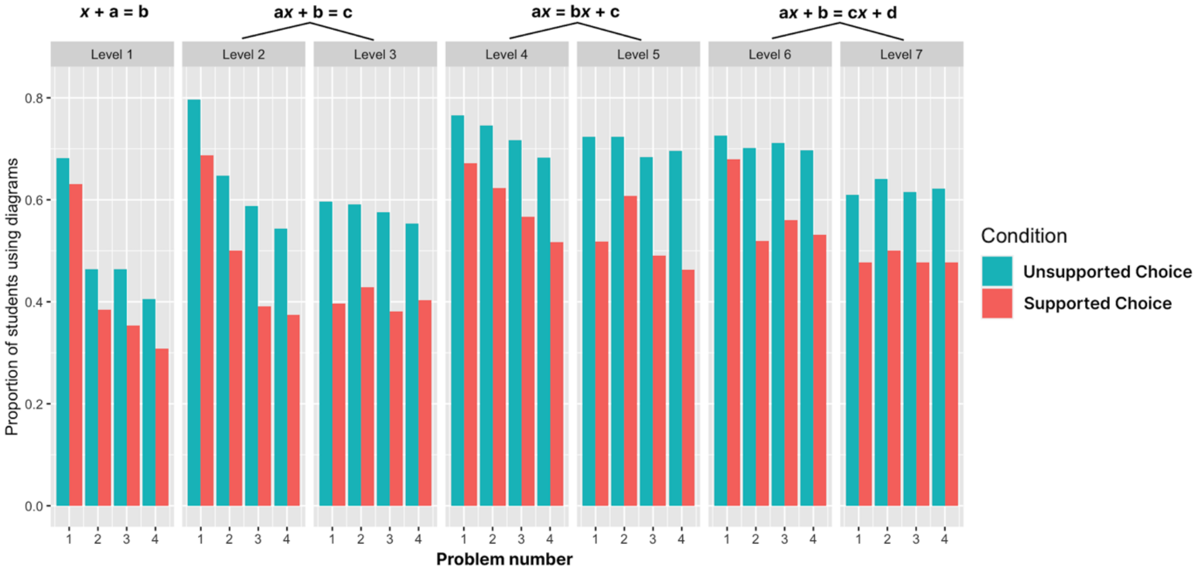
How did the intervention influence students' self-regulated diagram use?

To investigate students' diagram use across the two conditions, we examined tutor log data on the frequency of diagram use (i.e., how many times students requested to use diagrams). On average, students in the Supported Choice condition chose to use diagrams 0.12 times (*SD* = .10) per problem-solving step while those in the Unsupported Choice condition used diagrams 0.16 times (*SD* = .12). A two-sample t-test with the condition as an independent variable showed that students in the Supported Choice condition, on average, chose to use diagrams less frequently, $t(135.3) = 2.03$, $p = .04$.

To further investigate how students' choice behaviors *changed over time*, we then looked at the frequency of diagram use for each problem in the tutor. Figure 4 shows the proportions of students who chose to use diagrams at least once on each problem in the tutor, grouped by problem level. The graph reveals several notable patterns in their choice behaviors. First, many students in both conditions chose to use diagrams when they saw a new problem type (the first problem in Levels 1, 2, 4, and 6). Second, for the first problem in Levels 3, 5, and 7, in which students saw the same type of problems that they practiced in the previous level, students in the Supported Choice condition show a relatively low level of diagram use whereas at these levels students in the Unsupported Choice condition used diagrams at the rate that is not very different from their diagram use in the previous levels (Levels 2, 4, and 6, respectively). Finally, students in the Supported Choice condition show significant drops in their use of diagrams from the first to the second problem in Levels 1, 2, 4, and 6. This pattern indicates that many of the students in the Supported Choice condition chose not to use diagrams when they solved the same type of problem for the second time. This trend is also observed in the Unsupported Choice condition but is not as pronounced as it is in the Supported Choice condition (e.g., most notably in Level 6).

Figure 4

Proportions of students who chose to use diagrams at least once on each problem across problem levels. Only Levels 1-7 are shown, as Levels 8-12 were bonus problems with the same content introduced in Levels 1-7.



Discussion and conclusion

Prior work on choice behaviors in using visual representations does not offer insights into students' *choice behaviors that change over time* during learning processes despite its importance in understanding self-regulated learning processes. In our study, we first worked with middle-school students to design several intervention components to support self-regulation during learning with diagrams in the Diagram Choice Tutor. These components included a tutorial on benefits of using diagrams, adaptive recommendations that encourage students to think about using diagrams or not, and a personalized learning dashboard showing the student's recent problem-solving performance with and without diagrams. We then conducted a classroom experiment to evaluate the effectiveness of the intervention. We found that students who received the intervention learned greater conceptual and procedural knowledge, even though they chose to use diagrams less frequently overall than those without the intervention. How could less diagram use lead to greater learning in our study?

A closer look at students' changing choice behaviors in the tutor log data allowed us to understand what one form of self-regulated use of diagrams might look like. Specifically, the data suggested that students in the Supported Choice condition used diagrams more frequently when they saw a new problem type (at the outset, many students were not familiar with the problem types used in the study, according to participating teachers) but chose to use them less frequently when they kept seeing the same type of problem in the tutor. On the other hand, this pattern was not observed for students in the Unsupported Choice condition, where students made choices without the help of the intervention. These insights suggest that students whose choices were supported used diagrams when the use of diagrams may have been most helpful for learning, neither over-using nor under-using them. We conjecture that students in the Supported Choice condition, by engaging with the intervention components, were able to monitor and reflect on their own use of diagrams and were able to choose to use diagrams when they thought doing so would be helpful. For instance, it is possible that students, when seeing the graph on the dashboard, were able to deeply reflect on how useful it is to use diagrams in each problem level and on whether or not to use diagrams on the next level. Such informed choice-making practices may have contributed to the greater conceptual and procedural learning that was observed for the students in the Supported Choice condition. They focused their practice on learning how to solve new types of problems with diagrams (which may have led to conceptual learning) and then chose to practice problems without relying on the visual aid too much (which may have led to procedural learning). These insights would not have been gained only with aggregated data points but were possible with the temporally fine-grained log data collected with the technology. Such learning processes might also have contributed to faster, more efficient problem solving. Despite several additional activities (e.g., the tutorial and dashboard) that students in the Supported Choice condition had to complete (Figure 3), no difference was found on the average total number of problems completed in the tutor between the conditions.

Due to the design of the experiment, it is not possible to tease apart the effects of individual intervention components on student learning and diagram use. However, we argue that the design of the intervention as a *package* was aligned with and promoted different stages of self-regulation, as opposed to designing and testing a single intervention element. This decision was informed both by idea generation sessions with school students and a theoretical view on self-regulation. Still, we acknowledge that these speculations cannot be fully validated using the data from the current study and that other interpretations are possible. Also, the changing choice behaviors we observed in the tutor were not validated with statistical significance testing. Finally, self-regulated use of diagrams can take other forms than that addressed in the current study, depending on the context and domain of diagram use (e.g., self-constructing diagrams, Uesaka & Manalo, 2006; Uesaka et al., 2010).

The current study makes several contributions to the field of the learning sciences. First, the study contributes novel insights into how students' choice behaviors change over time, when students can choose to use or not use diagrams in the context of problem-solving practice in an intelligent system. Aggregated measures of choice behaviors (e.g., mean frequency of diagram use) do not afford the same insight. This insight is key to understanding and supporting self-regulated choice behaviors that lead to greater domain learning. The study also illustrates, by investigating students' choice behaviors, what effective use of diagrams during learning might look like. Further, we demonstrate that an intervention informed by ideas generated by students supports not only an effective self-regulated behavior but also greater domain learning, which is not typically achieved by interventions designed to support self-regulated learning with technology (but see Long & Aleven, 2016).

Abstract: This paper analyzes two teachers' participation in professional learning (PL) activities designed to help them learn to support students when they face uncertainty during a computationally-rich science inquiry unit and their subsequent enactments of the unit. In this unit, students assemble a physical computing system (PCS) coupled with sensors to program and display streams of environmental data. Students inevitably encountered moments when they were "stuck" and required teacher help. The PL activities consisted of teachers taking on "student-hat/teacher-hat" roles attempting to solve buggy PCSs followed by a discussion. Analyses using a lens on teaching as improvisation illustrated how PL activities helped teachers develop an understanding of the PCS, confidence in enacting the unit, and pedagogical strategies for making in-the-moment decisions to support students facing uncertainties. Analyses also revealed teachers' approaches for managing students' uncertainty level and the improvisation it required: one more constraining and one more expansive.

Introduction

Science education standards in the U.S. highlight several practices that are intended to reflect the work of modern scientists and engineers (NGSS Lead States, 2013). In particular, the Next Generation Science Standards (NGSS) foreground "uncertainty" as a key driver in students' developing scientific knowledge and making sense of the world. Manz and Suarez (2018) argue that "uncertainty is endemic to science" (p. 772) as "scientific practices are largely concerned with managing uncertainty and drawing conclusions in light of it" (Manz & Suárez, 2018, p. 772). For students, these moments of uncertainty arise as they engage in science inquiry when there are often "nonobvious decisions about what to do" (Manz & Suarez, 2018, p. 772). The science standards thus speak to the importance of having teachers help students grapple with uncertainty in inquiry-driven instruction as they orchestrate student learning. For many science teachers, enacting pedagogical practices that effectively support students in managing uncertainty for productive learning remains a challenge.

Moreover, just as modern science inquiry is increasingly driven by computation, so too is science classroom inquiry. Traditional classroom science instruments are being replaced with physical computing systems (PCS), like the BBC micro:bit. A PCS can be programmed and coupled with sensors to gather, process, and display streams of environmental data. By creating these systems, students engage in computational thinking practices that can have deep synergies with their disciplinary science learning.

In the context of these computing-rich inquiry activities, uncertainty often arises during moments when students' artifacts do not function as they intended, such as displaying the wrong unit of measurement (F° vs. C°). When students are unable to make their artifacts work as intended and unable to progress until they have received some kind of help, they are considered "stuck" (Huadong & Brennan, 2019). These moments of being "stuck" add additional layers of complexity for teachers as they must attend to the students' immediate concerns, help them fix their errors, while also support them in increasing their problem-solving strategies and persevering in the face of difficulties. This can be a challenging orchestration task as science teachers also often lack the necessary computing knowledge to troubleshoot and debug such systems (Tsan et al., 2022).

While prior work has examined student troubleshooting of physical computing (e.g., DesPortes & DiSalvo, 2019) and debugging programs in STEM and science contexts (e.g., DeLiema et al., 2022), much less has examined how teachers learn to support students engaged in these processes (Tsan et al., 2022). Even less has examined how teachers support students working with PCSs and engage with uncertainty as they troubleshoot bugs in the hardware (e.g., a faulty wire connection), debug the software (e.g., an incorrect conditional statement), or resolve issues across their interactions (DesPortes & DiSalvo, 2019).

To address this gap, we previously analyzed the in-situ strategies as teachers enacted a science inquiry instructional unit using a sensor-equipped PCS. We examined how teachers supported their students when they assembled their PCS. This analysis led to the design of professional learning (PL) activities focused on helping teachers learn to support students during troubleshooting and debugging (Hennessy Elliot et al., 2022). We implemented these activities as part of a four-day summer professional learning (PL) workshop with middle and high school science teachers. In this PL activity, teachers took turns in the role of a student who is stuck with a buggy system (produced with bugs previously encountered in classroom implementations of the unit) as well as the role of a supporting teacher. Participants in the PL then reflected on their experiences in this activity. The goal of the activities was to help teachers better understand their students' challenges during debugging and develop strategies to help students navigate moments of uncertainty during classroom enactments.

In this paper, we present an analysis of two teachers' participation in this PL. We examine their problem solving during the PL debugging activity, their reflections on this activity, and how their experiences shaped subsequent classroom enactments of the instructional unit. Our research was guided by the question: In what ways did the PL activities help teachers learn about managing their students' uncertainty as they engaged in debugging during a computationally-rich science inquiry unit?

Literature review

As teachers increasingly integrate programming into science classrooms, research has only begun to examine how teachers, often new to programming themselves, support their students during moments of debugging (e.g., DeLiema et al., 2022; Tsan et al., 2022). This perspective is particularly important as teachers' interactions with students are core to how students develop debugging skills and address gaps in understanding (Blikstein & Moghadam, 2019; McCauley et al., 2008). To address this gap in the research, we previously analyzed the in-situ strategies teachers used during a computationally-rich science inquiry unit to support their students when they became stuck while wiring and programming their PCS (Hennessy Elliott et al., 2023). We found that teachers do not necessarily have to be programming experts to effectively support students in debugging their physical computing systems. This work also highlights that debugging moments are highly unique and contextual and therefore require varied approaches on the part of the teacher.

To best prepare teachers for these moments of uncertainty, recent research has explored how professional learning workshops might be designed to help teachers support their students' debugging. For example, DeLiema et al., 2022 demonstrate the effectiveness of having teachers practice debugging instruction in mock classrooms and reflect on video of classroom debugging practices. Similarly, Tsan et al. (2022) describe a debugging model where teachers used a mnemonic device to assist in debugging and reflected on how they would help their students. However, they found that this strategy led to teachers mostly focused on helping students fixing the bug rather than understanding the cause of the bug.

Because learning the skills of debugging is essential to computer science (McCauley et al., 2008), PL opportunities should provide scaffolding for teachers to support students in developing debugging strategies. Strategies can help students when they run into other similar bugs in the future and can help students "handle unforeseen, novel impasses" (DeLiema et al., 2022, p. 7). Debugging can serve as rich learning opportunities as they naturally spark discussions about the learning process that help students develop critical thinking strategies and important thinking processes (Fields et al., 2021). Such thinking strategies and processes are important for teachers to support students as they encounter uncertainty in science and STEM (Manz & Suarez, 2018).

Several researchers have argued that disciplinary learning in science must go beyond a focus on scientific knowledge and practices to include epistemic affect, or learning how to feel like a scientist (e.g., Jaber & Hammer, 2016). Feeling like a scientist involves encountering and learning to grapple with the kinds of uncertainties central to the discipline (Jordan & McDaniel, 2014; Manz & Suarez, 2018). Scientists describe feeling uncertainty not only when modeling and explaining phenomena, but also when working with various tools, measurements, and determining how to analyze their data (Manz & Suarez, 2018). Further, scientists increasingly use computational tools and design processes in their inquiry and must therefore be able to debug the tools they use. Therefore, students engaging in authentic science practices that use computation to produce data should be equipped to debug and redesign tools by drawing upon technical and scientific knowledge (Hardy et al., 2020) when they encounter moments of uncertainty.

In the context of this paper, the scientific tool students used for scientific inquiry was a PCS, which offers an alternative set of introductory activities to engage students in computing (Kafai et al., 2014). PCSs are relatively user-friendly and affordable (Anastopoulou et al., 2012; Blikstein & Moghadam, 2019), but they are a challenge for debugging as bugs can occur in any part of the system: the software (or program), hardware, or the interactions between the two (DesPortes & DiSalvo, 2019).

The process of debugging PCSs used in science classrooms, similar to data collection and analysis, therefore involves encountering moments of uncertainty as students come to decision points where they do not know exactly what to do with the system. Debugging physical computing systems to use in science classrooms is a step in the process of becoming data producers (Hardy et al., 2020) that offers students – and their teachers –

pedagogical experiences with wrestling with uncertainty that they all can build on when making sense of real-world data.

Conceptual framework: Teaching debugging as improvisational

In this paper, we conceptualize teaching as "disciplined improvisation" (Sawyer, 2004), involving a strategic balance of structure and open-endedness. In exploring the integration of physical computing in science classrooms, conceptualizing the improvisation that teachers undertake is particularly important in developing teachers' ability to support student sensemaking exploring the uncertainty of questions without a single answer (Jurow & McFadden, 2011) and position science – and in turn computing – as a practice rather than a set of facts. Through experience and professional learning, teachers develop a shared repertoire of methods and strategies they draw on supporting students wrestling with uncertainty; yet their work requires being flexible enough to react to the changes, shifts, or needs of each moment.

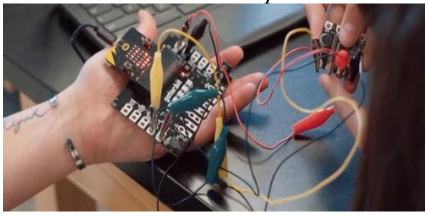
This framing affords a conceptual lens on what decisions teachers make in-the-moment to support students as they debug their PCSs and what strategies and/or structures they draw on – possibly developed in professional learning activities – to make those decisions. Improvisation, whether in art or in teaching, does not mean that "anything goes" (Sawyer, 2004); rather, improvisation has its own structures and methods (DeZutter, 2011; Halverson, 2021). Considering teaching as improvisational offers a window into how effective teaching involves authentically listening to students and facilitating students to build on each other's ideas (Phillip, 2019). Phillip (2019) describes further that when done well, teaching as improvisation involves, as a classroom community, crafting critical questions that examine issues of power in relation to historical, social, political and economic processes. Science teachers, as Jurow and McFadden (2011) argue, must make moves to set the stage by providing "slots" for students to participate in disciplinary practices using student contributions to extend the classroom community's scientific thinking.

Instructional unit and professional learning activities

This study is part of a larger multi-year, multi-site design-based implementation research project that is co-designing NGSS-aligned instructional units and PL activities that use the PCS in service of science inquiry (Biddy et al., 2021). The instructional unit in this paper introduces secondary school students to physical computing as a tool to support sensor-driven inquiry in science and STEM classes. The instructional unit uses a storyline approach (Reiser et al., 2021), where the lesson is grounded in students' generating questions about particular phenomena, planning and conducting investigations to address their questions, and creating models to explain findings.

In the storyline unit, students explore the phenomenon of the PCS that collects data streams such as classroom sound levels, local environmental conditions, or soil moisture levels in classroom plants. During this unit, students investigate the capabilities of the technology by wiring and programming physical data displays that respond differently based on data stream values (see Figure 1). The data displays incorporate a micro:bit which is wired to various sensors and programmed with MakeCode, a block-based programming language.

Figure 1
One student's PCS set up with one sensor (sound sensor)



Before implementing the storyline, participating teachers attended PL sessions which provided training on wiring and programming the PCS to explore scientific phenomena. The focus of this study is on the PL activities designed to help teachers support their students during moments of uncertainty while debugging. The PL activities were designed to provide teachers experience debugging both from the student and teacher perspectives (called student-hat/teacher-hat) (Biddy et al., 2021). During the activity, teachers were organized into groups of three, with two acting as a pair of students debugging a PCS and the third playing the role of the teacher. Each group was given a buggy PCS, planted with commonly occurring bugs that students encountered in previous implementations of the unit. The teacher pair, playing the role of students, collaboratively debugged the provided PCS, trying to find and fix the various hardware and software bugs that had been planted. The person in the teacher role gave the "students" a few minutes to work on the bug prior to entering into the conversation and facilitating the debugging process. After the activity, the PL facilitators engaged teachers in a reflective discussion about the activity, focusing on strategies teachers found helpful for supporting students during moments of uncertainty.

Methods and study context

This study took place in a rural-serving district in the western United States. Teachers participated in a four-day PL workshop designed to help them learn about computationally-rich storylines using the PCS. Two teachers were selected for further analysis because we had complete records of their PL activities and classroom enactments. These two teachers are representative of the other teachers in the project in that they were middle and high school science teachers who took part in the four day workshop and enacted the instructional unit in their classroom during the fall of 2022. The teachers, Eric and Trevor, were in their first year participating with the project and neither had prior programming experience. Eric was a third-year high school science and physics teacher and Trevor was a fourth-year middle school science teacher.

The data sources included video recordings and transcripts from the professional learning workshop's debugging activity (41 minutes) and reflective discussion (12 minutes); video recordings of debugging moments, transcripts, and field notes from Eric and Trevor's enactments of the storyline; and email correspondences. We focus our analysis on two lessons (lesson 2 and 4) where students collaboratively program and wire the PCS. We consider a debugging moment to involve the moment the teacher approaches the student(s) working on their PCS until the teacher walks away. Reviewing Eric and Trevor's classroom video, we located five debugging moments for Eric and four for Trevor. Debugging moments lasted between 49 seconds to six and a half minutes.

To answer our research question, we conducted a thematic analysis (Braun & Clarke, 2006) of teachers' discussions during the PL activities as well as their strategies during classroom enactments. We developed inductive process codes (Miles et al., 2014) to surface the strategies teachers used for debugging during the PL activity, discussion, and classroom enactments. We conducted second level descriptive coding of these strategies tracing the situations where teachers did not have a consensus or obvious strategy. To compare the strategies teachers took up, which ones they adapted, and new strategies that arose in the moment, we created a checklist matrix (Miles et al., 2014). Finally, we distilled themes based on our analysis.

Findings

In this section, we describe the themes we distilled through analyzing the debugging PL activity, the reflective discussion afterwards, and Trevor and Eric's later classroom enactments of the storyline unit. These themes drive our findings section: 1) developing strategies and understandings that promoted confidence and 2) setting the stage for managing how their students engaged with uncertainty.

Developing strategies and understandings that promoted confidence

The debugging PL activity helped teachers gain knowledge about the hardware and software and develop debugging strategies that assisted them in making decisions to support their students. While in "student-hat", teachers practiced different debugging strategies – e.g., reading the code aloud, checking the wiring, and using the available instructional resources like a wiring diagram – examining their effectiveness from a student perspective. By working in the role of a student, teachers developed knowledge about the hardware and software interactions, interrogating the relationship between the environment, the sensors, and their program. They collaboratively made sense of how the hardware and software worked together, a task that is often difficult for novices in working across the physical system and programming simultaneously (DesPortes & DiSalvo, 2019).

Teachers did more observing than talking when in the role of the teacher (teacher-hat) during the PL, often positioning themselves behind the "students" so they could look over their shoulder and examine the code. During the reflective discussion, Trevor described that his trepidation to step in stemmed from: "when I saw those two, … [I felt that] I was already watching the professionals and they were already figuring out stuff that I wouldn't have thought."

When in teacher-hat mode, we only coded two strategies to support "students'" debugging during the activity: asking questions and giving directions. Both Trevor and Eric used initial questions to get a sense of what the "students" were working on when they first walked up (e.g., "so what are you guys working on here?") and questions about hardware (e.g., "What else controls how much if you get power or not?"). While these strategies are helpful, they only touch the surface of possible moves that teachers can do to support students in engaging with uncertainty. Despite observing only surface level engagement in these practices. Participating in this activity led to Eric and Trevor in discussing a multitude of deeper strategies during the reflective discussion.

The PL reflective discussion proved to be a rich activity to help teachers in building a repertoire to draw upon during the enactment of the unit. Our analysis of classroom debugging moments revealed that the teachers used seven of the eight strategies that were mentioned during the reflective discussion and two of the strategies used during the PL activity (see Table 1). Eric left the PL experience with a clear checklist he imagined he would use in his classroom, saying: “It's literally wire. It's power supply, wires, switches, code…That's the checklist and that's the order I want it.” In contrast, Trevor only mentioned strategies for troubleshooting hardware. He mentioned wanting to know the wiring so well that he could walk up to students and quickly assess if there was an issue with the wiring. This strategy was evident during his later classroom enactments as he focused on asking students questions to make sure their hardware was working correctly.

Table 1
Teacher strategies derived from PL and classroom enactments

Strategy	PL Activity	PL Reflection	Classroom Enactments
Asking questions	√	√	√
Articulating the problem		√	
Articulating the goal		√	√
Reading code aloud			√
Talking to other students		√	
Pointing students to resources		√	√
Switching hardware		√	√
Allowing students to figure it out		√	
Giving directions	√		√
Checking switches or lights		√	√

Through participating in the PL activities, teachers also devised strategies to support students in learning the process of debugging, rather than focusing on simply fixing the bug. They imagined asking students questions to get them to explain or talk through their code, pointing students to tutorials or other instructional resources, and asking students to check with other students or compare their code.

During the classroom enactments, both Trevor and Eric regularly asked questions of their students as their main support strategy, building on the foundational practice they developed during the PL. However, the questions Eric asked of his students were more disciplinary-specific than the questions he asked during the PL. Most of the questions he asked during the PL were questions that could be asked in most instructional contexts to assess what students were working on (e.g., “what are you trying to do?” or “what is your goal?”). In contrast, Eric’s most frequent question during enactments was “how are you going to display your data?” This question became a regular strategy for Eric in determining students’ goals while also getting them to explain how they intended their system to work.

The PL reflective discussion revealed a tension among teachers about how to best support students when assembling and using the PCS. In the discussion, the teachers considered when it is appropriate to step in and when it is better to let students struggle, moving back and forth between thinking from the student’s perspective (e.g., “I'm the kind of student that doesn't want someone to just tell me the answer. I want to work on it long enough that I get the chance to find it myself before”) to the teacher’s perspective (e.g., “Like you're a bad teacher if you don't walk around and hover so you can check and say, How's it going…if they're not ready… you move on”). Discussing this tension, Trevor reflected that students are often appreciative when teachers step in, yet not all teachers participating in the discussion agreed with this assertion.

In the reflective discussion, Trevor and Eric recognized that many debugging moments would require them to enter a situation where they would not necessarily know where students were in the process of debugging. They noted that they would want to quickly determine how to support students while also quickly assessing where students were getting stuck. They concluded that asking questions such as “what are you trying to do?” would support both their students and themselves in deciding how best to proceed.

Setting the stage for students’ engagement with uncertainty

In this section, we describe debugging moments excerpted from the two teachers’ enactments, illuminating how they both drew upon the repertoire developed during PL and moved beyond these strategies, improvising to best support their students. In addition, we share the ways both teachers structured lessons 2 and 4 as part of their grounding for engaging with students working with the PCS. By setting the stage for the kind and amount of improvisation necessary to support their students, Eric and Trevor expanded or contracted the amount of uncertainty available for students. Eric’s use of strategies and structure of lessons 2 and 4, compared to Trevor’s, resulted in a more expansive approach and required a broader improvisational repertoire that he had to call on in-the-moment when supporting students.

For example, there were several times when Eric approached students who were stuck where he followed a similar checklist he had devised during the PL activity. In an email written after implementing the storyline, Eric wrote “that debugging activity we did [in PL] was a life saver because now I know all the mistakes they make and how to fix them” (email correspondence, September 2022). While using his checklist and asking questions were helpful in the initial stages of approaching students who were stuck, Eric improvised when these initial questions did not get to the root of the problem and when neither he nor his students could locate the bug. In one instance, after reading the code aloud (the last step in his mental debugging checklist), he checked which tutorial students were using, suggested students pull up a new tutorial to compare their code to the code in the tutorial, read the tutorial code aloud, moved back and forth between the students’ code and the example code, and changed a variable in the code all the while narrating to his students what he was doing and his hypothesis about what might be causing the bug.

While in this instance these strategies ultimately did not help Eric and his students resolve the bug, he approached the experience positively by saying to his students: “I don’t know if I’ve ever seen this before, this is fun!” At the end of the debugging experience, Eric proposed a hypothesis about what might be causing the issue, explaining the details to his students and expressing that while the sensor was still not returning a value they expected, the reason might be that they did not have enough variability in moisture level and that they could try measuring in a new environment. Eric’s approach here involved improvising new approaches while also modeling how not knowing the answer or direction can be an enjoyable act. At the end of the moment, Eric also allowed his students to remain in uncertainty as they came to no obvious way to debug their system. Instead, he proposed a new strategy of trying to try out the PCS in another environment. Overall, Eric’s approach, as indicated in his facilitation of lessons 2 and 4, expanded possible stuck points students could encounter thereby creating more room for them to encounter and deal with uncertainty.

Trevor also drew upon many resources from the PL, including asking questions of students; however, his questions were often in the form of more answerable “yes or no” questions, such as “did you hit download again?” and “you’ve wired it correctly?” Trevor started his interactions with students with these types of questions, geared towards troubleshooting the hardware and its connection to the program. When these did not help resolve the issue, Trevor would then examine the code. When there, he most often directed students about what to do by pointing to different blocks on the screen and directing students what to do. For example, leaning into the screen to decipher the code, Trevor explained to two students where to move a different block in their code: “Pull that one back out. [points at screen and moves finger to match verbal directions]. And then take this right here and put it, is there a circle in it? Or just put it right here and move this up here into the show...” Overall, this directive approach was more focused on the product of getting a working PCS rather than the process of developing debugging skills.

Trevor’s approach to setting the stage of the unit limited the possible stuck points students might confront. He structured lessons so that his students were always at the same place, providing all directions aloud to the whole class in a step-by-step fashion, and asking students to stop after they finished each step in order to wait until all students were ready to move on. In addition, Trevor chose to modify lesson four (where students designed PCSs using multiple sensors). Instead, he asked students to write in their science journals about what they could create with their PCS. Through these actions, Trevor constrained students’ opportunity for engaging in uncertainty, which also minimized the amount of improvisation needed to support students in debugging moments. In this way, Trevor’s range of improvisational moves were more constrained than Eric’s.

Conclusion and implications

This paper examines two teachers’ participation in professional learning (PL) activities designed to help them learn to support students when they face uncertainty during a computationally-rich science storyline. It also examines how this participation shaped their subsequent classroom enactments. Findings revealed that the PL activities helped the teachers understand the PCS from their students’ perspectives and develop a repertoire of strategies to support students. Eric and Trevor’s classroom enactments also revealed divergent approaches to facilitating the storyline unit that enabled students to engage in and wrestle with varied levels of uncertainty.

In terms of classroom enactments, the two teachers set the stage to allow for distinct levels of student uncertainty. This meant differences in the kind and amount of improvisation needed to support their students. One teacher, Eric, created opportunities for students to encounter uncertainty by how he taught the storyline and approached students when they were debugging their PCS. In this way, giving students more opportunity to encounter and persevere through uncertainty with the PCS, Eric faced more instructional decisions to be made in-the-moment and therefore presented a more complex setting for improvisation.

In contrast, Trevor appeared to constrain opportunities for his students to encounter uncertainty – thus limiting his need to improvise while teaching. During the storyline unit, Trevor had his students all work at the same pace and provided instruction that applied to many students at once. This reduced students’ chances to encounter uncertainty on their own. This more structured approach also meant that the bugs students encountered were often routine and easily "fixed" without them necessarily learning more about the PCS and related science. While this approach constrained students from experiencing uncertainty, it may have provided Trevor an amount of comfort as he learned to integrate a new science unit and physical computing systems into his classroom. Of course, a variety of external factors may have influenced these differences in enactments, for example, class size, students' age, time, or comfort with the science and technology. In addition, rather than simply asking why some teachers' practices changed more than others after PL, it is important to recognize that teacher learning coevolves with classroom practice over time (e.g., Kazemi & Hubbard, 2008).

Trevor's approach also aligns with findings from recent studies of teachers enacting inquiry science instruction, where although teachers seek to empower student inquiry, they may only take up student answers or ideas they had previously anticipated (Miller et al., 2018). This approach can minimize students' agency (Miller et al., 2018) and lead students to strive toward a single, correct solution. Moreover, when students do not have a chance to wrestle with uncertainty, they miss out on important opportunities to develop their own strategies to work through this feeling, potentially even finding pleasure in uncertainty or inconsistencies, as many scientists describe their work (Jaber & Hammer, 2016).

Findings for this work help inform future designs of professional learning where teaching for uncertainty is foregrounded. First, our work contributes to research on the benefits of providing both "student-hat/teacher-hat" experiences in PL by giving teachers the chance to engage in the discipline, experience uncertainty from both perspectives, and empathize with their students (Lowell & McNeill, 2020). We found that the approach was an effective tool to introduce teachers to unfamiliar computing concepts (Goode et al., 2014) and help them develop strategies to support their own students in debugging. Second, we found that while in "teacher-hat," the teachers mostly observed what the "students" were doing rather than offering support. While teachers may have felt their own uncertainty about how to support students during debugging (Yadav et al., 2016), the experience sparked a rich discussion and helped teachers develop new strategies and confidence.

Finally, the design of the PL activities was intended to support teachers in developing their own flexible approaches that could be adapted to a variety of debugging and uncertainty contexts. We considered alternate PL designs that would provide teachers with pre-planned debugging scripts and checklists. However, we feared that providing such guidance would turn the focus of the activity on simply fixing bugs rather than supporting teachers in developing a more expansive set of pedagogical strategies. Whether teachers actively participated while in teacher-hat or merely observed, our PL activities appeared to engage teachers in theorizing about the nature of uncertainty in the science classroom.

Missing Command as a Debugging and Problem Solving Task for Elementary Students

Laura Bofferding, Purdue University, lbofferd@purdue.edu
Mahtob Aqazade, Rice University, mahtob.aqazade@rice.edu

Abstract: Problem solving and debugging skills are important computational thinking practices that even young students can and should experience. We investigated 28 first graders' and 27 third graders' efforts to determine commands missing in three programs, where the missing command occurred at either the beginning, middle, or end of the program. Students attempted to find the missing command before and after an intervention where they learned how to program using a tangible programming game. Students often chose commands that resulted in bugs due to having the character move too much or too little and in the wrong direction. When the first command was missing, students often tried a pattern matching debugging strategy. When the middle command was missing, they wanted to reprogram the end. When the last command was missing, they traced the code but struggled. Implications include helping students trace their code when making sense of a new program.

Introduction

Since Wing (2006) brought attention to the wide-spread importance of computational thinking, there has been a marked increase in attention on practices that support computational thinking, especially in relation to programming, in schools. Computational thinking involves problem solving skills (Pérez, 2018), including decomposing problems, creating and reasoning about algorithms, and debugging (Anderson, 2016; Angeli et al., 2016; Grover & Pea, 2013). Especially at the early elementary level, the bulk of explorations around students' programming has focused on their learning to program using tangible and digital tools, often focusing on which commands are easy or more difficult to learn (e.g., Elkin et al., 2016). Some of these reports have also provided initial insights into how young students debug (e.g., Bofferding et al., 2022; Sipitakiat & Nusen, 2012). Related to debugging, when students play together to make programs, they must also make sense of their peer's code and what pieces they might need to add. We build on prior work on problem solving and debugging skills by presenting results of a study where first and third graders had to determine the missing command in a series of programs before and after an intervention in which they played in pairs to program using tangible coding blocks, Coding Awbie. Coding Awbie is meant for students in early elementary school. Our results highlight sequence (i.e., location of missing commands in programs) and conceptual factors (e.g., understanding of functions of the commands) that can play a role in young students' creation and debugging of programs.

Tangible programming

Tangible programming applications generally have a few forms. The first form of application involves directly programming a robot by pushing buttons on a controller to make the robot turn or move forward or backward (e.g., Code and Go Robot Mouse, Code-a-pillar, Botley the Coding Robot). A drawback of these applications is that debugging is difficult because students do not have a record of the commands they used unless they keep track of them elsewhere. A second form of application has students put together a series of blocks, each of which is a command, to program a robot (e.g., KIBO, Elkin et al., 2016). Students can trace back through their code (i.e., the blocks) to make sense of any unexpected results or bugs. The third form of application involves students putting together a series of blocks, but the blocks control a character in a game on a tablet or iPad (e.g., Coding Awbie; see Bofferding et al., 2022). The benefit of controlling a character on the screen is that students are motivated to play the game, and it allows for resetting the game and debugging the tangible blocks while also being a closer approximation to fully online block-based programming applications like ScratchJr.

Incomplete worked examples and debugging framework

As identified by Dahn and DeLiema (2020), debugging can be an emotional process and could involve changing one's goal to work around a bug or rereading the code. One type of task that can help students make sense of programs and reveal their current understanding of the steps of the code is having them work with incomplete worked examples (Hanna, 2015). One potential benefit of debugging or fixing someone else's code, is that students are not invested emotionally in the code and the goal of the program as with their own programs (i.e., when their own program does not work). In a programming context, incomplete worked examples indicate the goal of a program and provide some of the code. Students must then fill in the missing step (or steps) to complete the code for the program, much like they would when working with faded worked examples (e.g., Skudder & Luxton-Reilly, 2014). When provided with an incomplete program, students need to understand what the program is supposed to do, what the individual commands will do, and what needs to be fixed or added (Fitzgerald et al., 2008). However, students might introduce new bugs during the process of determining a program's missing code. Within Coding Awbie, bugs tend to involve students using the incorrect movement or having a different interpretation of what the movement does, having the character move in the wrong direction, having the character move the wrong number of spaces, or a combination of these.

Typically, students have more difficulty finding a bug than fixing it (Fitzgerald et al., 2008). In an incomplete worked example, we consider the missing code as the bug that is already identified. Therefore, the location of the missing code or type of missing code might influence the difficulty of correctly fixing it. When working with this existing code, students need to leverage several of the computational thinking practices, focused on problem solving, in order to interpret the code and add to it or modify it as necessary. Murphy et al. (2008) laid out a series of strategies that novice programmers use when debugging code that are relevant for both making sense of the code and fixing it (see also Bofferding et al., 2022; see Table 1).

Table 1
Debugging Strategies (Bofferding et al., 2022; Murphy et al., 2008)

Debugging Strategy	Description
Tinkering	This strategy applies to situations where students can change the code and see the results of their changes. When tinkering, students randomly make changes.
Reprogramming	This strategy involves starting over and rewriting the program.
Understanding the Code	This strategy involves trying to figure out what the program is doing by reasoning about the code and the situation.
Tracing the Code	This strategy involves starting at the beginning of the program and walking through each line step-by-step and following along with the result at each step.
Pattern Matching	This strategy involves a realization of what needs to be done, almost intuitively. Students might just notice something missing. For example, students might subitize the distance they wanted Awbie to move.

There has been little work investigating young students' efforts to make sense of incomplete worked examples, particularly before second grade and for developing programming and computational skills (see Bofferding et al., 2022 for one example). Therefore, we build on these prior works around incomplete worked examples and debugging to explore the following research questions:

1. How do first- and third-grade students debug the programs and determine the missing command in a program?
2. How does the location of incomplete commands impact students' problem solving and the type of bugs students make over time?

Methods

Participants, setting, and study design

Our study and use of human subjects was approved by our institutional review board. We recruited students from all first and third grade classrooms at a suburban, public elementary school in the midwestern US. At the school, 45% of students qualified for free and reduced lunch, and 11% were classified as English Language Learners. Overall, 55 students participated in the study (28 first graders, 27 third graders). The study's design involved a pretest, midtest, and posttest, all of which took place individually with a researcher at a table in a hallway of the school. The three tests included items where students had to explain what was happening in video clips of a hypothetical student programming Awbie to move, items to debug buggy code, and the items presented here. For the intervention, students participated in three programming sessions before the midtest and three programming sessions after the midtest. During the intervention, students worked with a pair and played Coding Awbie, a tangible programming game using the Osmo system. The pairs also engaged with a series of correct and incorrect worked examples (complete or incomplete programs) either before their first three sessions or last three sessions to provide them with further opportunities to problem-solve around the use of the programming commands in the game (see Bofferding et al., 2022). All individual and pair sessions were video recorded, and we took notes on students' responses to the items for this analysis.

Background on coding awbie

Coding Awbie is a tangible programming game that young students can play on the iPad. Using the Osmo^{TM} gaming system, students use tangible programming pieces (movement actions, direction arrows, and numbers) to make commands for their lines of code (see Table 2). Awbie must jump over bushes and trees, and if he runs into or jumps onto one of them, which we considered faulty programming, he will bounce off of it. A mirror on top of the iPad reads the code that students place in front of the iPad and then runs the program. In the game, students try to program the character, Awbie, to collect strawberries and get to the end of each level.

Table 2

Examples of How to Use the Tangible Coding Pieces to Move Awbie

The parts of the program run from top to bottom as follows:

	Walk right 2	Students can turn the arrow on the button to change the direction they want Awbie to go.
	Grab up (1)	When grabbing, Awbie stays on the current square and reaches into the next square. If no number is used, it defaults to the value of 1.
	Jump down 3	A jump skips a space, so if Awbie jumps three times, he would have moved six spaces from his starting point.

Data sources and analysis

In this paper, we focused on three "missing programming command" items from the pretest and posttest. These items reflect incomplete worked examples. Each item had a picture of Awbie (the character to move) in a scene from the game, which had a series of strawberries for Awbie to collect. Near the picture, we also listed lines of code that when run needed to fulfill the goal of Awbie collecting all of the strawberries. However, in each item, one of the programming commands (i.e., line of code) was missing. Across the three items, one had the first command missing, one had a middle command missing, and one had the last command missing (see Table 3). The three items were similar in that they each had a slightly non-intuitive element. With the first command missing item, students needed to program Awbie to go up past the first strawberry, rather than collect the first strawberry and jump left over the bush. In the middle command missing item, students needed to have Awbie collect the strawberry on the beaver before finishing walking down the long line of strawberries. For the last command missing item, students needed to realize that Awbie was jumping all the way to the right before going up and then jump back to the left. During these tests, students reasoned about these items. We asked students to figure out what command (movement, direction, and number) should be in the missing spot in order to make Awbie collect all of the strawberries. We presented the same three items on the midtest and posttest but changed the order of the items each time. Given the time needed for students to complete the sessions, there was about one month in between each testing session, and students gave no indication that they recalled what they had answered on the previous occasions.

Table 3

Three Missing Command Programming Items and Analysis Categories

	First missing	Middle missing	Last missing
Missing programming command item			
Works without faulty code	*walk up 2*	*walk left 2* or *jump left 1*	*jump left 1*
Works with faulty code	If a student used the command *walk up 3* (incorrect number), Awbie would bounce off of a tree but still collect all of the strawberries.	If a student used the command *walk left 3* or *jump left 2* (incorrect number), Awbie would bounce off of a tree but still collect all of the strawberries.	If a student used the command *jump left 2* (incorrect number), Awbie would collect all of the strawberries and continue jumping. However, students often thought that *jump 2* meant Awbie would jump to the second space (as opposed to jump over a space and land two times), so we treated this as similar to a bug.
Does not complete the goal	Although *jump up 1* (incorrect action) would help Awbie get to the final strawberry, he would jump over the first strawberry, so this command would not properly complete the code.	Students might try to put two lines of code in the missing spot, such as *walk left one, hand left one* (incorrect number, incorrect action - extra), which would get the strawberry by the beaver but would not properly complete the code.	Students might jump in the wrong direction, such as *jump up 1* or *jump right 1* (incorrect direction), which would not help Awbie get the final strawberry.

For our analysis of each item, we identified common debugging strategies (see Table 1). We then focused on results from these three items in terms of whether students identified a command that worked without bugs, a command that worked with bugs, or a command that did not complete the goal (i.e., would not result in Awbie collecting all of the strawberries; see Table 3). When students did not provide a command that worked without a bug, we categorized their bugs into incorrect movement actions, direction arrows, numbers, or a combination of those. For example, students might use the wrong movement (e.g., a jump instead of a walk) or use an extra movement (e.g., insisting two commands were missing). For direction bugs, students either did not specify a direction or gave a wrong direction. For number bugs, students either had Awbie move too little (e.g., walk one space when he should walk two spaces; number too little) or too much (number too much). Some students skipped an item or insisted the missing code went in a different location in the program. If a movement or number resulted in Awbie hitting a bush or tree but still completed the goal of collecting all of the strawberries, we considered this as working with faulty code. After categorizing the bugs, we then investigated how students' commands and bugs differed among the items and how they changed over time, focusing our discussion of results on the pretest and posttest.

Findings

Across the pretest and posttest, students used several debugging skills as they attempted to identify a command that would work in the missing command programming items. For the first command missing item, students primarily relied on *pattern matching* and thought Awbie would only need to walk up 1. However, some students would *trace the code* by simulating the movement of Awbie on the paper as they figured out or checked the program. For example, on the first command missing item, Goat5, a female third grader, originally traced the code and said, "It would be *go* [walk] *up* (with the one implied), and then he'd go up." With her finger, she motioned Awbie moving up one space to the first strawberry and then showed his next movement would be jumping left over the small bush to another strawberry (see Table 3) while saying, "Jump, and then, it doesn't." At this point, she used an *understanding the code* debugging strategy and realized continuing the code would not allow Awbie to get the strawberry at the top, so she revised her initial command and said, "It [walk up] does have a number. Two."

On the middle command missing item, students often *traced* the beginning half of the code but then wanted to *reprogram* Awbie so that he would walk all the way down instead of stopping part way. Sometimes students suggested a programming command that would result in faulty code but would still result in Awbie collecting all of the strawberries. For example, on the middle command missing item, Horse8, a female third grader, used *pattern matching* by quickly indicating that Awbie should "go here" and pointed to the missing strawberry. She then moved her finger along the square to count the spaces he would move–including the spot where Awbie would be standing before moving–getting three (instead of two). As a consequence, she qualified her statement of how Awbie should move by indicating he would have to move three spaces. If Awbie would move three spaces to the left as the missing command, he would bounce off of the trees (what we could consider a bug), but he would still complete the rest of the code.

On the last command missing item, students primarily used a *tracing the code* debugging strategy. In some cases, students did so incorrectly, resulting in them choosing a missing command that would not complete the program correctly. For example, Robin1, a male first grader, traced Awbie walking left 1 and walking down 3. However, when tracing how Awbie jumped right 2, he only jumped once (perhaps thinking a jump of two was moving two spaces). He then walked up one but still had two strawberries left. Therefore, for the missing code, he thought Awbie would still need to jump right and then walk down.

Overall, from pretest to posttest, all students improved in correctly identifying a command for the missing command across all three items (see Table 4). The largest gain was for the last command missing item (first graders: 25%, third graders: 34%, and total: 29%).

Table 4
Percent of Students' Responses with Commands Working without Faulty Code (with Faulty Code) on Pretest and Posttest Missing Command Programming Items

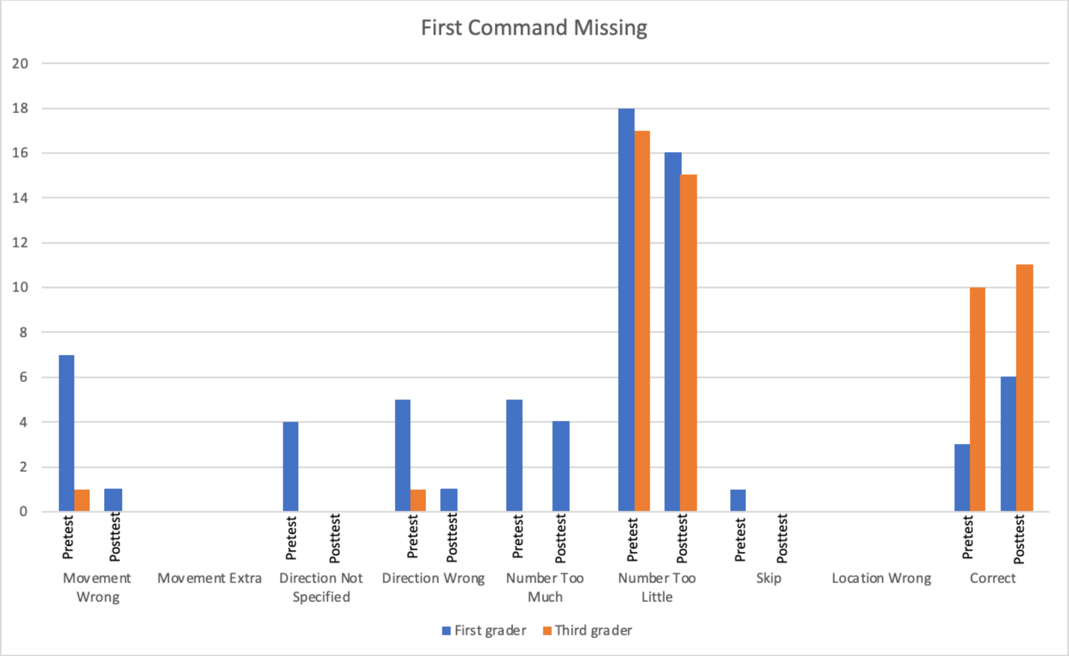
	Grade level	First command missing	Middle command missing	Last command missing
Pretest	First graders (*n* = 28)	14% (25%)	21% (28%)	4% (11%)
	Third graders (*n* = 27)	37% (37%)	15% (26%)	22% (41%)
	Total (*N* = 55)	25% (30%)	18% (27%)	13% (26%)
Posttest	First graders (*n* = 28)	21% (32%)	36% (43%)	29% (36%)
	Third graders (*n* = 27)	41% (41%)	41% (45%)	56% (71%)
	Total (*N* = 55)	31% (36%)	38% (43%)	42% (53%)

Note. Percentages in the parentheses represent students' responses with commands working with bugs.

On the pretest, across the three items, students were most likely to identify the correct command (without bugs) on the first command missing item. There were interesting differences between the types of bugs students made among the three items (see Figures 1, 2, and 3). In particular, when the first command was missing, students typically thought they only needed to move Awbie up one space instead of two (i.e., *number too little* bug). Once they saw that moving up one space would work with then jumping left, they were less likely to continue tracing through all of the code (see Figure 1). Interestingly, this trend did not change much by the posttest.

Figure 1

Number of Coding Choices Made on the Pretest and Posttest First Command Missing Item



On the middle command missing item, students were most inclined to program Awbie to continue walking downward on the pretest (and even more so on the posttest). Therefore, they both had the direction wrong but also thought they only needed to move Awbie one space (see Figure 2). On the last command missing item, students had difficulties with the direction, movement, and number. The difficulties with the last command missing item, particularly on the pretest, was that students' varied interpretation of the code led them to trace the code differently. Interestingly, the third graders had a few students on the last command missing problem who programmed Awbie to jump left 2 (instead of jump left 1), which worked with faulty code (since Awbie jumps too far to the left after collecting the last strawberry). First graders continued to struggle with the direction.

Figure 2

Number of Coding Choices Made on the Pretest and Posttest Middle Command Missing Item

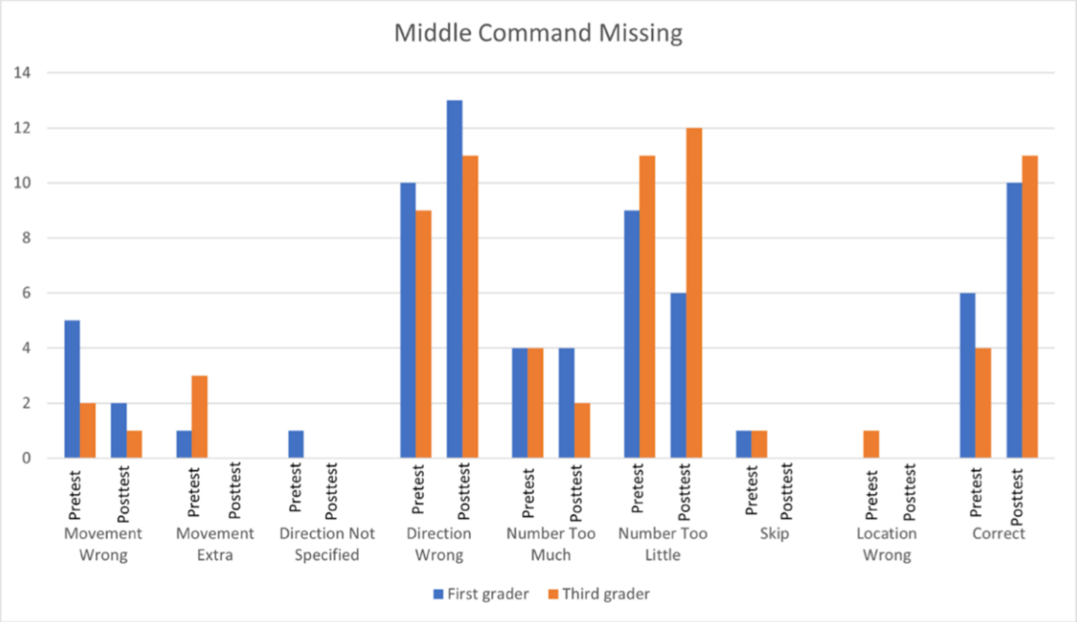


Figure 3
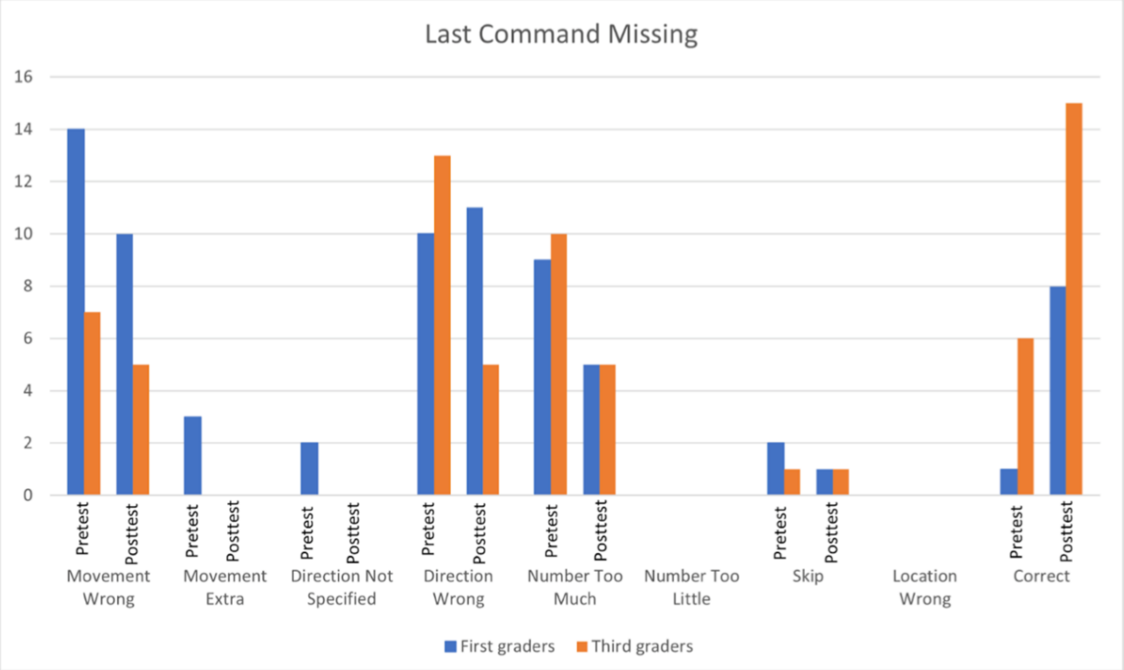
Number of Coding Choices Made on the Pretest and Posttest Last Command Missing Item



Discussion and implications

Overall, our study extends the work around young students' problem solving and debugging skills when they begin to learn to program. The results from this study indicate that young students' efforts to debug might depend on several conceptual factors, including which types of movements they need to debug, whether they can change surrounding code, and whether the bug (in our case, missing code) occurs at the beginning, middle, or end of the program. Students may have had more difficulty with the last command missing item on the pretest because they had to interpret a lot more code before determining the missing command, providing insight into their understanding of the code (e.g., Hanna, 2015). The missing middle command item was initially difficult for many students because they wanted to reprogram the entire end of the program. By the posttest, they had more experience debugging their own code, which may have made it easier for them to figure out a piece in the middle of the program. We were surprised to see that there was little improvement from pretest to posttest when the first command was missing. Students who continued to struggle might benefit from more explicit encouragement to trace their code (e.g., Murphy et al., 2008) to make sure their programs work beyond the first few lines of code. Tracing the code with the actual coding pieces might also help those students who indicate the wrong direction of movement (particularly if the difficulty was with right versus left directions). Having the coding pieces could illuminate if the direction they picked and the word they used to describe the direction align. Finally, some students, especially on the last command missing item had Awbie jump to the left two times instead of one. Their choices might have resulted from not understanding how the jumps work or because they counted different squares. In either case, having the option to run the code in the game environment could help students receive feedback on their debugging efforts.

Although in our study students identified the missing code during individual interviews, having students discuss the items in a whole class setting could help them pay attention to different parts of the code and support their problem solving and debugging. In particular, some students wanted to change the program to work around the missing code (i.e., similar to revising the goal, Dahn & DeLiema, 2020). Students could provide reasoning for their choices of the missing code or how the remaining code could be changed, and their peers could agree or disagree. Such sharing could illuminate situations, such as with the middle code missing, where there are multiple correct answers (i.e., walk left 2 versus jump left 1). Such discussions would also provide the opportunity to have students compare and discuss the differences between using a walk and a jump command within the programming game.

Research as Relational: Stories of Ever-Present Learning Between Undergraduate Research Interns and Project Researchers

Abstract: This paper consists of two stories that span three years of a learning sciences research project in order to demonstrate how 1) participating in this project shifted how undergraduate interns understood themselves as researchers and as practitioners within our project—and in other communities—in relation to our shared research; and 2) in turn, how the research practices in our project community shifted in relation to their participation. We leverage Lave and Wenger's (1991) legitimate peripheral participation framework as a way of showing how the learning and becoming of "newcomers" in a research community of practice can influence research practices within that community. As stated in the ISLS 2023 conference theme, this analysis helps us consider expansive ways in which we might want to "sustain our community" so we are becoming a community of practice where we make space for supportive and generous forms of relationality.

Introduction

According to Lave and Wenger (1991) learning is relational, becoming, and always happening. That means as researchers, our ever-developing practices of inquiry support learning as we grow and change with others. We take Lave and Wenger's statements to heart to reflect on what it means for a community of learning scientists working on a shared project to learn with undergraduate interns as "newcomers" to this community. In particular we consider relations between learning and identity at the intersection of multiple, sometimes conflicting, communities of practice in the context of the Participating in Literacies and Computer Science (PiLa-CS) project. We tell two stories that span three years of the project to demonstrate how 1) individual undergraduates' becomings in a learning sciences research community influenced their identity development in and across disciplinary contexts (e.g., creative writing and social science research) and 2) these newcomers' shifts influenced what counted as research practice in our community. Thus, we consider the importance of how our learning and becoming is intertwined through research.

Our stories feel important for learning scientists to contend with as we engage in research with newcomers all of the time, and as a field we are striving to broaden the ways of knowing and becoming that we engage in in our own research practices (Bang & Vossoughi, 2016; Zavala, 2016) in order to "sustain our community." Internships especially serve as a vector for communicating what it means to be a researcher, who is meant to take up that role, and what they are allowed to do as one. An exploration of the process of becoming a researcher and engaging in research from the perspective of individuals with marginalized identities in the field is critical to reckoning with how gatekeeping prevents the growth of new and established researchers and the community as a whole (Tanksley & Estrada, 2022). Tanksley and Estrada's work focuses on the ways in which the prioritization of whiteness as property and source of power affects the perceived legitimacy and authority of Women of Color researchers within Research Practice Partnerships. Our paper borrows the insider-outsider perspective to analyze how practices from other communities that are not held in esteem within typical research communities can change the course and character of the research done within a project when they are instead viewed as worthwhile and valid.

Analytic framework

Lave and Wenger's (1991) legitimate peripheral participation (LPP) as a theory of learning disrupts many of the common conceptions of what learning is and how it happens. First, and most importantly, it posits learning as inherent in social practice, as opposed to an outcome of deliberate teaching. This means learning is *always* happening, whether there was an intention to teach or not. As learning is not the direct consequence of intentional teaching, what is learned in any given situation may not be at all related to what was intended to be taught. In this way, learning unrelated to a teacher's intentions becomes more visible during analysis. For example, undergraduate interns on a research project might pick up on ideas that it is possible and necessary to remove their biases from field observation, thus sanitizing the context provided by their own identities or experiences. Additionally, LPP rejects the idea that knowledge can be abstracted, and that learning is about the acquisition of pure or "general" knowledge that can be applied in any and all situations. So even the proposition that one can "write objective field notes" is impossible according to these scholars. Instead, Lave and Wenger argue that all knowledge is situated in both the context in which it was learned and the specific circumstances in which it is applied, in contrast to theories of learning that posit that learning is the collecting of concrete knowledge in the brain. LPP focuses on learning as a result of the interaction between the people that are present as a community of practice. It is their interactions with each other that causes learning to occur. Thus, LPP asserts that learning is relational.

Lave and Wenger (1991) also put forth the notion that learning is becoming: that learning causes shifts in an individual's identity as they move from newcomer to old-timer, and since learning is *always* a result of social practice, a learner's identity is also always shifting. Furthermore, being a newcomer to a community of practice means that the assigned tasks may be simpler and much lower stakes, yet no less useful than those of a full participant and still contribute to the practice as a whole. On a larger scale, communities of practice shift their overall identity in the same way: as strangers are added to the community in the form of newcomers, they bring their own identities and practices to the pool, thus shifting the identity of the community as a whole. These new ideas sometimes align with those of the old-timers, and sometimes do not. Communities of practice often strive for continuity of shared practices, but the fact that old-timers are constantly replaced by "newcomers-turned-old-timers" guarantees a shift in practices as time goes on. Thus conflict between ideas and practices arise, and it is up to both newcomers and old-timers— who invariably need each other in order to maintain the community of practice, making their paths inextricably intertwined— to negotiate the shared future of their community. As we take the time to reflect on the sustainability and future directions of the learning sciences, we find Lave and Wenger's (1991) framework important for illuminating tensions between learning from the history and past practices within the field and our hope of expanding and shifting it towards more humanizing ends. In particular we seek to question the push to sanitize our humanity and perspectives from "sciences" in ways that work to separate them from our learning. When we understand learning as a form of becoming we can begin to conceptualize research as a process of learning in relation to and with others. As apprentices and mentors in the learning sciences, we seek to disrupt processes that assert the dominance of certain ways of knowing as rigorous and scientific and others as inferior.

Methods

Context

Our stories of learning come from the Participating in Literacies and Computer Science (PiLa-CS) project. PiLa-CS is an NSF funded grant that began in 2017 focused on partnering with teachers to integrate CS into their classrooms in ways that explicitly support bi/multilingual learners in developing CS literacies. Over the past five years the research community on the project has consisted of faculty member PI and co-PI's, postdoctoral associates, graduate assistants, undergraduate interns, and teacher partners who have come and gone and shifted roles within the project (e.g., Sarane was one of the first undergraduate interns hired on the project and is now the only intern working on it, and Sara began as a graduate assistant, became a postdoctoral fellow, and is now a research scientist on the project). The majority of the interns who have been a part of the project's history have been Women of Color, while those who were not came from other often marginalized backgrounds. The project itself has also shifted its focus, beginning with working in classrooms with teachers to develop and utilize a curricular approach for their students to now working on building professional learning communities consisting of teachers who can support each other to do similar work. Interns have worked on ethnographic data collection in classrooms, animation and graphics for pedagogical videos, and co-design of curriculum with teachers for their classrooms. They have supported logistics, materials creation, and workshop design for year-round teacher professional development and for a summer professional learning community (PLC). Interns also created storytelling artifacts to reflect back to teachers their generative learning trajectories as equity-oriented CS educators (e.g. editing data from a summer PLC into documentary episodes about teachers' learning). Many also attended project team meetings and gave ongoing feedback on project activities and writing.

Our stories come from the first two authors' experiences. I (Sarane, first author) am a Black girl from the Bronx. I grew up with a love of storytelling that, with help from a strong interest in anime and Japanese culture, had grown to encompass a fascination with language and its usage in general. I came to the project in the fall of 2019 as a freshman creative writing major. While taking a class on the Structure of Modern English, my professor posted a flier recruiting undergraduate interns from CUNY and NYU for the PiLa-CS project. I didn't know any

Spanish, but I had spent four years learning Japanese, and specifically enjoyed learning about the structure of different languages and the way cultural values are reflected in grammar and vocabulary and vice versa. I had experience teaching Scratch during a previous internship, and this project seemed like an opportunity to delve further into language use in the everyday and how it can be used in creative or non-standard ways to convey ideas to each other, even across language barriers.

I (Lauren, second author) am a white, Jewish woman from the suburbs of Chicago. I grew up with a love for creatively communicating ideas whether it was choreographing dances, reading autobiographies written by funny women, or choreographing to chapters from the audiobook of Bossypants (Fey, 2011). I came to the project in the winter of 2022 as a postdoctoral associate, fresh off of defending my dissertation (there were three days between my defense and starting this job as a postdoc; it was a quick turnaround and a big transition). As I was hurtling towards finishing up my PhD, I was on the job market in the Fall of 2021 and came across the posting for a new PiLa-CS postdoc. I was interested in joining the project because of its focus on expanding the multimodal resources for STEM learning, related to my dissertation research which focused on expanding sensemaking resources in STEM learning through choreographic inquiry practices. During my interview for the position I was enamored by the way both (co)PI's and graduate students asked and rephrased questions in generous ways, giving me multiple opportunities to express my thoughts. I was excited at the prospect of doing important equity-focused work in STEM education and becoming a member of a community that respected and lifted up the voices and concerns of all participants regardless of "rank."

Data

Data for this analytic storytelling came from Sarane and Lauren's lived experiences as newcomers on the PiLa-CS project. As part of reflecting on our experiences we also referenced and reviewed documented reflections undergraduate interns left behind before their time on the project ended, artifacts interns created as members of the research team (e.g. documentary episodes, website text), and recruitment flyers – all created over three years of the project. Our stories were told in conversation with what we heard and read from our undergraduate collaborators. We wrote our stories down, shared them unedited, and in the process of sharing them made comments to each other. As detailed in the next section, the data for the paper was co-created between Sarane and Lauren in the fall of 2022 (after the incidents in both stories occurred) through writing and commenting on stories about our experiences as newcomers on the project and thus our methods for data construction and analysis became closely intertwined.

Data analysis

The analysis for this paper began with multiple meetings in which we (Sarane and Lauren) reviewed artifacts from undergraduate interns' participation on the project and reflected on our experiences as/with undergraduate interns on the project. We read previous interns' reflections and detected themes in these gifts, such as feeling valued in this community, identifying as a researcher and a disciplinary practitioner in another field (e.g. undergraduate major), thinking about their majors in new ways as a result of their internships, and becoming a lodestar for other Black and Brown students that looked like them. As we started to collect quotes from various interns surrounding these themes, we found ourselves returning to stories from when we first joined the project that we had told each other orally. It was clear to us that our experiences as and with undergraduate interns on the project were consequential in shaping certain research pathways and differed from the collection of quotes we had accumulated. Influenced by Sarane's experience and history as a creative writing major we chose to take a memoir approach to our storytelling (Cannady, 2015). Whereas autobiography, its counterpart, focuses on getting facts exactly right, often by fact checking them to assure accuracy, memoir focuses more on a person's memory of the event and how it made them feel. Thus, in memoir, the stories that are told are tied explicitly to the identity of the author and how they interpret the world around them, making them extremely personal. Drawn to our experiences as forms of analysis we each created a written version of the stories we had shared about our experiences as newcomers. We then swapped stories, leaving comments on the other's story that highlighted noticings about our learning on the project.

Our methods for storytelling put practices from memoir into conversation with practices prominent in autoethnography. Autoethnography is often used as a way to directly oppose methods of cultural research that seek to scrub the researcher from the narrative, thus hiding the biases and/or insights that are an inherent part of their perspective. Instead, autoethnographers, especially those from marginalized backgrounds, seek to both write and analyze stories about themselves that illuminate the many shades of their lived experiences, and connect their individual stories to larger cultural narratives in a way that sheds new light on them (Ellis, Adams, & Bochner, 2011). One important byproduct of memoir as a method of storytelling is that memoirs can sometimes be little worlds of their own, causing an interesting phenomenon to happen when they come in contact with other people's viewpoints. In the work that inspired our methodology, Jennifer Lundan's *Evidence in Track Changes* (2016), this dissonance between the viewpoint of the author and that of her mother, who experienced the same moments but came away with a much different interpretation of them, became part of the text through her mother's comments on her writing. Even though their viewpoints contradicted each other often, neither were false, creating conflicting yet equally true realities. Our stories don't conflict, but our different perspectives and life experiences provide for rich observations when they come in contact with each other. Sarane's story took place three years ago in the fall of 2019, when she was still a newcomer to the project, while Lauren's story was more recent (only 9 months ago in the winter of 2022), when she was a newcomer and Sarane was a more established member of the project. Commenting on each other's stories allowed us to bring our various expertise in conversation with each other in a way that allowed us to be newcomers and old-timers at the same time. Since our stories were about times in the project when we were newcomers, comments allowed us to share perspectives gained since we became older-timers in this and other communities.

Findings

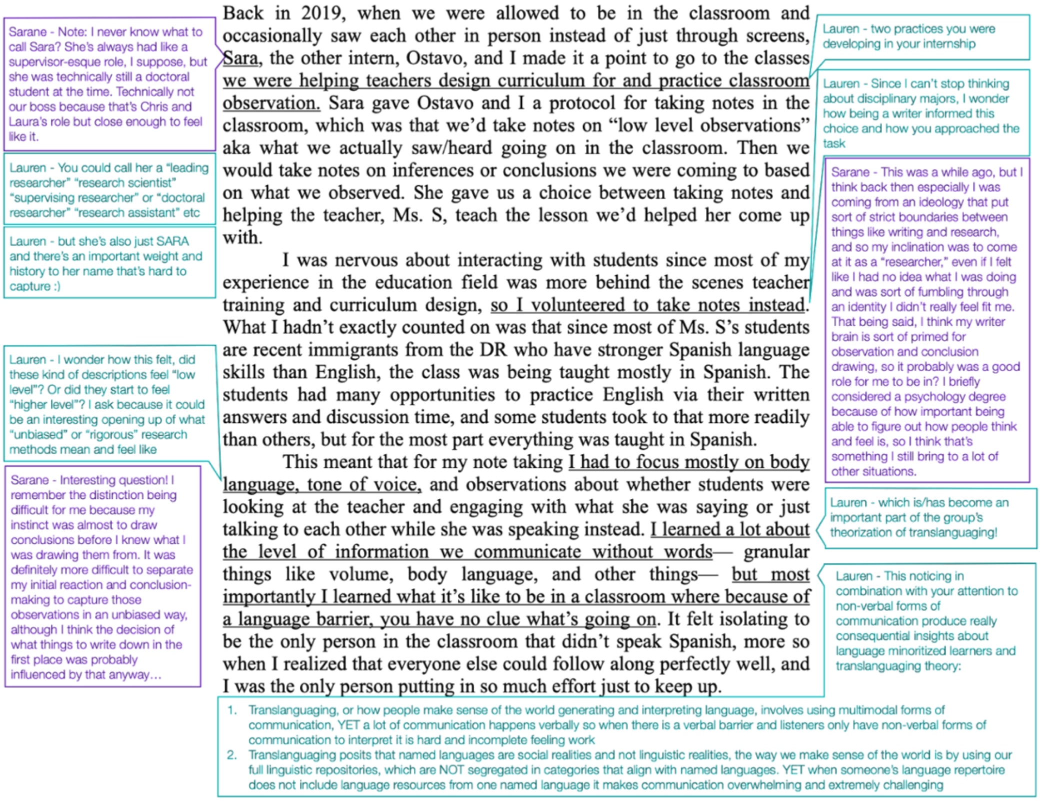
Our findings consist of two stories with commentaries told and responded to by Sarane and Lauren. These unedited stories come from times when we were newcomers to the project, negotiating personally and communally what it meant to be a researcher and research in this particular community of practice. We encourage you to read through the stories in the following figures in any way that you please (Toliver, 2021) (1). This might entail reading through the primary, center story text once and then reading again and stopping to attend to comments as they pop up, or reading through both in a first pass. Both the stories and the dialogue through the comments are meant to be engaged with.

Story 1: Sarane's first experience as a researcher in the field

Sarane's story is about her first time conducting observations in a classroom with the research team in the fall of 2019, a moment that was consequential for her in coming to identify as a researcher and thinking about the phenomenon of study on the project (bi/multilingual learners' experiences in CS classrooms). You can find this story in Figures 1 & 2 along with Lauren's commentary and a few responses to these comments from Sarane (1). At this point we recommend reading story 1 as it is shared in Figures 1-2.

Figure 1

Sarane's story with commentary from Lauren and responses from Sarane (Part 1)



Back in 2019, when we were allowed to be in the classroom and occasionally saw each other in person instead of just through screens, Sara, the other intern, Ostavo, and I made it a point to go to the classes we were helping teachers design curriculum for and practice classroom observation. Sara gave Ostavo and I a protocol for taking notes in the classroom, which was that we'd take notes on "low level observations" aka what we actually saw/heard going on in the classroom. Then we would take notes on inferences or conclusions we were coming to based on what we observed. She gave us a choice between taking notes and helping the teacher, Ms. S, teach the lesson we'd helped her come up with.

I was nervous about interacting with students since most of my experience in the education field was more behind the scenes teacher training and curriculum design, so I volunteered to take notes instead. What I hadn't exactly counted on was that since most of Ms. S's students are recent immigrants from the DR who have stronger Spanish language skills than English, the class was being taught mostly in Spanish. The students had many opportunities to practice English via their written answers and discussion time, and some students took to that more readily than others, but for the most part everything was taught in Spanish.

This meant that for my note taking I had to focus mostly on body language, tone of voice, and observations about whether students were looking at the teacher and engaging with what she was saying or just talking to each other while she was speaking instead. I learned a lot about the level of information we communicate without words— granular things like volume, body language, and other things— but most importantly I learned what it's like to be in a classroom where because of a language barrier, you have no clue what's going on. It felt isolating to be the only person in the classroom that didn't speak Spanish, more so when I realized that everyone else could follow along perfectly well, and I was the only person putting in so much effort just to keep up.

Sarane - Note: I never know what to call Sara? She's always had like a supervisor-esque role, I suppose, but she was technically still a doctoral student at the time. Technically not our boss because that's Chris and Laura's role but close enough to feel like it.

Lauren - You could call her a "leading researcher" "research scientist" "supervising researcher" or "doctoral researcher" "research assistant" etc

Lauren - but she's also just SARA and there's an important weight and history to her name that's hard to capture :)

Lauren - I wonder how this felt, did these kind of descriptions feel "low level"? Or did they start to feel "higher level"? I ask because it could be an interesting opening up of what "unbiased" or "rigorous" research methods mean and feel like

Sarane - Interesting question! I remember the distinction being difficult for me because my instinct was almost to draw conclusions before I knew what I was drawing them from. It was definitely more difficult to separate my initial reaction and conclusion-making to capture those observations in an unbiased way, although I think the decision of what things to write down in the first place was probably influenced by that anyway…

Lauren - two practices you were developing in your internship

Lauren - Since I can't stop thinking about disciplinary majors, I wonder how being a writer informed this choice and how you approached the task

Sarane - This was a while ago, but I think back then especially I was coming from an ideology that put sort of strict boundaries between things like writing and research, and so my inclination was to come at it as a "researcher," even if I felt like I had no idea what I was doing and was sort of fumbling through an identity I didn't really feel fit me. That being said, I think my writer brain is sort of primed for observation and conclusion drawing, so it probably was a good role for me to be in? I briefly considered a psychology degree because of how important being able to figure out how people think and feel is, so I think that's something I still bring to a lot of other situations.

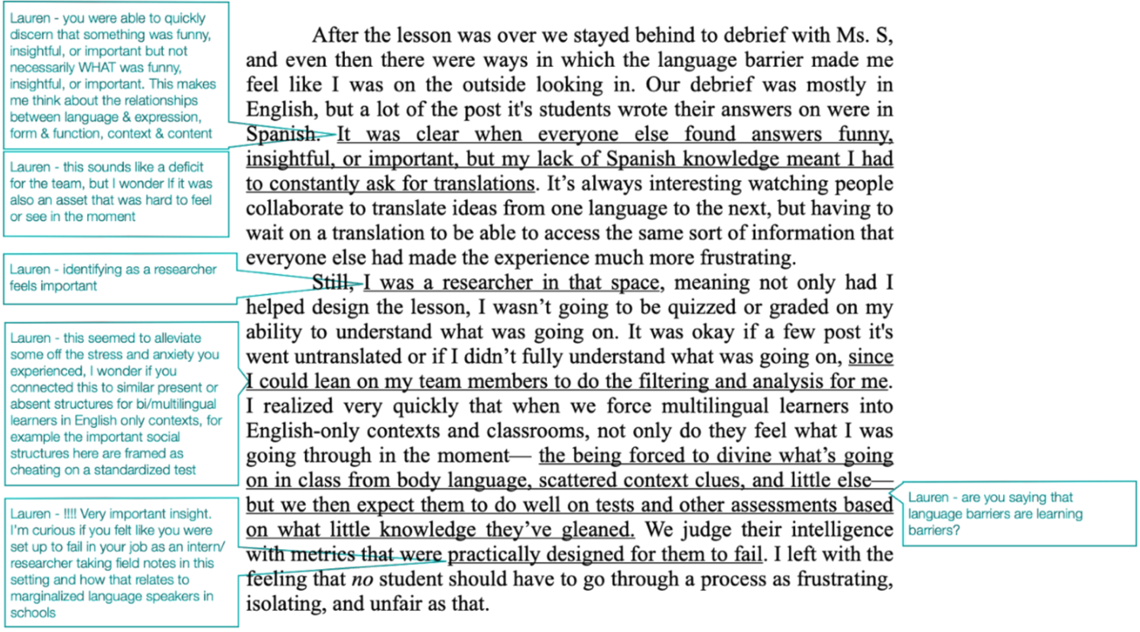
Lauren - which is/has become an important part of the group's theorization of translanguaging!

Lauren - This noticing in combination with your attention to non-verbal forms of communication produce really consequential insights about language minoritized learners and translanguaging theory:

1. Translanguaging, or how people make sense of the world generating and interpreting language, involves using multimodal forms of communication, YET a lot of communication happens verbally so when there is a verbal barrier and listeners only have non-verbal forms of communication to interpret it is hard and incomplete feeling work
2. Translanguaging posits that named languages are social realities and not linguistic realities, the way we make sense of the world is by using our full linguistic repositories, which are NOT segregated in categories that align with named languages. YET when someone's language repertoire does not include language resources from one named language it makes communication overwhelming and extremely challenging

Figure 2

Sarane's story with commentary from Lauren and responses from Sarane (Part 2)



Lauren - you were able to quickly discern that something was funny, insightful, or important but not necessarily WHAT was funny, insightful, or important. This makes me think about the relationships between language & expression, form & function, context & content

Lauren - this sounds like a deficit for the team, but I wonder If it was also an asset that was hard to feel or see in the moment

Lauren - identifying as a researcher feels important

Lauren - this seemed to alleviate some off the stress and anxiety you experienced, I wonder if you connected this to similar present or absent structures for bi/multilingual learners in English only contexts, for example the important social structures here are framed as cheating on a standardized test

Lauren - !!!! Very important insight. I'm curious if you felt like you were set up to fail in your job as an intern/ researcher taking field notes in this setting and how that relates to marginalized language speakers in schools

After the lesson was over we stayed behind to debrief with Ms. S, and even then there were ways in which the language barrier made me feel like I was on the outside looking in. Our debrief was mostly in English, but a lot of the post it's students wrote their answers on were in Spanish. It was clear when everyone else found answers funny, insightful, or important, but my lack of Spanish knowledge meant I had to constantly ask for translations. It's always interesting watching people collaborate to translate ideas from one language to the next, but having to wait on a translation to be able to access the same sort of information that everyone else had made the experience much more frustrating.

Still, I was a researcher in that space, meaning not only had I helped design the lesson, I wasn't going to be quizzed or graded on my ability to understand what was going on. It was okay if a few post it's went untranslated or if I didn't fully understand what was going on, since I could lean on my team members to do the filtering and analysis for me. I realized very quickly that when we force multilingual learners into English-only contexts and classrooms, not only do they feel what I was going through in the moment— the being forced to divine what's going on in class from body language, scattered context clues, and little else— but we then expect them to do well on tests and other assessments based on what little knowledge they've gleaned. We judge their intelligence with metrics that were practically designed for them to fail. I left with the feeling that *no* student should have to go through a process as frustrating, isolating, and unfair as that.

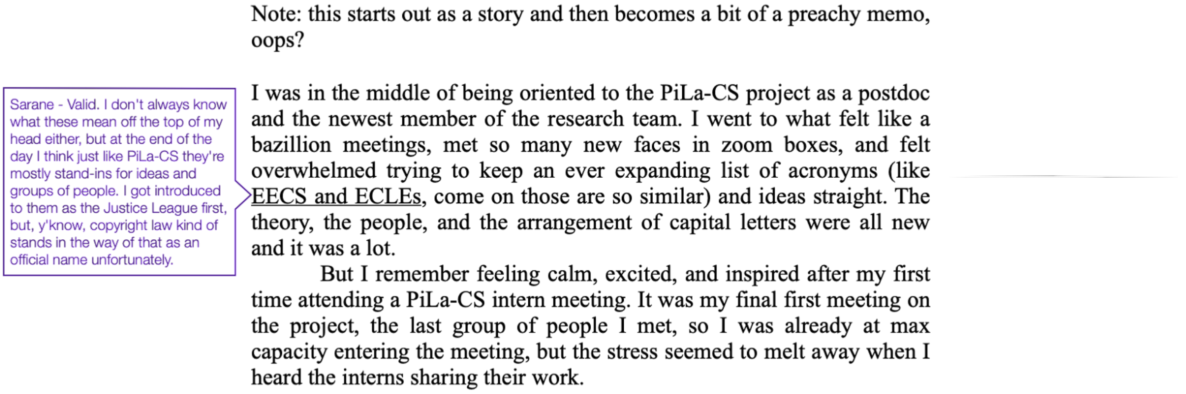
Lauren - are you saying that language barriers are learning barriers?

Story 2: Lauren's first introduction to the project's undergraduate interns

Our second story comes two and a half years after Sarane's first experience in the field as a researcher when Lauren joined the project as a postdoc, meeting Sarane and the other undergraduate interns for the first time during one of their weekly intern check-in meetings. You can find this story in Figures 3-5 along with Sarane's commentary (1). At this point in time we recommend reading story 2 as it is shared in Figures 3-5.

Figure 3

Lauren's story with commentary from Sarane (Part 1)



Note: this starts out as a story and then becomes a bit of a preachy memo, oops?

Sarane - Valid. I don't always know what these mean off the top of my head either, but at the end of the day I think just like PiLa-CS they're mostly stand-ins for ideas and groups of people. I got introduced to them as the Justice League first, but, y'know, copyright law kind of stands in the way of that as an official name unfortunately.

I was in the middle of being oriented to the PiLa-CS project as a postdoc and the newest member of the research team. I went to what felt like a bazillion meetings, met so many new faces in zoom boxes, and felt overwhelmed trying to keep an ever expanding list of acronyms (like EECS and ECLEs, come on those are so similar) and ideas straight. The theory, the people, and the arrangement of capital letters were all new and it was a lot.

But I remember feeling calm, excited, and inspired after my first time attending a PiLa-CS intern meeting. It was my final first meeting on the project, the last group of people I met, so I was already at max capacity entering the meeting, but the stress seemed to melt away when I heard the interns sharing their work.

Figure 4

Lauren's story with commentary from Sarane (Part 2)

I don't remember all of the details, but I remember Danielle, a NYU film major at the time, shared an episode of the documentary she was working on for the project. Danielle had edited clips from project data in a teacher PD into a public facing documentary episode to share how teachers got to know their students and their students' language practices. Maybe it was Danielle's calm demeanor, or the soothing music she had chosen as the backdrop to the episode that helped ease any uneasiness I was feeling at the time, or maybe it was the clear evidence of how careful and thoughtful she had been with the responsibility of telling teachers' stories, the way she allowed the care teachers brought to their practice to shine on the screen. The care put into this video (am I using the word care too much?) made me feel like I was in good hands myself in this community.

Sarane - Wendy's intention from day 1 as part of the team has been about telling marginalized peoples' stories in ways that is both respectful to them and values their input above all else, and is in conversation with ideas of storytelling as a form of protest that have been developed by Latinx artists and thinkers called testimonios. Her insight into building off that work respectfully have been integral to the team as we share the stories of our teachers, and I think no one has taken up that mantle more than Danielle and her documentary episodes. There was a lot of pressure and expectation (and love and support, obviously) surrounding what we hoped to get out of these videos and I think she took all of that and made something really beautiful!

My jaw was on the floor, this was beautiful, this was amazing. The conversations the team was having about how to tell these teachers' stories in clear and nuanced ways were just wonderful. Artistic research was being leveraged as academic research. Documentary filmmaking and editing are both artistic and research practices, something that I value myself and always try to bring out in my research on dance, choreography, and STEM learning. My new community not only got it but was making it happen in such meaningful ways. I was in awe, I felt like I belonged, and that there was a lot for me to learn in this space.

Sarane - I think I'm the sort of person who has grown up around a love of science and exploration my whole life. My mom used to buy those kiddy science kits and do the experiments with my brother and I as a kid, and my (brother's, technically) godmother gave me a real microscope and beakers and stuff like that as gifts. I think, especially going to a school like Bronx SCIENCE that valued science and math more than other things, I got really jaded about the positionality of the humanities vs the sciences in our society? So my instinct whenever I get told a "truth" about the sciences-- for instance, what should or shouldn't count as computer science-- my first instinct is always to push back against it. I think it's felt like "fighting" the idea of academic research, but seeing it posited almost as a different approach, a new way of getting at the same thing, feels... good? Yeah.

Sarane - I guess the point of my whole big comment above is that the thing you clocked instantly didn't feel to me like we were using art as research? Not that we WEREN'T doing that, but to me it felt like as much as we call it a research-practice partnership, and we had to go through the whole research certification process to work with kids and such, it still felt to me almost like we were being allowed a space to do artistic things where we would usually be made to do research instead. And I think the fact that your perspective allows both the research and the art to be one and the same and starts from a place where they're equally valuable is really amazing.

After being introduced to every corner of this project I confidently discerned that the most innovative work on the project was coming from undergraduates who were supported and given space to bring their passions and expertise to the project as forms of valued and rigorous research.

Over time as I got to know the interns and their work better I came to see how not only were their developing perspectives and expertise supporting the aims of the PiLa-CS research, but their involvement in the project was supporting their own development. I found this particularly striking with respect to their majors in school for Danielle the film major, Kyla the Computer Science major, and Sarane the creative writing major.

Sarane - Capitalization

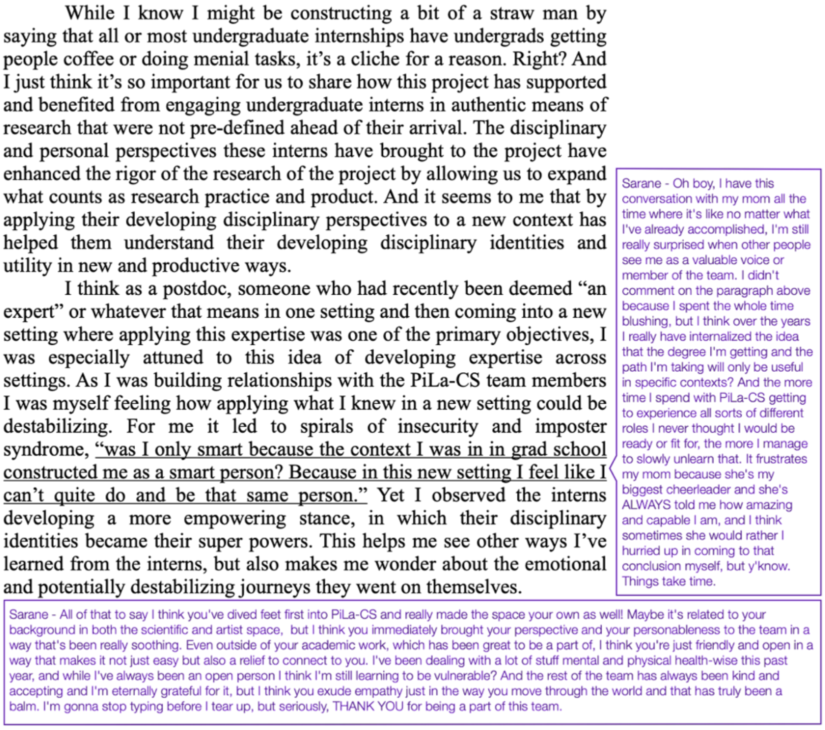
While Danielle was crafting documentary episodes, Kyla and Sarane were supporting a middle school teacher with curriculum development for her after school coding club. The ethical dimensions of coding were an important concern in the development of this curriculum as the teacher wanted to center what students cared about in the unit. Kyla saw a significant disconnect between the CS curriculum she was carefully developing and the CS curriculum she was experiencing herself as an undergraduate CS major. She openly questioned and critiqued her own course requirements, sharing that she felt like there was a big hole in the ethics of coding and becoming a coder in her own course requirements. How can a university turn out so many coders without ever asking them to consider the ethics of their work?

Sarane - Again related to the essay I wrote in the comments above (oops), but this is the thing about the way we talk about science majors. Obviously I'm not one myself so I don't know what those conversations are like from the inside outside of my high school experience, but there's almost this feeling like "what we're doing is smart and noble and important and things like English or philosophy or literature are a waste of time," and I think it creates this environment where it's OKAY to not think about ethics or the real-life affects of your work on different populations as long as you're creating something innovative and new. And it feels like you SHOULD be taught to value history classes, or English literature, or even philosophy, because how else are you supposed to know the historical ways in which tech and innovation has hurt people and thus avoid replicating it yourself? Then again, if you don't care who you hurt, then what do those things matter?

And last but not least Sarane, the heart and soul of the intern community and one of the longest running members of the research team was one of the most insightful thinkers I have been lucky enough to work with. It was and continues to be a common occurrence that Sarane's utterances are written down as key insights, or sometimes were even recorded as explanatory footage for Danielle's documentaries. When Sarane speaks everyones' ears perk up with extra attentiveness because we know her ideas are insightful and generative. This positioning, however, does not necessarily match Sarane's disciplinary expectations. She has shared with the project on multiple occasions that as a creative writing major her mentors have told her that she only has two relevant career options: (1) become an academic or (2) work in publishing. Yet on PiLa-CS her expertise as a writer has helped the research team in multiple ways from her insights as a collaborator to her written work on our website to share the meaningful stories from the project with others.

Figure 5

Lauren's story with commentary from Sarane (Part 3)



While I know I might be constructing a bit of a straw man by saying that all or most undergraduate internships have undergrads getting people coffee or doing menial tasks, it's a cliche for a reason. Right? And I just think it's so important for us to share how this project has supported and benefited from engaging undergraduate interns in authentic means of research that were not pre-defined ahead of their arrival. The disciplinary and personal perspectives these interns have brought to the project have enhanced the rigor of the research of the project by allowing us to expand what counts as research practice and product. And it seems to me that by applying their developing disciplinary perspectives to a new context has helped them understand their developing disciplinary identities and utility in new and productive ways.

I think as a postdoc, someone who had recently been deemed "an expert" or whatever that means in one setting and then coming into a new setting where applying this expertise was one of the primary objectives, I was especially attuned to this idea of developing expertise across settings. As I was building relationships with the PiLa-CS team members I was myself feeling how applying what I knew in a new setting could be destabilizing. For me it led to spirals of insecurity and imposter syndrome, "was I only smart because the context I was in in grad school constructed me as a smart person? Because in this new setting I feel like I can't quite do and be that same person." Yet I observed the interns developing a more empowering stance, in which their disciplinary identities became their super powers. This helps me see other ways I've learned from the interns, but also makes me wonder about the emotional and potentially destabilizing journeys they went on themselves.

Sarane - Oh boy, I have this conversation with my mom all the time where it's like no matter what I've already accomplished, I'm still really surprised when other people see me as a valuable voice or member of the team. I didn't comment on the paragraph above because I spent the whole time blushing, but I think over the years I really have internalized the idea that the degree I'm getting and the path I'm taking will only be useful in specific contexts? And the more time I spend with PiLa-CS getting to experience all sorts of different roles I never thought I would be ready or fit for, the more I manage to slowly unlearn that. It frustrates my mom because she's my biggest cheerleader and she's ALWAYS told me how amazing and capable I am, and I think sometimes she would rather I hurried up in coming to that conclusion myself, but y'know. Things take time.

Sarane - All of that to say I think you've dived feet first into PiLa-CS and really made the space your own as well! Maybe it's related to your background in both the scientific and artist space, but I think you immediately brought your perspective and your personableness to the team in a way that's been really soothing. Even outside of your academic work, which has been great to be a part of, I think you're just friendly and open in a way that makes it not just easy but also a relief to connect to you. I've been dealing with a lot of stuff mental and physical health-wise this past year, and while I've always been an open person I think I'm still learning to be vulnerable? And the rest of the team has always been kind and accepting and I'm eternally grateful for it, but I think you exude empathy just in the way you move through the world and that has truly been a balm. I'm gonna stop typing before I tear up, but seriously, THANK YOU for being a part of this team.

Discussion conclusion

The structure of our methodology means the discussions around these stories are recursive. Each layer of analysis becomes fodder for new conversations, preserving our thoughts and feelings and allowing us to build on them in the future, serving as artifact and analysis at the same time. Similarly, LPP (Lave & Wenger, 1991) posits that shifts in identity and practices are related as the relationships between newcomers and old-timers change over time.

Undergraduate interns' shifts in identity inside and outside of our research

These stories helped us crystalize how undergraduate interns' identities with respect to our research community and to their "major discipline" communities shifted in relation to each other. For Sarane, her emerging identity as a researcher was in direct conversation with her identity as a writer. Some of these tensions came out in her story, sharing how when she first joined the project she felt "strict boundaries between things like writing and research." Yet, Lauren saw lots of connections between Sarane's practices as an established writer and emerging researcher, such as feeling most comfortable writing field notes but feeling conflicted about trying to remove her perspective and bias to take scientific, "objective" ones. Lauren wrote about how Sarane repeatedly shared the limited career paths she had been told were possible as an English major (teacher or publisher) and contrasted that with how Sarane's writing practices have been used to write material for PiLa-CS's website and for our methods in this analysis. Sarane is a central and successful member of the PiLa-CS research team, evidence that her writing practices can be generative and productive outside of those pathways. Lauren also shared how Kyla began to question why ethical considerations were taken into account in the CS curriculum she was co-developing for middle schoolers but not for undergraduates like herself. For Kyla, being a computer scientist now meant needing to think about the ethical implications of her work, and not having formal spaces to think about this in her coursework increasingly frustrated her. The confluence of multiple identities within the context of our research community led to the emergence of new, critical perspectives on disciplinary practices for the undergraduate interns such as Kyla's questioning of her university's CS curriculum and Sarane reclaiming the power of reinstating her perspective, "the I in research," into her academic writing.

Our research community's shifts in relation to undergraduate participation

The research practices we engaged in as a community also shifted. Sarane wrote about attending to body language when she felt lost on her first day of field work and Lauren commented on the connection between Sarane's experience and the PiLa-CS team's shifts in theorization: conceptualizing translanguaging in terms of a larger range of multimodal communicative resources (e.g., gesture, emojis) and not just verbal language use. The intern projects, such as Danielle's documentary episodes and Kyla's identifying as a CS teacher interactive timeline, also became new forms of analysis. These analytic artifacts had a meaningful impact beyond the usual formal academic papers in our project team and our dealings with practitioner partners. Seeing how teachers reacted to having their stories told back to them was a highlight from our PD work together. Lastly, the methods and structure of this paper developed out of changing research practices in our team as autoethnography morphed into writing memoir-like excerpts with each other.

As our practices grow and shift so does our attunement to the importance of relationality in learning. We found while engaging in these new research methods that what we shared became more personal, making salient parts of ourselves that had not seemed so before. This was present when Sarane shared stories about insecurities her mom tried to help her unlearn in response to Lauren sharing insecurities about her imposter syndrome in her story. Sharing and commenting on each other's stories was a vulnerable process that sometimes felt scary and uncertain. It took a lot of reassurance and conversations before we felt comfortable sharing them with each other, yet what came from our sharing and comments brought value to bringing our perspectives together. We reassured each other about our contributions to the team, whether theoretical or interpersonal, through our comments. In the process of crafting this paper we continued to grow and learn from each other because learning is always happening as a relational enterprise and thus new forms of relationality are always blossoming. We are excited at the prospect of cultivating these supportive and generous forms of relationality, something we feel should not be taken for granted in research contexts.

Conclusion

As Lave & Wenger (1991) posit, learning is relational, becoming, and always happening. Thus it is not a surprise that undergraduate interns' identity development in the context of their internship was tightly connected to observable shifts in research practices within our community of practice. Since internships are often vectors for communicating what it means to be a researcher, it is important for research communities to reflect on and make explicit how interns contribute to shifts in research practices. This has allowed us to collaboratively reimagine what counts as research using both the goals and experience of senior project members and the interests and expertise of interns. Senior members of the team trusted undergraduates as experts in their major discipline while also widening the potential applications of these disciplines, allowing their contributions to meaningfully affect the future of our community.

What Counts? Play as a Mechanism for Disrupting Participation Patterns in School Mathematics

Abstract: This paper explores how making space for mathematical play can disrupt existing participation structures in classrooms and create space for inclusive and robust mathematical engagement. We analyze one episode of children's play that involved counting and unitizing to measure a rocket created with Magna-Tiles, addressing two research questions: 1) How does children's collaboration during a playful activity contribute to mathematical activity? 2) How did one child (Quentin), who is often removed from mathematics, participate in this activity? Our findings reveal how the collective interactions that led to this moment involved Quentin's sustained engagement, which was outside the norm for him. Quentin was a full participant in the counting and unitizing episode and his thinking had status and was valued by others. This episode points to the possibilities of play as a transformative space that affords creates opportunities to engage in mathematics in ways that disrupt patterns of exclusion.

Introduction

The goal of this paper is to explore how making space for mathematical play can disrupt existing participation structures in classrooms and create space for inclusive and robust mathematical engagement. We situate this analysis in a collective moment of mathematical joy and rigor, which involved four playmates engaging in rich mathematical thinking. We examine how this moment emerged, and specifically, how the act of play—of exploring and sharing materials, and of posing one's own question for inquiry—contributed to this moment. To understand both the final moment and the trajectories of play that contributed to its development, we draw on literature about humanizing mathematics, about disrupting structural racism that leads to alienating participation practices, and about the potential of play for transforming engagement.

The focal moment occurred approximately one month into the school year, during a period of free play in a kindergarten classroom. The four students in analysis, Laura, Briona, Max, and Quentin, chose to play with Magna-Tiles, transparent 2-D shapes with magnets along the sides that can be joined. Throughout the episode, the children played both independently and together. However, one creation received the most attention and the most resources a tall "rocketship" built by Laura that required many magna tiles. About 10 minutes into their free play, taking a pause from his own creation, Max turned the group's attention towards Laura's rocket. What initially began as a single student's reaction to the grandeur of Laura's creation eventually evolved into a mathematically rich conversation involving all four students, as seen in the transcript below.

1 Max: Dude, this is a tall, it's a tall building! *(Looks at rocket and smiles).*
2 Briona: It's a toy rocket! *(Walks around K, touches top of rocket, and smiles. Returns to seat).*
3 Max: Wait so it has levels? *(Gestures at rocket).* The building has levels. One, two, three, four, five, six, seven. *(Points to each level of rocket for each counted number, then pauses).* Eight. *(Points to roof).* Eight levels! This thing has eight levels! *(Looks at Quentin and gestures towards rocket while smiling).*
4 Briona: It's eight levels cause it's a hotel. *(Looks at rocket).*
5 Quentin: One, two, three, four, five, six, seven. *(Touches each level of rocket, excluding roof, for each counted number).* Seven levels! *(Looks at Max).*
6 Max: I thought it was eight levels. *(Looks at Quentin).*
7 Briona: You're counting too much. *(Walks around Laura to rocket).* One, two, three, four, five, six, seven, eight. *(Touches each level of rocket, including roof, for each counted number).*
8 Laura: No that's the roof. *(Touches roof).* There's no layer to the roof. *(Turns to face other students).*
9 Briona: The roof don't count. *(Looks down at table).*

This moment was significant for several reasons. First was the *collective engagement*—all four students were involved in this conversation, exchanging ideas and taking turns, as seen in turns 3, 4, 5, 6, and 7. Second was the *mathematical content* of the students' discussion: counting that demonstrated one-to-one correspondence (turns 3, 5, and 7); and debating about minimally defining characteristics of a set (turns 8 and 9). Third was the fact that this occurred *independently and spontaneously*, as no adult was present, and the students were never asked to count (their only task was to play). And finally, was the *absolute joy* that was evident amongst the group. The students were smiling, laughing, and generally celebrating the eye-catching creation of their peer. It was a moment of mathematical joy, mathematical rigor, and legitimate mathematical inquiry.

This episode is also an instance of *disruption* of established participation practices in the classroom. In this class, math instruction typically involves working on prescribed tasks that are highly structured, with little space for spontaneous decision making. Thus, free mathematical play served to disrupt the typical practices around what it means to do math. Equally importantly, these different mathematical practices resulted in very different forms of participation for the students. Max, who is often quiet and hesitant to share what he knows, was talkative, engaged, and initiated the mathematical inquiry in the episode (turn 3). Quentin, who is frequently excused from the mathematical work of the class because his behavior is seen as disruptive, was engaged, collaborative, and offered his own mathematical expertise as a legitimate contribution to the group's discussion. In what follows, we consider how this spontaneous moment developed between the four students, and how it served to disrupt existing structures of what it means to do math, and who gets to participate in the activity.

Literature review and framing

Although play is acknowledged to be a crucial aspect of general well-being (Brown, 2009; Gray, 2011), and an important mechanism for learning (Vygotsky, 1967), it is also often dismissed as non-essential and is quickly removed as a consequence for bad behavior or to bolster instructional time (Chang & Coward, 2015; Jarrett et al., 1998; Massey et al., 2021). Consequently, play is becoming increasingly scarce in classrooms, even for the youngest kindergarten students. Although this is a problem for any subject, we argue that play in mathematics classrooms is particularly important to consider, as the discipline is often introduced in prescriptive ways that primarily focus on computation (Wager & Parks, 2014). This creates a challenge when supporting learning, for while prescriptive and streamlined activities are an efficient solution to the task of moving large numbers of students through many topics, it does not support students to develop robust number sense. Further, the practices that such approaches to teaching mathematics require, such as a focus on efficiency, speed, and memorization, are known to undermine students' enjoyment and deep understanding (Boaler, 2002; Boaler & Staples, 2008). In contrast, classrooms that offer time for exploration, that emphasize reasoning and understanding over accuracy and speed, and which place student identity at the center of instructional design, have been found to support a more productive relationship with the domain of mathematics (Grant et al., 2015; Gresalfi, 2009).

The mathematician Francis Su describes his own vision for mathematical engagement as follows: "I hope that…you can see yourself as a *mathematical explorer*, who can think in mathematical ways and who is welcome in mathematical spaces" (2020, p. 12). As Su and others explain, "expert" engagement with mathematics involves exploration, play, aesthetical judgement, and joy (Bergen, 2009)—terms that are not commonly associated with school mathematics. However, when students are invited to engage with mathematics in this way, they have opportunities to reason about the why of mathematics, to engage in the "call-and-response" of mathematics, when "…the mathematics calls out to the explorer and asks, 'What do you notice? What do you wonder?' and the explorer responds with an observation" (Su, p. 54).

Play not only offers the potential to disrupt mathematical practices, but it also can serve to disrupt who gets seen as mathematically capable. Many scholars have argued that mathematics classrooms are sites of white supremacy, offering narrow conceptions of what counts as mathematical excellence (Ladson-Billings, 1998), recognizing only some kinds of thinking and people as mathematically relevant (Joseph et al., 2017), and conflating mathematical aptitude with overall intelligence (Martin, 2019). While these practices interfere with students' likelihood of engaging with rich mathematics in general, they are particularly problematic for students of color, who are more likely to have less-qualified teachers (DeMonte & Hanna, 2014), to be removed from school by suspension (Gregory & Roberts, 2017), and to face stereotyped low expectations for their mathematical success (McGee & Martin, 2011; Nasir & Shah, 2011).

Analytic framework

This paper connects with the concept of play in two ways. In addition to grounding our analysis in studies of the potential efficacy of play, as described above, we also use the concept of play as an analytic framework to explore the potential of play as a productive practice. Specifically, we explore whether and how play offers a potential inroad to the question posed by Martin: "What can and should refusal of dehumanizing and violent mathematics education look like in principle and practice?" (2019, p. 461). This is also responsive to the proposal made by Joseph et al., (2019), who wrote: "A second area for further research is the idea of humanizing Black girls by creating a space for play—a place for them to be happy, gregarious, social, and "goofy" …. Our emerging analysis illuminates that when the Black girls in this study were afforded the opportunity to be both serious and silly, they were more engaged in mathematics learning" (pp. 149). However, before making the fundamental error of romanticizing children's activity, we note that play is not a panacea—it characterizes a form of human interaction that is fraught with the same perils, biases, and oppression that characterizes all interactions (Bryan, 2020). We know that children's play can be racist, mean, gendered, and exclusionary. Although it has the potential to liberate students from the conventions of the discipline, it by no means transcends the everyday structures that dictate our interactions. Therefore, even as we look for sites of potential disruption, we must stay vigilant at noticing the ways it might fail, lest we contribute to the continued reproduction of mathematics reform that ultimately serves to change nothing for students who are already being oppressed by its structures (Martin, 2019)

Although there is variation among the definitions of play, most involve characterizations of spontaneity, interest, choice, and pleasure (Brown, 2009; Burghardt, 2010). This is not to say that play is divorced from rules or constraints—part of what makes play enjoyable is the opportunity to explore in relation to a set of existing structures (Ginsburg, 2006). In this work, we define play as pleasurable activities where children can explore, engage with interesting materials and make choices. We use this understanding of play to explore how and why young children constructed their own rich mathematical engagement, and how, in doing so, they managed to include all members of their group in reaching a conclusion. We look at students' interest, their agency, their mathematical reasoning, and their emotions, to better understand whether and how situating mathematics in the context of play was ultimately productive for the group. In so doing, we ask the following questions:

1) How does children's collaboration during a playful activity contribute to discussions about the rocket?
2) How did one child, who is often removed from mathematics, participate in this activity?

To address these questions, we analyzed each student's specific contributions, both leading up to and during this episode, and how play afforded their collective mathematical engagement towards Laura's rocket.

Methods

Participants and context

This episode comes from the fourth day of co-designed "play lessons," which focused on the properties of shapes, part of a larger study about how early-grades teachers integrate play into their mathematics teaching. The teacher, Ms. Rosinsky, co-designed lessons that included whole-class introductions and reflections but predominantly centered on guided play centers, in which students engaged with playful mathematical materials. At the end of the lesson children were invited to choose a table and play with mathematical toys—no other instructions were given. Children played at these free play stations for approximately 15 minutes.

The four students in analysis, Laura, Briona, Max, and, Quentin, chose to play with Magna-Tiles. Laura is a white girl who was typically quiet but attentive in mathematics lessons. Brionna is a Black girl who generally worked independently, particularly during center work. Max is a Latino boy who was often reserved but engaged during mathematics activities. Quentin is a Black boy who was often called out for not paying attention or for disrupting his peers. In general, Quentin often spent time during math lessons at the back table, rather than sitting on the rug with the rest of the class engaging with the lessons. For example, in the activity before the free play episode, the children were participating in guided math centers. At his table, in response to other children who were making loud noises, Quentin started to yell, "QUIET! QUIET!" A moment later, the teacher came over to Quentin and guided him to a table on his own.

We collected data in two forms: observation notes and video. Observation notes served as the initial place we used to identify the focal moment, which was then selected for in-depth analysis collectively. Video was taken by a GoProMAX, a small camera which sat in the middle of the table and captured a 360-degree visual field. The video can be replayed either by flattening the image as you might unwind a sphere, or by swiveling the view in 360 degrees, seeing only a subset of the view at a time. We looked at the video first as a flattened view to see the entire group and then looked closely at each child. The episode lasted approximately 16 minutes, beginning with their first negotiations about play rules to the deconstruction of their creations during clean-up.

Analysis

The analysis began with all seven members of the research group and all five cooperating teachers watching the video. We discussed the instance and shared ideas about what was taking place in the video. These initial viewings confirmed that the instance of collective engagement felt important and interesting and was worthy of additional investigation. A smaller group used interaction analysis to analyze the video more closely, first developing an emergent set of inductive codes, and then a second set of inductive codes that we used to document the ways that children were working together, how they were working independently, and when and how their work came into contact, as depicted in Table 1. Our final analysis focused our view on the ways each child contributed to the final moment of "counting the levels," attending to the construction of the rocket, and the times and ways that different children felt that its size was worthy of commentary and documentation. Ultimately, we used this coding to tell a story of each of the four children and the ways their work came together.

Table 1

Final Set Of Codes Used To Examine Each Student's Contribution to Laura's Rocket

Resource Codes	Mathematics Codes	Intention Codes
Sharing	Counting	Articulating Plan
Grabbing	Discussing Unit of Measurement	Articulating Imagined Storyline
Protecting	Fitting	
Co-Building	Making Shapes	
	2-D Building	
	3-D Building	

Resource codes focused on the ways students shared, grabbed, and protected resources, and co-built alongside Laura. We also coded for each student's *mathematical* contributions, which included counting, discussing the unit of measurement, fitting shapes together, making shapes from other shapes, 2-D building, and 3-D building. Finally, we considered the ways students communicated their intentions by coding for moments when students articulated a plan or imagined storyline. From the codes, we crafted narratives of each student's trajectory towards the focal moment with Laura's rocket, which formed the basis of our conjectures about the participation practices and mathematical opportunities that their free play afforded.

Findings

We begin with a brief story of each of the four children, before turning our lens to their collective work.

Laura

When Laura sat down at the table, she immediately asked "Can we build together?" However, even as she was speaking, she slid a stack of squares over and placed them directly in front of herself and started to build. It appeared that Laura already had an idea in mind of what she wanted to do, as there was no observable exploration of shapes. Instead, she took several squares off the pile and arranged them into a net of five squares, which she then folded into an open-topped cube. Although she did not hesitate when laying down the 2D net, she did pause when folding up the sides (because Magna-tiles are magnetic, you must place the tiles adjacent to each other in order for them to stay up). For her first cube, Laura placed a square on top, then removed it. She then created a second cube using the same 2D net to 3D cube strategy, this first by counting off five squares from her pile of squares, and then time adding it on top of the first cube. She continued to build a tower using this method for every single level, stopping only to defend her resources or to secure the resources that she needed for the roof of the building. Laura's building required many Magna-Tiles, something that her group mates noted and challenged her about. Overall, despite Laura's expressed interest in working with her peers, much of her free play was characterized by single-minded determination. She rarely participated in conversation with the other members of her group, and stayed focused on her design until it was completed. After its completion, she was happy to engage with her peers and began to build with Brionna, before the group's attention turned to the height of her rocket.

Briona

From the onset of her free play experience, Briona consistently weaved in and out of her own Magna-Tile creation and Laura's rocket, which predominantly showed up in the form of sharing resources and protecting resources. Briona very quickly articulated her imagined storyline of constructing a three-dimensional garden house. This initially consisted of fitting large squares together to form a cube; however, as she approached the roof of her garden house, she realized the limited resources at her disposal and thus turned to the group to articulate her plan and elicit help. She stated, "I need four!" to her fellow playmates, but did not specify which shape. Therefore, Laura shared small squares and Quentin shared small triangles, but neither shared the large squares that Briona had been using up until that point. Briona explored with these shared resources by forming large squares from the small squares to construct the remaining side and roof of her garden house. This period of exploration was notable, as it led to a shift in Briona's original plan. In creating shapes, rather than already having large squares, she experimented with forming shapes from other shapes, eventually realizing that she no longer needed the small triangles that Quentin had shared with her. Consequently, Briona shared these triangles with Laura, who later sought this resource to complete the end of her rocket.

Briona was also instrumental in protecting Laura's resources. For example, as Briona worked on the roof of her garden house, she realized that she needed another small square, which Quentin then removed from Laura's rocket and placed on Briona's roof. Briona, however, quickly removed this piece and returned it to Laura's rocket. In other instances, Briona went so far as to create a physical barrier between Laura's rocket and the other students by putting her arms around the rocket to protect it from Quentin or Max. Although she was invested in her own garden house, she appeared equally invested in contributing to and protecting what Laura had created.

Max

Like Briona, Max's fluidity between independent and collaborative play also contributed to the focal moment of analysis. Of the four students, Max took on a more explorative approach, rather than executing an articulated plan. Although he did eventually decide to construct his own rocket, which differed considerably from Laura's, his initial play began as collecting various shapes that other students were not using. After evaluating the resources that he had available, he started fitting small triangles together to create a two-dimensional pattern, similar to how tiling might occur. As Laura's rocket became taller and taller, Quentin started commenting on its height, which then caught Max's attention. Noticing that Laura's rocket was almost complete, he gathered four isosceles triangles and handed them to Laura, stating, "Here Laura! For your end. Here for your end. That's for your end." Laura took these triangles and although she did not end up using them for the tip of the rocket, she did include them as embellishments on the sides. By sharing these resources, Max demonstrated an early investment in Laura's rocket. Like Briona, he frequently negotiated the materials that he was willing to share (or not share) based on a consideration of his own construction in relation to Laura's.

Quentin

Quentin was fully engaged with the Magna-Tiles, working independently most of the time. He said he was creating a car which then morphed into a bus as the play progressed. There were only a few instances where his attention was directed toward anything other than his own building. The first occurred when Quentin was out of Magna-Tiles and started looking for more. It was during this instance that he noticed Laura had many pieces, resulting in the interaction reviewed above. After this initial interaction, Quentin kept the Magna-Tiles that he took from Laura and continued building his structure for roughly one minute. He then looked up at Laura's rocket and exclaimed, "What!" and pointed at the rocked and started to count as he pointed to the different pieces and noticed that she had "seven stacked." In one instance, Quentin made a square out of 2 triangles and offered it to Laura, although this was his only contribution of physical objects to her rocket. Beyond this one instance, Quentin only attended to her rocket when he was looking for more pieces for himself or others and when he was counting the layers. As the playing progressed, Quentin directed Max and Briona to take some pieces from Laura as she had the most. Quentin even took one square piece from Katharine's rocket and gave it to Briona, who immediately gave it back to Laura. After Quentin had finished building his structure, he played with it pretending it was a car. He moved it around, making noises that sounded like a car accelerating or turning quickly. He then stepped away from the table just as Max counted eight levels of the rocket. This drew Quentin back to the table as he ran over and counted seven levels. Quentin's engagement and participation in the counting episode were collaborative and not disruptive toward the other children or the teacher.

The focal moment—Mathematical play as disruptive

As indicated earlier, these interconnecting trajectories of play resulted in collective inquiry into the question of the height of Laura's rocket. The moment began with Max's observation—and seeming delight—at the height of Laura's creation (turn 1). Briona echoes this endorsement, gesturing to the very top of the rocket (which is above her head). Although this was Laura's creation, insofar as she is the person who created and stacked each cube, each member of the group has contributed by protecting or offering resources for its creation. Perhaps as a consequence of these contributions, all children at the table seemed equally delighted by the rocket, and perhaps even a bit proud of its scale. However, what turned this into a mathematical moment was Max's decision to *count* its levels as a means of documenting its height (turn 3).

Figure 1
Laura's rocket

(1) Max: Dude, this is a tall, it's a tall building! *(Looks at rocket and smiles).*
(2) Briona: It's a toy rocket! *(Walks around K, touches top of rocket, and smiles. Returns to seat).*
(3) Max: Wait so it has levels? *(Gestures at rocket).* The building has levels. One, two, three, four, five, six, seven. *(Points to each level of rocket for each counted number, then pauses).* Eight. *(Points to roof).* Eight levels! This thing has eight levels! *(Looks at Quentin and gestures towards rocket while smiling).*
(4) Briona: It's eight levels cause it's a hotel. *(Looks at rocket).*

At this point, at least two members of the group were invested in connecting Max's count with evidence of the scale of the creation. Mathematically, this was an important moment, particularly for new kindergarten students. Max's counting is sophisticated in that it demonstrates *one-to-one correspondence*—counting each item separately, only once. His counting also demonstrates *cardinality*—knowing that the last number counted refers to the total number in the set. This act of counting—of documenting the height of the rocket—appears to continue to give Max delight, and he shares his excitement by turning towards Quentin as he speaks, smiling (figure 2).

Figure 2
Quentin counting the levels of Laura's rocket

(5) Quentin: One, two, three, four, five, six, seven. *(Touches each level of rocket, excluding roof, for each counted number.* Seven levels! *(Looks at Max).*
(6) Max: I thought it was eight levels! *(Looks at Quentin, smiles).*

In turn 5, Quentin undertakes his own count of the rocket, again demonstrating one-to-one correspondence and cardinality, but this time arriving at a different number—seven—due to excluding the roof in his count. Max does not dispute Quentin's count, but instead seems to simply remark on their different numbers, finding this amusing, as demonstrated by his smile and laugh (turn 6). In this moment, Quentin's experience in the mathematical conversation is different from what we typically observed in the class. First, and most noticeably, Quentin was a part of the mathematical work, not removed from it. Second, his participation was invited by his friends, and his contributions were valued and ultimately endorsed. Quentin's contributions to the rocket were often related to resources, as his interactions with the other children were mainly about Laura having the most and Quentin trying to gather or share her resources. Notably, Quentin was engaged in this Magna-Tiles free-play activity in ways we (the first and third authors) had not observed previously. He sat and quietly played while he independently built his structure. He shared a piece he built with Katharine. He attended to Laura's rocket and was even drawn back to the table after he walked away to participate in a conversation about the number of levels in the rocket. Quentin's engagement was productive and collaborative, which deviated from his frequent patterns of disrupting others.

> (7) Briona: You're counting too much. *(Walks around Laura to rocket).* One, two, three, four, five, six, seven, eight. *(Touches each level of rocket, including roof, for each counted number).*
> (8) Laura: No that's the roof. *(Touches roof).* There's no layer to the roof. *(Turns to face other students).*
> (9) Briona: The roof don't count. *(Looks down at table).*

Briona and Laura also enter the conversational space, introducing a new idea—what ought to be counted in the determination of the number of levels contained in the rocket. Briona's count—which also demonstrates one-to-one correspondence and cardinality—includes the roof, echoing Max's approach. However, Laura—the rocket's creator and therefore apparently the definitive voice on its components, sides with Quentin, asserting that "there's no layer to the roof," a perspective immediately affirmed by Briona. In this interaction the children's conversation about what counted as a level (turns 3-9) reflects an important mathematical concept related to measurement – *unitizing*. As the children discussed what counted, they were discussing the unit of measure to determine the height of the rocket. In their conversation, it was determined that the unit was the levels, rather than the individual pieces of Magna Tiles.

Conclusion and implications

This study explored an episode of free play that resulted in children's spontaneous and joyful engagement in a conversation about measurement and counting. This moment served to disrupt typical math practices in the classroom which involved students working on questions and problems that were posed by the teacher and was instead a moment when the children themselves articulated a mathematical question and went about answering it themselves, collectively. This moment also served as disruption for one child, Quentin, who was a full participant in counting and unitizing, and whose thinking had status and was valued by others.

In contrast to the idea that play might take time away from mathematics instruction, this episode suggests that play can create new opportunities for mathematical engagement, which has the potential to transform and disrupt what it means to do math and who is seen as mathematically competent. The play activity and the participation norms that were established for this free play activity allowed children to talk, laugh, play, and move around the classroom at will. Children were also encouraged to think about mathematical concepts like shape attributes and counting, but the goals were less narrowly defined as compared to the playful mathematics lessons and math centers that occurred before the episode. As a consequence, this episode created space for young children to engage in problem posing, asking a question (how tall is it?) that was interesting and important to all students in the group. It was not a requirement but rather a choice to count and discuss what gets counted. In addition, the activity created space for Quentin to engage productively—he participated for a sustained time, returned to the conversation after leaving, and was not disruptive to the children around him. His contributions were considered by other students, and valued—it was clear they regarded him as a legitimate and important member of the group. Thus, we argue that play acted as a mechanism for disrupting and transforming patterns of exclusion. We conjecture that other activities that offer these kinds of freedom and engagement to children have the potential to disrupt patterns of exclusion in similar ways. However, to this promising note, we also offer the observation that play did not disrupt all ingrained participation structures, as the activity of the group centered the demands and wishes of a single child: a while girl who effectively dominated resources through a combination of whining and demanding. The instance needs to be considered from that lens as well, as we must take seriously whether and how we might truly challenge and disrupt a broad range of existing inequities and hegemonic practices (Bryan, 2020).

This study adds to the literature on learning through play in early grades as it highlights another way that play can create opportunities to learn. The literature on learning through play, particularly after pre-school, is very small, and such rich examples add to our burgeoning understanding of what playful mathematics learning looks like. The findings also offer an example of possible strategies to disrupt ingrained classroom practices, such as patterns of exclusion, authority, and positioning of children. Future work may explore how offering play rather than taking it away can impact the participation of children in classrooms beyond this single case study. In fact, a limitation of this study is that it is focused on a single instance, which inspires but does not persuade that free play is necessarily always mathematical. While we do not make such a claim, we note that continued research is necessary to identify the conditions under which free play can become mathematical, work that we will continue as the project continues and we collect more data about student learning through play.

Incorporating Community and Citizen Science into Schools: How Youth Develop Science Identity in California Forests

Shulong Yan, Jadda M. Miller, Heidi L. Ballard
shlyan@ucdavis.edu, jaymiller@ucdavis.edu, hballard@ucdavis.edu
University of California, Davis

Abstract: Community and citizen science show promising outcomes of democratizing scientific endeavors by engaging non-professionals in scientific research. Thus we incorporated this program model into elementary schools to support youths'' science learning. Informed by multiple threads of scholarly works - *situated learning*, *figured worlds*, and *place-based learning*, we collaborated with teachers and community stakeholders to design and implement a forest monitoring protocol to study fire behavior and invasive species in a local Northern California forest. After analyzing 15 youths' post-program interviews, we found that youth-focused community and citizen science have great potential to support youths' development of scientific knowledge, practice, and identity. Using authentic scientific tools and collecting place-based data not only supports youths' disciplinary practice learning but also mediates their science identity development by broadening what counts as science and how and where science is executed.

Introduction and background literature

Through engaging non-professionals in authentic scientific research processes, Citizen Science (CS) and other participatory approaches to science can serve as critical channels for broadening participation in scientific research and promoting equitable access to scientific data (de Sherbinin et al., 2021). Citizen Science and related programs support scientists in collecting larger volumes of ecology and environmental science data (Silvertown, 2009) across a wide geographical area, which could otherwise be an impossible task, and simultaneously open up opportunities for laypersons to directly engage with research to advance scientific knowledge (Bonney et al., 2009), in formal education settings (Lüsse et al., 2022) as well as informal settings (Ballard et al., 2017). More importantly, this approach has the potential to empower participants to take ownership of the scientific data and develop a deeper understanding of their local environments, and ultimately, take action to make changes and establish a healthy nature-culture relationship. However, many scholars argue that to realize this potential and strengthen the reciprocal relationship between scientists and citizens, these programs must go beyond data collection and engage participants in the full process of generating scientific knowledge, including data analysis and disseminating the findings to outside audiences (Ottinger, 2010) to drive community-level change. Specifically, we refer to Community and Citizen Science (CCS) includes participatory approaches to research and monitoring primarily driven by scientists but also includes community-driven endeavors, where members of the public co-create the project focused on community needs and interests, incorporate local knowledge and expertise, and are involved in defining what research questions are asked methods design, and findings generated and disseminated (Harris et al., 2020).

Alongside emerging interest in CCS as a way to make science processes and structures more democratic, scholars in education are calling for more equitable approaches to science education for rethinking science literacy from individual disciplinary knowledge to a collective endeavor (Bang & Medin, 2010; Roth & Barton, 2004; Songer & Kali, 2022). This expansive view of scientific literacy not only extends the goal of science education to also include the understanding of scientific practices, such as collaborative argumentation and reasoning (Andriessen & Baker, 2022), but also using science as a vehicle for societal change. The Next Generation Science Standards argue that science education's ultimate goal is to help youths deepen their understanding of the natural world, recognize the urgency of environmental issues, and take cautious actions to make changes (NGSS Lead States, 2013; Roth & Barton, 2004). Some argue this must include creating informal learning spaces to broaden participation and support multiple ways of knowing (Bang & Medin, 2010). We argue with Songer and Kali (2022) that CCS represents a *coevolutionary connection* between science education and the Learning Sciences fields, with the potential to strengthen youth's disciplinary knowledge, science practices, and crosscutting concepts through situated and place-based learning.

As hundreds of CCS projects worldwide have started to engage schools in studying environmental threats and impacts on planetary health, there is enormous potential for CCS to transform science learning (Roche et el. 2020), particularly in elementary schools (Trautmann et al., 2013). Research has shown that youth-focused Community and Citizen Science (YCCS) serves as a promising approach for fostering the development of agency and identity among participants (Ballard et al., 2017; Calabrese-Barton & Tan, 2010; NAS, 2018; Nasir & Hand, 2008). However, limited research has been conducted on the impact of YCCS in school settings. As more teachers and schools adopt YCCS programs for youth learning (Trautmann et al., 2013), there is an increasing need to understand what is required to develop YCCS projects in schools (Barron et al., 2016). This raises the question of how best to incorporate authentic, community-relevant scientific research into the fabric of formal school systems at large scales, and whether or not these programs yield impactful science learning while also contributing to local environmental problem-solving.

Little to no empirical research on science learning outcomes of YCCS exists for the elementary-level age group, particularly in school settings (NAS, 2018). Researchers and educators assume that youth participation in scientific research and monitoring will support engagement in scientific reasoning practices (NAS, 2018), and address required Next Generation Science Standards (NGSS, National Research Council, 2012). However, there is much variation within YCCS program design and therefore learning outcomes from engagement in educational settings. To address these gaps, we designed and examined a YCCS program centered on elementary students conducting forest monitoring to address California's unprecedented increase in catastrophic wildfires in recent years, resulting from historical fire suppression policies and the effects of climate change. These factors redefine Northern California's wildfire season and directly impact rural communities throughout the Western U.S.. This project provides a test bed to examine the links between real community engagement by students and schools in locally important science questions and science learning outcomes for youth (Calabrese Barton, 2012).

This empirical research addresses the literature gaps and informs the broader community of formal education professionals, environmental educators, and ecologists seeking to understand and undertake YCCS initiatives. It also addresses questions about how the design, duration, and intensity of a YCCS program impact various outcomes for student learning (NAS, 2018). To guide our study, we ask the research question: ***how does collecting locally relevant place-based forest data during a Community and Citizen Science Program foster students' development of the three aspects of the Environmental Science Agency?***

Theoretical framework

Learning as the change of participation in the community of science

This study defined learning as an ongoing change of participation in the community (Lave & Wenger, 1991). Informed by this perspective, we examine learning through the change of participation, which includes how participants interact with conceptual and physical tools used in the science community (Sadler, 2009), how their science identity develops, and how youths exercise agency in their community (Calabrese-Barton & Tan, 2010)., Learners' participation in CCS programs can both be supported or constrained by physical tools depending on their accessibility to the learners (Ghadiri Khanaposhtani et al., 2022). More importantly, tools have the potential to afford and constrain the science identity formation depending on the relations constructed among the learners, activities, and tools (Weidler-Lewis, et al., 2022). We also view identity and agency as fluid, situated, and constructed in practice and in relation to the tools use, the activities and the community the youth are part of. Though identity and agency are two different constructs, Basu et al. (2008) argued that as learners construct their identities through interaction within communities of practice, the process of *coming to be* provides opportunities for learners to exercise their agency to alter one's environment *to become*. In this way, developing disciplinary knowledge is another critical step in supporting identity development and exercising agency. As learners' knowledge in the subject deepens, they start identifying their own expertise in science.

To theorize learners as becoming change agents, we applied Holland et al.'s (2001) *Figured worlds* to conceptualize the design of the space as allowing students to develop a new identity, to voice their positions in the world, and to alter the world towards their visions as re-establishing a healthy nature-culture relationship with the environment (Calabrese-Barton & Tan, 2010). Stemming from this, for this research, we use the Environmental Science Agency (ESA) framework to conceptualize learning for the YCCS programs (Ballard et al., 2017). This framework prioritizes disciplinary science knowledge and youth development of identity and agency with science as the key learning practices we seek to observe. Specifically, ESA includes three aspects: 1) the science content knowledge and skills to ensure accurate data production, 2) self-identification with roles within the community of practice, and 3) a sense of agency to apply scientific findings to leverage for change (Ballard et al., 2017).

Place-based data collection as an approach to support learning

Place-based learning as a pedagogical approach is central to and "foundationally implicated" in science education and CCS (Bang et al., 2014; Roth & Lee, 2004). Grounding learning within the community and place where youths are familiar with and personally connect to, this approach can facilitate learners to create meaningful learning experiences and ultimately empower youths as agents of change (Gruenewald, 2003). Though place or place-base was not used in Vygotsky's writing, he argued that the knowledge constructed through youths' everyday personal experiences as spontaneous concepts plays a foundational role in developing scientific concepts (Vygotsky, 2012). Spontaneous concepts, or youths' initial observations, serve as the steppingstone for learning scientific concepts or disciplinary knowledge developed historically within the scientific community. That is, the spontaneous concepts need to be sufficiently differentiated for the disciplinary knowledge to develop systematically. In other words, to develop scientific concepts or disciplinary knowledge, youths need to develop spontaneous knowledge to reflect upon. From the environmental education perspective, Kudryavtsev et al. (2012) conceptualized the sense of place as *place attachment* and *place meaning* which captures both the emotional bonding and symbolic meanings that people created to the place. When accompanied by first-hand data collection within CCS, youths can use their place-based expertise, including geographical, emotional bonding, and social and cultural dimensions of place, to inform their scientific work (Bouillion & Gomez, 2001). This includes using their understanding of place to contextualize their data findings (Taylor & Hall, 2013) for learning and, more importantly, developing pro-environmental behaviors as a result (Bang et al., 2014; Kudryavtsev et al., 2012).

Method

YCCS program overview

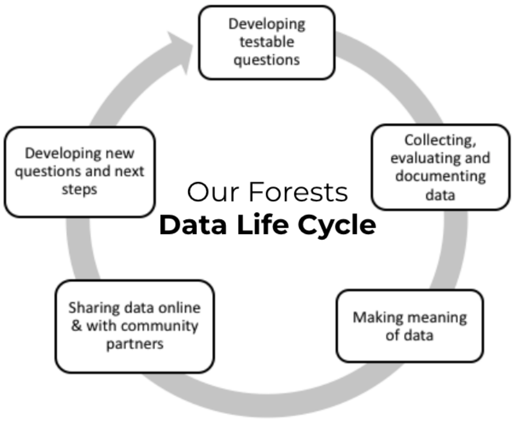
This project was a collaborative program development and research project between university researchers and a community-based watershed organization in Northern California, USA. In the first fully in-person, our program development team partnered with a county-wide school district (3rd through 5th-grade students and their teachers), local forest scientists, and land managers to design and implement the forest ecology protocols. The protocol consists of monitoring and assessing sites near partner schools for variables such as forest density, recruitment of pines and oaks, fuel load, and biodiversity, as well as the lesson plans that they delivered for each class at the forested field sites and in the classroom. The curriculum and program consist of a year-long program that includes 4 all-day visits to the nearby forest investigation zones (FIZ) specific to each school, a "share-out" lesson where students present to their forest scientists community partners, several teacher-led classroom lessons for building foundation knowledge about the program and local forest ecology.

Curriculum design

Informed by place-based environment learning theory, this YCCS program design focused on developing a forest monitoring protocol and accompanying lessons on data needed by local forest managers for managing fire risk and invasive species. Together with designated forest managers and iterative feedback from teachers, the community-based watershed organization led the development of forest ecology protocols for students to monitor and assess sites near their school for variables such as forest density, recruitment of pines and oaks, fuel load, and biodiversity. The 2021-22 iteration of the curriculum included 4 field investigation activities throughout the year-long program. Each activity started with a classroom lesson, followed by a field trip to each school's forest Field Investigation Zone. Based on our team's previous research on YCCS (Ballard et al., 2017; 2020) and building from sociocultural (Lave & Wenger, 1991) and critical perspectives (Roth & Barton, 2004; Basu et al., 2009), we intentionally focused the design of the curriculum on three mediating YCCS Design Features. We argue that the Design Features play an important role in supporting youth to situate themselves within a scientific community of practice (Calabrese-Barton & Tan, 2010).

The three Design Features reflect the NGSS Science and Engineering Reasoning Practices and are framed around the community science notion of the Data Life Cycle (Bird et al., in press): 1) place-based data collection, 2) making meaning with data, and 3) sharing findings on forest ecology data with community partners to understand forest health and fire resilience to answer important questions about measures in their local forest (see Figure 1). First, youths collected place-relevant ecological data during 4 field investigations of a nearby forest site (some traveled by bus for 20 min, others walked to the site). These data were used to inform land management decisions throughout the year. Second, youths analyzed data they gathered, scaffolded and facilitated by our program development team and teachers, including graphing their data to visualize the results. Finally, youths shared their findings with local communities and land managers to use that information to increase forest fire resiliency.

Figure 1
Design Features - Data Life Cycle (Bird et al., In press).



Data collection and analysis

Overall, we used a case study design (Yin, 2013) and collected ethnographic informed data in this study. After observing all 15 classes from 4 schools during the first field investigation, 10 classes were chosen based on how they represent all participating grades at the 4 schools and for teachers' level of interest and eagerness in the program. Researchers worked with each focal class teacher to select 5-8 focal students per class and conducted ethnographic observations of all field-based and in-class forest investigations (5 days each), and post-program semi-structured interviews with focal youths. Researchers conducted semi-structured interviews with photos from the students' forest investigations to spark recall. We used semi-structured interviews (Merriam, 2014) with focal students to understand how and when data collection mediated and/or hindered the development of aspects of the ESA. Interview questions centered on topics relating to student experiences in the program, their thoughts on the health of the forest ecosystem, and on understanding if students demonstrated ESA. We made analytic memos immediately after each field observation and semi-structured interviews to capture researchers' reflections and initial processing of these data (Mile, Huberman & Saldaña, 1994).

The findings in this article resulted from analyzing interviews of three 4th-grade classes with 15 focal students participating in the first year of the in-person program. Challenges related to the COVID-19 pandemic, fluctuations in student attendance, and unfavorable weather conditions caused some focal classes to have incomplete sets of researcher-derived data. As a result, the findings from three 4th-grade classes were chosen for this study for their complete datasets. Interviews with 15 focal youth (ages 9-10) underwent thematic coding analysis (Braun & Clarke, 2006) conducted by two researchers using Dedoose software. The first and the second authors familiarized ourselves with interview transcripts from each case and discussed the preliminary findings and patterns to ensure a shared understanding among coders. This effort resulted in focusing on three aspects - Environmental Science Agency, data collection activity, and sense of place. Transcribed interviews and memos were coded using Dedoose qualitative software individually, then calibrated between two researchers to reach a consensus across 2 coders. Coding focused on thematic schemes: 1) each of the 3 aspects of the Environmental Science Agency (ESA 1-3), 2) each of the 3 key Design Features (data collection, analysis, sharing results with an outside audience) and 3) Sense of Place (Kudryavtsev et al., 2012). ESA thematic coding disaggregates the three elements of ESA into codes and includes student affective experiences. Thematic coding indicated when youth were engaged in data collection in different settings.

Findings

The findings from our in-depth analysis show that involving students in the entire data life cycle enabled students to take ownership of their scientific work throughout the program but seemed to limit their personal sense of agency when tools were not accessible. We focus here on the findings around learning linked to students participating in Data Collection resulting from the in-depth analysis of 15 students' interviews. Overall we found that nearly all students could describe not only what data were collected and how, but also for what purposes, providing evidence of their learning a range of forest science content knowledge, skills, and practices. Specifically, students demonstrated disciplinary knowledge such as plant identification of poison oak and key tree species, fire behaviors, controlled burns, forest density, species diversity, and abundance associated with the data collection phase. Below we focus on selected key findings about the specific data collection and data analysis activities that frequently lead to particular aspects of the Environmental Science Agency.

Finding 1: Using authentic scientific tools helps mediate students' development of scientific knowledge and practices and, ultimately, science identity

Students described using forest science measurement tools as an inseparable part of data collection and as useful and fun experiences. Specifically, throughout all 15 interviews, we found tools were often contextualized as physical tools (Figure 2) used to measure in the field, such as Biltmore sticks (used to measure tree diameter) and quadrats (to delineate areas for measuring understory plant diversity). For example, Logan (all student names are pseudonyms) mentioned in his interview that "*Um, it was fun 'cause, um... 'Cause I don't really get... I don't really use those tools at school or at home, so it was fun to use them out there. And it was useful 'cause we were able to, um... We were able to measure things, and we were able to identify things better*". Interestingly, without prompting, Emma extended the tools to also include cognitive tools such as graphing (a data visualization) as useful tools to help them learn along with other physical tools. When asked how it felt to use the graph, Emma shared that "*Um, I liked using them a lot because it helped. And like those others, other tool, tools we use, like the Biltmore stick and the quadrat, I think it was at least as helpful as those*".

Figure 2
Youths used scientific tools to collect data

Using authentic scientific tools in the program also seemed to mediate what it meant for students to identify themselves as a scientist or as doing science. We saw the tools seemed to signal a scientific identity to students since it is the "*real"* tools used by the scientists. Seeing or hearing that the same tools students used were legitimate scientific tools inspired those who used the same tools in the program to identify themselves *as having a* science identity. As Gideon explained in the interview, he felt like he was doing science or feeling like a scientist because he saw the community partner (a local forest scientist) using the same tool in the field with them. He then continued to show his amazement after seeing how a quadrat created from PVC pipes (figure 2, right) can be a "*real"* tool: *"Cause we were using things that, uh, I would not even imagine would be 'real'. Like the quadrat. I wouldn't even think that would be it. I would just think that they would just draw, uh, a circle or something like that and they would count the plants in that"*.

In fact, students clearly equated using scientific tools with doing science. As tools are highly contextualized and associated with data collection activities, students seemed to associate scientific practice with using tools. The intention of incorporating science tools into the curriculum was to create authentic learning activities to conduct scientific research on a local environmental challenge to support youths to exercise their agency, even if only imagined or discussed. When students were asked the question in their one-on-one interviews, "*Would you utilize any of the skills or knowledge you learned in Our Forests outside the program*" in addition to mentioning the use of plant identification skills, students frequently responded, "*Yes, if I had access to the scientific tool*".

Finding 2: Students' development of a sense of place, scientific knowledge, practices, and identity were closely intertwined

We found a strong and reciprocal relationship between students' developing sense of place and developing scientific knowledge and practices. First, our data analysis showed that youths' sense of place was connected to their embodied creation of scientific knowledge in the places where they live and the inherent responsibility for stewarding these landscapes as a way to scientific contribution and as a result of them developing ESA. The design of each field trip was combined with a classroom portion. When researchers asked kids which portion they liked better, almost all 15 kids shared that they liked working in the forest better. Youths made a distinction between doing intellectual science such as reading and writing and the embodied and direct experience of science, creation of scientific knowledge, and contribution to science in the place with space. As described by Luke, "*like you're actually, um, in the forest so you can have a lot like better sources, not just like a document that they hand you. But like you can actually be in the moment and like get the information for yourself and write it down.*" Luke made a distinction between reading and hearing about the forest and the direct experience of the scientific knowledge, "*Because, um, cause then like you're actually there and you're not just talking about it".* When research asked Olivia to describe her role or contribution to the project, Olivia responded: "*I felt like I was in my place, just like doing what I needed to do, letting the grown-ups talk*".

The intertwining relation among sense of place and disciplinary knowledge, practice, and identity was also demonstrated by their ability to transfer their knowledge to daily life. Students reported that plant identification was a skill they developed during the program and reported that they were able to share this knowledge with others, specifically family members that enjoy the outdoors. For example, Austin shared that "*Yeah. When I'm hiking, I tell, um, like my parents that, that plants named that and that plants named that*". Students also responded that they see and think about the forest differently now that they have gone through the Our Forests program. This finding suggests that scientific knowledge and skills have the potential to deepen students' sense of place. For example, Amelia shared *"Cause now, like, I know more stuff about it. It's more interesting than it used to be"* to address the researcher' question on whether she now saw the forest differently.

The analysis also showed that engaging youths in scientific research to study the place, in the place, and about the place helps transform their experience to broaden their perception of science. When asked whether youths would prefer the classroom or the forest to study, Julia shared that she would prefer the forest because the forest is more spacious than the classroom. As the researcher followed up with the question "*how did it make you feel when you were doing science in the forest", Julia shared,* "*Well, it's just, like, you're not just doing science in some lab where it's like everything's just white. You actually get to do it in, like, a place where like, what you're studying. Like, you don't just do it in a lab where you're studying it. You're studying what you're in, I guess*". Julia's sharing demonstrated how the YCCS program changed her perception of what a scientist looks like and where science happens. During the interview, she shared that she realized science is more than just wearing a white coat working in a lab, but also includes "*studying what you're in*".

Discussion

The scientific tools used in the program not only served as the physical tools to collect forestry data but also as the entry point to enter the scientific community legitimately (Lave & Wenger, 1991). Youths use authentic scientific tools in collecting and analyzing forestry data to help create a *figure world*, as described by Holland et al. (1998), for them to imagine their new actions and identity - as someone who does science or is a scientist. However, scientists or doing science was not confined to the use of tools, but more importantly, the use of fundamental scientific observation skills to form a hypothesis, collect data, and further document the observations accurately to ensure the data accuracy (Eberbach & Crowley, 2009). From identifying trees to using tools to collect and analyze data, all 15 students demonstrated strong observational skills in the field trips, but none credited exercising this important skill as doing science or being a scientist. Since the emphasis was placed on the tools to gather scientific data throughout the program, we suspect that the students were attributing a greater sense of power to the tools producing the data as opposed to recognizing how they've already exercised agency such as the deployment of tools as resources (Basu et al., 2009) and use their sensory skills as tools to observe. Alternatively, placing too much emphasis on the physical tools may establish a linear model and a means to an end, i.e., students are simply a cog in the wheel instead of being the driver of scientific knowledge creation. Additionally, for students to develop ESA fully, we argue that there's a need to support them to adopt an expansive definition of tools to also include all levels of the scientific process, from developing the research question(s), to analyzing the data, and sharing their findings (Roth & Barton, 2004).

The goal of creating community-based science education is "to foster students' development of keen appreciations of the places where science and technology intertwine smoothly with one's experience of life" (Roth & Lee, 2014, p. 271). In achieving the goal of transforming the place into a learning setting, place-based learning approaches also need to support youth to exercise *creative agency* (Headrick, 2017) to reimagine their relationship to place and to develop new ways of observing, noticing, and viewing beyond familiarity to the place. Apart from its role in disciplinary knowledge learning, a sense of place in this study embodies an emotional form and broadens students' perception of what counts as science. As Amelia explained in the interview, the engagement in scientific research helped her develop positive experiences in the forest and allowed her to see the forest differently. Place-based Community and Citizen Science programs have the potential to deepen youth's sense of place by leveraging their deep *place attachment*, along with intentional instruction to create new *place meanings* through observing, identifying, and measuring (Kudryavtsev et al., 2012). As a result, youths developed different views, which go beyond seeing the place differently, but also science differently, as Eli stated in their interview (Bouillion & Gomez, 2001).

Our empirical research has shown that YCCS programs can bridge the gap between informal community citizen science and formal science education in elementary schools, blurring the binary distinction between formal and informal educational spaces. This research also addresses a gap in the current understanding of the learning outcomes for youth participants in citizen science programs inside and outside school settings The outcomes of this research can inform the design and approach of citizen science and science learning projects to yield best practices of citizen science programs for environmental education, including science learning, environmental stewardship, and civic engagement by youth. This research aims to make science more accessible, equitable, and generative for youths. The first finding suggests that, using scientific tools to collect real data alone is not enough to create an authentic learning environment in a YCCS program. Instead, we suggest instructors and facilitators to frame the meanings and purposes of using scientific tools and understand how tools support the greater meaning of the data collection and ultimate scientific practice (Sadler, 2009). With the goal of empowering youths, instructors should also take a step further and help youths recognize how they are also powerful instruments to science. As suggested by the second finding, we argue that place-based data collection played an important role in supporting youths in generating place-based scientific knowledge, using scientific knowledge to change daily life, broaden what it meant to do, and contribute to science.

Caregiver Assessments of Learning During School Closures: Perceived Virtues of Practice-Based and Open-Ended Activities

Caitlin K. Martin, Brigid Barron, Rose Pozos, Flora Troy

Stanford University

Abstract: Pandemic-related disruptions to normal schooling required educators to adapt academic activities for the home setting and caregivers to tailor them according to their unique circumstances. In this paper, we analyze caregivers' perceptions of activities that contributed to generative learning. We focus on documentation of 668 unique learning moments across 109 families and provide an analysis of the relationship between activity structure and caregiver ratings of enjoyment and meaningful learning. We find that (1) most families shared a mix of more and less engaging activities; (2) activities that centered inquiry, expression, or play were more likely to be perceived as highly engaging than those focused on skills; (3) caregivers perceived both practice-based and exploratory activities as generators of learning opportunities; and (4) caregiver ratings of enjoyment and learning were positively correlated. From these findings, we share three directions for future research to support fruitful collaborations between teachers, caregivers, and students.

Introduction

When schools across the United States closed in March 2020, learners, parents, and educators were confronted with the reality that our educational systems were not designed for remote instruction. Although buildings were shuttered to protect public health, most districts continued instruction during the academic year. Schools rapidly reorganized supports for academic learning, ranging from paper packets to synchronous class sessions, and approaches varied widely by school and classroom (Reich, 2020). Caregivers at home, including but not limited to parents, stepped in as proxy-educators to sustain academic learning. Often this involved securing additional materials, assisting with technical support, and learning to facilitate lessons (Barron et al., 2021). Although hundreds of quantitative studies have documented the stresses associated with arranging learning at home (e.g., Kuhfield et al., 2022) far fewer have described what forms of activities worked well (e.g., Greenberg et al., 2020). Conceptualizing enjoyable and meaningful learning experiences during remote instruction is essential for understanding variability in what schools were able to offer early in the pandemic and identifying innovative home-based practices that contributed to productive learning environments critical for children's growth and family well-being.

We contribute to this broader agenda with a remote diary study with families across the United States during the first phase of school closures in the spring of 2020. Our goal was to provide insight into the impact of the Covid-19 pandemic on family life and the ways families were adapting to remote learning. Using remote diary methods allowed us to engage caregivers as participant researchers, putting them in the role of documenting learning activities and providing reflections on the experience of remote learning more generally. Our data captured information about school- and home-initiated learning activities, caregiver assessments of children's engagement in and learning through activities, and families' approaches to supporting academic assignments or enrichment opportunities. For this paper, we analyze over 600 diary entries to characterize the nature of learning activities described and report comparative analysis of caregiver ratings of child enjoyment and learning based on whether the activity was more practice-based or open-ended.

Challenges of pandemic parenting

Families' experiences differed dramatically with more challenges faced by families who had fewer financial resources, lacked broadband access, and or had greater demands for work outside of the home (Davis et al., 2021; Vogels 2020). Across the developed world, caregivers struggled to access distance learning due to a lack of digital resources, lack of communication with the teachers, child learning differences, and limits of their own content and pedagogical knowledge (Bhamani et al., 2020). Caregivers were challenged to motivate their children to keep up with their academics. Parents reported children lacking motivation to engage with remote learning citing attention span, boredom, and missing their peers and teachers as contributing factors (Garbe et al., 2022) and struggling to focus (Lau & Lee, 2021). Another challenge to engagement was the burden placed on parents to guide their children through poorly communicated lessons (Fontenelle-Tereshchuk, 2021) and increased stress when taking on roles to support their children with distance learning, regardless of the type of support they offered

(Sonnenschein, 2021). Additionally, families were handling more than just remote schooling; learning to live in the pandemic and helping their children adjust to "the new normal" demanded caregivers' attention (Pozos, 2022).

Caregiver assessments of enjoyment and learning

The nature of enjoyable activities is particularly important to understand given the motivational challenges of remote schooling. Our focus on enjoyment is grounded in learning sciences research documenting the importance of playful, interest-driven, and meaningful learning in sustaining engagement. Engagement in learning is a multidimensional construct and includes affective, cognitive, and behavioral dimensions (Chi, 2022). Long-term interests, momentary catalysts of curiosity, or interactions with social partners can boost attention and support enjoyment (Hidi & Renninger, 2006). Children help shape learning opportunities by asking questions, contributing ideas, and designing playful learning settings as they pursue their social and domain related interests. In this view, sources of engagement are highly situated, dynamic, have roots in prior experiences, and often connected to idiosyncratic social or activity-based preferences (Azevedo, 2013). The design of learning activities can play a role in setting up these types of opportunities. In this paper, we foreground caregivers' reports of activities and their related perception of engagement and learning. We ask: (1) What did activities look like across families? (2) Is there a relationship between learner engagement and activity type? (3) How do ratings of activity enjoyment relate to ratings of learning from the activity? (4) Do caregivers judge exploratory activities as more meaningful for learning than those that are practice-based?

Methods

Ethnographic research with families has been a key feature of the literature on family learning and parent roles in supporting children's learning. However, Covid-19 challenged the field to quickly respond at scale to understand changes that families were experiencing within the constraints of public health orders. To document the impact of the pandemic on families as it unfolded and the ways in which families were adapting to remote learning, our team conducted a remote diary study with a socioeconomically diverse sample of families in the United States. Diary studies are a form of experience sampling (Csikszentmihalyi & Larson, 1984) allowing researchers to systematically collect participant reflections on moments in their lives as those moments occur. During May and June of 2020, several weeks after schools began closing, we collected daily documentation from 109 families across the U.S., with children aged 5-10 using dscout, a smartphone-based remote qualitative research platform. dscout maintains a panel of over 100,000 participants around the U.S. who are roughly representative of the smartphone owning population. This platform allowed our research team to interact with families and collect rich qualitative data without face-to-face contact, affording broader geographic reach and pandemic-safe practices (Takeuchi et al., 2021).

Participants

A total of 1,375 people from dscout's participant panel expressed interest in participating by completing an initial screener questionnaire, which included IRB consent to participate in research; 264 respondents fit our study criteria: (a) having a child between ages of 5-10 living at home, (b) the child's school had moved to remote instruction and was in session for the entire duration of the study, and (c) the applicant had given consent for their responses to be used for research. These applicants were sorted into three household income groups ($0-49K (15%), $50-99K (44%), $100K+ (41%)) and 37 participants were randomly selected from each group. In total, 109 participants from 28 states completed the study. While most participants were parents, some were other adult caregivers in the homes of children (for example, adult siblings, grandparents, live-in partners of a biological parent). Most (67%) were female and 55% self-identified as white, 16% as Black, and 15% as Latinx, 9% as Asian, and 4% as Middle Eastern or North African. In our final sample, 45% of families reported household incomes below the national median for families in the United States ($75,000) and 55% reported incomes above that level (U.S. Department of Housing and Urban Development, 2020), groups that we have used to investigate differences in findings across families that differ in terms of household income (Barron et al., 2021).

Multimedia diary entries

If caregivers had more than one child in grades K-5 at home, they were asked to select one to focus on throughout the study. Data collection was organized around five themes: (1) school-provided resources and connections pre-pandemic, (2) school-provided resources and connections during remote learning, (3) 6 examples of daily learning moments, (4) how the family learned about Covid-19, and (5) reflections on learning and family life during this time. For each theme, participants answered a series of questions using short videos, photographs, responses to multiple/choice and rating queries, and direct messages to the researchers. This paper focuses on caregivers' documentation of daily learning moments. Data for each entry included a 2-minute video (and transcription), of the caregiver describing and reflecting on a learning moment they observed that day, a photo of the activity, as well as multiple-choice items where caregivers reported social partners present (e.g., siblings, classmates, or teachers via videoconferencing), origins of the activity (e.g., school, caregiver, child, friend), content area (e.g., art, writing, math), resources leveraged (e.g., books, computing devices), time of day (e.g., early or late morning, afternoon, or evening), and challenges (e.g., time, content, technical difficulties). Caregivers also rated their perception of how engaged the child was in the activity (likert items with a 0-10 range) and how much they believed their child learned. Participants were asked to submit 6 examples, though some submitted more.

Analysis

To learn more about the unique learning moments shared by caregivers beyond the submission metrics queried, the 668 diary entry descriptions were organized by family and uploaded to an online collaborative qualitative analysis platform (Dedoose) and coded along multiple dimensions including broad categorization of the learning activity described, caregiver roles played in the learning moment, reflections on activity purpose, synchronous connections to classrooms (Pozos et al., 2022), and expressions of positive or negative affect. We focus here on our coding of the open vs. closed nature of the activity as this dimension emerged as a major category during open coding, was able to be clearly determined across entries, and maps broadly onto existing typologies of learning activities (e.g., Chi, 2021). Nine percent of the sample (n = 60) could not be classified because they lacked detail or were descriptions of a series of moments rather than a particular activity and were excluded from this analysis. In later rounds of coding with those learning moments with sufficient detail for activity analysis (n = 608), we identified subtypes of activities within these two broader categories (see Tables 1 and 2) and surfaced parent reflections about what worked or not, and why. The open-ended descriptions of the learning moments varied significantly in terms of length and level of detail provided about the content and context of a particular activity. Quantitative data were organized into two relational datasets for analysis in SPSS, one representing families (N = 109) and one representing learning moments (N = 668). Qualitative codes were exported from Dedoose and merged into the learning moments SPSS file, supporting analysis of the moments' unique characteristics and how moments played out across different families, as well as comparative analysis of the characteristics of activities rated as more and less engaging.

Findings

(1) Families documented a wide range of open-ended and practice-base activities

Across the 668 shared learning moments, families described a rich and varied set of activities. Of the coded learning activities, 59.0% (n = 358) were classified as practice/skill development, indicating moments where a child received direct instruction and/or practiced a skill through repetition with few if any choices made by the learner (Table 1). Open-ended activities accounted for 41.0%, (n = 249) describing moments when the learner has some autonomy in how to proceed and where the final product or outcome may look different for different students (Table 2).

Of the total sample, three quarters of the activities (75.6%) originated from school, 16.5% were initiated by parents and other caregivers at home, and 7.0% were initiated by children. Activities originating from school were more likely (64.9%) to be focused on skill/practice ($X^2 = 28.822$, $p<.001$) while those sparked by families were more likely to be open-ended (parent-initiated activities were 59.9% open-ended ($X^2 = 12.276$, $p < .001$) and child-initiated activities were 65.1% open-ended ($X^2 = 10.840$, $p < .001$)). Tables 1 and 2 illustrate the range of activities within these two types through thematic descriptions and examples. Most families shared examples of both open-ended and practice-oriented activities and a mix of school-required and family-initiated options.

Table 1
Practice/Skill Development Activity Types and Examples

Subtheme	Descriptor	Examples (including child grade in school)
Workbooks	Working through paper skill-based worksheets and workbooks	● Filling in numbers on a number line on a worksheet with numbers 1-100, while counting out loud (K) ● Adding multi-digit numbers with decimals through a series of problems on a math worksheet (grade 5)

Individualized learning platforms	Activities using skill-based individualized learning platforms (including those that are game-like but focus on basic skill building)	● Answering math questions to earn points and win battles on Prodigy, a game-based content site (K) ● Picking topic sentences to fit a reading passage on IXL, a site marketed to teachers and families to prepare kids to meet state standards (3)
Direct instruction through video	Synchronous video classes or assigned videos that include content "lectures" and/or comprehension and practice activities	● Watching teacher-created video of teacher demonstrating cursive writing (2) ● Attending a live zoom session with teacher and class to check math homework (5)

Table 2
Open-Ended Activity Themes and Examples

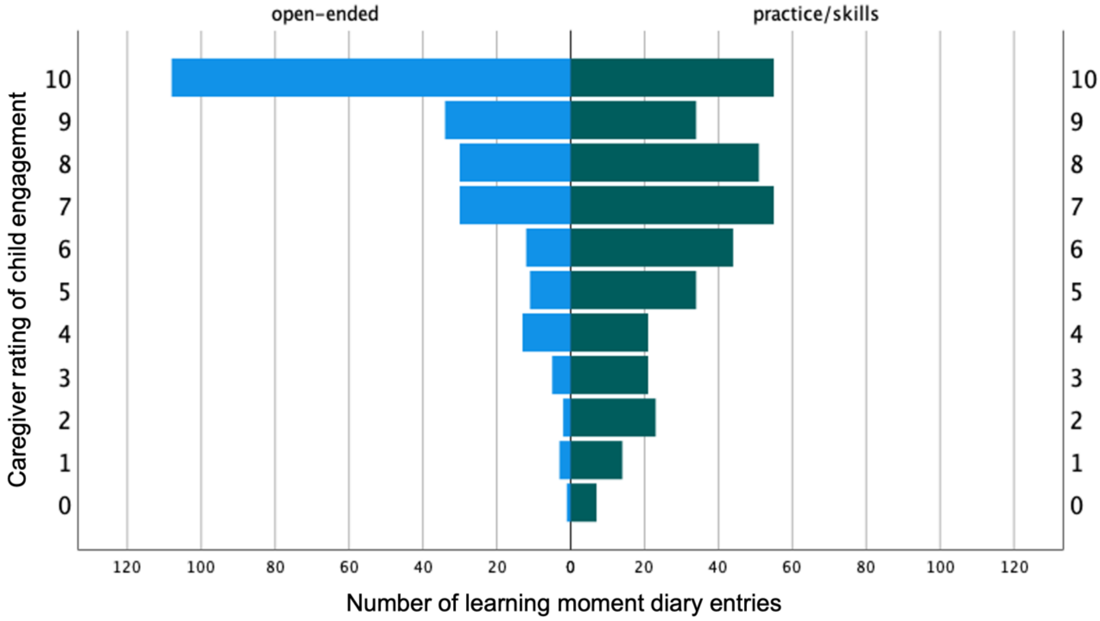
Subtheme	Descriptor	Examples (including child grade in school)
Inquiry	Investigating, observing, documenting, doing research	● Exploring and making observations during sea visit, then co-creating and writing a story with parent (K) ● Recording observations of plant growth in a plant journal, part of a longer-term planting project (3)
Exploratory	Reading or talking to learn about a topic, including open-ended discussions that go beyond comprehension, watching media on a topic that is chosen by the child	● Watching an instructional video from teacher explaining a social studies assignment to research an inventor and using Google to conduct research (3) ● Participating in a "makerspace" class learning about earthquakes and preparing a presentation on how earthquakes happen (4)
Constructive and expressive	Building, making, and designing; crafting stories; making music and art; sharing during online show-and-tell	● Siblings construct model solar system from a kit (K) ● Learn to sew with a sewing kit from Etsy (1) ● Making cupcakes with mom and practicing measuring and translating measurements (K)
Play-based	Play-based such as games, toys as context for learning	● Identifying and discussing animals and food chain as part of playing a board game with family (K) ● Playing interactive online Pictionary during a live Zoom session with whole class (2)

(2) Caregivers perceived higher learner engagement during open-ended activities

For each learning moment submitted, caregivers rated how engaged their children were on a scale from 0 ("they were pretty bored") to 10 ("they were having a ton of fun"). The quantitative ratings by parents show that most families, regardless of their unique circumstances, noted fluctuations in how enjoyable learning activities were for their child and most caregivers included at least one instance of a highly engaging activity (rated above the median) in their diary records (77% percent of families). Figure 1 shows the number of activities by rating for both activity types, showing scores skewing higher more extremely for open ended activities. In fact, open-ended activities were three times as likely to be rated a "10" than those categorized as practice/skill development (45% vs. 15%).

This pattern held when mean ratings of engagement were compared. Caregiver ratings of engagement were higher for learning moments that were more open-ended ($F(1,606) = 73.771$, $p<.01$). The mean rating of enjoyment for the skill development/practice activities was 6.38 (SE = 0.134) while for those activities that were classified as inquiry/project based, the mean was 8.18 (SE = 0.161).

Figure 1
Histogram of Caregiver Rating of Child Engagement Rating by Activity Type



While ratings of engagement were higher for open-ended activities, Figure 1 makes clear that there is variability within open-ended experiences and that highly engaging moments were observed by caregivers across activities in both categories. Our analysis of caregiver documentation of activities is guided by an understanding of learning as collaboratively constructed by children, caregivers, and teachers and embedded in a broader sociotechnical ecology made possible by the specific material, conceptual and relational resources that were available (Barron, 2006). Taking a sociotechnical systems view to understand the emergence of learning opportunities is particularly important given the reliance on digital and networked resources to connect homes and schools. This systems perspective aligns with caregivers' documentation of moments. Across activity types, caregivers note engagement supported by social interaction, flexible content, and opportunities for choice and exploration often connected to personal interests. Below we provide descriptive examples from caregiver accounts to illustrate the types of activities that were perceived as highly engaging within our open-ended and practice-based categories.

Collaborative, project-based opportunities were often rated by parents as highly enjoyable for learners, sometimes leading children to do more than what was required or to request similar experiences. For example, Jake described an assignment that involved building and measuring the interior of a tent, an activity that led to the whole family pitching in for more than two hours and left both father and his fourth-grade son interested in doing additional measurement-related projects. Some examples were parent initiated, such as when Tene realized her third grader was missing out on art she asked him to use online resources to design a city, encouraging him to be expansive and personal, challenging him to include spaces that he would like to have in this imagined future place. Other caregivers described inquiry projects that encouraged exploration of local environments along with varied opportunities for documentation. Todd took his son to the local beach to find sea stars, sea anemones, and small crabs, "just kind of exploring…the environment around you, and making some observations, and working on you know what observations are, and what is an observation, and then kind of working that into a story that we wrote out together…We had a lot of fun, we were able to get out of the house and explore the area around us. … it led to several conversations throughout the course of the day about the environment around us and the ecology of the ocean around where we live."

Engaging practice-oriented activities often utilized digital resources with interactive features—including game structures, personalized content, digital libraries that allowed children to choose books based on their interests, and use of video—that reduce frustration and tedium expressed in other practice-based learning moments. For example, Ava describes her first grader, who is "really into science and likes sharks, fish, all that kind of stuff," accessing EPIC through her Chromebook to "look for books that she was interested in." As she finds a few books about sharks and whales, Ava notes that EPIC has a feature that reads aloud to the child, highlighting words for her to follow along. Ava says her child is excited to read on EPIC (going beyond weekly reading expectations) and is learning science content. In another example, Anna describes the fun her first grader is having doing a collaborative math quiz on Kahoot! with her class, citing the game-like aspect and friendly competition with classmates.

(3) Caregivers associated higher learner engagement with more learning

While the relationship between learning and engagement is well documented (e.g., Chi, 2021), we were interested to learn how caregivers associated the two dimensions in their own observations of learning at home. Along with ratings of engagement, caregivers were asked to rate the learning taking place during each activity, on a scale from 0 = "I don't think they learned anything" 10 = "Lots, my child is spending meaningful time learning in this activity!" The average learning rating across the 668 activities was 7.44 (SD = 2.22). Ratings of engagement and learning were found to be moderately positively correlated, $r(666) = .40$, $p = <.001$.

(4) Caregivers perceived child learning from both practice and open-ended activities

Interestingly, an ANOVA indicated no significant difference in terms of perceived learning for the different activity types ($F(1,606) = .058$, $p = .810$), indicating the parents saw the value of both types of learning experiences. Those activities that were more focused on practice and skill development had a mean rating of 7.59 (SE = .110) while those that were more open-ended had a mean rating of 7.63 (SE = .133).

Summary and future directions

In this paper we provided an analysis of caregivers' perceptions of enjoyment and meaningful learning, two potential virtues of the home-based learning activities children experienced. The exploratory nature of our method invited caregivers to submit a wide range of examples. While we found that three times as many open-ended activities were rated as highly engaging as practice-based activities, parents also observed engaging practice-based activities. In other words, the activity structure was only one characteristic of a highly engaging experience. Practice-based activities were appreciated for supporting independent work, flexible pacing, feedback, game-like feel, and entertaining narratives. More open-ended activities were valued for supporting creativity, imagination, affordances for family collaboration, and shared exploration. These activities are productively understood as co-created by the efforts of teachers and caregivers, children.

Schooling in the US and across the globe continues to undergo multiple stressors as extended pandemic disruptions to daily life and well-being take their toll. In this report, we focused on positive learning experiences that are important to build upon going forward. These results need to be put into the broader context of national data that projects growing inequities, trauma, and an urgent need for reimaging educational environments (Azevedo, et al., 2020). A major concern is the loss of learning opportunities, particularly for families with less technological access, less prepared teachers, and fewer financial resources to supplement school learning with extra materials, tutors, and enrichment activities. Our sample was unique in that all caregivers were technologically connected and comfortable using a remote tool to engage in our study. And, like all accounts based on self-report, views into how interactions emerged and evolved are limited. At the same time, asset-based approaches that capture caregivers' appraisals and observations are critically important. Our findings have implications for future work that will build on asset-based perspectives of caregivers supporting their children's learning at home. We outline three directions below.

Longitudinal portraits of learning and well-being over time

The extensive prior work on family resilience shows the importance of understanding the dynamics of well-being in relation to systems of support, opportunities for relief, and the impact of new pressures as acute stressors become chronic (Patterson, 2002). At this point in time, families around the world are continuing to cope with the aftermath of remote learning, remote work, and economic stressors. Research designs are needed that span multiple units of analysis; our project has followed up with fifty of our original sample with analyses of pandemic learning pathways underway. Although tracking individual's learning is important, developing approaches that include family and community level practices, resources, and well-being measures will be essential for supporting innovation in the design of resilient communities (Greenberg et al., 2020; Lee, 2010). Asset mapping of public access to technologies, availability of informal educational institutions like libraries, availability of parks and other shared resources will be important as well as data that conceptualize how networks are activated (Pinkard, 2019; Erete, et al., 2020).

Design-based research on family-school-community partnerships

Educators and caregivers alike are working hard to support children as they also adapt to their own ongoing challenges stemming from the social, economic, and health related shifts in daily life. As empirical studies of how teachers and learners are coping are still in their infancy, this moment provides unique opportunities for research and design. As policy-focused reports have pointed out, providing Internet access and high-quality devices is a top priority for equity (Darling-Hammond et al., 2020). However, equally important is theorizing and designing novel forms of relational learning. Many parents are extremely creative and responsive learning partners yet are under-confident in their capacity to teach. There is significant potential to advance models that help parents understand the validity of multiple ways of knowing and affirm diverse approaches to supporting their child's development in consequential ways as brokers, collaborators, and interested co-learners (Barron et al., 2021).

Evolution of remote methods that can yield policy and theory relevant data

In this study we leveraged an industry-facing remote diary tool to study families' experiences. The software was designed to allow for the collection of quantitative data, video-records, and photographs, as well as to interact with participants via messages or live-video interviewing. These features are powerful, but there is significant potential for the future development of tools better suited to the Learning Sciences and other related fields (e.g., adding capacities for brief learning assessments, incorporating tools for collecting biometric health data, screenome data and analytic tools that could speed data analysis. Our experience with this method indicated that parents enjoyed interacting with researchers around their child's learning and that the opportunity to reflect on their own parenting experiences was valued (Barron et al., 2021). Future research might develop research designs that offer learning resources, capture examples of learning interactions, and include standardized measures of learning and of well-being. These forms of data would also yield opportunities for a variety of analytic techniques including discourse and interactional analysis that could be connected to measures of learning and engagement.

Conclusion

As our field continues to reflect on this unprecedented period of pandemic-linked school closures and prepare for a future that includes new forms of remote and hybrid learning that can handle disruptions and support more equitable opportunities, it is essential to recognize and build on the implicit collaboration between teachers, caregivers, and children. The variety of activities and structures to support learner engagement that emerged from the emergency collaboration between teachers, caregivers, and children provides a basis from which to intentionally design learning bridges between home and school. In these future designs, it will be essential to position caregivers as learners and co-designers, families and schools as educational teams, and children as active participants in their own learning while addressing historic patterns of inequities and advantages that were manifest during this unplanned experiment in distance learning. The Learning Sciences has an important role to play in curating research that will help families and educators learn from our collective experience, especially in ways that foreground engagement in learning and reimagine what education might look like with true collaboration at the center.

Abstract: This paper unpacks forms of socioemotional engagement that emerged in professional development (PD) efforts in the RepTaL project across two sites, as researchers helped elementary school teachers expand their practices around teaching science with representations. Authors analyzed video data from teachers at both sites, using interaction analysis to highlight the social and emotional layers of one-on-one and group PD interactions. Findings suggest that PD spaces afford many opportunities for expressing epistemic affect, in which teachers articulate and collaboratively process emotions that emerge as they build understanding around scientific representations and science teaching. Our analysis showcases forms of socioemotional engagement that were visible as teachers took up the conceptual work of teaching science in new ways, highlighting emotional and social engagement as core interactional processes that support teacher learning.

Introduction

The goal of this paper is to unpack forms of socioemotional engagement in the professional development (PD) of elementary teachers. Engagement is a multidimensional construct consisting of cognitive, emotional, social, and behavioral dimensions (Fredricks et al., 2004; Sinha et al., 2015). In this analysis, we explore how teachers socioemotionally engaged in the complex cognitive work of learning new science teaching practices involving representations. By socioemotional engagement we mean interactional evidence of public displays of emotion (emotional engagement), as well as the building and maintenance of social bonds (social engagement). Both are distinct forms of engagement that can overlap in practice to influence how collaborative interactions unfold. Within this overlapping space, we pay particular attention to the *epistemic affect* of teachers, which are emotional experiences that emerge in the process of building new knowledge (Jaber & Hammer, 2016a). Epistemic affect is a unique form of emotional engagement that highlights how learners navigate the emotional aspects of conceptual work (e.g., frustration at a difficult problem, excitement at finding a solution).

This analysis of teacher socioemotional engagement is situated in the RepTaL project across two research sites, as researchers worked with elementary school teachers to expand their practices around teaching science with representations. RepTaL works to engage teachers in learning how representations can support students in learning about science phenomena, and then learning how to integrate them in their teaching (Danish et al., 2021; Pierson et al., 2022; Lee et al., 2022; reptalproject.org). Using representations in elementary science is tricky for teachers because representations are rarely discussed explicitly in teacher training, and many teachers already struggle with implementing effective inquiry learning (Danish et al., 2021; Prain & Waldrip, 2006). Professional development (PD) with representations presents teachers with additional responsibilities, often without on-the-ground support that is crucial to introducing new pedagogy (NASEM, 2022; Gibbons & Cobb, 2016). Our PD model creates a teacher-centric learning environment via long-term, collaborative relationships between teachers and PD facilitators. This approach involves viewing teachers simultaneously as experts in their grade-level and as learners in science teaching, a position which honors teachers' classroom knowledge while considering scaffolds they may need as learners of new forms of practice. This analysis considers how PD can be designed to support teachers' long-term success through a focus on socioemotional engagement, grounded in our efforts to help teachers integrate representations into their practice.

We seek to (1) understand teachers' socioemotional engagements within long-term professional development designs, and consequently (2) share teachers' own explanations about the benefits of their socioemotional engagement.

Theoretical framework

When working with teachers in PD, our designs must account for the dual identities of teachers as both educators and learners (NASEM, 2022). As teachers expand their science teaching practices, they are also expanding their identities as science learners (Askew et al., 2021). Research on factors influencing learner engagement highlight the core role that socioemotional dimensions play in unfolding classroom interactions in terms of sustaining engagement and deepening learning (Humburg, 2020; Ryu & Lombardi, 2015).

For example, in considering how to deeply engage science learners, Jaber and Hammer (2016a, 2016b) conceptualize epistemic affect as a central dimension of scientific inquiry. In their conceptualization of epistemic affect, across multiple papers, Jaber & Hammer (2016a, 2016b) describe both distinctly positive affective epistemic work of scientists (e.g., joy, excitement, reward, pleasure, triumph, fulfillment, clarity, passion) that may come with the "feeling of knowing" (Jaber & Hammer, 2016a, p. 160) and negative affective epistemic work (e.g., uneasiness, impatience, irritation, anxiety) that may accompany "the feeling of error and epistemic anxiety" (p. 160). They argue that the full range of affect is a part of how scientists are "driven by the 'intellectual and sleuthing challenge' (Lorimer, 2008, p. 392) of their work" (p.160). They make the clear claim that affect is "inherent in the work of science" (p. 160) and name "epistemic anxiety" in particular as what "compels us to support our claims with more evidence and to thoroughly weigh in the evidence before making up our minds" (p. 161). This affective work is distinctly "the affect *within* science" (Jaber & Hammer, 2016b; p. 190) rather than feelings about or towards science or scientific inquiry. Jaber and Hammer (2016b) also examine the role of meta-affect, or reflection and reframing of affective experiences, "for instance, perceiving confusion as motivation, associating puzzles and uncertainties with pleasure rather than intimidation, and perceiving inconsistencies as simultaneously bothersome and stimulating rather than menacing (Jaber & Hammer, 2016b, p. 194)." This epistemic affect can also engage teachers-as-learners, giving them emotional experiences that mirror what their students may feel during investigations in science class. PD coaches and teachers together can navigate these moments of puzzlement and uncertainty to highlight how teachers can support their students to engage in similar affective epistemic work.

In subsequent work, Jaber (2021) also states that as teachers learn to shift towards centering students' as epistemic agents in the classroom, we must in turn focus on teachers' own affective epistemic work in their inquiry about teaching science. As Davidson, Jaber, & Sutherland (2020) articulate, affective dimensions are always relevant in "the work of constructing knowledge or developing understandings" (p. 1012). In this way, we might consider multiple lines of scientific inquiry as relevant to supporting science teacher professional learning; first, the inquiry of students and teachers-as-learners as they engage in scientific phenomenon-first inquiry, and second the inquiry that teachers pursue as they build knowledge about their practices for science teaching. Both of these forms of inquiry can be understood as including epistemic affect as they both include "emotions, feelings, and dispositions that are experienced in the epistemic work of constructing and critiquing knowledge within epistemic pursuits and in reflection around those pursuits (Jaber & Hammer, 2016a, 2016b; Jaber, Southerland, & Dake, 2018)" (p. 1011) whether those pursuits are understanding science phenomena or teaching practice.

We examine how epistemic affect is central to supporting the socioemotional dimensions of *teachers*' inquiry as they explore representations and new professional practices. Within professional learning spaces for teachers, their inquiry into their pedagogy brings with it feelings professional scientists experience, such as "the joy of going at it" while gaining "a feeling" for the flow of professional activity (Keller, 1983) and playing with ideas and designs (Jaber & Hammer, 2016a) as they extend students' ideas towards expansive understandings of science. Our project focuses on helping teachers investigate their knowledge and use of representations, such as drawings and graphs, which are crucial to science and science learning (Tippett, 2016) and place epistemic agency into children's hands as they learn to read, make sense of, and create their own representations (Pierson et al., 2022). However, sifting through the variety of representational choices and possible features (Eilam & Gilbert, 2014) makes PD around scientific representations difficult. Teachers may also struggle with determining relationships between different representational forms (Schwarz et al., 2012) and centering students' diverse practices and epistemologies (e.g., Hudicourt-Barnes, 2003). Despite this difficulty, supporting teachers to understand and use multiple representations helps position students to build from them, foregrounding a variety of scientific concepts and practices (Gouvea & Passmore, 2017) which deepens student engagement with concepts (Lehrer & Schauble, 2015).

We wish to explore how professional development learning spaces create the setting within which teachers can engage in inquiry about their professional practice and students learning, and how in turn engage in inquiry with coaches, PD providers, and teacher peers creates opportunities for teachers' affective-epistemic sensemaking.

Project design & data collection

The RepTaL project is a design-based research study (DBR Collective, 2003) supporting elementary science teachers towards phenomenon-first science inquiry learning (NRC, 2012). Our professional learning designs aim to integrate teacher communities for collaborative inquiry into teachers' professional practice. This included shared commitments to immersive demonstration lessons for teachers as learners in phenomenon-first science inquiry (e.g., Crawford, 2012), student artifact analysis, reflections on video-recorded teacher implementations of lessons, and planning support. Through iterating on these designs over four years, our team has consistently held space for the affective-epistemic work of teachers as we seek to support their development in a shared vision of inquiry-based, equity-oriented science engagement (Crawford, 2012; Windschitl et al., 2018).

Our project team shares an explicit commitment to responsive designs both at the level of the communities served by each partner institution (Site A, Site B) and responsive in-the-moment professional learning implementations to meet the evolving needs of our teacher partners. Responsive design included attending to the needs of both sites. Both sites hosted whole cohort summer experiences focused primarily on immersive demonstration lessons and planning support. We conceptualized teacher PD as a form of inquiry in which teachers tested out science concepts in lessons together and gathered observations about how different representations functioned in learning activities. However, academic-year work was designed to attend to geo-spatial needs of both contexts. During the academic year, Site A, a small, rural Midwestern city hosted both virtual and school-based gatherings to attend to the larger distances between the university and teachers' classrooms. During the academic-year, Site B, a large Southeastern metropolitan city, hosted whole-cohort gatherings as teachers were able to travel to meet in person after school hours. In response to the needs of both sites and the expertise of each site's professional learning experts, we designed two different versions of academic year support for teachers' inquiry which share key features but centered the needs of teachers in rural and urban areas. These shared features included a focus on developing teachers' understanding of science and scientific representations, prompting teachers to reflect on their practices in terms of their emotions and support needs, and collaborative, community-oriented interactions between teachers.

Coaching model with one-on-one video reflection

In Years 1-2, teachers at Site A participated in a model of instructional coaching referred to as Holistic Individualized Coaching (HIC; Cross Francis et al., 2021; 2022). HIC is an individualized coaching approach that acknowledges and attends to the cognitive and affective nature of teaching and learning. In particular, in the context of professional development, teachers are considered learners. Thus, in preparing for and engaging with teachers, the coach considers the cognitive strain, dissonance and emotional fluctuations that typically accompany learning experiences, as well as teacher change processes. As the teacher and coach interact through cycles of individualized coaching, the coach tracks and remains responsive to shifts in the teachers' pedagogical content knowledge, orientations, identity, efficacy, and emotions. Prior to the first coaching session, the coach gathers data from teachers about these constructs in order to inform what the coach says and does in pre- and post-coaching conversations, as well as how the coach supports the teacher and engages with their students during the coached lessons. Prior to the post-coaching conversation, the teacher and the coach watch the video recorded lesson, then meet and discuss clips they both selected to workshop difficulties, unpack student responses, and build shared ideas about what works (or not) and what to try next. Central to the HIC model is the responsiveness of the coach, not only to the teacher's needs related to pedagogical content knowledge and instruction, but also to their psychological and emotional needs. In response to the pandemic and emerging teacher needs, Site A shifted to a collaborative PD model in Year 3 onward, in which teachers met once a month with facilitators and other participants from their school to try out potential science activities and reflect on representations and lesson ideas together.

Video club model with small group video reflection

Teachers at Site B participated in collaborative PD sessions with other teachers throughout the year to achieve similar goals. Sessions involved a combination of analyzing student work (Langer et al., 2003) to support reflection on expansive representational forms, and video clubs to reflect on students' sensemaking and repertoires of practice (Gutiérrez & Rogoff, 2003; Sherin & van Es, 2005). Our collective work features shared commitments accomplished through nuanced designs that attend to geo-spatial and other contextual needs of the local community. Additionally, all sessions at both sites were video recorded for analysis (Derry et al., 2010).

Data analysis

The goal of our analysis is to understand how teachers' socioemotional engagement, and in particular their epistemic affect, can be supported across different PD contexts and experiences. Therefore, we used a case study approach (Yin, 2013), following two teachers from each research site (Site A: Heather and Luna and Site B: Maria and Jill; all pseudonyms). The teachers were selected to represent a range of experience in the project at different points in time. At Site A, Heather (2nd grade) began participating in Year 1 and stayed on for four years, while Luna (Kindergarten) was a new participant in Year 4. At Site B, Jill (Kindergarten)–who heard about the project while lesson planning with fellow teachers–joined in Year 3 and stayed on through Year 4, while Marie (4th grade) began in Year 1 and left the project after Year 2. Our goal was to understand the range of socioemotional interactions teachers experienced across PD models, not to directly contrast teachers.

The first and second authors reviewed data at each site using AI-generated transcripts, content logs (Erickson & Schultz, 1997), and raw videos from the first year of each teacher's project participation. We began our analysis by reviewing data for instances when teachers and/or facilitators explicitly mentioned feelings around teaching practices and what teachers reported as the impact of affective interactions in the PD. More specifically, we analyzed two related forms of interactional evidence of socioemotional engagement: (1) explicit social support and collaboration between facilitators and teachers and (2) explicit display of emotional reactions (e.g., tears, laughter) within and around teaching science and representations. Once noted in transcripts, the original video was viewed using Interaction Analysis (IA) methods to "chunk" moments for analysis (Jordan & Henderson, 1995), and multimodal elements such as PD-generated artifacts were also explored in relation to video clips to triangulate data sources (Sakr, Jewitt, & Price, 2016). Across the two sites, common forms of socioemotional engagement were noted (e.g., similar emotions being expressed, similar forms of social support), and these overlaps in socioemotional evidence led to the development of the hypothesized patterns detailed below.

Results

Three patterns of socioemotional engagement emerged related to the influence of the PD and interactions in the PD activities with supporting epistemic affect: 1) holding space for worry and frustration, 2) expressing surprise, joy, and celebration, and 3) offering social support for the process of becoming a science teacher. Our results explore how teachers at each site demonstrated their emotional engagement through expressions of both negatively- and positively-valenced epistemic affect during their PD interactions. We also outline how the interactions between teachers and between teachers and facilitators supported teachers' learning as they identified, articulated, and negotiated the meanings behind their emotions.

Engagement form #1: Holding space for worry and frustration

As teachers planned for incorporating new forms of science representations in their instruction, anticipatory emotions such as anxiety or frustration were evident in their interactions with facilitators and each other. Teachers also reported experiencing challenges while implementing new instructional techniques. Luna (Site A, Kindergarten teacher) noted "feeling a bit uncomfortable" when reflecting on perceived missteps in a new lesson and said she "felt a little disappointed" when her students struggled to understand the material. To address teacher needs and encourage growth, while maintaining socioemotional support, interactions included using humor and relational care alongside problem-solving and sensemaking conversations in ways that affirmed teachers' perspectives and validated teachers' feelings.

In response to a teacher's expressed uncertainty about a suggested lesson, rather than offering prescriptive rules for how representations should be used, a facilitator at Site A said, "If [the students] get confused, I'll just take the blame," and the teacher and facilitator laughed together. These moments of light-hearted socioemotional support framed PD as a collaborative effort and uncertainty as part of the evolution of practice. Also, the Site A facilitator often opened up discussions with *wonderings* such as, "I wonder if you had considered reversing the order of these activities" or "I wonder what the students would do if…" These interactional moves promoted articulations of epistemic affect within the conversational space, and it allowed teachers to explain the emotional aspect of their pedagogical efforts–in this instance, the anxiety around balancing time and effort between science lessons and other subjects.

In response to these moments of negative affect, facilitators and teachers engaged in open reflections that honored teachers' emergent emotions and supported problem-solving discourse with an intention to avoid a deficit-based or judgmental framing of teachers' feelings. For example, at Site B, a small group of teachers worked with partners in an immersive PD lesson about electrical circuits to put a broken flashlight back together, using a diagram. During the lesson debrief, Marie told the room full of teachers and facilitators that she "was literally stuck" and "literally having a moment" trying to figure out "why don't the stinking thing work?" after she and her partner reassembled it. She continued: "I thought I knew, kind of, you know, mechanisms of how a flashlight works, so I was truly puzzled." In this discourse, Marie's tone, facial expressions, and gestures evidenced frustration with not being able to solve the problem in front of her.

Despite her frustrations, Marie described pressing on with her partner to fix the flashlight. They "tested and retested," they "checked the batteries," and they "went through a process of elimination" as a scientific inquiry. Upon hearing this reflection, a facilitator told Marie, “I love how you describe how you really *felt* that problem.” In validating Marie’s frustrations, the facilitator positioned emotions as relevant to learning through and about science. To turn the immersive learning experience into a teacher-centered perspective, the facilitator explained that Marie having these emotions as a learner made the lesson “feel like a success” because if “learners don’t feel puzzled” then “I am actually failing.” This facilitator move intentionally centered the struggle of inquiry within science learning, highlighting how teachers should consider emotional support for students (even emotions oft-perceived as uncomfortable or negative). After the facilitator explained how they set up the lesson with the flashlight, another teacher pointed to Marie’s ah-ha moment–which would not have occurred without her struggle–as key to scientific inquiry for learners.

By considering the role that epistemic affect plays in teaching, these interactional spaces made processing emotions not only permissible but expected, which also opened up opportunities for engagement with emotionally risky topics, such as challenging deficit-based assumptions about students. For example, Heather (Site A) described one student as “somewhere on the spectrum, I’m guessing. And so, it’s very important to him for things to be right.” In response, the facilitator reframed the conversation by noting that being preoccupied with accuracy is actually a great example of “thinking like a scientist.” The teacher later expanded on this framing, noting, with regard to students’ writing, that “scientists often write things down so clearly enough that somebody else can check it.”

At Site B, Jill confronted her own deficit-based biases when reflecting on her experience using a representation to match parent to offspring. Realizing how her choice of representation made visible the sensemaking of a kindergartener, Jill’s voice cracked with emotion as she explained that “because of what we were doing here [in PD], I’ve learned a lot about her, and became very aware that even when we try not to, we have bias [...] I was able to see a lot of what she knew because I got out of the way.” The facilitator normalized and validated this experience, saying, “Everyone in this room has–could look back and see ways we stood in the way, that we were the problem, or we didn’t make space…every student I’ve ever taught didn’t get this version of me.” This interactional move further opened the space for the whole community to identify and leverage emotions for powerful self-reflection.

Engagement form #2: Expressing surprise, joy, and celebration

In identifying epistemic affect as a way to make central socioemotional engagements, our PD models not only held space for teachers to process difficult feelings, but also provided opportunities to express excitement and joy about their work. PD sessions contained numerous moments of shared laughter and communal enthusiasm as facilitators and teachers shared interesting student responses and joked about missteps. When asked what surprised her about a lesson, Heather (Site A) noted her students’ impressive scientific observations, saying, “They were excited, they were motivated, and they seemed to understand it pretty well.” She often called out particular student responses in the coaching reflections with enthusiasm (e.g., “Wasn’t that cool?” and “That’s awesome, that’s really great thinking”). The facilitator emphasized celebrating teaching successes, saying things like, “You’re very good at this conversation about being like scientists” and “I’m seeing what you’re doing there, and kids are responding,” which helped balance teachers’ anxieties about new strategies with emphasis on where their teaching expertise was visible.

In a different instance during Summer PD at Site B, Marie expressed her surprise after an immersive lesson in which a facilitator conducted a short science lesson entirely in French. At first, Marie explained that she “felt horrible because having ELLs, there’s so much they don’t understand.” Through her tone and body posture, she displayed a sense of shock when she imagined how difficult it must be for her multilingual students to learn science in English. Nevertheless, Marie’s deficit-based notions quickly turned to something joyful when she described the French lesson as “very humbling” and “awesome.” Continually, Marie explained that while learning vocabulary she “loved the choices” that the PD facilitator presented in the lesson, and kept interjecting positive affirmations (e.g., “oh yes!”) as other teachers shared their thoughts about the experience. Marie’s surprise as well as her positive affect in response to gaining a new perspective on her ELL students’ experiences demonstrates how epistemic affect is often wrapped up in how teachers learn to consider the varied needs of their students.

Teachers were explicit about the positive feelings that emerged during PD sessions as well, reporting that they enjoyed opportunities to talk through their lessons with facilitators and teachers. Jill, a kindergarten teacher at Site B, reflected at the end of the first day of the Summer PD workshop that she was “excited about” working with other teachers to plan new lessons about equity-oriented science topics, explaining that it “sounds very joyful to me.” She also noted PD was “helpful just to be thoughtful and reflective,” highlighting in the same turn of talk how emotions and learning are interconnected in teachers’ own inquiries. This explicit recognition of excitement and joy became realized when, on the fourth day, Jill jumped from her seat to lead a group discussion in connecting lessons about the presence of urban tree canopies to issues of climate and social justice. Such moments that promoted epistemic affect positioned processing emotions as a core part of the work of teacher learning and practice.

Engagement form #3: Social support for the process of becoming a science teacher

In expressing and negotiating the range of positive and negative emotions that emerged during science teaching, teachers also socially engaged with one another in ways that built community support and held space for vulnerability. Many of the teachers came to the project not labeling themselves as "science teachers" and expressed hesitancy and discomfort when trying out activities and forms of representation that were unfamiliar to them. This potential discomfort was visible in some of the ways that teachers teasingly set boundaries for how the group should critique each other's work, with comments such as "don't discuss my spelling" and a worried "I just like, chicken-scratch wrote," when asked to share a diagram with the group (Site A, Luna's cohort). As the teachers tested out different scientific representations that they planned to use with their students, they used humor and laughter to dispel some of the tension that appeared to build up as they presented ideas for public discussion. One example at Site A was the "significant circle" activity, which asked participants to create a diagram of how plants are significant for their personal lives. This activity was intended to support emotional and social connections to science topics, and in creating and sharing their circles, the teachers demonstrated and experienced the kinds of vulnerability their students might experience when completing the activity in class. One teacher noted, "I was like, I don't remember how to spell this, I probably could've done it but I panicked," highlighting how the collaborative PD activities generated experiences of epistemic affect that helped teachers anticipate how their students might feel when working with scientific representations. The teachers talked through the different ways they might use the information their students would provide to guide the activity, sharing their expertise with each other in supportive and generative space.

To similarly build space for social support, Site B facilitators began the fourth year of summer PD with collaborative, relationship-building activities, such as sharing personal stories, developing community agreements, creating a community word cloud, and talking about past experiences within the project (Figure 1). Not only were these key tools in integrating the new teachers into the project alongside the veteran teachers, but they also indicated how the teachers themselves wanted to support each other as a collective. To create the community word cloud, all participating teachers were given a live url to share "what comes to mind when they hear the word community" using their mobile phones. These words then helped the group expand their sense of community into a broader list of agreements that we wrote down together and kept on display throughout the summer PD experience.

Figure 1

Community word cloud (left) and community agreements (right) created by teachers at Site B

- We commit to be a safe base for others.
- We will advocate for ourselves + others.
- We commit to being present.
- We commit to making space for one another.
- We commit to building relationships with each other + our students.
- We commit to generous assumptions.
- We commit to listening and asking questions.
- We commit to a brave, vulnerable, and transparent space.

Outcomes for teachers

Across these forms of engagement, we observed that socially and emotionally engaging with facilitators and fellow teachers helped participants to normalize the idea that a range of positive and negative emotions are central to the practice of being a science teacher. Teachers reported that the PD work helped them to think through difficult lessons, as well as to develop a better understanding of how to implement representations. Teachers also noted the value they found in sharing their emotions with other teachers and talking through ideas in a supportive space. For example, Luna (Site A) wrote in a post-PD reflection, "My understanding of representations has solidified after the article and discussion/activity tonight." Later in her Year 4 post-interview, Luna reflected on how these PD experiences influenced her teaching style overall, saying that she now uses a more "holistic style" where science is integrated into her various lessons, rather than keeping science, math, and reading lessons siloed from one another. Heather (Site A) reported benefits as well, explaining in her post-interview that her experiences helped her build lessons around science as an inquiry activity, rather than as basic information gathering and "whatever was in the book." Heather also noted that after four years in the project, "the other kids and teachers in the building think of me as the science teacher."

In her end-of-year interview, Jill (Site B) described the impact of participating in RepTaL in multiple ways. Specifically, we asked her how the practices and frameworks of the PD influenced her teaching throughout the school year. Jill "found it to be freeing because the ways things have been the last few years–because of the pandemic, because of the curriculum [they]'ve been asked to implement–[she] felt very constricted." Clearly, a major outcome for Jill was a feeling of freedom to explore her teaching in different ways. Because of this freedom, Jill noted that the science teaching practices she was implementing from her PD experiences "really made space for [her] to see the depth of knowledge of some of the students" that she "would have missed" otherwise.

Conclusion

Across these forms of engagement, we observed that opportunities to socially and emotionally engage with facilitators and teachers helped participants embrace a range of positive (i.e., joy) and negative (i.e., frustration) emotions as central to the practice of being a science teacher and doing science. Teachers reported that the PD work helped them to think through difficult lessons with the use of representations. Teachers also noted the value they found in sharing their emotions with other teachers and talking through ideas in a supportive space. Our paper argues that epistemic affect highlights socioemotional engagement as central to the growth of teachers' inquiry-based science practices. Teacher emotions are not secondary to the learning process; rather, they are evidence of deep learning and a teacher's investment in their craft. Our analysis highlights how teachers took up and valued opportunities both to 1) share their feelings in a supportive environment while working toward solutions, and 2) share their joy and success. We see these opportunities as inseparable from the intellectual work of PD; teachers made important conceptual challenges and solutions visible as they articulated and navigated these emotional experiences within inquiry about teaching practice. Setting up immersive PD spaces in which emotional and social aspects of teaching are honored and shared together provides teachers with opportunities to connect to the emotional work of both doing and teaching science.

Quantitative Analysis of Mathematical Word Problems in the Estelle Reel Papers

Julie Sherman, University of Utah, sherman@math.utah.edu
Luke Kim, Kenyon College, kim6@kenyon.edu
Mary Smith, University of Utah, mary.smith@utah.edu
José F. Gutiérrez, University of Utah, jose.gutierrez@utah.edu

Abstract: In this work, we present a database of mathematical word problems intended for use within Indian boarding schools under superintendent Estelle Reel. The database was constructed via manual transcription from historical documents dating from 1905 to 1909. These documents also contain curriculum guidelines, lesson plans, and contextual information such as grade, author, and school. Quantitative analyses were conducted, such as determining the questions' distributions by grade and location. Natural language processing tasks, including frequency distribution analysis and sentiment analysis, were also applied to the database. Our findings show that the mathematical questions were primarily intended for early elementary school students and written by authors from the Western United States. These questions most commonly reference commerce, agriculture, or measurement. Further analysis of the most polarized questions demonstrates a clear political position embedded within them. We briefly discuss the historical context and implications of these findings.

Introduction, background, and objectives

Within the learning sciences, there is increasing equity-focused research examining the social and political contexts of learning (e.g., Esmonde & Booker, 2017; McKinney de Royston & Sengupta-Irving, 2019). At the same time, the field of mathematics education is developing ground-breaking approaches that put issues of racial equity and justice front and center (Crespo et al., 2022; Matthews et al., 2022), including critical historical inquiry (e.g., Joseph et al., 2021; Zelbo, 2022). Our work advances research at the intersection of the learning sciences and mathematics education by contributing a quantitative historical analysis of the mathematics curriculum used in Indian boarding schools during the late 19th and early 20th centuries in the United States.

The myth of mathematics education

The common wisdom around mathematics is that it is objective and, therefore, a neutral domain of social practice. Mathematics *education*, the story continues, is a politically neutral enterprise. What does the teaching and learning of math have to do with politics or history? While scholars have long argued against the apparent objectivity or neutrality of mathematics education (Bishop, 1990; D'Ambrosio, 1990), still more research that directly challenges this notion is needed. Our project, *Mathematical Reservations* (Gutiérrez et al., 2021), presents historical evidence that subverts the discursive formations that continue to leave mathematics education uncritically interrogated.

Indian boarding schools – where's the math?

The United States established and operated dozens of Indian boarding schools (IBS) from the late 1800s through the 20th century. Research has documented how IBS policies and practices aimed to forcibly assimilate Native American children into white American society and prepared them to become subservient workers (e.g., Lomawaima, 1994; Lomawaima & McCarty, 2006; Trennert, 1998), including through exploitation of the children for domestic and manual labor (Tanner et al., 2022; Whalen, 2016). There is growing scholarship focused on the IBS system, curriculum, operations, student experiences, and its intergenerational consequences (Adams, 2020; Lajimodiere, 2019; Williams, 2022). However, no research has examined the mathematics curriculum in Indian boarding schools and how it was used to enforce U.S. citizenship and values.

The overarching questions guiding the *Mathematical Reservations* project are: What types of mathematics were taught in IBS and why? How did the IBS mathematics curriculum promote federal assimilationist goals? These questions are important for two main reasons. First, the historical record is incomplete. Our archival research on the mathematics policies and curriculum in the IBS system has begun to fill this crucial gap in the literature. Second, emerging efforts for educational equity have paid little attention to the experiences of Native students, despite critical discussions on equity and justice in mathematics education regarding Black, Latinx, and multilingual learners. Deepening our understanding of the legacy of colonization—

how children were colonized through math—can inform new policies, pedagogies, and theories of learning that center the experiences of Native students today.

Quantitative historical analysis of math word problems in the "Estelle Reel Papers"

Estelle Reel served as the Superintendent of Indian Schools between 1898–1910 and was a crucial figure in the education and assimilation of Native children during her tenure. She wrote a uniform course of study (Reel, 1901) and developed training programs for teachers in the Indian service. The *Estelle Reel Papers* is a collection of primary documents related to her work and is well-known among historians and Indigenous Studies scholars (see Lomawaima, 1996). Here, we describe the construction and initial quantitative analyses of an extensive bank of mathematical word problems discovered in the *Estelle Reel Papers* collection. To our knowledge, these word problems had not been analyzed before our project.

Methods

Database construction

Source documents

The *Estelle Reel Papers* collection, housed at the Northwestern Museum of Arts and Culture (NWMAC) Research Library and Archives, contains several boxes of historical documents, including biographical material, curriculum and lesson plans related to IBS, information on educational administration and Indian affairs, newspaper clippings, and photographs representing everyday life in Indian boarding schools across the U.S. We were graciously granted electronic copies of the contents of four folders (9-12) from "Box 1," labeled "Arithmetic." Combined, we received 225 scanned pages of materials.

There is limited information on the exact origins of the arithmetic problems in the *Estelle Reel Papers*. The museum authenticated the records as part of Estelle Reel's work with the Office of Indian Affairs, but we do not have the exact dates for the documents. We narrowed the relevant dates to 1905–1909 by cross-referencing some schools and teachers with other records. This period was around when Reel conducted summer institutes for teachers working in Indian schools. Given Reel's plan to professionalize the IBS teacher corps (Lomawaima, 1996), teachers likely submitted these worksheets for Reel's review as part of the summer institutes and later used them in curricula she designed. In some instances, the worksheets are labeled with the teacher's name, some of which can be confirmed in the historical record. Many of the problems are labeled as "pupil," which suggests they were authored by students.

Transcription

To construct a problem bank, arithmetic word questions were transcribed "by hand" into Excel spreadsheets. This task, as well as data cleaning and lemmatizing, is completed manually rather than automatically so we could simultaneously analyze and form qualitative impressions of the questions and information available. Additional information provided with the math problems (such as grade level, author information, school information, etc.) was included with the entries. Purely numeric problems (no words) and questions unrelated to mathematical practices were excluded. Similarly, long, multi-part, often Q&A-style lesson plans and commentary on curriculum and/or pedagogy were also excluded. Transcription was completed without correction to spelling, grammar, punctuation, or other typos. A few examples of "typical" questions are reproduced below:

> If John can sew on 4 buttons and James can sew on 2, how many can both sew? (Kindergarten, Rainy Mountain, OK)
>
> If we pay each man $1.50 per day, how much do we pay 5 men for 1 day? For 7 days? (Grade 3, Charles Ammon, Blackrock, NM)
>
> About 1500 bushels of potatoes were harvested. What was the yield per acre? (Grade 5, Pupil, Haskell, KS)

Data cleaning

After the word problems were transcribed, several data cleaning tasks were required, mostly completed "by hand" and on a case-by-case basis. First, spreadsheets were standardized to contain the same columns of information as follows: Question, Grade, Author Name, Author Position, School Name, School Location, Notes, and Folder.

Schools that did not list their state were cross-referenced with the list of Indian boarding schools in the 2022 Federal Indian Boarding School Initiative Investigative Report (Appendices A and B).

Several authors appeared across multiple folders with differing titles or types of additional information. In these cases, information was combined in a way that retained all available data. For instance, the author "Chas. E. Burton" from Grand Junction, appearing in Folder 9, was determined to more than likely be the same person as "C. E. Burton, Superintendent" from Grand Junction in Folder 10. Therefore, all questions written by this author were given cross-referenced additional information; Author: Chas. E. Burton, Position: Superintendent, School: Grand Junction, Location: Colorado.

Finally, we addressed duplicate and "nearly-duplicate" database entries. True duplicates (identical questions and additional information) were deleted, with one copy retained. When multiple entries had identical questions yet differing amounts of otherwise identical additional information (i.e., both questions attributed to the same author, but one also lists grade level,) the entry with more information was kept. If the additional information was different or contradictory between the otherwise identical questions (such as different grade levels), all distinct entries were kept.

After accounting for differences in additional information, "nearly-duplicate" questions were addressed. For questions that were "essentially identical" up to one or two words, abbreviations, and/or spellings in a way that did not change the meaning of the question nor its mathematical solution, one was randomly selected to keep. If the questions differed by a number, it was considered a distinct question, and all versions were retained.

Analysis

Natural language processing (NLP) analyses such as frequency analysis and sentiment analysis were conducted. Unlike in the construction of the database, most of the tasks described below were automated using the Natural Language ToolKit (nltk) library (Bird et al., 2009) for Python programming language. For frequency analysis, the questions were tokenized (broken up into words), and stop words, numbers, and punctuation were removed. In addition to the standard list of nltk stop words, we excluded common words describing mathematical operations and their results, such as "many," "will," "much," "left," "per," and "find" as well as any spelled-out numbers. Next, words with multiple spellings, abbreviations, plural forms, tenses, and the like are combined as one root word. For instance, "lb", "lbs", and "pounds" are all equated with "pound." Rather than using nltk's lemmatizer, this task was again completed "by hand" by iteratively viewing the top 100 most commonly used words, determining possible variations, then combining until the list consisted of only root words. Finally, the frequency distribution of the modified word list is calculated.

Sentiment analysis was completed using VADER (Valence Aware Dictionary and sEntiment Reasoner), a pre-trained model in the nltk library that uses rule-based values tuned to social media sentiments (Hutto & Gilbert, 2014). VADER was used to automatically assign to each question in the database a compound polarity score between -1 and 1. The model is sensitive to both polarity (positive/negative) and strength of emotion conveyed by words in its dictionary. A score of -1 is considered very negative, 0 is neutral, and 1 is very positive. The compound polarity score is computed by summing up the sentiment scores of each word of the question and then normalizing. For instance, the word "horrible" contributes a score of -2.5 for having very negative connotations, while "okay" carries a value of 0.9, corresponding to a somewhat positive sentiment. VADER can also identify negation ("not") and amplification ("very").

It is important to note that VADER may have a different vocabulary than IBS teachers and pupils nearly a century ago. Therefore, it is likely that training a model on different data could yield more contextually specific results. On the other hand, VADER is an extremely accurate classifier found to even outperform individual human raters (Hutto & Gilbert, 2014), hence we did not attempt to take further measures to ensure the scorer reliability of the model. Indeed, due to the convenience of a pre-trained and trusted model, the difficulty of learning historical texts (Piotrowski, 2012), and the qualitative nature of our sentiment analysis, we proceed using VADER.

Results

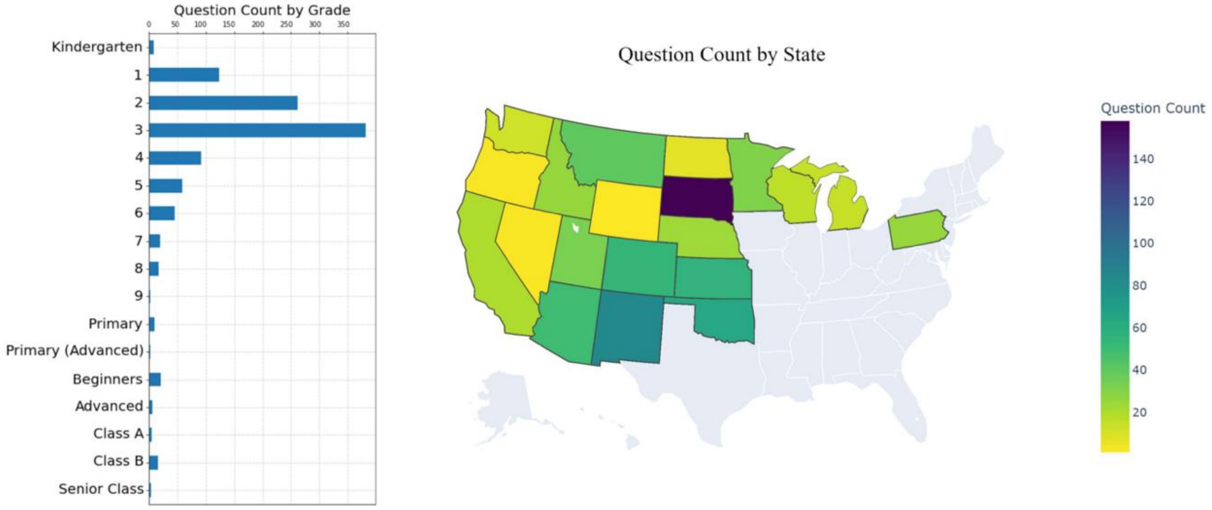
Summary statistics

The final problem bank database consists of 1604 unique combinations of 1576 word problems written by 98 authors from 63 schools across 20 states. Before cleaning, the total question count was 1741. In total, 1051 questions reported a grade, of which approximately 36% are intended for grade 3, 25% for grade 2, and 12% for grade 1. There were dramatically fewer questions for later grade levels, with a combined 3% for grades 7-9. See Figure 1 (a) for the exact distribution of question counts across all grades.

For 720 questions the school's location (by state) was reported or could be found in Appendix D of Federal IBS Initiative Report (Newland, 2022). Figure 1 (b) demonstrates the number of questions from schools within each state. The state with the most questions is South Dakota (158), from which there are eight schools in our dataset. New Mexico has the second most questions (84) from five schools.

Figure 1

Distributions of questions across grade (a) and state (b).



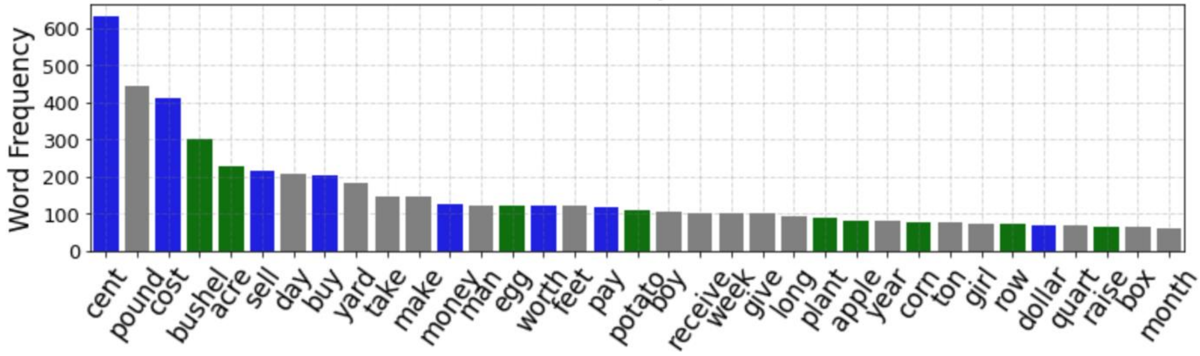
(a) (b)

Natural language processing

The frequency distribution of the most common words from database questions, post stopword removal and lemmatization, is shown in Figure 2. The most commonly used word is “cent” (combined with cents but not ¢), used 633 times followed by “pound” (combined with pounds, lb, lbs) used 444 times and “cost” (combined with costs, costed) used 411 times. Noting themes within the words, they were categorized into monetary words, farm words, and other. Of the top 35 most commonly used words, nine are related to money and eight related to farming, including two of each type in the top five.

Figure 2

Counts of the number of occurrences for the thirty-five most commonly used words from the problem bank. Colors correspond to monetarily-related (blue), agriculture-related (green), and other (grey).



Sentiment analysis yielded polarity scores indicating the “mood” of each question. The majority of the problems were labeled as very neutral with a polarity score of zero (n = 1213). Only 13 questions obtained a polarity score greater than 0.75 in magnitude (ten positive and three negative). Below are the three questions with the most negative polarity scores.

> [Write these numbers.] The late strike in Chicago cost the company twenty thousand dollars a day in fares, besides ten thousand dollars for property destroyed, while seven hundred fifty thousand people were deprived of their right to ride. The Freight Handlers' strike cost Chicago twelve million dollars in fruit, eggs, and other perishable stuff. (Grade 2)

> [Write these numbers.] The oleomargarin swindle takes seventeen million dollars, annually, out of the pockets of the poor (Grade 2)
>
> A doctor usually chargest $1.50 for a visit to a sick person if he does not go over a mile. A lady was sick for two weeks and the doctor called every day during that time. What was her doctor bill? (Grade 3)
>
> Similarly, the three questions with the most positive polarity scores are as follows:
>
> In playing a game of marbles a boy won 12 games and then lost 5. How many games did he win. He played another hour and won 13. How many did he win altogether?
>
> The Government farm produced this year 1350 bu. of potatoes from 9 acres of ground. The items of expense are as follows: for plowing $2.50 per acre, for harrowing, marking, furrowing and planting $2.00 per acre, for seed 12 bu. per acre at 60 cents per bu., cultivating 4 times 1 man and 1 horse 1 day each time, Paris green $27., harvesting 1 man and 1 horse 1 day for each acre, marketing 2 cents per bu. Allow $2. per day for the labor of a man and $1. per day for the labor of a horse. Allow 25 cents per acre for wear and tear of tools. Allow interest at 6% on land at $40. per acre, and taxes at $.002 on a dollar. What is the profit on 1 acre of potatoes if they are worth 40 cents per bu.? (Alice M. Peck, Hayward, WI)
>
> If we raise $25 worth of potatoes, 2 worth of beets, 5 worth of corn, 3 worth of tomatoes, 2 worth of cabbage, 1 worth of radishes,1 worth of peas, how many dollars worth of vegetables do we raise?

Discussion

In this work, we have described the construction and initial analyses of a new database consisting of mathematical word problems from the *Estelle Reel Papers*. Mostly, questions are intended for early-elementary school students with grades 1-3 comprising nearly three-quarters of the questions with documented grades. Less than five percent of questions were written for grades 7-9. Questions were primarily sourced from schools located in the West, Southwest, and Midwest.

Commonly used words are often associated with money, farming, and measurement. This is consistent with the assimilationist goal of the IBS system to force Native children to act and interact as white Americans (Adams, 2020; Child, 1998; Lomawaima, 1994). Furthermore, the emphasis on farming gives evidence that even math instruction in IBS was used to promote sedentary, farming lifestyles for Native Americans as part of a federal policy of Indian territorial dispossession and Indian assimilation through education (Adams, 2020; Newland, 2022).

A majority of questions were given polarity scores of exactly zero (approximately 76%). We acknowledge that this may appear to support the claim of neutrality of math and math education. However, it is important to know that classification was completed via an artificial intelligence model pre-trained on contemporary social media data. If the sentiment in the rules and training data is generally neutral regarding mathematical words and sentences, the model would have learned to classify them as such. Furthermore, neutral phrasing does not necessarily equate to neutral content. Indeed, bureaucratic and even "positive" language have oftentimes been employed by colonial powers to obfuscate violence and dehumanizing policies. Therefore, we use polarity scores and sentiment analysis with caution and as a tool to inform but not drive our analysis.

Nevertheless, the results of sentiment analysis indicate there are several questions that are far from neutral. It is interesting to note that the negative questions are particularly politically motivated, addressing freight worker strikes and Oleomargine, both considered a threat to farmers during that time (Burns, 2009). Furthermore, it is of interest to find that the question with the second most positive polarity score refers to the Government farm. The purpose of the positive phrasing in this question may be to influence students to see the Government, as well as farming, in a favorable way.

The purpose of this work is to introduce the database and provide several initial, broad, and quantitative descriptions. Further analysis of this problem bank is currently underway, including a discussion of gender roles and wage labor (Kim et al., 2023) and relationships with land and land ownership (Smith et al., 2023). We hope that this data will provide evidence and inspiration for other research directions, particularly those aimed at uncovering the political and sociological agendas of IBS and the role of the math curriculum as a tool to achieve them.

Who Writes Tomorrow's Learning Activities? Exploring Community College Student Participation in Learnersourcing

Steven Moore, Huy A. Nguyen, Norman Bier, Tanvi Domadia, John Stamper
StevenJamesMoore@gmail.com, hn1@cs.cmu.edu, nbier@cmu.edu, tdomadia@cmu.edu, john@stamper.org
Carnegie Mellon University, Pittsburgh, Pennsylvania, USA

Abstract: Generating multiple-choice questions (MCQs) is a popular form of learnersourcing that benefits both the students' higher-order thinking and the instructors' collection of assessment items. To better understand the type of students that engage with learnersourcing activities and inform whether these interventions are targeting all students or just a select few, we deployed multiple optional MCQ generation activities across three courses at two community colleges. To measure if these interventions were reaching all students, we analyzed how students' demographic data and performance in the course influenced their participation in a set of optional MCQ generation tasks. We found that students who performed better on the formative and summative assessments in the course contributed a greater number of learnersourcing activities; however, most of the top 10% of students in terms of quiz scores did not make any contributions, likely because they did not perceive these activities as necessary.

Introduction

Having students develop assessment questions has a long history as a learning activity, one that has shown real benefit in supporting student learning (Aflalo, 2018). These types of activities integrate deep engagement around subject matter with critical thinking and creative practices (Denny, 2015). Through the instrumentation of this process, student engagement can be leveraged in ways that provide meaningful data around student interaction, in addition to new student-generated learning assets that can support future learners (Denny et al., 2017). This is known as a form of learnersourcing, where students complete activities that produce content that can be leveraged by future learners (Kim, 2015). The continual creation and improvement of these questions allows for a greater breadth of topic coverage, helps to identify well-constructed and valid assessments, and as a result, enables improved learning opportunities.

While asking students to write new quiz or exam questions is a time-honored approach in many classrooms, current learnersourcing investigations emphasize the online context, where students' efforts to master domain content within a digital learning environment can be effectively studied at scale (Glassman et al., 2016). Specific implementation of learnersourcing activities can vary greatly between instructors, however, particularly in whether completion of these activities are treated as mandatory or optional (Moore et al., 2021). This distinction between mandatory and voluntary implementation is important: students who are offered a choice in completing learnersourcing tasks perceive these activities as having a greater value, gain more autonomy in the course, and contribute higher-quality questions compared to students that are required to participate (Singh et al., 2021). Indeed, efforts to force student engagement may backfire; requiring these tasks can lead to student disengagement as they participate with minimal effort in order to satisfy the requirements of the activity (Khosravi et al., 2021).

On the other hand, making the activities optional comes with its own risks: the activities may be neglected by the students who could benefit the most from these interventions, as oftentimes only the most driven students choose to participate in optional tasks (Inglis et al., 2011). This type of self-selection would have an impact beyond the individual students for learnersourcing activities, as only the top performing students may be generating data and new questions. This would in turn influence the question banks, hints, analytics, etc. generated by the students, limiting the diversity of the contributions, creating potential bias in the generated content, and potentially excluding a novice point of view that could be beneficial to learners (Nathan et al., 2001). Ideally students of all backgrounds and knowledge levels would participate in learnersourcing activities, but previous work has indicated otherwise – that participation for these question generation activities can be as low as less than 5% (Denny et al., 2018). These findings are further complicated by where such investigations take place, with a majority of the learnersourcing activities being deployed at top R1 four-year universities around the world (Wang et al., 2019).

Therefore, more research is needed to investigate which students are participating in these learnersourcing activities, how these interventions work and who they are targeting. To this end, we deployed several optional MCQ generation activities in three online courses across two community colleges in the United

States. Accompanying these tasks is a demographic survey to help better understand the students in the courses. As students worked throughout the first four or five weeks of their online course, they were presented with several opportunities to generate a MCQ for the given unit they were working through. We analyzed which students were participating and how their demographics and performance in the course may have influenced their participation. Our two research questions are as follows: (1) How does student participation with learnersourcing activities vary by student demographics? (2) How is student performance in the course related to their participation in optional learnersourcing activities? Through the investigation of these research questions, our work makes the following contributions towards online learning and learnersourcing tasks. First, we provide insights into the attributes of students that participate in learnersourcing activities. Second, we derive a set of performance measures commonly found in online courses that can serve as predictors of student participation in related activities.

Theoretical framework

We research in a climate that has appropriately prioritized equity and brought the larger challenges of fairness and related ed-tech into sharper focus. In the context of learnersourcing, diverse student engagement is critical, not merely to support a research agenda, but also to expand learning materials to reflect the broadest possible student experience. In contextualizing this research, we first look at how student participation and performance in online courses are potentially influenced by their demographic background. We then detail the process of question generation as a learning activity and how these questions can be utilized. This approach works to prioritize students' prior knowledge as a critical input into the larger learnersourcing effort.

Online courses offer students different affordances compared to traditional in-person ones, which can be both beneficial and detrimental to learning depending on the student. A study by (Ruthotto et al., 2020) found that over 90% of the students enrolled in online computer science courses participated at least once, but overall participation rates ranged along a continuum from active to passive participation. They found that student participation within these courses varied by demographics, such as ethnicity and age. Particularly in STEM, evidence suggests that online courses can perpetuate enrollment and participation gaps for women or ethnicities that are traditionally underrepresented in these courses (Kizilcec & Halawa, 2015).

Student engagement with an online course can be defined by their participation in its learning activities (Gledson et al., 2021). Multiple studies have linked student performance to their engagement with the course materials, indicating that students who actively participate and do more activities have a higher chance to pass the course and receive a higher grade (Brunskill et al., 2018). While research supports the benefits of having students participate in optional activities found in online courses, other factors such as the demographics of the students may also influence their participation and ultimately their success in the course (Rizvi et al., 2019). For instance, student motivation in STEM courses can be affected by stereotype threat, causing a lack of a sense of belonging (Bathgate & Schunn, 2017). This lack of participation, particularly when it involves learnersourcing, presents several challenges that propagate throughout the course. When students have lower levels of participation, they do fewer activities, which can pose difficulties in modeling their learning (Long & Aleven, 2013). Students doing fewer activities also leads to less data being generated, which can hinder the efficacy of instructional interventions, such as recommending practice problems (Andrade et al., 2016).

Learnersourcing has been used in many online courses across a variety of domains, where students are typically tasked with generating questions, making hints, or providing feedback (Khosravi et al., 2021). Having students generate short answer or multiple-choice questions (MCQs) that can then be used as practice opportunities in the current or future courses is a particular focus of much learnersourcing research (Wang et al., 2019; Yeckehzaare et al., 2020). An obvious challenge that arises from optional activities is getting the students to participate with them and making a meaningful contribution (Carvalho et al., 2018). Previous research has demonstrated that completing optional course activities is strongly related to a student's performance in a course (Koedinger et al., 2015). As researchers and educators, we want students to participate in learnersourcing activities, given that such activities can provide useful learning data, contribute to the instructor's assessment question banks, and benefit student learning (Aflalo, 2018). However, it is important to understand what factors might influence students's decision to participate in these optional activities, as addressed in the study by (Singh et al., 2021). To determine if such activities are reaching all students in the course, or only those from the commonly represented demographics or top-performing group, we need to investigate these factors as they relate to students contributing to these learnersourcing tasks.

Methods

This study was conducted in three different courses at two 2-year community colleges located on the west coast of the United States. All three courses took place online during the fall 2021 semester and IRB approval was received for the survey and activities added to the courses. The three courses were introductory chemistry, advanced chemistry, and introductory statistics. The two chemistry courses were taught at the same community college, but by different instructors. Students taking introductory chemistry were required to have previously passed a course covering the topics of linear algebra. For the advanced chemistry course, students were required to have passed both a linear algebra course and an introductory chemistry course at the college-level. The statistics course was taught at a separate community college by a third instructor. The only prerequisite for students in that course was to have passed a college-level intermediate algebra course.

We utilize data that came from four to five week-long units that were used towards the beginning of each course. This data consists of student interactions in the course along with their performance on the quizzes found at the end of each unit. There were a total of 64 students across all three courses, who were taking the courses to receive credit towards their respective degrees. There were no students enrolled in both of the two chemistry courses. Table 1 shows the number of learners in each course, along with a breakdown of their self-reported gender, ethnicity, and first-gen status. It also includes the number of units, and therefore quizzes, in the respective course, as introductory chemistry had five units and advanced chemistry and introductory statistics had four units. Our demographic questions accepted free text input to allow students the highest flexibility in identifying their background.

Table 1

Breakdown of the students in each course, their demographic information, and the number of units

Course	Units	Students	Male	Female	First-gen	Hispanic/Latin	Asian	White
Introductory Chemistry	5	17	5	12	8	12	3	2
Advanced Chemistry	4	18	4	14	12	12	5	1
Introductory Statistics	4	29	6	23	19	15	6	8

All three courses were deployed on the same learning platform, known as the Open Learning Initiative (OLI), which has been used in previous studies involving online learning at community colleges (Bälter et al., 2018; Ryan et al., 2016). It contains functionalities akin to popular learning environments often utilized at universities or in MOOCs. Each unit in these courses was equivalent to a chapter in a textbook, consisting of five to ten related topics and taking up roughly one week to cover. The units contain multiple pages of instructional content featuring text and brief instructional videos. These webpages also host multiple low-stakes activities interspersed amongst the instructional content for students to use as practice opportunities. They include multiple-choice, short answer, essay, matching, and fill-in-the-blank style questions. All of these activities act as formative assessments, intended to provide students with instructional feedback. As such, they are completely optional and do not account for the students' grade in the course. Additionally, students may make any number of attempts on these activities, receiving instant feedback on their response with each attempt. In all three of the courses, each unit concludes with a summative assessment in the form of a quiz that tests students on the material covered in that unit. The quizzes consisted of only multiple-choice or fill-in-the-blank questions and ranged from 4 to 22 questions. Students' scores across all of the quizzes counted towards a low percentage (5-15%) of their final grade in the course. All student data collected from OLI is securely stored in accordance with its IRB approval. In addition to the OLI platform, students in these courses utilized a learning management system for the other parts of their course, such as submitting homework assignments or viewing announcement posts.

Data collection and analysis

Our dataset came from the four to five week-long units at the beginning of each course, with four primary components: 1) Demographic survey, 2) Formative assessments, 3) Summative assessments, 4) Learnersourcing activities.

Demographic survey

When students first accessed the learning environment which hosts the formative and summative assessments, they were prompted with a brief demographic survey to complete. The survey asked the students to specify their gender identity, ethnicity, and if they were a first generational (first-gen) college student in their family. Students that did not fully complete this survey were not included in the present study. Additionally, as many of the responses were free-form, we had two researchers standardize the student responses (e.g., fixing typos), during this process there were no discordant cases.

Formative assessments

Throughout each course there are multiple formative assessments, commonly referred to as problems, embedded amongst the instructional text and videos intended to provide the students with practice opportunities and immediate feedback. They consist of multiple-choice, short answer, essay, matching, and fill-in-the-blank style questions. These activities are optional and do not impact the student's grade in the course. Table 2 shows the total number of formative and summative assessments in each course – note that these do not include the count of the MCQ generation activities, which we describe below.

Summative assessments

The end of each unit concludes with a page summarizing the content that was covered in the unit. This page also contains a link to the unit's quiz that students complete for a small percentage of their final grade. It consists only of multiple-choice and fill-in-the-blank style questions that can be automatically graded. In this study, the smallest quiz contains 4 questions, and the largest quiz contains 22 questions.

Learnersourcing activities

At the end of each unit in each course, we placed a learnersourcing activity that prompts students to generate an MCQ targeting any concept they learned from the unit. The interface of the MCQ generation activity includes the brief instructions for the students. The two bullet points shown in the activity's instructions reflect the unit's learning objectives which the MCQ should target. The number of MCQ generation activities is equal to the number of units in the course.

Table 2

The number of formative and summative (quizzes) assessments in each course

Course	Formative Assessments	Summative Assessments
Introductory Chemistry	126	5
Advanced Chemistry	94	4
Introductory Statistics	37	4

Our primary variable of interest is student participation with the learnersourcing activities in their respective course. In this study, we consider a student as having participated in the learnersourcing activity if they submitted a contribution that contains a question pertaining to the course's learning objectives, a correct answer choice, and three distractor options. If a student submitted a blank response, a random string of characters, or made no submission, they were not counted as having participated in the learnersourcing activity. Note that it was rare for students to exhibit this behavior, as the vast majority of them either skipped the learnersourcing activities or made an honest effort in their contribution to generate a MCQ. To measure student performance on the formative assessments, we used their accuracy on the first attempt they made on the problem. If they correctly answered the problem on their first attempt, then they would have the first-attempt correct for that problem. Previous research indicates that a student's first attempt at a problem is a strong indicator of their knowledge of the material (Corbett & Anderson, 1994). In the forthcoming analysis we utilize the average quiz scores of the students, as it represents their performance in the course up to that current point in the course.

Results

To understand which students were participating in the optional learnersourcing tasks, we first analyzed their demographic information in relation to their potential contributions to the learnersourcing activities. Next, we investigated the different patterns of student participation and performance by looking at their interactions with the formative and summative assessments embedded throughout the courses.

Student demographics

In total, 37 of the 64 (*57.81%*) students participated in at least one of the learnersourcing activities in their respective courses. To further investigate student participation with the learnersourcing activities in the courses, we looked at the demographics for students that contributed to any of the MCQ generation tasks. A Fisher's exact test revealed that there was no statistically significant association between gender and participation with any of the learnersourcing activities (*p=.484*). Similarly, there was no significant association between first-gen status and student participation with the learnersourcing activities (*p=.794*). We also looked at participation on the tasks related to the students' self-reported ethnicity. A chi-square test of independence showed that there was no significant association between ethnicity and task participation, $X^2(2, N=64)=.27, p=.873$. Table 3 provides the count of students who participated in the learnersourcing activities in each demographic group.

Table 3
Student participation with any of the learnersourcing tasks and their demographic information

Participated in learnersourcing	Students	Male	Female	First-gen	Hispanic/Latin	Asian	White
Yes	37	9	28	26	23	7	7
No	27	6	21	18	17	6	4

For the 37 students that participated in at least one or more of the learnersourcing activities, we investigated if their demographic background had any statistically significant effect on the percentage of learnersourcing activities they completed. Note there were four learnersourcing opportunities in advanced chemistry and introductory statistics, and five opportunities in introductory chemistry. An unpaired two tailed t-test revealed that there was no significant effect of gender on the number of learnersourcing activities students worked on, *t(35)=.95, p=.348*, with females *(M=.59, SD=.09)* doing slightly fewer of the learnersourcing activities than males *(M=69, SD=.10)* on average. There was likewise no significant difference in the percentage of learnersourcing activities between first-gen students (*M=.62, SD=.08*) and others *(M=.61, SD=.13)*, *t(35)=-.12, p=.452*. A Kruskal-Wallis test was conducted to examine the differences of the students' self-reported ethnicity and the percentage of learnersourcing activities they completed. There was once again no significant differences in participation found between groups, *H(2)=0.516, p=.773*.

While students' demographic background had no significant association with their participation with the learnersourcing tasks or the amount of learnersourcing tasks they engaged with, we also looked at how this information might be associated with their overall performance and participation with the other material found throughout the course. We found no significant effect of gender on the percentage of other formative assessments done in the course, *t(62)=1.48, p=.144*, where males (*M=.54, SD=.11*) and females (*M=.41, SD=.09*) had similar participation levels. There was likewise no significant effect of gender on the average quiz scores, *t(62)=.61, p=.546*, with males (*M=.73, SD=.05*) and females (*M=.68, SD=.09*) receiving similar scores. Similar null effects were found for the formative assessments, *t(62)=-1.07, p=.287*, and quiz scores, *t(62)=-.83, p=.407*, between first-generation students ($M_{formative}=.46$, $SD_{formative}=.09$; $M_{quiz}=.71$, $SD_{quiz}=.07$) and others ($M_{formative}=.38$, $SD_{formative}=.11$; $M_{quiz}=.65$, $SD_{quiz}=.11$). Finally, a Kruskal-Wallis test revealed no significant formative assessment participation, *H(2)=3.913, p=.141*, or quiz scores, *H(2)=1.233, p=.539*, between students' self-reported ethnicities.

Student performance

We focus on how student participation and performance within their respective course might reflect their contribution to the learnersourcing activities. Our study showed that students who participated in the learnersourcing activities (*M=.62, SD=.07*) had a significantly greater percentage of the formative assessments completed in their respective course than those that did not (*M=.18, SD=.02*), *t(62)=-8.07, p<.005*. Relatedly, there was a significant positive correlation between the percentage of formative assessments done by the students with the number of learnersourcing activities they completed, *r(62)=.28, p<.005*. Table 4 provides the average amount of formative assessments completed in each course by students who participated or did not participate in the learnersourcing activities, including those students that only did the quizzes in these averages.

Table 4

Average percentage of formative assessments completed in the courses and the average quiz scores, out of 100, by students that participated in the learnersourcing activity (Yes) and those that did not (No)

Course	Learnersourcing Participation			
	Average Percentage of Formative Assessments Completed		Average Quiz Scores (out of 100)	
	Yes	No	Yes	No
Introductory Chemistry	73.71	26.98	72.83	67.00
Advanced Chemistry	61.70	10.99	67.50	73.03
Introductory Statistics	49.83	22.45	64.23	71.27

While participation in the course was positively correlated with doing the learnersourcing activities, as expected, we wanted to further investigate if these activities were more likely to be done by students already performing highly in the course or if it was a true mix of the students. We found that students who performed better on the formative assessments in the course were also more likely to contribute to the learnersourcing activities. These students who participated in the learnersourcing activities ($M=.48, SD=.10$) compared to those who did not ($M=.66, SD=.03$) had a higher percentage of correctness on their first attempt in the formative assessments, $t(62)=2.99, p<.005$. For the 37 students that participated in one of the learnersourcing tasks, there was also a positive correlation between the number of learnersourcing activities completed and the percentage of correctness of first attempts on the formative assessments, $r(35)=.35, p<.005$.

Next, we examined student performance on the summative quizzes at the end of each unit. Table 4 also shows the average quiz scores across all three courses divided into two groups based on if the students participated in any of the learnersourcing activities. We analyzed how a student's performance on the quizzes correlated with the amount of learnersourcing activities they completed. Ultimately, we found a significant positive correlation between a student's average quiz score and the number of learnersourcing activities they did in the course, $r(s)=.26, p<.05$. Interestingly, across all three courses, seven students had a perfect quiz average, receiving full credit for all four or five quizzes depending on the course. However, of those seven students, only one of them participated in the learnersourcing activities, contributing to all four of them in the advanced chemistry course.

Discussion

In this study, we investigated how student demographics and performance within online community college courses influenced their participation in a learnersourcing activity that involves generating a multiple-choice question. We found that 37 of the 64 students across the three courses participated in at least one of the learnersourcing activities; these students came from a variety of demographic backgrounds, expressed in terms of self-reported gender, ethnicity, and first-gen status. Our analysis revealed a correlation between the completion of formative assessments and the likelihood of students participating and contributing to a higher number of learnersourcing activities. Interestingly, the top 10% of students, as determined by their quiz score averages, did not participate in any of the learnersourcing activities.

We found no significant relationships between the students' demographic background and their participation with the learnersourcing activities. This may in part be due to our students primarily reporting the same gender and ethnicity, thus decreasing the potential diversity of our sample. While we did not identify any significant effects, our data indicates that a majority of the students from all the reported ethnicities, genders, and first-generation status made at least one contribution to an optional learnersourcing task. While we were encouraged to see that students of all backgrounds were participating, learnersourcing research should continue to collect demographic information to ensure all students are being reached by the activities and interventions. A core benefit of learnersourcing student-generated questions is that their unique perspectives and backgrounds can be incorporated into the questions they create, ultimately avoiding expert-blindspot and contributing to a more diverse pool of questions (Nathan et al., 2001). However, if the learnersourcing activities are skipped by students, knowing why they are not participating in them and the backgrounds of those students, could potentially inform methods on how to better include all students.

As expected, due to prior research in the area, student participation with the formative assessments in the course was positively correlated with their performance on the summative assessments (Brunskill et al., 2018). We found that students who did more of the formative assessment were also more likely to participate in the learnersourcing activities. There was also a strong positive correlation between the number of formative assessments done and the number of learnersourcing activities students completed. This further suggests students might follow a completionist approach when working through the online materials and not skip the learnersourcing activity, which has been previously reported by (Singh et al., 2021).

In addition, student performance on both the formative and summative assessments was found to correlate with participation and the number of learnersourcing activities completed. These results indicated that the highest performing students were skipping the task. As mentioned, 7 of the 64 students achieved a perfect score on all the quizzes in their respective courses, yet among these seven students, only one participated in the learnersourcing activities, doing all four offered in their advanced chemistry course. This brings into question if the optional presentation of the learnersourcing activities could be potentially excluding the lower performing students that might benefit the most from these interventions, as well as the top performing ones. While we seek to ideally find a middle ground and engage the full range of learners in the current study, such activities may potentially exclude both the most and least in-need students. The MCQs generated from these top students might be closer to the level of instructor ones due to the advanced domain knowledge they possess (Mitros, 2015).

Our contributions should be interpreted against the following limitations. The three community college courses used in this study feature students from three different self-reported ethnicities. While this is representative of the institution-wide demographics, courses at other community colleges might yield a different student population. Additionally, we focused our analysis on data from three STEM courses. Extending this research to more courses from other domains, including non-STEM ones, might provide a more representative sample of students. However, since previous learnersourcing work neglects to provide demographic information, our current focus provides a first step at investigating how the different student populations of a course might be contributing to learnersourcing tasks. Additionally, we did not ask the students to report their native language, which might influence students' willingness to participate in the MCQ generation process.

Conclusion

In this work, we investigated the optional participation of students in the form of learnersourcing, where they generated multiple-choice questions relevant to the course content. Across three community college courses, our results showed that student demographics had no significant effects on their participation with the learnersourcing activities. However, we had moderate participation from a wide range of students on the task across all courses. Our analysis suggests that students' likelihood of participation with a learnersourcing activity is more dependent on their participation and performance with the other assessments found in the course, rather than on their demographic background. Additionally, we identified several features of student performance in the courses that influenced their participation with learnersourcing activities. These findings demonstrated that better performing students were likely to participate in learnersourcing, yet students at the lowest and highest end of the performance spectrum may still neglect such activities. This work contributed the first study which explicitly investigates the demographics of students participating in learnersourcing activities. It demonstrates that optional learnersourcing activities can still garner participation from a diverse set of students. Future learnersourcing efforts may incorporate participation and performance analytics to encourage students to contribute to learnersourcing tasks.

Assessing Young Children's Computational Thinking Using Cognitive Diagnostic Modeling

Chungsoo Na, Jody Clarke-Midura
chungsoo.na@outlook.com, jody.clarke@usu.edu
Utah State University

Abstract: This study illustrates how Cognitive Diagnostic Modeling (CDM) can be used to assess fine-grained levels of computational thinking (CT). We analyzed scored responses to the *Computational and Spatial Thinking assessment* (CaST) from 271 children. We identified four key attributes required to solve tasks: *sequencing of codes, fixing a program, spatial orientation of an agent, and rotation on a point*. Results indicated that younger children did not master all the attributes, particularly *spatial orientation of an agent* and *rotation on a point*. We identified four common mastery profiles of children that were associated with age. Our findings illustrate that mastering *spatial orientation* is critical to CT ability. Finally, the nuanced information about children's mastery levels has potential to provide teachers with useful information about what concepts and skills their students are struggling with so that they can adjust instruction to emphasize those concepts.

Introduction

Providing children opportunities to engage in computational thinking (CT) in early elementary school is becoming increasingly important. CT is "the thought processes involved in formulating a problem and expressing its solution" (Wing, 2014) and is often operationalized in the context of coding. Accordingly, there is a need for a better understanding of the instructional approaches, practices, and assessments that support children's development of CT in early elementary classrooms (Luo et al., 2022).

While instructional resources and assessments of CT for early elementary exist (e.g., Relkin et al., 2020), most assessments report a single total score of overall CT ability. Although these assessments are valuable, they provide an *audit* of CT learning as opposed to granular evidence of children's CT understanding that can be directly linked to classroom instruction. In order to better support the development of CT in elementary classrooms, we propose using cognitive diagnostic models (CDMs), an approach to assessment that provides fine-grained information about what skills or attributes a child has or has not yet mastered. In CDMs, multiple latent concepts and skills, referred to as attributes, are identified and linked to assessment tasks indicating which attributes are required to solve each individual task. The scored responses of the tasks are used to provide a categorical classification (i.e., mastery vs. non-mastery) of the attributes. For example, if a child correctly responds to all the tasks that are linked to the attribute *identify bugs in buggy programs*, we infer they have mastery of the attribute. But what if they only answer half of those items correctly? Or what if a task is associated with more than one attribute? Knowing which attributes students have and have not mastered allows teachers to adjust classroom instruction based on their students' needs. The purpose of this paper is to explore how we can use CDMs by conducting an analysis on existing assessment data from a study where 271 children between the ages of 4 and 8 participated in a performance assessment, *Computational and Spatial Thinking* (CaST) assessment, designed to assess CT. Given the large range in ages, we are interested in whether performance is related to age. Our analysis was guided by the following questions: (1) *How does the CDM fit the performance assessment data? (2a) What mastery profiles of CT do children exhibit? (2b) Are these profiles associated with children's age?*

Assessment of computational thinking for emerging readers

As part of a larger project, we operationalized CT for early elementary classrooms and developed curricular resources and an assessment (CaST) around coding toys and coding environments that involve programming with directional codes *forward, backwards, rotate right, and rotate left* (see Clarke-Midura et al., 2021). Figure 1a shows children working on curricular tasks (on the left) and 1b shows a child taking the assessment and the materials associated with it (on the right). The development of the assessment was connected to and dependent on the development of the CT model and curricular tasks. We engaged in iterative cycles of design-based-research (DBR) where we refined each element (CT model, curriculum, assessment) based on new information learned in the process. We identified algorithmic thinking (AT), decomposition (modularity), debugging, abstraction, and spatial thinking (ST) as developmentally appropriate components of CT. We also identified mathematical knowledge (MK) that was required to solve CT tasks such as rotation on a point, linear units, and counting on.

The Evidence Centered Design (ECD) framework (Mislevy & Haertel, 2006) guided the design of our CaST assessment tasks. The systematic process helped us articulate: the skills we wanted to assess, what inferences we wanted to support, what evidence we would need to support our inferences, the situations that would elicit the behaviors and observations of the skills and provide evidence, and how we would measure the skills. We used design patterns to document variable features of the tasks and the knowledge we thought each task was assessing. We specifically designed tasks to measure some of the skills we noted were necessary for CT tasks but were not part of most published CT models (e.g., rotation on a point and orientation of agent).

The CaST assessment is designed around a series of performance tasks (n = 19) that involve children either writing sequences of codes to navigate an agent from one location to another on a 6 × 6 2D grid, enacting programs by physically moving the agent on the grid, or debugging and fixing given programs using the four directional codes presented in Figure 1b (*forward, backward, rotate left, rotate right*). Given that the children we are assessing are emerging readers, the assessment is standardized and administered via a one-on-one format. The tasks are unplugged so the assessment can be used with a variety of coding toys and contexts that rely on navigational codes, which are common for pre-literate children. Some tasks have multiple correct answers, and all tasks were scored as incorrect or correct resulting in a total possible score of 19 points.

The assessment was validated in a prior study in which the items fit well to a two-parameter unidimensional Item Response Theory model (2PL IRT, see Na et al., 2023). The results of item analyses showed a high item discrimination (M = 2.26) and a moderate item difficulty (M = -.21), on average, with a high marginal reliability (r_{xx} = .87). IRT can estimate individuals' true ability score (θ) on a continuous scale, whereas CDMs classify examinees by whether or not they mastered each of the attributes that are required to successfully respond to the assessment tasks. Examinees are then classified into profiles based on the similarity of their responses. A benefit of CDM is that teachers can be provided with information on attribute mastery at both student and class levels.

Methods

Sample, procedures, and data source

Our sample included 271 children (girls = 142; aged 4-8; M_{age} = 6.54) from five elementary schools in the Western United States. For the analysis, age was categorized into three groups: young (< 72 months; n = 83), middle (72 ≤ months < 84; n = 104), and old (≥ 84 months; n = 84). The assessment was administered in a one-to-one interview format, by trained researchers in a quiet area in the schools. The administration took an average of 16.4 minutes per child. All assessments were video recorded and later scored by two independent researchers. Each task was scored as correct or incorrect. The two raters had high agreement (κ = .91). Tasks where there was no agreement were reviewed by the research team.

Data analysis

Statistical analysis was a multi-step process. The first step was to map the assessment tasks to a task-by-attribute table, which is called a Q-matrix. Identifying attributes entails hypothesizing what skills are needed to answer each task. We then validated and refined the Q-matrix. Our next step was to fit the Q-Matrix to the data by using a CDM model. We fit and compared three CDMs – DINA, DINO, and G-DINA – all of which have been widely adopted in empirical studies using CDMs. As a non-compensatory model, DINA (Deterministic Input, Noisy "AND" gate model) assumes that to answer a given task, children must possess all required attributes. For example, in the case of task 18 which is linked to two attributes, *fixing a program* (A2) and *spatial orientation of* *an agent* (A3), the assumption under the DINA model is that a child must possess mastery of both attributes to successfully solve it. DINO (Deterministic Input, Noisy “OR” gate model) is a compensatory model, which assumes that if children have at least one attribute, they are likely to correctly respond to a task. In the case of task 18, if a child has mastered either *fixing a program* (A2) or *spatial orientation of an agent* (A3), they can correctly answer this task. Lastly, as a saturated model, G-DINA (Generalized Deterministic Inputs, Noisy “AND” gate model) assumes both compensatory and non-compensatory features within the test and therefore models the main effects of each attribute in conjunction with all possible interaction effects among attributes. Hence, in the example of task 18, children could have different levels of mastery probabilities depending on which attributes they have mastered or not. Both DINA and DINO are nested to G-DINA, which allows for log-likelihood test in model comparison. From the selected model, we conducted mastery profiles of each attribute, their classification accuracies, and identified mastery profiles to address our research questions. All statistical analyses were conducted in R (version 4.2.2) with *GDINA* package (Ma & de la Torre, 2020). Details of each step are described below.

Constructing, validating, and refining the q-matrix

To construct a Q-matrix, we reviewed the assessment tasks and existing test specifications. The ECD process we used to design the assessment required that we document details of the tasks, such as variable features and knowledge being assessed, that we were able to use and share for identifying the attributes. We identified four attributes that were required to solve the tasks: *sequencing codes, fixing a program, spatial orientation of an agent, and rotation on a point* (see Table 1) and then mapped them onto the items into a Q-matrix.

Table 1

Four Attributes of the CT Assessment Tasks

	Attribute	Concept	Description
A1	Sequencing codes	AT	Represents the skill of ordering and arranging codes based on knowledge of syntax and semantics
A2	Fixing a program	Debugging	Represents the skill of implementing a successful strategy to fix bugs
A3	Spatial orientation of an agent	ST	Represents the skill of knowing that the codes always produce the same movements but depend on the agent’s orientation
A4	Rotation on a point	MK	Represents the skill of knowing that a rotation occurs by rotating on a fixed point at a set angle, not translating to an adjacent point

Note. AT refers to algorithm thinking; ST refers to spatial thinking; MK refers to math knowledge.

Table 2

Refined Q-matrix for Four Attributes of CT and their PVAF values

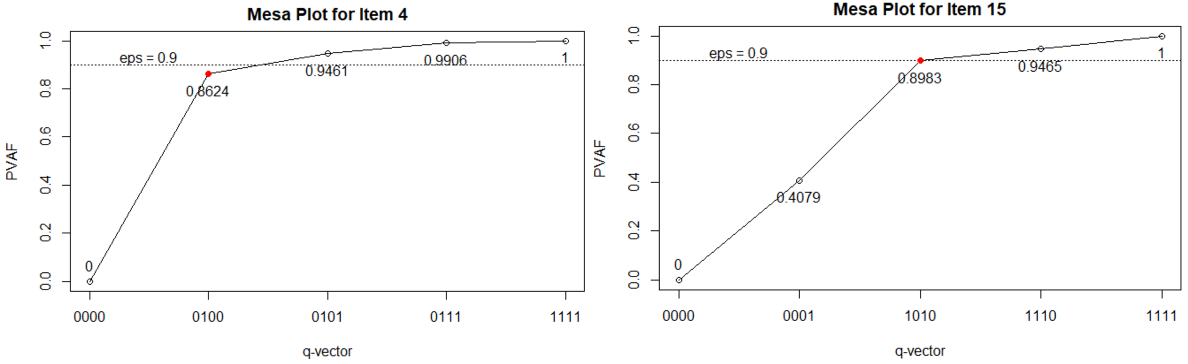
Item	Attributes				PVAF	Item	Attributes				PVAF
	A1	A2	A3	A4			A1	A2	A3	A4	
1	1	0	0	1	.941	10	0	1	0	1	.988
2	1	0	0	0	.949	11	0	1	0	1	.990
3	1	0	1	0	.994	12	0	1	1	1	.999
4	0	1	0	0	.862	13	0	1	1	1	.991
5	0	0	0	1	.966	14	1	0	1	0	.933
6	0	1	0	1	.999	15	1	0	1	0	.898
7	1	0	1	1	.984	16	1	0	1	0	.981
8	0	1	1	1	.994	17	1	0	1	0	.974
9	0	1	0	1	.997	18	0	1	1	0	.993

Note. “1” refers to required attributes to solve given items, whereas “0” indicates non-required in the attribute of each item. A1 refers to sequencing of codes, A2 refers to fixing a program, A3 refers to spatial orientation of an agent, and A4 refers to rotation on a point. PVAF refers to the proportion of variance accounted by q-vectors.

The Q-matrix was qualitatively validated by expert review of two raters (κ = .82). In order to validate the Q-matrix quantitatively, the proportion of variance of accounted (PVAF, de la Torre & Chiu, 2016) by each item-attribute specification (i.e., q-vector) was calculated and the acceptable PVAF values set to .90. We also used a mesa plot (see Figure 2), which visualized the relationship between possible q-vectors in the x-axis, and PVAF values in the y-axis to visually investigate possibilities to refine the Q-matrix. Fitting the initial Q-matrix to the assessment response data (19 tasks) did not yield acceptable model fits, so we eliminated one task and modified q-vectors of five tasks. After iterative modifications of the Q-matrix, we refitted the refined Q-matrix to the response data (18 tasks), resulting in acceptable model fits. While most tasks showed acceptable PVAF values, a mesa plot suggests that task 4 (PVAF = .862) and task 15 (PVAF = .898) need further modifications of q-vectors (see Figure 2). However, we did not modify q-vectors of these two tasks because these changes led to only minuscule increases in PVAF (less than .10 of changed PVAF) and were not aligned with what these tasks intended to measure from expert reviews. As a result, we used data from 18 of the 19 tasks with the refined Q-matrix (see Table 2) in which three tasks were assigned to one CT attribute, eleven tasks were assigned to two CT attributes, and four tasks were assigned to CT three attributes.

Figure 2

Mesa Plots of Unfitted Items (Item 4 and 15); Note. X-axis refers to item-attribute specifications (q-vectors) and Y-axis refers to PVAF refers to proportion of the variance accounted for the q-vectors. A filled dot in the mesa plot means the q-vector denoted in the Q-matrix, and black dots mean possible q-vectors in the Q-matrix. Eps (epsilon) refers to a designated threshold value of PVAF.



Selecting the appropriate CDMs

In order to select the most appropriate model, we evaluated the model fits of the three models (see Table 3). We specifically looked at the Akaike Information Criterion (AIC) and the likelihood ratio test (LRT). As shown in Table 3, G-DINA showed the lowest AIC and the LRT was significant when comparing the general model (G-DINA) to the reduced models DINA (LR: 205.11, *df* = 46, *p* <.001) and DINO (LR: 232.80, *df* = 46, *p* <.001). Thus, G-DINA was selected for the CDM model for subsequent analyses.

Table 3

Model Fit Indices for G-DINA, DINA and DINO

Model	AIC	*n*Pars	Loglik	Likelihood Ratio Test		
				LR	*df*	*p*-value
G-DINA	4635.68	97	-2220.84			
DINA	4748.79	51	-2323.40[a]	205.11	46	<.001
DINO	4674.47	51	-2337.24[b]	232.80	46	<.001

Note. AIC refers to Akaike information criterion; *n*Pars refers to number of model parameters; Loglik refers to log likelihood; LR refers to likelihood ratio; [a]G-DINA versus DINA; [b]G-DINA versus DINO.

To address RQ 1, using the G-DINA model, we estimated mastery probabilities and classification accuracies for each attribute. Using expected a posteriori (EAP, Huebner & Wang, 2011), children were classified as mastery of attributes (“1”) when their mastery probabilities of each CT attribute were above .50; otherwise, they were classified as non-mastery (“0”). For example, if a child has .373 for *sequencing of codes* (A1), .829 for *fixing a program* (A2), .992 for *spatial orientation of an agent* (A3), and .171 for *rotation on a point* (A4), their mastery status of each attribute is “0” for *sequencing of codes* (A1), “1” for *fixing a program* (A2), “1” for *spatial orientation of an agent* (A3), and “0” for *rotation on a point* (A4), resulting in a mastery profile of “0110”. Mastery proportions of each attribute – the ratio of the number of children who have mastered a given attribute to the total number of the sample - represent their relative difficulty, and their classification accuracies indicate the reliability of classifying children’s mastery status as either mastery or non-mastery.

To address RQ 2, we estimated individuals’ mastery profiles of the four CT attributes from the CDM results. For example, a mastery profile of 0100 refers to a set of children who have mastered *Fixing a program*

(A2) but have not yet mastered the other three CT attributes. We evaluated which mastery profiles were common or rare among our sample. We further conducted a chi-squared test of independence to examine the associations between identified mastery profiles and age groups. Results of this analysis are presented below.

Results

The viability of classifying children's mastery status of CT attributes

As we see in Table 4, approximately 48% of children mastered *sequencing of codes* (A1) and *fix a program* (A2), respectively. Fewer children mastered *spatial orientation of agent* (A3; 37.3%) and *rotation on a point* (A4; 40.6%). While mastery proportions of four attributes were higher for the older children (see Figure 3), we note that mastery proportions of *spatial orientation of an agent* (A3) were substantially lower (59.5%) than the other three attributes in older children. Likewise, in middle age children, *spatial orientation of an agent* (A3, 27.9%) and *rotation on a point* (A4, 26.0%) showed lower mastery proportions than the other two attributes. The estimated classification accuracies at the attribute level were high; they ranged from .90 to 97 and were .85 at the test-level. These values the G-DINA model reliably classifies children into attribute mastery. Figure 3 presents the mastery proportions of each attribute within the total sample and by each age group.

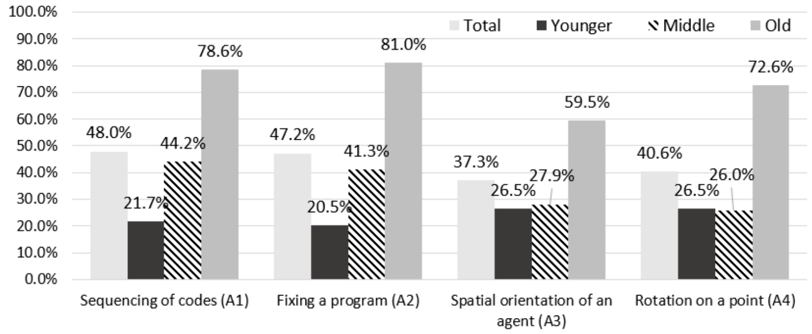
Table 4

The Proportion of Mastery of Four CT Attributes and their Classification Accuracies

	A1. Sequencing of codes	A2. Fix a program	A3. Spatial orientation of an agent	A4. Rotation on a point
Mastery proportion (%)	48.0%	47.2%	37.3%	40.6%
Classification accuracy	.96	.96	.90	.97

Figure 3

Mastery Proportions of Each Attribute in the Total Sample and Age Groups

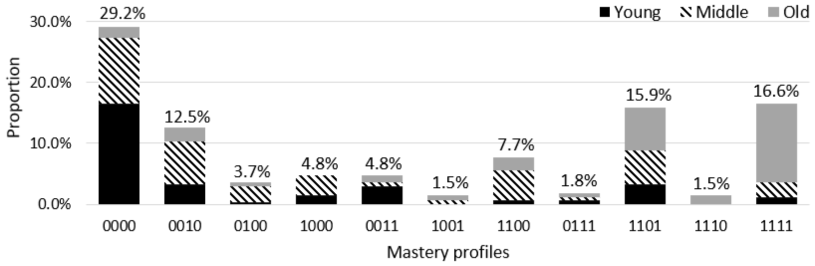


Detecting CT mastery profiles and the profiles association with children's age

CDM results yielded 11 mastery profiles out of a possible 16. Figure 4 shows the distribution of the profiles by age group where 0000 means that none of the four attributes were mastered and 1111 means that all of the four attributes were mastered. A chi-squared test of independence confirmed that the mastery profiles are statistically associated with the age groups, $\chi^2(20) = 123.83$, $n = 271$, $p < .001$, Cramer's V = .478.

Figure 4

Identified 11 Mastery Profiles of CT Components by Age Groups



We focus on the four most common profiles (those with proportions > 10%):

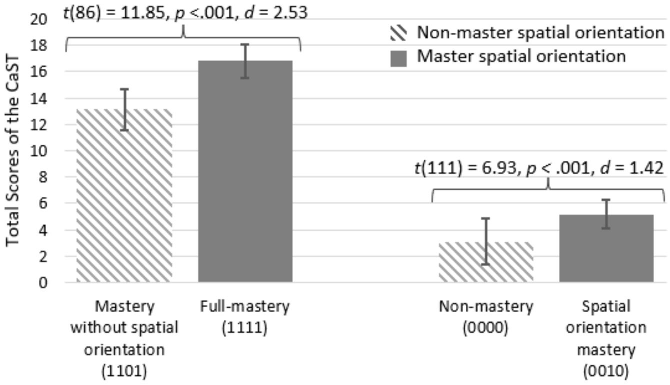
- *Non-mastery profile* (0000, *n* = 79). This profile represents children who have not mastered any of the CT attributes. It is the most common profile (29.2% of children). It is comprised of mostly young (*n* = 45) and middle (*n* = 29) children, compared to a small number of the older children (*n* = 5). This profile had the lowest total scores on CaST assessment among all 11 mastery profiles, *M* = 3.09, *SD* = 1.53.
- *Full-mastery profile* (1111, *n* = 45). This represents children who have mastered all four CT attributes. It is the second most common profile (16.6%). The group is comprised primarily of older children (*n* = 35) and some middle (*n* = 7) and younger (*n* = 3) children. This profile scored the highest CaST total score, *M* = 16.80, *SD* = 1.10.
- *Mastery without spatial orientation profile* (1101, *n* = 43). This profile represents children who mastered all of the CT attributes except *spatial orientation of an agent* (A3). It includes 15.8% of the sample and was comprised mostly of older children (*n* = 19) and middle children (*n* = 15) compared to younger children (*n* = 9). This profile had relatively high total scores on CaST assessment, *M* = 13.14, *SD* = 1.74.
- *Spatial orientation mastery profile* (0010, *n* = 34). This group only mastered *spatial orientation of an agent* (A3). It includes 12.5% of the sample. This profile was comprised of middle (*n* = 19), young (*n* = 9) and older (*n* = 6) children. This profile had relatively low total scores on CaST assessment, *M* = 5.18, *SD* = 1.29.

Importance of spatial orientation of an agent

Based on the attribute mastery results, we decided to conduct an ancillary analysis to explore the role of *mastering spatial orientation of an agent* (A3) on overall CT abilities. Using the total assessment score as a proxy of overall CT abilities, we conducted independent *t*-tests between the *full-mastery* profile (1111) and *mastery without spatial orientation* profile (1101); and between the *non-mastery* profile (0000) and s*patial orientation mastery* profile (0010) to check the role of spatial orientation in the overall CT ability. The result of the independent *t*-tests showed that the *full-mastery* profile (*M* = 16.80; *SD* = 1.10) significantly outperformed the *mastery without spatial orientation* profile (*M* = 13.14, *SD* = 1.74) on the CaST assessment, based on the CaST total score, *t*(86) = 11.85, *p* <.001, *d* = 2.53 (see Figure 5). The *spatial orientation mastery* profile (*M* = 5.18, *SD* = 1.29) had significantly higher CaST total scores than the *non-mastery* profile (*M* = 3.09, *SD* = 1.53), *t*(111) = 6.93, *p* < .001, *d* = 1.42 (see Figure 5). The results suggest that mastering *spatial orientation on an agent* (A3) played a significant role in children's overall CT abilities.

Figure 5

Mean Differences in the CaST Total Scores by whether Children Mastered Spatial Orientation



Discussion

This study explored the viability of using CDMs to diagnose mastery levels of children's CT abilities on a finer grain size by looking at four attributes: *sequencing of codes, fixing a program, spatial orientation of the agent, and rotation on a point*. We were able to fit a CDM model, G-DINA, to the CaST assessment response data and yielded information about the mastery proportions of the four attributes as well as profiles of attribute mastery in the sample, by participant's age. We conducted an additional analysis based on our results to explore the role of spatial orientation on overall CT ability using the CaST assessment total score as a proxy.

We hypothesized that knowledge of sequencing of codes, fixing a program, spatial orientation of the agent, and rotation on a point were required for children to answer the tasks on the CT assessment. Looking at just the mastery of attributes, our results indicate that higher proportions of older children mastered the four CT attributes and that the proportion of older children who mastered spatial orientation of an agent was lower than for the other three CT attributes (Figure 3). Overall, much smaller proportions of middle and younger children mastered all four attributes. Smaller proportions of middle children mastered spatial orientation of an agent and rotation on point. Yet for the younger children greater proportions showed mastery of spatial orientation of the agent and rotation on a point than the sequencing of codes and fixing a program attribute. Overall, the older children had higher proportions of mastery in the CT-related concepts than the spatial and mathematical concepts whereas the younger children had higher proportions of mastery in the spatial and mathematical related concepts. These findings align with the results of RQ 2a that show the most common mastery profile was the *Non-mastery profile*. The mastery profiles show how children's responses and attribute mastery cluster into patterns. Focusing on the four most common mastery profiles, we see that the old and middle age children were likely to be assigned to the *full-mastery* and *mastery without spatial orientation profile*, whereas the young age group were more likely to be assigned to the *non-mastery* profile. Put differently, the young children in our sample (< 72 months) have not yet mastered most of the attributes of CT, while some of the children in the middle and older age groups (≥ 72 months) either mastered all the CT attributes or needed only more experiences with spatial orientation of the agent. These findings align with Relkin et al. (2020) who in a sample of a similar age range of children found that older children performed better on measures of CT. These findings suggest that children's understanding and proficiency in CT may be associated with their age, which supports the need not only for developmentally appropriate curriculum, resources, and assessments for fostering and measuring CT in early childhood but a need to provide younger children with opportunities to engage with CT through playing with coding toys.

Perhaps the most interesting mastery profile is the *spatial orientation mastery profile* (0010, $n = 34$). This group only mastered one attribute: *spatial orientation of an agent* (A3). While it only included 12.5% of the sample, it was mostly comprised of middle age children ($n = 19$), with some young ($n = 9$) and older ($n = 6$) children. This profile had relatively low total scores on the CaST assessment ($M = 5.18$, $SD = 1.29$). We conducted additional analyses to explore the role of the spatial orientation of an agent attribute on CT knowledge, using the total CT assessment score as a proxy. The results suggest that mastering *spatial orientation on an agent* (A3) played a significant role in the overall CT abilities, as measured by the overall score on the CT assessment. Spatial thinking (ST) entails understandings of space and objects' positions in space, reasoning with objects or representations in space, and operations on spatial relationships (NRC, 2006). A component of ST, spatial orientation is the understanding of different positions in space, and children first develop spatial orientation concepts in relation to their own position in space and later develop external-based reference systems using landmarks outside themselves (Sarama & Clements, 2009). Researchers have identified a number of factors constituting spatial thinking skills; however, there is no consensus in its exact structure or consistency in measurement (Atit et al., 2020). Existing research on the relationship between CT and ST has looked at children's relation of CT skills with non-verbal visuospatial reasoning (Tsavara et al., 2022), mental rotation skills (Città et al., 2019), and spatial ability (Román-González et al., 2017) and found significant correlations between concepts of ST and CT in early childhood. Our findings further support the importance of the relationship of ST and CT and the need to better understand this relationship in early childhood.

The older and middle age group of children in our sample had higher mastery probabilities of sequencing codes and debugging programs, than spatial orientation of the agent (see Figure 3). It could be that the kinds of exposure to CT that the older children have through coding provide more experience with practices like sequencing and debugging and less with spatial orientation of agents. In the US, kindergarten standards mostly focus on applying spatial knowledge as relational from their own perspective and not from different perspectives, which means children do not get a lot of exposure to this in kindergarten. Previous research on young children playing with tangible coding toys observed children shifting back and forth between egocentric and allocentric perspectives, or reference frames, while programming robots to navigate paths on the floor. Children's inability to take on an allocentric perspective, the robot's perspective when the robot was facing a different orientation often resulted in coding errors such as selecting the wrong code (Clarke-Midura et al., 2021; Wang et al., 2021). Our findings support these findings and suggest the importance of playing with tangible coding toys at a young age to aid in the development of both ST and CT skills. Finally, research has shown that ST is a critical component of STEM learning and practices and is domain dependent (Atit et al., 2020). While ST skills are malleable and can be improved through training and instruction (Uttal et al., 2013), instead of fostering ST independently, it is more critical to situate ST into overall CT learning activities. As mentioned above, more research is needed that explores the relationship of ST and CT skills in early childhood.

Limitations and conclusion

Despite the multi-faceted nature of CT, we only selected four CT attributes due to our limited sample size. There is a need for future studies that include larger samples and more attributes, especially those related to ST and MK.

Nevertheless, identifying which CT attributes children have not mastered as well as what attributes are foundational to CT learning is an important step toward designing and implementing tailored learning experiences, and minimizing potential gaps in CT and STEM learning from an early age. Furthermore, there is a need for developmentally appropriate curricular resources and assessments of CT for early childhood. CDMs offer a potential way to provide teachers with informative information about their students' CT understanding that they can directly link to their instruction. As a field, learning scientists tend to talk about the design of assessments and learning environments separately. The present study shows the affordance of thinking about instruction, assessment, and theories of learning as an integrated system.

Integrating Global and Science Education Perspectives on Epistemological Plurality

Mary E. Short, Smithsonian Institution, shortm@si.edu

Abstract: Recent conversations in learning sciences have pressed the field to attend more explicitly to multiple ways of knowing, or epistemological plurality, as a means for disrupting Northern/Western onto-epistemic supremacy (e.g., Warren et al. 2020). Similar conversations have been taking place in global education with a priority placed on elevating knowledge and ways of knowing from the Global South (de Sousa Santos, 2018). This paper works to integrate these perspectives by asking: How can critical perspectives found in global education literature inform research on student epistemological plurality during science classroom discourse? This paper integrates perspectives from global and science education to present to the field of learning sciences a new approach to considering epistemological plurality in science discourse.

Introduction

Global environmental issues like climate change currently do and are projected to continue to disproportionately impact the Global South (IPCC, 2022). Despite this, current efforts to identify and mitigate the impacts of climate change in science continue to prioritize an imposed perception that "the Eurocentric epistemological North" is "the only valid source of knowledge, no matter where, in geographic terms, that knowledge is produced" (de Sousa Santos, 2018, p. 6, see also Harding, 2008). This system of knowledge creation establishes a false separation between science and society in which scientists hold a "monopoly of authority on nature itself" (Harding, 2008, p. 56).

Meanwhile, the instantaneous movement of information and imagery in the current era has fundamentally altered our constructions of reality as the outer world of media becomes a central aspect of the "inner world of society" (Beck, 1999, p.1). In this vein, the very stuff that makes up knowledge, the basic building blocks of our cognition are also associated with and influenced by globalizations. Or as Hammer et al. (2004) might suggest, depending on the framing of a particular activity, we may now reliably activate various sets of conceptual and epistemological resources that are tied to systems of globalization and their inescapable presence. This recent shift requires us to rethink what types of knowledge we anticipate students will bring to classrooms and figure out new ways to leverage them for student sensemaking. Foundational to this shift is the importance of acknowledging and incorporating multiple ways of knowing in science classroom discourse.

The presence of the sociology of globalization as a mediating factor in student thinking presents us with an opportunity for re-imagining disciplinary practices as emergent from a vast wealth of values, cultures, and identities which have long been erased from scientific discourse (Pierson, 2022; Warren et al, 2020). Here, I explore student discourse about global environmental issues from the perspective of epistemological plurality (Andreotti, 2007; Bang & Medin, 2010; Warren et al., 2020). I have found through an examination of both global education and science education literature, that there are parallel movements taking place within both bodies of scholarship that seek to disrupt Northern/Western onto-epistemic supremacy to pursue a vision of cognitive justice as an essential part of social justice (Andreotti et al., 2011). This paper integrates perspectives from global and science education to present to the field of learning sciences a new approach to considering epistemological plurality in science discourse.

I analyzed student thinking using a multimodule interaction analysis (Erickson, 2010) to present an illustrative example of epistemological plurality during student discourse. The example presented here is taken from a larger study focused on operationalizing a framework for identifying evidence of global thinking in science classroom discourse using multimodule interaction analysis (Short, 2023).

Conceptual background

Recent research in science education has highlighted the importance of epistemological plurality in science learning as a critical step towards desettling disciplinary knowledge and practices from "colonial matrices of power" (Warren et al., p. 278). This perspective places substantial value on students' ways of knowing and making sense of the world as valid and productive cognitive processes inextricably linked to culture and identity (Pierson et al, 2022; Warren et al. 2020). Reorienting science education for multiple ways of knowing is essential for multiple reasons. First, by recognizing the socially and culturally embedded nature of knowledge construction, deconstructing epistemic hierarchies becomes a pathway for unsettling myths of science that are deeply embedded in racism, sexism, and colonialism (Harding, 2008; Medin & Bang, 2014). Second, orienting science education for epistemological plurality is essential to expanding the possibilities of human knowledge (de Sousa Santos, 2018; Warren et al., 2001).

As de Sousa Santos (2007) explained, the modernist tendency to prioritize Eurocentric ways of knowing serves to, "divide social reality into two realms, the realm of 'this side of the line' and the realm of 'the other side of the line.'" Knowledge and process for producing knowledge on the wrong side of this 'abyssal line' is "radically excluded because it lies beyond the realm of what the accepted conception of inclusion considers to be its other. What most fundamentally characterizes abyssal thinking is thus the impossibility of the copresence of the two sides of the line (de Sousa Santos, 2007, p. 47). Here, de Sousa Santos (2007) argued that scientific canon serves not only to establish whose knowledge counts, but also to establish that anything outside of those boundaries is outside the confines of reality. In doing so, Andreotti et al. (2011) argued, a vast wealth of lived experiences are wasted, as they are excluded from mainstream human endeavors to understand the universe.

In short, epistemological plurality is an indicator of a socially just approach addressing global problems (Misiaszek, 2015). Incorporating epistemological plurality in academic settings is a critical step towards transforming society away from oppressive hegemonic approaches to knowledge and progress that have led to the manufacture of the ecological calamities we find ourselves confronted with (Andreiotti, 2011, 2021; de Sousa Santos, 2018; Misiaszek, 2015).

Co-presence

Epistemological plurality in science education does not represent the end of canonical knowledge and ways of knowing; rather, it calls for the copresence of canonical and noncanonical knowledge and ways of knowing (Andreotti, 2007; de Sousa Santos, 2007, 2018). According to Andreotti et al. (2011), epistemological plurality includes "equipping students to respond and adapt to a sacred realm (of both visible and invisible realities) that is both elusive and tangible and where multiplicity and uncertainty are natural givens" (p. 47).

In learning sciences, Pierson et al. (2022) recently outlined heterogeneity in science curriculum as a pathway for centering classroom epistemic aims on students' epistemic values. At the heart of such an approach was a commitment to science that was generative but often unresolved and steeped in multiplicity (Pierson et al., 2022). A similar perspective was elucidated by Bang and Medin's (2010) accounting of how students' perspectives of sources for science knowledge included indigenous knowledge. One specific example was a sorting task in which "urban Indian middle-school children" were given "a series of 16 pictures (i.e., animals, plants, water, sun, rocks, artifacts) and asked" to consider if each would be considered alive from the perspective of a science teacher or an elder (Bang & Medin, 2010, p. 1017). In this example, students explained that an elder would say that rocks and water are alive, while a science teacher would say they are not alive. This example illustrates well the generative nature of multiplicity as an epistemic aim. Students in this example parsed the difference between canonical science knowledge (what their science teacher would answer) and noncanonical knowledge (what their elder would answer; Bang & Medin, 2010). From a pluralistic epistemological perspective, both pieces of knowledge can be true at the same time.

Similar calls for multiplicity can be found in global education research. Andreotti et al. (2011) described epistemological plurality as a copresence with Western/Northern ways of knowing, which she refers to as "unequivocal/universal knowing", and nondominant ways of knowing as "equivocal/relational knowing (p. 45). The first is characterized by a "win–lose debate of opposing ideas based on criteria of legitimacy and validity grounded on predefined parameters of empirical evidence" in which analysis reflects "neutrality, universality and objectivity" and intellectual freedom is based on the idea of "autonomous thought related to universal reason and the Cartesian subject" while the latter is characterized by uncertainty, complexity, diversity and includes space for a consideration of "visible and invisible realities" (Andreotti, 2011, p. 46).

Student resources

This work takes an ontological approach to research on epistemology that focuses on epistemological resources individuals draw on during moment-to-moment sensemaking (Russ & Luna, 2013). This resources-based perspective of student epistemology treats students' conceptualizations as dynamic and manifold (being composed of several pieces of information). From this perspective, what students "know" is dynamic and context dependent, composed of a range of cognitive resources activated during an event, interaction, or activity as the student perceives those resources to be relevant within their expectations of an interaction or activity (Hammer et al., 2004).

Interactions with students during this study sought to activate a nearly limitless range of epistemological resources by prioritizing the epistemic values students brought to the discussion. Andreotti et al. (2011) describes how instructors in higher education might go about creating discourse norms of this sort within academia. She calls for the "valorization and legitimation of suppressed or silenced knowledges" and argues that this includes supporting "student's capacity to re-situate themselves in different knowledge systems (including the experience of language/stories as metaphor), as well as re-situating themselves in their bodies, emotions and spirits" (Andreotti et al., 2011, p. 46). Thus, interactions were framed (Hammer et al., 2004) for epistemological plurality through flexible discourse to encourage contributions from students that incorporate the metaphorical, the use of story as knowledge, and the acknowledgement of affect and spirituality all as valid and productive intellectual resources (Andreotti et al., 2011).

Research context, data, and analysis

Data collection took place within an interdisciplinary and international project focused on urban sustainability in the Arctic. During the project participants from Anchorage developed 60-second digital environmental stories about an environmental problem that was important to them. Interview data selected for analysis in this study are from a single site located in Anchorage, Alaska. The participating classroom was a small private school in Anchorage. The school has a long history of student-centered teaching and learning. Participants were fourth, fifth, sixth, seventh, and eighth graders, many of whom participated in the project for 3 consecutive years, during which time data was collected. An important note is that while several students participated in the project for multiple years, not all of the students completed all three prompts all 3 years. Additionally, while several students participated in the project multiple times, quite a few completed videos only once. Semi-structured video-elicitation interviews were framed around the digital stories created by students. Video elicitation interviews took place in groups of three to four students and lasted approximately 45 minutes each. During the interviews, the students watched videos created by their classmates as well as students of a similar age from a major metropolitan area in the Southeastern United States. Interviews were video recorded using the same laptop on which students watched digital stories.

Data analysis

Data transcription processes reflect Erickson's (1992) *microanalysis*. First, video and audio recordings were listened to thoroughly. Illustrative events were identified and tagged based on the framework for epistemological plurality described here. During that process I was cognizant that limiting the data transcribed limited my ability to recognize important patterns present within the complex interrelations that make up the social ecology of students' experiences (Ratcliff, 2003). To mitigate this limitation, the corpus of data was revisited iteratively. Next, continuing to use the process described in Erickson (2004), I watched each video in its entirety again, this time stopping and replaying at the boundaries that were noted earlier. During this viewing I also looked for sustained topical conversation from or between individuals, as well as sustained posture or listening behavior. Again, timestamp data was recorded to denote the start or end of an episode of talk.

The episode presented here was selected out of the corpus of 34 events that were initially tagged as salient for illustrating evidence from a broader global thinking framework. I followed a process described by Erickson (2004). I began by reviewing the corpus of video data at regular speed without stopping. As I watched, I took notes, similar to field notes, when I noticed student utterances or segments of the interview that were consistent with the codes for global thinking as well as verbal and nonverbal cues to indicate the end of a topic of conversation. Most often these cues included a long pause, looking around, or adjusting their seated positions to indicate a transition in the activity. I watched each video in its entirety again, this time stopping and replaying at the boundaries that were noted earlier. During this viewing I also looked for sustained topical conversation from or between individuals, as well as sustained posture or listening behavior. Again, timestamp data was recorded to denote the start or end of an episode of talk. During this second pass, I began to establish specific episodes of student talk. Episodes often included several events, or moments in which student talk was consistent with my codes. Episodes were established when there was a topical shift in the conversation, or students' nonverbal behavior indicated a shift based on their posture, gaze, or proximity to peers (Erickson, 2004).

Transcriptions included all student dialogue, word for word, including annotations for pauses and phrase stops, laughing, and other verbal behavior not defined as "talk." Nonverbal transcription was created with the use of screenshots from the video along with accompanying notes to clarify exactly which words accompanied which gestures. Also, in that column were notes about voice quality (tone, prosody, and pace), consistent with Norris (2016).

As Ochs (1979) pointed out, segments of video or audio data selected reflects "the particular interests, the hypothesis, examined of the researcher" (p. 44). To be clear, this does not mean that non-salient events were not treated as important for shedding light on the types of talk moves that were effective in framing for global thinking; this is discussed in more depth in the next section. This data, including student videos, classroom observations, and teacher interviews, offered important clues to indicate underlying cognitive processes at play for individual students during the interviews, in ways similar to Russ et al. (2012). I relied on interactive analysis

(Jordan & Henderson, 1995) to systematically identify evidence of epistemological plurality. Student interactions were analyzed with attention to multiple modes of communication. The approach taken here is similar to Norris (2004), in which I rely on annotated video stills to attend to nonverbal modes and the ways they appear to contribute to students' perceptions about the nature of the interview, what was expected of them, and dynamic construction of the purpose of each conversation as it progressed.

I relied on gesture to shed light on ideas and utterances shared by students that were supported and sometimes completed through gesture (Johnson, 2017). Verbal aspects of communication beyond words were also examined as I analyzed each of the interviews. This includes attention to pauses, self-interruptions, and restarts and the ways interlocutors respond to them in interaction (Erickson, 1992; Goodwin, 2018).

Epistemological plurality

Throughout the analysis, I used the coding scheme developed through my larger conceptual framework which included indicators for epistemological plurality as it is presented here. Codes were applied line by line to indicate how they are tagged in relation to each individual speaker, which is consistent with a resources-based ontological perspective which asserts that students experience activities in individually subjective ways. This provides a more robust view of the myriad ways individual students drew on their lived experiences and existing epistemological resources when discussing global environmental issues. The description for the epistemological plurality code is included in Table 1.

Table 1

Description of Code for Epistemological Plurality

Code	Description	Salient Examples
Epistemological plurality (EP)	Students draw on canonical and noncanonical knowledge while working to understand global environmental issues. Examples of types of knowledge include religious beliefs, held values, and intuitive knowledge as well as school-based science content. Ways of knowing include community-based ways of knowing, traditional ways of knowing, ethical and moral frameworks, as well as more conventional claim/evidence-based reasoning reflective of canonical habits of mind.	Um // Well / there are / uh / the / uh / the leaves with the photosynthesis / right // And um / I don't know / I just think that / um / if we planted more trees // well and there's also a a difference / like here we have / we don't have / like smog / or anything like that / um / and / and we have more trees / […] I think a place is more healthy when it has more.

Illustrative episode: Respect our elder species

Epistemological plurality is not contingent on students drawing on an epistemological resource other than those associated with canonical science. Rather, I use it here in ways consistent with Andreotti (2011) and de Sousa Santos (2007) in which epistemological plurality is defined as the copresence of canonical and noncanonical knowledge and ways of knowing while seeking to develop understanding. This pluralistic approach to epistemology is reflective of what Misiaszek (2015) described as knowledge approaches from below, or which de Sousa Santos (2007) referred to as post-abyssal thinking, in which boundaries around what constitutes valid forms of reasoning are moved to include a broader range of lived experiences. Importantly, as Beck (1999) and Harding (2008) pointed out, modernist Western/Northern approaches to epistemology, or epistemology from above, are globally pervasive to such a degree that they often saturate the cognitive realm. As Andreotti et al. (2011) pointed out, they are always present in academic settings. Therefore, evidence of nondominant forms of epistemology that are treated as equally valid to dominant Western/Northern approaches indicate the copresence of canonical and noncanonical knowledge and ways of knowing.

Epistemological plurality includes the use of everyday intuitive knowledge, indigenous knowledge, spiritual knowledge, and ethical/moral beliefs, as well as intellectual resources typically associated with more Western/Northern science perspectives and knowledge. It may also include community-based ways of knowing, home-based ways of knowing, and ways of knowing that are drawn from the spiritual realm alongside Western/Northern approaches to constructing knowledge. The following excerpt offers a salient example of how students may establish a copresence of canonical and noncanonical knowledge and ways of knowing by incorporating nondominant forms in discourse while making sense of a particular issue. In the transcript excerpt Ashley has been asked about a video she created that focused on keeping moose safe from automobiles. In response, Ashley explains in Lines 1–3 that all of the videos she has created focus on protecting animals: "I actually think that the last / like / three videos I've done are / have been about animals / um / animal awareness //."

1	Ashley	I actually think that the last / like / three	
2		videos I've done are / have been about	
3		animals / um / animal awareness //	
4		and I think the main reasons is / um / we	
5		as humans / um / our tendency is that we	
6		respect someone who's older than we	*EP*
7		are // And when you look at our species /	*EP*
8		our species is very young compared to	*EP*
9		some other species // turtles and other	*EP*
10		animals / um / even chimpanzees they	*EP*
11		come before us so / like we respect people	*EP*
12		who are older than us and our elders / we	*EP*
13		should respect species that are older than	*EP*
14		us / and help keep them alive //	*EP*

As Ashley continues, she draws on her everyday knowledge, adding a value-laden statement that people tend to respect their elders. In Lines 4–7 Ashley says, "We as humans / um / our tendency is that we respect someone who's older than we are //." Next, Ashley continues to make the case for respecting nonhumans in the same way we do our elders, by drawing on more traditional science content knowledge. Specifically, she uses knowledge about evolution and she begins listing animals that evolved prior to humans. In Lines 7–11, Ashley says, "when you look at our species / our species is very young compared to some other species // turtles and other animals / um / even chimpanzees they come before us." Thus, Ashley is integrating her everyday knowledge about how she has been taught to treat her elders with school science knowledge about when different species evolved on Earth. Furthermore, Ashley's description of nonhumans as "elders" is reminiscent of findings from Bang and Medin (2009) in which participants treat nonhumans as relatives with something to teach humans. Similarly, respecting elder species suggests that having existed longer, the animals at the center of Ashley's video have a greater sense of living on planet Earth that should be treated as intrinsically of value.

15	Interviewer	So when you say respect can you / you	
16		mean / can you say more about that //	
17		What do you mean by respect // like	
18	Ashley	Well / um / if we're respecting our animals	EP

19	making sure it’s not us who kills them // it’s	EP
20	not our fault // because just doing what	EP
21	they’re doing / like moose right now	EP
22	they’re not trying to kill the world / not	EP
23	trying to end the world // They’re not going	EP
24	end another species / but um / humans /	EP
25	we’ve already killed so many species //	EP

In Lines 15–17, the interviewer presses Ashley to expand on the term “respect.” I asked, “So when you say respect can you…you mean? can you say more about that? What do you mean by respect?” Ashley’s response to this question appears to draw on yet another set of epistemological resources. Specifically, she appears to draw on her personal sense of ethics and moralism Lines 20–24 when she says, “because just doing what they’re doing, like moose right now, they’re not trying to kill the world, not trying to end the world, they’re not going to end another species.” In essence, Ashley appears to be making the case that because moose are not a threat to the existence of humans, that we are obligated to avoid harming them. This point is further supported in Lines 24–25, when she follows up with “but, um, humans, we’ve already killed so many species .” Here Ashley is comparing human impacts, and specifically human-caused extinction, to the potential threat nonhumans have to humans. She considers those impacts to be unbalanced, in which humans “kill so many species,” as opposed to moose who are “not trying to kill the world.”

Similar accounts of students attempting to balance the needs of humans and the needs of nonhumans fairly are found in Koprina (2019), in which students were assigned a specific position for a classroom debate. The position included placing the needs of humans on equal standing as those with nonhumans as a means to think beyond androcentrism. While the essays discussed in Koprina (2019) are taken from university students, the underlining sentiment is similar. Like Ashley above, Marina compared and contrasted human and nonhuman destructiveness in making the case for eccentric approaches to development. The student wrote: “After all, we should not forget that we are the most destructive species in terms of our unsustainable practices and lifestyle” (Koprina, 2019, p. 13).

This event is salient for illustrating epistemological plurality because Ashley is intermingling canonical and noncanonical knowledge and ways of knowing that she perceives to be relevant to the issue that is being discussed. She does this while situated in school, an environment in which the abyssal line described by de Sousa Santos (2007) is firmly in place to prioritize canonical knowledge and ways of knowing while treating alternatives as nonexistent. But Ashley uses knowledge and reasoning that moves beyond those limitations, thus *establishing a copresence* of canonical and noncanonical knowledge and ways of knowing through discourse.

In other episodes, epistemological plurality often took the form of integrating information obtained through media, or in conversations with parents, and students’ sense of care and empathy for nonhumans. In one segment, for example, another student, Allison, explained that she chose to film her digital environmental video about the palm oil industry to raise awareness about habitat destruction and its impact on orangutangs. Allison begins by describing the reasoning behind her choice to focus on palm oil as the subject of her video. She says she wants people to “know what they are doing” when they buy products with palm oil in them. Up until then, her tone had remained flat, until it shifted with the phrase “what they’re doing.” When she is asked a follow-up question, “what *are* they doing?” Allison says ,“they’re KILLING another species,” her pitch increases through the entire phrase, peaking on the word “killing” until dropping again to the flat tone she began with when she says “sorry, um, I don’t know, I just think it’s sad”.

Implications

In considering important implications for research and practice, this paper offers several. First, the framework from which the epistemological codes used in this paper were drawn needs to be shared and evaluated by people from a diverse range of cultures and backgrounds to reveal areas I was not able to anticipate from my own sociocultural perspective. Likewise, additional studies using the coding system are needed to determine the ease with which the codes may be transferable to other researchers. Therefore, it is my hope is that this work will be taken up by others who have different backgrounds, are of different generations or races/ethnicities, and speak languages other than English. For this work to reflect a truly globally situated perspective on epistemological plurality, it needs to be built on by people from across the globe to address ethno-political considerations that I may not be able to anticipate (Raveendran, 2018).

There have been times when students have contributed conceptual resources that I was unable to recognize as epistemology. For example, Connor, one of the students from Anchorage, created a video that was, essentially, filming his backyard. He aimed the camera at the trees and asked viewers to listen. When I first watched the video, I was confused. What I was watching did not immediately register as knowledge sharing. It was later, after reading Bang and Marin (2015) in which they discussed Indigenous ways of knowing, that I began to acknowledge that Connor's video was sharing epistemological resources that were reflective of his Alaska Native upbringing. Connor did not need to tell me about the trees and the wind. The trees and the wind could speak for themselves. I needed to learn to hear their language (Bang & Marin, 2015). Sharing this work with people from other cultures may reveal other areas I am not able to anticipate. This is a critical next step for this work if it is to be taken up and used in learning sciences.

Concluding thoughts

Throughout this paper I have suggested and subsequently shown that it is possible for researchers and educators to explicitly attend to the epistemological plurality during science teaching and learning. To do so, I argue, creates opportunities to activate epistemological resources students possess but may otherwise overlook based on perceived expectations during instruction. More firmly conceptualizing epistemological plurality within learning sciences as productive to science learning serves a broader goal to reimagine epistemological disciplinary activities as dynamic, emergent, and intrinsically linked to culture and values (Warren et al., 2020).).

Currently, attending to epistemological plurality is a challenge to science classroom teachers, especially within the era of the *Next Generation Science Standards* (NGSS), which places significant value on teaching disciplinary practices (NGSS Lead States, 2013) and the development of canon consistent knowledge products (Pierson et al., 2022). There is a potential disharmony between this work and the pressure science classroom teachers face to meet educational standards like the NGSS. To have any chance of success, widespread attention to epistemological plurality in classrooms requires co-presence (Andreotti et al., 2011). Co-presence requires us to make space for the epistemic aims of participants at all levels. For many teachers this includes epistemic aims imposed from above by powerful external forces, such as federal, state, and local policies including educational standards. For students it may be a range of epistemic aims from external forces as well as those from below, which are grounded more locally and tied to students' everyday experiences both in and out of school. These may include diverse linguistic resources, and community and cultural values students carry with them as they navigate the complex web of expectations that characterize students' experiences in school. The potential copresence offers the field is one in which epistemic aims from above in science education become entangled with those from below to bridge the abyssal line between Western/Northern onto-epistemic supremacy and the vast wealth of knowledge that falls beyond (de Sousa Santos, 2007).

Being a Good Student: Risks and Reactive Coping Strategies Encountered in a Summer STEM Makerspace for Black Youth

Kevin Hall, Christina Krist, Michael Tissenbaum
knhall@illinois.edu, ckrist@illinois.edu, miketissenbaum@gmail.com
University of Illinois Urbana-Champaign

Abstract: There has been a large push over the last decade to drive STEM interest during the formative years of adolescence through computer science related initiatives such as computational makerspaces that allow students to design and build personally connected artifacts. However, these programs are not often designed to be culturally relevant to the students they aim to motivate. This paper presents a case study of one student who participated in the first iteration of a summer makerspace camp for Black youth ages 12-16. The design principles guiding this STEM camp adapted pedagogies for computational making for belonging and becoming (Escude et al., 2020) with a goal of fostering culturally relevant STEM identity development. Using the phenomenological variant of ecological systems theory (PVEST; Wigfield et al., 2007) as a theoretical and analytical lens, we present three phenomenological episodes representing an overview of the student's arc from Days 1-8 of the 12- day camp. Over time we see the student extend the boundaries and objects of their coping strategies, moving from just utilizing the resources in front of him to thinking more flexibly about where help can be found. We argue that this student is an ideal case for refining design principles and providing insights into supporting belonging and becoming in the context of computational making.

Introduction

Students of color and girls have historically been underrepresented in STEM, and even after recent upticks in CS enrollment and federally funded programs like CS4All, Black students especially still lag well behind their contemporary counterparts in the increase of enrollment in STEM fields (Brown et al., 2013; Boroush, 2020).

As one potential solution, educators have leveraged informal learning environments to offer engaging computer science-related programming in hyper-locally relevant ways. Makerspaces are one such format. Makerspaces promise to bring together the worlds of "creativity and curricular content" in STEM, especially for students that previously found themselves at odds with traditional schooling (Hughes et al., 2018). In makerspaces, students can design and build projects of their interests using equipment and materials of their own choosing. The design process is typically driven by "ill-structured problems" solvable in numerous ways allowing for a wide range of unique and personal outcomes (Dousay, 2017). The constructivist and constructionist principles guiding the design of such spaces have been termed *computational making pedagogies* (e.g., Dousay, 2017; Hughes et al., 2018; Lee et al., 2020).

However, makerspaces have largely not delivered on the promise of fostering a new industrial revolution for all (Anderson, 2012; Blikstein, 2014). Makers are largely white, college-educated men, and the makerspaces themselves tend to reflect this by continuing "tensions and contradictions present that can give rise to inequalities that further suppress meaningful engagement from women and people of color" (Martin et al., 2018, p. 36). Without adopting critical lenses, computational making pedagogies remain neutral to the sociopolitical forces present in the communities they offer to serve. Such neutrality (unintentionally) perpetuates the status quo of makerspace environments.

This paper presents a case study of one student who participated in a summer makerspace camp for Black youth ages 12-16. This design guiding this STEM camp adapted pedagogies for computational making in order to design for belonging and becoming (Escude et al., 2020; Tissenbaum et al., 2021) with a goal of fostering culturally relevant STEM identity development. Using the phenomenological variant of ecological systems theory (PVEST; Wigfield et al., 2007) as a theoretical and analytical lens, this study examines the vulnerabilities that one student faced and the adaptive coping strategies they used to ultimately complete a computational making project. We argue that this student is an ideal case for providing insights into how to support belonging and becoming in the context of computational making.

Background: Adolescence and STEM identity development

Much of the decision-making around STEM identity is formed well before college, starting even before students make it to high school. Adolescence serves as a critical time of identity formation, and it is often here that students think most deeply about who they are and where they fit into society. Even when students of color express an interest in science at a young age, this interest can be lost in a short time, often due to students developing an image of doing science that seems incongruent with who they, or the world, see themselves as (Carlone et al., 2014). There is also a negative trend in student engagement and motivation between elementary and secondary school, specifically in math and science (Carlone et al., 2014). While this is not a trend specific to Black students, students of color are often viewed negatively regarding their STEM abilities, including by teachers (Carlone, 2014). This ever-increasing understanding that the world views them in a specific way is rarely experienced as a protective factor regarding STEM identity development in students of color or girls (Brown et al., 2013; Carlone, 2014). Black students become hyper-aware that they are not often represented or wanted in STEM fields and that technology can act in racist ways (Benjamin, 2019).

Theoretical framework: understanding culturally relevant identity development using the phenomenological variant of ecological systems theory (PVEST)

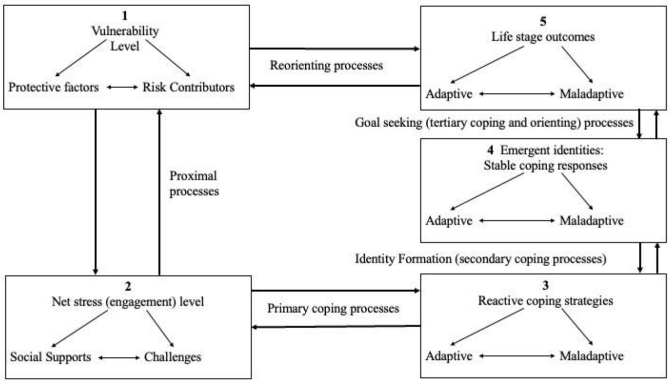
Identity development is a situated phenomenon that involves the dynamic interaction between an individual and their environment(s). Ecological systems theory (EST) is an ecological model that captures these interactions to describe an individual's identity development as being affected by systems outside of and including the self (Bronfenbrenner, 1977). Identity development, therefore, is the "outcome of an individual's interaction with their environment, including the people and physical objects within" (Ozaki et al., 2020 p. 256). These interactions, over time, affect the development of the individual's beliefs about themselves and who they are concerning these environments and other connected environments.

The Phenomenological Variant of Ecological Systems Theory (PVEST) introduced by Spencer et al. (1997) expands on EST by describing more clearly the mechanism by which individuals' interactions with their proximal processes (see Figure 1), moments, where net vulnerability interacts with net stress level, over time, can result in students drawing conclusions as to "who they are, with the goal of responding to negative feedback" (Wigfield et al., 2007). PVEST takes a magnifying lens to proximal processes and looks more specifically at student and environmental assets and how they might interact with each other during points of friction.

We will walk through this model using an example of one familiar type of friction a student might encounter in schooling: being called on out of the blue to answer a question by their teacher. Different students will react differently to this situation. For some, it may be inconsequential. PVEST describes these students as having low net vulnerability in this situation (see Figure 1, Box 1). One's net vulnerability is the outcome of particular individual-level risks and protective factors at play at that moment, such as race, gender, or social stereotypes. For others, however, it may be perceived as a challenge: they may perceive it as a test of themselves as an intelligent individual, a good student, or a myriad of other perceived beliefs about self. For these students with a higher degree of net vulnerability, this perceived challenge may raise their net stress (Box 2).

People respond to stress with reactive coping processes (Box 3). These coping processes can either be maladaptive or adaptive. For instance, the uncertain student, may attempt to answer the question, or they might avoid answering altogether by saying, "I don't know," or staying silent. Their decision about coping processes will depend largely on their past experiences and the perceived effectiveness of similar strategies in similar situations. Over time, these coping processes become part of who they are and how they respond to similar situations throughout life: in other words, one of a student's emergent identities (Box 4).

Figure 1
Phenomenological Variant of Ecological Systems Theory, reprinted from Wigfield et al., 2007, p.708.



Inherent in this model is the assumption that microsystems are not neutral grounds. Rather, they bring challenges and supports that compose an individual's net stress, and, if high enough, may challenge the student's perception of self. By the same token, if higher levels of support exist, the situation will elicit less net stress. Based on what we see of Black STEM students, it is plausible that lowering the challenges of a specific microsystem could reduce their net stress. For example, a Black student who perceives themselves as a good student receiving critical feedback from an instructor may respond differently depending on how they experience this in relation to their racial identity within the institution (Cohen & Garcia, 2008). In other words, different microsystems influence what counts as a risk and for whom.

Importantly, PVEST also explains how students develop productive identities and coping outcomes while navigating risks, stresses, and vulnerabilities. All humans experience some level of vulnerability, and net stress in itself is also not necessarily a negative. In fact, overcoming challenges is an integral part of "positive growth and development" (Wigfield et al., 2007). Students may develop numerous strategies for engaging and succeeding in stressful environments, and over time, could transform these risks into support. As such, this model is helpful for understanding the mechanisms of resilience while simultaneously acknowledging the environmental, sociological, and systemic influences requiring that resilience.

Aims of the paper and research questions

This paper presents a micro-analysis of one student's (Jordan – pseudonym) participation in a 6-week summer maker camp to illuminate the tensions and proximal processes that Jordan encountered. In analyzing his specific reactive coping processes as well as how we as facilitators responded to these coping processes, we aim to address:

1. What aspects of the designed environment did Jordan experience as risks?
2. What kinds of reacting coping processes did he demonstrate?
3. How did those reactive coping processes evolve over the course of his interaction in the makerspace, including continued interactions with both facilitators and materials?

Methods

Study context and participants

During the summer of 2021, we (the first (Black male) and third (White male) authors) implemented a 6-week summer camp in an informal community center setting in the Midwest. The summer camp focused on computational making that aimed to foster and positively support the emerging identities of Black middle school boys. These goals were in alignment with those of the local community center, which had a mission of promoting college and career readiness as well as providing social and emotional support for Black boys and men between the ages of 3 and 24. Our camp focused on middle school boys and met twice a week for two hours each meeting period, for a total of approximately 24 hours of contact time. Participants were 12 middle school boys that were in the broader summer camp program at the community center. All except two students identified as Black. On any given day, the number of students in attendance ranged between 6 - 12. While they had all signed up for the broader summer camp, they had not specifically signed up for the makerspace camp. Students had little to no prior in-depth experience with physical computing.

Program design

Our overall program design was driven by twin commitments to supporting belonging and becoming (Escude et al., 2020; Tissenbaum et al., 2021). Central to these commitments were principles for reflexively supporting student agency. Inspired by Escude et al.'s (2020) metaphor of stretching and releasing a rubber band, we tried to "open up" as much of the curriculum as possible, both in material usage as well how we as facilitators responded to student tensions in the moment. More specifically, three key design principles guiding this "opening up" included (1) *Maintaining curricular and pedagogical elasticity* - allowing for flexibility in student expectations and being responsive when they appear; (2*) Practicing transformative inclusion* - changing the space for the student instead of expecting the student to change; and (3) *Balancing organizational and structural priorities* - thinking more deeply about imbalances in expectations brought about by the organizations involved. Ideally, students would learn some basic skills in the use of microcontrollers that would then allow them to explore and build their own personal projects during the second three weeks of the implementation, followed by a symposium where they would share their projects with other tribes and community members. Over the course of three weeks, students built and modified artifacts that contained LEDs, motors, and a variety of onboard and external sensors, before following a design process to create their **own** personal or community-based project.

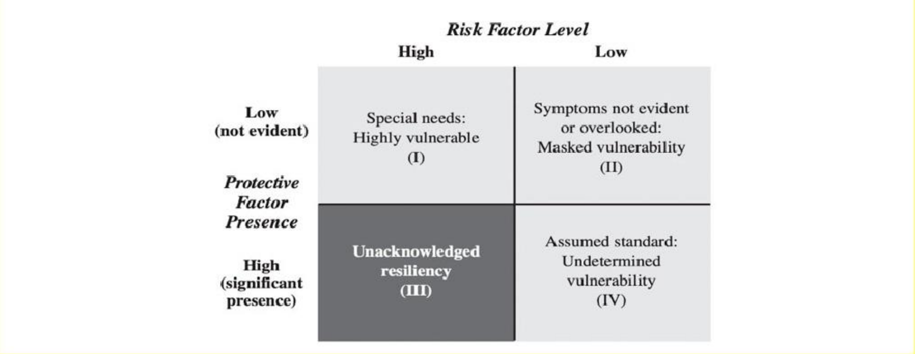
We utilized the BBC Micro:bit microcontroller due to its approachable nature and being purpose-built for education. For example, the numerous physical connection pins that one normally sees when looking at microcontrollers, have been abstracted away and are replaced with circular spaces where wires can be connected to by alligator clips or even screws. We also chose to initially expose them to a limited but useful array of electrical components such as LEDs, motors, and several useful onboard or external sensors.

Data collection, case selection, and analysis

Data included audio recorders at each table in the camp (often just two) and two cameras, one at the front and one at the back of the room, positioned to capture the students as they worked and their movement through the room. In total, approximately 24 hours of video and audio were captured across all the devices. Field observations were also captured, and the facilitators did daily debriefs on the days' activities to adapt the curriculum to student needs or other emergent factors.

Figure 2

Spencer's dual axis coping formulation of PVEST reprinted from Wigfield et al., 2007, p.731.



Video clip segments were stitched together for each hour of the 24-hours recorded and imported into MAXQDA software for analysis. We utilized content-logging (Jordan & Henderson, 1995) of student interactions with each other and with materials of all the videos, close microanalysis of key moments, and interactions of the students throughout the process (Jordan & Henderson, 1995). This content-logging process led to the selection of a single student, Jordan, whose low literacy would be viewed as a large educational risk factor that would mark him as a quadrant I (see Figure 2) "highly vulnerable" student in Spencer's Dual Axis Coping Formulation (DACF) of PVEST (Wigfield et al., 2007). Jordan's reactive coping processes often mitigated this risk factor. We looked at this as an opportunity to look at his strategy selection, which could offer insight into his identity development and foreground possible areas of challenge or support for other students. Based on our repeated viewings, we began to identify sources of "unacknowledged resilience" in Jordan's interactions. This "unacknowledged resilience" that Spencer describes as individuals falling into quadrant III (Q3) of the DACF. Spencer describes these Q3 individuals as being often overlooked in research while also describing their importance in informing the design of programs and policy:

> "The group is also important for careful study since the unpacking of their experiences allows one to determine how much risk is facilitative…and how much risk…undermines positive health and development (i.e., pushing individuals from functioning as Quadrant III members and, instead, deteriorate into Quadrant I level of high vulnerability) (Wigfield et al., 2007, p. 733)."

We identified moments where Jordan was mentioned in the video content logs and re-watched those clips, generating more detailed logs. We began to identify emerging themes about Jordan's interactions and progression through the summer based on these detailed logs. These themes were related to Jordan's experiences of "friction" and his help-seeking strategies. We then identified four distinct moments that captured pivotal moments of "friction" for Jordan's trajectory and conducted close microanalysis of those four moments (Jordan & Henderson, 1995). The four identified moments represent *phenomenological episodes:* tensions that required Jordan to utilize a reactive coping strategy and could have been facilitative or undermined his protective factors. We documented Jordan's reactive coping strategies, as well as how we, as facilitators, responded to these coping strategies. We then examined how Jordan leveraged them differentially over time to (ultimately) successfully navigate his own path through the program. In the interest of space, three of those four moments are presented here.

Findings

We present three phenomenological episodes that represent Jordan's arc from Days 1-8 of the 12-day camp.

Across these three episodes, he shifted from passive reactive coping strategies to more active mechanisms by identifying and taking advantage of available supports. Across all three episodes, we provide in-text the connected strategies (S1, S2, etc.) that we saw Jordan use during the camp as revealed by our thematic analysis.

Phenomenological episode 1: Passive signals for help

Jordan's first phenomenological episode occurred during the initial task of the camp: messing around with a micro:bit and following some basic instructions to get it set up. Throughout this episode, Jordan's body language signaled that he was uncertain about how to proceed. He also utilized three distinct reactive coping strategies in response to this uncertainty: (S1) Sending silent signals while waiting for help to come; (S2) Shifting focus to others and the environment when "stuck" - what are other people doing?; (S3) Asking questions of available resources; and (S4) Attempting to figure things out on his own. The following vignette illustrates how Jordan utilized these coping strategies throughout the initial micro:bit activity, which lasted a total of 16 minutes.

After students completed a pre-survey, the instructors passed out the micro:bits and instructed students to "mess around" with them. Jordan's micro:bit can be seen sitting, wrapped, in the corner of his table. After sitting, arms folded, waiting (S1) He began to look around, saw others interacting with their micro:bits, before finally reached for his own. (S2). He picked it up, a gave it a quick turn in his hand, looking at it for 20 seconds before putting it back down and glancing around the room again (S4). He looked towards F1 for 2 seconds before verbally calling over for help and sat with his hands folded in front of him making small glances around the room (S4). As F1 arrived. Jordan held up the USB cable and asked something about it (S3). F1 told him he could plug in the micro:bit, to which he asked another inaudible question while holding up the USB cable. F1 held up his micro:bit and said that he can plug the USB cable into the micro:bit and then walked away (S3). He immediately reached for the micro:bit and struggled to unwrap it for 30 seconds before looking at Garfield, the student at the same table who had already plugged his in (S2).

At this point, Garfield finally succeeded in getting his micro:bit powered up, causing it to go through a sequence of flashing lights. This caught Jordan's attention, and after observing Garfield's micro:bit, Jordan connected his USB cable to his laptop (keeping it rolled up in the same way as Garfield), but struggled to plug it into his micro:bit. Jordan glanced around almost nervously, then tapped Garfield on the arm and asked for help (S3). Garfield helped Jordan get his micro:bit powered up, but Jordan sat there, looking around, not knowing what to do next (S4). Jordan continued this cycle of being shown what to do but not knowing how to proceed, moving between Strategies 3 and 4. F1 then told the class that he had handed out sheets with additional support, which Jordan picked up and turned right way up (S2). Jordan briefly glanced at the sheet before once again looking over at Garfield (S2). After several minutes F2 came over and helped Jordan use the document to go to the needed URL, including helping correct Jordan's typing.

Throughout this episode, Jordan encountered friction at nearly every encounter with materials and his coping strategies were incredibly passive. When he did leverage more active strategies, such as asking Garfield for help, it was coupled with a nervous look that suggested he may have felt that he was cheating. In addition, when I (F1) responded to Jordan's question, I did so operating under the principle of "student agency": wanting students to be able to "mess around" and manipulate things on their own without relying on a facilitator to do it for them. Upon reviewing the data, it's clear that this choice may have served to reduce belonging and prohibit opportunities for becoming, in that they essentially rendered Jordan's initial reactive coping strategies ineffective.

Phenomenological episode 2: Jordan's wheel-spinning cycle

This episode occurred on the second day of the first week of the program, where we wanted students to use their understanding of "addressing" LEDs to make a digital design on a larger 8x8 grid LED matrix. To help facilitate this, F1 coded a design of the Jamaican flag and used that as an example for them to think with. Our scaffolding required students to start by following a URL to get to (https://craftdesignonline.com/pattern-grid/) to develop their design using the interactive grid tool. After coming up with their design, we then asked them to transfer the design to paper, which would then later allow them to input these colors into MakeCode for use on the micro:bit.

The design document gave a basic set of directions for completion as well as abbreviations to use to denote what color the specific LED should be set to when they set it up. It is easy to overlook the tensions faced by Jordan during the episode. At first glance, each cell in his worksheet looked filled in, but on closer inspection, we noticed that Jordan had erased everything he had originally written in the grid. He originally seemed to be trying to number his grid with a one in the 63rd cell and count to 64 by the time he got to the last cell. It is unclear truly why or what he was doing with these numbers, but numbering the grid was his takeaway from this portion of the design process.

Jordan faced the first of a chain of challenges immediately while trying to log in to the laptop with the password on the board. Jordan glanced around and noticed that others had opened their laptops and were typing. He, too, opened his laptop (S2). Jordan then focused on his laptop and began typing something. When F2 was close to Jordan, Jordan raised his hand (S3). This portion of the overall episode shows one of Jordan's consistent coping responses: "reading the room," collecting information from what others are saying or doing.

Throughout this interaction, F2 seemed to recognize that Jordan was having some trouble following the spelling of the URL and could be seen pointing to each letter as he said each out loud, even slowing down in his spelling of the URL. When they completed the URL, F2 took charge of the laptop to point out to Jordan what he needed to do before moving on to help another student.

After the facilitator left, Jordan entered what we refer to as the "wheel-spinning cycle" (WSC). The WSC loops Jordan's coping strategies endlessly until a source of external input arrives. For example, when the F2 moved away, Jordan's gaze followed his movement (S3). Jordan continued to glance around until F1 passed by. Jordan engaged him with a question: "What are these?" F1 responded that they were the different colors that he could use to design, then asked, "Does that make sense?" Jordan took the opportunity to ask a follow-up question about the paper. F1 again replied that "the screen is the place where you can do it and then transfer it to the paper." Jordan nodded his head, and F1 walked away to help another student.

F2 then walked by and said to the student sitting next to Jordan, "Cool checkerboard pattern!" Jordan craned his neck towards the student's screen before returning focus to his laptop (S2).

When Jordan engaged with his laptop on this occasion, he did not exhibit wheel spinning, rather, he continued to engage with his trackpad for the next ten minutes with all attention focused on his screen. After ten minutes, Jordan glanced over at the F2, who was helping another student, and raised his hand. F2 acknowledged Jordan but continued working with the student first. As he waited, Jordan sat back in his chair for several seconds before he got the attention of Garfield and Amari across the table from him. He turned his laptop screen around to them, and to the camera for the first time. He broke out into a wide smile and asked them to "check it out." Jordan had completed his design of a four-color checkerboard pattern that he was clearly happy with. Amari responds, "that's better than mine." In this episode, we saw Jordan break out of his WSC by utilizing a risk strategy (S2) to achieve a successful making outcome, promoting positive identity development.

Phenomenological episode 3: Jordan uses his laptop to help him complete a sentence

On the eighth day, students were completing a design planning document and being introduced to the materials and components to start building their personal projects. Here we saw Jordan using a different form of his strategies, as he needed to write sentences on the planning document. He moved to sit right next to Garfield. He glanced down at his planning document, on which he should have been working on a basketball game. F1 mentioned Jordan's basketball hoop and how he could use the design of the first one to make an improved version. He is attentive throughout F1's instructions, as well as when F2 begins to also give directions for the day, his gaze focused on the speaker with his hands clasped.

F2 asked if the directions made sense before looking directly at Jordan, who gave a small nod of yes. Jordan glanced down at the design document in front of him but still did not move it (S1). Jordan spent some time rubbing his eyes while he glanced around and looked over at the table where F2 was helping another student (S2). Jordan then pushed back from the table as he moved his hands away from the laptop (S1). Seemingly without conversation, Garfield reached over the table and picked up Jordan's paper, turning it to the correct page before placing it back in front of him. Jordan then looked at his paper but still seemed stuck. He looked at F2 and continued to wait (S2). After a moment, Garfield got up to get something to write with and Jordan also immediately followed, coming back with a pen before going back and replacing it with a pencil (S2). After coming back, his glances followed F2 until F2 sat down with another student. Jordan then looked down at his paper and began WSC, looking from F1 to F2 to the paper in front of him. After 3 minutes of holding the pen and staring at the page and the front of the room, Jordan turned to Garfield and asked, "What am I supposed to do?" (S3). Inaudibly Garfield explained something to him, after which he seemed to show more interest in interacting with the page. Jordan wrote on the paper off and on for the next 3 minutes before asking Garfield something again. Garfield looked at Jordan's paper and responded again (S3).

A minute later, Jordan got up again and went back to the materials table, coming back with a laptop. This time Jordan seemed to enter the password for the laptop correctly from the board. Two minutes later, Jordan started using the laptop as a reference (S3 + S4): he had typed something in and was now writing on his paper while glancing back and forth to the laptop. This behavior went on for seven minutes, at which point he turned around to F2, raised his hands, and called for his help (S3). F2 acknowledged Jordan but was trying to finish something with another student, and Jordan began to wait. He did no more writing while waiting (S1).

Discussion

We presented a close analysis of three instances in Jordan's trajectory that allows us to see both how our design principles unintentionally functioned as risks for Jordan, as well as the reactive coping strategies that were more or less effective in this context. Looking across these episodes, it seems that Jordan's most persistent challenge was one of uncertainty, which then elicited a Responses Arc (RA): (RA1) Silent call for help (sitting away from the laptop with his arms folded). (RA2) Reading the room (Where are facilitators, what are they saying to others, are they close by? What are other students doing? What counts as good work?) (RA3) Public call for help (raising hands when a facilitator entered in proximity). (RA4) Where is help located in the room? (Going to look over someone's shoulder, asking student directly for help). (RA5) What can I figure out on my own? (Reading of board, looking at the instruction sheet) Throughout the camp, Jordan would enter this arc if it seemed that help was going to take too long for him to proceed or if he had just received help and was still uncertain as to how to proceed. By episode three, we can see that Jordan has started being more active in solving some of the problems that he runs into. Instead of waiting for the facilitators to make it to him, he instead breaks out of the wheel-spinning cycle by both specifically asking Garfield direct questions, as well as utilizing the laptop to help him spell out a sentence. This problem could have been solved by waiting for facilitators, but instead of waiting for direct assistance Jordan formulated alternative ways. In this case Jordan was able to leverage a computational resource to help get him past the friction brought about by his uncertainty. Over time we began trying to do more checking to see if Jordan understood what we explained, as seen in episodes 2 and 3, but these attempts did not always help.

These re-orientations seem to reflect the movement from a formal classroom to an informal learning environment: Jordan's initial responses were ones that would have been supported, even praised, in formal education settings. In addition, a teacher in a formal education setting would have had more information about Jordan's reading abilities than we did. Jordan's vulnerabilities were most exposed when he was asked to read and write, especially without the aid of the laptop. His silent bids for help when instructions were available and readable (e.g., on worksheets) were often overlooked. His main question was always, "What should I be doing?" While a knowing teacher would have immediately leveraged at-level literacy strategies, we most often simply redirected him to the written instructions. Still, Jordan was one of the few students that were consistently present throughout the camp, and he also started and completed a personal project by the last week of the camp. Jordan showed persistence in both his attendance and in his desire to complete what was asked of him.

Although Jordan was often more focused on completion than creation due to having to deal with consistent uncertainty, he was able to build off examples that he knew to be exemplars, including his final project. One of the problems with Jordan's reactive coping, especially for educators that are not his formal educators, is an ability to overlook both his efforts and subsequent achievements. Jordan's project, while being a remix of an earlier one, showed the ability to reason by working with the modular nature of the electronic components. His project utilized an infrared sensor that sensed when a ball went into a cup, sending a signal to his micro:bit, replicating an automated basketball hoop. With his understanding of these components, he was able to come up with a design that merged skills learned from separate projects by making the external LED strip light up when the infrared sensor was triggered. The basketball court that he built looked identical to the court that he drew on his design document, and the sentence that he wrote to describe it on his design sheet, while very rudimentary, is exactly what he ended up doing.

Jordan is more than a Black middle school boy. He is an intersection of so much more, and aspects of those intersections were overlooked during design. While trying to focus on a portion of his identity, we overlooked others. The scaffolds that we offered him were largely literacy based. This was exacerbated by Jordan's seeming belief that he needed to work largely as an individual. While Jordan found many of the holes present in our design, he also serves as a resource for improving future iterations of improved design. These responses also seemed to evolve over the course of the summer camp and moved from passive reactive coping to more active processes.

Conclusion

This paper explored the complexities of designing computational making curricula in a culturally supportive and responsive manner by closely following the experiences of Jordan, a Black student, during the first iteration of a makerspace summer camp. To better design future spaces that facilitate resilience in students like Jordan, we propose the following strategies: (1) *Maintaining curricular and pedagogical elasticity* – Our focus on flexibility to allow personal choices in projects could be enhanced by considering elasticity in the context of instructional scaffolding. Jordan would have benefited more from exemplars, collaborative grouping, and one-on-one conversations rather than the numerous paper-based handouts provided. (2*) Practicing transformative inclusion* - the program would have benefitted from us as facilitators being more direct about recognizing and supporting students' individual coping skills, especially since our overall goal was supporting their emergent maker identities. (3) *Balancing organizational and structural priorities* – While community center members knew more about each participant student, the structure of our communication did not effectively support the exchange of personal student information. In subsequent iterations, we engaged more directly with staff members and parents to better understand the intricacies of each student. Jordan as a model is helpful in understanding the mechanisms of resilience while simultaneously acknowledging the environmental, sociological, and systemic influences requiring that resilience. Overall, this case study provides valuable insights for refining design principles and supporting belonging and becoming in the context of computational making for students similar to Jordan.

Dialogues Without Words: Multispecies and Multimattered Creativity in Maker Education

Isabel Correa, Nathan Holbert, Blake Danzig, Lucius Von Joo

Abstract: In response to the tendency of making to control and harness the material world, we propose the ‘creative pluriverse,’ which can fit many worlds, as a framework to design and study the possibility of multispecies and multimattered creativity. We ground this concept in process philosophies, theories of embodied cognition, and ecological materialism to advance a posthumanist conception of creative making. Using a design-based research approach, we reimagine making, particularly biomaking with fungi, as a ‘dialogue without words’ that nurtures didactic tensions and relations between learners and other-than-human entities and elements. By examining a series of dialogues–between a boy, a tree, clay, and fungi–we observe instances of learning through multispecies creative production and discuss implications for learning design in hybrid pluriverse worlds.

“Queremos un mundo donde quepan muchos mundos.”
[We want a world where many worlds fit]. (Zapatista Movement, in Escobar, 2018, p. xvi)

Introduction: Makers, not masters

In the past few years, we have learned that viruses can jump from corralled animals into human bodies, that wildfires and rising seas know nothing about urban boundaries, and that human-made stuff now weighs more than all remaining living biomass (Elhacham et al., 2020). As the tensions between social, environmental, and technological forces grow and manifest at all scales, we wonder *what counts* as making and *who counts* as a maker in a world that seems to be making and unmaking itself. In times of human-nature fragmentation and reconfiguration, we explore how posthumanist and embodied lenses can help us make sense of maker education as a practice situated within the creative ebbs and flows of the earth.

Informed by constructionist pedagogies, we have explored how constructionist maker education provides students with opportunities to critically engage with social and environmental challenges in personally meaningful ways while gaining valuable knowledge and skills (Holbert, Dando, & Correa, 2020). Still, we are becoming increasingly aware of the subtle ways maker education reproduces the rhetoric of mastery and control that leads us to the same crisis we aim to confront. Contemporary maker education remains situated mainly in the modern imaginary of progress, growth, and innovation. The environmental crisis is acknowledged but framed as yet another technoscientific challenge for young minds in preparation for their future ahead (Kohtala & Hyysalo, 2015). Methodologically, most maker education initiatives leverage human-centered design and problem-solving frameworks for students to produce innovations that respond to immediate problems without questioning their root causes. In the meantime, the planet can barely keep up with the pace of human-centered innovation and its associated patterns of linear extraction, production, consumption, and disposal.

Although practices of recycling, upcycling, and repair are increasingly encouraged (Dew & Rosner, 2019), it is commonplace to give students open access to tools and materials to generate prototypes and artifacts that tend to be discarded as fast as they are produced (Song et al., 2019). It can be argued that the main purpose of rapid prototyping and tinkering with materials extend far beyond the innovation itself through the long-lasting learning gained in the process (Ratto, 2011). However, learning in these terms ignores planetary boundaries and reinforces anthropocentrism. Learners are situated at the center of the material world and in a position of relative power. This leads to a fundamental contradiction: We actively seek students’ empowerment; we ask them to problem-solve, figure-something-out, put-it-together. Yet, we feel increasingly powerless amid the magnitude of more-than-human forces disrupting everyday life. Are we unintendedly asking students to be masters knowing that humans can only be makers? How can we expect them to *harness* the material world when the most we can do is to humbly join its untamed flows of matter?

The narrative of the master is not unique to the social trend branded ‘maker movement’ and its patriarchal imaginary of the maker (Buechley, 2013; Vossoughi et al., 2016). Even in well-intended educational research, maker and master tend to get muddled when learners are seen above the rest of the world. Students are undoubtedly relevant, but they exist only in relation to a larger complex socio-ecological system, and the condition of this system will inevitably shape learning. Socio-cultural frames of constructionism call us to look beyond the learner and consider learning as a “bidirectional” dialogue with artifacts, materials, spaces, and communities (Holbert, Berland, & Kafai, 2020, p. 9). The question then is how to credit all parts in this dialogue without resorting to listening only to the human voice. Posthumanist scholars argue that the problem of socio-constructivist paradigms is that, by assuming human-meaning making and discourse as the starting point of the construction of reality, we inevitably get caught in an *anthropocentric gaze* that obscures the active participation of other-than-human entities and elements (Alaimo & Hekman, 2008; Hultman & Lenz Taguchi, 2010). Rousell and colleagues (2022) note that the participation of materials gets constrained to the role of *resources* as they hold no value aside from imposed socio-cultural meanings. Furthermore, the participation of other living beings, and their idiosyncratic ways of meaning-making, are often ignored, silenced, or relegated as resources alongside other materials.

To make sense of our hybrid socio-techno-ecological world, several scholars in maker education (Keune & Peppler, 2019; Lemieux & Rowsell, 2020; Sheridan et al., 2020) and creativity (Chappell, 2018; 2022; Rousell et al., 2022) are looking into posthumanist frameworks. These perspectives emphasize how creativity and learning emerge from the enmeshment of people, materials, and artifacts through what Chappell (2018) describes as an “embodied dialogue” in which people and things are continuously “making and being made” (p. 282). Whereas most research has focused on foregrounding the participation of materials, objects, and technologies in making, we investigate the participation of other living beings in making with biology, also known as biomaking (Lui et al., 2019). We embrace a radical ontological and epistemological pluralism where humans and other-than-humans can coexist and create meaningfully through embodied dialogue.

In his book “Designs for the Pluriverse: Radical Interdependence, Autonomy, and the Making of Worlds,” Escobar (2018) proposes an inclusive conception of design as world-making, a practice devoted to the creation of multiple ways of being and doing in attunement with the earth based on the radical interdependence of all beings. With the concept of pluriverse creativity, we aim to advance a multimattered and multispecies understanding of creative production that encompasses the unique ways in which all biotic and abiotic entities, in their different ways of being and doing, actively participate in the ongoing production of new worlds.

Creativity in the pluriverse shifts away from innovation and mobilize making towards lost meanings of creativity. To that end, we draw a theoretical framework from process philosophies, theories of embodied cognition, posthumanism, and ecological materialism. We then apply this framework to designing and implementing a biomaking program described as a “dialogue without words” in the methods section. Finally, we examine a series of dialogues–between a boy, a tree, clay, and fungi. We use this case to discuss instances of emerging learning through multispecies creative production and outline preliminary directions for a renewed understanding of creativity in maker education.

Theoretical framework: Reclaiming pluriverse creativities

To move away from anthropocentric conceptions of maker education, we consider it necessary to reorient our practices toward creativity instead of innovation. However, as Rousell and colleagues (2022) observe, creativity and innovation are often treated as interchangeable concepts in education, emphasizing the latter. Except for recent deviations towards distributed (Glăveanu, 2014) and participatory (Clapp, 2016) models, the primary concern of creative research in education has been restricted to exceptional individuals and remarkable products. Research on individual subjects focuses mainly on psychometrics (Feldhusen & Goh, 1995) and giftedness (Howe, 1999) while research on final products evaluates them in terms of novelty and social value (Amabile, 2018). What is mainly absent is the study of creative processes. Sawyer (1998) noted that creativity research has “separated ideation, divergent thought, and insight on the one hand and execution, implementation, and performance on the other” (p. 11). The problem with this dualism, Ingold (2013) notes, is that creation is not the sudden actualization of preconceived ideas but the actual making of them.

Rather than proposing a new definition for creativity, some scholars propose a return to the word’s etymological roots and its original meaning in process philosophies (Ingold, 2013; Rousell et al., 2022). According to Meyer (2005), it was Whitehead, the 20th century philosopher and mathematician, who first introduced the noun ‘creativity’ as derived from the Latin verb *creare* meaning to bring forth, to produce, to grow. Although Whitehead (1978) avoided defining creativity directly stating that “there is no meaning to ‘creativity’ apart from its ‘creatures’” (p. 344), he referred to it as the principle of *becoming*, the “temporal passage to novelty” by which many disjunctive entities move towards unity or what he called the “production of novel togetherness” (p. 21). In his view, creativity is universal, embodied, procedural, and collective. Such perspective contrasts sharply with contemporary notions of creativity as an internal human trait or a property of socially acclaimed masterpieces. For Whitehead (1978), creativity is not about *who* produces or *what* is produced but about production and movement because there are no products but only moments, occasions, or creatures. A creature we see at any given moment, he argues, is just a moment in the flows of material circulations. In Whitehead’s process philosophy, creativity, as well as thinking and becoming, are inherently productive processes that emerge not from individuals but from their relations in the ongoing reconfiguration of reality (Pickering, 2005).

Similarly, theories of the embodied mind see cognition not as an internal operational process but rather as a relational domain that emerges *between* the mind, the body, and the environment (Maturana & Varela, 1992). Thompson (2007) argues that cognition emerges from this interrelated system and defines it as "the exercise of skillful know-how in situated and embodied action" (p. 13). Cognition is not an exclusively human property but transversal to all adaptive life. From apes to amoebas, all living organisms are cognizant and autonomous, given their capacity to purposely regulate the flow of matter and energy through them to generate themselves, sustain their identity, and avoid dissolution (Thompson, 2007). Maturana and Varela (1992) coined the term "autopoiesis" (from Greek αὐτο- [auto-] 'self,' and ποίησις [poiesis] 'creation, production') to describe the recursive process by which a system produces and maintains itself by creating its own parts. In the words of Weber and Varela (2002), "[f]orm, then, is not just an abstract goal in a genetic program, but a material task to fulfill from moment to moment" (p. 117). Biological forms crystallize the active role of the organism in its morphogenesis and its species' evolution in the long term. While genes set the parameters for development, the actual form of each living being emerges from ongoing *sense-making* of the environment through situated and embodied action (Weber and Varela, 2002). Thompson and Stapleton (2009) add that sense-making involves not just cognition but also emotion because, in making sense of its surroundings in relation to its current bodily state, the organism determines their value or relevance in the degree it feels attracted or repelled. In the words of Fuchs and Koch (2014), emotion emerges "from the circular interaction between affective qualities or affordances in the environment and the subject's bodily resonance," which suggest a correspondence between motion and emotion (p. 1).

In anthropology, ecological materialism brings these ideas together to discern the relations between making and growing. Ingold (2013) argues for an understanding of creativity not divorced from the material unfolding of the living world. Like other creatures, he observes, humans gather materials from a world already going on and redirect material flows in anticipation of what may emerge. Ingold and Hallam (2016) observe that the designs of both natural and human worlds are the outcomes of skilled response to a mutually responsive material environment; skilled makers know their materials and work *along* them to keep creation going; likewise, thriving organisms know their medium to keep life or self-creation going. Notably, what is fabricated does not escape the flows of life–artifacts do not transcend nature by the imprint of culture–but remain as material gatherings prone to dissolution, corrosion, wear, and breakdown (Ingold, 2013).

The concept of pluriverse creativity assembles these ideas to enable the possibility of multispecies and multimattered creativity as a form of embodied dialogue. We wonder what forms of sustainable and fertile living result when flattening hierarchies and allowing creativity to emerge from the enmeshment between living beings, materials, technologies, and humans. Pluriverse creativity aims to hold a dialectic and didactic space to consider multiple ways of being and their idiosyncratic ways of moving the world towards novel togetherness.

Methodology and research design

Building on the theoretical framework, we designed an implementation to support pluriverse creativity. We invited middle-school students to build creative relationships with the living world and each other through hands-on biomaking with fungi. An online invitation called youth to join a different story of the environmental crisis: 'Sometimes, climate change can feel overwhelming. Especially if you are young and surrounded by adults who think *you* are the future and need to find solutions to literally save the planet! What if rather than trying to fix it, we join the creative and regenerative power of the earth?'

We recruited twelve participants, seven girls and five boys, aged 11-12 from two public schools in a heavily developed American city. Students did not have previous experience with biomaking and had little exposure to outdoor landscapes beyond urban parks and playgrounds. Divided into two groups, we met after school for three hours a day, once a week for a six-week period. In total, participants dedicated 18 hours to the workshop. The activities were evenly distributed into two settings: A local urban park and a maker lab on a university campus. At the park, students could wander independently within 6.5 acres of woods labeled as wild but relatively managed. The makerspace was adapted as a biomaking lab that more closely resembled an apothecary. It mixed technological tools and gadgets with all sorts of gathered materials displayed in jars and boxes labeled as fungi food, biomaterial ingredients, stones, twigs, dried mushrooms, etc. By bringing elements from the park into the lab and vice versa, we wanted to intentionally blur the boundaries between indoor and outdoor settings. The aim was to introduce a persistent presence of more-than-human elements and entities–such as fungi, mosquitoes, trees, worms, logs, moths, spiders, and even bacteria and mold–into the making process.

The central non-human participant of the workshop was fungal mycelium. In previous work, we have detailed the properties that make fungi a suitable organism to facilitate interspecies creativity (Correa & Holbert, 2021). Mycelium is a multicellular organism that grows as a white meshwork of threadlike tissues. It lives underground or beneath decaying wood or leaves. Under certain conditions, it produces the fruiting body we know as mushrooms. It can be cultivated relatively easily by inoculating a carbon-rich substrate (e.g., woodchips, grains, cardboard, etc.) and providing certain temperature and humidity conditions. Broadly speaking, building with mycelium involves leveraging the organism's capacity to fuse pieces of organic matter by allowing the organism to grow through a substrate inside of a mold which is subsequently released after several days of growth.

Workshop activities were facilitated by two or three facilitators (first, third, and fourth authors) and documented by one or two research assistants. All workshop sessions were audio and video recorded through a rich tapestry of equipment, each with its own affordances and constraints. We used 360-degree cameras to record group activities in the park and lab and chest-mounted action cameras for students' solo work at the park. Action cameras allowed a (relatively) less invasive capture of participants' intimate work (remote from the researchers) at the park and aimed at capturing their embodied sense-making. We held two group interviews and had individual walking conversational interviews. We also took media videos and photographs of the maker activities, drawings, and in-process creations. The first and fourth authors also took observational notes about participants' behavior and the fluctuating state of the park and its creatures.

As design-based research, the workshop's aim was to both be informed and inform our theoretical and practical understanding of making as a multispecies and multimattered practice. Iterative cycles between theoretical and practical development are characteristic of design-based research (Wang & Hannafin, 2005). We designed a program that reimagined biomaking to afford mindful interspecies creativity. By implementing and analyzing the program in two iterations (with the two different groups), the aim was to refine existent theory and incrementally advance practical applications of creativity beyond humans in education.

To leverage pluriverse creativity, we centered the body as an interface between human and non-human participants. Drawing from Chappell's (2018) notion of creativity as embodied dialogue, we framed making as a *dialogue without words* by which multiple entities and elements can gather to make something together. Learners were invited to practice different ways of establishing wordless conversations with other bodies. This involved tuning into non-human ways of being in the world and responding through making while also attending to other beings' ways of making. Some design decisions we took to support dialogue without words were:

- Listening to other non-human bodies: We asked students to find a personal place in the park they felt drawn to while exploring the area. We let students move freely around the park and be moved emotionally and physically by other bodies. We facilitated activities to heighten students' reception of the movement of the forest in order to build awareness of other creatures' ways of perceiving the world.
- Allowing non-human bodies to have the first word: Instead of asking students to problem-solve, ideate, and project ideas on materials, we framed making as a response to a living world that is already going on. Specifically, we asked them to focus on one specific feature of their personal place–a crack in the soil, the twisted way of a trunk, the sound of leaves–as a starting point for making.
- Responding through making: After allowing enough space and time for something to call students' attention, we invited them to use clay and later mycelium to respond to the specific feature–by extending it, disrupting it, or repeating it–just as they would do in a conversation with a friend.
- Listening to their human bodies: Rather than providing recipes or techniques, as is often the case in biomaking, we leveraged students' intuition and sense-making to guide the creative dialogue. For example, instead of telling students exactly how much water mycelium needs, we invited them to recall their experiences of seeing mycelium growing in moist places in the park. This was facilitated with the prompt what do you feel? (Rather than what do you think?).
- Assembling bodily rhythms: Human and non-human bodies transform matter at different paces; while students are able to build a mold and fill it with an inoculated substrate in a couple of hours, mycelium can take three to five days to completely colonize the substrate and be ready to unmold. As facilitators, we had to coordinate activities accordingly to allow human and non-human parts to express themselves fully while being open to integrating unpredictable human and non-human responses.
- Allowing non-human bodies to have the last word: Instead of dehydrating the resulting mycelium pieces for students to take them home, we brought them alive to the park, where they were shared with families and friends on the last day of the workshop. We chose to work with a strand that was endemic to the area and beneficial to the forest ecology so that the organism could continue to live beyond the duration of the workshop and grow publicly at the park as a statement of interspecies possibility.

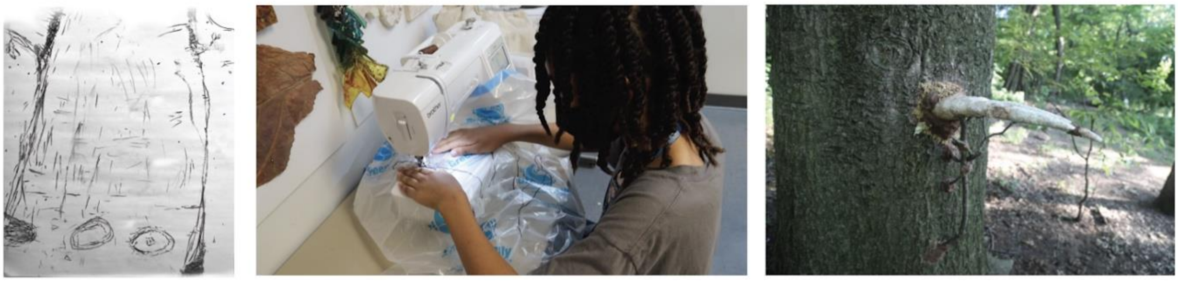
Guided by Tsing's "arts of noticing" (2015, p. 37), the analysis gave attention to multispecies relations often ignored or bypassed in traditional qualitative research. Tsing asks us to "look around rather than ahead" (p. 22) to make room for possibilities in "latent commons" (p. 135). We attempted to look at entities and matter around students as much as we looked at them and tried to make sense of events through the theoretical framework. Whereas process philosophy drew our attention to material transformations occurring between bodies, embodied cognition led us to interpret the behavior of organisms without anthropomorphizing by considering their role in driving material flows and their diverse forms of making sense of the world. These insights were assembled through multispecies storytelling (Tsing, 2015), which uses lively writing strategies (see also Blaise & Hamm, 2019; Goebel, 2022) to convey immersion in a multispecies world.

Findings: Dialogues without words

First dialogue

The slender red oak and its ancestors had felt human dwellings grow heavy over their roots. Yet, the tree knows the river keeps flowing nearby; every autumn, it counts on its breeze to spread leaves over its acorns and protect them from the coming snow. After the winter, bright green buds are slowly uncoiling from the tree's bare branches. A pack of young and noisy humans pass next to its trunk layered in warm clothes and carrying heavy backpacks [as described in notes]. The oak was there when one of them decisively walked towards it, sat over its roots, and pressed his back against a cavity on its bark that 'felt like somebody sat there before' [as shared in group interview]. The roughness of the northern side of the trunk captures his attention [as captured by action camera]. He never looks up at the branches or peers around the trunk but focuses on the crevices and foldings of its darker side. He is particularly drawn to a circular mark the size of a fist [noted in individual interview, student's drawing (Figure 1a), and captured by action camera]. When prompted about how the bark came to be that way, he points to the mark: 'there used to be a branch over here … hmmm maybe I can make another branch for it.'

Figure 1
Student's drawing of the tree and the circular marks on its bark (a), sewing bags to make a branch-shaped mold (b), and the 'prosthetic branch' installed on the tree with the support of clay and twigs (c)



(a) *(b)* *(c)*

Second dialogue

Mycelium threads unfolding and branching outwards through an intricate world of hardwood chips, exploring all crevices, filling every corner, breaking down everything on their path until reaching an inscrutable plastic membrane that refuses to break down. Moving sugars and oxygen through a tangled body and releasing carbon dioxide until the air around feels stale and thin. Suddenly, a stream of fresh and dry air wraps the newly formed body of mycelium. Using scissors, the kid carefully begins to tear apart the plastic mold and release what he called 'the prosthetic branch.' He had made the branch-shaped mold at the lab by sewing together two layers of compostable plastic bags (Figure 1b). Later he had filled the mold with loose hardwood chips inoculated with mycelium so it could grow in that shape. Three days later, the kid is back at the tree [captured by action camera], sitting cross-legged on the ground, finally opening the mold: 'I feel like a mad scientist, buah ha ha.' Yet, his human hands do not seem to know how to harness the odd body of mycelium. Not knowing how much pressure it can handle, the mycelium branch breaks once 'crap!' and twice 'creep!' The dismembered mycelium branch lays in front of him next to a block of clay that seems to suggest a way forward. He grabs a chunk of clay and connects the broken pieces back: 'clay is so heavy…I hope mycelium can grow through clay…cause if it can't then this part never grows again…I hope you can grow through clay dude.'

Third dialogue

Despite the kid's efforts, the clay refuses to hold the broken mycelium branch together, 'don't die on me,' he whispers. As he tries to save his mycelium branch, other creatures come by [captured by his action camera]. A white moth finds on his fingers a good place to land but, after realizing they are moving, launches off to the ground only to be chased after. ‘Do you wanna die?’ asked the kid while firmly holding the scissors. The moth tries to open its white wings to fly away, but they are broken and useless. The boy grabs a stick from the ground whispering, ‘yes you do, yes you do.’ The white moth attempts a final jump before disappearing under the stick. ‘The dude was done.’ Soon after, a mosquito finds the boy’s warm skin while he was wrestling with the clay. ‘Aaaaghh bugs, nature,’ claimed the boy with a contemptuous tone that was immediately followed by a new exclamation in a high-pitched voice: ‘I love nature, but I just don’t like bugs […] when I have a kid he is going to be partly made of glass.’ Finally, a second boy arrives to the tree screaming and running from a hive of bees that does not seem interested in him [as captured by his action camera]; breathing heavily, he exclaims: ‘am I the only one scared of all these animals?’ A brown squirrel passing by hears the kid's heavy steps and freezes staring at him. ‘Aaaahhh! There is a squirrel! The squirrel is looking at me!’

Fourth dialogue

The harsh bark of the tree refuses the clay and the prosthetic branch altogether. Six tangled human arms wrestle with the branch and clay against gravity. Together, all bodies–hands, tree trunk, clay, mycelium branch, and sticks–finally suspend the prosthetic branch in a delicate and almost impossible balance (Figure 1c). A human group of friends and relatives gather around the tree and look puzzled at the branch. Holding a pencil in his hand, the boy shares proudly about the prosthetic branch and his hopes for it: ‘it’ll stay on here and mushrooms will grow. It can be like a patio for squirrels […] if we get lucky this might actually grow into the tree so it can stay there without the clay.’ His voice spreads through the forest and a thick layer of fully-grown leaves dresses the canopy, cycling matter, crafting atmosphere, and giving breath to all bodies under its shadow.

Discussion: Making sense of creativity in the pluriverse

Dialogues without words are lively, messy, and prone to misunderstandings, contradictions, and discomfort. Instead of bringing students back to pure nature ecologies that no longer exist or asking them to dream distant techno-utopian futures, we choose with Haraway (2016) to “stay with the trouble” and give space for learners to craft ways forward from the midst of our hybrid, odd, messy, and unraveling pluriverse worlds.

The first dialogue positions maker activities within a larger hybrid ecology. Not a wild and innocent landscape but a place of resistance; a seemingly wild but managed patch of woods in a city of manicured parks and playgrounds. The dialogue was initiated by the encounter between the kid’s back and the tree’s bark pressing against each other and, later on, by the circular mark that captured his attention. His reading of the mark as a trace of a fallen branch suggests an incipient understanding of the tree not as a finished and static object but as an unfolding body. Giving living beings the chance – space and time – for learners to notice them and giving learners cognitive tools for noticing is a necessary first step to acknowledging creativity in the world. It is worth considering how this incipient noticing could have been nurtured further, through prompts or discussion, for the student to consider something as still as a tree as an unfolding creature that is in movement within itself despite its solid appearance. Subtly, this was suggested by the practice of making itself through which the student entered into conversation and joined the tree on its becoming.

The second dialogue presents a series of embodied conversations that gave rise to the ‘prosthetic branch.’ The actual form of the branch emerged from the relational engagement of mycelium growing outwards through the wood chips and against the surrounding plastic mold. The mold’s shape, in turn, emerged from the dialogue between the sewing machine, the boy, and the plastic bags. Later on, at the park, the student, the mold, and the branch wrestled with mutually responding forces until the final shape was released. In the process, his unskilled bodily movements, not knowing the body of mycelium well enough, broke its delicate fibers apart. When looking for a way forward, the student demonstrated both thinking like the organism and thinking through clay in an embodied manner. The myceliated substrate, which is as light as styrofoam, contrasted with the weight of the clay. When holding the clay in his hands, the question of mycelium’s ability to grow through clay emerged from his embodied understanding of density and his past experiences growing mycelium at the lab.

The third dialogue shows how the students’ presence in the forest was not without friction. Despite our efforts to build awareness of their bodies and other fragile non-human bodies around them, they inadvertently and, at times, intentionally smashed seedlings, made trails, and displaced or killed critters. When learning occurs outdoors, Pacini-Ketchabaw (2013) suggests important questions: “Who lives and who dies with children's visits to the forest? What worlds are created? What futures are generated and regenerated in these visits?” (p. 356). The boy’s care for mycelium contrasted with his reaction toward other creatures that interrupted his work. Non-human bodies moved the students’ bodies–emotionally and physically–and awakened visceral reactions that they attempted to tame rationally, perhaps given the presence of the chest camera. In these intimate yet uncomfortable encounters, human-nature boundaries dissipated, allowing for what Taylor and Pacini-Ketchabaw (2015) describe as the “mutual vulnerability” inherent to everyday interspecies encounters. Being observed by piercing non-human eyes, feeling the fragile body of a moth breaking down, becoming porous and edible for mosquitoes, having a skin that is not 'made of glass.'

Finally, the fourth dialogue illustrates the student's emerging understanding of making within a larger scheme of multispecies events. For him, the branch is not finished; mushrooms will grow, squirrels will play, and mycelium may even continue to grow toward the tree. An understanding of making in continuity with the ongoing transformations of the earth facilitates a mindful consideration of its implications. Creativity in the pluriverse demands responsibility for the "creatures" (Whitehead, 1978) that we make and the traces we leave behind. Thinking of making as growing offers paths to re-weave human threads into the fabric of life.

The presented dialogues without words describe how a multiplicity of beings accommodate to each other in their discordant ways of being. Every-body–children, facilitators, mycelium, clay, bugs–was doing its own thing, immersed in embodied sense-making. Yet, when intentionally assembled, collective sense-making can bring forth novel togetherness. As primary steps in the path of re-thinking making in the pluriverse, we highlight the importance of giving space for learners and other beings to notice each other and discern shared participation in the creative reconfiguration of the earth. Whereas this research focused on biomaking, its principles extend towards all making practices considering the active participation of materials and technologies in the collective making and remaking of the earth.

Conclusion

We explored the pluriverse creativities as a space to study making as an embodied process by which a multiplicity of entities and elements give rise to the forms and features of the world. By recognizing the intricate ways natural and artificial forces build and grow upon each other, we aim to advance understandings of making in which humans are not in a position of management and control but instead immersed in a complex socio-ecological world in ongoing material reconfiguration. This way, rather than trying to save the planet through making, we invite makers to join the earth in its creative dynamics and regenerative capacity. Recognizing the challenges ahead, we look forward to new paths in maker education where students and other beings can learn from each other through productive differences, create collective sense-making, and move towards novel togetherness.

Three Chronotopes for Humanizing the Language of Mathematics

Anna Zarkh, University of California, Berkeley, annazarkh@berkeley.edu

Abstract: This paper explores how discourse practices in advanced mathematics can center, rather than obscure, the human role and experience in the discipline. Inspired by renewed calls to humanize mathematics (R. Gutiérrez, 2018), I draw on Bakhtin's (1981, 2010) notion of chronotope (space-time configuration), to conceptualize three types of moves that humanize mathematical discourse. The humanizing moves are characterized by the space-time scales of human activity they evoke: (1) here-and-now experience doing math, (2) social-historical context of math activity, and (3) cultural-discursive hybridity. I illustrate the three categories with excerpts from Real Analysis lectures. While the illustrative data are from a proof-based university math course, the intended contribution of the paper is theoretical and the categories are applicable to other contexts and modality of math communication as well.

Introduction

Math, and in particular, contemporary academic math (i.e. the discursive practice of research mathematicians), is often experienced as alienating and decontextualized from human issues and experiences (Davis & Hersh, 1981; Schoenfeld, 1994), especially among students who are already underrepresented and marginalized in the discipline (R. Gutiérrez, 2018; Herzig, 2004). One aspect of practice that contributes to such feelings of alienation are the discipline's norms of talking and writing (Lemke, 1990). Language practices in contemporary academic mathematics are centered on the register of the formal text, which is known to obfuscate human agency, e.g. through linguistic devices such as passive verbs and nominalization (Burton & Morgan, 2000). These dehumanizing features are pervasive in part because they help constitute the community's epistemic goals of creating abstract, indubitable, objective and universal knowledge (Hersh, 1991). Language choices, however, are not set in stone. In communication contexts such as lectures, instructors can embellish the textual register with movement, speech and inscription that put "humanity in the machine" (Shaw, 2001, p. 27) and have the potential to cultivate a feeling of disciplinary belonging for students (Rodd, 2003).

The term humanizing has been gaining popularity in mathematics education in recent years, following R. Gutiérrez's (2018) call to shift away from mainstream equity discourses, which are obsessed with "fixing" students' (perceived) deficits and hence counterproductive (Adiredja, 2019; R. Gutiérrez, 2018), to a conversation that focuses instead on how classroom mathematics itself can be reconfigured to better reflect the human beings it lives through and serves. Yet, despite the increased popularity of the term, there is no clear agreement on what humanizing actually means or looks like in concrete mathematical interactions. In this paper, I aim to unpack what humanizing can mean for communication in contemporary academic mathematics. I propose a framework for thinking about this issue and illustrate how lecturers' small discursive moves in advanced math courses can contribute to a more humanizing experience and image of the discipline.

What about mathematical language and interactions can be humanized?

What might we mean by *humanizing* mathematical language? R. Gutiérrez (2018), for example, listed eight (non-exhaustive) dimensions along which math classrooms can be rehumanized for "students and teachers who are Latinx, Black and Indigenous… They include (1) participation/positioning, (2) cultures/histories, (3) windows/mirrors, (4) living practice, (5) creation, (6) broadening mathematics, (7) body/emotion, and (8) ownerships." (p. 4) This list casts a wide net. Other scholarship focuses more specifically on one or two of these issues, and does not necessarily frame them under a single umbrella term such as humanization. Also, in contrast to R. Gutiérrez's work, the starting point for other research is not necessarily the concerns and experiences of marginalized students. Nevertheless, similar aspects of discourse are taken up. For example, in the embodied cognition tradition, researchers attend to how mainstream math teaching discourse, seeped in Cartesian dualism, can devalue and make invisible important affective and embodied resources by focusing primarily on seemingly 'mental' processes, abstraction and formalism (e.g. J. Gutiérrez, 2018; Núñez et al., 1999). In the social-semiotics tradition, researchers studied the linguistic features of written mathematics, such as academic research articles and textbooks, to highlight how pervasive practices such as nominalization (turning verbs into nouns; e.g. "I counted" to "counting" to "a count") and the use of passive voice (e.g. "as shown by the count in theorem 2.7") contribute to the obfuscation of human agency in the creation of mathematics (Burton & Morgan, 2000). Rotman (1988), building on Pierce's semiotic theory, observed that mathematical texts make extensive use of inclusive imperatives such as "formalize" "define" and "let", and suggested that these are instructions for an abstract semiotic agent he called "Subject". The Subject is an idealized reader and writer of the text, a decontextualized scribbler that does the epistemic work of mathematics. Importantly, this idealized writer-reader has no social identity, nor is it situated in any cultural-historical context. It does not have preferences, goals, nor does it get excited or scared. There is nothing besides text and cognition in the universe the formal text evokes.

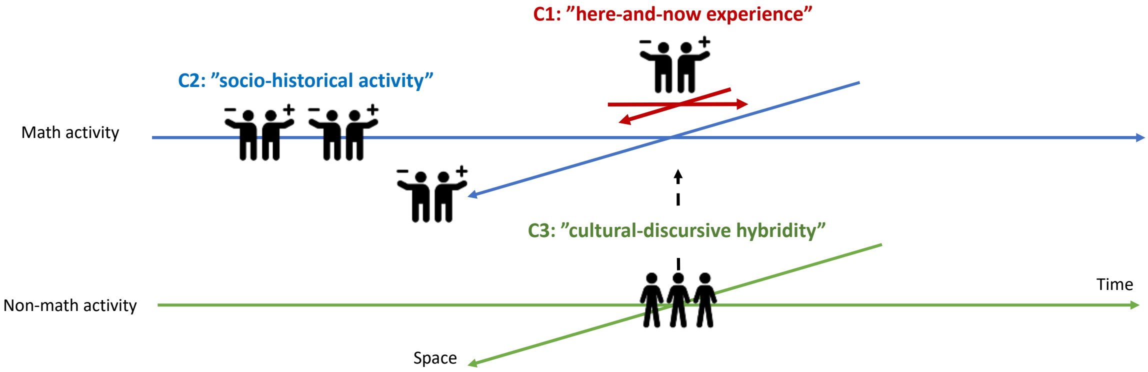
Humanizing mathematical language through three space-time scales

To provide room for human experience, mathematical texts need to construct a world in which human beings can be situated. Bakhtin's (1981, 2010) concept of chronotope is a useful tool for thinking about how this can be accomplished through language. In his study of the evolution of the novel as a literary genre, Bakhtin coined the term chronotope (in Greek, "time-space") to refer to "the intrinsic connectedness of temporal and spatial relationships that are artistically expressed in literature." (p. 84). This construct allowed Bakhtin to effectively contrast and characterize different novel types (e.g. adventure, metamorphosis, biographical novel), which in turn allowed him to track the historical evolution of the genre through concrete examples of texts. Important for my purpose here is that a text's chronotope "determines to a significant degree the image of man… The image of man is always intrinsically chronotopic." (Bakhtin, 1981, p. 85)

In this paper, I use the concept on a much smaller scale of speech genres (Bakhtin, 2010) to characterize three broad types of mathematical utterances that can be humanizing. I propose that human experience in mathematics can be discursively situated in three time-space arenas: (1) the here-and-now experience doing math, (2) the social-historical context of math activity, and (3) cultural-discursive hybridity. Figure 1 illustrates these three chronotopes within a single space-time diagram. The first chronotope (in red) is about the in-the-moment experience, the micro-genesis of doing math. The second chronotope (in blue) expands both the space and time scales, attending to the synchronic and diachronic dimensions of activity; it invites us to look at how math is a collective cultural practice, spanned across historical time and across socio-geographic space. The third choronotope (in green) entails a further expansion of space-time, inviting us to consider other discourses and cultural-historical activity systems that are parallel, interwoven, and seep to and from the social history of what we typically label as "mathematical".

Figure 1

A chronotopic framework for situating the human in mathematical discourse



This conceptual framework was developed in the context of a video based micro-ethnographic study (Derry et al., 2010; Erickson, 1992) of language practices and ideologies in an advanced math university course called Real Analysis. The data corpus consists of video recordings of lectures and auxiliary documents (e.g. lecture notes) from Real Analysis courses taught in a large research-oriented university in the United States. The study's participants are five research mathematicians who taught the observed lecture-courses. Data was obtained in two rounds of data collection: one course in Spring 2015 (taught by Henry, in person), and four courses in Fall 2020 (taught online by Alex, Cai, David and Emmett). In this paper, for coherence, I only use data from Henry's lectures. These data were analyzed first and feature a large amount and variety of moves that can be humanizing.

The framework emerged through inductive coding of transcripts and document data (Saldaña, 2021). The focal question orienting analysis was: What aspects of advanced math lecture discourse may contribute to a more humanizing experience and image of the discipline? In an initial round of coding, I flagged and labeled lecturers' discursive moves that I broadly interpreted as humanizing. This process generated a long list of codes such as "performed affect", "personification" and "out-of-math metaphors". I then synthesized the codes into broad categories. Bakhtin's chronotope construct was then brought in to help characterize the categories and situate them within a single coherent theory. The resulting framework, of three chronotopic scales for humanizing mathematical discourse, is operationalized and exemplified in the sections below.

An important caveat is in order. I do not claim that the examples provided below were indeed experienced as humanizing by the students attending those lectures. Nor that these moves should or are likely to result in a humanizing reaction for most readers. How utterances are responded to is a function of context and of the interpretive repertoire that each individual addressee draws on. This is always true, but particularly salient for the third chronotope, as different experiences with 'out of math' discourses and activities shape how such references are taken up. My initial flagging of episodes as potentially humanizing certainly involved subjective judgement. When making these determinations, I drew on my experience as a student in advanced mathematics courses (in both my undergraduate and graduate education), and my ongoing work as a university math instructor. My experience and positionality as a white immigrant woman in the US have no doubt influenced these interpretations as well. Thus, rather than claim a definite humanizing effect, my intention is to convince the reader that certain *types* of discursive moves are worth considering to humanize math talk. Ultimately, the efficacy of deploying any such move in interactions rests upon deep familiarity with the background and perspectives of one's interlocutors.

Chronotope 1: Multidimensional here-and-now experience doing math

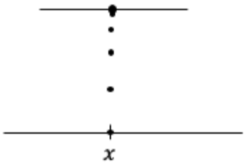
How do we talk about and enact the in-the-moment experience of doing math; how does mathematical activity *feel like* to the person doing it? If we look at the formal register, the language of formal mathematical texts, the vast majority of actions are attributed to an abstract agent (Rotman, 1988) and are cognitive and epistemic in nature. But when actual people engage with math, they do more than "consider", "assume" or "know". They also have affective experiences such as excitement and fear, they imagine pictures and motion, and they have bodily experiences moving in and around inscriptions and virtual mathematical landscapes (Ochs et al., 1996). These experiences are rarely reported on in writing, in part because that would jeopardize the epistemic goal of the text by making the mathematical ideas bound to the concrete human body. An abstract free-floating cognitive agency "assumes," but *a person* also feels, imagines, and moves.

Example 1.1: Embodied interpretation

When math is done by humans, it is always done with bodies and material artifacts (Núñez et al., 1999). Mainstream discourse about math, seeped in traditions of mind-body dualism, tends to erase or at least decenter the material and bodily aspects of math activity (J. Gutiérrez, 2018). Bodies either do not exist at all, or are inconsequential. One way to humanize math, to frame math as done by actual human beings, is to explicitly talk about and enact the body in mathematical activity. The example below illustrates how attending to the body can be done in lectures within the specific context of "interpreting formal definitions", a discursive practice central to academic math. The episode begins after Henry finished writing the formal definitions for pointwise and uniform continuity. Actions are described in double brackets (( )). Inscriptions are reproduced within the transcript as well.

1 The question is what image do I get in my mind. So, let's try to see this one here
2 ((points at 'pointwise' convergence condition, sketches a diagram)). My image of it is

3 It says. For every x in S. OK. So, let me stand on x. What does it then say? It says that
4 fn of x minus f of x should be less than epsilon. That means that the fn of x <u>converges</u>
6 to f of x. So, that simply means going up going up going up and converging to a point



7 over there. I have (been)- ((stomps feet)) I stand on a point ((pulls fists down)) and
8 then I look (at) ((raises hands up)) fn going up to the point that's sitting up there.
9 That's my feeling of it.

The interpretation is personal. Henry speaks with the voice of an "I" when he says "what image do *I get in my* mind*"* (line 1), "*my* image of it is" (line 2) and "that's *my* feeling of it" (line 9). He also inserts himself into the graph: “let me stand on x” (line 3), “I stand on a point” (line 7), and “I look at” (line 8). Henry constructs a subjectivity that imagines (lines 1 and 2) and feels (line 9). This subject imagines moving in and around the world of inscriptions (Ochs et al., 1996); he “stands” on a point and looks at function values “going up going up going up” to a point above. But this is not just visual imagery. It is a full body experience. To “stand on x” Henry firmly stomps his feet on the ground and holds his hands tight to stay put (lines 8-9). Looking up involves raising his hands and pointing up in the graph (line 9). The subjectivity Henry enacts is vastly different than the one in the formal math text (in fact, the definition text Henry wrote does not refer to a human subject at all). Henry’s “I” is one that imagines and feels, not just “considers” and “defines.” And it does this imagining with a body.

In this episode, Henry enacted interpretations of the pointwise convergence definition using language and gestures that depict an embodied experience. These interpretations explicitly evoked and mobilized the whole body, and in so doing, conveyed the idea that math is felt and that we do it with our whole body.

Example 1.2: Emotional reactions and stances

Discourse about math and math learning often describes “cold” cognition (Pintrich et al., 1993). However, whenever people do math, they do not cease to have feelings. Emotions and emotional stances toward the objects of activity are not only part of mathematical experience, but also central to it. It is often the very emotions bundled up with the math that propel our mathematical activity forward (Jaber & Hammer, 2016). Thus, one way to more accurately and expansively depict what math *feels like* in the moment, is to explicitly center emotional reactions and stances in our discourse in and about math.

In the observed lectures, there were many instances of instructors displaying affective reactions to the math they were talking about. At times, affective stances were labeled explicitly (e.g. “I’m scared” or “I’m excited”). Most often, however, affect is conveyed through describing the object of focus and through other modalities such as prosody and gestures. The excerpt below illustrates this latter type of “performed affect.” In this episode, Henry discussed errors in recalling the radius of convergence formula ($\mathcal{R} = \frac{1}{\overline{\lim}\sqrt[n]{|a_n|}}$):

1 Some people were confused about $\mathcal{R} = \overline{\lim}\sqrt[n]{|a_n|}$. That’s of course wrong.
2 [should be] one divided by it $\mathcal{R} = \frac{1}{\overline{\lim}\sqrt[n]{|a_n|}}$. That’s why it’s a bad way of remembering it.
3 In some sense, the best way of remembering it is $\overline{\lim}\sqrt[n]{|a_n||x|^n} < 1$. Right?
4 That’s a lim sup. That’s maybe the most natural way of remembering it.
5 I know this is this horrible beta ( ) instead of 1 over R

The episode ends with a display of an affective stance (Ochs, 1996) toward a “horrible beta” (line 7). The word “beta” refers to terminology introduced in the textbook $\beta = \lim\sup|a_n|^{\frac{1}{n}}$. What I wish to call attention to is Henry’s use of the the adjective “horrible”, which enacts an affective stance toward the mathematical signifier. What makes the beta horrible? And importantly, to whom? The beta is not “horrible” in a platonic mathematical universe. It is horrible to Henry (and possibly students) in the here-and-now and perhaps also in past experiences of encountering the signifier (e.g. when reading the textbook). Thus, this affective stance marker centers the here-and-now experience of people doing math. The overt affective display constructs engagement with math not as an unemotional view from nowhere, but as a person that can get intimidated by the presence of symbols.

Chronotope 2: Socio-historical context of math activity

The first chronotope entailed zooming in on how it *feels* to do math *in-the-moment*, attending to how mathematical experience is, like any other human experience, multidimensional. In particular, doing math is not purely a cognitive and epistemic experience; it involves affective, somatic, and aesthetic dimensions as well. In the second chronotope, we zoom out and look at the broader socio-historical context of mathematical activity.

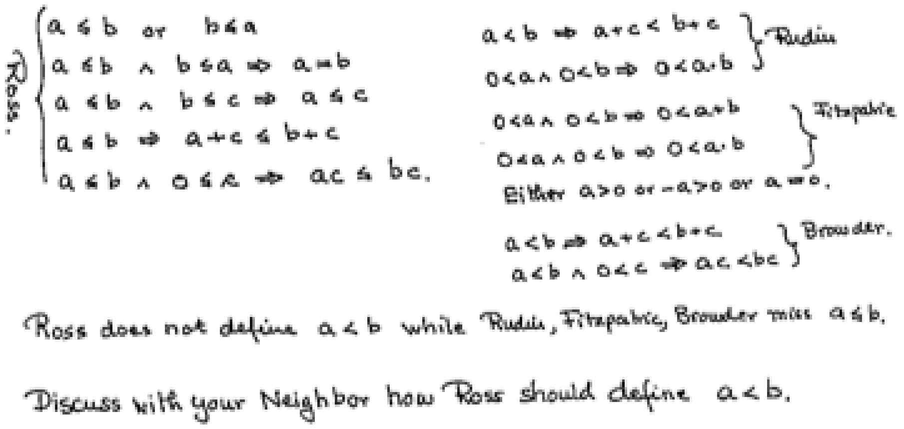
Doing math is not just a random experience that people come to have. Mathematical activity is a *social* practice (Schoenfeld, 2016); it has a history and it is shared by a community of other people who “do math”, past, present and future. That is, mathematical experience is part of a cultural-historical activity system (Cole, 1998). The socio-historical context of mathematical activity is not typically centered in disciplinary discourse, with the formal register often avoiding it altogether. The history of mathematics – the fact that mathematical texts such as definitions and theorems were and continue to be *written by people*, based on decisions, errors, circumstances, purposes and preferences – is rarely discussed in official texts. Likewise, the fact that mathematical texts are not decontextualized archives of truths but rather artifacts that people use (today and in the past) for different kinds of purposes and in different kinds of ways is not emphasized. If mathematical texts were to be historically contextualized, they run the risk of being seen as historically contingent, of being one of many possible alternatives, and thus lose their status of universality and objectivity.

Example 2.1: Authorship, social persona and choice

One way to portray mathematical activity as situated in socio-historical context is to explicitly attribute authorship to mathematical text units (e.g. theorems, definitions and proofs). In the formal register, mathematical text units often come from "nowhere". Definitions are "defined" by abstract semiotic agents (e.g. "we define a metric …") or there is no agent at all (e.g. "a metric is defined…"). In contexts of practice, however, definitions are always written by people. These people have names, purposes, and preferences. Classroom discourse can highlight that. As an example, consider the following excerpt from Henry's lecture notes (shown in Figure 2 below).

Figure 2

Lecture notes excerpt inviting students to compare definitions in four textbooks



Ross.
$a \le b$ or $b \le a$
$a \le b \wedge b \le a \Rightarrow a = b$
$a \le b \wedge b \le c \Rightarrow a \le c$
$a \le b \Rightarrow a + c \le b + c$
$a \le b \wedge 0 \le c \Rightarrow ac \le bc.$

$a < b \Rightarrow a + c < b + c$
$0 < a \wedge 0 < b \Rightarrow 0 < a \cdot b$
Rudin

$0 < a \wedge 0 < b \Rightarrow 0 < a + b$
$0 < a \wedge 0 < b \Rightarrow 0 < a \cdot b$
Either $a > 0$ or $-a > 0$ or $a = 0$.
Fitzpatric

$a < b \Rightarrow a + c < b + c$
$a < b \wedge 0 < c \Rightarrow ac < bc$
Browder.

Ross does not define $a < b$ while Rudin, Fitzpatric, Browder miss $a \le b$.

Discuss with your Neighbor how Ross should define $a < b$.

In the above notes, Henry presents excerpts of definitions from four different textbooks, one for the sign (top left, labeled "Ross") and three others for the sign (top right, labeled "Rudin", "Fitzpatric" and "Browder"). Presenting these definitions side-by-side invites students to engage in a mathematical practice that is ubiquitous in mathematicians' day-to-day work, yet not often centered in pedagogy: comparing and contrasting alternative definition formulations for "the same" (or similar) mathematical object. Designing a classroom task that mimics this practice is an interesting pedagogical move in and of itself, but what I wish to highlight for the purpose of the discussion on humanization is that Henry does not "just" ask students to compare features of different definitions. By labeling each definition by its respective textbook author Henry associates them to people. This does not only raise the consideration of alternatives but further suggests that these definitions were chosen and written by specific people, identifiable by their last name.

Furthermore, the verbs in the next sentence in the notes ("Ross does not define $a < b$" and "Rudin, Fitzpatric, Browder miss $a \leq b$") explicitly attribute definition formulation as an action by the mentioned authors. Ross, Rudin, Fitzpatric and Browder are presented here as agentic mathematical actors that choose between alternatives (even if not knowingly, as suggested by the verb "miss"). Such a formulation promotes an image of mathematics as a living practice (R. Gutiérrez, 2018), one that "… underscores mathematics as something in motion. When students can see mathematics as full of not just culture and history, but power dynamics, debates, divergent answers, and rule breaking, it highlights the human element and helps promote a vision that is a verb rather than a noun" (p. 5). While this excerpt from Henry's notes does not go as far as revealing "behind the scenes" power dynamics, it does suggest at least the possibility of debate. What we see in this example from Henry's notes is more than just attaching a name to a mathematical text unit (a common practice in math texts, e.g. "Cauchy's theorem"). Here, the names are positioned as agents. They perform actions such as "define" and "miss" and students are invited engage in mathematical activity from these agents' perspectives

Chronotope 3: Discursive hybridity

In the first two chronotopes we looked at the human experience in mathematical activity on different time scales; the micro (chronotope 1), and meso and macro (chronotope 2). Each dimension further involved an expansion of features and contexts under consideration. From a cognitive micro experience, to one that is also affective and multimodal. From decontextualized abstract math, to one that incorporates various mathematical histories and futures. So far, we stayed within contexts that are traditionally considered mathematical. However, mathematical activity is just a small fraction of the human experience. For people to feel fully human in math classrooms, to be reflected in mathematical interactions, non-mathematical discourses and activities should permeate too (R. Gutiérrez, 2018). Such a hybridization of math language does not only affirm students; it can also expand the mathematical meaning potential to new contexts, thus enriching mathematics itself (Adiredja & Zandieh, 2020).

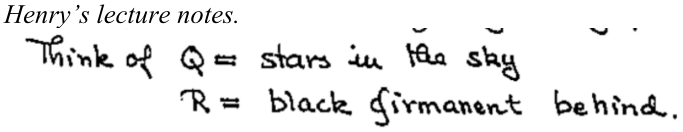
Looking at the textual register and many math classrooms, one may have the impression that other human activities and discourses do not exist. Written texts will sometimes reference "applications" in other STEM fields, but that is as far off from "pure" math that the text would stir from. But no activity is ever in isolation, and no discourse is ever entirely separated from other voices. Hybridity is an inherent feature of all languages (Bakhtin, 1981), and so too in math, other voices seep through. This chronotope invites us to celeberate this feature of language, and strategically furnish math talk with voices that index other spheres of social activity, those typically considered outside of the discipline. Rather than demarcating disciplinary boundaries (e.g. "now we are talking 'off topic'"), it highlights discursive moves that enact mathematics as blended, permeable and truly diverse.

Example 3.1: Out of math context as a metaphorical resource for mathematical concepts

One way to hybridize the discourse in math classrooms is to use out-of-math contexts or situations to make sense of mathematical concepts. Everyday experiences are a powerful resource for making sense of mathematical ideas, and also used by experts (Sfard, 1994). Yet, the role of out-of-math experiences in mathematical understandings are rarely discussed out in the open. In advanced math courses such as Real Analysis, even when "informal" interpretations are allowed, the evoked context (e.g. physical-dynamical models such as moving graphs) still tends to be removed from the everyday world. The example below (Figure 3), taken from Henry's lecture notes, illustrates how the everyday activity of "looking up at the night sky" can be leveraged to make sense of the relationship between the sets of real and rational numbers.

Figure 3

The night sky context as the sets of Real and Rational numbers, Henry's lecture notes.



Think of $\mathbb{Q}$ = stars in the sky
$\mathbb{R}$ = black firmament behind.

In this excerpt, Henry invites students to think about $\mathbb{Q}$ (the set of all rational numbers) and $\mathbb{R}$ (the set of all real numbers) in terms of two parts of the night sky: the stars and black background "behind" them. The metaphor helps highlight important properties of these two sets: the set inclusion relationships $\mathbb{Q} \subset \mathbb{R}$, and the density of $\mathbb{Q}$ in $\mathbb{R}$. It illustrates the crucial and complex idea of different types of infinity. Of course, the metaphor has limitations. Because the stars and the black firmament are distinct entities in the metaphor, it may suggest that $\mathbb{Q}$ is not contained in $\mathbb{R}$ (which is wrong per normative usage of the terms). But metaphors are not powerful because they are absolutely correct. When mathematicians leverage metaphors as tactical tools of sense making in local contexts, they capitalize on their affordances all the while acknowledging their limitations.

It is important to exploit metaphors, not only because they buttress the mathematical sense-making of experts (Sfard, 1994), but because they are humanizing. They provide important spaces for intersection between official mathematical texts and students' lived experience (Adiredja & Zandieh, 2020). In this example, Henry's invocation of the night sky context may provide students with opportunities to connect everyday experience with mathematical ideas. A student can recall or imagine themselves looking up at the night sky, and use that rich and imaginative experience as a sensemaking resource in the classroom. And perhaps more importantly, by explicitly referencing this metaphor in the notes, Henry does not only invite students to make sense of numbers in terms of the night sky. This move implicitly sanctions the practice of leveraging everyday experiences for mathematical sense making as a legitimate resource in advanced mathematics. It makes drawing on everyday experiences not only "allowed," but encouraged.

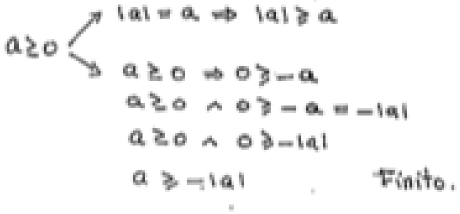
Example 3.2: Using language resources not typically associated with math

In the previous example, we looked at how an everyday situation ("looking up at the night sky") can be evoked to make sense of mathematical ideas. Next, I would like to examine how math lectures can use various types of language resources from spheres of human activity not commonly associated with math (e.g. MEMEs, slang words, everyday forms of speech, etc.). Why is seeing social diversity in the language of mathematical activity important? This goes back to R. Gutiérrez's (2018) idea of Mirrors/Windows and to a general call for more diverse representation in mathematics. Bringing in out-of-math language forms can help youth see themselves reflected in the activity. The more we diversify the language practice, the more diverse forms of self can be reflected in "official classroom discourse," the more inviting the space becomes. By using particular words, phrases, even intonations, a speaker can invoke out-of-math voices that make the activity feel a bit more familiar. What's humanizing about it is the idea that as people doing math, we are also always embedded in other discourses, and bringing resources from those other discourses acknowledges that aspect of our humanity. As with out-of-math metaphors and contexts, out-of-math language resources is not only *for students*. Rather, making disciplinary boundaries more permeable has the potential to enrich mathematics itself.

The example below (Figure 4) can serve as a small illustration of this. In the third lecture in the semester, Henry wrote a proof of the $a \geq 0$ case of the inequality $-|a| \leq a \leq |a|$ in the following way:

Figure 4

Lecture notes excerpt: Finito in place of Q.E.D.



$$a \geq 0 \begin{cases} |a| = a \Rightarrow |a| \geq a \\ a \geq 0 \Rightarrow 0 \geq -a \end{cases}$$

$$a \geq 0 \wedge 0 \geq -a = -|a|$$

$$a \geq 0 \wedge 0 \geq -|a|$$

$$a \geq -|a|$$

Finito.

What stands about this example in terms of discursive hybridity is the use of the word "finito" at the end of the proof. It is common to mark the end of mathematical proofs. Two commonly used signifiers to mark ends of proofs in math are: "Q.E.D.", which initializes quod erat demonstrandum (in Latin "which was to be demonstrated"), and the tombstone symbol , imported into mathematical usage by Paul Halmos. In contrast to these two standard forms, Herny's use of 'finito' is idiosyncratic. The word is borrowed from Spanish and Italian, where it means "finished" or "finite". In English, it might evoke a playful connotation. Thus, using the word "finito" instead of the more traditional or Q.E.D can lighten, or signal a feeling of relief (though an addressee's actual take-up such connotations dependents on their familiarity with and acceptance of the word's playful usage). Finally, as with the above example of using an out-of-math metaphor, using such a word in the notes can sanction similar kinds of language-blending for students too, using terms and references they are more familiar with.

Discussion and conclusions

In this paper, I argued that Bakhtin's (1981, 2010) chronotopes are a useful tool for conceptualizing the discursive construction of human-math relations. I proposed three mathematical chronotopes – (1) here-and-now experience of doing math, (2) social-historical context of math activity, and (3) cultural-discursive hybridity – as concrete arenas for situating the human in mathematical discourse. I provided illustrations of small discursive moves in advanced math lectures that can be considered humanizing in terms of these three broad categories.

The proposed framework can be used to humanize advanced mathematical language in two ways. On one hand, it can help scholars and university math educators who routinely observe talk in advanced math courses notice humanizing discursive moves lecturers make. This includes researchers who use lecture discourse as data, practitioners who observe lectures for the purposes of peer-evaluation and feedback, and instructors, who may reflect on how they themselves talk and routinely evaluate the talk and writing of students. I suggest that the moves I highlighted are helpful for humanizing, and thus critically important to note in the talk of both instructors and students. Second, I aim the framework to be helpful to instructors who want to humanize their lectures but are not sure where to start in tackling this broad and perhaps vague objective. What I offer is three dimensions to think with, and some examples of things one might try in classroom talk or writing. This is not a one size fits all recommendation of "pedagogical tricks." I provided examples of one lecturer's moves, and hope these can function as a springboard for new ideas about how advanced math discourse can be humanized.

There is no intention or presumption that this study gives a definitive answer to what humanizing math lecture discourse is or can be. Such an objective is neither feasible nor desirable. Arguably, any researcher's attempt to give a definitive answer in a top-down manner is in itself dehumanizing (Vossoughi & Gutierrez, 2016). Rather, I aimed to provide an initial conceptual framework and empirically grounded taxonomy of discursive phenomena that can be considered humanizing in advanced mathematics lectures. This objective – of descriptive detail and theoretical grounding – is motivated by the assumption that the resulting language can help practitioners talk about "teaching math in a humanizing way" in ways that will better support us to consciously and collaboratively work toward this goal. Simply agreeing to "teach math in a humanizing way", or tell others to do so, without agreeing on what that means in the micro-detail of classroom practice is not sufficiently specific as a description of practice to be actionable (Erickson, 1992).

Literacy for Knowledge Building in Two Partnering Science Classrooms

Jianwei Zhang, University at Albany, State University of New York (SUNY), jzhang1@albany.edu

Abstract: Using an interactional ethnography approach, this study analyzes student literacy practices in two Grade 5/6 classrooms that engaged in a science inquiry organized based on the Knowledge Building pedagogy. Students studied human body systems for 10 weeks with the support of Knowledge Forum. While students conducted collaborative inquiry in each classroom, a shared meta-space was available for cross-classroom collaboration. Analysis of classroom observations, interviews, and online discourse elaborated five core features of literacy for knowledge generation, which integrates reading, writing, and dialogue across multiple inquiry forms, media, and discourse spaces for sustained knowledge building.

Introduction

In an open informational world with constant changes, education needs to prepare students as critical knowledge consumers as well as knowledge generators, who can work with multiple sources of information to develop creative solutions to challenging problems. As a specific change, the pervasive use of digital technologies has transformed traditional reading and writing, changing from reading single source documents for comprehension to reading across sources, forms, and media platforms for creative problem solving (Leu et al., 2004; Liu, 2014; Goldman & Scardamalia, 2013). In reflection of these changes, education reforms call for efforts to develop productive literacy that supports knowledge generation in different subject areas (Council of Chief State School Officers, 2010; National Council for the Social Studies, 2013; NGSS Lead States 2013; Ontario Ministry of Education, 2013; Wright & Domke, 2019). To meet this demand, educators need to better understand what such new literacy looks like in practice and how to support students of various age groups in literacy engagement.

Content literacy teaching used to focus on supporting students' role as knowledge consumers; literacy to support authentic disciplinary practices needs to additionally support student knowledge generation. What does such literacy for authentic disciplinary practices look like? Goldman and colleagues (2016) identified literacy related to five core constructs of disciplinary practices: epistemology (beliefs about the nature of knowledge and knowing); inquiry practices and reasoning strategies; overarching concepts and principles; types of texts and media in which information is represented and expressed; and discourse and language structures essential to the disciplinary practices. As literacy for science practices, students engage in close reading of science information to construct knowledge that involves multiple representations, synthesize information from multiple sources, construct explanations of various phenomena, justify and critique explanations using science principles and evidence, and understand the nature of scientific discourse. These core constructs represent key features of "reading for understanding" that supports evidence-based argumentation using multiple information sources.

Complementing the above framework that focuses more on reading, researchers underline writing and dialogue as tools of disciplinary inquiry (Applebee et al., 2003). Reflecting on how technology transforms reading and writing, Bereiter and Scardamalia (2005) proposed the concept of *dialogic literacy* as an alternative to print literacy. Dialogic literacy refers to "the ability to engage productively in discourse whose purpose is to generate new knowledge and understanding." (Bereiter & Scardamalia, 2005, p. 758) Such discourse involves careful and genuine listening, understanding different perspectives, building on others' ideas, developing common ground, and negotiating new ideas and challenges beyond the status quo. Researchers further emphasize the shift of reading, writing, and sensemaking in networked environments. A group of researchers (Liu, 2014; Thomas et al., 2007) developed the concept of *trans-literacy*: the ability to read, write and interact across a range of platforms, tools and media from signing and orality through handwriting, print, to digital media and social networks (Thomas et al., 2007). Given the pervasive use of digital and interactive environments, researchers call for efforts to incorporate trans-literacy as an important part of disciplinary literacy (Goldman & Scardamalia, 2013). Such high-level literacy is essential to scientific sensemaking in which students not only comprehend given information but also continually identify problems of understanding, search for and work on potential ideas, and develop coherent explanations that make sense (Odden & Russ, 2019).

This study investigates disciplinary literacy in a student-driven, open-ended inquiry organized based on the Knowledge Building (KB) pedagogy. KB aims to transform classrooms into knowledge-building communities in line with how knowledge creation takes place in the real world (Scardamalia & Bereiter, 2006). Students not only work on pre-defined problems and tasks, but also identify new and deeper problems based on their interests and needs. The space of problems continues to evolve as student understandings advance, driving ever-deepening inquiry processes. Networked environments, such as Knowledge Forum (KF) (Scardamalia & Bereiter, 2006), are used to support knowledge building discourse and processes. KF provides a collective knowledge space that gives student ideas a public permanent representation. Students contribute to ongoing conversations by sharing and building on each other's ideas. They continually identify new/deeper problems while their understanding deepens. Recent research further expands student interaction and collaboration to a larger social context. Students not only collaborate with their own classmates but also share their knowledge advances in a meta-space accessible to a network of classrooms (Laferrière, Law, & Montané, 2012; Zhang et al., 2020). They engage in collaborative inquiry as members of a community who also learn from and reference the works of other communities.

Several studies have examined student literacy practices in knowledge building communities. Sun and colleagues investigated how students engaged in productive writing and reading as an integral part of their knowledge building in science and social studies (Sun et al., 2010; Zhang & Sun, 2011). Their reading practices demonstrate new features: reading for advancing the knowledge of their classroom community; reading for continual problem finding and solving; reading embedded in ongoing knowledge building discourse, both online and offline; and connecting student knowledge with knowledge built by others in the larger world (Zhang & Sun, 2011). A two-year study traced students' online discourse during Grades 3-4 to examine vocabulary growth. Knowledge building discourse served as an authentic context for students to use and expand productive vocabulary, including academic vocabulary and domain-specific words. Their use of high-order vocabulary positively correlates with their participation rate in collaborative knowledge building (Sun et al., 2010). In a more recent study, Hong and colleagues (2020) found that children who engaged in knowledge-building inquiry outperformed those receiving traditional instruction in an assessment of reading. Beyond reading and writing of text, students also incorporated rich graphic representations in their online discourse (Gan et al., 2021).

Building on the above studies, the current study aims to depict a more comprehensive picture of disciplinary literacy for knowledge generation. Our conceptual lens integrates the above-reviewed concepts of disciplinary literacy (Goldman et al., 2016), dialogic literacy (Bereiter & Scardamalia, 2005) and trans-literacy (Liu, 2014; Thomas et al., 2007). Through the analysis of rich classroom data, we hope to capture how students read, write and interact across multiple sources, forms and spaces to advance their knowledge. As an expanded context for knowledge building, the current study included a cluster of classrooms that conducted collaborative inquiry supported by an online environment. Students engaged in cross-classroom interaction organized using a multi-layer model (Zhang et al., 2020). While members of each individual classroom pursued collaborative inquiry and discourse to deepen their understandings in a domain area, they had access to a cross-community space ("meta-space") where they shared their knowledge advances and challenges with other classrooms that studied the same curriculum area. As a common structure for synthesizing and sharing knowledge advances, students working on a shared problem or topic co-authored a "super note" that included three sections: Questions explored, "big ideas" learned (framed as "We used to think…now we understand…") and deeper research needed. The super notes were shared in the meta-space, as boundary objects (Star & Griesemer, 1989), to support cross-classroom discourse. In this context, our data analyses address an overarching question: What characterizes student literacy practices essential to their collaborative knowledge building? As part of this question, we were also interested in the teachers' role in supporting student engagement of disciplinary literacy.

Classroom context

This study analyzed student literacy practices in two Grade 5/6 classrooms based on the dataset generated in our research project focused on cross-classroom collaboration for knowledge building (Zhang et al., 2020). Two teachers taught science in the two classrooms: Mr. B and Mr. M. Both teachers had multiple years of teaching experience; Mr. B was more experienced with teaching science using the KB pedagogy and technology. There were 24 students in Mr. M's room and 23 students in Mr. B's room.

The two classrooms studied human body systems for 10 weeks with the support of Knowledge Forum (KF) (Scardamalia & Bereiter, 2006). On an ongoing basis, students in each classroom contributed and built on each other's ideas. With their teacher's support, students in each classroom generated questions about the human body that stemmed out of students' interests, put forth initial ideas, and then subjected these ideas to testing through observations, experiments, and peer discussion to improve them. They read books and online materials and conducted knowledge building talks in small groups and as a whole class to share and build on one another's ideas. They further continued their discourse and interaction online in KF. Students in each classroom worked in their home class views (workspaces), where they read and built on peers' ideas in the online discourse. At the same time, they had access to the "Super View" that was shared between the two classrooms. A visual was added to the Super View consisting of two trees with a number of branches where super notes about various inquiry topics could be placed (see Figure 1). As they made progress in various lines of inquiry, students created syntheses of their journey of thinking, which were called "super notes." Each super note was structured using the following scaffolds*: Our research topic and problems…, We used to think…Now we understand…, We need deeper research*. Prior to this study, several classrooms from two schools had studied human body systems and created super notes. These achieved super notes were also shared in the Super View.

Figure 1

The "Super View" for sharing super notes (Journey of Thinking syntheses) across classrooms.

Super Note about the Nervous System and the Spinal Cord (Ideas from Ben's Grade 5/6 Class)

[redacted]
2016-05-02
14:16

We used to think - that the nervous system didn't have to do anything with the spinal cord. Also, we used to think that the brain was the only part of the nervous system. -

Now we understand - That the spinal cord is actually the main part of the nervous system, and that the nervous system works by sending messages from the reaction nerves to the brain by traveling through the spinal cord to the brain. The spinal cord travels through the spine, so the spine has a very important role in the nervous system (Even though it isn't part of the nervous system). -

We need deeper research - On what the nerves are actually doing when they react and how do they determine the intensity of the reaction. -

The teacher in each classroom first introduced the Super View in the third week of the inquiry when their students had generated their own questions and conducted initial research about the various topics related to the human body. Students read the Super Notes from the previous classes and reflected on what they could learn from the questions and ideas. Once students conducted deeper research in each classroom in the next two to three weeks, students working on various themes started to create super notes to summarize their progress for sharing with their own classmates as well as with the other classroom. Students from the two classrooms read each other's super notes and discussed insights gained.

Data sources and analyses

This study analyzed student literacy practices in the human body inquiry as a telling case. Our data sources included classroom observations of the science lessons (11 from Mr. B and 8 from Mr. M), video recordings of whole-class discussions and small-group work, records of online discourse (146 notes from Mr. B's classroom, and 243 from the class of Mr. M), 16 super notes shared between the two classrooms, and student and teacher interviews. A researcher interviewed 13 students from the two classrooms focusing on how they pursued their inquiry, created super notes, and read and learned from the super notes of the partner classroom.

Our data analysis used an interactional ethnography approach, which offers a logic of inquiry for investigating what learners do and construct in a temporal sequence of events as viewed through multiple levels of analysis (Green & Bridges, 2018). As the main data sources, we analyzed the classroom observations and video recordings in relation to student notes written on KF. A researcher observed each science lesson and created a rich documentation of the classroom events, which were indexed and mapped based on time. The data organization provided contextual information about each major classroom event observed, time and topic of the inquiry activities, highlights of student and teacher participation, and sources of data recorded. As a visual representation of what happened in student inquiry, we constructed a timeline-based map (Green & Bridges, 2018) of the learning events identified from the observation sheets of each classroom. Each learning event was then analyzed focusing on the literacy practices reflected in student work as individuals, groups, and interacting classrooms. Specifically, we used a grounded theory method (Strauss & Corbin, 1998) to code the specific forms of inquiry which students carried out, involving reading, writing, and interacting for knowledge generation. Each inquiry event was tagged based on its prevalence in the whole lesson period, ranging from a major episode (#3) to a small moment/branch of work (#2), to brief occurrence embedded in the whole classroom process (#1). We further traced backward and forward to search for empirically grounded connections between the current event and what happened before and after. Through reviewing the various forms of inquiry and discourse in the historical context of the whole human body inquiry, we identified compelling patterns (themes) that characterize how students wrote, read, and interacted during knowledge building (see Results).

Additionally, focusing on features of dialogic and trans-literacy, we conducted social network analysis to examine students' online peer responses within each classroom (i.e., who had built on whose ideas on KF) and used content analysis to examine the quality of student super notes shared between the two classrooms. Drawing upon our prior study (Zhang et al., 2020), the analysis coded each super note based on students' questions investigated and the complexity level of their knowledge syntheses. We also analyzed student interviews to understand how they generated super notes for cross-classroom sharing. Two researchers read and re-read the interview transcriptions, created open codes, and identified compelling themes representing various notions of super notes.

Results

Tracing diverse forms of inquiry and discourse over time

The analysis of classroom observations traced students' engagement in various forms of inquiry and discourse that involved reading, writing, and interacting with one another for knowledge building. Due to space limit, we provide the timeline-based mapping of inquiry events in one classroom only (see Figure 2). Major activity episodes (tagged with three stars in coding) are highlighted green with three stars. Small branches of work are tagged with two stars, and very brief occurrences are marked with one star. The upper section shows the various forms of inquiry. The lower section traces the different forms of social discourse.

As the tracing of inquiry practices (upper section of Figure 2) reveals, students carried out diverse forms of inquiry to understand core issues and concepts related to human body systems, supported by rich information resources in different media and forms. Specifically, they read print materials related to their research topics as individuals or groups; searched and read information on various science websites; watched online videos; observed and analyzed visuals including 2D images, 3D models, X-ray images, and cartoons. While they made close reading and analysis, students engaged in generative processes such as taking notes of important information, ideas, and questions; generating and sharing questions as directions of inquiry; building connection across different topics and sources; using the sources to write and refine their online posts; creating personal videos to share knowledge; and playing dramas (skits) or participatory games to show how different body systems work. Over time, students continually referenced their prior works and ideas as they carried out new and deeper inquiry.

Over the course of the human body inquiry, students interacted with peers in flexible groups to discuss ideas and conduct experiments and observations. They participated in whole class knowledge-building talks to build on one another's ideas and investigate specific questions. As an important form of classroom discussions, the teacher facilitated meta-talk: metacognitive conversations in which students shared reflections on their online discourse or face-to-face inquiry focusing on metacognitive issues, including inquiry directions and questions, progress, plans, and ways to organize and enhance their online discourse. Drawing upon the information, ideas, and questions generated in the face-to-face activities, students wrote individual and co-authored notes on KF to have online discussions with their own classmates. Each major time slot for writing KF notes involved reading and building on peers' notes. Additionally, special time was scheduled for students to make extensive reading of their peer notes. Beyond the regular online discourse with each classroom, students engaged in cross-classroom sharing in the later part of the inquiry through writing and reading super notes in the meta-space (Super View) shared between the two classrooms. Both regular and super notes became objects of discussion when students read and referenced specific notes and super notes in face-to-face classroom talks.

Compelling patterns of how students wrote, read, and interacted for KB

On the basis of the holistic tracking, our analysis further investigated the temporal connections among the diverse forms of inquiry and discourse, with information generated in one activity feeding to what students inquired in the next activity. A set of compelling patterns (themes) emerged characterizing how students wrote, read, and interacted for continual knowledge building.

Working across multiple sources/media of information to solve problems and deepen understanding

Connecting multiple sources and forms of information to build progressive understandings was a key aspect of student literacy practices. The observation notes documented students' practices of using multiple sources of information such as books, online resources, videos, and images. For example, on April 7 in Mr. B's room, "Some students are copying text from their previous Word documents. Some are using their paper notes. Some are looking into books laying around. Some are going online to find information." On the same day, students engaged in generative activities along with their reading, including taking personal notes, generating questions, and drawing upon the sources to write KF notes (see Apr 7 in Figure 2). Their selection of reading was driven by the questions they had generated about the human body. As they read for understanding, they generated further questions. Students took notes of the information from the readings, personal understandings and questions in personal notebooks. They further reviewed their personal notes to consider what might be worthwhile to share on KF. "To write the notes, some students are using books (2 students are looking at Genes and DNA, 5 students on digestive system –> see the note on how food is processed"). One student is looking at her own notes in the binder." The observational notes also point to teacher's encouragement to use resources with proper practices of citing them: "The teacher is helping students to focus and enrich their ideas; he is encouraging them to use authoritative sources and reference them." Another observational note mentions how the teacher showed students how to use videos. The needs to contribute to the community's knowledge drove students to think further, read more closely across sources, discuss with peers, and reflect on what they had known as well as what they needed to better understand.

Integrating multiple forms of inquiry to advance knowledge

Students integrated multiple forms of inquiry and thinking, ranging from concrete experiences to personal questions, theories/explanations, video presentations, participatory games, and role play. Each form of inquiry was often embedded in the context of other inquiry activities supported by multiple sources of information. Personal experiences (e.g., dreams, injuries) were shared in the classroom talks and online discourse, feeding to student question generation and explanation/theory building. Conceptual explanations of how the body systems work were further elaborated, demonstrated, and applied through role-playing games. For example, on April 18, the teacher built on student interests to introduce a role play: "Last time you were interested in medical problems. Today, I have some medical activities for you: to do what doctors may do." With different X-rays of the bones (and other body parts) hanging on walls around the room, students acted like doctors to figure out if the bone is broken or not. Students were given a blank form for patient notes. This form had three columns: 1 - patient's name, 2 - injury (yes or not), 3 – name of the bone displayed on the X-ray. To support their diagnose, students could use iPads to view virtual 3D images of the human skeleton or observe skeleton models in the room. Rich conversations took place in the role-play groups and later on KF.

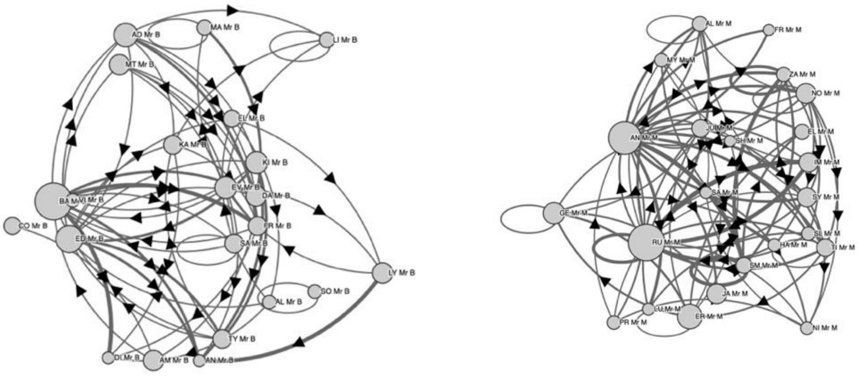
Navigating multiple discourse spaces for ongoing knowledge sharing and mutual build-on

The members of each class navigated multiple spaces of discourse over time, including personal notebooks, small group talks, whole class meetings, online discourse in the regular KF views of each classroom, and the Super View that served as a meta-space shared across classrooms. The teachers worked with students to develop a reflective sense of how the difference spaces could be used productively: Using personal notetaking to keep track of quick thoughts, questions, and information collected; bouncing ideas during small group and whole class meetings; writing "worthy" notes on KF focusing on meaningful ideas and questions; and writing super notes to synthesize "big ideas" of value to broader peers. For example, on April 7, Mr. B facilitated the following meta-talk on what is "note worthy."

> Mr. B: What makes a note worthy for grade 5/6?
> S1: More details and deeper questions you can research into.
> S2: Don't just say "I agree", instead explain why you agree or disagree.
> Mr. B: Do not forget to support your reasoning.
> S3: Give reasoning and explain why.
> S4: Add theories to your questions to explain why.
> Mr. B: If you add links or pictures, describe them, explain why you put them in there. Do not forget the title of the note.

Students wrote KF notes to share their ideas, questions, and information from various sources. Their online contributions were often rooted in the various types of activities that students engaged in face-to-face, such as whole class discussions, small group talks, and experiments. They read and built on (responded to) one another's notes for continual online discourse, which enabled ongoing idea sharing and build-on based on student need. A total of 146 notes were written by students in Mr. B's classroom and 243 by Mr. M's students. Figure 3 shows the sociogram of mutual build-on among students in each classroom. Each node represents a student, and each line a build-on relationship. The extensive build-on links show dialogic interactions among students in each class with everyone included.

Figure 3
Social network analysis of who built onto whose notes on KF in each classroom



Meta-talk to reflect on the history of ideas, from the past to the present and to future inquiries

As noted above, students engaged in meta-talk (metadiscourse) to reflect on and structure their ongoing inquiry and discourse. They shared reflections on their "juicy" questions generated by themselves and their peers; planned how they could collaborate in groups to investigate these questions, and made input on how their KF views should be organized, used and linked. As a central feature of cross-classroom collaboration, students worked in groups to co-author super notes to reflect on their journey of thinking in each line of inquiry, which were shared in the Super View. Writing and sharing super notes functioned as a specific form of metadiscourse by which students reviewed knowledge progress achieved through their online and face-to-face discourse. In the final interview, students reflected upon how they approached super note writing and reading. As the themes emerged, students considered super notes as a way to capture and share their journeys of inquiry: "It's like one huge note that reflects on all of your ideas, and what you used to think and what you now know." Students commented that super notes should focus on the "big ideas" they had developed, as "a summary of the big idea and knowledge basis." As a student said, "I think it is to focus on the entire idea of the topic you are focusing on and not just the tiny details you wanna share with the whole class." Students recognized the need to share accountable and valuable knowledge through super notes: "Well, we definitely did not include like the information that we did not know much about, because that would mean that… like if you were not sure if that was right or not, then it would not be good to include it." They further commented that the super notes should be well-phrased and accessible: "When you look at normal notes… there maybe some spelling errors, and maybe some like grammar errors… If you look at super notes that are amazingly written and they are really simple and they help people understand what is the main focus of this super note." Our content analysis examined the questions and ideas summarized in the super notes. In the 16 super notes generated, students identified 32 questions for deeper inquiry, mostly searching for reasons, mechanisms, and connections. Students' summaries of knowledge advances show a high level of scientific quality focused on offering elaborated explanations of how things work (see Zhang et al., 2020).

Working across communities to advance personal and collective understanding

Students read the super notes from their own and the partner classroom, reflected on the different perspectives, and identified knowledge connections and gaps. For example, Mr. B asked: "What was the idea that came from the super notes that you hadn't thought before and that pushed your thinking further?" A student shared the following reflection on a super note she read about the brain: "Well I never really thought about what side of the brain controls what side of the body… but it turns out that your left side of the brain controls the right side of your body." Similarly, Mr. M facilitated a discussion of the super notes among his students, asking: "What topic either strikes you as new information or something that you'd like to pick up as a thread and go deeper into?" Two students responded that they had learned something interesting about allergies, a topic they did not study in their home class. Students also reflected on how the super notes of Mr. B's class related to their own work: "Me and J are doing the immune system… and we saw these notes about white blood cells, and that was really cool 'cause white blood cells were part of your immune system. We don't really know about them… it was really helpful for us…" Key ideas and questions picked up from the super notes of their partner classroom became the focus of deeper inquiry and dialogues.

Discussion

This study contributes a deeper view of student literacy practices that take place in elementary classrooms engaging in scientific sensemaking and knowledge building supported by digitally mediated environments. The findings identified five core features of reading, writing and interacting for knowledge generation. These features are characteristic of the new dimensions of literacy proposed by researchers such as dialogic and trans-literacy for authentic disciplinary inquiry (Bereiter & Scardamalia, 2005; Goldman et al., 2016; Liu, 2014; Thomas et al., 2007). As a key aspect of such literacy for knowledge generation, students *work across multiple forms and sources of knowledge* to make meaning and develop new understandings. Students may use a variety of sources such as books, websites, videos, and models to support their problem solving. Sometimes, when the resources are beyond their reading level, the teacher may provide help accessing them. While working with the information resources, students further generate personal ideas, questions, and narratives that build on their own life experiences and carry out experiments and investigations. What they think and encounter in each moment successively triggers deeper questions and new ideas, driving sustained cycles of sensemaking and idea improvement (Odden & Russ, 2019; Zhang & Sun, 2011).

Students engage in *dialogic literacy* as a social practice that supports dynamic networking of people and ideas in technology-augmented communication. Students participate in whole class discussions, form and work in interest-based groups, and continue their interactive discourse in an online environment. Ideas developed by some of the participants in any of these dialogic settings can be carried over to other dialogic settings that involve the same or different participants. Through the extended interaction, high-potential ideas may be further improved and diffused among the broader participants. Interrelated ideas may be combined and synthesized to develop coherent and complex ideas. New problems and challenges emerge from ongoing dialogues, informing directions of deeper inquiry.

Such literacy practices involve *boundary-crossing* between social groups and across different time periods. Ideas are continually developed on the basis of their intertextual past and further project into future contexts of inquiry and discourse. Specifically, students pay sustained attention (Liu, 2014) to ideas and information generated/encountered in various time-bound interactions, selectively revisit and build on the prior ideas as they pursue new/deeper inquiry. With the support of online environments that archive students' knowledge artifacts, students have the chance to access and build on the knowledge generated by a network of classrooms, including previous student cohort groups who had studied the same (or related) topics. Generating knowledge artifacts that will be continually used by future students gives students an authentic purpose for productive inquiry and writing (Zhang et al., 2020).

We are conducting deeper analyses of the teachers' role in scaffolding the key aspects of disciplinary literacy for knowledge generation. Future studies may design a reflective framework to guide teachers' scaffolding of student literacy engagement in science inquiry. Analytics tools may be designed to help students monitor and improve their literacy practices as part of their knowledge building across disciplines.

Abstract: Science education needs to be transformed to meet the needs of the current "post-truth" era. One way to face these challenges is for science educators to promote apt epistemic performance in classrooms. In this paper, we use Barzilai & Chinn's (2018) Apt-AIR framework to analyze teacher instructional moves as they work to encourage apt epistemic performance in their science classrooms. Findings present a portrait of teacher moves directed at epistemic performance. Specifically, we highlight teacher epistemic moves that emerged from our analysis. We discuss trends in teachers' moves and implications of these for improving classroom epistemic discourse, and we discuss the potential to develop epistemic routines that coordinate productive sequences of moves. We conclude with the affordances and implications of our analysis for science education.

Introduction and theoretical background

As science denialism and the spread of misinformation become ever more rampant (Cooke, 2018), there is a widespread rejection of well-justified scientific consensus on matters such as COVID- 19, vaccination safety, and climate change. Current science education has failed to meet the growing challenges of this "post truth" world (Chinn et al., 2021). Thus, there is an urgent need for teachers to develop and implement instructional strategies that enable students to accurately appraise scientific information (Barzilai & Chinn, 2018; Chinn et al., 2020; Duncan et al., 2018). One way to address these concerns is to develop science instruction to promote *apt epistemic performance* that can extend to thinking about scientific issues outside of school (Chinn et al., 2020; Gorman & Gorman, 2021; Hussain-Abidi, et al., 2022).

Apt epistemic performance is successful epistemic performance (e.g., developing a good understanding of climate change) achieved through competence (e.g., skillful appraisal of scientific expert consensus on the topic and consideration of the many lines of supporting evidence) (Barzilai & Chinn, 2018). Apt epistemic performance is further unpacked along two dimensions that define the *Apt-AIR framework* (Barzilai & Chinn, 2018). The first dimension specifies three components of epistemic thinking: (a) Aims, or goals (e.g., aiming to reach an accurate conclusion), (b) Ideals, or standards for evaluating whether an aim has been achieved (e.g., fit with relevant evidence and the consensus of experts as ideals for determining whether an accurate conclusion has been reached), and (c) Reliable processes (RPs) that are used to achieve the aims with a good likelihood of success (e.g., evaluating multiple sources of information, evaluating the expertise of sources, determining the degree of scientific consensus, and so on). Current science education has often not explicitly addressed all these components (see Chinn et al., 2021, for arguments). Therefore, there is a need to support students' development and use of appropriate aims, ideals, and reliable processes to evaluate scientific information.

The second dimension of apt epistemic performance in the Apt-AIR framework consists of five aspects of engagement with aims, ideals, and processes (Barzilai & Chinn, 2018). These include a *cognitive* aspect, involving the use of reliable cognitive processes to achieve valuable epistemic aims that meet appropriate ideals (e.g., testing a toy car to determine how it works and ensuring that the resulting explanation fits the evidence gathered); a *metacognitive* aspect, encompassing metacognitive skills and metacognitive understanding of appropriate aims, ideals, and reliable processes (e.g., reflecting on what the best methods are for testing the car to see how it works); a *social* aspect, including working effectively with others along with an awareness of the role of social processes in producing knowledge (e.g., working in groups, receiving and responding to critiques from others, and using these critiques to improve one's explanation); a *caring* aspect, which involves positive affect and dispositions towards pursuing and achieving apt epistemic performance (e.g., being deeply committed to making sure the explanations fit the evidence); and an *adaptive* aspect, which includes adjusting aims, ideals, and reliable processes to meet the demands of diverse contexts (e.g., considering how the best investigative methods might differ between trying to figure out how a toaster works, and trying to figure out how a toy car works).

The crossing of the 3 components and the 5 aspects of Apt-AIR yields 15 cells in a 3x5 table; apt epistemic performance involves coordinating adept engagement across all of these cells (see Table 2). For science instruction to successfully promote students' apt epistemic performance, instruction needs to encourage adept engagement in all 15 cells. One way to encourage such engagement is through *teacher epistemic moves* in classroom discourse, which we define as discourse-based moves that aim to support apt epistemic performance in students. To do this, teachers might call attention to, or prompt engagement with the components and aspects of Apt-AIR. This raises the question of how often teachers *do* employ moves that engage students with each of the components and aspects, as well as what kinds of moves they make. The purpose of this study is to investigate these questions. To facilitate this, we have performed an initial analysis of teacher moves using the 3x5 Apt-AIR framework.

Recent scholarship has made great progress in developing frameworks for categorizing teacher moves in different contexts, including within discourse-based science instruction (e.g., Soysal & Yilmaz-Tuzun, 2021; Wei et. al., 2018). We consider our approach as complementary to this work. What distinguishes our approach is that we have organized our analysis around a comprehensive evaluation of apt epistemic performance. Accordingly, our goal is to develop a portrait of a range of teacher epistemic moves when there is a focus on student apt epistemic performance.

More specifically, the objective of this study is to examine the variety of teacher epistemic moves employed by three high school science teachers in order to analyze how they encourage apt epistemic performance. Understanding how these teachers implement a unit focused on epistemic performance in science classrooms allows us to identify excellent practices as well as to spot areas in which improvement is possible. This in turn will ensure that students learn to engage with all of the aspects and components needed to achieve apt epistemic performance. Thus, in this preliminary analysis, we seek investigate: (1) How often do teachers address each aspect and component of apt epistemic performance? (2) What kinds of teacher epistemic moves do teachers use to address each aspect and component of apt epistemic performance? (3) What particular aims, ideals, and processes do teachers address? (4) How do teachers use sequences of epistemic moves to promote apt epistemic performance?

Method

Context

In July 2022, researchers and teachers collaborated to create an inquiry unit focusing on epidemics and the nature of science, largely within the context of a fictional viral outbreak. This unit was created with a deliberate focus on developing apt epistemic performance incorporating all five aspects discussed above. The epidemic unit featured a game-like, agent-based epidemic simulation that combines graphical blocks-based StarLogo programming with a 3-D game-like interface (see Figure 1) (Yoon et al., 2016; 2017). Students engaged with the epidemic unit while working in groups of 2-5 as they tried to control an outbreak by running experiments and gathering data in order to find which mitigation strategies they would recommend for their town in the simulation. Although the unit was constructed to span eight class periods, teachers tended to run the unit over four to six periods to fit scheduling and curriculum constraints.

For the present study, a particularly important characteristic of this unit is the focus on teacher epistemic moves. The unit aimed to accomplish this by including activities that directly focus on aims, ideals, and reliable processes across the five aspects of apt epistemic performance. Further, teacher reminders called "epistemic callouts" were embedded within the teacher guide of the unit to remind teachers of opportunities within the lessons to highlight apt epistemic performance. Examples of activities within the unit include co-creating class criteria of the characteristics of good scientific models and practices (metacognitive engagement with ideals), peer review and iterative revision of student models (reliable social processes), and reflection on applications of classroom activities to science practices encountered out of school (adaptive engagement with aims, ideals, and processes). An example of an epistemic callout while students peer reviewed models is a reminder to encourage students to justify why particular criteria are important (metacognitive/caring engagement with ideals) and explain why particular criteria are or are not found in different models that they looked at (metacognitive/adaptive engagement with ideals).

Participants

In order to develop a preliminary method of analysis, we started with three of the five high school science teachers who taught the epidemic unit. We selected these teachers due to their rather different pedagogical styles, allowing the method of analysis to be tested on a wider array of styles. Two of the teachers, whom we call Catherine and Aaliyah, taught ninth grade biology. The third teacher, whom we call Rohini, taught tenth grade chemistry.

Catherine taught at a private boarding school, Aaliyah taught at a charter school in an urban district, and Rohini taught at a public high school in a suburban district. All schools were in the northeastern United States. All teachers spent time during summer professional development familiarizing themselves with the curriculum and the simulation (see Figure 1).

Data sources and analysis

Implementations of the unit were recorded through Zoom meetings, which were active through the teachers' computers during their in-person classes. From these recordings, we analyzed the teacher epistemic moves that were employed in the classroom and classified these moves within the 3x5 Apt-AIR framework. That is, as shown in Table 2, we examined whether teacher moves addressed aims, ideals, and/or reliable processes within each of the five aspects (cognitive, metacognitive, social, caring, and adaptive). In Table 1, we show four general types of moves used by teachers when addressing aims, ideals, and/or reliable processes, which were determined through bottom-up and top-down coding methods during data analysis.

Table 1
Types of teacher epistemic moves used to promote epistemic performance

Type	Definition	Examples
Describe	The teacher directly describes or explains an epistemic aim, ideal, or process	"One way that scientists can test something is by running multiple trials."
Label	The teacher attributes value or clarity to an epistemic aim, ideal, or process	"It's better to say 'make accurate measurements' instead of just 'make measurements'."
Justify	The teacher provides a reason or argument for an epistemic aim, ideal, or process, sometimes justifying it with another aim, ideal, or process	"They need to run multiple trials because there can be variation in each trial, and error in each measurement."
Prompt	The teacher prompts students to use, describe, evaluate, or justify an epistemic aim, ideal, or process.	"What are some good processes to follow to make sure that we test things thoroughly?"

Results

In Table 2, we present the Apt-AIR framework, along with the specific teacher epistemic moves that are being described. We also include examples of teacher epistemic moves for 13 of the 15 cells (we found no instances of teacher moves addressing the adaptivity of aims or ideals). Note that most teacher moves can be coded into multiple aspects. For example, "Let's put together a list of criteria for good scientific models" is a statement about an epistemic aim that is both social (collaboration with peers) and metacognitive (planning and evaluating epistemic performance).

Table 2
Examples of teacher epistemic moves analyzed within the Apt-AIR framework

	Aims	Ideals	Reliable processes
Cognitive	Describing **cognitive aims**	Describing **cognitive ideals**	Prompting justification of **reliable cognitive processes**
	"And so you're going to **make a model** that is going to explain how **the cars** work."	"So, this is an example of a model that a student has for their car to see how it works, right? **That explains their car's internal mechanisms** to determine how this car is working. Okay? And then, in addition to that, they have an explanation."	"The sugar pill didn't do anything. So, let's talk about that sugar pill, does anyone know why **they would give them a sugar pill**? That's not just a random detail, that's something scientists do."
Metacognitive	Describing **metacognitive aims**	Prompting description of **metacognitive ideals**	Describing and labeling **unreliable metacognitive processes**
	"So your goal with your partner or your group, are to now **come up with one characteristic of good scientific methods** with your partner, and referencing part two of the homework if needed, initial your idea with both of your initials, and try not to repeat something that's already written."	"Alright, so, I want us to think about what would be some great criteria for our, for a model. So, thinking about what you have actually reviewed, right? Let us come up with **a list that we all agree upon that would be great criteria**."	"Now sometimes when we write a prediction, we become very biased in collecting the data, because we only look in one direction. We have to prove our hypothesis, **let's just cherry-pick the data that we like, and let's write it down**. And let's say it proves our hypothesis. We tend to do that, it's very common, but that is incorrect science."
Social	Labeling **social aims**	Justifying **social ideals**	Describing and prompting justification of **reliable social processes**
	"Why do we need to critique each other's work?" [student says, "So that everyone can improve?"] "**So that everyone can improve**. What else could be the reason?" [student says, "So we can get other people's perspectives?"] "Why is it important for us to know other people's thoughts and perspectives?"	"We are trying to read what is written, we don't go around and explain our process. I should not be hearing, oh, this is how you should be reading my process, or my step-by-step procedure that is written there. No. We don't get to do that in real science. When someone publishes it we get to read their thought process. That's why **it has to make sense to everyone**."	"You are critiquing, nothing personal is happening here. It's what we do in science, we **critique each other's work**. Why is it needed in science? Why do we need to **critique each other's work**?"
Caring	Labeling and describing **caring aims**	Prompting justification of **caring ideals**	Justifying reliable metacognitive processes with a **reliable caring process**
	"Very good, very good, if we're not **following good scientific methods**, we	"Why do we need to critique each other's work?" [student says, "So that everyone can	"Even if you're like our prediction was totally wrong, I want you to still put it here,

	might give out false information, and then	improve?"] "So that everyone can improve. What else could	because **it's important for us to see where we started**."
	someone will start believing the false information."	be the reason?" [student says "So we can get other people's perspectives?"] "Why is it **important for us to know** other people's thoughts and perspectives?"	
Adaptivity			Describing and justifying **reliable adaptive processes**
			"So when we just did our model, the car, you couldn't take the car apart. Because **scientists can't always take something apart** in order to determine if something is working. **Scientists have to, sometimes, test things out**. Because, can you take a cell apart?" [inaudible response] "Why?" [inaudible response] "It's too small, it's microscopic."

From this initial analysis, several trends stand out that highlight some of the affordances provided by the use of our Apt-AIR 3x5 analysis, which we discuss below.

Identifying coverage of components and aspects

The analysis readily points to components, aspects, and their intersections that are addressed more frequently, less frequently, or not at all. For example, we found a very small number of teacher epistemic moves addressing the aspect of caring, and even fewer moves addressing adaptive engagement. In contrast, there were more moves that involved engagement with the cognitive, metacognitive, and social aspects. Indeed, we found no moves addressing adaptive engagement with aims or ideals. What follows are some examples of prompts that teachers could conceivably use to ask students to engage adaptively with aims or ideals in the epidemic unit:

Example of adapting an aim: "How do you think that our goals relate to what the goals of scientists studying COVID are?"

Example of adapting an ideal: "Are there situations when a smaller sample would be OK?"

The aspect of adaptivity may be especially important in encouraging students to connect what they are doing in class with the scientific issues they encounter out of school. Teachers could encourage students, for example, to contrast the processes they are using to conduct research (e.g., careful control of variables within their simulation environment) to what scientists do (e.g., controlling variables in real-world research settings).

Identifying patterns of moves across components and aspects

The analysis also enables us to observe patterns of the types of teacher epistemic moves used across and within cells. For example, although there were many epistemic moves that addressed aims (typically, teachers described the epistemic aim of the activity), there were very few that explicitly prompted students to evaluate their quality (is this aim a valuable one?) or to justify them (why should we try to accomplish this aim?).

Furthermore, there were few justifications or prompts for justifications of metacognitive aims, ideals, and processes outside of the activities in which classes developed lists of criteria for good models or good methods. When students give justifications, they are providing reasons for why the aims or ideals they are advocating are valuable, and why the processes are reliable. These justifications help the students understand the aims, ideals, and processes, as well as to care about their use. For example, a prompt asking students whether evidence is good or not (evaluation) and to explain why (justification) supports them in developing an understanding of what counts as good evidence and why good evidence is valuable.

In addition to identifying significant trends in how teachers' epistemic moves contributed to students' thinking across the five aspects of engagement with aims, ideals, and processes, our classification provides insights into longer sequences of teachers' interactions with students. We provide examples below.

Identifying particular aims, ideals, and processes

A third affordance of the Apt-AIR analysis is that it enables educators to identify the particular aims, ideals, and processes that are the focus of discussion. It is possible then to consider whether these are productive components to focus on, whether alternatives might be better to introduce, or whether some might be problematized. For instance, in one of the examples in Table 2, a teacher asks, "Why do we need to critique each other's work?" This prompt asks students to justify the value of critiquing in science, which could help students appreciate the role of the process of critique. Critique in science is a core reliable process that is well worth pursuing. On the other hand, the teacher's remark "we are trying to read what was written; we don't go around and explain our process" describes a process of scientific communication that relies exclusively on written work. This is not compatible with what is known about scientific communication, in which interpersonal and other oral interactions are often important for scientists to understand each other's work (Collins, 2014). Rather than endorsing the process of relying on written documents alone, teachers might consider problematizing this process in discussions with students, perhaps considering a fuller range of scientific communication.

The Apt-AIR analysis thus enables us to provide, for any teacher at any time, a portrait of the particular aims, ideals, and processes that are the focus of the community's work, as well as how those components shift over time. This analysis then allows teachers and analysts to reflect on which aims, ideals, and processes are currently the focus, and whether it might be good to consider alternatives.

Sequences of teachers' epistemic moves

Our analysis also provides a lens to examine sequences of teachers' epistemic moves, and how well these are orchestrated to promote better student thinking. Teachers could use productive sequences of discourse repeatedly to promote advances in students' thinking—we refer to such sequences as *epistemic routines*.

In the analyses below, we discuss epistemic routines used by two teachers, Catherine and Rohini, as they led their students' in generating criteria lists for good scientific methods. In presenting these moves, we highlight their classification in terms of our Apt-AIR analysis and note what insights are provided by this analysis.

Catherine starts this activity by pointing the students to open a shared slide in Google Slides on their computers, where each student can see and edit the text on the slide at the same time. The slide has eight blank lines where students can type in responses. Around the classroom, students are seated in small groups of two to three each. Catherine asks that each group of students come up with one characteristic of a good scientific method, or in other words, a criterion that a scientific method should have to meet in order to be considered to be good. She asks each group to type their characteristic into the shared slide, and to make sure that the characteristic they enter is not the same as another groups. Catherine also mentions that, after all of the groups have entered a characteristic, she will ask each group one at a time to clarify the meaning of what they typed and to provide justifications of why they chose that characteristic. What follows is an excerpt from this clarification process.

- "So, first group, having measurable evidence without having to worry about people's opinions, can you tell me a little bit about why you put that?" *Catherine first describes a metacognitive ideal by restating the characteristic that the first group of students typed. This is metacognitive since the characteristic is a criterion for evaluating, and possibly planning, other cognitive or metacognitive performances (scientific methods). Catherine then prompts the students to justify this metacognitive ideal.*
- [student says, "How you measure your evidence is also part of how you support your hypothesis or the claim you're making, and while if you use that evidence people's opinion might not really matter, you still have to deal with it because sometimes if people are fighting it still effects things."] "Mmm. Ok. So can you give an example using our drug experiment of what measurable evidence would be, and what not measurable evidence would be?" *After the justification, Catherine responds by labeling the clarity of the student's metacognitive ideal, though only partially. She then prompts the student to further justify their metacognitive ideal with an additional metacognitive ideal (what makes evidence measurable).*
- [student says, "Like their fevers?"] "Ok, so like, a numerical, your fever is 101. And what's non-numerical evidence? Or like vague evidence?" *Catherine again responds by labeling the student's metacognitive ideal (though this time it is a different ideal), and then follows up by repeating the second part of her previous prompt for justification.*
- [student says, "Some person saying they feel better."] "Ok so I'll agree with that, so having measurable evidence, I'm going to add a little bit, like a fever measurement versus just "I feel better." Because that

kind of gets away from people's opinions, right? So maybe if I'm in the hospital I don't feel better, I still feel bad even if objectively, I'm healthier." *This time, Catherine responds by labeling the value of the student's metacognitive ideal, and further describes that ideal herself before moving on to the next group.*

This excerpt shows a relatively simple epistemic routine that may be useful for expanding students' responses and getting a clearer picture of the student's metacognitive understanding. The routine takes the following form: (1) the teacher prompts for a description of metacognitive ideals (2) a student describes an ideal, and the teacher prompts for justification of the same metacognitive ideal (3) the student justifies, and the teacher labels the clarity of the student's justification before prompting for justification of the same metacognitive ideal with an example of other metacognitive ideals (4) the student justifies with an example, and the teacher endorses the value of the student's metacognitive ideals, and further describes those ideals before moving on.

Rohini begins the activity by opening a slide that is projected to the front of the room. The slide has multiple empty lines, and she describes to the students that they are going to make a class list of good scientific methods. She then immediately prompts the class for what they think one good method would be. Below is the fourth time she prompts this during the activity.

- "Okay, moving on to four, yes?" *Her statement here of "moving on to four" serves as a prompt for a description of metacognitive ideals, as it is a continuation of her initial prompt for such descriptions.*
- [student says, "A control group?"] "A control group. Why do we need a control group?" *Rohini gives an implied label of some amount of clarity of the metacognitive ideal when she restates the student's response. She then prompts for a justification of that metacognitive ideal.*
- [student says, "You need something to compare it to?"] "Okay, we need to include comparisons. Very good." *Restating the student's response, Rohini then labels the correctness of the metacognitive ideal.*

This excerpt shows a routine similar to, but simpler than Catherine's. The structure of this routine is: (1) the teacher prompts for a description of metacognitive ideals (2) the student describes, then the teacher labels the clarity of the student's description of a metacognitive ideal and prompts for justification of the same metacognitive ideal (3) the student justifies, and then the teacher labels the correctness of the justification before moving on.

Something seen in both teachers' routines is evaluation of the value of the student's response at the end, which could lower students' agency and personal investment in the class list. This is especially the case with Rohini's routine, where the assertion of correctness likely directs the students away from further discourse, and towards searching for an answer deemed to be correct. One benefit of our analysis could be the identification of how and when teachers evaluate student responses, and how these routines may affect student outcomes compared to routines that lead the class to evaluate ideals themselves. Otherwise, these two routines are mostly centered around a single component—students' description of metacognitive ideals. However, as Catherine's routine shows, additional components (aims, ideals, reliable processes) can be brought in, and maybe also additional aspects (cognitive, social, etc.) as suggested by some entries in Table 2 (see the example for social aims). Being able to analyze how such sequences of moves shift between the cells of Apt-AIR allows for comparison between the usage of different sequences and student outcomes, enabling the identification and creation of robust routines that can best promote a full coverage of apt epistemic performance.

Discussion

The results of this preliminary analysis present a new way of analyzing teacher moves that aims to promote students' thinking. The Apt-AIR 3x5 analysis yielded a portrait of the range of teacher epistemic moves that were used by the three teachers as they taught a lesson designed to foster apt epistemic performance. Below we discuss our four main findings to date and the affordances of each.

1. Teacher epistemic moves provided little to no coverage of some aspects and components. There were no examples of epistemic moves addressing the adaptivity of aims or ideals. Furthermore, there were relatively few examples of moves addressing the caring aspect. This finding has implications for teachers and researchers for strengthening curriculum to address these aspects and components.
2. There are opportunities to strengthen teacher epistemic moves across the components and aspects. Teachers overemphasized description of aims, ideals, and reliable processes in each of the five aspects, yet rarely pushed for justifications of the described components. Encouraging students to describe, label, and justify aims, ideals, and processes would also increase students' epistemic agency when conducting science inquiry, because students can develop their own sense of which aims, ideals, and processes are valuable and build their own understanding of why they are valuable.
3. This analysis provides a portrait of the aims, ideals, and processes science educators thought were most important to discuss during this unit. This allows teachers and researchers to step back and consider

whether the emphasized aims, ideals, and processes are the most productive ones to focus on. They can also consider whether these aims, ideals, and processes appropriately reflect the practices of science.

4. Lastly, our analysis highlights patterns of epistemic moves that could be developed into epistemic routines. Epistemic routines are a series of teacher epistemic moves that teachers are able to embed in their instruction to target apt epistemic performance. For example, teachers can make soliciting feedback from peers an epistemic routine in the classroom, using it every time students engage in science inquiry.

Ultimately, our findings can help researchers and educators identify how teachers can engage in productive discourse with students to improve their scientific thinking during classroom inquiry and beyond. For example, if students are taught to value gathering ample evidence as a well-justified ideal of science reasoning, we expect them to gather ample evidence as they make sense of socioscientific issues in the public sphere. The analysis identifies particular components and aspects that teachers can address with students, and where further growth might be needed for educators to better prepare students to engage in apt epistemic performance. The analysis also identifies areas in which the moves themselves could be enriched beyond describing, labeling, justifying, and prompting in order to advance students' thinking to better prepare them for reasoning in the post-truth world.

How Do We ‘See’ Engagement in a Classroom?: A Comparison of Researcher, Student, and Teacher Perspectives

Megan Humburg, Indiana University, mahumbur@indiana.edu

Abstract: This study compares three sources of inferences about the engagement of young science learners: researcher observations of classroom video, student self-reports, and teacher reports. 21 third-grade students participated in a series of embodied learning activities in their music classroom centered on the science behind musical sound. Perspectives from the researcher, music teacher, and students are compared in the context of two video clips from classroom activities that participants co-watched with the researcher during post-interviews. The results highlight the overlaps in how the researcher, teacher and students reported their perceptions of social and emotional engagement, as well as the similarities in reasoning around generative sources of positive emotional engagement. The analysis also surfaces the unique interpretations of events that each source of data offers. Overall, this paper argues that multiple participant and researcher perspectives together can offer a more robust understanding of how and why students engage with learning.

Introduction

Student engagement is a highly desired outcome of learning environments that researchers have struggled to define and operationalize (Appleton, Christenson, & Furlong, 2008). Some studies take an individual-centric approach, using self-report surveys to gather learners’ perspectives after the fact (Greene, 2015) or experience sampling to measure perceptions of engagement in the moment (Beymer et al., 2018). Others use teachers’ observations as proxies for a measurement of students’ experiences, gathering perspectives on how teachers perceive and interpret evidence of engagement in their classrooms (van Uden et al., 2013). Still others take a more sociocultural approach and use video and audio recordings to capture and analyze moment-to-moment shifts in engagement within particular student interactions (Ryu & Lombardi, 2015). The selection of a lens to understand engagement–the student’s, the teacher’s, or an outside research-trained observer’s–shifts what data is available to us and what features of classroom interactions become visible or invisible to our analyses. Some have argued that triangulation across multiple sources of engagement can offer a richer picture of what factors influence the ever-shifting dynamics of how students engage with learning (Fredricks & McColskey, 2012; Karabenick & Zusho, 2015). In this study, I take up a framework of student engagement grounded in sociocultural perspectives on learning, which consider engagement to be a complex and dynamically unfolding process that emerges from interactions between learners and their social, physical, and cultural environments (Humburg, 2020). I define student engagement as the shifting set of actions, and patterns of actions, that influence opportunities for learning in context. Thus, the goal for this paper is to compare multiple sources of engagement data to uncover what different approaches to measuring engagement offer in terms of revealing the contextualized, moment-by-moment mechanisms through which dimensions of engagement influence opportunities for learning.

While observational studies of moment-to-moment engagement patterns have demonstrated the value of a detailed researcher perspective (Sinha et al., 2015; Greene, 2015), this outside perspective may offer a different picture of engagement when compared with individual student perspectives on their own experiences. There may be aspects of socioemotional engagement that are only visible and intelligible to the participants directly involved, as evidenced by the potential disconnects between how teachers and students report students’ emotions in classroom activities (Skinner et al., 2009). Researchers may also wish to honor the expertise of teachers, who are more closely involved and thus attuned to the socioemotional and cognitive dynamics of their classroom than an outside observer. Comparing what aspects of engagement become more or less visible through different lenses gives us a more complex and dynamic understanding of how engagement influences the unfolding learning process. To track and compare these different perspectives on student engagement, this study asks: How do students’ reported ideas about their cognitive, behavioral, emotional, and social engagement with the science of sound match or differ from what we see in the video data as researchers, as well as what their teacher reports?

Literature review

While quantitative self-report surveys remain a common method for capturing student engagement, learners’ perceptions of their own behaviors do not always align with what is visible in records of classroom interactions, or what others in the environment report (e.g., teachers, peers) (Azevedo, 2015). Research that speaks across data collection methods to analyze the temporally unfolding nature of engagement in context is needed to better understand how dimensions of engagement influence learning. Methods of data collection and analysis that focus on individual learners may also miss out on ways that engagement is distributed across individuals and produced through collaborative sensemaking (Ryu & Lombardi, 2015). Analyzing engagement at the group level in unfolding activity can reveal how functional and dysfunctional group dynamics influence the extent to which students are able to cognitively engage with learning (Sinha et al., 2015). The present study demonstrates how triangulating an analysis of engagement between student reports, teacher reports, and classroom video observations reveals the benefits and unique contributions of each source of data, offering a more complete picture of how engagement unfolds (Sinatra et al., 2015).

Despite the value of analyzing the unfolding, moment-to-moment shifts in students' engagement across time, the resources and time required for this form of analysis is substantial. Reliable video analysis of complex interactions can require multiple rounds of watching and re-watching video both individually and with wider research teams (Jordan & Henderson, 1995). To account for the large amount of time and resources required to conduct in-depth qualitative analysis of engagement, some researchers have developed streamlined rubrics to help researchers quickly evaluate and record key features of student interactions when viewing classroom videos (Rogat et al., 2022) or during unfolding classroom interactions (Hsiao et al., 2022).

While much can be learned from detailed analysis of classroom video, and self-report surveys bring with them the limitations discussed above, this measurement approach continues to be popular due to the value of analyzing learners' own perceptions of their learning, even if they cannot capture the variance of learning processes across contexts and time (Karabenick & Zusho, 2015). Some features of students' experiences and engagement are by their nature not visible to an outside observer and are only interpretable by the participants within the interaction. For example, a study comparing students' ability to adapt to challenges found that student self-reports of their adaptability was linked to their engagement levels in mathematics, whereas teachers' reported perceptions of students' adaptive behaviors were not correlated with engagement levels (Collie & Martin, 2017). This suggests that students may in some cases be able to report factors influencing their engagement with more specificity or relevancy for their engagement than their teachers can. Prior research has also found that teachers tend to rate students' behavioral engagement lower than students do themselves, and teachers may also underestimate the strength of students' negative emotions (Skinner et al., 2009). Thus, students may offer a distinct perspective on their levels of engagement that cannot be duplicated by an outside observer.

However, relying solely on student perspectives may not always offer the full picture of why students engage with learning, even if students' perceptions can offer valuable data about their engagement. For emotional engagement in particular, learners are not always able to determine the causes of their own emotions (Silvia, 2006), so triangulating across multiple sources of data (learner self-report, researcher observations, teacher reflections) can give us a more multidimensional picture of how our designed activities might foster particular forms of engagement. Gathering teacher perspectives on engagement can be beneficial when working with young students in particular, given that younger students may encounter verbal and literacy-related challenges when completing self-report surveys and tasks (Fredricks & McColskey, 2012). Teacher reports of engagement can also give educational researchers a better understanding of how teachers make decisions about adopting new instructional practices and the benefits that teachers perceive for student learning (Huizenga et al., 2017).

Overall, the literature does not suggest one clear "best practice" for measuring student engagement, but rather suggests that some blend of multiple methods is ideal for capturing the complex mechanisms of engagement in action and over time (Fredricks & McColskey, 2012; Greene, 2015). A self-report of how learners felt about an activity after the fact does not necessarily offer data about how the designed activity produces particular socioemotional interactions in the moment, but a researcher observing unfolding interactions may also categorize emotional and social displays in ways that don't reflect learners' own labeling of their experiences. Given the varied benefits and drawbacks of observational, self-report, and teacher-report methods of gathering data on student engagement, the present study utilizes these three forms of data side by side within a single classroom context, to further elaborate on what aspects of cognitive, behavioral, social, and emotional engagement are made more or less visible through each analytic lens.

Design and methods

The study took place in a small suburban public school in the U.S. Midwest. Participants were students in a third-grade music classroom (n=21, 8-9 years old) and their music teacher. Students participated in eight days of embodied learning activities centered on the investigation of the science behind musical sound. Students experimented with musical instruments and a tablet oscilloscope app in order to figure out how different sound features (e.g., pitch, volume) produced different patterns of sound waves. They also used their hands and arms to create gesture representations of sound waves as well as their full bodies to collaboratively build embodied representations of how sound waves move in response to different sounds. Both students and their teacher were interviewed immediately before and after the unit to gather perspectives on students' engagement. They also participated in video co-watching with the interviewer to reflect on the emotional and social engagement visible to each participant during particular moments of interaction. The use of videos to elicit participant perspectives helps recenter student voices in the analysis of their learning (Takeuchi & Bryan, 2019), offering a richer understanding of how students' behaviors emerge from their own social and cultural worlds, which is not often explored in studies of engagement. The interviews lasted roughly ten minutes each and explored ideas about interesting or boring moments, as well as any "good" or "bad" feelings that participants recalled seeing or experiencing during the activities. Participants were also asked questions about social engagement via the idea of teamwork, to elicit reflections on how participants identified productive versus unproductive collaboration. Interviews were chosen (as opposed to surveys) because in-depth interviews with students and teachers have been shown to help reveal indicators of engagement that may traditionally be overlooked by researchers (Fredricks et al., 2016). All class activities and interviews were video recorded for analysis.

To set up the comparison between researcher, teacher, and student perspectives, clips from the classroom activities were selected to represent different forms of embodied activity, as well as what appeared to the researcher to be different visible levels of social and emotional engagement. Two 30-second clips were selected– one in which students shook strings of pom-poms together to demonstrate how sound waves travel through the air (Figure 1, left) and another in which students stood in concentric circles and used back and forth movements together to create a full-body representation of how air particles move in response to sound (Figure 1, right).

Figure 1
Students moving strings of pom-poms to represent air particles (left) and pretending to be air particles (right)

In clip #1, a pair of students decided on a sound to demonstrate (e.g., high pitch and loud), and their peers mimicked the leading group to show how sound ripples outward to carry information to the ear. Other students sat on the floor and used signs with vocabulary words (e.g., "High Frequency", "Soft Dynamics") to guess what the students were showing. In clip #2, the students were investigating the same conceptual idea (the movement of air particles in response to sound), but using their full bodies coordinated together. As a student in the center played different notes, the rest of the class was tasked with moving back and forth in response to the sounds to represent how the air particles move to carry sound waves out from the source.

To ensure that the researcher perspective was not overly guided by interview responses, interaction analysis of classroom video (Jordan & Henderson, 1995) was fully completed before the interviews were analyzed. Next, the student and teacher post-interviews were analyzed using thematic analysis (Braun & Clarke, 2012). 133 initial codes were generated based on 19 students' post-interviews. Codes were sorted first into initial categories based on apparent overlaps, which led to the generation of six draft themes. Any codes that appeared to be similar were merged together into more general codes that still captured the essence of each subsumed idea. For example, "interested in how sound is made", "felt good to know how air particles move", and "liked seeing what sound looked like" were all collapsed under the broader code of "liked learning ideas about science". This process of merging and renaming codes continued in multiple cycles. After all codes were re-sorted, the six initial themes had been restructured to be five themes. 37 unique codes remained spread across five themes: 1) What it means to be a team, 2) Awareness of social and emotional engagement, 3) Reasoning around emotional engagement, 4) Perceptions of different class activities, and 5) Challenges of embodied activities.

After the thematic analysis of student post-interviews was complete, the teacher's post-interview was then analyzed using the 37 codes drawn from student responses. Codes that overlapped with the teacher's responses were applied, but any responses that diverged were also open-coded for the construction of teacher-specific themes and sub-codes that might contradict or expand on students' ideas. 9 additional codes were added to the existing themes to reflect teacher-specific ideas, and 11 codes were added to create two additional teacher-specific themes: 6) Benefits of embodiment and scientific inquiry for learning, and 7) Challenges around teaching with embodiment and science. Finally, the themes that were created around participant responses were compared with the results of the researcher's video analysis. This comparison highlighted aspects of the classroom activities that were interpreted similarly across all three perspectives, as well as features of the classroom interactions that were attended to more or less closely through each lens. Student and teacher reflections were not assumed to align with how participants experienced emotions and social interactions in the moment of activity, but rather were meant to elicit the broad perceptions that participants may be taking away from the activities. The comparison below is thus not a comparison of how students felt in the moment to what the researcher sees. Instead, it is an analysis of how students reflect on their learning experiences and interpret video evidence in comparison to how teachers and researchers interpret that same evidence through their professional lenses.

Results

The students' perspectives on their own and peers' engagement

In general, the majority of students (18 of 19) reported that the sound and music activities overall felt fun, happy, and/or good when asked questions about their feelings about the lessons. 14 of those 19 students brought up the idea of having fun or feeling happy either three or four times throughout the interview, suggesting that the general perception of positive emotional engagement was a significant feature of how students framed their experiences. Three students (including the one who did not mention having fun or feeling happy) noted that the activities elicited a mixture of positive and negative feelings. Students also overwhelmingly reported that they thought their class worked well together as a team (17 students). In their explanations, students offered a variety of definitions for what it means to be a good team, some of which aligned with typical classroom rules (e.g., following directions, not goofing off; reported by three students) while other definitions of teamwork were specific to embodied activities. 10 students mentioned that the class was successful at coordinating their movements together as evidence of good teamwork. For example, Jeremiah explained good teamwork during the circle of air particles clip (clip #2) by saying, "Erik in front of me, he moved, so when he moved, I moved, and then he ran back and then I knew to run back. So we did the same thing, went backwards backwards, then forwards forwards." Seven students defined teamwork in terms of communicating, discussing, and understanding ideas together with their peers, and four students noted positive socioemotional climate as evidence of good teamwork. Angelica defined evidence of good teamwork in her explanation of Andy's positive social engagement during activities, saying, "he always has great ideas [...] he tries to invite everybody in. Him and Amara always help me when I feel left out." This focus on how peers contributed to the classroom climate provided a complimentary perspective to the researcher's analysis. While the researcher's perspective highlighted moments of positive engagement that were visible during class, the student reflections made visible some of the work students did outside of music class to build patterns of positive social and emotional engagement that could serve as a foundation for in-class activities.

Comparing student perspectives and researcher observations

Within students' reasoning around their emotional engagement (theme #3) and their perceptions of class activities (theme #4), many overlaps were visible between how students discussed the mechanisms of their engagement and the sources of emotional engagement observed by the researcher. In particular, the researcher noted body movement, scientific inquiry, and the creation and experience of musical sound as core sources of emotional engagement for students. Importantly, none of the interview questions asked directly about these sources of engagement, so all student explanations were offered without guidance towards particular topics of discussion.

Responses in students' post-interviews provided significant support for these hypothesized sources of engagement. Seven students discussed being engaged by the challenge of creating embodied representations, and five of those seven (plus two additional students) also noted that in general getting to move their bodies and be active was an engaging feature of activity. Kinsley explained that she liked the embodied activities because the class "got to be the xylophone instead of playing a normal one". Evidence was similar for scientific inquiry as a source of emotional engagement. Seven students noted enjoying activities that involved inquiry and discovery, such as when Elia viewed the circle of particles activity (clip #2) and then explained "I figured out the pattern [for how to move], so then it was really fun." Another six students (plus one from the previous seven) also talked about liking that they were learning things about science. Kinsley reported that the most interesting activity was "when we got to see like how things vibrated and stuff…well, got to be the- how it vibrated, and got to the ear." Here Kinsley notes not only that learning how sound vibrates was interesting, but also that the opportunity to embody the vibrations (or "be" how it vibrated) was a factor that impacted her engagement in the activities.

By far, the most frequent source of engagement recalled by students was the playing of instruments and the experiencing of musical sound. 14 of the 19 students mentioned playing instruments, making music, and/or listening to sounds as reasoning behind their positive feelings about the class activities, and these students mentioned ideas around creating and experiencing music a total of 26 times. Students also offered context for this link between musical expression and positive emotion by discussing additional factors that may be interrelated. Four students noted that the quality of a sound (e.g., loudness, musicality vs. noise) impacted whether they liked an activity, and seven talked about the newness of experiences (e.g., getting to play instruments they'd never seen before) as a source of their emotional engagement. Opportunities to collaborate with peers (four students) and the freedom to explore with fewer constraints (three students) were also discussed by some as reasoning for their feelings about the activities. For example, Layla noted that when using the ropes to demonstrate sound waves, "there was no limit to how high you could go, or how fast you could go." Students' perceptions of which activities were more or less engaging seemed to broadly align with the researcher's analysis, though the students' reasoning about their emotional engagement offered additional depth to the researcher's understanding of why different forms of embodiment might encourage or discourage expressions of positive emotion.

When analyzing the video clips during their post-interviews, students also highlighted much of the same social and emotional evidence that the researcher called out in research notes. Four students noted the frustration that they and/or their peers felt when trying to coordinate movements together. Another five talked about how it was hard to figure out how to move together. These observations mirror the researcher's findings, which highlighted moments of negative social and emotional engagement in which students appeared to struggle to move together or coordinate the movements of materials productively and shouted directions to each other in frustration.

There were also aspects of these collaborative moments where student perspectives sometimes diverged from the researcher's interpretations. For example, at the end of the circle of air particles clip (clip #2), Owen shouts "go!" at his peers several times and then follows up with "Do I have to say go every time?!" Interestingly, while the researcher had noted Owen's shouted directions as negative social and emotional engagement, given the intensity of his tone and the complaints of his peers in the moment, the students were somewhat split in their post-interview reports. Of the 11 students who co-watched this clip during their interview, three students explicitly mentioned that they disliked being yelled at or bossed around by their peers, and Elia explained her interpretation of Owen's shouting in the video clip by saying, "I don't like that because I mean we were just learning, so it was kind of annoying." However, other students did not comment on Owen's directions at all, instead focusing on the ways their peers were moving well together and helping each other figure out how to coordinate their movements (three students). Still others (three students) directly complimented what they viewed as Owen taking charge and directing others, like when Erik said, "I liked how Owen just kept- had to like remind people to go when they needed to. Like he was kind of the leader I guess." Owen himself did not report feeling any certain way in his post-interview when asked how he felt during the circle activity, and he noted only that "everybody they needed to move a little more, they had to listen to if it got quieter."

These contradictions in students' responses remind us that there is not one "true" interpretation of a moment of engagement, and that participants are always in the ongoing process of building intersubjectivity together. Considering the varied ways that students may interpret and react to an expression of emotion from their peers can help to guide our understanding of what such moments might contribute to learning for different students. This also suggests that negative emotional and social engagement may influence different students' learning in unique ways, depending on how they make sense of their peers' comments and reactions. This example highlights how classroom video data may reveal potential emotional engagement that is not reported in students' interviews, but also that researcher interpretations of potential negative emotions may not be remembered or experienced by participants in the same way that an outside observer perceives them. The difference in overlap between interpretations of positive emotions (which were very similar across student and researcher perspectives) and the interpretations of negative emotions (which were more varied) also suggests that student interviews may be more vital in understanding the possible sources of negative socioemotional interactions.

Comparing student and teacher perspectives on engagement

As with student and researcher comparisons, the overlap between student and teacher perspectives on engagement was clearly visible in the reasoning that participants offered for students' emotional engagement. In her explanations, the teacher noted the opportunity to move one's body, the freedom of movement and actions, the novelty of new experiences, and collaboration as sources of students' positive emotional engagement, all of which were brought up by multiple students in their post-interviews. The teacher also noted the idea of turn-taking and everyone wanting their turn to be a leader, which overlapped with the students' ideas around fairness and making sure everyone got a chance to participate. The teacher called out many of the specific activities that students brought up as being engaging as well, such as playing instruments, doing inquiry activities, and using materials in the embodied activities. She recalled noticing during the activities that "you could see pure joy and freedom in them just being able to play music and enjoy it." The teacher's general perceptions of the activities as fun, exciting, and full of good teamwork also aligned with the majority of the students' reported perspectives.

The evidence the teacher used to reason about students' engagement also overlapped with how the researcher looked for positive emotions in the video data (e.g., "I heard a lot of laughter and a lot of excitement in their voices, and they just seemed overall relaxed and enjoying the activities"). The teacher accurately identified one of the less-common perceptions of students as well, which was that some students found the group discussions boring or less interesting than the more active and embodied activities. However, there were other less-common perceptions articulated by the students that the teacher did not bring up in her interview, such as Angelica's comment that she wished the teacher would have been more encouraging when students tried out new ways of moving. She noted that the teacher and facilitator were sometimes quick to critique students for not moving properly, or to praise some students and not others. Explaining how these interactions impacted her emotional engagement, Angelica said, "it feels really sad cause you're like but I tried my best, no one's noticing me." While the teacher reported many overlapping ideas with students' perceptions, these examples highlight that there were still unique and valuable aspects of students' perspectives that were not captured via teacher or researcher forms of data. Attending to these less-common but still valuable perceptions may be key to addressing hidden sources of negative emotional engagement that can trigger students to disengage with learning.

On the other hand, the teacher also provided additional forms of reasoning around students' engagement that were not found in the student data. For example, when co-watching the video clips, she noted that levels of negative social engagement that she saw during the sound activities were on par with the levels she usually sees during class. She added that she did not perceive any "terrible misbehavior" or anything that signaled the embodied activities were encouraging more negative engagement than normal. The teacher also discussed how students enjoyed using technology like the oscilloscope, that they looked forward to the sound activities, and that emotional and cognitive engagement seemed to co-exist during the lessons (e.g., students were "having a good time at the same time that they were learning"). The teacher mentioned that she thought students were engaged by the agency and responsibilities that the activities offered, as well as the open-endedness of scientific inquiry, which was a new pedagogical strategy for her classroom. For example, she explained that "they enjoyed getting to move and move around, and being able to have kind of open-ended answers, to where they didn't feel like they had to be right all the time, that they were just exploring." Like the students' interviews, the teacher's discussion offered additional contextual insight for the researcher that was not available in the classroom video, such as information about the pre-existing socioemotional history of this particular class of students that may have laid the foundation for their productive engagement. She explained that "I feel like this class is connected to me and to each other even more than some of my classes," and that "I give them a little more leeway to have fun and do things because of that." The teacher's perspectives presented another dimension for the analysis of the embodied activities, suggesting that the effectiveness of positive emotional and social engagement for learning may be somewhat dependent on the level of pre-existing mutual trust between students and their teacher.

The teacher's perspectives in the post-interview also offered perceptions that student interviews did not address. The teacher-specific themes that were built around these responses concerned both the benefits and challenges of using embodiment and scientific inquiry for teaching and learning. In terms of benefits, the teacher reported that collaborative embodiment helped students to figure out ideas, observe their peers, and self-correct their movements to learn more deeply (e.g., "they'll remember it more, because it's not just somebody telling you how the air particles move"). She also noted that she thought students' learning was improved by the opportunities for exploration and prediction, and that bringing science ideas into music class could support students' vocabulary learning. The teacher also discussed the value of positive emotional engagement for students' perceptions of music class, saying, "I think even if they don't remember five years from now or even one year from now what amplitude is, I think they'll remember having fun in music." This perception of music as both enjoyable and important was something that the teacher returned to several times, as when she noted the benefits of blending science with music: "I think it helps students to see that science and music are combined, and they play off each other [...] the more you kinda relate music to other disciplines, it helps the kids see a need for it and see the importance of it." Overall, many of these observations were specific to the teacher's perspectives and were not findings that could have been gleaned from student interviews or classroom video alone. The teacher noticed both potential reasons for students' engagement that the students themselves did not report, as well as aspects of students' learning that helped support some of the researcher's hypotheses about the benefits of embodied learning and scientific inquiry.

Discussion

Across the three perspectives, general levels of positive emotional engagement were reported similarly. Many of the potential influences on students' engagement were also reported in similar ways across different participant and researcher perspectives. Some factors, like the novelty of experiences and freedom/choice, are well-known sources of student motivation and engagement (Evans & Boucher, 2015), and this study further supports the benefits of these design features for engaging students' positive emotions. To add to our understanding, this analysis also provides evidence that embodied learning and the ability to move one's body in the classroom can be highly engaging for some learners in terms of emotions as well as social and cognitive engagement. The current study also highlights the importance of disciplinary-specific sources of engagement, such as the creation of beautiful music and the experience of discovering something new during scientific inquiry, which were noted by student, teacher, and researcher perspectives together as key reasons for positive emotional engagement. The large overlap in the ideas discussed by students and the observations of the researcher and teacher give support to the idea that triangulation across multiple participant perspectives can lend strength and complexity to our understanding of the mechanisms at work behind students' engagement with learning.

Beyond the benefits of strengthening existing claims, the use of student and teacher perspectives on engagement can offer the researcher valuable contextual information and insights into the less-visible features of participants' socioemotional interactions both inside classroom activities and in other overlapping spheres of students' lives. While the researcher perspective captured the overall emotional valence of interactions in ways that aligned with the teacher and majority student opinions (e.g., positive or negative), the nuance of why these emotions appeared, as well as negative emotions that were not expressed by the majority of students, were not always visible to the researcher. These insights that are unique to participant viewpoints caution us to not over-focus on our instructional designs as the only mediators that might be influencing learners' social and emotional engagement with one another and their teacher.

The teacher lens opened up a window into both the benefits and the challenges of implementing practices of embodied learning and scientific inquiry into non-STEM classroom spaces. Her perspectives also offered ideas about the benefits of blending science and music teaching together to more deeply engage students in the pursuit of both disciplines. The teacher was able to offer vital contextual information about the socioemotional dynamics between the class at a baseline, to more clearly reveal the ways that designed learning activities intersect with existing engagement patterns. The student lens also provided a similar yet distinct window into the personal histories between students and the socioemotional foundation on which activities were taking place. Participant perspectives overlapped in useful ways for confirming researcher observations, but students and teachers each offered specific reasoning around engagement that was not fully covered by the other viewpoint, as well as the articulation of small moments of engagement that the researcher overlooked. While a standard self-report survey with pre-determined rating scales may not fully uncover these context-specific and dynamically changing interactional details (Karabenick & Zusho, 2015), the present study suggests open-ended interviews can surface valuable information about how and why students engage with learning. Students were also able to communicate reasons for their emotional engagement that neither the teacher nor the researcher noted in their reflections, such as the need for more socioemotional support when being offered feedback. Thus, we should not assume that young students do not have anything meaningful to tell us about how and why they engage with learning, or that teachers and researchers alone have all the answers about what drives learners' engagement. The researcher's perspective was well suited to analyzing broad patterns in engagement across the dataset, but the student and teacher perspectives offered contextual detail that made the mechanisms driving these overarching patterns more visible.

Conclusion

In comparing different perspectives on engagement, the goal is not to argue that one is more true or more accurate to some hidden reality of "what's actually going on" in the classroom when students engage with learning. Rather, gathering and comparing both participant and observer perspectives brings us closer to an intersubjective understanding of best practices for designing engaging learning environments. This process, which was named above as triangulation, has also been framed by qualitative researchers as a process of crystallization (Ellingson, 2008), in which each additional form of data comes together not to locate the position of a singular "reality" but instead to add complexity and depth to a still-incomplete understanding (Tracey, 2010). This perspective on engagement honors the unique and complementary perspectives of students, teachers, and researchers, highlighting what each view brings to our collective picture of what engagement looks like in the classroom and what interactional mechanisms support it. Whether we draw our evidence of engagement from video-recorded moments of negotiation, laughter, and disagreement, teachers' perceptions of how their students experienced learning, or students' reported experiences of joy, frustration, and collaboration, each lens reveals both distinct and overlapping facets of our pedagogical designs that can be further refined to promote more frequent and meaningful engagement with learning. The goal then for future studies of engagement is to continue to expand the crystallization of the concept, by revealing new angles of understanding in regards to how our designs can generate, evaluate, and sustain learners' multidimensional engagement with complex ideas and with each other.

Design Principles for Teacher Dashboards to Support In-Class Learning

Allison Poh, Francisco Enrique Vicente Castro, Ivon Arroyo
apoh@cs.umass.edu, fcastro@cs.umass.edu, ivon@cs.umass.edu
University of Massachusetts Amherst

Abstract: When using learning technologies within classrooms, teachers often face challenges around supporting their students' learning within a digital space. To address this, prior work typically augments learning technologies with teacher dashboards that display real-time student data. Although common similarities in dashboard designs can be found, not all dashboards are designed similarly as teachers and learning technologies vary greatly. There is a lack of prior work around what design principles offer best practices for designing teacher dashboards. Our work addresses this gap through a systematic literature review of research on K-12 dashboards. Our review yielded (a) a concrete list of teacher tasks that teacher dashboards should support and (b) design principles that best support the design and development of teacher dashboards.

Introduction

K-12 teachers are increasingly integrating learning technologies into their classrooms. While learning technologies can be used to support the learning and engagement of students (Bergdahl et al., 2018), they also introduce challenges to teachers' pedagogical practices. Since these technologies shift the learning environment into a digital space, teachers also experience a push to shift their pedagogical practices to best support students within the digital space.

One way to support teachers is by augmenting learning technologies with teacher dashboards. Teacher dashboards can enhance teachers' understanding of student learning by leveraging real-time data collection and analysis to display student progress and engagement within digital learning environments. Recently, there has been an increase in research for designing dashboards for teachers, such as Luna (Xhakaj et al., 2017), PROGDASH (Ez-Zaouia et al., 2020), and MetaDash (Wiedbusch et al., 2021). While these dashboards share several similarities (*e.g.,* display student progress, aggregate data on student and class levels), there are a number of key differences between them. These differences stem from the specific support needs of teachers and the learning technology in which a dashboard is designed to augment. For example, teachers incorporating a computer-supported collaborative learning system in their classrooms may want to observe the collaboration between students within the digital space. Dashboards could display the amount of talking between students (van Leeuwen et al., 2019) and enable teachers to stimulate collaboration between quieter or off-topic students (Tissenbaum & Slotta, 2019). On the other hand, teachers incorporating a learning technology designed for individualized learning may prefer to observe how students interact with the system itself, such as requesting hints from the system (Xhakaj et al., 2016). While these dashboards support teachers in observing student interactions (student-to-student vs. student-to-system), each dashboard displays metrics and visualizations specific to the needs of teachers and capabilities of the learning technology. Thus, one dashboard design does not support the needs of all teachers and learning technologies. Designing dashboards should therefore center teachers' needs; this calls for design principles that can guide the design process of teacher dashboards. Uncovering these design principles by identifying the common support needs of teachers is the focal point of this paper.

While prior work describes the design processes behind certain dashboards, we still do not have a framework that informs the design process of teacher dashboards grounded on the pedagogical practices of K-12 teachers. There are some studies focused on reviewing the current scope of dashboards in education, including Schwendimann et al., (2016) and An et al., (2020). Schwendimann et al., (2016) focuses on multiple contexts, including dashboards for students, teachers, administrators, and researchers, and does not propose a design framework. An et al., (2020) focused on creating a design framework, but one for any type of teacher augmentation tool. Our goal in this paper is to draw design principles from prior literature that speak to designing K-12 teacher dashboards in ways that tie into real-world teacher needs and practices. This paper provides a systematic literature review of research on K-12 teacher dashboards for supporting in-class learning. In this study, we address the following research questions (RQ):

- *RQ1*: What role(s) do teacher dashboards play in supporting the pedagogical practices of K-12 teachers?
- *RQ2*: What design principles could guide the design process of K-12 teacher dashboards and how do these principles support the pedagogical practices of teachers using the dashboards?

Related work and theoretical framework

Our work is driven by insights and theoretical constructs from prior work with teacher dashboards, including, among others, how teachers make sense of data from dashboards to enhance pedagogical practices within K-12 classrooms and work on co-designing with teachers to elicit meaningful design principles for dashboards.

Impacts of teacher dashboards on k-12 classroom pedagogical practices

As learning technologies continue to be integrated into K-12 classrooms, teachers shape and adopt their pedagogical practices to incorporate these technologies to aid in classroom teaching and learning. Eppard et al. (2021) uses the term *EdTech culturation* to describe a pedagogical approach that centers the sociocultural contexts of classrooms through an understanding and adeptness in technology use within and outside classroom teaching. They emphasize the importance of reducing student-teacher barriers by forefronting the needs of students. Teacher dashboards are a common avenue for reducing student-teacher barriers. Often integrated with learning technologies, teacher dashboards display student data to teachers in real-time, enabling teachers to immediately and more effectively respond to students' needs. While researchers have observed that teacher dashboards improve the frequency and efficiency of teacher support for students, we still don't have a profound understanding as to how teacher dashboards shape teachers' pedagogical practices (Molenaar, 2017).

Data sensemaking for teachers

Sensemaking is the process of encoding information to answer task-specific questions. By allowing teachers to reflect on and answer their own questions about student data, sensemaking promotes the ideation of new insights about student and class progress toward learning goals (Bodily & Verbert, 2017). Since teacher actions are based on their sensemaking of student data, it is important for the data to be presented with simplicity and clarity. Although considerable work has been done on data sensemaking, there is still a gap in understanding the sensemaking process of teachers when connecting dashboard data to their pedagogical goals and strategies.

One factor for this gap is the variability of how teachers react toward data visualizations. Teachers' emotional, analytical, and intentional responses affect how they interpret data (Campos et al., 2021). During sensemaking, teachers build narratives around data by using their own unique reactions and experiences. The variability is increased for data with some level of uncertainty (*e.g.,* data that presents open-ended and interpretable questions, such as "*How to improve teaching?"*) (Nguyen, 2021). Therefore, when designing visualizations for teacher dashboards, the variability of reactions, needs, and understandings of the data needs to be considered (Epp & Bull, 2015). While several teacher dashboards exist, there is a lack of empirical evidence around how certain visualizations aid sensemaking of teachers (Bodily & Verbert, 2017).

Co-designing teacher dashboards

Co-design involves the inclusion of participants in the design process, allowing for their unique expertise to drive design and analysis (Penuel et al., 2017). The practice of co-designing teacher dashboards with teachers has been widely adopted and has enabled researchers to identify and address factors that impact teachers' use of dashboards, including experiences, perceptions, pain-points, and frustrations (Ez-zaouia, 2020). Ez-zaouia's (2020) process model for dashboards strongly emphasizes co-design as it enables designs to be robust, attractive, diverse, and equitable. Matuk et al., (2016) addresses the importance of identifying the right tasks for teachers to complete within the design process, including discussing physical artifacts and reacting to scenarios, with each task providing a list of key insights that could positively impact the success of the co-design.

A drawback to co-design is the potential tension between teachers and researchers due to a lack of understanding of the competencies and contributions of all members. Researcher-designed solutions may not seem practical to teachers, and teachers may not be able to articulate their needs to researchers well. Tensions may also arise from time and productivity pressures due to lengthy co-design processes. However, Penuel et al. (2007) notes that when tensions arise and are appropriately addressed, they have the potential to lead to innovative results. Thus, educational technology researchers value the inclusion of teachers in the design process and may consider collaboration with teachers to be a design principle for these technologies.

Methodology

To understand the role that teacher dashboards play in supporting classroom pedagogical practices and the principles that drive the design of teacher dashboards, we conducted a systematic literature review on K-12 teacher dashboards. In this work, we define pedagogical practices as the methods and strategies behind teachers' teaching and learning approaches. Within these pedagogical practices are specific *teacher tasks* that teachers perform to promote learning in students (adopted from Medley & Crook's (1980) definition), and which teacher dashboards may be of aid to. We also sought to identify design principles for teacher dashboards. We define design principles to be guidelines with context considerations for designing a system like a teacher dashboard. We followed Okoli and Schabram's (2010) 8-step guide for systematic literature reviews. Our search string included keywords used by Wiedbusch et al. (2021): "teacher dashboard", "learner analytics dashboard", "instructional panel", "teacher interactive dashboard", "educational dashboard", "learning dashboard", "data visualization dashboard", and "learner progress monitoring".

We used Google Scholar for our search engine. To account for recency of the results, we limited the result list to the last 20 years from January 2002 to April 2022 (we retrieved results in May 2022). Our search string and publication date range returned 2620 results. We first screened the results by reviewing their titles, abstracts, and publication details based on the following criteria: (a) published between January 2002 and April 2022, (b) peer-reviewed journal or conference proceeding, (c) abstract available, (d) paper available in English, (e) context of paper is K-12 teacher-facing dashboards for in-person learning, (f) research includes teachers as a participant or co-designer, and (g) article addresses at least one of our research questions. Criteria (f) is specifically important for this study as teachers have been considered guides to the design process of teacher dashboards and can act as validators to whether a dashboard meets their needs (Ez-Zaouia, 2020). If an article failed to meet any of the eight criteria or if an article focused on MOOCs or was a review of other studies, it was excluded from this study. Following Ojoli and Schabram (2010), if we had any doubts about the alignment of a paper with our inclusion criteria, we included the paper in our results list. As we reviewed the results (ordered by Google Scholar's relevance filter), we found that relevance significantly decreased as we approached 1000 articles; we thus limited our analysis to the first 1000 articles. In total, 118 research papers passed the first screening.

We conducted a second screening of the 118 eligible articles by applying our inclusion criteria from the first screening round to the entire content of each article. Criteria (f) and (g) were of particular importance during this screening round. Articles needed to clearly state how teachers were included in the design process and what needs those teachers expressed. Design processes also needed to be detailed to include the logistics and justifications for each phase of their process. Of the 118 articles, 19 articles passed the second screening (1).

Finally, we performed Braun & Clarke's (2012) six-phased thematic analysis on the 19 articles. In Phase 1, we reviewed the 19 articles once more to further familiarize ourselves with the studies and dashboards that each article presented. We then performed an initial coding of the articles (Phase 2) by manually extracting data from each article into a spreadsheet. We coded for publication details (*e.g.,* date, publication type, authors, keywords), study protocols (*e.g.,* research questions, methodology, results, limitations), teacher dashboard details (*e.g.,* input data, features, data visualizations, stage of development, role in supporting teachers), design processes (*e.g.,* design methods, teacher involvement, duration, evaluation, limitations), and learning technologies (*e.g.,* name, targeted grade level and subject, key features). Within our codes, we searched and identified themes (Phase 3) and used the themes to cluster similar codes. We reviewed our findings (Phase 4) by collaboratively discussing relationships between the codes within each theme. In Phases 5 and 6, we labeled our themes and created tables to summarize them (Tables 1 and 2). In the end, we found themes across the 19 papers focusing on two key dimensions: teacher tasks and design principles. In the following section, we describe our findings, exploring these dimensions that we distilled from our systematic literature review.

Results

While our search criteria included a publication range from 2002 to 2022, all 19 articles were published between 2013 and 2021. Most of the teachers described in the articles taught at the middle school level (middle: 8, secondary: 6, primary: 4, multiple levels: 1) and most teachers taught math (math: 9, science: 4, history: 1, grammar: 1, problem-based learning: 1, unknown: 3). Additionally, all 19 articles only involved screen-based dashboards, which was not an inclusion criterion. In the following subsections, we list our results from (a) identifying teacher tasks that were supported by the dashboards and (b) the design principles we synthesized.

Teacher tasks supported by dashboards

Table 1 summarizes the seven teacher tasks that the teacher dashboards were designed to support (column 1), and the specific dashboard features that afforded those tasks (column 2). Using van Leeuwen et al.'s (2019) terminology, we assigned *dashboard roles* (*mirror*, *alert*, *advise*) to each teacher task to describe how the dashboard supported the teacher. A *mirroring* dashboard displays data to a teacher without prompting or alerting the teacher (*e.g.,* displaying data using a line chart visualization). An *alerting* dashboard mirrors and flags a teacher's attention to data that may need immediate attention (*e.g.,* using colorful symbols to draw attention). An *advising* dashboard mirrors, alerts, and suggests actions to a teacher to act upon flagged data (*e.g.,* suggesting support interventions for a student). We additionally define two new dashboard support roles: *mediate* and *reduce workload*. A *mediating* dashboard enables teachers to directly communicate with—or promote communication between—students (*e.g.,* chatboard). A dashboard that *reduces workload* handles the orchestration of learning activities (*e.g.,* assigning students to groups). In defining dashboard features, we identified the common features among the dashboards that support each teacher task.

Within the papers, teachers reported a need to view data across multiple levels: at the student level (individual students), group level (collaborating students), class level (all students), and task level (lesson tasks). Of the 19 papers, 13 discussed dashboard aggregation of data into separate views (e.g., student view vs. class view). 13 demonstrated (either in text or in screenshots) the use of simple data visualizations, including 3 that explained specific ways teachers can interact with the visualizations. For alerting teachers, 7 papers exhibited alert indicators. Four papers additionally explored how dashboards can advise teachers on alerted events. While only 3 dashboards discussed chat features for teacher-to-student communication, several papers did discuss how teachers communicate with students in-person after dashboard consultation. One paper found teachers requests for data about subsequent teacher-to-student interactions. Five papers discussed features for observing student-to-student collaboration, 2 of which plotted the amount of talking per student, and another 2 that displayed conversation transcripts. Five dashboards mention features to save data, with 1 mentioning that teachers would print dashboard-generated reports for review offline. Although only 1 paper described the software agents implemented into their dashboards, all papers expressed automation of some orchestration tasks.

Table 1
Teacher Tasks Supported by K-12 Teacher Dashboard Features

Teacher Task (Dashboard Role)	Dashboard Features (Number of Papers)
View data at student, group, and class levels (mirror)	Multiple views (13), Simple data visualizations (13), Interactions on visualizations (3)
View students' task performance on specific tasks (mirror, alert)	Multiple views (13), View of class trends (10), Simple data visualizations (13), Alert indicators (7)
Provide feedback and support (alert, advise, mediate)	Alert (7) and warning (3) indicators, Suggestions (4), Chatboard (3), Details about subsequent interventions (1)
Personalize learning for students (advise, reduce workload)	Grouping of students based on performance (2), Automated activity recommendations (1)
Monitor and support collaboration between students (mirror, mediate)	Talking indicators (2), Conversation transcript (2), Chatboard (3)
Reflect (mirror)	Student and class reports (5), Metrics for specific time periods (1)
Orchestrate activities (reduce workload)	Automate orchestration/managerial tasks (19)

Design principles for teacher dashboards

Table 2 summarizes the design principles (column 1) that drove the design of K–12 teacher dashboards and the context considerations (column 2) that designers should think about when applying each design principle. Although the inclusion criteria for this study enforced the involvement of teachers, it is worth pointing out that the number of teachers involved in each study varied greatly, ranging from 1 (Tissenbaum & Slotta, 2019) to 17 (van Leeuwen et al., 2019). Of the 19 papers, at least 18 *evaluated dashboards on real classroom data*. One paper stated they used "simulated, fictitious situations" to evaluate dashboard design effectiveness but it was unclear if the simulations used real student data (van Leeuwen et al., 2019). All 19 papers designed for *simplicity* and *glanceability* (to various degrees) and 13 designed for *modularity*. Lastly, all 19 papers *focused on informing to support sensemaking*, a primary goal of dashboard design.

Discussion

In this section, we discuss our findings regarding (a) teacher tasks supported by K-12 dashboards and (b) design principles for teacher dashboards.

Teacher tasks supported by dashboards

We describe below our findings from our systematic literature review on what dashboard features best support teachers in their tasks during in-person classes.

Table 2
Design principles for designing K-12 Teacher Dashboards

Design Principle (Number of Papers)	Context Considerations
Design for simplicity (19)	Clarity of information, time and effort needed for sensemaking, familiarity to teachers
Design for glanceability (19)	Clarity of information, time and effort needed for sensemaking, summaries of information, indicators for immediate attention
Design for modularity (13)	Aggregation of data, layout of interface, transitions to focus on specific modules
Focus on informing to support sensemaking (19)	Tasks teachers do and do not want automated, teacher sensemaking and resulting actions
Evaluate on real classroom data (18)	Methods, classroom setting, teacher experience

Teacher task 1: View data at student, group, and class levels

Most of the papers focused on the goal of aggregating data into views to reduce the information overload of teachers. This was done by mirroring data that has been aggregated into student, group, and class levels to reduce teachers' experience of information overload. Some papers also provided multiple dashboard views and enabled teachers to toggle between these views. Some papers also enabled teachers to filter data on students such that they design their own views. Overall, dashboard designers should consider displaying simple visualizations that summarize views on a main screen and enable teachers to further explore those views by selecting visualizations of interest.

Teacher task 2: View students' task performance on specific tasks

Several of the papers discussed displaying aggregations of students' performance data based on tasks. Some papers displayed tasks that belong to the same lesson on a single view, often referred to as the *lesson overview*. These papers indicate students' performance, progress, and engagement using colors in the *lesson overview* (*e.g.,* green: task complete, red: task attempted but not complete). Some papers also displayed students' progress and engagement for a single task as a separate view, referred to as the *task view*. For the *task view*, these papers included metrics such as student actions, attempts, and performance trends, among others. Overall, dashboard designers should consider a *lesson view* that acts as a gateway to specific *task views* to reduce information overload for teachers, especially for lessons composed of many tasks.

Teacher task 3: Provide feedback and support

Some of the papers focused on helping teachers to support students more efficiently. This was done by alerting teachers to students in need of intervention. Some papers used colors to highlight students' names, while others used symbols to draw attention to students. In addition to alerting, some papers included dashboards that display advisory text to teachers for providing suggestions on supporting students. One paper addressed teachers' needs for reviewing support suggestions from previous student interventions. Overall, dashboard designers should consider strategies to flag teachers' attentions and to advise teachers in supporting flagged students.

Teacher task 4: Personalize learning for students

A few papers displayed a need for dashboards to assist teachers in creating a personalized learning experience for students. Some papers showed how grouping students with similar performance metrics can assist teachers in personalizing their instructions for specific groups. In doing so, it was found that teachers could support more students in less time. One paper demonstrated how dashboards can advise teachers in finding additional materials that may aid particular students. Overall, dashboard designers should consider affording teachers the ability to group similarly performing students so teachers can communicate to students more effectively.

Teacher task 5: Monitor and support collaboration between students

Some of the papers addressed designing dashboards for learning technologies that support student collaboration. Those papers displayed two ways to mirror collaboration to teachers. One approach used line charts to display the frequency of communication per student. The other method used live transcripts of speech or chat messages to show the entirety of communication between students. Some papers involved color-coding the transcripts by students. Other papers used highlighting to draw attention to concept-related words within the transcripts. Some papers also addressed the need for teachers to intervene and stimulate task-focused collaboration between students by supporting teacher-to-student chat messaging. Overall, designers for collaborative learning technologies should consider ways to present communication with clarity to allow teachers to quickly observe the ideas and engagements of collaborating students.

Teacher task 6: Reflect

A few of the papers addressed the need for dashboards to support teacher reflection. Some papers indicated that reflection can be supported if dashboards allow teachers to save reports. Some papers also showed that filtering the data by date can aid teachers' reflection on trends in class performance. One paper discussed the option for teachers to add summaries to saved dashboards so they can revisit their summaries during reflection. Overall, dashboard designers should consider how teachers intend to use dashboards after class.

Teacher task 7: Orchestrate activities

All papers discussed ways in which dashboards can reduce teachers' workloads by automating orchestrational tasks. One paper mainly focused on the use of software agents to automate some teacher duties such as assigning students tasks and forming groups. Overall, dashboard designers should consider which tasks that teachers would benefit from being automated. However, designers should be cautious of the negative impact that much automation can cause on data sensemaking for

Design principles of teacher dashboards

Design principles have been studied greatly within the human-computer interaction space, and many proposed principles can be carried over to the design of educational technology. However, there is a gap in understanding how to apply these principles to the design of technologies for real-world classrooms. In the following subsections, we discuss the common design principles found in the literature for teacher dashboard. We aim for the design principles that we identified to provide a starting point for designers of teacher dashboards and to support the iterative design processes that are often adopted when designing these systems.

Design principle 1: Design for simplicity

A common theme among all papers is designing for simplicity to minimize teachers' sensemaking efforts and maximize teachers' ability to support students. Several papers emphasized the importance of simple data visualizations for displaying student data. One study found that, by showing simple data visualizations to teachers in the early stages of the design process, teachers were able to propose changes that they believe would work best in their classrooms. Overall, dashboard designers should consider using data visualizations that are easily interpretable and reflect what teachers need in a classroom setting.

Design principle 2: Design for glanceability

As with designing for simplicity, all papers reflect dashboards that are designed for glanceability. Some papers reported the need for teachers to glance at dashboard data and quickly process the data during class. These papers emphasized that, immediately after students have completed a task, teachers' glance at the dashboard to check students' performance. Some papers noticed that visual alert indicators supported teachers in identifying low performing students at a glance. Additionally, providing glanceable summaries and comparisons of students aided teachers in quickly identifying students who need additional support. Overall, dashboard designers should consider using alert indicators and visual comparisons to increase glanceability in a classroom setting.

Design principle 3: Design for modularity

Here, modular design refers to splitting a dashboard's user interface into independent sections. Some papers split the dashboard's design using a grid layout. These papers aggregated data into tiles reflecting separate modules that correlate to different views. Some papers additionally allowed teachers to interact with tiles by clicking, which expands a tile's view. Rather than tiles, some papers addressed modularity by using buttons on a main screen. The buttons allow teachers to transition to different views. In both examples, modularity organizes student data displayed on a screen, reducing the teachers' experience with information overload. Overall, designers should consider modularity for organizing and reducing the display of student data.

Design principle 4: Focus on informing to support sensemaking

All dashboards focused on informing teachers to support their sensemaking of student data. While some papers address the use of automated advisory to support teachers, no papers forced teachers to accept the suggestions. Rather, these papers adopted the "show, don't tell" motto, in which information was presented to teachers but the sensemaking of the data was left to teachers. Some papers explored how software agents could automate tasks, but no papers automated all teacher tasks. Thus, dashboard designers should be wary as to what teachers want automated. Overall, dashboard designers should explore the automation needs of teachers and avoid automating tasks that are important to teachers' pedagogical practices.

Design principle 5: Evaluate on data from real classrooms

Almost all papers explicitly stated their use of real classroom data in the evaluation of teacher dashboards. Most papers evaluated the dashboards during the co-design process by including observations and interviews. Thus, these studies used real teachers and/or live classroom data. The papers that evaluated dashboards using real-class observations noted the benefits of watching exactly how and when teachers use the dashboards during class. Furthermore, papers that interviewed teachers after observing them found that the interviews uncovered more specific details as to teacher usage of the dashboard during class. Overall, dashboard designers should consider including observations and interviews with teachers using real student data (*e.g.,* live classroom data) when evaluating the dashboard design and effectiveness.

Conclusions, limitations, and future work

In this study, we conducted a systematic literature review of research on K-12 teacher dashboards to understand the role(s) dashboards play in supporting the pedagogical practices of teachers, and to understand the design principles that guide dashboard design. We found that dashboards typically support teachers with the following tasks: viewing data at student, group, and class levels, viewing data at task level, providing feedback and support to students, personalizing learning for students, monitoring and supporting collaboration between students, reflecting on class outcomes and pedagogical practices, and orchestrating activities to reduce workload. We also found the following design principles for building dashboards that support teachers: design for simplicity, design for glanceability, design for modularity, focus on informing to support sensemaking, and evaluate on real classroom data.

Systematic literature reviews come with the inherent risk of bias due to subjective interpretations of literature. In this study, researchers may have experienced additional bias due to author and publication details not being blinded. Additionally, articles selected for this study were limited to Google Scholar's coverage. One strategy for expanding beyond a search engine's coverage is backward searching in which references of selected articles are screened as well. However, this strategy was not implemented in the present study.

In studying the design processes of K-12 teacher dashboards, we uncovered ways in which designers and teachers can collaborate to design systems that will better support teachers in helping students effectively engage in learning. Future studies can use our findings as a starting point for their design processes for teacher dashboards, and we encourage further research on validating and expanding on the design principles presented here. Furthermore, we encourage further research on testing our findings on the design of teacher dashboards within informal learning environments. Going forward, we plan to follow the design principles identified in this study to implement and pilot a teacher dashboard for our own learning technology, *WearableLearning (wearablelearning.org),* designed to teach math and science through interactive games with wearable technologies (Castro, 2022).

Analyzing Teacher Learning in a Research Practice Partnership

Enisa Selimbegovic Akgul, Alison Castro Superfine

University of Illinois at Chicago - Learning Sciences Research Institute

Abstract: Teachers are increasingly participating in RPPs with the goal of improving their schools and districts. This context provides teachers with unique learning opportunities as they directly take part in district-level instructional improvement work. However, we know little about what teachers learn from their involvement in RPPs. This study explores teacher learning over the course of the first year of a multiyear RPP which involves a group of elementary teachers and a team of researchers from a local university. Findings reveal shifts in three areas: teacher reasoning about relevant problems of practice, teacher contributions, and teacher roles. These findings not only shine a light on the nature of teacher RPP participation, but they also highlight how RPPs can be a context for teacher learning.

Introduction

Research practice partnerships (RPPs) are long-term collaborations between practitioners and researchers in which the collective engages in school improvement work by investigating persistent problems of practice and solutions (Coburn & Penuel, 2016). RPPs are increasingly utilized for school improvement purposes because they address local problems of practice and enable greater use of research in decision making (Coburn & Penuel, 2016). Despite a growing body of literature related to RPPs, there is still a need for more detailed research, including the need to better understand conditions that foster or inhibit their success (Farrell et al., 2021) and the processes and outcomes of these partnerships (Klar et al., 2018). Increasing our understanding of how teachers participate in and what teachers learn from RPPs, may provide some insight into what helps these reform efforts either succeed or fail. Previous studies have focused on the learning of district leaders (e.g., Rigby et al, 2018), but few previous studies have focused on teacher learning within RPPs.

Teachers and research practice partnerships

RPPs promote productive relationships between researchers and school district personnel, during which goals are collaboratively determined with the aim of achieving districtwide instructional improvement (Henrick, et al., 2016). Five key features of RPPs have been recently identified (Farrell et al., 2021): (1) they are long-term collaborations, (2) which often disrupt traditional power relationships, (3) whose goal is educational improvement, achieved through (4) the application of research (5) by its members who hold diverse expertise. Since addressing challenging educational issues is generally the goal of RPPs, these partnerships must therefore provide ample time for goals to be achieved. This means that RPPs in their first or second year are in the early stages of the work, and an RPP is only considered mature after 3 or more years (Farrell et al., 2021). While other change initiatives also rely on research, expertise, and shifts in power, the way RPPs leverage such resources is unique. RPPs both produce and promote the use of research in decision making. In terms of expertise, RPPs tap into the diverse knowledge and experiences the various participants bring with them. This commitment to engaging all participants meaningfully in the work of the RPP contributes to shifts in traditional power relationships, such as those between teachers and school administrators.

Given the previously listed features of RPPs, they can be considered as a community of practice. A community of practice is a group that collectively engages in a shared repertoire of routines as the group works towards a common goal (Wenger, 1998). RPPs can be considered a community of practice as they consist of a group of individuals who come together regularly to collectively investigate and solve persistent problems of practice. Previous studies have explored teacher learning as they engage in various types of communities of practice and Levine and Marcus (2010), in particular, found that different teacher collaboration structures provide different opportunities for teacher learning. However, we know little about what learning opportunities for teachers are provided by an RPP structure.

One of the defining characteristics of RPPs is that they require participants to take on roles that are unfamiliar or even oppose traditional norms (Farrell et al., 2019). This is especially true for teachers who often do not have opportunities to be directly involved in district-level instructional improvement efforts as districts' hierarchical leadership structures diminish the likelihood of such teacher participation (Leithwood et at., 2007). Unlike typical classroom-based instructional improvement efforts, RPPs have the potential to directly involve teachers in the design stages of district-level improvement efforts because they intentionally employ flatter, less hierarchical, structures (Farrell et al., 2019) which encourage distributed leadership (Leithwood et at., 2007).

Given the nontraditional roles that teachers may take on in RPPs focused on districtwide improvement efforts, it raises the question of how teachers engage in and what teachers get out of such an experience. More specifically, what do teachers learn as they participate in RPPs? In this study, we investigate teacher learning in these partnerships by examining teacher reasoning of, contributions to, and roles in RPP work. Our three research questions are: As teachers engage in RPP work, (1) how does their reasoning about improvement work shift over time?, (2) how do teacher contributions shift over time?, and (3) how do the roles teachers take on change over time?

Previous studies of teacher groups

To better understand the unique context that RPPs can provide for the study of teacher learning, an overview of more typical studies and contexts involving the study of teachers is necessary. Studies of teacher groups have become more popular in recent years (Lefstein et al., 2020) because teacher collaborative groups have been recognized as a potential structure to support school improvement (Horn & Little, 2010). For example, Kazemi and Loef Franke (2004) examined how math teachers' participation in after-school workgroup meetings shifted over time as teachers came together to discuss students' work samples. Horn (2007) compared the conversations of two different teacher groups as they discussed the problems of practice they encountered in their classrooms. Bannister (2015) provided an empirical example of teacher learning within a community of practice by focusing on teachers' framing of various problems of practice. Although the studies differ in terms of methods and goals, they reveal how the study of teacher groups is typically tied to classroom-based problems of practice. RPPs however, have the potential to provide a context for teachers to engage in work that falls out of the realm of classroom. In this study, we explore teacher learning as teachers participate in conversations about problem identification and solution formulation that will not only impact their own classrooms, but all classrooms across the district.

Conceptual framework

This study is grounded in a situated theory of learning which identifies learning as shifts in participation within a community of practice (Lave & Wenger, 1991). In this study, we explore how teachers' participation patterns shift over time as they engage in a routine of participating in district-level instructional improvement meetings. Through these regular meetings, a community of practice is formed between the participants.

We define the teachers' participation in this community of practice as their contributions to the collective reflective and planning discussions. More specifically, we conceptualize these contributions as episodes of improvement work reasoning (EIWRs), an adaptation of Horn's (2007) episodes of pedagogical reasoning (EPRs). Horn (2007) defined EPRs as detailed instances of teacher reasoning, focused on issues or questions about teaching practice. Horn used EPRs to identify conversational category systems, or the classification of things through everyday language. By building on Goodwin's (1994, as cited in Horn, 2007) work on category systems, this allowed Horn to identify teacher talk as one resource for professional learning in a teachers' community of practice. Following a similar line of thought, we too recognize teacher talk as a resource for professional learning. This reasoning aligns with Little's (2002) suggestion that all talk should be treated "as evidence of what is known and as a potential resource for learning" (p. 932).

We define EIWRs as episodes in which teachers exhibit reasoning through talk about the purposes, obstacles, and methods of instructional improvement work. This distinction is necessary because we are interested in what teachers learn about instructional improvement work and not teaching practice. Horn's examples of EPRs clearly illustrate how her definition of EPRs is tied to classroom practice: "I am not using that worksheet because it bores the kids," and "I have a handful of kids who are not successful. How is this going to impact our classes next semester?" (Horn, p. 46, 2007). EIWRs, unlike EPRs, focus on issues outside the classroom that are tied to districtwide instructional improvement efforts. For example, when reflecting on interview data, one of the teachers argues that team members having differing definitions of high-quality math tasks is problematic and should be addressed before further work is done: "…if we still have team members… that are still questioning high quality. Like what does it that look like, I think we definitely need to back up and like assess what we want to continue with because we want to make sure everyone's on the same page." By examining EIWRs, like Horn, we hope to explore professional teacher learning in relation to districtwide instructional improvement work.

Methodology

This study draws on a case study approach (Yin, 2014) and employs an embedded multiple-case study design of four middle school teachers. The data for this study comes from a larger multiyear RPP project, Collaborating

Around Structures, Processes and Instructional Routines (CASPIR), in which a team of researchers from a large Midwestern university collaborates with several local K-8 school districts. The aim of these collaborative efforts is to investigate issues and solutions surrounding math teaching and learning within each district. Each district's RPP team is composed of district administrators, district teachers, university researchers, and university-affiliated math instructional coaches. A subgroup of members from each of these teams meets regularly to plan the work of the respective whole RPP team (see Table 1).

Table 1
Bay School District Subgroup Members

Subgroup Team Member	Role
Frankie	Teacher
Kim	Teacher (Joined after 6th subgroup meeting)
Kristina	University-affiliated Math Coach
Leah	University Researcher
Lenny	Teacher
Mary	District Administrator
Nicole	Teacher

Subgroup meetings are the focus of this study because they prompt teachers to join in rich discussions as they engage in meaning making (Horn, 2007) surrounding problem identification and solution formulation. The four teachers on the Bay School District subgroup are the focus of this study. The district's subgroup also includes a district administrator, one university researcher, and one university-affiliated math coach, all of whom participate in the subgroup's discussions (all names are pseudonyms).

Data sources and analysis

This study utilizes two data sources: video recordings of subgroup meetings and transcripts of subgroup meetings. The subgroup met 15 times over the course of the first academic year of the partnership, for a total of 26 hours. To answer the three research questions, two units of analysis were identified. The two units of analysis allowed us to investigate participation through two different lenses and they also made it possible to analyze the data at two different levels of analysis.

The first unit of analysis is individual EIWRs shared by teachers during subgroup meetings. First, EIWRs were identified in each meeting. Then, EIWRs were coded by topical content so that similar themes can be compared over time (Horn, 2007). We identified six major codes emerging out of the data (Charmaz, 2014): problem identification, norms, individual roles, subgroup role, data, whole group planning, and solution formulation (see Table 2). Some EIWRs fell into only one category, while others fell into multiple. EIWRs can be analyzed individually or collectively. When considered individually, an EIWR allows us to gain an understanding of an individual teacher's reasoning about a specific topic. For example, Table 2 includes an EIWR by Kim about problem identification. From this EIWR, we can see that Kim thinks that looking at the math curriculum is a good starting point for the team as they explore ways to improve the district's math program. When considered collectively, consecutive EIWRs allow us to gain an understanding of multiple teachers' reasoning about the same topic. Since EIWRs allow for the exploration of teacher reasoning and their spoken contributions to collective discussions, this unit of analysis was used to answer the first two research questions (i.e., How does teacher reasoning about improvement work shift over time? and How do teacher contributions shift over time?).

Table 2
Seven EIWR codes used for data analysis

Code	Description	Example
Problem Identification	Talk about issues associated with the district's math program.	Kim: "Well, I think, first we want to look at what we're… our curriculum and what we're teaching day to day."
Norms	Talk about group customs and etiquette.	Frankie: "To kind of piggyback on what Nicole was saying. I was thinking honesty, but also being respectful for each other's ideas, and being trusting that we're all educators and we're all working toward what's best for our staff and our students..."

Solution Formulation	Talk related to formulation of solution(s) that will address issues with the district's math program.	Nicole: "...to me it just to have a conversation with somebody makes them feel like they're not in this by themselves, you know, they're in it together, so I would almost like to have that conversation with Owen (non-subgroup teacher), and then I can even ask additional follow up questions…"
Data	Talk about the use of any sort of data, such as student performance data or the feedback from a teacher survey.	Lenny: "…if they read it and digest it and then I think once they look at the tasks that they can then make those connections to the data, along with the tasks."
Whole Group Planning	Talk about whole group meeting agenda and activities.	Nicole: "We don't want them to make a mission statement."
Subgroup Role	Talk about the function or purpose of the subgroup.	Frankie: "I love that idea of us finding tasks already like pre-selecting them and bringing it to everybody, but I feel like we need to do something else before we do that, like we have to get everybody's brain in the zone..."
Individual Role	Talk about one's own role.	See example from the Solution Formulation row.

Ellipses indicate the removal of words without altering meaning due to space limitations.

Analyzing EIWRs sheds light on teacher reasoning and spoken contributions but they do not allow for the analysis of teacher roles, thus a second unit of analysis is necessary. To identify changes in teacher roles, the other unit of analysis, which we call major decision events (MDEs), were used and this allowed us to answer the third research question (How do the roles teachers take on change over time?). MDEs are important decisions made about RPP work. By important, we mean decisions that move the work forward but are not administrative decisions, like picking the time for the next meeting. An MDE is bound by the start and end of talk about that specific decision so MDEs are very lengthy. Due to space limitations, only excerpts from MDEs (see Table 5) have been included here. Many decisions were made during each meeting, such as what norms the team should use, or what sort of work should be done during the next whole group meeting to move the district's improvement efforts forward. Since we are interested in teacher roles, we only focused on MDEs that concerned what a specific teacher did or will do. To identify changes in teacher roles, MDEs which included teacher roles were identified in each meeting.

Findings

Three major findings arise from our analysis. The first finding is that teachers' reasoning about relevant problems of practice shifted over time (see Table 3). In initial meetings, as the subgroup laid the foundation for districtwide instructional improvement work, they discussed problems associated with the district's math program. During this phase, each of the teachers pointed to a different issue they thought contributed to unsatisfactory outcomes of the math program. In the first meeting, Lenny brought up the lack of cross-grade level collaboration opportunities for teachers. During the third meeting, Nicole spoke about low test scores, while Frankie highlighted the lack of math interventionists and coaches. During subsequent meetings, as they continued to engage in discussion surrounding problem identification, all three teachers zeroed in on the fact that the district's teachers lacked a uniform understanding of high-quality math tasks. Thus, as the teachers engaged in RPP work, their reasoning about issues associated with the quality of their math program shifted, becoming more unified and clearly defined.

Table 3

Teacher's reasoning about issues associated with the quality of the district's math program

Teacher	Early EIWR	Later EIWR
Lenny	**Subgroup meeting #1**	**Subgroup meeting #4**

	"… I know that we've talked about before was talking across grade level teams, but then also, fifth grade being able to spend time [with] sixth grade and vice versa, some of those types of things."	I think that that was the question that was asked in the interview is, what do you think a high-quality task is... Some people [are] like I don't know if I'm right or not... So then, having an opportunity to look at what other people are thinking to refine as a district what we think."
Nicole	**Subgroup meeting #3** "…we just feel that there is a problem and we need to address that problem… the staff knows that there's some sort of… we are seeing them [MAP scores] flat line."	**Subgroup meeting #6** "…teachers have to have a reason why they're picking, choosing something [a task]. Not just because they feel like it…. There has to be a reason."
Frankie	**Subgroup meeting #3** "Like what's going on? Why is this not progressing, not changing? Reading has tons of interventionists and coaches... Well, we've brought up a lot of times, well what about math?"	**Subgroup meeting #7** "…if we still have team members… that are still questioning high quality. Like what does it that look like, I think we definitely need to back up and like assess what we want to continue with because we want to make sure everyone's on the same page."

Data for Kim is omitted because she did not participate in initial meetings.

We also found that the content of teachers' contributions changed throughout the course of the year. As time passed, teachers increasingly offered central input to the collective conversations. Table 4 includes two examples of teacher contributions that are noncentral. In the example from meeting #1, we see Mary, the administrator, share her thoughts about the vision the subgroup is crafting and then Lenny, one of the teachers, follows up by saying she agrees with Mary. In the second example from meeting #2, Leah, the university researcher, suggests how something the subgroup is working on should be worded and two teachers follow up by saying that they agree with Leah. Examples of central teacher contributions can also be seen in Table 4. In the first example from meeting #11, Nicole, a teacher, suggests that a tricky task should be included when the whole group engages in a task analysis activity because this may spark some good conversation. In the second example from meeting #13, Lenny, a teacher, suggests that it is important to remind teachers that tasks which are not considered to be high-quality are still necessary sometimes. When comparing the two earlier teacher contributions to the two latter contributions, it is easy to recognize the difference between the two. Central contributions are a teacher's input into the collective discussion that reveals the teacher's thinking about how things should be done. Noncentral contributions simply amount to teachers agreeing with the administrator's or researcher's ideas by saying something like "I agree," "Yeah," or "True." Not all teacher contributions in the earlier meetings were noncentral, but there are more instances of such teacher contributions during earlier meetings than there are in later meetings. Likewise, there are fewer examples of central teacher contributions in earlier meetings than there are in later meetings. For example, there are five instances of noncentral teacher contributions in meeting #2, two instances in meeting #6, and zero in meeting #15.

Table 4
Noncentral versus central teacher contributions

Noncentral EIWRs	*Central* EIWRs
Subgroup meeting #1 Mary: "Yes. And it kind of goes together. The DLT, the BLT, and the vision. It's kind of like a cycle. That's the way I envision it." Lenny: "*Yeah, I agree.*"	**Subgroup meeting #11** Nicole: "And keep the ones that are a little tricky. Like even that eighth grade one that looked like a MARS task that everybody's going to jump in, kind of like what we did, jump in, and go 'Oh, that looks like a MARS task, that should be high quality.' Well just because it looks like it, it doesn't necessarily mean it is. That would lend itself to that conversation."
Subgroup meeting #2 Leah: "So maybe this should say something like rigorous tasks invite multiple strategies?" Nicole: "*I agree.*"	**Subgroup meeting #13** Lenny: "And one of the things that came up that I think it's important to remember is that just because it's not a high-quality task doesn't mean that it's not still

Lenny: “*Yeah.*”	necessary. And so, I think that that's something that's important, so people don't think that they shouldn't be teaching, you know, that they're only teaching just these lessons...”

Like teacher contributions, the roles teachers took on also changed, becoming more teacher-directed over time. The MDE excerpts from meetings #1 and #2 (see Table 5), show how the early roles teachers took on were directed by others. During meeting #1, Leah, the university researcher, suggested roles for the teachers to take on by proposing that they introduce an activity during the next whole group meeting. The MDE excerpt from meeting #2 also shows Leah suggesting a role for a teacher. In both of those examples, a decision was made about what teachers should do, but the decision was made by someone other than the teachers themselves. The self-directed examples from meetings #14 and #15 show examples of teachers making decisions about the roles they take. In the MDE excerpt from meeting #14, we see Kim, one of the teachers, share how she made the decision to include something in the notes from a whole group meeting because she wanted one of the teachers to feel heard even though she did not agree with the teacher’s thinking. In the MDE excerpt from meeting #15, Frankie, a teacher, shares how she and Lenny picked some days for their group to meet over the summer so that it would be easier for them to invite other teachers to join their group. From these two examples, it is easy to see that as the year progressed, the teachers began to take on more self-directed roles as they began to increasingly make decisions about the work they do as part of the RPP initiative.

Table 5
MDE excerpts illustrating teacher roles

Directed by Others	Self-directed
Subgroup meeting #1 Leah: “So, I'm wondering if the three of you, Nicole, Frankie, and Mary, *if you would introduce this activity to the group* next Wednesday, in the way you think it should be. And what I would offer to do, if this is OK with everybody, and Kim can go back and forth a little bit, just to create the instructions on the first slide, send it to you guys to revise it. And if you guys want to, and if it's ok with you, if you could introduce it to your colleagues and kind of shape it the way you think it should be presented, that would be fabulous. As far as I'm concerned, and if you're willing.”	**Subgroup meeting #14** Kim: “Yeah, and then the, the other part was the multiple choice. Selma (non-subgroup teacher) thought that that should be taken out but, I was trying to explain that we kind of wanted to have a start, it was like a pretest posttest. So, we wanted to have a starting point, so we knew where to go. But she was still very uncomfortable with having that multiple choice. She’s like, ‘The teachers are going to want to know,’ but I’m like, ‘That’s the whole point.’ So, we kind of, we’re at a deadlock there. But again, *I wanted to give her voice to be heard, so I typed it in* the Google doc.”
Subgroup meeting #2 Nicole: “Yeah, why start from scratch and start researching new images when we have all of these images already.” Leah: “Yeah, *you sound like somebody who might want to introduce this activity* to your colleagues.”	**Subgroup meeting #15** Frankie: “About that too about trying to reach out and recruit. *We had, Lenny and I, had gone through our calendars to pick some weeks that worked* for us to try to create a doodle poll, to send out to at least the people who have already committed. And we thought that maybe *if we can narrow down some time, then we could approach somebody from K-3* and say these are the three or four dates that we're going to meet. And that might not sound so threatening, like ‘Oh, we're going to meet 10 to 20 hours this summer, can you do it?’ Maybe if we said we're going to meet this day for two hours and this day for three hours, then maybe they'd be willing to commit.”

Discussion and implications

In this study, we set out to explore teacher learning in the context of an RPP through a situated theory of learning lens, in which learning is defined as shifts in participation within a community of practice (Lave & Wenger, 1991). The clear changes in the contributions teachers offered during subgroup meetings and the changes in the roles teachers took on suggest that teacher learning did in fact occur during the first year of the partnership. The findings show that by the end of the first year, teachers made more central contributions during planning meetings and they also began to increasingly take on self-directed roles. Therefore, we can say that the teachers learned how to become productive members of an RPP.

A closer examination of teachers' contributions and roles reveal that the teachers not only engaged in work that is outside their normal daily teaching practice, but we also see that teachers talked about issues not traditionally associated with teachers. Content and pedagogical knowledge are usually associated with teachers (Hill et al., 2018), yet in this study we see teachers engage with ideas that fall outside the realm of those two categories as they took part in districtwide instructional improvement efforts, discussing issues not directly tied to the issues of daily teaching practice. Teachers are not generally responsible for, nor trained in addressing issues at the district level. However, here we see teachers doing exactly that. The RPP context provides teachers an opportunity to engage in nontraditional roles (Farrell et al., 2021) which then creates an opportunity to explore teacher learning in this unique context. Further study of this teacher learning context and how it relates back to what we already know about structures for teacher learning or teacher collaboration is necessary.

Our findings not only offer insight into teacher learning, but they also provide insight into how RPPs function. Addressing major educational problems of practice takes time, thus, one of the things that we know about RPPs is that they are not considered mature partnerships until the third year (Farrell et al., 2021). In our findings, we see one example of the time requirement to do this sort of collaborative work. The teachers did not speak of the same issue, in this case, the lack of a unified understanding of what high-quality math tasks are amongst all district staff, until the seventh meeting. In our study, the subgroup teachers, who participated in planning and steering the work of the whole RPP team, did not come in with a unified understanding of the issue that they should address. Instead, it took several meetings of rich conversation for the teachers to develop a collective understanding of which problem to tackle. In fact, all the teachers did not reach a unified understanding of the main issue that needed to be addressed till the seventh subgroup meeting. This provides one example of how long it took an RPP group to agree upon which direction to take.

While looking for shifts in teacher contributions, the intentional moves the researcher and the administrator made to directly involve the teachers in the subgroup's work became evident. During the first meeting, Mary the district administrator said, "I am looking to build teacher capacity. And starting to, you know, in their buildings, be able to take on more of an integral leadership role." Mary's intention to empower teachers can be also seen in a comment she made later. After sharing her ideas, Mary said, "I feel like I am talking a lot, and I do not want to talk too much," as a way to invite more teacher input. Leah, the researcher, also made multiple moves throughout the year to encourage the teachers to take more of an active role in the work they are doing. For example, during the fourth meeting, Leah said, "Hey, I have done way too much talking so I am going to let you guys take the lead," as a way to encourage the teachers to take charge. One of the defining characteristics of RPPs is a shift of power to those who do not traditionally have it (Farrell et al., 2021). In our study, we see that the traditional power holders, the university researcher and the district administrator, made conscious efforts to empower and involve the subgroup teachers in the group's work. By the end of the first year, we see major changes in teachers' contributions and roles, however, to what extent the efforts of the university researcher and the district administrator facilitated the shifts in teacher participation is not clear. Future studies should explore characteristics of RPPs that successfully engage teachers in the partnership's work. The researcher's intentional moves to invite active teacher participation also provide insight into how researchers can create productive working relationships with teachers, which is something we know little about (Coburn & Penuel, 2016). From this example, it seems like continual reminders and encouragement by a university researcher can help teachers meaningfully engage in the partnership's work.

This revelation about the intentional moves the researcher and administrator made to fully engage the teachers also offers a design implication for RPPs that involve school administrators and teachers. Administrators and teachers typically fall into two very different spots on the hierarchy of power since administrators usually hold all the decision-making power. Furthermore, teachers are rarely positioned as peers to administrators when it comes to decision-making at the district or even school level. Thus, if researchers want to successfully simultaneously engage teachers and administrators, they have to account for this traditional power dynamic. In this case, the district administrator was interested in empowering teachers and creating a space where teachers could participate equally in the decision-making process, so the researcher did not have to take any further action to create such a space. However, even though the administrator was open to sharing decision-making power with the teachers, the researcher still needed to facilitate the transition through which teachers become more active participants. In this case, that transition happened through two specific actions. As mentioned previously, the researcher would pause speaking at times and would then invite teachers to provide input. The researcher also initially volunteered the teachers for roles they were to take on during whole group meetings. RPPs may have the potential to disrupt traditional power dynamics but this disruption may not come to fruition if researchers don't actively work toward it. Therefore, researchers must first be aware of the traditional power dynamics that are present in the RPP context and then they have to be intentional about disrupting them.

This study explored changes in teacher contributions and roles only during the first year of an RPP, so future studies should explore such changes over longer periods of time and they should also investigate how such changes relate to the RPP's overall success.

What do Log-Files and Learning Outcomes Reveal about Developmental Differences in Self-Regulated Learning with Serious Games?

Abstract: To explore self-regulated learning (SRL) processes with log-files and learning outcome data across developmental levels in game-based learning environments (GBLEs), 26 high school and 26 undergraduates learned microbiology playing Crystal Island as their test scores and log-file data about scientific reasoning activities were collected and analyzed. Results show that undergraduates were more likely to solve a mystery than high school students despite no significant differences in test scores. The frequency of SRL for undergraduates was greater than the frequency for high school students, but the proportional duration of SRL within total duration showed that both groups utilized different strategies. Moreover, developmental levels were related to how likely students were to solve the mystery. Our findings emphasize not only an important theoretical contribution by demonstrating how SRL models should take developmental variations into account, but also educational implications for GBLEs by showing the advantages of providing scaffoldings across developmental levels.

Introduction and theoretical background

Learners often struggle to use effective cognitive, affective, metacognitive, and motivational self-regulated learning (SRL) processes while learning (Winne & Azevedo, 2022). To help learners, educational games have been developed to foster effective SRL (Cloude et al., 2022; Dever et al., 2020; Taub et al., 2020). Beyond understanding the increase of motivation and engagement game-based learning environments (GBLEs) provide, it is critical to investigate our assessment of student learning and the effectiveness of their learning processes as they relate to the contents of GBLEs. Learners may acquire knowledge from GBLEs by interacting with game system elements (e.g., non-player characters, instructional materials). However, these elements may be designed to help learners to enjoy the game, rather than leverage the elements for SRL during GBLEs (Taub et al., 2020). To evaluate the degree of learning in GBLEs, diverse methods can be utilized including game scores, external assessments, and embedded assessments. For example, game scores may reflect if students acquired targets or overcome obstacles during game while external assessments may be post-test scores based on multiple choice questions (Ifenthaler et al., 2012). However, despite efforts to establish best practices for evaluating the effectiveness of GBLEs, there is still a lack of scientific rigor (All et al., 2021). Since assessment after learning in GBLEs which frequently concentrates on outcome and not process may neglect significant changes during the learning process (All et al., 2021), evaluating GBLEs with only post assessment might not be sufficient.

To deal with this issue, trace data can be utilized since trace data can uncover fundamental learner interactions for learning design, identify specific patterns or strategies learners use, and determine key predictors of specific behaviors (Azevedo et al., 2018; Owen & Baker, 2020). Specifically, trace data in GBLEs have the potential to dynamically evaluate learning and provide feedback in ways that are not achievable in traditional learning settings (Nietfeld, 2018). For instance, diverse data could be collected from learner's interactions with some elements in GBLEs such as time spent reading scientific text and collecting evidence, the number of times interacting with non-player characters, the quality of hypotheses generated when collecting and testing data, etc. (Dever et al., 2020). Utilizing various types of data collected with GBLEs can lead to better insight or understanding of learning processes in broader and deeper ways, especially when it comes to identifying the underlying cognitive and metacognitive self-regulatory processes (Taub et al., 2017).

Even though many previous studies have pointed out the effectiveness of GBLEs, there are few studies focusing on learners' SRL from their developmental perspectives (Plass et al., 2020). In addition to this, research related to SRL tends to concentrate primarily on younger children and academic achievement (Bjork et al., 2013), leaving open the question whether different developmental groups would perform tasks with the same SRL processes. Through the previous studies presenting that learning outcomes and learners' metacognitive skills were varied across learners' developmental levels (Mayer, 2019; Veenman et al., 2004), it can be expected that learners' SRL processes and learning outcomes are different based on learners' developmental levels in GBLEs. For example, previous research has shown that undergraduate students typically know and can use more learning strategies and fair better when it comes to the metacognitive monitoring accuracy (Taub et al, 2020), but there has been no comparison across developmental levels and their use of self-regulatory skills with serious games. More studies related to students' developmental levels on SRL with GBLEs are needed to understand differences in self-regulatory behaviors and to subsequently use the data to provide more adaptive scaffolds in order to meet learners' individual needs based on their developmental levels. Therefore, the purpose of this study is to enrich the understanding of SRL based on developmental levels by using log-files and learning outcome data. Our study focuses on whether there are developmental differences in students' learning outcomes with two indicators and SRL processes with log-file data in GBLEs.

Theoretical framework

SRL assumes learners monitor and regulate their cognitive, affective, metacognitive, motivational, and social processes (Azevedo et al., 2022; Winne, 2018). Specifically, students can engage in a variety of cognitive, affective, metacognitive, and motivational self-regulatory and reflective processes during GBLEs to ensure they are learning efficiently (Taub et al., 2020). Game-based learning concentrates on the complexities of game design and requires a theoretical framework focused on specific learning processes that are used during SRL (Plass et al., 2020). As such, this study focuses on SRL suggested by Winne and Hadwin's (1998, 2008) model of SRL. According to this model, learning occurs throughout a series of four phases: 1) task understanding, 2) setting goals and planning, 3) engaging in learning strategies, and 4) making adaptations. Each phase which is cyclical and may occur simultaneously allows learners to engage in different self-regulatory processes. While this theory makes assumptions about underlying cognitive and metacognitive processes, it does not make predictions about GBLEs across developmental levels.

Current study

This study aims to further understand developmental differences with self-regulated learning using log-files and learning outcome data during game-based learning. As such, we ask:

RQ 1) Are there differences in learning outcomes (test scores vs. solving mystery) based on learners' developmental levels with Crystal Island? Based on previous studies showing that learning outcomes were different across developmental levels in traditional learning environments (Mayer, 2019; Veenman et al., 2004), we expect that undergraduates will perform better on post-test and solving a mystery during the game compared to high school students.

RQ 2) Are there differences in the frequencies of scientific reasoning activities based on learner's developmental levels during Crystal Island? Considering that learners metacognitive skill increases with age (Veenman et al., 2004) and that undergraduate students can know and utilize more learning strategies (Taub et al., 2020), we expect undergraduate students more often use scientific reasoning activities while learning with Crystal Island.

RQ 3) Are there differences in the proportional duration (compared to total play time) of scientific reasoning activities based on learners' developmental levels during learning with Crystal Island? Considering that learners metacognitive skill increases with age (Veenman et al., 2004) and that undergraduate students can know and utilize more learning strategies (Taub et al., 2020), we expect undergraduate students will spend higher proportion of duration within total game play duration engaging in scientific reasoning activities while learning with Crystal Island.

RQ 4) What is the likelihood that a learner's ability to solve a mystery is related to learner's developmental level during learning with Crystal Island? Prior studies show that learning outcomes are varied across developmental levels (Mayer, 2019; Veenman et al., 2004) and that the correlation between students' use of cognitive strategies and academic performance became significantly stronger across developmental levels (Dent & Koenka, 2016). Therefore, we expect that the likelihood of a learner solving a mystery will be significantly related to developmental levels.

Method

Research context: Crystal island

Crystal Island is a game-based learning environment designed to teach microbiology and scientific inquiry skills. During the game, participants play the role of a medical detective investigating a mysterious infectious disease outbreak on a remote island. To solve this mystery, participants are required to identify a type of disease (e.g., influenza or salmonellosis), a type of infection (e.g., viral or bacterial), a cause of the infectious disease (e.g., egg, bread, etc.), and a solution treatment for the disease (e.g., rest or vaccination). To do so (see Figure 1), participants read complex texts (e.g., articles and books) and posters and then summarize the texts, as they gather important clues. These clues can be collected by finding objects to put into their backpacks while exploring the island, by scanning the objects with hypotheses that they create, and by communicating with non-player characters (NPCs) (e.g., a nurse, patients, a virus expert, etc.) through dialog selection. Based on this evidence, they complete a diagnosis worksheet to solve a mystery. Thus, SRL is fundamental in Crystal Island to foster content knowledge in microbiology and scientific reasoning abilities (Dever et al., 2020).

Figure 1
Activities in Crystal Island to support scientific reasoning and learning about microbiology

BACTERIAL REPRODUCTION

Bacteria reproduce asexually by binary fission, which results in the production of two cells exactly like the parent cell.

Sample complex text (e.g., book)

Sample poster

Objects found in Crystal Island including food items

An inventory in backpack to collect objects

A scientific scanner to test objects

The process of scanning objects by choosing hypotheses

Communication with non-player characters (NPCs) through dialog selection

Diagnosis worksheet to be used throughout the learning session to record data, findings, hypotheses, etc.

Data collection and analysis

Data were collected from 26 high school students (*M*_age=16.04; *SD*_age=0.34; 65% female) and 26 undergraduate students (*M*_age=19.73; *SD*_age=1.49; 69% female). The data for the high school students were collected in a classroom setting while the data on the undergraduates were collected from individual students in a university research lab. On average, high school students spent 48 minutes (*SD*=6.96) and undergraduate students spent 87 minutes (*SD*=22.50) with the game.

This study focuses on two ways to assess learning outcomes in GBLEs (game scoring and external assessment) distinguished by Ifenthaler et al. (2012). We operationalize game scoring by determining if participants solved a mystery while playing Crystal Island. External assessment was operationalized as performance on the post-test about knowledge of microbiology while accounting for pre-test knowledge. Pre-test scores and post-test scores were calculated as normalized change score to alleviate pre-test score biases (Marx & Cummings, 2007).

Log-file data collected during game play was extracted and several activities were analyzed to compare across development levels. Through these data, we identified how many times students interacted with scientific reasoning activities in the GBLE (e.g., opening articles, books, posters, scanning objects, opening backpacks to gather clues, communicating non-player characters (NPCs) through dialog selection, and opening a diagnosis worksheet). Also, we analyzed the proportion of the duration that students interacted with the scientific reasoning within their total amount of the game play.

Results

Learning outcomes

A *t*-test using participants' normalized change scores did not show any significant differences (t=-1.92, p=0.061) between high school students (*M*=0.12, *SD*=0.23) and undergraduate students (*M*=0.23, *SD*=0.22) (see Table 1). Despite no significant difference in pre-test scores, there was a mean difference in normalized changes scores for each group, but the huge variabilities in both groups lead to no statistically significant difference between developmental levels. That is, both developmental levels showed evidence of learning about the same with Crystal Island.

When it comes to a difference in solving the mystery based on developmental levels, a 2X2 chi-square test revealed a significant difference in the distribution of students who solved the mystery correctly across development levels ($\chi2$=16.65, p<.01) (see Table 2). More specifically, 24 undergraduates (92%) solved the mystery compared to only 10 high school students (38%). This suggests that outcomes or performance-based goals were different, but microbiology content knowledge acquisition was not.

Table 1
Pre-test and normalized change scores across developmental levels

	High school students *M(SD)*	Undergraduates *M(SD)*	*t*	*p*
Prior knowledge (pre-test scores)	10.15 (48.33%) (2.09 (9.95%))	11.15 (53.10%) (2.44 (11.62%))	-1.59	.119
Normalized change score (pre-test and post-test scores)	0.12 (0.23)	0.23 (0.22)	-1.92	.061

Note. *p<0.05

Table 2
Frequency of participants who solved the mystery

	High school students (*N*=26)	Undergraduates (*N*=26)
Mystery solved	10 (38.46%)	24 (92.30%)
Mystery unsolved	16 (61.54%)	2 (7.7%)

Frequency of scientific reasoning activities

A *t*-test was calculated using a Bonferroni correction for multiple tests ($p<0.05/6 = 0.008$) and showed that undergraduates had significantly greater frequencies of opening complex scientific texts (*M*=23.00, *SD*=6.79; *t*=-4.90, *p*<.008), scientific posters (*M*=13.88, *SD*=5.48; *t*=-4.79, *p*<.008), scanning evidence with a scientific tool (*M*=26.85, *SD*=15.62; *t*=-5.81, *p*<.008), opening backpack with objects (*M*=100.31, *SD*=38.03; *t*=-6.33, *p*<.008), communicating with NPCs through dialog selection (*M*=59.65, *SD*=18.87; *t*=-3.52, *p*<.008), and opening diagnosis worksheet (*M*=29.81, *SD*=15.92; *t*=-6.29, *p*<.008) compared to high school students (see Table 3). Overall, frequently using these game features related to scientific reasoning by undergraduates is indicative of their high use of SRL strategies compared to high school students.

Table 3

Summary statistics in frequency of scientific reasoning activities

Activities	High school students *M(SD)*	Undergraduates *M(SD)*	*t*	*p*
Complex text (Books and articles)	15.12 (4.59)	23.00 (6.79)	-4.90	.000*
Poster	7.46 (4.10)	13.88 (5.48)	-4.79	.000*
Scanning	7.88 (5.74)	26.85 (15.62)	-5.81	.000*
Backpack open	47.69 (18.79)	100.31 (38.03)	-6.33	.000*
Dialog selection	44.46 (11.31)	59.65 (18.87)	-3.52	.001*
Diagnosis worksheet	9.00 (5.59)	29.81 (15.92)	-6.29	.000*

Note. **p*<0.008 after Bonferroni correction for multiple post-hoc comparisons

Duration of scientific reasoning activities proportionate to total game play time

High school students played the game for an average of 48 minutes (*SD*=6.96) while undergraduate students played for an average of 87 minutes (*SD*=22.50). A t-test was calculated using a Bonferroni correction for multiple tests ($p<0.05/4 = 0.012$) in order to compare the two groups' time spent on each scientific reasoning activity within their total game play time. Considering each proportion of activities within total game play duration (see Table 4), high school students spent a higher percentage of their time reading complex text such as articles and books (*M*=43.77, *SD*=11.91; *t*=2.88, *p*<.012) during the game compared to undergraduates. This can help explain our earlier finding such that it appears high school students were focused more on the concrete knowledge acquisition through reading and information gathering while undergraduates were focused more on solving the mystery and potentially using scientific reasoning skills. There was no significant difference between high school students and undergraduates in the proportions of poster (*p*=.165) and diagnosis worksheet (*p*=.020). However, undergraduates had a significantly greater proportion of durations on scanning objects (*M*=2.33, *SD*=1.10; *t*=-3.70, *p*<.012) compared to high school students while they played. These results show that undergraduate students spent a considerable amount of time within the total time on gathering clues by scanning objects to test hypotheses for solving the mystery rather than reading complex text or poster while playing games while they learned in GBLE.

Table 4

Summary statistics in proportion of activities within total game play duration

Activities	High school students *M(SD)*	Undergraduates *M(SD)*	*t*	*p*
Complex text (Books and articles)	43.77 (11.91)	34.95 (10.05)	2.88	.006*
Poster	1.06 (0.63)	1.29 (0.54)	-1.41	.165
Scanning	1.30 (0.92)	2.33 (1.10)	-3.70	.001*
Diagnosis worksheet	6.45 (3.29)	8.90 (4.02)	-2.41	.020

Note. **p*<0.012 after Bonferroni correction for multiple post-hoc comparisons

Predicting solving the mystery based on learners' developmental level

A binomial logistic regression analysis was conducted to determine the likelihood that a learner solves the mystery illness given the learners' developmental levels with Crystal Island (see Table 5). The likelihood of a learner solving the mystery was significantly related to learners' developmental levels (p<0.025). In other words, the higher learner's developmental level was, the more likely the learner was to solve the mystery. Specifically, the odds of a learner solving the mystery were 0.05 times greater if the learner was an undergraduate student.

Table 5
Logistic regression analysis of solving mystery by developmental levels

Predictor	β	*SE*	*Wald*	*df*	*p*	e^{β}
Constant	2.49	0.74	11.40	1	0.001	12.00
Developmental levels	-2.96*	0.84	12.40	1	0.000	0.05

Note. e^{β}= exponentiated beta or odds ratio; *SE*=standard error; **p*<0.025

Discussion and conclusion

Despite the panacea of using GBLEs to solve STEM learning issues, we argue that these environments do not always lead to significant learning outcomes because students have different self-regulatory skills. Secondly, GBLEs designed on the principles of agency or without instructional scaffoldings need to be examined especially when it comes to understanding how students of different ages use and learn from them. Results found that undergraduate students were more likely to solve a mystery than high school students with Crystal Island although there was no significant difference in learning gains measured by test scores. The fact that both age groups did equally well on the post-test learning outcomes could reflect the fact that high school students are not that much younger than the undergraduates. High school students are currently learning about biology while it may have been several years since undergraduates learned about biology. Furthermore, high school students may have spent just enough time while undergraduates spent significantly more time (to activate their prior knowledge) while learning with Crystal Island. The significant difference in solving the mystery in Crystal Island can be understood through investigation of learner's SRL processes with previous studies (Nietfeld et al, 2014; Sabourin et al, 2013) showing that students' use of SRL was different based on their learning gains or performances. For instance, Nietfeld et al. (2014) found that the use of SRL strategies was positively related to performance in Crystal Island by revealing that learners using more SRL strategies had higher game-score performance.

Furthermore, there were significant differences in the use of SRL strategies depending on developmental levels. In terms of frequency, undergraduates not only opened books, articles, posters, or diagnosis worksheets more often than high school students, but also scanned food items by opening backpack more often than high school students. Also, the undergraduates spent more time communicating with NPCs through dialog selection than high school students. Considering the higher frequency of dialog selection compared to the frequencies of scanning and opening backpack for both groups, we can assume that high school students did not have huge difficulties communicating with non-player characters (NPCs) while they played compared to university students. This can be explained by the fact that NPCs may be easier to find than other clues such as food items which students need to explore carefully to find on the island. For example, some specific items (e.g., cheese) which give students important clues for the mystery might be hard to detect for the students since they only can find certain food items when they open a refrigerator during the game. They then must develop a hypothesis about that food item (usually through talking with NPCs) and then scan the items that may be important. This difficulty to utilize game elements for high school students is also supported by the frequencies of scanning and backpack open. Compared to university students, high school students showed significantly lower frequency in scanning and opening backpack. This shows that high school students might have difficulties finding clues while playing or did not make it as much of a priority as reading materials about microbiology. To scan food items to formulate hypotheses in Crystal Island, students need to find and put food items into their backpack or change the items, which means that the more they find the food items, the more they can open backpack and scan. These features led to a low possibility to solve the mystery, presenting that learners' use of SRL strategies with GBLEs is varied based on their developmental levels.

The difference in frequency of activities might not be surprising since undergraduates spent more overall time playing Crystal Island than high school students. This is also true that undergraduates spent greater durations on all elements related to scientific reasoning while they played Crystal Island compared to high school students. In addition to this, the fact that there was no significant difference between normalized change scores showed that high school students performed just as well as on the post-test with less time compared to undergraduates. However, considering the proportion of each activity within total game play duration, the results could provide a different new perspective in the students' SRL abilities. Although high school students showed a greater proportion of durations on reading articles and books within their total game play duration compared to university students, they were less likely to solve the mystery. Unlike high school students, college students spent a significant proportion of time gathering clues and formulating their hypotheses through scanning objects, which led to a higher possibility to solve the mystery. This shows that high school students might lack the same level of SRL abilities such as planning or monitoring the difficulties of utilizing game elements while learning in GBLEs. This is consistent with the previous study showing that learner's metacognitive skillfulness increases with age (Veenman et al., 2004). However, we also acknowledge that the main goal of these two groups could be driving their action differences. That is, if high school students were more focused on learning as much as they could about microbiology (knowing there is a test at the end of the game), they would not be as focused on the game goal of solving the mystery. In comparison, the undergraduates appear to be more focused on solving the mystery as shown by the larger duration time spent doing other activities (e.g., scanning objects with a scientific tool to test hypotheses). Both goals were presented to the learners, however, our results suggest that each developmental group focused on a different aspect of these two goals. Task-wise learning about microbiology is simpler and more straightforward while developing non-explicit scientific reasoning skills through exploratory learning is more abstract and requires more metacognitive skills and abilities.

According to the binomial logistic analysis, older learners (i.e., undergraduates) are more likely to solve the mystery than high school students. This is supported by the results of the previous studies indicating that learning outcomes were different for different age groups (Mayer, 2014; Veenman et al., 2004). Specifically, Mayer (2014) presented that GBLEs influenced learning outcomes differentially across learner's developmental levels with different effect sizes; the effect size for college students was higher than secondary school students.

An important theoretical implication of our work is a general suggestion for models to incorporate the role of developmental differences in the assumptions of monitoring and strategy use (e.g., Winne's [2018] COPES and SMART schemas should have different assumptions based on learner's developmental levels). Our work provides empirical evidence to further support the idea that even when close in age, SRL processes may have developmental differences that impact one's efficiency of learning with GBLEs. Moreover, our findings have implications for designing various types of scaffolds in GBLEs, depending on developmental levels. Since the effects of learning at the age groups can be different through theoretical background and instructional strategies (Dignath & Büttner, 2008), utilizing differentiated scaffolds based on developmental levels in GBLEs can lead to more effective learning. For instance, high school students may benefit from procedural scaffolding to help them to fully explore learning elements in GBLEs or to foster increases in the frequency and duration of specific activities which might be useful for learning and scientific reasoning. In contrast, undergraduates may benefit from more conceptual and metacognitive scaffolds given their higher frequency and duration of activities (Lim et al., 2023).

Despite these results worth noting related to developmental differences of SRL in GBLEs, this study still has several limitations for future studies. This study focused on two different age groups related to developmental differences with the small sample size. In order to understand specific SRL patterns from various age groups with developmental differences, more studies comparing the diverse groups with developmental differences are needed. Furthermore, while log-file data were effective in measuring learning processes in this study, a deeper understanding of developmental differences of SRL in GBLEs can be strengthened with the consideration of more diverse trace data (e.g., eye-tracking, facial expressions of emotions, think-aloud protocols, etc.). Along with the rich trace data, a mixed methods approach and semi-structured interviews can be supplemented to lead to a richer and better-informed explanation of learners' SRL and decision making within GBLEs. Future research should compare multimodal multichannel data to provide a comprehensive understanding of the temporally-based developmental differences across age groups and design intelligent, adaptive scaffolding in GBLEs for STEM.

Abstract: This paper reports on the recent developments of the Critical Action Learning Exchange (CALE) project, an international network of Professional Learning Communities (PLCs) where teachers are supported to design and enact new forms of critical action curriculum (Carvalho et al., 2021; 2022). CALE curriculum is dedicated to empowering students as transformative agents when facing socio-environmental issues (i.e., climate change, social justice, pandemics, economic inequality, etc.) that affect themselves and their communities. This paper presents a comparative analysis of activity-theoretical formative interventions in CALE communities in China, India, and Canada. For each of these enactments, we present the professional development designs and evaluate the efficacy of the interventions by analyzing teacher participation and resulting curriculum products. We close with a discussion of sustainable teacher PLCs and the next steps in the CALE research.

Introduction

This paper reports on the recent developments of the Critical Action Learning Exchange (CALE) project (Carvalho et al., 2021; 2022). CALE is an international network of Professional Learning Communities (PLCs) where teachers are supported to design and enact new forms of critical action curriculum. CALE teachers join professional development workshops and other activities designed to facilitate the collaborative creation and exchange of lessons, resource sharing, and reflective discussions about critical pedagogy and practice. CALE curriculum is dedicated to empowering students as transformative agents when facing socio-environmental issues (i.e., climate change, social justice, pandemics, economic inequality, etc.) that affect themselves and their communities. This paper presents a comparative analysis of activity-theoretical formative interventions in CALE communities in China, India, and Canada, where the third version also included a wider international component. We adopted the formative intervention methodology, which has been advanced by Engeström and his colleagues as a design-oriented approach that intends to enhance the agency of practitioners and students in the design process (Engeström et al., 2014). An important value of formative interventions is their sensitivity to the context of the intervention, making this approach responsive to cultural, historical and systemic factors.

This work endeavours to deliver on the promise of Freirean pedagogy (Freire, 1970), which has deep relevance to education in the world today, but whose implementation is considerably challenging, for it demands from teachers a radical paradigmatic shift in regards to classroom practices (Duncan-Andrade & Morrell, 2008; Tinning, 2002). Our work takes on the challenge of making this pedagogical approach more practicable and accessible to teachers within diverse international contexts. CALE responds to this challenge by offering a framework for critical action (Carvalho et al., 2021; 2022) as well as scaffolds to support the design and enactment of critical action curriculum. However, we also require a professional development approach that allows us to work closely with teachers in any given context, and to be responsive to that context in order to support teachers develop their own understandings and applications of these ideas. This has led to the establishment of distinct teacher professional communities in India and China, as well as a third multi-cultural online community, centred in Canada. For each of these enactments, we present the professional development designs and evaluate the efficacy of the interventions by analyzing teacher participation and resulting curriculum products. We close with a discussion of sustainable teacher communities and the next steps in the CALE research.

Theoretical framework

Critical action education

The *critical action* component in CALE's name refers to the behavioural component in the Freirean concept of *conscientização*, which can be understood as the process of acquisition or development of critical consciousness. Critical consciousness is conceptualized as comprising three mutually reinforcing elements: critical reflection, critical motivation, and critical action (Watts et al. 2011). Critical reflection refers to the process of learning to distinguish *culture* from *nature*, or in other words, of acquiring a perspective that allows for social constructs and structures to be perceived as questionable and malleable, instead of being regarded as inescapable, naturally imposed realities. Critical motivation is an individual's perceived capability and commitment to contribute to social advancement through the reinvention of social structures that enable unjust, oppressive, harmful, or unhealthy conditions. Finally, critical action refers to the engagement in action dedicated to producing socio-political changes perceived as conducive to more just and healthy conditions (Freire, 1973; Watts et al., 2011). We employ the term Critical Action Education to refer to educational practices that aim to support students through the process of *conscientização*, so they are empowered as transformative agents capable of assuming an active stance when facing complex socio-environmental issues that affect themselves and their communities.

Professional learning communities (PLCs)

For many teachers, incorporating Critical Action into their practice would constitute a significant departure from their more traditional modes of teaching and learning. To support such a paradigmatic shift, CALE organizes PLCs, in which participants learn from one another, stay in touch during their efforts, and share and exchange ideas and resources. The research literature describes professional learning communities (PLCs) as groups of professionals collaborating in an ongoing, learning-oriented, critical interrogation of their practice (Toole & Louis, 2002). Hipp et al. (2008) argue that success in establishing such a community “requires informed and purposeful action based on learning”. Slotta (2002) argued that successful communities require three elements: critical mass, critical identity, and critical function. PLCs may offer a powerful context for professional development of teachers, with opportunities for knowledge building, collaborative design and exchange of resources, new curricula and teaching practices, social and emotional support, and continuing development of one's professional identity.

Members of any CALE PLC participate in synchronous and asynchronous professional development activities to advance their understanding of critical action education and engage in designing new curriculum. Over the past two years, CALE researchers have supported PLCs in the design of activities, resources, and technology environments to support their activities. This sustained effort has allowed us to test our design ideas through cycles of implementation with teachers, and continuously improve our framework to help the PLCs become sustainable communities of practitioners (Carvalho et al., 2021). Participants can find technology support within the CALE online environment, where they can share their experiences designing and enacting new critical action lessons and engage in further authoring, discussion, and resource sharing.

In the CALE PLCs, our goal has been to understand how educators' critical interrogation of their practice leads to transformative action. This question has guided our development of distinct interventions for several PLCs that respond to sociocultural contexts. The underlying questions we have asked in developing these formative interventions, which include workshops, small group design teams, and individual reflections, were: (a) What interventions are productive in a particular context? (b) How can those interventions be conducted to generate actionable knowledge that enables transformation of participants' teaching practices? (c) How can our workshop model help teachers become critical action educators?

Method

Activity-theoretical formative intervention

The Activity-Theoretical Formative Intervention methodology (Engeström et al., 2014) relies on two epistemological principles: double stimulation (Vygotsky, 1978) and the principle of ascending from the abstract to the concrete (Ilyenkov, 1982). The first stimulus is typically a conceptual *mirror* that "reflects" the problematic situation experienced by practitioners, while the second is a series of external artifacts, or *visions*, that support or sustain the transformation of practices (Engeström et al., 2014). These stimuli help participants to visualize and advance toward their collective zone of proximal development (ZPD), which is “the distance between the present everyday actions of the individuals and the historically new form of the societal activity that can be collectively generated as a solution to the double bind, potentially embedded in the everyday actions” (Engeström, 2014, p.

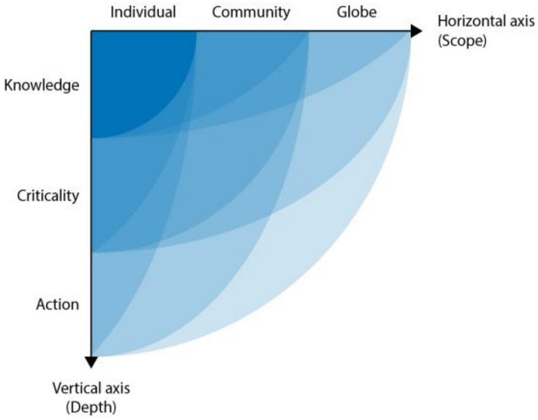
138). Below, we describe three elements of our formative interventions: (1) a framework for designing critical action curriculum, (2) a knowledge base with information on four pedagogical approaches suitable for Critical Action Education; and (3) a design guide to scaffold teachers' development of new curricula.

We report on the enactment of three formative interventions in teacher PLCs in distinct cultural contexts. Two of these communities are deeply embedded in their own local contexts (i.e., country, local region, culture and economy, educational system, students, families): 68 teachers in southern China are engaged in designing climate action curricula; and 60 elementary and middle school teachers in Bangalore, India, coordinated by local partners, are creating curriculum to address a variety of issues confronted by students and their families. The third is an online community of 45 teachers, centred in Canada, but with members joining from several other countries, including the US, the Netherlands, Colombia, Turkey, Egypt, and Iran. This third PCL, therefore, has an important multicultural context that must be taken into account. However, the pedagogy and discussions in this PLC were largely focused on North American and European contexts, and many participants arrived from the International Baccalaureate schools, thus sharing a common, largely western, curriculum and teaching framework.

CALE curriculum design framework

The first conceptual artifact that served as a *vision* for the communities was the CALE curriculum design framework, which intends to help teachers move from theory to practice in designing activities, lessons, units and courses that incorporate critical action. The CALE framework has six components, divided into two axes (Figure 1), and includes design questions elaborated to help teachers advance their designs in these two dimensions. The vertical axis includes components intended to move students "deeper" towards action: from knowledge, to criticality, to action. The horizontal axis increasingly expands the scope of the students' critical action: from the individual, to the community, and finally to the globe.

Figure 1
Components of the CALE curriculum design framework



Vertical Axis: (1) *Knowledge*: Critical Action begins with an understanding of the issue being addressed. This goes beyond helping students acquire knowledge within a domain, to help them develop abilities to acquire, assess, and build new knowledge. (2) *Criticality*: The process of social transformation implies a value judgment on the forces and structures that affect the issue and how they might constrain or empower their actions. (3) *Action*: Critical Action Education aims to reinforce students' sense of agency and to empower them as transformative agents, shifting their perspective from "that's just the way things are" to "that's a problem that I can act upon."

Horizontal Axis: (1) *Individual*: This component aims to provide opportunities for students to explore their intersections with the issue, helping each student create personal meaning and purpose in learning and develop a sense of direction. (2) *Community*: aims to help students work collaboratively, and recognize the value of community in any action. (3) *Globe*: Problems such as climate change, social injustices and economic inequalities are global, and the efforts to find solutions must transcend borders. This component aims to help students recognize and understand how the problems—and their actions—affect the whole world.

Pedagogical approaches to critical action education

A second aspect of the *vision* offered to teachers in all PLCs were four approaches to Critical Action Education. While there are many approaches within critical pedagogy, and this remains an active area of research in the learning sciences, we sought to define a set of approaches in terms of: (1) how it implements critical action, (2) the requirements and roles for the teacher, (3) richly described examples, and (4) design guidelines. For each approach, we collected additional examples and resources, as well as discussions from the CALE community. These approaches and their associated content were also instrumental for the communities to construct a vision of possible ways to incorporate Critical Action Education into their practices. The approaches are as follows:

Arts-based Critical Action, which often includes a written and introspective component (e.g., artist's statement), offers a vehicle for students to communicate abstract or complex ideas, express their identities, and tell their stories in an intellectually and emotionally engaging way. One effective strategy is that of theatre games, such as the "Theatre of the Oppressed" (Boal, 1992), which engages participants in activities such as the Forum Theatre, where members of the audience are encouraged to intervene by coming on stage to replace the protagonist. Through this process, participants are able to assume a critical stance on the situation being enacted and experience the challenges of implementing their envisioned changes (Monfort, 2003). In another example, students created an interactive drama that addressed issues related to one's body image and social pressures to conform to beauty standards (Howard, 2004). As a result, students created knowledge and renegotiated meaning about personal behaviours and engaged in critical reflection on cultural norms and expectations.

Critical Making includes but is not limited to drawing, painting, sculpting, crafting cardboard creations, folding origami, performing puppetry, and making with e-textiles, paper circuits, Arduinos, Raspberry Pis, micro:bits, littleBits, and web tools (Gerstein, 2019). Critical making emphasizes the situated, context-specific, and material selection aspects of the design process (Ratto, 2011). This approach helps teachers and students explore the relationship between process and end product; the role of collaboration; the entanglement of theory and practice; the relationship between art, craft, design, and making; and connections between makers and communities, among other things. Critical Making contributes toward critical action by putting the human experience above the technological one and making a conscious effort to make space for thoughts, emotions, and feelings to permeate and leverage the resources available at the maker's disposal.

Storytelling has been used to empower and engage students, allowing them to craft their own stories that connect learning with their own lived experiences (Burk, 2000). In addition, storytelling can bring forward multiple perspectives and artistic interpretations, allowing teachers to build on the breadth of ideas in support of an inclusive learning environment. As a Critical Action approach, storytelling allows students to adopt a critical perspective in which they interpret and respond to the world, in relation to a particular topic or issue, adding their voice to the communities in which they may otherwise feel silent or silenced. One study reported by Rish (2022) asked students in India and Mexico to create graphic novels related to their experience of the Covid-19 pandemic, with an emphasis on their local neighbourhoods and households. This study reported differences in complex systems thinking abilities between students who viewed the pandemic as a primarily personal issue versus those who viewed it as a collective issue. This work also explored different representations of community and the extent to which community played a role in the students' pandemic experience.

Youth-Led Participatory Action (YLPA) can empower students by engaging them directly with the socio-environmental issues that concern them personally, as well as their families and local communities (Ozer, 2017). Through YLPA, young people engage directly with organizations and members of their community to generate positive transformations and feel empowered by adding their own voices. YLPA is a cyclical process of learning and action in which students work in small groups or individually to conduct their own research, brainstorm ideas, survey community members, and develop designs that respond to problems they care about. A range of YPLA strategies has been used by teachers and scholars to engage students in personally meaningful community engagement. In Civic Planning and Youth Design, students work with city planners or other stakeholders to offer their own design ideas for problems that directly concern them. This strategy involves engaging youth in thinking about design and partnering with some "authentic client" (i.e., in the real world) that listens to their designs and potentially gives input. For example, in the Y-PLAN project (McKoy & Vincent, 2007), teachers engage their students with city planners to address real problems. Working in small design groups, students advance possible solutions, which are ultimately presented to the city planning partners, with the prospect of potentially influencing specific planning projects.

Design guide

In addition to offering teachers the CALE framework and critical action approaches, we prepared a technology scaffold that could be used by design teams in developing a critical action lesson of their own. This scaffold, which has employed different platforms depending on the context (i.e., paper, Google Doc, web forms), is referred to as the CALE Design Guide. It includes seven major sections: (1) *Overview of Team*, including members, topic and age level of students, and creative team name; (2) *Getting Started*, in which teachers reflect on issues confronting their students, such as climate change or food insecurity, and define a critical action challenge that can guide their design; (3) *Learning Goals*, in which they articulate the specific content, competencies, and perspectives they wish students to gain, how the curriculum will empower students, and what some of the main activities will be; (4) *Approaches and Resources*, which could be one or more of the CALE approaches, links to similar designs, websites, other projects, or student resources; (5) *Fitting the Framework*, in which the two dimensions of the CALE framework (with three levels each) are outlined in terms of guiding questions to help teachers fit their designs into those elements; (6) *Outline of Activities*, in which they further explicate a sequence of curriculum activities; and (7) *Enactment Plan* in which they articulate some details of when the curriculum will run, what class of students, any remaining challenges or concerns, and final to-do list.

Outcomes

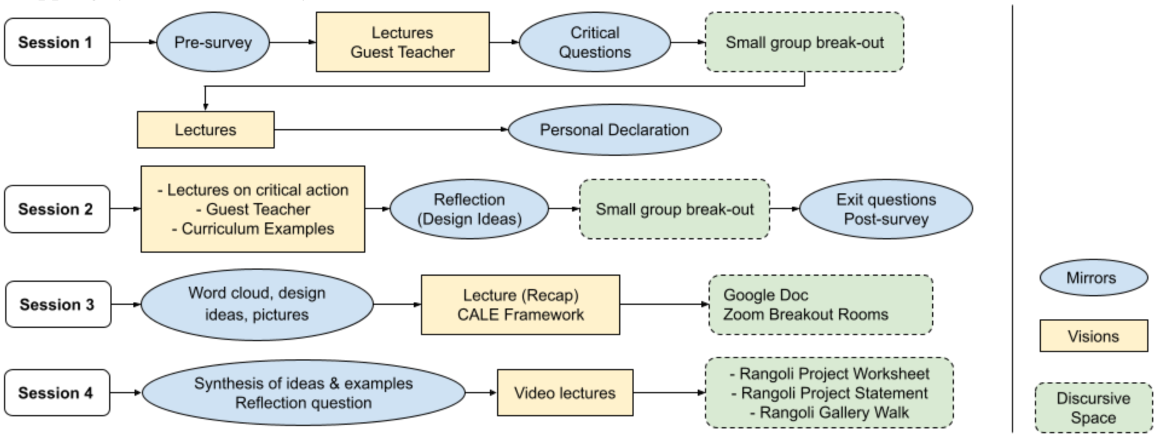
Design of PLC activities

While the elements above are common to all CALE teacher participants, the remaining elements of our formative intervention varied amongst the three PLCs, reflecting how the communities conceptualized their collective ZPDs, the efforts the communities made to realize their visions, and the outcomes of teacher design efforts. The sections below describe the activities of each PLC and map them in terms of the conceptual components of activity-theoretical formative interventions (i.e, *mirrors, visions,* and *discursive spaces*).

India

The formative intervention in India was organized in four sessions (Figure 2). One distinction from the interventions in Canada and China was the inclusion of paper handouts that aimed to help participants interrogate their current educational approaches and reinforce the sense of identity as a professional learning community. The first two sessions were planned to function as *mirrors* of participants' current teaching practices and offer possible *visions* in the form of lectures, examples of critical action curriculum, and discussions with a teacher guest. The final two sessions included a representation of the ideas and understandings of participants as *mirrors* and reiterating the discussion of *visions* to reinforce the pathway toward transformations.

Figure 2
Mapping of activities in the formative intervention in the CALE PLC in India

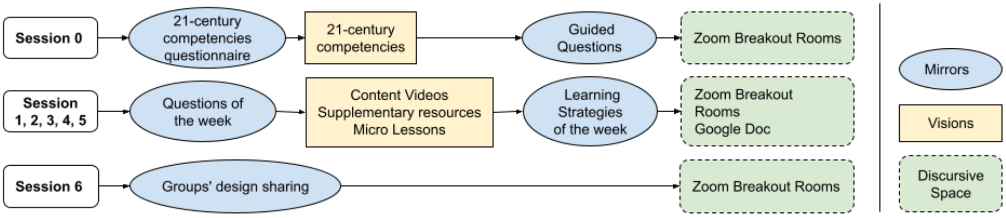


China

The first stimulus that showed up for the China PLC, from data gathered in pre-surveys and interviews, was to break the epistemological commitments of exam preparation. While educators in China reported being experienced with problem- and inquiry-based approaches, these were characterized as being largely extracurricular, given the heavy focus on lecture and exam preparations at the secondary level. We organized six one-hour workshop sessions that were conducted after a week of pre-workshop discussions and introductions (Figure 3). The aim of the pre-workshops was to function as a *mirror,* aiming to engage teachers with new ideas about 21st-century competencies. In the following five sessions, a pattern was implemented with detailed and specific expectations of topics and activities. Weekly questions served as *mirrors*, content videos served as resources, and "micro-lessons" functioned as *visions*. Reflective questions on learning strategies were presented as a second *mirror* of each week. Zoom meeting rooms and Google Docs were provided as a *discursive space*.

Figure 3

Mapping of activities in the formative intervention in the CALE PLC in China

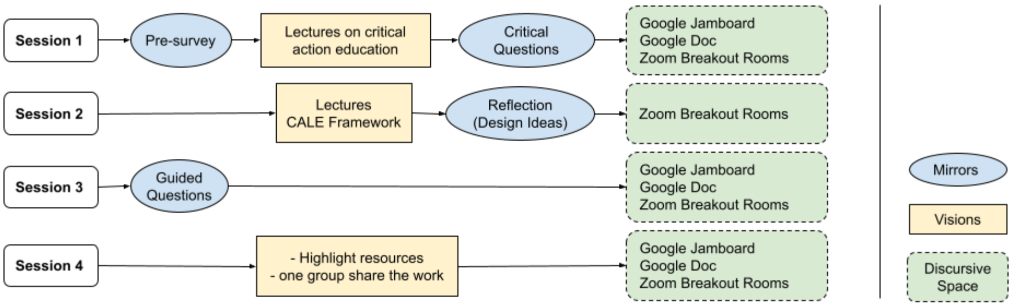


Canada

This community was established amongst climate change educators who were interested in designing and implementing “climate action” lesson plans to address environmental issues. Four sessions were carried out in the summer workshop (Figure 4) A pre-survey and critical questions functioned as *mirrors*; lectures and resources on critical action pedagogy and the CALE pedagogical framework for designing critical action curriculum were offered to generate *visions*, and Zoom breakout rooms, Google Jamboard, and Google Docs functioned as a *discursive space*. Since educators of the International online PLC were interested in understanding the importance of changing teaching practices relating to climate change education and student climate anxiety, the socio-cultural context was adjusted to provide critical questions to help educators conceptualize and respond to these interests.

Figure 4

Mapping of activities in the formative intervention in the CALE PLC in Canada



Teacher progress within the CALE PLCs

In a previous paper (Carvalho et al., 2022), we identified two main *contradictions* in activity systems for all three communities: (1) the demanding curricular expectations encumber a deep exploration of topics needed for critical inquiry; (2) teachers experience conflicting pressures between the demand to equip students with “21st-century competencies” (e.g., critical thinking and collaboration) and heavy content standards measured by standardized tests. Participants found this working hypothesis consistent with their experience and articulated their *conflict of motives* in terms that express their anxiety about being expected to incorporate 21st-century competencies and critical action into their practice, while also facing barriers to do so. Finally, communities were able to articulate their *collective ZPD*. Teachers in the Chinese PLC identified a need for enhancing students' communication and collaboration skills. Participants of the Indian PLC manifested a particular interest in the arts and critical making as approaches for critical action. Teachers in the international PLC focused on climate anxiety and climate action and identified the need for ideas that promote collaboration, the exchange of ideas and resources, and a sense of community.

In Summer 2022, we have successfully run another workshop in each of the three PLCs, and guided teams of teachers in designing and enacting CALE curriculum projects. While this is a longitudinal study of PLCs, and not all teachers have yet enacted their designs, here we can report on those who have participated.

India projects

(1) *Rangoli Festival (6 teacher-designers)* - Students of the whole school used the traditional art form of rangoli (i.e, coloured drawings with sand and other materials) to discuss a series of socio-environmental issues. They will discuss and explore issues such as the Covid-19 pandemic, gender inequality and climate change, and will design rangolis that represent their critical reflection on these themes.

(2) *Impurities Toward Purity (2 teacher-designers)* - 7th-grade students engage in the Critical Making approach to explore wastewater management. They develop and test a water filtration system and

conduct water quality tests, interview people lacking access to clean water and present their solutions to the community.
(3) *Rainwater Harvesting (2 teacher-designers)* - 9th-grade students explore rainwater harvesting as a solution for the lack of access to clean water, design and install rainwater collectors and investigate their effectiveness.
(4) *Data Pirates (2 teacher-designers)* - 10th-grade students investigate the correlation between educational level and income in their community. Students design and conduct a survey of their community and learn concepts of statistics while discussing possible career paths and how they are remunerated.
(5) *Equality of Opportunity (2 teacher-designers)* - 7th-grade students investigate the consequences of inequality of access to education while learning about fractions.
(6) *The Ultimate Guide (3 teacher-designers)* - 10th-grade students use storytelling to explore the link between human activity and climate change and possible actions to minimize environmental degradation.

China projects

(1) *Design and creation of future Cantonese architectural model (2 teacher-designers)* - 11th-grade students investigate the characteristics of Cantonese architecture and develop ideas for adapting buildings to respond better to climate change. Over 500 students will showcase their solutions to the school community.
(2) *Prosperity and Trauma: Mangrove forests on Dongguan coast (2 teacher-designers)* - A transdisciplinary unit engages students in an inquiry-based project on the mangrove communities in the Dongbao estuary in Dongguan. Students will discuss ways to protect the coastal mangrove.
(3) *Vegetable Garden Plan (7 teacher-designers)* - Students of grades 4 and 5 work on an inquiry-based project to investigate how food is produced and devise ways to make food production more efficient and sustainable.
(4) *"Low-Carbon" Food Plans (3 teacher-designers)* - Students of grades 4 and 5 investigate how food consumption affects carbon emissions.
(5) *Creating a "zero waste" campus (8 teacher-designers)* - Students of grades 7 and 8 investigate the garbage production of households and devise ways to minimize it.

Canada projects

(1) *The Community of Trust (3 teacher-designers)* - Pre-service teachers engage in arts-based or critical making lessons so they can learn how they can use those methods themselves. They explore concepts of critical pedagogy to learn how to empower their students and support critical action.
(2) *Water Action Decade (7 teacher-designers)* - Engineering undergraduates take a chemistry course with a focus on water-related SDGs. Using the YPLA approach, students explore issues such as the impacts of fertilizers on waterway systems, the impacts of salting the road on the environment around it, etc.
(3) *The Trees of Uxbridge (7 teacher-designers)* - 9th-grade students take a lesson that connects Citizen Science with the SDGs and Ecology. They investigate how they can influence changes in their community as they seek to recover from the F2 tornado that impacted their town.
(4) *Stories of Food From My Family (1 teacher-designer)* - Students use storytelling and arts to explore socio-environmental issues related to food, such as the culture of food, where our food comes from, how our food is prepared, food insecurity, climate change and food, etc.
(5) *Water Heroes (1 teacher-designer)* - Kindergartners learn about the importance of water conservation and marine biodiversity and how they can help preserve the oceans.
(6) *How will our children find water and clean air? (2 teacher-designers)* - Students of grades 8 to 11 explore the effects of climate change in Iran and the middle east. They use critical making to design possible engineering solutions and create a podcast to communicate their findings to their communities.

Discussion and conclusion

In this study, we have applied cultural-historical formative intervention as a methodology to understand how PLCs can facilitate teacher professional development in critical pedagogy, and how teachers progress in such communities. In order to help teachers incorporate Critical Action Education, CALE PLCs scaffold teachers' work as curriculum designers, while responding to local cultural contexts and preserving teachers' agency. This study helps to identify important attributes of such communities, including how they can accommodate cultural differences. The teachers in each CALE PLC are now entering their third year of engagement in classrooms. While not all CALE teachers have yet succeeded in putting their lesson designs, there are dozens who have done so, and many who have enacted their lessons twice. While our three PLCs may not yet be fully established, there is in each of them a core group of teachers who are engaged and reflective practitioners. These teachers are committed to critical action pedagogy, and many will return for next summer's workshop. Still, we are concerned with how to sustain such a community, and what forms of evidence can be shared that engage all members in reflection and peer support. This will be one focus of our future work. Another will be to study the impact of CALE curriculum on students, in terms of the six components of the CALE framework. Technology developments will include scaffolds that allow teachers to share and modify curriculum designs, socially annotate designs, and curate resources. We will also establish partnerships for the various critical action projects.

Arguing Racialization: Race Talk Dilemmas, Disciplinary Learning, and Student Socialization in Doctoral Coursework

Aireale J. Rodgers, University of Wisconsin - Madison, arodgers4@wisc.edu

Abstract: Despite being a consequential site for graduate student learning and socialization, doctoral-level coursework remains undertheorized in higher education literature. Even less explored is how faculty pedagogy in coursework shapes students' understandings of their discipline's racialized histories and legitimated practices. Drawing on insights from critical theories of racialization and Cultural Historical Activity Theory, this paper highlights the contours of a race-talk dilemma and its implications for doctoral student learning and joint activity in a political science Ph.D. course on international law and politics.

Introduction

People describe doctoral education as being marked by a shift from being a consumer to a producer of knowledge. However, the truth is that learning is central to pursuing a Ph.D. In addition to amassing extensive content expertise to carry out original research, doctoral students are expected to internalize, master, and perform the legitimated ways of knowing and being in their discipline (Rodgers et al., under review). Indeed, socialization, or "how to behave, what to hope for, and what it means to succeed or fail" (Tierney, 1997, p. 4), remains the dominant framework for conceptualizing learning in doctoral education (e.g., Walker et al., 2008). Faculty evaluate students' engagement with the valued tools and artifacts that are valued in their field via various milestones in a doctoral student's developmental trajectory (e.g., coursework, qualifying examinations, dissertation defense) (Posselt, 2020; Rodgers et al., under review). If doctoral education functions as the "academy's own means of reproduction" (Shulman, 2008, p. xi), we might ask what is being reproduced and how?

One possible answer is racial meanings. Racial meanings are the taken-for-granted beliefs and (mis)understandings people have about race. In the racial capitalist and colonial U.S. context, where race is one of the most salient social identities, systems of power, and sources of stratification, race talk is omnipresent (Thomas, 2015), and racial meaning-making is a routine form of joint activity in formal learning environments (Nasir & Hand, 2006). Pollock (2009) introduced the concept of race talk to describe everyday conversations about when and how race matters. Ironically, despite race talk being a typical dimension of classroom joint activity, engaging in race talk remains a threatening activity that causes feelings of discomfort, stress, and danger for many people (Bryan et al., 2012; Leonardo & Manning, 2017). The tensions that arise during race talk in classrooms can generate race talk dilemmas, or situations wherein the discussion of race can become contentious (Pollock, 2009; Thomas, 2015). As these dilemmas emerge, members of a classroom community decide whether to speak and what to say. For faculty, whom I perceive to have a pedagogical responsibility to develop students' capacity for generative racial meaning-making and racial literacy, the implications of their interventions are deeply consequential to doctoral student learning and socialization. This paper highlights the contours of a race-talk dilemma and its implications for disciplinary learning and joint activity in a political science Ph.D. course on international law and politics. Mainly, I focus on one faculty's pedagogical move to 'play a devil's advocate,' discussing the importance of race in their discipline.

Literature review

Traditionally, faculty have conceptualized the primary aim of doctoral education to be the socialization of their graduate students to enter the professoriate in their discipline (Walker et al., 2009). Moving beyond pursuing intellectual expertise and content knowledge, a focus on formation in doctoral education encompasses "the scholar's professional identity in all its dimensions" (Walker et al., 2009, p. 8). Scholarly formation often occurs by way of apprenticeship, which is considered "the signature pedagogy of doctoral education" (Golde et al., 2009, p. 54). Apprenticeship "focuses on a system of interpersonal involvements and arrangements in which people engage in culturally organized activity in which apprentices become more responsible participants" (Rogoff, 1995, p. 143). Through interacting with faculty members in a variety of settings, doctoral students learn how to become members of their disciplines. For instance, students in a political science Ph.D. program learn to *become* political scientists (explicitly and implicitly) through their engagement with faculty in classrooms, research groups, and other professional settings. In this way, faculty-student interaction is "the lynchpin of doctoral education" (Anderson & Anderson, 2012, p. 249).

Despite being central to doctoral student learning, socialization, and scholarly formation, doctoral coursework and faculty teaching therein have largely been understudied (Khost et al., 2015). The scant literature on doctoral coursework has emphasized that the premise of learning in many graduate-level social sciences and humanities courses revolves around conversation. Khost and colleagues (2015) described the role faculty play in graduate seminars as "orchestrat[ing] conversations about texts, figures, periods, and methods" (p. 20). As students engage in classroom discourse, faculty often encourage students to raise questions, make assertions, and extend the readings in new and exciting ways. Yet, the discourse that students leverage in classrooms is about much more than content knowledge; classroom discourse serves a socializing function and is guided by a set of occluded norms (Cazden, 2001). Within higher education, faculty, who help form students' scholarly identities, often set the stage for what is considered acceptable forms and frames of talk and sensemaking (Author, 2022). Thus, studying how faculty support or impede certain forms of talk and meaning-making is an important topic for empirical inquiry.

Conceptual framework: Racialized cultural-historical activity theory

Racial meaning-making is a dynamic sociocultural process that can and should be understood as a *learning* process. Race is a sign system (Wertsch, 2007), "…made real, in part, through the dynamic systems of thinking and speech that reinforce the hegemonic racial values mediating people's interactions with the world" (Leonardo & Manning, 2017, p. 20). In this way, racial meanings do not just exist—they are made and re-made as people engage in cultural practice over time. People *learn* the diverse meanings of race in various settings, a vital setting being classrooms.

Given how power unfolds in classroom settings, paying attention to the instructor is vital for understanding classroom learning. Even in the most democratic classroom environments, instructors are imbued with positional power and authority over students. Instructors are considered 'a more knowledgeable other,' someone who has a greater level of proficiency and can therefore support the learning and development of their students. In some instances, that assertion is accurate. For example, faculty generally have more experience and expertise with the subject matter they teach than their students (Postareff et al., 2006). However, given that People of Color remain underrepresented in the professoriate (NCES, 2020) and race talk is often not considered central to the intellectual work of most disciplines (Bryan et al., 2012), faculty are rarely the experts on race in university classrooms (Jones, 2021). Because faculty directly influence the shared sensemaking that happens in classroom contexts, who faculty are, what they believe, and how they approach the work of their discipline matter for student learning and the social organization of joint activity within classrooms. Surfacing how faculty subjectivity, including the various epistemological, axiological, and ontological commitments faculty hold regarding race and racism, influences classroom learning is essential to transforming doctoral education. While CHAT scholars have emphasized that tools and artifacts are products of cultural practice (Engeström, 1999), many scholars underemphasize the cultural histories and subjectivities of the subject (i.e., the people acting agentically within activity systems) and how they impact joint activity. I needed a conceptual framework that put subjects (e.g., faculty) and their subjectivities *in* the shared work of teaching and learning.

R-CHAT pairs the best parts of CHAT with wisdom from scholars of racialization (Omi & Winant, 2015; Saha, 2018) to provide important affordances for articulating the nuances of racial meaning-making in learning environments and theorizing its implications for supporting or impeding learning. A key distinction in R-CHAT's model of classroom joint activity emphasizes the role of faculty and their subjectivity in mediating what gets taken up in the shared work of classroom learning and development. Instead of using a triangle to symbolize joint activity, I employ the metaphor of a prism. A prism is a transparent, triangular figure that refracts or disperses a light beam. As light enters the prism, it undergoes a process of refraction, becoming bent and separating the light into wavelengths as it exits the other side. R-CHAT (reference Figure 1 below) illuminates how racial meanings (like beliefs about racial hierarchy, the fallacy of white supremacy, and antiracism) relate to the subject matter learning faculty and students do together in doctoral-level courses. Notably, I situate faculty's subjectivity as the lens of the prism—it refracts the racial meanings they reflect onto the activity system. As students and faculty collectively engage in classroom learning (via discourse and interaction), those meanings are often refracted—bent, extended, and shifted in ways that produce multiple new meanings. Moreover, by understanding CHAT's focus on community, division of labor, and rules as racialized, I consider questions like: Who gets included/excluded as members of an academic or classroom community? Who does the work of raising race-conscious perspectives in class? Is the division of labor equitable, or is it racially stratified? What are the rules? Whom might the rules disproportionately impact? Are the rules equitably enforced?

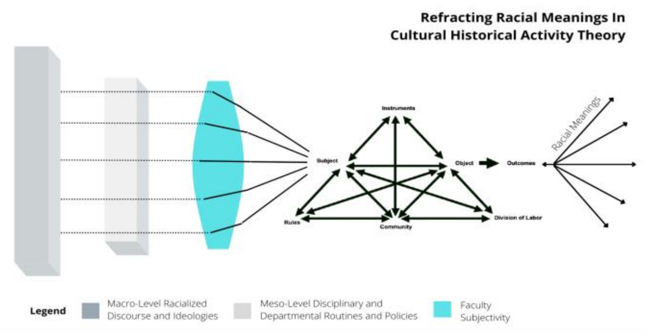
R-CHAT Framework Visualization



Methods

This paper presents findings from one case in a more extensive comparative case study (Yin, 2018) of racial meaning-making in doctoral coursework. I collected data in three Ph.D. courses at an R-1 university in the Chicagoland area in the Fall of 2021. Because I was interested in understanding how faculty's racialized identities and their perceptions of the salience of race to their course content might inform their pedagogy, I sampled based on those criteria. The final sample included a Black woman sociologist, a Native woman and White man learning scientists, and a White woman political scientist. While all faculty appreciated how race and power impact their fields, the faculty Women of Color expressed explicit commitment to critiquing racism in their teaching. In contrast, the White faculty were more agnostic about how race and racism informed their pedagogy. Additionally, there were 29 student collaborators across all three courses, with great diversity in students' race, gender, and nationality.

Site & context

This manuscript focuses on the International Law and Politics course taught by Dr. Berr, a tenured white woman professor in the Political Science and Legal Studies departments. Having served as a professor at her institution for over 20 years, Dr. Berr is an internationally recognized scholar of international law and politics, capitalism, and the global economy. This doctoral-level seminar was offered as an in-person, 3-hour per-week elective course in the Political Science department. The course enrolled seven students: four in the Political Science Ph.D. program, two students from a local university, and one visiting scholar who was auditing the course. All seven students identified as men. Interestingly, and perhaps appropriate for an international relations (IR) course, students were from all over the world: Argentina, Canada, Palestine, India, and Kazakhstan, to name a few places. In fact, only the instructor and I were from the United States.

Data collection

To gather thick and rich descriptions of how race talk unfolded in the moment-to-moment joint activity of classroom learning, I focused on three primary data collection approaches: faculty interviews, classroom observations, and student interviews.

Faculty interviews. I engaged in two interviews with faculty – pre-interviews and think-aloud interviews. I conducted pre-interviews the summer before observations, which allowed me to sample with the faculty's teaching philosophy and course design/structure in mind. These pre-interviews not only supported the final case selection but they also informed the development of observation protocols for each course.

In March 2022, I conducted 30-minute retrospective think-aloud interviews with three of the four faculty members I observed (2). Faculty and I reviewed video clips of their teaching where I asked them to interpret what was happening in each clip, provide insight into their pedagogical moves, and reflect on what, if anything, they might do differently in the future. Overall, these interviews allowed me to highlight the interpretive frames that faculty collaborators used to make sense of how their pedagogical moves mediated racial meaning-making. These data were an essential complement to the observation data and boosted the trustworthiness of my analysis.

Classroom observations. With consent from all faculty and student collaborators in the political science course, I attended and audio-/video-recorded approximately 22 hours of classroom teaching and learning throughout the semester. I used one camcorder to capture all class discussions. I chose to record class sessions because video constitutes a robust information source for ethnographic and microanalytic studies of teaching and learning (Jordan & Henderson, 1995). Using video sources as data in my study allowed me to gather a repeated and up-close analysis of joint activity in doctoral coursework. I also took detailed fieldnotes during class sessions, paying particular attention to how faculty leveraged tools like the curriculum, multimedia, and guest speakers to mediate learning and racial meaning-making, as well as the social organization of racial meaning-making in classroom discourse. Observations were spread throughout the academic term.

Student Interviews. I conducted interviews with students across the courses I observed. While all students were invited to participate in a focus group, I employed purposeful sampling techniques to ensure racial and gender diversity. Of the nine total student learners enrolled in the course, five students agreed to participate in one-on-one interviews. During these conversations, I prompted students to share their perceptions of faculty's equity-minded praxis. I asked students to describe their faculty's teaching philosophy and their overall learning experience in the class. I also inquired about whether and how issues of racial meaning were being generatively taken up in classroom practice.

Data analysis

For data analysis procedures, I drew specifically on interpretive traditions stemming from studies of classroom discourse analysis and ethnography traditions (e.g., Cazden, 2001; Erickson, 2004). I began by coding all the interview data. I coded the interviews thematically using critical narrative analysis (Souto-Manning, 2014) in NVivo, a popular qualitative research software. Critical narrative analysis uses key principles from critical discourse analysis (van Dijk, 1989) and narrative analysis (Wortham, 2001) to study how discourse becomes real and enacted in people's lives. For this study, I am particularly interested in how faculty and students' discussions of race have implications for doctoral student learning and socialization.

I utilized the constant comparative approach to data analysis (Fram, 2013), going through cycles of open, axial, and selective coding. I conducted close, line-by-line readings of all transcribed data to arrive iteratively and inductively at my coding scheme. Then, I refined extant codes into concepts during axial coding by aggregating some codes and theorizing relationships between other codes. As I digested collaborators' rich reflections, I wrote analytic memos while coding to keep stock of ideas and connections throughout the data analysis process. Before creating broader case narratives through the selective coding process, I switched my attention to video analysis.

I ultimately took a narrative approach to video analysis in which the "[researchers'] aim is not to make the complex simple, reducing data to theorem. The aim is to make the complex understandable" (Derry et al., 2010, p. 12). I selected relevant clips for analysis by reviewing my fieldnotes and memos across class sessions to identify instances I previously noted as moments in which I perceived racial meaning-making was occurring. Once I noted a few salient instances of racial meaning-making in each course, I reviewed all video footage of the class session in which that moment took place. As I watched the recordings, I created content logs featuring a detailed breakdown of the discourse and interaction in the class session in 2-minute chunks. The content logs supported cycles of interaction analysis, enabling me to identify "hot spots" of activity and choose the final focal events upon which I focus my findings (Jordan & Henderson, 1995, p. 43). Notably, I used R-CHAT to illuminate the interactional dynamics of racial meaning-making in each video. Then, I turned to a finer grain of analysis—the focal events.

Focal events are "stretches of interaction that cohere in some manner that is meaningful to the participants." (Jordan & Henderson, 1995, p. 57). In my study, focal events are short moments of interaction—particularly intervention—by the faculty member that facilitates (or sometimes impedes) racial meaning-making. I identified one focal event in the Political Science course, then I transcribed the dialogue and began analysis by creating playscripts (Goodwin & Heritage, 1990). I sought to understand and appropriately re-story collaborators' shared sensemaking, recognizing it as a collaborative endeavor—a critical emphasis in interpretive research.

Findings

We enter at Week 6 of the academic term, where the topic of the class session was the Racial Foundations of International Law. Students voted to choose the focus of the last four weeks of the academic term from a list of potential topics. Many students were excited to discuss readings on race and international relations and international law (IR/IL) because the discipline, broadly, has not seriously contended with this topic. Lin, a visiting student taking the course through a partnership with a local university, told me, "Usually, when we're talking about international relations and international law, the scholarship was mostly Western-dominated. Race was not really an issue that they wanted to talk about. They focused more on the generic principles like justice and the role of law." Dr. Berr also mentioned in an interview that the discipline of international law "is very clearly extremely Eurocentric, very associated with empire." Moreover, as Daniel, a Ph.D. student in political science and a self-identified critical scholar, shared, "…in political science, the expression in the U.S., the dominant epistemological framework is that of positivism, and the way in which questions are framed, using a positivist framework is—often erases the kinds of concerns that I have and many others completely out of view."

In summary, there was broad agreement that the role of whiteness and the legacy of white supremacy in the field generally get taken for granted by many IR/IL scholars.

According to the syllabus, this class session was designed to interrogate "…whether the entire international legal and political system is predicated upon sustaining a racial divide." Students read six articles focusing on race and IR/IL and came to class prepared to engage in discussion. As class began, Dr. Berr sat in her usual spot at the head of the table in the seminar room. After doing their routine get-to-know-you icebreaker, Dr. Berr began her lecture rather unusually – with hesitation. In our pre-interview, I asked her to describe her teaching philosophy. She quipped, "I am opinionated, as all academics are." Then she elaborated with a sense of deep assuredness:

> I do feel that I create room to disagree with me, but I'm not gonna not—you're gonna know where I stand on issues. That's a pedagogical choice. That can also—I've got the authority. I've got the power. I have the knowledge. I have a huge amount of knowledge. This is totally in my area of expertise so disagreeing with me is really hard.

Nevertheless, Dr. Berr begins this lesson on racialization in IL/IR by telling students, "This topic…it's not like I'm…it's pretty new to me, too, [1-second pause] it shouldn't be, but it is, and so I thought, 'Gosh, I should've asked if you guys wanted to lead a session." This discursive move suggests a sense of hesitation regarding her experience, and by extension, her expertise, with talking about race in IL/IR. Moreover, the second part of her statement seems to yield the role of expert to students. There was one student in particular whose research focused on racialization and colonialism in IL/IR, and Dr. Berr repeatedly referenced his expertise throughout the class session – a move that the student noted as being peculiar.

To spark conversation, Dr. Berr posed a provocation to students: "I wanna learn what you guys learned, discovered, revealed, talked for the first time about the racial foundations of the stuff we've been talking about for five weeks now. That's never mentioned – the racial foundation. It's in there, but we haven't talked about it at all." After listening to some students' reflections on racial capitalism and the pervasiveness of racial inequality in the international order, she made an intervention using a particular pedagogical move – to play devil's advocate. MacDougall and Baum (1997) defined a devil's advocate as "a person who tests a proposition by arguing against it" (p. 536). Notably, people who play devil's advocate generally do not agree with the position they are arguing. Instead, it is used as a tool to test the strength of an argument. Dr. Berr interjected in the discussion to say:

1	>I think I'm gonna be the devil's advocate.<
2	That's how I'm gonna do it,
3	because I want you guys to address how it's important to name the racial foundations.
4	To do that,
5	I'm going to tell you that there's <u>no</u> racial foundation to this.
6	It's not that international law for a long time has not denied that it has its civilized/uncivilized-
7	<in fact,> it was written in, and in terms of barbaric-
8	and that international law was civilizing.
9	That was the legitimating narrative,
10	that all involved told themselves that they were doing.
11	It's not just that it permitted, it <u>legitimated</u> imperialism.

She then turned to mention slavery, telling students,

13	The other thing to say is slavery also existed in a non-racialized form.
14	>I mean<, the Vikings used slavery.
15	The spoils of war were that you won, and everybody became a slave.
16	You won against your European neighbor, and they all became a slave.

In line 13, Dr. Berr argued that "slavery also existed in a non-racialized form." This move to position slavery was a direct attempt to separate slavery from race and racism, thus preempting the use of slavery as a marker of racial foundations of IR/IL. From a CHAT perspective, this move effectively created a rule that the reality of slavery c was no longer a form of 'evidence' that students could use in their argument. She then restated her question, "why is it impossible not to think about the racial dimensions of [international law] and important to bring it in?"

Admir, a Political Science student, tried to answer this question. He told Dr. Berr:

> I feel that there is a difference of treatment that is obvious if we try to look and actually compare which countries are poor, which countries are suffering. There was, for example, a—just as a hypothetical, would the international reaction to South Africa be in the form of economic sanctions if it was a Black majority dominating a white minority?

Dr. Berr at first empathized saying, "I hear you saying that," but then she went back into character and rebutted:

> I can see that you're saying that the pattern is self-evident, but what is the problem with ignoring the pattern? Because I can give you alternative facts—alternative narratives…I don't wanna call 'em alternative facts—alternative narratives that actually are true. I think they're true. They just are whitewashed.

Putting aside the revelatory nature of first accidentally calling alternative narratives "alternative facts," Dr. Berr emphasized that those narratives are still true (read: legitimate forms of argumentation) despite being whitewashed. Admir nodded and said, "True, but that is the problem with whitewashing is that there is less recognition of what is actually driving—" At that moment, Dr. Berr quickly cut Admir off to ask, "Why do we have to name the racial foundations of international law?" Admir then let out an exasperated chuckle and responded:

> Because then that is not the causal variable that is actually influencing what is happening. It's not like internal process of law that's influenced this. It's also an implicit structural understanding of race that influences your decision with various—we all are here in that monocausal goal, but I feel that recognizing that is important if you wanna actually understand the consequences of policy.

Note that at this point, Admir leaned on a postpositivist framing to make his argument – pointing to the efficacy of a causal variable. Still, Dr. Berr seemed to be unsatisfied with his argument. The focal event ended with her cutting Admir off again to embody the role of the devil's advocate by saying:

> I can tell a whole Iraq story that doesn't have race in it. It's about not having nuclear weapons. Why aren't we invading North Korea? Because they have nuclear weapons, and they could conventionally destroy Korea. I can tell a whole narrative that doesn't have race in it.

Throughout the analysis of this focal event, I highlighted how Dr. Berr's choice to take on the role of the devil's advocate functioned to shift the object of learning for students. Although the initial premise of the conversation asked students to articulate why the racial foundations of international law could not be avoided, as the conversation unfolded, Dr. Berr made clear that what constituted legitimate forms of engagement was narrowly conceived. Rather than the object of joint activity demanding that students deeply contend with the importance of naming the racial foundations of their field of study, it became an exercise of argumentation. Where the rules for what counted as evidence of a persuasive argument were arbitrated by Dr. Berr. Multiple students shared with me in interviews that there was often an expectation of what Dr. Berr expected students to leave the class believing. Reflecting on his own experiences of discourse in the class, Admir shared:

> It was often very clear to me where Dr. Berr stands and what kinds of answers…. I felt that there was a particular range of acceptable thought that was clear to me that I could say, and it would fly. I was very aware of the kinds of things that might not…and it caused a lot of back and forth.

Although Admir found those exchanges entertaining, it caused him to wonder when it is best to be completely transparent about his beliefs about the reading versus when to "take a middle-of-the-road approach."

Indeed, Dr. Berr admitted in an interview that she believed that argumentation is "the name of the game and social science, I mean…Most of the interesting stuff in politics are about argumentation and putting together persuasive evidence and believing it when you're confident you believe, because you believe it." Moreover, argumentation for the purpose of persuasion was key, especially for graduate students who are learning the field. She continued, "When they go on the job market, they're going to have not a hostile audience, but a lot of people who are going to be poking holes. And so, they have to get practiced in how to come back when someone pokes a hole." Centering the activity of persuasive argumentation rather than more expansive forms of knowing was a pedagogical move that also re-established Dr. Berr's role – as she previously described to me – as the one with authority, power, and a vast amount of knowledge and expertise in the classroom community.

Discussion & conclusion

I have argued that within the context of doctoral education, coursework is a socializing context. As my findings elucidates, the classroom is an environment where faculty introduce students to key scholars, histories, and debates in the field. It is also a space where students learn (implicitly and explicitly) whose voices are respected, which types of research questions are (de)valued, and which writing styles and argumentation conventions are validated. This type of learning is not a passive process. In this focal event, we witnessed a conversation between Dr. Berr and a student about the racial foundations of international law. They discussed why it is important to name explicitly that there *are* racial foundations to the field. What is most remarkable about this intervention, however, was that Dr. Berr took on the role of a devil's advocate to do it. By giving students a direct argument to contradict, she turned the object of activity away from prioritizing racial meaning-making and towards traditional conventions of persuasive argumentation. I wonder about the implications of rendering racialization, a deeply significant part of people's lived experience, as merely a topic of argumentation.

Faculty play an active and agentic role in student socialization. Although faculty-student interactions are known to shape doctoral student learning and socialization (Anderson & Anderson, 2012; Felder et al., 2014), classroom practice and faculty pedagogy remain a black box in doctoral coursework. Borrowing Walker and colleagues' (2008) language, if doctoral education is the formation of scholars, the field must take seriously that the classroom, and the bustling interactions that take place within it, is a necessary site of empirical inquiry.

I developed Racialized Cultural-Historical Activity Theory (R-CHAT) as a model to explore how racial meanings are constructed and organized in the everyday unfolding of classroom joint activity. R-CHAT is a transdisciplinary framework that allows researchers to situate racialization, or the discursive (re)production of racial meanings, not only as an outcome of learning, but as constitutive of the learning process itself. A striking feature of R-CHAT is its focus on faculty subjectivity that positions faculty as whole as dynamic people instead of reducing them to a monolith. It also honors their active and agentic ways that faculty (acting as stewards of their discipline) facilitate learning and racial meaning-making within their classroom context. It is clear that doctoral students enter into spaces and interactions that are racialized (and too often racist) during their time in graduate school. Yet, few scholars have explored the dimensions of how these spaces and interactions are *racializing*—learned and negotiated in the context of joint activity. Given faculty's own socialization into the norms and routine practices of the discipline, I found that the racializing dimensions of faculty's pedagogy also took on a disciplining character. This paper demonstrates how Dr. Berr's embodiment of devil's advocate effectively legitimated "whitewashed" perspectives about racialization. In their paper detailing the dangers of "both sides" argumentation, Vea and colleagues (forthcoming) posit that "Through repetition, harmful perspectives without an evidentiary base become normalized as reasonable, which effectively shifts the range of viable political possibilities" (p. 4). Towards the construction of more just learning experiences in graduate education, it is my hope that scholars will employ R-CHAT to enrich deep sociocultural and microanalytic studies of racial meaning-making within and beyond the context of doctoral coursework.

Endnotes

(1) Racial meaning-making is the interpretation of racial differences.
(2) The fourth faculty member temporarily fell ill and was unable to participate in the think-aloud interviews.

Sharing the Responsibility for Learning and Attentiveness to Student Data: Lenses for Equitable College STEM Teaching

Abstract: To improve equity in STEM higher education, it is critical to support instructors in learning and adopting inclusive teaching practices. This study advances the conceptual foundations for two lenses on pedagogical change, the Responsibility for Learning Lens and the Data Lens. These lenses can serve as mechanisms that support the adoption of equity-oriented pedagogies, such as Adaptive Equity-Oriented Pedagogy (AEP). Using preliminary findings from a randomized controlled trial of STEM instructors, we elaborate on how these lenses aid in distinguishing low- and high-growth instructors on equity-oriented practices. We conclude by arguing that without application of these lenses when making pedagogical decisions, instructors can run the risk of reinforcing a racialized status quo of individualistic and competitive learning cultures prevalent within STEM. This work has implications for improving faculty development, encouraging instructor self-reflection, and reducing systemic barriers to student success through equity-oriented pedagogies.

Introduction: Problem statement and research questions

Research shows that the quality of college teaching directly impacts student achievement and retention in STEM, especially for underrepresented students (URM; Weston et al., 2019). To improve STEM teaching, we studied adaptive equity-oriented pedagogy (AEP). Previous randomized controlled trials found that compared to an active learning control course, STEM instructors applying AEP improved mean student achievement by over a letter grade and narrowed achievement gaps for all students (Phuong & Nguyen, 2019; Phuong, Nguyen, Vo, et al., 2022).

This study extends previous work by examining how pedagogy courses teaching AEP principles can support STEM student-instructors' implementation of inclusive pedagogies. For simplicity, we use the term "instructor" for graduate and undergraduate students who teach and are enrolled in the pedagogy courses. The term "facilitators" refers to the pedagogy course instructors. 129 instructors participated in a treatment or control AEP pedagogy course where they completed a teaching portfolio that included written reflections, evidence of student learning, and feedback on their teaching. The treatment course was adapted weekly based on instructors' written reflections, whereas the control was not. Using qualitative methods, this study focuses on treatment instructors because the treatment course was more effective at increasing AEP competencies over time (Phuong, Nguyen, Vo, et al., 2022).

We focus on the research question: In the treatment, how do low- and high-growth instructors on AEP competency differ with respect to their data use and responsibility for learning lenses?

Background context: AEP pedagogy course design

The AEP pedagogy courses teach instructors about the key AEP principles. AEP is a framework for adapting teaching to address equity barriers to learning based on student data (e.g., formative assessment, observations, surveys) (Phuong et al., 2017a). AEP practice is characterized by instructors' use of 6 competency elements:

(1) Clarify learning outcomes and prerequisites, and build equitable course policies (e.g., adjust course policies and practices based on students' needs and contextual challenges, can include elements of grading for equity (Feldman, 2018))
(2) Align formative assessments and activities with outcomes
(3) Identify students' competencies, interests, and needs
(4) Understand equity barriers and contextual challenges to meeting outcomes
(5) Adapt teaching practices based on students' needs and barriers
(6) Iterate: Reflect upon pedagogy to support continuous learning, adaptation, and growth.

Unique element of treatment: Facilitators modeled and applied the 6 AEP elements explicitly as a tool for instructor learning by using weekly instructor reflection data to continuously adjust pedagogy course discussion and activities. Applying AEP, the facilitators adjusted the treatment based on instructors' reflections of their cultural perspectives and backgrounds, which include their lived experiences, racial experiences, discourse, and STEM department culture (e.g., what is valued methodologically and epistemologically).

Conceptual framing

We are interested in the reasons that drive instructors to learn and implement pedagogical changes. We are inspired by the notion of professional vision (Goodwin, 1994), which refers to developing ways of seeing phenomena that reflect growing levels of expertise. We focus more specifically on *lenses for pedagogical change*, which include the following: instructors' values around the types of data sources used for instructional decision-making and where they place the responsibility for learning. These lenses, or mechanisms, allow us to address content-specific and non-content specific teacher noticing skills (e.g., stereotype threat, imposter syndrome) (Phuong, Nguyen, Vo, et al., 2022; van Es & Hand, 2017). We build on the teacher noticing literature to examine how instructors adapt teaching based on more than unaided classroom observations, but also on information such as data on student equity barriers. We define 2 lenses below: Data Lens and Responsibility for Learning Lens.

Data Lens. The Data Lens is defined as the kinds of knowledge and data that are important and relevant in an academic and socio-organizational culture (Phuong, 2021; Phuong et al., 2021). Here is a question that one may consider when reflecting on the Data Lens: Do I value certain kinds of practices because they are tested using data sources and methods that are important to me or my field (Hammer, 2005)? The Data Lens considers the sources from which instructors can make determinations about student competencies. An instructor can use the Data Lens to understand student perspectives and learning processes. This lens can be useful for diagnosing student needs and adapting teaching.

Prior research suggests that data is an important mechanism for promoting instructor pedagogical change (Birt et al., 2019; Phuong et al., 2021; Reinholz et al., 2019). In thinking about disciplinary and organizational culture, we plan to obtain a better understanding of how disciplinary epistemological traditions impact how instructors learn and adopt equitable pedagogies. Therefore, we argue it would be important to focus on how instructors value and use data to motivate pedagogical decision-making. For example, we are interested in whether and how instructors value and use different data sources (e.g., observations, clickers, formative assessments, surveys, summative assessments) to understand and address equity barriers and patterns in student learning. Thus, the Data Lens can help instructors notice more aspects of their students' perspectives and less visible equity barriers. We hope to examine whether the use of this lens motivates the adoption of equitable pedagogies. In this study, we are interested in examining whether low- and high-growth instructors value qualitative and/or quantitative data sources, which can provide insights on instructors' epistemological values.

Responsibility for Learning Lens. The Responsibility for Learning Lens refers to how the instructor views their role and the student's role in learning. Here are some questions to reflect on: Whose responsibility is it if a student doesn't learn a concept? Are the "good" students the ones who teach themselves or don't need help? (Phuong, Nguyen, Vo, et al., 2022). This lens contributes to scholarship on reflective college teaching since it accounts for the systems, structures, and/or beliefs that foreground individualistic notions of learning that have contributed to STEM students leaving the major because they felt under-supported and isolated in a competitive environment (Jackson & Cobb, 2010; Phuong, Nguyen, Vo, et al., 2022; Seymour & Hewitt, 1997). This issue can be intensified for low-income, first-generation, and minoritized students who have less support from home.

The Responsibility for Learning Lens would account for the beliefs, or logics, that can support and prevent adoption of equitable pedagogies. Identifying this lens in reflections would be beneficial in professional development programs to understand instructors' beliefs, values, and what is driving how they think about their role in their students' learning processes. For example, instructors may hold a faulty logic that the "good students" are the ones who teach themselves, do not need help, and/or do not ask for help. We argue that such a belief can echo the Protestant work where students are asked "to pull yourself up by the bootstrap", which elevates middle- and upper-class European cultural values as the standard for success (Markus & Conner, 2013). Adopting this racialized standard and belief (Bonilla-Silva, 1999) could inhibit the adoption of equitable teaching practices because instructors may not believe that their role is to be responsive to students' learning needs because students are supposed to teach themselves. Curating learning experiences that enable instructors to interrogate these beliefs is important for shifting instructors' logics and promoting pedagogical changes.

Prior literature has been focused on students' internal motivations, mindsets, and management to learn new skills (Broadbent & Poon, 2015; Heikkilä & Lonka, 2006). Other literature has focused on identifying an educational structure that is in the middle where students have some support, but not too much (Brennan, 2020).

In this study, we focus on conceptualizing what it means to share the responsibility for learning; we specifically focus on the role instructors can play in mitigating student learning and equity barriers.

Sharing the responsibility for learning means that all the following themes co-exist in an instructor's reflection response:

- The "It's up to me" theme refers to instructor responses that suggest instructors themselves should take responsibility to mitigate the impact of these barriers on student success. The instructor believes in their responsibility to proactively understand their students' questions, barriers, needs, interests, and experiences. They see an important part of their role to be proactively addressing student learning needs and equity barriers.
- The "It's on my student" theme refers to instructor responses that suggest the student should play a proactive role in advancing their own learning.
- The "It's something else" theme refers to instructor responses that indicate another contextual factor (e.g., equity barrier, stress on the community or family) plays a role in impacting student learning.

We hope to examine the extent to which the lenses, or mechanisms, above can explain the differences between low- and high-growth instructors on AEP competency. Identifying these lenses in reflections is beneficial for supporting instructors' learning of equitable pedagogies. Facilitators can focus on expanding instructors' critical consciousness so that they recognize the importance of using multiple forms of data and sharing the learning responsibility with their students. Using multiple forms of data and considering various factors that impact learning can enable instructors to have a more holistic view of their students, which is important for adapting instruction to respond to student needs. We hope to introduce these lenses to better understand how instructors can collect student data to design, iterate their pedagogies, and become more responsive to their students' learning needs.

Methodology

129 STEM instructors at an R-1 public university participated in semester-long AEP pedagogy courses for first-time instructors, where they completed a teaching portfolio. The pedagogy courses primarily served instructors who taught computer science, data science, math, and statistics courses. Instructors participated in either a treatment or control pedagogy course. The treatment and control courses were co-led by the same facilitators who employed exemplary active learning activities and provided an AEP curriculum. Instructors were randomly assigned to the treatment or control condition.

Using qualitative methods, our research question focuses on treatment instructors because the treatment course was more effective at increasing AEP competencies over time (Phuong, Nguyen, Vo, et al., 2022). For the purpose of this study, we want to understand how low- and high-growth instructors on AEP competency differ with respect to their data use and responsibility for learning lenses.

As explained in Phuong, Nguyen, Vo, et al. (2022), all instructors completed baseline, midterm, and final AEPC assessments. Each AEPC assessment elicits evidence about teaching philosophies, written reflections on teaching and assessment practices, evidence of student learning, student gain score visualizations, media, and peer/student feedback on their teaching. The AEPC assessment contained reflection questions that asked instructors to provide evidence of demonstrating AEP competencies. The scale was 0-22, with 3 items being scored 7 points each and 1 item being 1 point. A detailed rubric (See Table 1 for a summary) was applied independently by two researchers to blindly score assessments. Higher positions on the rubric imply that criteria of lower positions have been met. Based on partial credit Rasch modeling (Masters, 1982), the AEPC measure has high reliability (0.94), has strong validity based on Wilson's (2005) strands of validity framework, shows no gender or URM bias, and correlates significantly with researchers' review of teaching and pedagogical materials (Phuong, Nguyen, Hunn, et al. 2022; Phuong, Nguyen, Vo, et al., 2022).

Table 1
AEPC Scoring Rubric 0-7, originally reported in Phuong, Nguyen, and Vo et al. (2022)

Item Score	Learning Progression Level	Description
0	0	Provides an irrelevant answer, does not apply any elements
1	Low	Applies AEP element 1 and/or 2 (described above) Element 1: Clarifies learning outcomes Element 2: Aligns formative assessment with learning outcomes
2	Moderate	Applies elements 1-3: Diagnoses student learning competency ***Or*** Diagnoses interest

3	Moderate	Applies elements 1-4: Diagnoses learning competency and interest ***Or*** Diagnoses learning competency and learning barriers
4	High	Applies elements 1-5: Adapts based on full diagnosis, not only based on diagnosis of learning competency
5	Very High	Applies all 6 AEP elements
6	Very High	Applies all 6 AEP elements citing instructor and student evidence
7	Very High	Applies all 6 AEP elements with supporting instructor/ student evidence and explains how their practice impacts the student ***Or*** Applies all 6 AEP elements with instructor/ student evidence and explains rationale for how practice impacts student

We provide the AEPC scores in the treatment over time on a scale of 0–22 points: The pre-semester AEPC score was 0.12 points (SD=0.33) and the post-semester AEPC score was 20.65 points (SD=1.61). As noted in Phuong, Nguyen, and Vo, et al., 2022), this growth observed in the treatment was significantly greater than the growth in the control condition.

We drew from instructors' teaching reflections to identify the mechanisms that motivate instructors to learn and adopt Adaptive Equity-Oriented Pedagogy (AEP) in higher education. Specifically, 10 low-growth and 10 high-growth AEPC instructors, as determined by quantitative analysis, were selected from the treatment condition. To accomplish this goal, the bottom 25% (n=16) and the top 25% (n=16) of the 65 instructors were identified by the magnitude of the change in their AEP competency from pre- to post-semester. Next, all minoritized instructors in both of these groups were selected for inclusion. Finally, a different member of the research team randomly sampled additional instructors to create sets of 10 in the low- and high-growth groups.

On a scale of 0-22, the mean low-growth group AEPC growth score is 18.31. By contrast, the mean high-growth group AEPC growth score is 22. We selected 11 reflection questions from the end-of-semester AEPC assessment. These questions ask instructors to describe their teaching philosophies and values, what they have done, their evidence of demonstrating AEP competency, and their reflections on how they have adjusted their perspectives and pedagogical practices to advance student success.

When coding the data, we anonymized the instructors' names, condition, and whether they were in the low- or high-growth group. We deductively coded reflections using a codebook, tracking frequencies of codes, and exploring self-reported mechanisms for learning AEP (Saldana, 2011).

Findings

Data lens

Two subcodes under the Data Lens include "I value quantitative data" and "I value qualitative data." In the treatment, we examined the co-occurrence of "I value quantitative data" and "I value qualitative data" subcodes, which refers to instructors invoking the two subcodes in a response to a given question. All ten high-growth and three low-growth instructors were identified as representing both subcodes. Based on these findings, we found evidence that the Data Lens reflected major differences between low- and high-growth instructors.

As high-growth instructors make pedagogical decisions to advance student success, they value "qualitative" and "quantitative" approaches more often than low-growth instructors. This consideration of both data approaches may suggest that high-growth instructors have more inclusive epistemological values than low-growth instructors. In other words, high-growth instructors recognize the value of both numbers and lived experiences as sources of data for understanding where their students are at in the learning process.

Consequently, we also noticed that the high-growth instructors do not solely characterize students based on their test scores, cultural background, or equity barriers. Instead, the high-growth instructors are using multiple data points to address students' interests, strengths, and learning needs. This may suggest that high-growth instructors are looking at their learners more holistically as human beings, which is a more humanistic approach to teaching.

Responsibility for learning lens

An instructor who fully shares the responsibility for learning recognizes that the instructor, the student, and other factors each play a role in advancing student learning. Accordingly, in our qualitative analysis, sharing the responsibility for learning means that the following subcodes co-exist in an instructor's response:

- The "It's up to me" subcode refers to instructor responses that suggest instructors themselves should take responsibility to mitigate the impact of these barriers on student success. The instructor believes in their responsibility to proactively understand their students' questions, barriers, needs, interests, and experiences. They see an important part of their role to be proactively addressing student learning needs and equity barriers.

- The "It's on my student" subcode refers to instructor responses that suggest the student should play a proactive role in advancing their own learning.
- The "It's something else" subcode refers to instructor responses that indicate another contextual factor (e.g., equity barrier, stress on the community or family) plays a role in impacting student learning.

Based on preliminary qualitative analysis, all the high-growth instructors, but only one low-growth instructor, expressed fully sharing the responsibility for learning. Therefore, the Responsibility for Learning Lens appears to distinguish low- and high-growth instructors.

Discussion

Consistent findings with a previous study. In a recent study, Phuong, Nguyen, and Vo et al. (2022) examined the top and bottom 25% of the 129 instructors on AEPC growth in the treatment and control condition. There were 32 instructors in the low-growth group and 32 instructors in the high-growth group. We provide some context on these low- and high-growth groups from Phuong, Nguyen, and Vo et al. (2022): "For the bottom 25% of instructors (n=32), the average growth on the 22-point AEPC scale was about 9.22 points (*SD=1.93*) and all these instructors were from the control group. The top 25% of instructors (n=32) had a mean AEPC growth of about 21.84 points (*SD=0.37*). For the top 25%, we found that at least 31 instructors were from the treatment" (p. 4).

Ten instructors were randomly sampled and qualitatively analyzed from the bottom and top 25%. We quote a table below from Phuong, Nguyen, and Vo, et al. (2022), which provides frequencies of qualitative subcodes for *responsibility for learning* and *data lenses* that were expressed by instructors in their reflections. Our analysis of the treatment instructors is relatively consistent with these findings from Phuong, Nguyen, and Vo et al.'s (2022) analysis of the top and bottom 25% of the combined treatment and control conditions.

Table 2
Frequency of selected responsibility for learning (RL) and data lens subcodes in bottom and top 25%, originally reported in Phuong, Nguyen, and Vo et al. (2022)

Sub codes in instructors' written reflections	Bottom 25% Frequency (%)	Top 25% Frequency (%)
1. Indicates student is responsible for proactively addressing learning challenges (*RL* subcode)	10 (100%)	10 (100%)
2. Indicates instructor is responsible for proactively addressing learning challenges (*RL* subcode)	0 (0%)	10 (100%)
3. Values and cites multiple forms of data to adapt teaching (*Data* subcode)	0 (0%)	10 (100%)
4. Gives an example and rationale for how adapting teaching will improve student learning based on data (*Data* subcode)	0 (0%)	10 (100%)

The sample size of 20 instructors is limited, and future research can explore additional reflection responses and a larger number of instructors in other college contexts.

Expanding Notions of Expertise and Standards for Success. We challenge simplistic conceptions of learning and expertise that focus on the progression from dependent to independent learning. Taking a sociocultural perspective on learning, we contend that learning is and remains inherently social. Many experts work independently and are nonetheless dependent on a range of resources (e.g., online forums, YouTube) and actors (e.g., mentors, managers, peers) that support their ongoing learning and success. Because we recognize that learning is social and distributed, we argue that educators need to play a role in the learning process by sharing the responsibility for learning when supporting the success of novice and advanced learners.

Furthermore, certain conceptions of independent learning echo the Protestant work ethic of "pulling oneself up by the bootstraps" and place white, middle- and upper-class Eurocentric norms as the standard for success (Markus & Conner, 2013). Elevating independence as the standard perpetuates whiteness in educational and performance evaluation standards. We therefore argue that equating expertise solely with independence is racialized, since it is a remnant of an archaic Protestant tradition rooted in white, upper-middle class norms.

The Protestant work ethic has been used to reinforce the myth of meritocracy, under which any success is attributed to hard work and any failure to the lack thereof (Markus & Conner, 2013). Faculty have echoed the Protestant work ethic by expressing that students, including minoritized students, who cannot succeed in STEM are not “cut-out” for STEM since they did not work hard enough (O’Leary et al., 2020). In some of our other preliminary research, instructors have applied this logic to primarily teach to the higher performing students, as these are the ones perceived to be working hard. Such logic does not account for the systemic and contextual barriers that students face, including minoritized students. Bonilla-Silva (1999) and Sears and Henry (2003) highlight that the Protestant work ethic of individualism reproduces symbolic racism and can be detrimental to equity.

We argue that elevating individualism as the standard of learning (e.g., through a “teach-yourself” model) can reproduce racialization and social inequities. For example, Stephens et al. (2012) documented that there can be a cultural mismatch for first-generation students with respect to individualism in higher education. They found that first-generation students tend to express more interdependent motives than continuing-generation students (Stephens et al., 2012). Moreover, Goode (2007) found that individualistic discourses were disempowering for international graduate students in higher education. In addition, Nguyen et al. (2022) found that first-generation, low-income, and minoritized students achieved greater success towards their personal and professional goals in higher education when they had educators who worked in partnership with them and had a “let’s do this together”, equity-oriented approach. Prior social capital interventions in higher education have been shown to increase first-generation and minoritized students’ sense of belonging, achievement, and retention (Rasco et al., 2020; Schwartz et al., 2017). Instead of focusing on assimilation, it is important to acknowledge, support, and engage the different kinds of capitals and strengths that students bring (Yosso, 2005).

Moreover, individualistic models of learning have also marginalized those who have less access to resources. We found that individualistic approaches to learning have contributed to persistence and retention challenges for all students, including minoritized students. Students cite learning alone, the lack of alignment of instruction and assessment, and curving down as part of the top five reasons for leaving STEM (Weston et al., 2019). In fact, curving grades down has been well documented in promoting competition over collaboration among students in STEM courses and other disciplines. Elevating individualistic norms and performance criteria for learners not only inhibits the transformative opportunities for social learning, but has also led to students being weeded out of STEM fields. We argue that these racialized norms of individualism and pervasiveness of whiteness in educational standards perpetuate cycles of inequity, opportunity gaps, and a lack of diversity in STEM. In sum, we contend that equating expertise and development with independence is racialized and can create barriers to learning and the development of social-emotional competencies for both instructors and students.

The Adaptive Equity-oriented Pedagogical Competency (AEPC) model combats the ramifications of racialized conceptualizations of expertise and development. In the AEPC model, an expert shares the responsibility for learning and draws on multiple data sources to develop as a scholar and practitioner. These two lenses advance anti-racist practices because they encourage ongoing critical reflection on the racialized systems and structures that reproduce systems of power that limit opportunities for students from minoritized and underrepresented backgrounds. We argue that expert instructors work both collaboratively and independently within a learning environment to continuously seek feedback and improve their practice. Part of this work includes expanding one’s critical consciousness to better understand the privilege and lack of privilege that students experience when they enter higher education learning environments. Furthermore, by collecting data on students’ lived experiences and circumstances, instructors can strengthen their social-emotional competencies in social awareness skills such as perspective taking and addressing areas for growth.

Within a higher education STEM context, our conceptual framework prioritizes equity in the teacher noticing process, which is grounded in a sociocultural perspective of learning (van Es & Hand, 2017). In particular, the AEP framework adds an equity perspective to teacher noticing as it seeks to create a culturally responsive community of reflective practitioners. The AEP framework further contributes to the teacher noticing literature by providing a framework with different pedagogical practices that encourage instructors to reflect and respond to their students’ socio-cultural context and equity barriers. Phuong et al. (2017b) argue that taking students’ perspectives is important for promoting student success for all students. Accordingly, part of being an equitable instructor entails using data to reflect on one’s own pedagogical frameworks and student perspectives in order to challenge unconscious biases and design for all students. We argue that relying solely on intuition to make pedagogical decisions can result in instructors being affected by unconscious biases and assumptions.

We want to broaden notions of teaching and learning that are common in STEM. We challenge the pernicious belief that the good students are the ones who teach themselves and do not need help. It is important to foster instructors’ efforts to take different perspectives when they are making pedagogical decisions and policies. An expert instructor under the AEPC model would not solely shift the responsibility for learning onto a student, tutoring center, counselor, or diversity officer. Furthermore, with respect to faculty development, the current findings suggest that it can be beneficial to support instructors in sharing the responsibility for learning and using multiple data sources to adapt teaching and advance student learning. As documented by Phuong, Nguyen, and Vo, et al., (2022), this approach expands instructors' critical consciousness since it asks them to rethink common cultural norms, values, meritocracy, and larger systems (e.g., structural racism) that reproduce inequities, where students from underprivileged backgrounds may not have equitable access to resources and opportunities that enable them to teach themselves. Therefore, critically interrogating the individualistic notions of STEM learning, the myth of meritocracy, and beliefs about self-reliance is key to advancing more equitable and anti-racist pedagogies.

Contradictions of Decolonial Literacy in an ESL Writing Space

Gautam Bisht, Northwestern University, gautambisht2025@u.northwestern.edu

Abstract: In the last decade scholars have called out the colonial elements of English language arts in order to move towards decolonial literacy practices. But what does decolonial literacy practices entail? I look at some ethnographic data from a online writing project to explore the notion of decolonial literacies. Youth from the Santhal community in a remote village in India participated in this work as students. For this paper, I analyze the process and products of two focal students Saroj and Manoj through the lens of contradictions within the decolonial literature. I show how these contradictions enabled them to simultaneously work with and against the standard conventions of English language and persuasive writing. The paper submits that one aspect of developing decolonial literacy is learning to negotiate with the contradictions it generates. The findings have implications for designing decolonial learning environments.

Decolonizing Language Arts

In the last few decades, scholars have investigated the norms and conventions of English language Arts, exposing their colonial and racial history(Flores & Rosa, 2015). Some common mechanisms of enforcing a colonial pedagogy within English language arts are monolingualism, native accents, standard grammar, genre conventions and subsumption of all kinds of difference as 'inappropriate.' To decolonize literacy is to make epistemic connections that comes with languaging(Cushman, 2016).Two prominent ways through which connections between literacy and epistemology is forged are Translanguaging and culturally relevant texts. Translingualsim challenge the colonial notion that languages are separate distinct entities with neatly defined borders and embrace the fluidity of the full linguistic repertoire of students. . Translanguaging is intended as a decolonizing project, revealing how bilinguals/multilinguals inhabit a world with different knowledge bases and linguistic/cultural practices(Wei & García, 2022). In addition to translanguaging educators have increasingly employed culturally authentic texts for minority groups. By culturally authentic texts I means inclusion of literature that speaks to the cultural reality and background of students. Student produced culturally authentic texts includes counter stories, testimonios, autoethnographies, literacy autobiographies and other versions of personal stories that centers the lived experience of students (S Canagarajah & Matsumoto, 2017;(Kelly, 2017)(Saavedra, 2011). Though there is much theoretical work on decolonization of language arts, we don't have many empirical studies that look at- What does it mean for students to actively develop decolonial literacies? What novel challenges are generated when designing for decolonial literacies? This paper claims that engaging with local languages and local knowledge systems in an ESL writing space creates contradictions for students. These contradictions enable students to develop novel strategies to not just negotiate dominant knowledge conventions but also to refashion them.

Contradictions within decoloniality

Decoloniality is considered a move beyond the apparent transparency and universality of the zero point of knowledge, by embracing the geopolitical and biographical politics of sensemaking(Mignolo, 2000). In that sense, a decolonial literacy practice is to read/write the world from 'somewhere.' But postcolonial scholars, like Spivak rejects the idea that there is an uncontaminated space 'outside' the hegemonic structure(Andreotti, 2007.). Therefore, rather than a simple rejection of colonial literacies, decolonial literacy is an act of negotiation from within. But how does one negotiate from within? What does such a negotiation mean for students? Scholars have pointed out that contradiction marks the existence of postcolonial subjects. The metaphors of being 'here' and 'there' or experiencing a split within one's own desire is a classic postcolonial condition(Asher, 2009). In such a situation, De Sousa Santos invites decolonial thinkers and practitioners to make use of the fertility of a contradiction by working with and through it(Santos, 2015). In my findings, I will show that two students experienced contradictions in engaging with the conventions (coloniality) of English language and persuasive writing. These contradictions enabled them to construct novel strategies to push the boundaries of what is persuasive writing and English language.

Context of the writing project and research question

In the Global South, English language was used as a colonizing tool and scholars argue that the imperial effect of English language is far from over(Phillipson, 2009). India has lost around 220 languages in the last 50 years, and over 500 are considered endangered (Mohanty, 2020). On the other hand, in a society where educational opportunities were reserved for some, English has become a tool to bypass the upper class/caste hegemony and is associated with economic opportunities(Chakraborty & Bakshi, 2016). Therefore, English is placed in a complex matrix viz a viz linguistic and cultural minorities in India(Babu M T, 2015). It was in this backdrop that this study was designed under one of the projects run by my not-for-profit organization in India. The project connects young volunteers from urban colleges to rural youth for skill development. For this particular research project, our goal was creative writing using English language. Students ended up writing fiction, nonfiction, and different kinds of personal narratives. Their writings were guided by the translingual and culturally authentic texts they read in class. We also invited some Santhali writers to conduct workshop with them. Overall, the goal was to write an article on any topic and genre, and if possible, get it published online. 12 young adults (18-21 years) from the Santhal community participated in the project and 6 mentors from different cities worked with them. I was one of the mentors and all of us designed this curriculum together. All the sessions were online, and they happened 2-3 times a week. The questions that guided our study were: What are the challenges that students faced in the development of their writing? How were these challenges engaged with?

Data

I collected three kinds of data for this project- interviews, Zoom recordings and written artifacts of students. I used an artifact-based interview that centered student's final writing to understand their composition process. I started with open coding the interviews. I was particularly stuck by some challenges that students mentioned in their interviews. I say so because they were challenges that related to the two design elements of Translanguaging and writing about one's cultural context. I had assumed that these two features will have great affordances, but when I discovered that they created new problems, I pursued them and wrote some memos. As a next step I became more sensitive to not just challenges but also strategies. By challenges I mean explicit statements in the interview like- " I was confused about this" or " I had great difficulty in doing this". By strategies I mean interview segments where students explained the decisions regarding selection of topics, how they started writing, what kind of openings they made, linguistic choices, etc. Going forward I refined my codes and organized them into five categories (Table 1). I developed a sense that the most prominent challenges were around the categories of 'Navigating Languages' and 'Development of content'. The first category deals with all codes that relate to the challenges and strategies of navigating *how and when to use the multiple languages* in their writing. The second category deals with all codes that relate to the challenges and strategies of navigating *what to write* within a topic to build its content. The frequency of codes in each category helped me develop a sense of what challenges were the most prominent. Next, I looked at classroom moments to get a sense of how and when these challenges and strategies were generated. Finally, I looked at the final writing of students to get a sense of how some of these challenges were dealt with. For this paper, I selected two students Manoj and Saroj, who exemplify the two prominent categories of challenge I described above(Stake, 2008). I have organized their cases as cases of enabling contradictions. This means that I established their challenges as a kind of contradiction which helped them generate certain rhetorical features in their writing.

Table 1
Code categories and frequency for challenges and strategies

	Navigating Language	Development of Content	Arrival at Topic	Structure	Text Comprehension
All	**62**	**44**	40	28	14
Saroj	**11**	3	5	3	3
Manoj	23	**14**	8	6	0

Findings

The central assertion of this paper is that decolonial literacy practices that engage with local languages and local knowledge systems creates enabling contradictions. To support this claim, I provide two cases. My first case is about Saroj (20, F) and her contradiction is organized around the challenges and dilemmas involved in navigating multiple languages. My second case is about Manoj (21, M), whose contradiction is organized around his challenges and dilemmas around the legitimacy of what is to be written. Both Manoj and Saroj (pseudonyms) come from the Santhal community, which has a historical background of socio-economic marginalization. In formal educational spaces, their local language Santhali is not used, hardly understood, and often looked down upon. In presenting both cases, I will first establish their challenge as a contradiction. Then I delve into classroom moments that encapsulates their contradiction. Finally, I look at their writing to highlight how their contradictions enabled them to develop novel rhetorical strategies.

Focal student Saroj: How to write?

Saroj is 20-year-old woman, and she wrote an article on her father's practice of local herbs. Her languagescape is diverse and English is her fifth language. She felt most challenged by the aspect of navigating her multiple language. By navigating multiple languages, I mean two things. First aspect consists of the challenges specific to English, the language of desire and intimidation. In her interview Saroj mentions- "*When I had to translate from Hindi to English then I used to face some difficulties, how to frame sentences? Which word will be translated into what?* The second aspect of this navigation relates to how, when, and why to use languages other than English in her article. In some situations, the first aspect of the challenge was mediated by the second. For instance, in her interview she mentions, "*I cannot write correctly in English, so I wrote it(article) in mixed language and then published it.*" So, one function of 'mixed language' or translanguaging was to improvise and compensate for current competence in English. In another instance of her interview, when asked about her Santhali usage, she mentions "*I wanted to make people aware of my language also, they should know that this word in Santhali means this.*" In that sense there was no single use or rationale for using multiple languages and she had to navigate diverse choices, often changing her stance, and sometimes feeling confused about how she should write. On the one hand she was pulled towards the conventions of standard English and on the other hand she was open to her other languages. This is the contradiction she experienced, which I will elaborate below through several classroom moments.

Saroj chose to write about her father and his practice of treatment with local herbs. She started by writing a few paragraphs in Hindi using Google documents and its default Roman script. Using the Roman script for writing in other languages is a popular practice due to social media communication and WhatsApp messaging in India. However, even at the vocabulary level her 'Hindi version' did contain some Santhali and English words, indicating the organic nature of translanguaging that the community is used to (1). After a few classes she was asked by her mentor to start writing some of what she has written using English.

> *1 Santhal samaj ke log anek prakar ke jari butiyo dawai banate hai.*
> *2 Santhal society ke people very very jari butiya medicine make.*
> *3 Santhal Samaj ren hor ko ayma lekan jaru buti ran ko benawa.*
> *(Taken from Saroj's google doc)*

Line 2 captures her first attempt at writing 'with' English. I say 'with', because she retains the sentence structure and even some of the grammatical features of Hindi language from Line 1 but transplants a few English words like- 'society', 'people', 'very very', 'medicine' and 'make'. Eventually, the mentor asked her to write the same line in Santhali (Line 3).

> *1 Mentor- So, how are you feeling after making your first translation? (Referring to line 2)*
> *2 Saroj- I am feeling kind of okay I guess (said with some skepticism and smile)*
> *3 Mentor- Okay, keep going-*
> *4 Saroj- I feel scared-*
> *5 Mentor- Don't worry, it's coming out well… So, why do you think I asked you to write in Santhali?(Line 3)*
> *6 Saroj- Maybe we have some people who will read this in Santhali*

In this conversation, Sarita is not very confident (2) about her performance in Line 2, which may relate to her skills in English. She is also not sure about the purpose of the third line and at best imagines an audience that would read in Santhali. As I mentioned above, all three lines can be categorized as translanguaging, one more implicit than the other. At this initial level, the nature of translanguaging is shaped by cultural habits, the apparatus of google doc and her limited sense of English grammar and vocabulary. Further down this conversation the mentor inquires if she has ever read texts which use multiple languages, to which she says- "*I have read some, where they use Hindi and English together, but not one where they mix Santhali.*" In the next few classes, the mentor brings some translingual texts and discusses them with her.

> *1 Mentor- This is his Facebook post, let's look at it, this is called Santali marriage and in brackets he has written Hor Bapla. So, you see he has used a lot of names for the marriages, which are in Santhali, why do you think he mentions these terms, instead of just writing about them in English?*
> *2 Komal- I know three kinds of marriage- love, arrange and chadwi*
> *3 Mentor- So I think chadwi is the one listed at number 10, okay, so as a reader how do you like this, with these Santhali words or would you prefer it in complete English?*

4 Saroj- Both are okay, with Santhali we get to know a little more about them…

The mentor text presented above is a more intentional version of translanguaging, where the author uses some very specific Santhali words that highlights cultural differences and complements the subject of his writing. But the students are not very clear about this usage in this interaction. The author has used some Santhali words that are not used in their particular region, and they are unable to recognize them. In this interaction, Saroj does not feel any strong preference for either mixing languages or using exclusive English (4). Although she does appreciate the text for learning some new Santhali terms, a move she makes in her own final writing. A big concern that translanguaging or non-conventional English poses is the challenge of comprehensibility. In our own study, when students started writing, they often wondered- "Am I making sense?" To test this internally, the mentor invited students to read and make sense of each other's writing. In the following interaction, another student (Student 2) is reading a paragraph written by Saroj.

1 Mentor- So do you understand what is written?
2 Student 2- Since we have discussed here writing for so long, so I can get it, but the sentences are not clear in the middle, so if someone else reads it, who is a stranger, I feel it will not be clear for them
3 Mentor- So how can we improve this?
4 Student 2- So, 'jari butiya', can be there as it is…but for instance 'Ke tree" is something which is not looking well…she could have used either Santhali word or full English there instead…but at the moment it's confusing.
5 Mentor- What do you think of this Saroj? How should we go about it?
6 Saroj- Lets go towards more English. As he said, some words I will retain and make more sentence in English

In this interaction we see a negotiation of understanding, as the student reading Saroj's text feels that a new reader may not be able to follow(2). He recommends less hybrid structures (4) and Saroj immediately feels that she should use more English (6). In response to Saroj's inclination, the mentor presented more examples of online writing, which was mostly written in English, not necessarily using standard grammar.

1 Mentor- Is this a good example for you, Saroj? It is mostly in English.
2 Saroj- But what about for those who don't know English?
3 Mentor-So should we have separate articles for the audience, or should we have one article but with mixing?
4 Saroj- Lets mix. But I think English should be separate, yes, so this version should be mostly English and the other with more mixing, maybe we can also put in brackets what is the English name for Munga.

In this interaction, Saroj feels a pull towards her other languages and expresses her concern for non-English readers (2). She is deliberating upon the possibilities of how she can 'mix' and yet have a 'mostly English' version (4). These pulls were elevated at different moments in the classroom. In another discussion she was part of, some other students highlighted the fear of being judged poorly if they mixed their language. Even though they do practice translanguaging in everyday life, they felt that translanguaging in writing will be perceived positively only if done by people who are already experts in English. Saroj moved between her position of translanguaging as a form of asserting her language and an improvisation for her inability to form full English sentences. This is the central contradiction that her case presented. Let's now turn to her final writing to look at what her contradiction enabled. Let's begin by looking at the evolution of the very first line she wrote, from its first draft to its publication.

Santhal samaj ke log anek prakar ke jari butiyo dawai banate hai.(1)
Santhal society ke people very very jadu butiya medicine make (2)
Santhal society people make many types of Rehe Raan (jari buti) medicine. (3)
The Santhals make many types of 'Rehe Raan' ('jari buti' / medicinal herbs) medicine. (4)

Line 1 is where she started, and Line 2 is her first attempt with English. Line 3 is what she eventually submitted for publication. It has mostly English words (like she wanted) but not necessarily in the conventional form or order. It has a Santhali word *Rehe Raan*, which is the local word for herbs. This strategy to translanguaging reflects how some cultural key words are to be articulated in Santhali, an understanding possibly shaped by continuous classroom discussions. So, she works around all her languages, her desire for English, comprehensibility, and inclusion of different readers to create line 2 But what gets published on the platform is Line 4, as the editors use their publishing standards to intervene. They restructure the first few words of her sentence and adds the word medicinal herbs next to Hindi word 'jadi buti'. There are many instances in her article where the editors changed her language to match their convention. This move by the editors underscores the place of convention in writing, and that sometimes resolution to Saroj's contradictions were decided externally.

> *♫♫Hane dular koyog mese bir buru sona disom haire. Bai Bai te Nana hunar dare nari ujar cabakan.*
> *Somaj tala re ayam hor do rehe raan ko badaiya .bir buru re ayam lekan rehe ran ko mena .*
> *bir buru dare nari re nidir do lago wen.*
> *cedam japetak ebhen me ♫♫*
> *♫♫Look friends, the forest mountain in our country is so lovely. Slowly, slowly many types of trees are getting finished. Santhal society people know many types of indigenous medicine. Forest is getting cut. Why are you sleeping? Arise and get up!♫♫*
> *(First part of the song that introduces Saroj's article)*

Saroj decided to open her article with a Santhali song. In Santhali culture, songs are one of the key mediums of persuasion and knowledge transfer. The strategy of opening with a Santhali song not just speaks of her desire to include Santhali audience, but also to address them first. The song, though appears in the start of her article, was actually the last thing she added to her writing and in some ways is a poetic culmination of her journey. In the interview she mentions, "*I started with a song because songs are my favorite and I wanted to make people aware about the gradual decline of the greenery, mountains and our beloved nation via the medium of the song."* The song captures the essence of all the paragraphs that follows it, persuading the readers with the evocative imagery of community in " Slumber" and a need to "Arise and Get up!" Working across multiple languages also enabled Saroj to engage with the 'mostly English' sections better. For her five paragraphs Saroj went from Hindi to English, but for the song she attempted a direct translation from Santhali to English. This indicates her increasing confidence with English. The song translation was the segment where she made the most agentive decisions regarding what English words really convey what she wants to say. For instance, Saroj went through several phrases like 'Stand Up', 'Get Up', 'Wake Up', before settling for "Arise and get Up"! She also overturned some word suggestions made by the mentor in favor of what she thought fits better. Reflecting on this process she said, *"The way in which I have written my article I had never done before…through the article I got the opportunity to learn English."*

I argue that her contradiction enabled her final article to embody both a sense of convention and a place for her whole personality. The convention is visible in the five paragraphs that follow this song, which is somewhat modeled after a Hindi article she read in class. She writes the five paragraphs 'mostly in English' and retains Santhali words for significant relationships, names of medicine or diseases. On the other hand, the song represents her existing expertise and inclination in her writing(Lee, 2003). I say this because, after the publication of this article, the mentor discovered that Saroj has sung some Santhali songs that have over 250,000 views on YouTube. This is one reason she felt most at ease when writing the song. In her interview she recollects- "*It didn't take much time; I easily thought about this and wrote it."* Eventually, Saroj's contradiction enabled her to indigenize English language and push the boundaries of persuasive writing by infusing in it the orality of Santhali music.

Focal student Manoj: What to write?

Manoj is 21-year-old man, and he wrote an article on the changing food habits of his community. Unlike Saroj, he has some exposure of living in a big city as a migrant labor, which adds to how he looks at his community life. Manoj wanted to write a persuasive nonfiction piece about the significance of non-cultivated forest food. In the standard conventions of persuasive writing, assertion should strongly align with evidence. But for Manoj the most prominent challenge was to make a persuasive case for his traditional food practice in the face of lack of 'conventional evidence'. For him the central contradiction was in asserting his traditional knowledge on one hand and the skepticism around its legitimacy on the other. In talking about the writing process in the interview, Manoj recalls several doubts he had. *"It was still difficult to write on this topic, there were many kinds of doubts, for instance, what exactly we are writing about the food, its nutritional status, what we are writing, is it true or not."*

Most of the non-cultivable forest food of Santhal community has not been written about and there is very little research around its nutritional status. Manoj and his mentor could not find a simple blog-like article that could model his writing. To develop the content of his writing, he relied mostly on his interactions with community elders and some existing practices of his community. But 'is it true or not' is something that he continuously wrestled with. His own confidence about his community's knowledge around food went through some shifts. The following interaction is from a class when he first discussed his topic.

> *1. Manoj: Yes, I don't care whether people do it or not. People never talked about madua (millet), but 20-25 years later they've started talking about madua.*
> *2. Mentor: Why do you think people have started talking about madua,..why are they talking now?*
> *3. Manoj: People were not valuing it.*
> *4. Mentor: Why were they not valuing it?*

> *5. Manoj: When people like you will come and tell us, people who've studied at good colleges, are government employees or doctors, are certified, are well educated, or earns a lot or are researching, that would be more credible.*

In this interaction, Manoj uses the example of *madua* (millets), which was historically consumed by the community but was socially looked down upon. Eventually the community stopped eating it and used it as animal fodder. But then large-scale campaigns were conducted by the government to revive millets for its nutritional benefits, something he refers to as 'they have started talking about it' (1). This notion of value and where it comes from is best characterized by his elaboration (5) on institutional validity. In this interaction Manoj not only looks confident about the significance of local food, but he also points out the politics of legitimacy and that sometimes conventions are late in catching up with local knowledge. Few sessions later, as shown in the following interaction, we can see a shift from his personal indifference to an exploration of why his community members may be turning away from local food items.

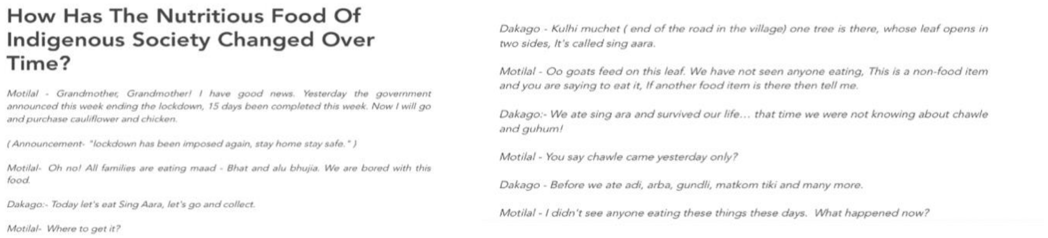
> *1. Manoj: Even though there is so much nutrition in Sahejan (local available green vegetable), the doctor would rather recommend spinach that is available in the market.*
> *2. Mentor: Why is that? No one is aware of these food items?*
> *3. Manoj: They are not aware about the vitamin content, like it's not in some books or google, so they are not confident about it.*
> *4:Mentor: So, you think people used to eat these items without any research.*
> *5. Motilal: They would have known this by some method or daily usage.*
> *6. Mentor: But how do you think they figured this out ?*
> *7. Manoj: yes, they didn't research but they would have found somehow, there are so many plants in the forest, but not all are consumed, so there must be some way to test.*

Manoj is still speaking with some confidence about the local food but brings up that the authorities on health and nutrition (doctors) do not recognize it (1). He attributes the decline of the local food items to lack of support from conventional sources of knowledge, as 'it's not in some books'(3). Therefore, lack of conventional evidence comes out as a strong factor that may be dissuading the consumption of local food. When the mentor poses a question about how the community generated this knowledge and its own form of evidence, Manoj feels that there must be a method of discernment within the community. There are two important points here. One is that this other way of knowing, and this other kind of evidence (7) suggests a tension in presenting indigenous knowledges in conventional forms of representation. The second point is about 'not being confident'(3), which if read from a structural perspective, can become a case of rendering some people underconfident. Later in the project, in another class, Manoj reads an article about 'natural medicine' as practiced by indigenous community, which makes him more skeptical about how confidently community knowledge is presented. In this class, the mentor directs Manoj's attention to the "Note" that the author had included at the top of his article, which recommends that people consult a doctor before consuming these medicines mentioned in the article.

> *1. Manoj- This (note) is written because these medicines are only based out of experience, and there is no research, so maybe it is not confirmed, because it is based only on experience, so this is just used by Adivasi community, so that is why maybe the author is recommending that doctor should be involved before its usage.*
> *2. Mentor- The title however does not look tentative. What do you think?*
> *3. Manoj- Yes, the title does not have it. When people see this title, they may get curious to know about such medicines, they would want to explore it, but then they have put this note.*
> *4. Mentor- Do you agree with the choice of the note being here?*
> *5. Manoj- Yes*
> *6. Mentor- if the article was written without a note, do you think it would have made any difference?*
> *7. Manoj- Maybe some people may have questioned this knowledge, not everyone knows about this , people just know that there are some traditional medicines, but what is its actual impact they don't know, I am actually not sure…*

Manoj interprets the "note" as the eventual deference to the validation of doctors' over lived experience of the community(1). If the article is written without the note, he can imagine some objections because 'not everyone knows about this' and its 'actual impact'(7). Eventually he connects this need to write a note to the lack of confidence in the community as discussed in the previous interaction. His own agreement to the choice of including that 'note' (5) can either be read as his pragmatism about the convention of publishing articles of this nature, or it could be indicative about his own skepticism about the status of community knowledge. There were classroom moments where the status of community knowledge on food was not in question, only the acceptable form of evidence was doubtful. But there were also moments when Manoj slipped into doubts about the knowledge itself. Manoj felt the need for confirmation in the way it appears conventionally for regaining cultural confidence in local food. Having a mentor who does not share his cultural background and practice may have alleviated the confusion about this topic. Eventually, Manoj developed the content of his article and published it. So, let's turn our attention to how his contradiction enabled certain rhetorical strategies in his final writing.

Figure 2
Opening segment of Manoj's article



How Has The Nutritious Food Of Indigenous Society Changed Over Time?

Motilal - Grandmother, Grandmother! I have good news. Yesterday the government announced this week ending the lockdown, 15 days been completed this week. Now I will go and purchase cauliflower and chicken.

(Announcement- "lockdown has been imposed again, stay home stay safe.")

Motilal- Oh no! All families are eating maad - Bhat and alu bhujia. We are bored with this food.

Dakago:- Today let's eat Sing Aara, let's go and collect.

Motilal- Where to get it?

Dakago - Kulhi muchet (end of the road in the village) one tree is there, whose leaf opens in two sides, It's called sing aara.

Motilal - Oo goats feed on this leaf. We have not seen anyone eating, This is a non-food item and you are saying to eat it, If another food item is there then tell me.

Dakago:- We ate sing ara and survived our life… that time we were not knowing about chawle and guhum!

Motilal - You say chawle came yesterday only?

Dakago - Before we ate adi, arba, gundli, matkom tiki and many more.

Motilal - I didn't see anyone eating these things these days. What happened now?

Manoj decided to have a title that has a quality of both asking and telling in the same gesture, which encapsulates both the process and product of his writing (Figure 2). He includes 'nutritious food' in the title and chooses not to provide any disclaimer or note, suggesting his confidence in what he is presenting. His strategy to open the article with a conversation he had with his grandmother during the covid lockdown is an interesting choice. Though this is an actual conversation he had, he retells and possibly refashions it. In this conversation, he positions himself as an outsider to this knowledge system, possibly representing the young people of the community, looking forward to "purchasing cauliflower and chicken" as soon as the lockdown is over. When his *Dakago* (grandmother) suggests eating *Sing Aara* (a local green vegetable), he is not just unaware of what it is, but by calling it a "non-food item" is also outright dismissive. He is making several rhetorical moves in this section that reads as a dialogue between local knowledge and convectional evidence. His voice embodies an acute sense of skepticism that he experienced in the classroom. The paragraph after this conversation entails a description of old food items and habits. These details are generated by what he calls, 'research at the *Aatu*(village)'. His voice moves back and forth between a distant sociological tone to that of personal lived experience. In support of these traditional and locally available food items, he writes- "*Old men says that 50 years ago eating fruits and leaves used to keep their bodies healthy and energetic. My grandfather is healthy and strong compared to the new generation.*" In attributing the first sentence to 'old men', he creates a distance between that claim and himself. But in the next line he presents evidence of that claim from his personal experience. The nature of evidence for the value of traditional food habits is not presented through a nutritional breakdown, but rather through an observation of his own grandfather's health.

> *When we are sick, then our community and doctor have not told us to take nutrition food like sahjan, sing arah, siti, and many more available in villages and forests. There is huge unawareness around nutritious indigenous food. These foods have more nutrition yet are left out. One reason for this neglect is also that experts and our community people are not taught about indigenous food knowledge. The people of the villages are also less educated and less knowledgeable about indigenous food nutrition. This is just self-knowledge and not published or recorded anywhere.*

From the standard conventions of persuasive writing that encourages a unidirectional claim backed by evidence, Manoj's writing may feel to be moving in multiple directions and sometimes undercutting its own stance. I would argue that the contradiction Manoj experienced between asserting his local knowledge and the skepticism around it, enabled him to develop a critical yet intimate voice that moves in many directions. This critical intimacy not only allows him to move between his admiration and critique of his own culture, but also provides him a space to both critique and respect conventional evidence. He implicates both the 'community' and the 'doctor' for 'huge unawareness around nutritious indigenous food'. As much as he claims that 'these foods have more nutrition', he is also mindful that 'this is just self-knowledge'. Finally, it allows him to move between a version of himself that comes across as ignorant and indifferent in the introductory exchange to a version of himself willing to take responsibility, as presented in the last few lines of his article. *"I also share with people about the food we find around our home. So that everyone knows and becomes aware about natural food. If we try to increase the awareness, then people will change."* Therefore, I argue that the contradictions enabled Manoj to creatively navigate the need for conventional evidence and his love for community food. He turns around his confusion into a playful rhetorical strategy of adopting multiple positions that gives a deconstructive edge to his writing. In the process, like Saroj, he too pushed the limits of persuasive writing. If a conventional template of persuasive writing, supports a clear assertion, his writing structure embraces complexity and contradictions.

Implications

In this paper I presented two cases of enabling contradictions from my study of decolonial literacy. One way to think of enabling contradictions is to think- what does it enables us to do? We can say that it is enabling us to transform the knowledge systems from within. In this case we saw how students constructed novel ways to push the boundaries of what is persuasive English and English language. Therefore, the study has implications for classrooms that want to engage with decolonial designs in general and more particularly with Translanguaging and culturally authentic texts. I want to mention two limitations of this work. First, in my data there were moments where the contradictions were confusing and demotivating for students, which highlights the pedagogical care required to work with decolonial frames. Second relates to the metacognitive awareness of students in the strategies they employed, some they articulated explicitly but some were inferred by me. Finally, I feel that contradictions were not internal states of students, but rather a distributed experience, that worked across students, teachers, and the mediating artifacts. But for this study I have privileged the perspective of students.

A broad implication from this study is that decolonial educational designs that are inclusive of alternative epistemological stances, create contradictions for students that are potentially enabling. For different contexts and different subject domains, different design elements and conventions will activate these contradictions differently. However, regardless of context and domain, the process of struggling through contradictions has the potential to deconstruct dominant knowledge systems. Therefore, in designing decolonial literacy spaces one can design *for* contradictions and also *for* the mediating processes that mentors, and students will use to engage with it productively.

Socially Constructive Interaction for Fostering Teacher Learning

Hajime Shirouzu, Shinya Iikubo, Moegi Saito

Abstract: In order to clarify the structures of successful teacher interaction for learning about the relation among lesson, student learning and technology, this paper analyzed a case of three elementary school teachers trying out six lessons of collaborative learning and lesson studies during five months in the COVID-19. The teachers first felt failures in their online collaborative lessons and attributed them to the technology, but later changed their views focusing more on student learning and lessons with the help of colleagues and technology. Our analysis revealed that the successive role-exchange among teachers contributed to inducing constructive interaction, indicating such mechanism of socially constructive interaction needs to be built in the community with the sharing and accumulating technology of the processes of lesson study.

Introduction

Responding to the conference theme of “Building knowledge and sustaining our community”, this paper aims to clarify the structures of successful teacher interaction that supports teachers in changing their views on the relation among lesson, student learning and technology. The COVID-19 pandemic forced many teachers to adopt new technologies into classrooms, even when they lacked appropriate *technological pedagogical content knowledge* (TPACK; Mishra & Koeler, 2006). Such situation tended to yield failures in lessons and invite the them to attribute the failures to the technologies. Even in that situation, it is desirable for teachers to acquire *principled practical knowledge* (Bereiter, 2014), which helps teachers go beyond what is required for solving practical problems such as recovering from failures, but little is known about how they build this kind of knowledge in what mechanism.

Countless studies of professional development indicate that it is important for teachers to experience designing lessons, conducting and reflecting upon student learning repeatedly in a professional community (Fishman, Davis & Chan, 2014). The *lesson study* approach, originated from Japan and known as an effective form of professional development, constitutes practices in which a group of teachers plan lessons, observe live classroom lessons, collect data, and analyze such data (Lewis, 2002). Recently, the technology-mediated lesson study is proposed, which uses the same cycle of lesson study but uses technology resources that allow teachers to interact and learn together when not co-located (3D-RST, 2023). If we combine this type of lesson study with the introduction of technology into classrooms, we would be able to offset or at least reduce disadvantages caused by the technology, since it keeps a record of student interactions for teacher reflection. As the first research question, therefore, we examine if the combination of technology with lesson study would help teachers change their views on lesson and student learning, even after they feel that their lessons have failed.

If this is the case, we then identify its mechanism. The lesson study, we hypothesize, enables *constructive interaction* (Miyake, 1986), through which each participating individual deepens her or his own understanding. The theory of constructive interaction explains that a role exchange between a *task-doer* who proposes solutions to a shared problem and a *monitor* who reflects upon such proposals contributes to deeper understandings. Saito and Miyake (2011) expanded the notion of the two-person constructive interaction into *socially constructive interaction* in two senses: first, the interaction takes place in the situation involving more than three persons, and second, the interaction occurs not only among individuals but also groups. It was observed in their case of science class by third graders that in the whole class discussion, a small group of active members engage in a long-heated discussion as a *task-doing* group, which is *monitored* by the other members. As the second research question, we examine if we could identify the socially constructive interaction in the teacher interaction during lesson study.

In order to answer these two questions, this paper analyzes a case in which three elementary school teachers of a town tried out six lessons of collaborative learning and lesson studies during a five-month period in the year 2020. We first explain a research field, and schemes of collaborative learning and lesson study, the latter of which emphasizes a pre-lesson study to make hypotheses about student learning explicit (Iikubo, Shirouzu & Saito, 2022), and then the board of education (hereafter BOE) of the town, teachers and lessons in the Method section. We analyze the case by tracing not only the lesson that was actually taught but also a pre- and post-lesson study and other lessons to retry that lesson and considering the learning outcomes not only of the main teacher but also of her or his colleagues in order to reveal the socially constructive interaction during lesson studies.

Method

Research field: Consortium for Renovating Education of the Future (CoREF)

As the research field, we focus on a learning sciences project led by the institute, CoREF, initiated by the University of Tokyo in 2010 and taken over by the Nahomi Institute for Learning Sciences from 2021. CoREF has been collaborating with twenty-nine BOEs distributed across Japan, hundreds of schools, and 1,305 teachers with the vision that the teachers as well as the administrative leaders at the schools and BOEs are learning the sciences of learning, not in an abstract form but through implementing them.

CoREF assumes that the learning processes are too diverse and complex for teachers to design lessons, listen to student dialogues and understand their processes without any common *constraints* (Norman, 2013). CoREF built on the theory of constructive interaction (Miyake, 1986), assuming that a key condition for the interaction to take place is sharing the desire to solve a challenging problem. Thus, CoREF introduced an instructional framework, the “Knowledge Constructive Jigsaw” method (hereafter “KCJ”) not only to bring the constructive interaction into classrooms for students but also for teachers to be involved in practical research of how to design lessons and reflect on student learning according to this framework as their shared problem.

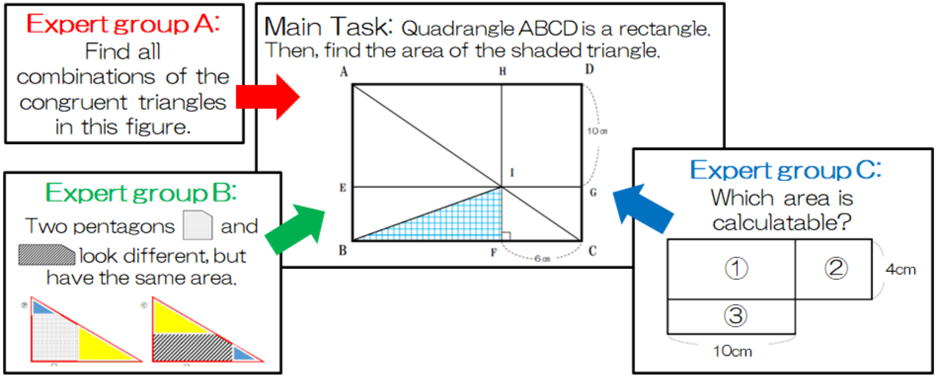
Framework of practices: Knowledge Constructive Jigsaw (KCJ)

The KCJ serves as the instructional framework as well as the stage for the collaborative reflection of teachers. It consists of five learning activities for students: (1) writing an individual answer to the day’s given problem using a rule of thumb, (2) an expert-group activity which allows each student to accumulate some (three in most cases) pieces of knowledge relevant in solving the problem, (3) a jigsaw-type activity where students from different expert groups get together to exchange and integrate the pieces of relevant knowledge and form an answer, (4) a cross talk activity to exchange their ideas for solutions across groups in the entire class, and (5) writing down an individual answer again to the same problem and newer questions (Miyake, 2013).

Figure 1 illustrates a KCJ lesson schematically. The main task is challenging since students need to find the area without knowing exact the lengths of side BF and side IF. Thus, they learn expert materials and integrate pieces of knowledge in the jigsaw activity: find three combinations of the congruent triangles (Expert A), subtract the areas of triangles AEI (AHI) and IFC (IGC) from that of triangle ABC (ADC) to find that the area of rectangle BFIE equals that of rectangle DGIH (Expert B), calculate the area of rectangle DGIH as 60cm^2 (Expert C), apply it back to the rectangle BFIE (Expert B), and divide the area by 2 and get 30cm^2 using the congruence between triangles BFI and BEI (Expert A). The students challenge these kinds of tasks, and teachers assess student learning through the improvement between the two answers to the same question at the beginning and the end of the lesson. They also utilize students’ dialogues during the expert, jigsaw and cross talk activities in order to understand what kind of interaction deepens understanding of each.

Figure 1

Example of the Knowledge Constructive Jigsaw lesson (Math, Grade 5)



Lesson study approach

The KCJ motivates teachers to engage in lesson study; as being only a framework, it requires teachers to design the learning content, that is, the “problem (main task)” and “learning materials (for the expert activity)” and to be proactive in discussing the content prior to the lesson. For this purpose, the project used a mailing list for online discussion on the planning and reporting of KCJ lessons in each subject group across the schools and the BOEs from the initial year 2010. When consulting others, the teachers have a shared understanding of the framework, which aids in making the discussions more efficient and pertinent. In addition, CoREF devised a common format of the teaching plan and the reflection sheet, accompanied by the teaching materials (e.g., worksheets, readings), which makes discussions even smoother. At the end of every fiscal year, CoREF published the annual report which includes sets of plan, material and reflection sheet of tested practices. This resource is not intended to guarantee a success of the lesson to other teachers, but to provide them with chances to retry or modify it to listen to and learn about the dialogues of *their* students. In this way, the community as a whole helps the participating teachers, experienced as well as novice ones, work together to take turns practicing the lesson as the main teacher (task-doer) and observing it (monitor), in order to make constructive interaction occur among teachers.

A remaining issue is what knowledge teachers need to acquire or build through such interactions. CoREF revised the lesson study approach with putting more weight on the pre-lesson study to turn the cycle of lesson study as the *hypothesis-formation and testing cycle* and accumulating its records by the two tools given below.

Hypothesis-testing lesson study

A "hypothesis-testing lesson study" combines hypothesis formation (*how students will learn*) and testing (*how they have learned*), where teachers participate in the following activities: (1) engage in the *simulation activity* of experiencing the lesson as students, anticipating the learning processes of students, and comparing their anticipation (hypothesis) with that of the main teacher, or just listen to it prior to the lesson, (2) observe the same student group together with multiple teachers during the lesson, (3) share and discuss observations, particularly on the learning processes of target students compared with the hypothesis of the main teacher, (4) make recommendations on the lesson design, (5) listen to the self-reflection of the main teacher and (6) write down their findings from the lesson study. As is evident from the activities, the word "hypothesis-testing" is not meant as the generalization, or *high-level abstraction* of causal relationships found between a specific teaching method and its learning outcomes, but the careful anticipation and reflection of *each* practice as in steps 1, 2, 3, 5 and 6 in order to extract hypothetical practice guidelines called "design principles" as in steps 4, 5 and 6 through dialogue among the participants involved. The hypothesis-testing lesson study differs from a typical lesson study in two senses: focusing more on student learning and letting not only the main teacher but also the participants take the role of task-doing of imagining what they would have done based on the reflection upon learning processes.

Learning note

A "Learning Note" system collects and categorizes the emails posted on the discussion list by lesson topic, displays posts with attached files in chronological order, enables searches using keywords and recommends related topics (IIkubo et al., 2022). All the teaching materials published in the annual reports were added to the system with links to the discussions. The members are able to download files to replicate and modify a lesson and read the discussions from where the lesson developed, as if to unpack the accumulated cycles of lesson study in which they have not participated. The system is equipped with a database page of 1,096 teaching materials, a topic page that discusses 1,893 lessons, and three "unit-map pages" which visualizes the structures of the learning units of social sciences, math and science of elementary and middle school and their relation to the KCJ lessons.

Online and hybrid lesson study

Although CoREF adopted various digital technologies as above, the KCJ lessons for students and lesson studies for teachers were mostly conducted via face-to-face. The COVID-19 pandemic, however, interrupted this practice. In Japan, all schools were closed at the end of February until May 14, 2020, but the participating teachers continued to create "undated lesson plans" for a time when their students would come back to school. Moreover, even when they became able to resume collaborative learning in the classrooms, they had to enforce social distancing such as by using a web-conference system. This is somewhat an additive usage of technology, not being situated in their socio-cultural context, which might intervene smooth interactions among students.

On the other hand, such use of an online platform, for example, Zoom's Breakout Rooms for the KCJ group activities enables a safely-distant, convenient lesson study, since other teachers and researchers outside the school and the BOE are able to sneak into the student group when the students engage in online discussions during the expert and jigsaw activities, followed by a post-lesson colloquium directly after the lesson. This style of lesson study is also innovative in the sense that the observers are able to chat online or discuss the points directly with one another during the lesson, which would have been impossible in an on-site observation where the observers would have been positioned right next to the students. We call it *online lesson study* when all the observers participate remotely and *hybrid lesson study* when both online and face-to-face observers are included.

Board of education: Akiota municipal board of education

Akiota municipal BOE participated in the project above from the initial year as one of the most proactive BOEs despite its disadvantaged conditions in terms of education (e.g., low SES, small population) and tried the online collaborative learning and lesson study at an early stage of the COVID-19 pandemic in 2020. The BOE has faced a problem of how to enable teachers to learn from other colleagues and experts outside the town due to its small population. A superintendent set a vision of participation in the CoREF project for the purpose of teacher professional development, while sharing the basic vision of reform for children. Under his leadership, the BOE set a standard requiring each core teacher teach a KCJ lesson at least three times every year. He also secured a budget to send core teachers to the University of Tokyo, not in the way of sending different teachers every year but selected teachers to engage in in-depth learning, who then returned to the town to act as a hub of innovative practices as well as a facilitator of lesson study. In 2020, there were two middle schools and four elementary schools comprising 305 students and 70 teachers. Three elementary schools, Schools TT, TG and KD had combined classes where one teacher taught two grades. Before COVID-19, the BOE provided these schools with chances once per semester to assemble students of the same grade to any one school, enabling a group learning with more members than usual, which served as a basis for the online collaboration.

Lessons in target

Table 1 summarizes the target for analysis: six lessons using the KCJ and their post-lesson studies conducted from June to November 2020. Although Teacher KO had been a teacher for 20 years, Teachers YN and KN had been teachers only for four and five years respectively. KO belonged to the elementary school TT, YN did to School KK, and KN did to School TG. In the fourth trial, students from the three schools assembled on Zoom. Although there were other KCJ lessons than these lessons during this period, we selected six mathematics lessons. The third trial by KN was a replication of the second trial by YN and the fifth trial by YN was a replication with some modification of the fourth trial by KN in turn. The first and sixth lessons were taught by Teacher KO to the same students, which makes an analysis of the development of the teacher and students easier. Lessons and lesson studies were conducted in various ways, drawing many teachers and researchers outside the schools.

Table 1
Summary of six lessons and lesson studies

Trial	Teacher	School/Grade	Unit in math	Lesson	Post-lesson study
1st	KO	TT/ Grades 5, 6	Congruence (Grade 5) Ratio (Grade 6)	Via Zoom (Combined class)	Online (27 teachers and researchers)
2nd	YN	KK/ Grade 4	Concept of "Times"	Via Zoom	Online (25)
3rd	KN	TG/ Grade 4	Concept of "Times"	Face-to-face	-
4th	KN	TG, TT, KD/G4	Round numbers	Via Zoom	Hybrid (33)
5th	YN	KK/ Grade 4	Round numbers	Face-to-face	-
6th	KO	TT/ Grades 5, 6	Area (Grade 5) Basic statics (Grade 6)	Via Zoom (Combined class)	-

Case analysis and results

We first report each case (lesson) in detail by using the data of posts on the mailing list, activity logs of the Learning Note, video recordings of lessons and post-lesson studies and the reflection sheets written by the main teachers, along with anecdotes reported from the BOE. We then present two analytical perspectives with the results of analysis: first, comparison between the interpretation of each lesson by the main teacher directly after the lesson and that after the lesson study, and second, identification of the successive role-exchange among teachers, that is, who made such interpretation and reinterpretation in a series of six lesson studies.

Case: Development of the six lessons

The first trial: "congruence" (grade 5) and "ratio" (grade 6) lessons taught by teacher KO

On June 17th, Teacher KO attempted the online KCJ lesson for the first time in the town, since she did not want to give up collaborative learning despite the pandemic and the pressure to cover mandatory content.

The lesson for six 5th graders was the "congruence" lesson shown in Figure 1, which had been devised in 2014 by a teacher belonging to another BOE. Teacher KO found the material on the Learning Note and considered it as a good review of students' learning about the area of rectangle as well as preparation for learning the area of triangle. She posted her plan and material on the mailing list on 28th April during school closure, followed by seven posts made by researchers SI and MS, a supervisor KM and a teacher KK of the town (see Table 3). The discussion centered on the expected dialogue for the students, especially the dialogue with drawing diagrams on the worksheets to find congruence. Teacher KO revised the material once before the lesson.

The lesson was conducted in fifty minutes. Her students sat down in a school format, apart from each other, and engaged in group discussions using Zoom Breakout Rooms. Since it was the first time most children used Zoom, they repeatedly asked each other "Can you hear me?". The functions of screen sharing and whiteboarding did not work well, preventing them from thinking and explaining while drawing and instead forcing them to communicate with only words. In addition, the class lost the Zoom connection due to the traffic overload, but the children were strong and flexible minded enough to raise mini-whiteboards at hand up to a distant classmate with speaking loudly. Both the two jigsaw groups did not reach a sound explanation at the beginning of the cross talk. Teacher KO invited one group member in front of the blackboard to let her explain a part of the answer, draw two combinations of the congruent triangles (AEI and AHI; IFC and IGC), and calculate the area of rectangle DGIH, which made some students notice the congruence of the two biggest triangles and the "part that had different shapes but the same area" with the rectangle DGIH. Although all students solved near-transfer problems correctly after that lesson, not all students created complete explanations.

Directly after the lesson, Teacher KO regretted, "If it weren't for the problem with the technology!". Twenty-seven observers participated in the online lesson study of one hour that covered the steps 3 to 6 of the hypothesis-testing lesson study. First, they shared and discussed observations of the student group in small groups via Breakout Rooms, and then shared what they had discussed among groups. For example, a representative of one group, Teacher FI reported, "Because one student said, 'The diagram of the main task looks like that in the material of Expert C', I thought they could deepen their understanding along this line of thinking. Right after that, however, he said, 'We can't find the area of rectangle unless we know the vertical length,' and a group eventually started thinking in terms of the length, not the area".

A week after the exchange of these careful observations and ideas for future lessons in the lesson study, KO submitted the reflection sheet to the mailing list, followed by three posts (see Table 3). KO still complained about the technical difficulty in monitoring conversations, but she focused more on the *cognitive difficulty* for children in reinterpreting the same figure from different perspectives, what the Expert B material required (Figure 1). The following discussion seconded her finding, with proposing various scaffolds for such perspective shifting.

Space does not permit us to detail the "ratio" lesson for five 6th graders. Teacher KO found the material on the Learning Note that asked students to decide which juice tasted the same using the concept of ratio. The 6th graders, facing the same technical issues as the 5th graders, solved the problem only by calculation without justification. Similarly, the online lesson study eased KO's feeling of failure with reports on observations of students' struggle to think.

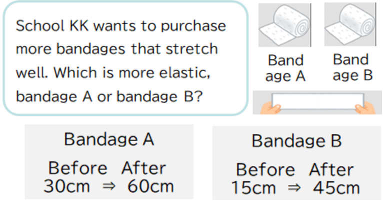
From the second to the third trial: "times" lesson (grade 4) taught by teachers YN and KN

Teacher KO's attempt and the lesson study encouraged other teachers to try the KCJ lessons online. On September15th, Teacher YN tried the online KCJ lesson in a computer lab for seventeen 4th graders. The unit "Times" had been newly introduced into the national curriculum of this grade and intended to connect students' understanding of multiplication and division with the concepts of ratio and proportion. The main task, which Teacher YN had chosen from the textbook, tells what the unit was about, as shown in Figure 2. In order to know the nature (elasticity) of the bandages, his students needed to use not subtraction but division and compare *double* (Bandage A) with *three times* (Bandage B), which was the first time they compared *two ratios*.

Twenty posts on the discussion list prior to the lesson focused mostly on the content of expert materials and the goal of mathematical understanding in this lesson. While Teacher YN revised his plan twice, the materials changed from the mere explanation of the correct solutions to the inquiry into why and when to use subtraction and division, as YN deepened his own understanding of the ratio. The final version expected his students to reach understanding of two points: first, subtraction was suitable when the basic amount for comparison was the same between two objects, but unusable when the basic amounts differ between the two, unless they made them the same, and second, division was applicable when the basic amounts differ using the concept of ratio or "times".

Although this lesson was the last lesson of the unit through which his students should have become proficient in seeing things in terms of *times*, and the students perceptually judged that Bandage B was more elastic, they stuck to the solution of subtraction throughout the lesson. At the end, 15 out of 17 students still wrote this solution, being unable to decide which bandage was "well-stretched" since the difference (30cm) was the same.

Figure 2
Main task for the 2nd and 3rd trials (Math, Grade 4)

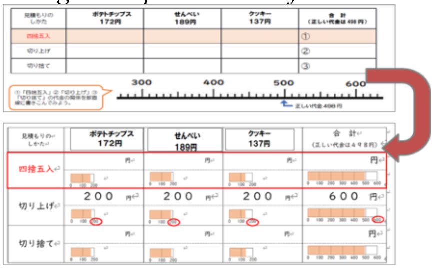


School KK wants to purchase more bandages that stretch well. Which is more elastic, bandage A or bandage B?

Bandage A	Bandage B
Before After 30cm ⇒ 60cm	Before After 15cm ⇒ 45cm

Figure 3

Change in Expert material from the 4th to 5th (Math, Grade 4)



見積もりのしかた	ポテトチップス 172円	せんべい 189円	クッキー 137円	合計（正しい代金は498円）
四捨五入				①
切り上げ				②
切り捨て				③

見積もりのしかた	ポテトチップス 172円	せんべい 189円	クッキー 137円	合計（正しい代金は４９８円）
四捨五入	円	円	円	円
切り上げ	２００ 円	２００ 円	２００ 円	６００ 円
切り捨て	円	円	円	円

In the online post-lesson study, he attributed the failure to the usage of technology, since it actually took longer time than planned to give the students instructions through Zoom. The observers, however, helped him change this interpretation by sharing comments on student learning such as complexity of expert materials and difficulty in understanding the difference between "stretchiness" and "stretched". From these observations, Teacher KN as a group representative proposed, "It would be a good start for the lesson where most of the students know the answer but are unable to fully explain the reasons", the hypothesis of which she tried in her own lesson.

A month later, Teacher YN submitted the reflection sheet to the mailing list with writing, "The *comparison* means subtraction (difference) to the children, and it is still unnatural for them to consider the ratio. …When given the real bandages, they naturally cut out them to make the basic length the same, but did not use that idea when solving the problem on paper", implying that he had learned from the lesson and got closer to student thinking processes.

In September, Teacher KN modified learning activities with the same teaching materials as YN's so that her students were able to grasp the main task more clearly, and tried the lesson at School TG via face-to-face. At the beginning of the lesson, all the students understood that Bandage B was more elastic and all what they have to as the main task was to justify the answer. The lesson worked so well that all groups adopted the solution of division and the idea of ration at their cross talk, Teacher KN countered, "Is it impossible to use subtraction to solve?" and the students replied, "If we make the basic amount the same, we can solve it by subtraction!" Although the post-lesson study was not conducted, Teacher KN posted report and reflection on the mailing list with gratitude to Teacher YN, writing that she would never have confirmed the answer at the beginning of the lesson, if she had missed YN's lesson study. She further proposed an idea of narrowing the content of materials down.

From the fourth to the fifth trial: "round numbers" lesson (grade 4) taught by teachers KN and YN

On October 22nd, Teacher KN taught the online collaborative lesson by assembling eighteen 4th graders from the three schools on Zoom. She found the material for the unit "round numbers" on the Learning Note, which was devised by a principal HH of School KK eight years ago. The main task asked children which rounding was appropriate for particular situation (e.g., to know if ready money is enough for shopping), rounding up, down or off. Teacher KN also used HH's reflection sheet as reference, which reported that the lesson itself had not met HH's expectation, but number lines had greatly improved students' understanding in the next lesson. Upon the discussion on the mailing list with nine posts including Principal HH (see Table 3), the expert material was revised as shown by the upper figure in Figure 3. It included the number line below the table to visually compare the original sum of prices of three items with that of calculated by rounding off, up and down.

As both the teacher and students had adjusted to the various technologies in October, the lesson went smoothly. The hybrid lesson study was conducted simultaneously, permitting the in-person participants to talk with each other about what they observed. For example, they noticed that the students rarely used the number lines provided as hints for thinking, but simply filled in the tables and thought about the answers to the questions. Although all the student groups were able to choose the correct approximation method at the cross talk, sufficient explanations were not shared as to why they chose that method.

In the post-lesson study and the reflection sheet, Teacher KN commented, "Since we listened to key expressions such as 'Rounding up makes estimation safer' and 'It leaves the leeway' during the cross talk, I wanted to solicit such verbalization more by grounding their thoughts on easier materials to understand".

On November 18th, Teacher YN, in turn, tried this lesson via face-to-face. Having learned from KN's lesson, he modified the expert materials as shown by the lower figure in Figure 3 to include the number line (or bar chart) in every item with the guide of how to use (number and red circle in the figure). He also added detailed procedural instructions in case students got lost. As a result, the students managed to achieve his teaching objective. In his reflection sheet, Teacher YN wrote, "New ideas are born more and more after the lesson was over".

The sixth trial: "area" (grade 5) and "basic statics" (grade 6) lessons taught by teacher KO

On November 18th, Teacher KO and her students tried the online collaborative lesson again. The fifth graders attempted to invent a formula of the area of a triangle using their knowledge of the areas of a rectangle and parallelogram; the sixth graders examined two datasets by calculating central values and reading histogram and plot diagrams. Both activities required physical externalization of their thoughts and reinterpretation of perceptual objects, but her students, having got accustomed to Zoom, reached the expected learning outcome. Although the combined class made monitoring of student learning hard since two lessons were proceeding simultaneously, KO switched two headsets attached to the computers fluently in order to listen to the group conversation of different grades. She reported that one student who had little confidence in the face-to-face communication used the whiteboarding tool to let his drawing creep onto the board as if to jump in the conversation without a word.

Analysis of socially constructive interaction among teachers

Table 2 summarizes how the main teachers felt about their lessons and changed their interpretation, especially attribution of the failure, in addition to the information of who participated in the lesson study, or *monitored*.

As seen in Table 2, the main teachers expressed their feelings of failure and frustration about the lesson and/or the technology in the first, second and fourth trials. However, the post-lesson study and writing of the reflection sheet revealed that they put their focus more on student learning and the improvable points in their lessons as in the three trials. The results indicate that, even when the main teacher felt that she or he had failed in teaching the lesson due to problems with the technology, the colleagues gave feedback to change her or his focus from the technology to student learning. The improvement from the first trial (failure) to the sixth trial (success) demonstrates that the same teacher came to cope with the technology for implementing the lesson as she liked.

Table 2 also shows the role exchange pattern. By focusing on the role of the main teacher, we found that the role exchange happened twice between Teachers YN and KN. Teacher YN practiced the second lesson as the main teacher (task-doer), while Teacher KN monitored it and took the role of practicing the modified lesson in the third trial. Teacher KN practiced the fourth lesson in the new unit with making Teacher YN the monitor, who then took the role of task-doer in the fifth trial. As the theory predicted that the monitor grasped the situation from a slightly broader perspective (Miyake, 1986), both Teachers YN and KN reflected more objectively including not only the factor of technology but also that of lesson design when they took the role of monitor in the second and fourth trials. In addition, the two teachers formed an active *task-doing group*, which were *monitored* by Teacher KO who took the role of task-doer first and last. In sum, these results indicate that the teachers learned from others' lesson and lesson study on how students learn, came up with their own hypotheses, or *design principles* (*principled practical knowledge*), and tested them with their own students in their own classroom.

The socially constructive interaction took place at the finer level than the one above. Table 3 represents who posted on the mailing list in what order by their initials (those in italic mean the main teacher at each lesson). The gray cells mean the posts after the lesson including the submission of the reflection sheet. All members were teachers other than two researchers (SI, MS), two managers (FI, HH), and two supervisors (KM, MK).

Table 2

Interpretation, reinterpretation and monitoring of six lessons before and after lesson studies

Trial	Teacher	Lesson	Interpretation after lesson	After lesson study	Monitors
1st	KO	Online	Failed	Reinterpreted	YN/KN
2nd	YN	Online	Failed	Reinterpreted	KN/KO
3rd	KN	F2F	Succeeded	-	-
4th	KN	Online	Failed slightly	Reinterpreted	YN/KO
5th	YN	F2F	Succeeded	-	-
6th	KO	Online	Succeeded	-	-

Table 3

Role-exchange patterns of posts to the mailing list for six lessons

	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22
1st	*KO*	SI	KM	*KO*	MS	KK	*KO*	*KO*	FI	MS	KM											
2nd	*YN*	SI	HH	SI	FI	*YN*	*YN*	KM	SI	FI	*YN*	FI	HH	YS	*YN*	FI	YS	FI	MO	*YN*	*YN*	SI
3rd	*KN*	SI	*KN*	SI																		
4th	*KN*	SI	*KN*	KM	HH	*KN*	KM	KK	HH	MK	FI	*KN*	HH									
5th	*YN*	SI	*YN*	SI	*YN*	SI	*YN*	SI														
6th	*KO*	SI	*KO*	SI	*KO*	SI	*KO*	SI	*KO*	KM	SI											

As seen in Table 3, various members were involved other than the main teacher and researcher, up to eight. In every lesson, Researcher SI responded to the post by the main teacher before anyone else, but the exchange between them (as if they were the task-doing group) invited others to further discussion, especially when the main teacher tried new things (1st, 2nd, 4th trials). In contrast, the discussion of replication and modification did not last long (3rd, 5th trials), as if the lesson study of the original had served as the *pre-lesson study* for these lessons, indicating a succession of lesson design cycles. Space prevents us from detailed content analysis of the posts, but the teachers, whether the lessons were successful or not, almost always found new things, as Teacher KN proposed newer ideas after the third trial and Teacher YN did so after the fifth trial.

Discussion

In a series of six lessons and their accompanying lesson studies, the three teachers first felt failures in their online collaborative lessons and attributed them to the technology such as getting to grips with Zoom, as the use of technology tended to come to the foreground in the COVID-19 pandemic. However, they later changed their views focusing more on student learning and lessons with the help of other colleagues' observations, comments, and the actual process data of student learning, all of which were also enabled by technology. When we compared the discussion before and after the lesson in all trials, the teachers, whether they were main teachers or not, almost always built some pedagogical practical knowledge about student learning to go beyond such practical problems as recovering from the failure. This long-term accumulation of experiences moved the technology from the foreground to the background, letting the teachers think "critically about how to use technology" (Mishra & Koeler, 2006), especially understand the role of technology to share and keep a record of the learning processes.

Our analysis revealed that the successive role-exchange among teachers at both individual and group levels contributed to inducing constructive interaction to change their views. The lesson studies, especially when coupled with the usage of mailing list, Learning Note and hypothesis-testing lesson study, made the hypotheses of the main teachers more explicit to compare them with the observations, preventing them from deviating from the lesson and student learning and causing constructive interaction more effectively. In addition, as five out of the eight lesson materials were taken from the Learning Note system, the teachers appeared to *stand on the shoulders of giants* while learning from the development of each material as if *monitoring* the discussion of the *active task-doing group* across time and space. All these results imply that the sustaining community for teachers' knowledge building needs to build the mechanism of socially constructive interaction in the everyday practice with the sharing and accumulating technology of the processes of lesson study.

Abstract: This inquiry is guided by a curiosity around the stories that teachers tell about their students, content, and pedagogical approaches focused on data and computational literacies. We present a form of storytelling *with* theory as we apply theories of syncretism and translanguaging to empirical vignettes about teachers' sensemaking. We also present a form of storytelling *of* theory, drawing on teachers' stories to help us better understand how these theories are related to each other. We bring two teachers' stories into conversation: one from the Writing Data Stories (WDS) project and the other from the Participating in Literacies and Computer Science (PiLa-CS) project. Both projects utilized translanguaging and syncretism in their conceptions and designs, working with teachers to design for expansive forms of data-based and computational literacies.

Introduction

Theories of syncretism and translanguaging highlight that people use diverse language, culture, and literacy practices to make sense of the world (Gutiérrez, 2008; Vogel & García 2017). Translanguaging and syncretic forms of design and pedagogy afford educators ways of leveraging learners' existing sensemaking resources to disrupt power dynamics that mark (or leave invisible) certain forms of sensemaking as unacceptable (or normative). Our past work has explored the potential for syncretism and translanguaging to inform more expansive forms of learning within computing and data science education (Ascenzi-Moreno et al., 2020; Lopez et al., 2021). These domains are often presented as objective, neutral, and only interpretable according to Western logics. Translanguaging and syncretic pedagogies suggest that computing and data can be presented to students as additional literacies that can work alongside and in interaction with students' existing linguistic and cultural practices to help express themselves and understand the world. While our focus has been on bi/multilingual students, these pedagogical approaches are meant to engage a diversity of students who have been marginalized or othered in typical school settings.

In this paper, we analyze data from two teachers' engagements with these theories and pedagogies, as we heard in their storytelling reasoning about disruption, improvisation, and attention to students' culture and language. We contend that even as teachers leverage power to disrupt boundaries, the work of equity does not end there. Along with inviting student voice, culture and language, re-listening helps to negotiate trust and power and helps inform how knowledge and language practices become unmarked. Additionally, we also interrogate how teachers' stories attend to student language and culture and contribute to theoretical and pedagogical understandings of syncretism and translanguaging in computing education. Undergirding our methods and analysis is an interest in storytelling. As learning scientists, we seek to expand accounts of learning that consider historicity, social practices, and culture, and to do so in humanizing ways. Storytelling affords creative ways to share nuanced and complex meaning and emphasizes the salience of literacies in STEM spaces. As researchers, we work to co-construct stories that help inform understandings of the nature of learning and the power of equity-oriented pedagogy. To do so, we focus on pedagogical design, such as the reorganization of academic and everyday literacies, to explore teacher sensemaking.

Theoretical framework: Theories as story

We bring theories of syncretic and translanguaging into conversation with each other in a rather syncretic way, to highlight points of alignment and tensions. Rooted in theorizing the experiences of multilingual and nondominant learners, both theories emphasize how language and culture are fluidly negotiated in meaning making.

Syncretic theories of literacy originated in the field of linguistic anthropology to examine the non-deterministic relationship between language, culture and literacy and debunk long held beliefs about multiculturalism such as language indicates culture, and people can only inhabit one culture at a time (Duranti & Ochs, 1997). These scholars demonstrated that literacy practices are complex, socially situated, and draw on a multiplicity of language and cultural practices: "when different cultural systems meet, one rarely simply replaces the other," (p. 173). In conversation with Duranti and Ochs, Gutiérrez was inspired by the ways language-minoritized speakers drew on a multiplicity of powerful literacies and extended these ideas to contend with critical perspectives of learning (personal communication). She felt compelled to show the expansiveness of *syncretism*, the bringing together of two or more ostensibly contradictory or distinct domains, in opposition to Vygotsky's (1987) use of syncretic as the most underdeveloped form of learning. Drawing on the multidisciplinary history of syncretism, Gutiérrez demonstrated the rigor and generativity in migrant youths' literacy practices, actively resisting deficit narratives that these ways of knowing were in any way underdeveloped (2014).

Consistent with the boundary-defying orientation of syncretic theories, translanguaging theory describes how language use defies social categorizations of languages (Otheguy, García, & Reid, 2015). *Translanguaging* (Vogel & García 2017) demonstrates that named languages (e.g., "Arabic", "academic" or "vernacular") are social and political constructs, not cognitive ones. As one of the most notable translanguaging scholars in the US context, García developed her conceptualizations of translanguaging from the work of Welsh educationalist Cen Williams who developed the term to describe the use of Welsh and English in the same school lesson to counter colonial monolingual efforts to erase Welsh (Lewis, Jones, & Baker, 2012). García's work on translanguaging in the US was influenced by the context she was researching in, engaging in descriptive inquiry in bilingual classrooms with bilingual teachers (García & Traugh, 2002). Descriptive inquiry with teachers emphasized understanding students' sensemaking in relation to their friends, adults, and various contexts, looking at the student as a full person to understand their work. This humanizing research in conversation with the language politics highlighted in the Welsh origins of translanguaging laid the groundwork for García's work on translanguaging theory in the US context, focusing on the expansiveness and fluidity of bi/multilingual speakers' language practices.

The pedagogies derived from these theoretical perspectives foreground how teachers can disrupt barriers between learners' lived experiences in and outside of classrooms. Syncretic pedagogies (Gutiérrez, 2008) recognize that hierarchies between academic and everyday knowledge are also socially and politically constructed and resist this hierarchy by emphasizing and privileging hybridized forms of knowledge that emerge. Translanguaging pedagogies resist the social construction of named languages by encouraging learners to openly leverage their full linguistic repertoires. These pedagogies encourage students to use their full linguistic and knowledge repertoires, developed across home and school contexts toward more equitable and consequential learning (Radke et al., 2022).

Methods

Storytelling across contexts

This paper brings together stories about teachers across two projects–WDS and PiLa-CS–that both worked with teachers to support bi/multilingual students' learning in computing related subjects. Partner teachers were encouraged to design learning environments that supported students to leverage everyday language and knowledge repertoires for expression. Our projects took up constructs from translanguaging and syncretism as guiding pedagogical principles, to socioculturally situate computing as literacies within the multiplicities of literacy repertoires learners can leverage in their expression. These projects illustrate the application of these theories in relatively new domains (computing) and contexts (formal yet interdisciplinary school settings). Situating computing as literacy helps to foreground the ideologies and power dynamics that shape these means of expression, which is often hidden in a depiction of computing practices as objective logics to acquire. As expansive theories of learning and language, syncretism and translanguaging challenge these a priori conclusions.

WDS and PiLa-CS have both helped teachers develop projects where computing is integrated as an expressive and sensemaking resource within other disciplines (e.g., math, language arts, and science) through the facilitation of online summertime teacher learning communities (TLCs). In both TLCs, teachers were encouraged to incorporate authentic discourses and personally relevant programming and data science tasks for their students. WDS's TLC took place in summer 2020 and focused on introducing teachers to the data analysis tool CODAP and reviewing model curriculum units concerning nutrition and climate using large-scale data sets. PiLa-CS's TLC occurred in summer 2021 and focused on sharing an approach to designing which encouraged teachers to juxtapose literacies students might have developed at home or in their communities, with literacies from disciplines and computing communities as they designed a unit for the upcoming school year. Our analysis involves sharing stories from two focal teachers across these projects: Calli and Sandy (pseudonyms). Both teachers participated in a summer TLC and then extended their work into the following school year by implementing new units they designed. Calli extended the nutrition unit in CODAP from the WDS TLC to a new unit about candy advertising and Sandy implemented a unit she designed around the ethics of hacking that she initially designed during the PiLa-CS TLC.

Data collection and analysis

Data collected from both projects were used for this analysis including 1) observations and recordings from both TLCs, 2) pre- and post-interviews with Calli and Sandy, 3) artifacts teachers made in planning their lesson, and 4) student work from Calli's lesson. We used this data to develop empirical vignettes (Gutiérrez et al., 2019) demonstrating how teachers reflected on their pedagogical designs and learnings. This method foregrounds the power of storytelling as a form of analysis that broadens how we talk about data and computational literacies.

Authors 2 and 1, postdocs on WDS and PiLa-CS respectively, met weekly over an 8-month period to develop these empirical vignettes about the focal teachers. The initial vignettes consisted of three parts: (1) an introductory story about each teacher, (2) analysis of what each story revealed about syncretism, and (3) translanguaging. The aim in empirical storytelling was not to evaluate whether or not teachers "got" these theoretical concepts as evidenced in their narrative. Rather, in "sister team meetings," the authors identified translanguaging and syncretic elements that surfaced in (1) how these focal teachers talked about the design of their lessons (2) what teachers shared about implementing these lessons, and (3) what clues these teachers' pedagogies provide us about how these theoretical traditions are related to each other. The history of these theoretical traditions became a salient part of this analysis, supported especially by the intergenerational analysis with senior PIs on the projects and foregrounding the human and historical contexts of theory building that often remain hidden in scholarly writing.

Findings: Stories with theory

Vignette 1: Calli, data analysis, & lived experience as data

Calli was a middle school STEM teacher who identified as Mexican-American and bilingual (Spanish and English). She participated in the TLC with WDS with the goal of having her students "look at data meaningfully and feel comfortable using this tool [CODAP]." For Calli, issues of racial justice and equity were integral to teaching STEM; she described science as "a social endeavor that involves institutions with systemic inequities and historical racism" and reported that she "[has] felt uncomfortable with how little culture has been integrated into science education." She framed data literacy as "so important for [students'] critical thinking and also advocating for themselves and their community." Calli took up WDS's use of CODAP, data visualizations, and nutrition-related content to design a unit for her students around a seasonal topic, Halloween, so they could analyze *and* construct a data set. Her storytelling–across both her learning design and the implementation–lifts up her sensemaking about data literacy.

Calli's storytelling about the learning design

Drawing from her experience in the TLC, Calli designed a Candy Ad unit, which she taught in the fall of 2020. She wanted to make ideas from the TLC "more festive" and used a Halloween theme. In the unit, students discussed their favorite candies, how they were introduced to them, and how professional marketing teams use focus groups to sell products. At the time, all instruction was online and Calli described the unit as an "opportunity for students to connect with others" including their own cohort and people in their households. These connections traversed boundaries of school and home in a time of remote learning and social distancing.

Along the same vein of boundary-crossing, Calli invited students' lives as data into their practices of data collection. In her "hook" or "launch" activities that introduce new topics, questions, or themes, Calli "[collected] data from students' own experiences." She stated that "no matter who you are, you're bringing in knowledge, you're bringing in your own data and connecting that to new understandings," which she believed can "support student knowledge and self-esteem in STEM areas." Calli echoed this support in a later interview:

> The reason why I've stayed engaged is because of the actual name of the project [...] and also the the mission in a sense of the project, which is–which I interpreted as teaching our students to not–to build confidence in reading data, becoming data analysts in themselves, and being becoming familiar with each step, of developing an inquiry question, figuring out a way to collect data that can possibly answer it, revising if it's if it's clunky, and then being thoughtful when making conclusions about it.

Calli repeatedly emphasized students' agency in the practice of data literacy. For example, her language around "confidence" and "becoming data analysts themselves" was also reflected in her desire for students to "be researchers themselves and they're not passive about it."

The Candy Ad unit allowed students to engage in disciplinary practices of data literacy for statistical inquiry (Wild & Pfannkuch, 1999). Students were asked to identify candy that would sell best in their local context. Students' planning included developing questions for focus groups of eighth grade peers, friends, and family. Then, using Google Forms, students designed a survey to generate data. For analysis, teachers imported the Google form data (.csv file) into CODAP for students to visualize and interpret the survey results. Students then shared observations and inferences as evidence for their claims and wrote a Claim-Evidence-Reason (CER) statement "explaining why they think their candy would sell successfully at a local level based on their CODAP analysis." Calli designed this unit to counter "what usually happens" in STEM classrooms, where students use "expert-collected data from a professional." Instead, Calli "wanted them to go through the process of being a researcher…being someone out in the field collecting information and collecting input."

Language emerged as a theme in Calli's storytelling about her design. In the TLC, Calli critiqued her school's "focus on English as the only way to communicate information in our classroom" and emphasis on English monolingualism to prepare students for high-stakes testing. In contrast, she argued that "disruption" can happen "at the classroom level when you allow students to reflect and share their knowledge in other languages, or you know discourses, with each other in other languages." For her, this practice "support[s] learning even if it's not in English." She contrasted her expansive approach to language with less productive approaches. Calli reflected:

> Providing opportunities for either more casual discourse, or discourse in their native language, I think does the opposite of limiting, right? It opens up opportunities for them to describe things that maybe they don't have access to in …academic language …yet. So instead of saying "well if you're not going to communicate in this way, I'm not interested in hearing it." Rather than that, we're going to support that skill, but at the same time provide you opportunities to share those observations that maybe you're not ready to, or not as accessible to you…without shutting it down.

She reflected on her students' language practices both in and out of the classroom, emphasizing that students have wide repertoires of language that they should be allowed to access. She affirmed that students translanguage all the time, and that limiting their communicative repertoires amounts to "shutting down" their ideas. These reflections connected to the focus on audience in her design, which she found important for data literacy: "that's such a huge component–who's your audience and how are you getting them to buy in on your claim for this dataset?" Students shared a link to the survey with family and friends via social media or email. However, if the survey was "not in the language that they read," teachers offered strategies to "get around that" like administering the survey "interview style" in a different language, then manually "fill[ing] out the form to submit" it to the class dataset.

Calli's storytelling about the implementation

In her implementation, Calli found that students did not use the data in their ads in the way she anticipated, identifying the candy most people enjoyed and advertising for it. Instead, Calli found three distinct approaches:

> Number one we had students who said, "Hey I'm going to just go off the data. What the data says is the most popular, I'm going to go with that." The second group of students was like, "Everyone is not in their right mind. They don't know what's good. I'm just gonna go with what I know everyone actually wants and not our focus group. Our focus group is wack, that data is wack. I'm not going to go with it." And then the third group were the ones that were like "Yeah, this and that, but I just want to be a creative mind, and I wanted to do what I want." So they were funky. You know, the funky creative minds are like, "I want to do something weird. I want to do something unique."

Calli acknowledged that "sometimes there was a contradiction with [students'] C-E-R paragraphs and their ads." Rather than evaluating their work as wrong or unsuccessful, she affirmed her students' sensemaking: "They're like, 'okay well if I were to go off the data, this is what I would say, but if you give me the opportunity and say it's whatever I want, I might not go that route.'" Students drew different conclusions and used different rationales to make sense of their data across assignments. While their C-E-R paragraphs might have taken on a more traditional "majority rules" logic, students took up the ad space more expansively by integrating scientific practices of data literacy (data generation, planning, analysis/trends) with their everyday knowledge of candy and their audience. Calli designed for students' lived experience to be used in data collection and came to see how students leveraged these experiences in their analyses. In doing so, she ruptured boundaries between the scientific and everyday by positioning students' cultural repertoires and everyday knowledge as generative for data-related sensemaking.

Vignette 2: Sandy, hacking, & centering student language

Sandy was a white, monolingual English speaker working as a librarian in an elementary school with predominantly bi/multilingual Asian and Latinx students. As a librarian Sandy saw each student at her school once a week for a library and technology class and joined PiLa-CS to learn more about translanguaging because, “I don’t really understand it yet. But I do work with, with a large enough population, and I can see it being very helpful for them.” In the TLC, Sandy co-designed a unit on hacking for 3-5th grade students that she implemented that fall. In the unit, students developed a hacker’s code of ethics for their classroom community. This syncretic text put students’ hacking literacies into conversation with those of computer scientists. Sandy’s pedagogical reasoning and her students’ engagement illuminates generative tensions in centering student language and ideas in academic spaces.

Sandy’s storytelling about the learning design

During the PiLa-CS TLC, Sandy and her fellow teachers were asked to design curricula that incorporated literacies from computer science (CS), the teacher’s disciplinary home (e.g., library), and students’ home communities. Sandy grounded her unit in students’ home literacies that had frequently been brought up in her class. Sandy shared how her idea for a unit on hacking came from students’ contributions in her class.

> [This] is the inspiration of the conversations my students were having that made me want to design this unit. Basically, every time I, if I mirror my screen onto their devices or if we're remixing a project in scratch and I change something that is that they think they owned and created and it's safe, and then I go in and change it, it's always a kind of, it turns into was a huge disruptive conversation of like, “Oh, you’re hacking me.” “Why are you doing that?” “How are you doing that?” And then it turns into how maybe their family members got hacked in there, in the game play Roblox. This is about 3rd to 5th grade where these conversations are happening. So, since they happen so consistently, with every lesson almost that we do, it almost always comes up, I thought it would be a good idea to design a unit that really gets into, “What is hacking? How does it look in our community and do you think it belongs in our classroom?” So that students can really get a realistic view of what they're talking about. The PiLa-CS approach to designing the unit really helped me to try and address all layers of the student learning experience. So having their initial interest in this topic and then bringing it into the disciplines of the classroom was a very, a very gratifying way to design the unit for them because I feel like they're going to be engaged right from, right from the beginning. It feels like they’re designing the lesson instead of me.

Addressing hacking was a deliberate and consequential design choice. Sandy had previously positioned students’ comments about hacking as ancillary to the focus in her class, but they became the content focus for the unit. Thus, she centered language and ideas students regularly brought into her classroom that had previously remained at the margins. Sandy shifted from positioning students’ conversations as “a huge disruption” to seeing them as productive to the point of commenting “it’s like they’re designing the lesson for me.” She quickly and confidently identified regularity in students' comments about hacking, sharing numerous examples like, “‘Oh you’re hacking me.’ ‘Why are you doing that?’ ‘How are you doing that?’” These comments are examples of students translanguaging, using home language practices to make sense of classroom activity. When Sandy took control of their screens, it reminded them of being hacked, hacking someone, or observing hacking in a video game. In their comments students raised concerns about hacking and issues of control over digital spaces. Sandy previously saw these utterances as unrelated to her class, which is why she felt the need to control students’ screens to focus them on the content at hand.

Sandy’s unit engaged students in the question “What is hacking?” through a collective defining process. In doing so, she elevated her students’ knowledge and ideas about hacking. By asking “How does [hacking] look in our community and do you think it belongs in our classroom?” she recognized that students believed that hacking was happening in their classroom and had strong beliefs about whether it belonged. Since the topic had previously been dismissed, students had not been given a chance to shape how hacking operated in their classroom. Sandy moved from observing translanguaging in her classroom to implementing pedagogy that supported translanguaging. By centering the unit on a topic brought to her attention by student language practices, Sandy signaled to her students that their full language repertoires were welcomed and their ideas about CS were consequential.

Sandy’s storytelling about the implementation

When Sandy implemented this unit in her classroom, however, her expectation for having students “engaged right from, from the very beginning” did not match the ease of feeling like they were “designing the lesson instead of me.” In fact, during Sandy’s follow up interview a year later, she shared that there was some initial push back from her students when she first wrote the word “hacker” on the board:

> Even the word hacking. When I first put the word hacker on the board, they thought they were in trouble. They thought I was gonna be trying to say “someone hacked somebody's iLearn account and now you're in a lot of trouble.” Like but they would kind of timidly uh approaching the idea, because they also, it was like, “I don't really want her to know what I know, because I feel like what I know is gonna get me in trouble,” you know, like, “I don't want to get in trouble for hacking someone else's account because I thought it was funny.” Or, “I don't want to get in trouble for knowing what hacking is when I change the code to this game, because then they're not going to let me play it anymore.” So, it kind of, it took a minute.

Sandy saw that students had knowledge of hacking, but initially they did not want to share it in class for fear of getting in trouble. They were hesitant to engage with the initial goals of the lesson: to build off of students’ knowledge to develop a hacker’s code of ethics for their classroom community. While Sandy made the syncretic move to attend to her students’ translanguaging practices and center their thinking about hacking in an academic space, her students did not yet trust that they could engage openly and honestly.

Sandy worked to gain students' trust in multiple ways. One way was asking students questions that made hacking the object of study and analysis rather than “spotlight them” or draw attention to their previous hacking activity: “I wouldn't use the word ‘you’ I wouldn't say. ‘What did you do?’ [...] I would say, Ah, ‘Based off of the video, What does hacking mean?’” Sandy described taking the pressure off students to reveal things about their experiences with hacking that they were uncomfortable sharing by asking them to reason about other people’s hacking practices. Focusing on what other people did and what her students might do in the future kept the responsibility off of youth in the present and only put it on them for speculative, future actions. This finding highlights tensions that can arise with the implementation of syncretic pedagogy. Students may contest how and what is a viable and safe unit of analysis in a classroom. Putting different literacies in conversation together can bring up unanticipated conflict and illuminate other assumed relations necessary to engage in this work, like trust.

Based on these interactions, Sandy identified an emergent goal for this unit: to create a “safe environment.” When asked what made the unit feel successful, Sandy shared, “bringing the idea of hacking that they saw as a bad thing, and, and teaching them how to talk about it and learn about it in a safe way, I think was a success overall.” Getting past students’ hesitancy to engage was an important outcome for Sandy. She started by noticing students' peripheral translanguaging practices in her classroom as students called her out for hacking them. This led her to leverage syncretic literacies in her class by bringing students’ home hacking practices into conversation with computer scientists’ hacking practices. Thus, in response to her students *calling her out* for hacking them, she *called them in* to share what they knew. As the unit progressed, she shifted the spotlight from her students’ hacking experiences to developing (previously taken-for-granted) trust with her students.

Conclusion & discussion

How these vignettes help build stories with theory

We share these vignettes because we want to learn about equity-oriented pedagogy from our focal teachers. By identifying how theoretical histories of syncretism and translanguaging were reflected in how these teachers talked about their pedagogical designs and classroom implementations we saw 1) teachers disrupt barriers between language practices inside and outside of school; and 2) tensions arise that teachers had to negotiate when students were given new opportunities to openly translanguage while developing computational literacies.

In both cases, while teachers’ syncretic moves afforded pedagogical opportunities, they also presented pedagogical tensions. Both teachers’ stories emphasize a goal of lessening barriers between learners’ lived experiences inside and outside of schools (everyday and academic). Calli’s data literacy design positioned student experience as an important source of data alongside normative constructions of what constitutes data. It brought together scientific practices (survey design, CODAP analysis, statistical rendering) with the everyday (family talk, candy, culture). Rather than engaging in data literacy as limited to pre-determined datasets shared by the teacher, students were invited to leverage their own cultural experiences, communities of participation, and voice to practice statistical analysis. Course activities and ideas were organized around student interests and experiences, which led to students incorporating their values and language practices as part of their analytic process. Sandy, on the other hand, engaged student language and home practices as a way to expand learning about computational literacies. Rather than limiting what might be seen as disruptive behavior for students, Sandy engaged their talk about “hacking” to lead to enriched learning experiences that engaged new relevant disciplinary content.

Both teachers’ stories also highlighted tensions that emerge when boundaries between academic and everyday knowledge and literacies were disrupted. In Calli's case, a tension arose as students' sensemaking with data did not appear to align with canonical forms of reasoning in the leading discipline (statistics). For example, disciplinary ways of understanding might encourage a "majority rules" approach to determining the "best" candy to advertise for, yet students' sensemaking drew upon other resources that might not have been captured in the data, namely their own experiences. They repositioned data beyond what existed in the dataset they generated, instead using it as a tool for imagining what could be (i.e., their original candies and successful advertisements for an audience). As Calli made sense of what seemed to be a disconnect between students' CER paragraphs and their candy ads, she validated students' moves as productive expressions of student skills, knowledge, and values, and not "incorrect" data reasoning.

Sandy faced an unexpected tension as she invited her students' language practices and interests into the lesson. When the topic of hacking was brought from the margins to the center, students hesitated to respond to this reorganization drawing from their understanding of boundaries between what was "okay" and "not okay." Hacking was not something that had been sanctioned as discussable in school previously, and students did not immediately welcome or trust breaking that boundary. Sandy approached this tension improvisationally, shifting from asking students to share about their own experiences with hacking to what they thought about others' hacking practices. What emerged was the creation of a new syncretic artifact–a Hacker's code of ethics–that focused on ethical considerations for students' future–not past–actions. We learned from these cases that designing and implementing equity-oriented pedagogy that disrupts disciplinary, academic, and linguistic boundaries can generate new tensions when teachers work to unmark certain ways of knowing and speaking. These tensions can generate opportunities to expand what and how we reason about disciplinary concepts. In the context of computational literacies, these stories present compelling examples of how to broaden what we mean by computational literacies (e.g., hacking) and towards what ends we use them (e.g., imagining new possibilities).

How these vignettes help build stories of theory

Inasmuch as these vignettes represent how we build stories *with* theory, they have also been insightful in constructing stories *of* theories of syncretism and translanguaging. These two lineages, each with their own history, are rooted in descriptions of fluid ways of being, knowing, and drawing on repertoires of language central to sensemaking. Yet humans' semiotic resources are also marked by social structures that may impede their full exercise. In classrooms, including monolingual ones, students' ability to foreground a full range of communicative practices is governed by unique boundaries of power and appropriateness. Similarly, while students draw on wide knowledge and experience to make sense of content and information in classrooms, certain forms of knowledge are routinely more welcome than others. Teachers leverage power to invite or reject students' cultural repertoires as aligned with their conceptions of the boundaries of relevant knowledge. The vignettes presented in this paper offer insight into teachers' syncretic pedagogical moves as related to translanguaging–a practice that is always happening but not always marked, sometimes more hidden, sometimes more visible.

Resonant with the lineages of this work, we also position teachers as theorists of their own practice, and reflect on how their stories add to the stories of translanguaging and syncretism. Both Gutiérrez (2008) and García (2002) worked closely with teachers as they began to theorize about syncretism and translanguaging respectively, collaborating with teachers as co-theorists to better understand and reframe bi/multilingual learners language practices as a generative asset for learning and not a deficit. Gutiérrez (2008) demonstrated how teachers brought students' language into a *third space*, where the official classroom discourse and unofficial discourses in the classroom met. Further, García and colleagues' (2002) descriptive inquiry enabled teachers to see possibilities for engaging students' use of unofficial discourses, which would create what we see as third spaces. These theoretical beginnings situated both teachers and students as initiating moves to create third spaces in classrooms where multiple ways of knowing, being, and (trans)languaging could intersect.

The two vignettes shared in this paper show that there are different ways of leveraging teacher power to co-create a syncretic third space (Gutiérrez, 2008) through practices of re-listening. Classrooms represent spaces where sanctioned language and knowledge are implicitly unmarked as norms. However, as illustrated by our two focal teachers, syncretic pedagogical moves can help unmark unsanctioned ways of knowing and doing. Both stories demonstrate that unmarking language and knowledge practices can be an iterative process that is negotiated with students as they accept or resist these invitations and involve teachers' re-listening as an important response. For example, Calli's candy ad unit design emphasized the importance of students drawing on their experiences and relationships in the construction of a data set for analysis. This design reflected a conjecture that opening up sensemaking resources in the construction of a data set would support students in leveraging traditional methods of data analysis. However, Calli noted that some of her students' conclusions countered traditional forms of CER because they drew on their lives and values as data outside of the dataset they had constructed. Not all students decided "what the data says is the most popular I'm going to go with that [in my ad]." In this case, unmarking the ways students might construct data resulted in a push for Calli to unmark their data analysis practices as well. Students extended Calli's pedagogical offering, widening the third space she invited them into in her classroom, and in validating their analysis she in turn re-listened to what students had to say about valid data-analysis practices. In contrast, Sandy's invitation to bring in students discourses around hacking, to unmark their language practices about a topic of interest they shared, was not initially reciprocated by her students. Sandy's story demonstrates how theories of syncretic pedagogy involve more than just invitations, but also require re-listening as a humanizing effort to reframe students' computational literacy practices. Re-listening involves identifying topical connections within students' discourse, and also recognizing ideological implications of language and concepts and how those might intersect with student engagement. In inviting hacking as a valid topic, Sandy attempted to unmark what could be talked about, but students' initial responses revealed that unmarking knowledge and practices is a process to negotiate *with* students. The act of naming alone does not mean students will publicly engage. Instead, relational trust needs to be built between students and teachers because language and concepts are powered and politicized.

Ultimately, the analysis presented across our two empirical vignettes forefronts how opportunities to support syncretism and translanguaging in classrooms can be taken up as humanizing pedagogies. This occurred in moments when teachers unmarked previously irrelevant or unwanted language and knowledge practices and attended to how students responded to these invitations by-relistening to student contributions. Bringing these stories and theories together help us understand how teachers' work to disrupt language and cultural boundaries in service of expansive student sensemaking can create new forms of disciplinary practices, in this case computational literacy practices, when negotiated with students' acceptance and resistance to such invitations.

Refiguring the Positioning Through Tabletop Game Redesign: What it Means to Engage in Culturally-Sustaining Learning as a Family

Reyhaneh Bastani, University of Calgary, reyhaneh.bastani@ucalgary.ca

Jerremie Clyde, University of Calgary, jvclyde@ucalgary.ca

Abstract: In this paper, we present our approach to culturally sustaining learning, enabling the contribution of non-dominant voices and cultural resources to collective learning activities. In our study, we proposed activities for families to redesign tabletop games with ideas, categories, and processes that reflect their interests and culture on their own time during the global pandemic. We collected data through online video communications and families sharing their own artifacts (e.g., photos, videos, and blogs). We describe how families expressed what matters to their members individually and collectively and how this was intertwined with shifting family members' relational positions.

I don't think it was as easy to relate to what was going through the minds of each creator of the game pieces…all of us had probably very different perspectives. Even within a family unit, it is probably really hard to even get on the same page because sometimes I am like, I don't get it, what is going on?
The mother of Family 1, during the final interview

Introduction

The above excerpt was taken from the final online interview with a Canadian family (the parents and both daughters have Chinese ethnic background) who redesigned a tabletop game together. The mother shared her experience of recognising and reconciling the diverse perspectives within their family. In conceptualising this work, we were concerned about how Canada's public institutions perpetuate dominant cultures' deficit perspectives toward minority languages and cultures, despite being a pluralistic society with over 200 spoken languages and cultural origins. We introduced tabletop game redesign to family learning contexts to harness how tabletop games are played across generations (e.g., *Mancala* in Africa) and reflect cultures. Previous research has shown that game play and design position learners as individuals who engage creatively and critically with disciplinary ideas. In exploring culturally sustaining pedagogy of pursuing linguistic and cultural pluralism (Paris, 2012), we sought to address the deficit perspectives of seeing difference as incorrect and focusing on fixing what is deemed as problematic by exploring culturally sustaining pedagogy supportive of linguistic and cultural pluralism (Paris, 2012). When we moved the learning setting to the family during the global pandemic, we learned that each family not only explored their cultures, but also learned to accept the differences within the family. In this paper, we discuss how redesigning tabletop games (i.e., games with boards, cards or other physical objects) can help participants reposition generational differences, practices, and ideas as resources for their social learning (Ladson-Billings, 1995) as a family, sustaining their varying interests and perspectives. In what follows we introduce the perspectives that we drew on in conceptualising and enacting this work and discuss findings that contribute to advancing our understanding of culturally sustaining learning in diverse learning contexts.

Perspectives on tabletop games and culturally sustaining learning

A tabletop game is a unique design form that deeply engages users as part of its underlying structure to enable game play. Players must make sense of the rules and create mental models of possible moves and dynamics in relation to game elements and other players in the social space of play (Pearce, 2006). Simultaneously, players become part of the game system, where their personalities and ways of doing (i.e., negotiating the play) come into play (Gatti Junior et al., 2020). Playing tabletop games, players have different experiences each time they play and with different playmates or opponents. Crist et al. (2016) similarly pointed out how tabletop games provide an intimate space of play that can bring people from different ethnic and social and economic backgrounds in contact and offer them new opportunities for engagement and relationship building. We discuss how the literature on tabletop games and their educational significance demonstrates the potential for culturally sustaining learning.

Sustaining and evolving tabletop games

Tabletop games are cultural artifacts that reflect values, beliefs, and interests in their system of rules and aesthetic elements. The ancient game of *Senet*, for example, reflects the value of divination, while players have "a metaphoric race against fate" (Flanagan, 2009, p. 68). The Chinese game *Go* (i.e., its system of layout and unfolding situations) is influenced by cultural norms and beliefs and may be connected to some divinatory practices of using black and white stones for predicting mystical events (Flanagan, 2009). Among other examples that Flanagan (2009) shared, many Japanese games reflected contemporary interests such as educating about the world through travel and contemporary poetry (e.g., *100 Poems by 100 Poets*). From another viewpoint, Crist et al. (2016) described how board games were used to facilitate interactions "across kinship, ethnic and socio-economic boundaries" (p.181), such as for traders to develop amity in Africa and South Asia allowing "individuals from distant regions and cultural backgrounds to interact across real and imagined boundaries" (p. 191). They argued that board games were historically used as "social lubricants" across cultures and were adopted into varying societies by being decorated and reimagined appropriately to their cultures (Crist et al., 2016).

The *Landlord's Game*, created by the activist Elizabeth Magie in the 1900s, is a notable example of how board games reflect their context and convey designers' interests. This game intended to teach the economic consequences of the rent system prevalent at the time, which perpetuated a vicious cycle of enriching the property owners, and to promote the idea of an alternative tax system (i.e., "Single Tax" theory by Henry George (1879), an anti-monopoly economist). Magie's *Landlord's Game* was about an even market competition and the creation of a just society (i.e., against monopoly). Ironically, the game evolved into the board game *Monopoly* by Parker Brothers, which gained enormous success without acknowledging Magie's contribution (Flanagan, 2009). These examples highlight that tabletop games were designed to express and record values and ideas (modeling, altering, or proposing the rules of the society), used to mediate activities (social interactions, disseminate new ideas), and redesigned and evolved to reflect different (sometimes opposing) values and purposes.

The above examples indicate that some aspects of the games communicated across different contexts. Danilovic and de Voogt (2021) saw a formal system, i.e., "coherent (logical) structure of the game" (p. 509), as the reason for these games' dispersion across time and space. The coherent structure is somehow noticed and understood regardless of the players' cultures and provides a common ground to understand the game, participate in play, and interact with the game and other players. When games enter the new context of people with different backgrounds and ideas, players imagine new narratives and rules, and give new meanings to the events and interactions through play (Brown & Waterhouse-Watson, 2016). Scholars indeed saw that game play or similarly playful actions create a space that encourages players or actors to seek alternative interactions, ideas and norms, and imagine and negotiate new possibilities. Such space might be called a liminal space (Crist et al., 2016), Third space (Gutierrez, 2008), or boundary space (Akkerman & Bakker, 2011). The spread of tabletop games across cultures and regions also demonstrates how such boundary-crossing spaces facilitated the redesigns of games, i.e., creating new possibilities. de Voogt et al. (2013) similarly observed that "crossing socio-cultural boundaries has positive effects on rates of innovation, likely as people reinterpret (i.e., translate) rules or other parts of the game from their own local and cultural perspectives" (p. 1728) from their historical review.

Culturally sustaining learning and tabletop game redesign

The scholars of culturally sustaining pedagogy view learning as critically enriching strengths rather than replacing deficits, moving away from aligning with linguistic and cultural hegemony (Lee & Walsh, 2017). In our view, culturally sustaining learning repositions diverse learners as catalysts for interdependence and their cultural and linguistic differences as the basis for understanding the world and creating novel and pluralistic outcomes (S. J. Lee & Walsh, 2017; Paris, 2012; Paris & Alim, 2014; Joyce, 2017). Culturally sustaining learning should involve critical consciousness to identify social structures and positions as well as biases and oppressive constructions against non-dominant groups, and efforts to decenter from the norms of the dominant group (Ladson-Billings, 1995; Paris & Alim, 2014). Repositioning and genuine transformation of positions happen through discursive practices and deepening social relations (Davies & Harre, 1990; Joyce, 2017; Ladson-Billings, 1995).

Our argument for tabletop game redesign as culturally sustaining learning is supported by the cultural-historical significance of tabletop games and how their evolution reflects pluralist outcomes as described above. The evolution of tabletop games through redesigns has happened in local gameplays as the games disperse in new contexts and encounter different cultures and languages (de Voogt et al., 2013; Crist, 2019). While designing games has been shown to engage learners in inventing alternative ways of knowing (Civil, 2002), we believe that *re*designing activities could facilitate enriching and repositioning linguistic and cultural diversity. In a study of students' redesigning the game *Inversé* for mathematics learning, a grade 4 new immigrant from China used his mathematical and cultural knowledge: using gestures and drawings, he demonstrated his reimagined play by adopting rules from the Chinese game, *Go* (*Weiqi*) (Kim & Bastani, 2021). The study showed that culturally-relevant games have the potential to bring historical and cultural contexts to disciplinary thinking (e.g., mathematics; Bayeck, 2018; Bastani & Kim, 2022) while helping learners position themselves as confident contributors and their culture and language as important resources in the learning settings.

Game play and design could encourage novel interactions that challenge established relational patterns. Crist et al. (2016) pointed to a "continuum between order and disorder in games" (p. 180) giving rise to new models and interaction paradigms. Through this interplay, games could encourage a liminal space "whereby people can step outside normal social practices and bend familiar cultural elements and societal structure." Such playful states do not mean to maintain the status quo and can introduce new unconventional possibilities, influencing dominant social and political practices and roles (Crist et al., 2016). They could persuade an borderland where limits of inclusion and exclusion can be revisited. This speaks to shifts in power positions that could encourage non-dominant voices (Davies & Harré, 1990). We see cultures as meanings and practices of the families and other social groups that individuals may belong to, inherited or (being) formed individually and collectively. Individuals' interests and views informed by their background and current practices could impact their ways of contributing to collective practices. When taking new positions becomes possible, individuals bring their cultural and social resources from their practices and views in their different life spaces (McVee et al., 2021). We argue that such negotiated spaces and positions truly bring out culturally sustaining learning opportunities.

Research design

We conducted this study remotely via video communications due to the global pandemic. We recruited six families through digital flyers, inviting them to participate as a family unit with at least one adult and one child. The study focused on the four families who completed most of the activities. We provided general guidelines for the game redesign process and held online video meetings with each family to explore their approach to the project, the game they chose to redesign, their ideas for designing their own game, and their experience of collaborative game redesign as a family. The researchers also brainstormed with families on possible changes to their selected games. The meetings were recorded with permission, and families shared their work through written descriptions, visual data (photos and/or videos) from their in-progress designs and final artifacts, and/or blog posts. The final games were exchanged among the families, to play another family's redesigned game and provide feedback.

The initial aim of the study was to investigate how families as collectives could use their cultural and linguistic resources in their game resign project. However, the researchers observed that individuals' differences within the family had a significant impact on the design processes. Therefore, the analysis shifted from a macro-level focus on the family as a collective to a micro-level focus on how family members' diverse backgrounds and perspectives influenced the development of ideas and artifacts. The researchers paid attention to how each family member's unique interests and viewpoints contributed to the game redesign process.

Analysis: Tabletop game redesign as culturally sustaining learning

The shift in research focus led us to explore the following: 1) how the family members engage in social learning through redesigning tabletop games (i.e., games with boards, cards or other objects), and 2) how they reposition generational differences, practices, and ideas as resources for their collective design and learning process.

Relational positions and social learning. Game play and design could encourage shifts in relational positions through discursive and somatic exchanges. Repositioning is intertwined with perspective taking/making, leading to a third problem space, whereby new collective possibilities could emerge (Davies & Harré, 1990; McVee et al., 2021). Game redesign builds on conscious game play, such as noticing others' strategies and interpreting the emergent situations in the game. The explicit requirement of evaluating an existing game structure could change the individuals' position from players to critics of games and the assumptions that back their system and narrative. We had access to family members' reflective accounts through online conversations. We looked for any indications of developing a critical stance towards the norms, expectations, and ways of being, implied by dominant voices in the tools and media of our shared activities.

Shared projects within families and other social groups often involve intergenerational collaboration. Critiquing familiar structures (i.e., games we play) and inventing new participation structures (i.e., redesigned game play) by families could invite family members' different forms of contribution stemmed from their various interests, backgrounds and different roles in and outside the family, i.e., bringing in their various cultural resources in shared activities. In analysing the interviews and artifacts, we also attended to how they evaluated the different aspects of games as the media familiar to both kids and adults. How they could make explicit their understandings and ideas in relation to other family members and how they were able to encourage new relationships and collective possibilities. Put differently, we examined how they might have actively engaged in refiguring their positionings within the family, and how they crossed established boundaries, developing self and mutual understandings, and engaging in creating hybrid spaces where "ingredients from different contexts are combined into something new and unfamiliar" (Akkerman & Bakker, 2011; p. 148).

In our analysis, we reviewed our notes and online meetings' recordings and identified how the participants worked as families and how they formed redesign ideas. We traced the evolution of family discussions and design practices (Barab et al., 2001). We identified the critical episodes of their redesign reflected in our online conversations and the designed artifacts they shared with us. These episodes showed development points, such as how they chose the game to be redesigned, the evolution of family members' participation (e.g., who takes the lead, etc.), and how they determined new objectives and strategies for their redesign. We also explored the playtesting opportunities within the family and the feedback they received from other families after exchanging their games. This led to identifying some overall themes and patterns in families' game redesign practices, including families' sharing critical perspectives on existing games, expressing their interests and attending to one another's perspectives, and connecting the game content with their interests and topics in school and life. We also looked for emergent patterns, such as how the family members' voices reflected in our online conversations and the redesigned games, and the changes in family members' relational positions. The analysis involved examining families' artifacts (i.e., their games, play-recordings, photos, blogs, feedback notes) to understand what connections they were making with their disciplinary and cultural practices and family members' interests.

Tabletop game redesign by families

Each family had an adult contact person, but who led the game design differed among them. The families' unique circumstances influenced their approach to the project, such as the age of their children. Some families used a child's interest to guide their game design, while others had an adult member who encouraged the diverse interests of their family members or sought to create a disciplinary learning experience. During our meetings with families, both adults and children identified the shortcomings of existing games, such as the lack of cooperation among players and the use of stereotypical gender roles. They also compared their cultural gaming practices to those that they played in their home country (if they were immigrants) and reflected how intergenerational relationships and social occasions impacted the games they played. Despite this, we noticed that the redesigned games and rules did not necessarily display overt cultural markers from the participants. Instead, culture was manifested in the decision-making process itself, which influenced the games and game design as a practice. Through this process, the families were able to explore and understand their own cultures and what mattered to their family members as they negotiated their views and interests through play and design. Below is a brief description of each family and their game redesign project. Pseudonyms are used for all names.

Family 1 (with a Chinese background) decided to redesign *The Game of Lif*e board game. The family had four members: Hailey (mother), Patrick (father), Alia (in 5th grade), and Eira (in 7th grade). They chose to redesign the game to make it more relevant to their current context and future expectations by altering the game's theme and introducing new choices, such as career options. Family 2 (Caucasian) chose to redesign the card game *Love Letter*. The family included four members: Katie (mother), Josh (father), Ellie (in 5th grade), and Aiden (in 1st grade). Ellie took the lead in redesigning *Love Letter* to align it with her current favourite book series, *Warriors* by Erin Hunter. Family 3 (with Chinese background) redesigned the board game *Mice & Mystics*. The family comprised three members: Kenny (father), Erika (mother), and Eden (in 1st grade). Their design goal was to integrate coding and logical thinking into the board game. Family 4 (Mexican immigrants) redesigned the board game *Survive*. The family included Lisa (mother), Diego (father), and Elena (in 7th grade). Their goal was to create a cooperative version of the originally competitive game *Survive*.

Positioning children's thoughts as resources for evaluating existing structures

Families considered various elements of a game before selecting one to redesign and while assessing what aspects they will want to change. During this process, families reflected on their goals for creating a new game and took critical perspectives towards the cultural norms, gender roles, and hegemonic ideas that shaped the original games' narratives and dynamics. Family 1, who chose to redesign The *Game of Life,* expressed the most explicit cultural critique of the original name. As a family who played the game often, they believed it represented Western life choices and wanted to create a game more reflective of their Chinese cultural context. Patrick, the father said: "when you play, it is definitely a very Western culture. You go to school, you pick where you want to go school or you just get a job. But if you fill in something more traditional like my Chinese background, it could be something totally different where you can maybe, you know, maybe your parents make you go to school ((laughing)) and you have to achieve a certain mark before you can start picking another career or something like that…there's a lot of cultural influence in there" (the first interview). They also criticized the limited options in the original game and how a redesigned game could reflect a different belief system. Patrick mentioned, "the careers, ...that path can be very different... In *Game of Life*, the more kids you have the better, maybe in the new modern China, too many kids may not be good". This process of rethinking the game's narratives allowed them to exchange and expand their perspective on culture and life choices beyond their game redesign project. In subsequent interviews, they pointed to their conversations on alternative career paths, such as if education is needed to pursue a career and how education could contribute to career choices or pathways. Hailey mentioned how Alia and Eira challenged the limited options for players to progress: "the pathway (in *The Game of Life*)… was ((you get)) married and then you have children. It was also interesting that they (kids) had noted ((this point))". They also discussed how they were going to adjust the game to include more diverse pathways: "((having)) children was one of the pathways we were going to adjust because…there's other ways to have a child" (Hailey).

Family 4 also discussed gender roles while playing the game redesigned by Family 3. Diego, the father, discussed their daughter's disappointment with the limited gender roles portrayed in the original game, *Mice & Mystics*: "She ((Elena)) wanted a different female character. There were only two female characters and at the beginning you could only choose one and she didn't like that female character". She wanted to play a female fighter, which was male in the game's option, not a healer, which was female in the game's option. "We learned that from ((her saying)), 'I want to be a fighter, I want to be a magician, I want to be something very powerful'" (Diego, Interview). In both Family 1 and 4, they used cultural background and children's ideas to critically evaluate the structures and expectations depicted in the original games.

Noticing different ideas and interests within the family

The families chose to redesign games they often played together as a family. This common goal of redesigning the game led them to explicitly evaluate and critique this familiar medium as discussed above. On the other hand, we observed that family members expressed their interests and ideas informed by their different roles in various life spaces. For example, Kenny, the father in Family 3 initially had the idea of redesigning a game representing Chinese cultural elements, using accurate historical stories and cultural aspects. As they progressed, they decided to redesign *Mice & Mystics*, the favorite game of their six-year-old son, Eden. In our interview, Eden discussed how he enjoyed playing with the game's figurines that model the characters. The parents mentioned that they found this cooperative game fun since Eden does not handle losing in competitive games well. They decided to use *Mice & Mystics* as their base game and integrate elements from other games. Kenny, who works at a tech company, and Erika, who has a background in Chemistry, wanted to create a STEM-related game. They did not think highly of trivia games labeled as STEM learning, and since Eden was interested in hands-on activities like playing with robot toys, they wanted to engage Eden in logical thinking and coding. They also saw programming as a skill he would need in the future. Kenny posited, "I think the idea of robotics…obviously at his age and skills…he can't really build a robot. But maybe this ((board game)) gives an idea of what might be possible in the future. I mean, it's very simple programming, logic and stuff, but he's gotta start somewhere, I guess."

They implemented the mechanics used in the game *Mechs vs. Minions* to replace the dice-based random moves in *Mice & Mystics* with command cards, allowing each player to program their characters' moves. They called their final game *Minions' vs Mystics* (Figure 1a). They coined the term "boardgramming" to describe their new game, and created rules that use game pieces and boards from both games. Kenney remarked on Eden's creativity, saying, "my son's never done a boardgramming kind of game, programming at all. That, uh, how he took to thinking about the logic was kind of what surprised me" (Interview).

Redesigned games: (a) Minions' vs Mystics setup; (b) Warriors game cards

(a) (b)

Family 2 decided to redesign the card game *Love Letter* because it was a favorite game of Ellie and her father Josh. The design process was led by Ellie after Katie suggested that she "re-work the cards of *Love Letter* to correspond to [her] current favourite book series, *Warriors* by Erin Hunter. This book series follows a variety of clans of feral cats" (blog post). In our conversation, they discussed how there are parallels between the renaissance courting theme of *Love Letter* and the hierarchal nature of the *Warriors* series' characters: "((In)) *Warriors* there's different ranks. There's a leader, a deputy and medicine cat or you're, um, kind of an apprentice" (Ellie, online meeting). The initial design process focused on incorporating the characters from the first arc of the series from an aesthetic perspective. Once the aesthetic choices were formalized, Ellie considered whether the card text/rules needed to be adjusted to reflect the changes to *Warriors*' characters, such as its hierarchy of "kits, apprentices, warriors, and medicine cats" (blog post). They crafted cards to play-test the game as a family (Figure 1b) to see how the game worked and to adjust the rules. The rest of the family members had not read the *Warriors* series and found the backstory complicated. Nonetheless, supporting the redesign process and playing the redesigned game provided an opportunity for the family to learn about the literature that Ellies was invested in.

Family 1 decided to redesign *The Game of Life* board game based on their two daughters' (Alia and Eira) interest. The parents (Hailey and Patrick) and the kids went through multiple brainstorming cycles to come up with alternative life paths. Hailey found the process of choosing the careers particularly interesting: it allowed her to learn about the careers her kids knew about and discuss other careers that they were not aware of. As a result, they created the set of career cards that reflected the interests and values of the family members (Figure 2a). Some of their shared interests, such as Japanese culture were reflected in their career choices, such as Sushi Chef and Sumo Wrestler. They decided to create game boards that reflected each family member's interest, and combined them to create the final game board (Figure 2b). Haily commented, "this game sort of allowed us to really showcase things we are interested in. So, I made the space part, Eira made the Harry Potter part, Alia made the newsprint type part and Patrick made the Japanese part. It all actually reflected, very interesting, that it reflected our interest, which actually made it more personal for us to enjoy."

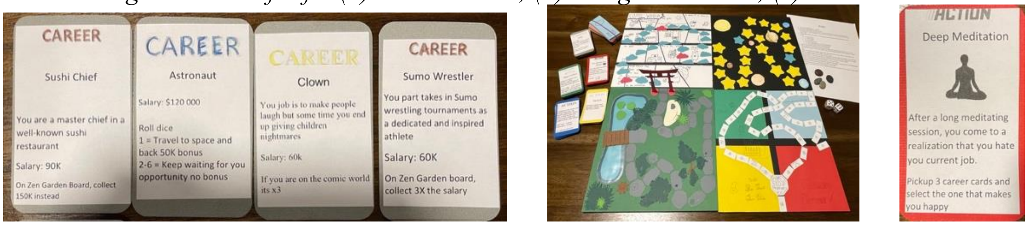
The Redesigned Game of Life: (a) Career cards; (b) The game boards; (c) An action card



(a) (b) (c)

In an interview with Family 4, Diego reflected on their family game play: "we came from Mexico to Calgary. So, we started playing games because we need to spend time as a family." Their family engagement with tabletop games, particularly the insights gained from the cooperative game *Forbidden Island*, led them to consider designing a cooperative version of the competitive game *Survive* (Figure 3). Discussing their interactions during the game play and redesign project, Lisa pointed out how their daughter, Elena, surprised them with unconventional strategies in her game play, while also suggesting very unique game ideas (e.g., incorporating grandmother's interest in physical activities). However, their different ideas often made reaching an agreement challenging. Diego and Lisa's background as teachers influenced their design approach, as they remained open to new ideas and changes, recognizing the uncertain and iterative nature of design process. Elena also believed Diego's math and teaching background influenced their redesign project. Connecting the game design experience to his teaching practices, Diego asserted, "I have been thinking, what are the strategies to talk to my students and get engaged with those. It's quite the same thing. What kind of activities, what kind of rules, you need to put there that make the game engaging to participants in that sense." He also compared his experience of making an educational game to this project: "it's quite different if you interact with your family in the design." The parents also talked about how their shared interest in fantasy literature, such as Lord of the Rings, Star Wars, and some Spanish fantasy novels, inspired them in their game choice and design ideas. The game redesign experience, however, allowed them to recognize differences in how each of them see and engage with the fantasy genre. Diego mentioned that this experience allowed him to better understand his daughter's media engagement.

Family members' shifting positions: Mutual understanding and imagining possibilities

In connection with what we discussed, we observed that the game redesign process changed the relationship between participants and games. Participants shifted from being just players to also being critics. Furthermore, family game play and redesign became intergenerational activities that allowed families to consider each other's perspectives and interests. This family project had an important impact on relational positions within the family. Parents came to see their children as experts and independent contributors, while the children could see themselves as leaders in redesigning a familiar medium (i.e., a tabletop game) of their shared activity. Participants in all families expressed their surprise at other family members' play strategies, design ideas, and methods of contribution, revealing emergent opportunities for learning about each other and refiguring their positioning through this project. The family members' shifting of positions challenged the power dynamics established within the family as everyone was able to negotiate their views, interests, and roles. This highlights how game redesign can not only facilitate communication within the family but also motivate new configurations in family members relations, which enabled opportunities for seeking out differences and children taking a leading role (Akkerman & Bakker, 2011). In Family 3, for example, the 6-year-old child's interest in robot toys was incorporated in their game redesign. While he was not able to guide the project at his young age, his father pointed out how "Eden has started thinking about and suggesting ways we can make changes in board games we play since we did this project." This demonstrates how the family game redesign enabled Eden to take on a new role in relation to games and redefine his position in relation to his parents by offering suggestions for modifying their shared activities.

One significant aspect of the work by Family 1 was how each family member designed individual, yet interconnected boards that incorporated everyone's individual interests in the game. This approached allowed them to appreciate the different perspectives that each family member brought to the project. For example, Hailey remembered how "Alia had the idea of adding other measures of success in life like happiness or experience." They explained that while their boards had similar configuration for player moves, each had a unique theme. The career cards were designed by specific family members to be more advantageous to players moving on the related thematic board, such as the Wizard career card being more advantageous on the Harry Potter board. They also explored how action and chance cards could be similar but also different for each board. Throughout the project, everyone made an effort to attend to each other's viewpoints and figure out what each family member valued in creating their board: "Even though we each individually created our boards, I think it was interesting because each of us had a role to guide one another... to have it all together" (Hailey).

Discussion and conclusions

This study investigated tabletop games as cultural artifacts that convey diverse beliefs and ideas through their systems (Flanagan, 2009). Tabletop games are open to different strategies, fostering diverse forms of engagement (Pearce, 2006) and allowing players to interpret the game situation from their unique perspectives while considering others'. These games often provide familiar and enjoyable spaces for families to interact, as they are suitable for both adults and children. Through analyzing data from four families who redesigned tabletop games based on their shared and individual interests, we explored how such an approach can enable families to invent alternative ways of connecting across intergenerational differences, and disciplinary and cultural practices. Although they did not explicitly explore their cultural or linguistic practices, they expressed what mattered to their family members, both individually and collectively. In all four families, the children's interests, perspectives, and prior engagement with media, including games, influenced the game redesign process. Working with these families, we learned that each family could explore their unique culture and learn to accept and appreciate differences within the family. Through this process, families were able to reposition generational differences, practices, and ideas as resources for their social learning, sustaining their diverse interests and perspectives (Ladson-Billings, 1995). By examining family settings, this study highlighted the multifaceted aspects of culture and language in culturally-sustaining learning. Our findings have significant implications for educational spaces, particularly in urban schools catering to culturally and linguistically diverse students.

Critical consciousness, interdependence and relational positions. The game redesign practices by families included game play and exploring games' structure and narrative. Game redesign provided opportunities for the families to explore and utilize their family culture as a resource for evaluating the underlying ideas, values, and beliefs expressed by the systems of a game. Family members could also make their individual views on the game explicit, and engage children and parents in new relationship configurations. Considering how children's culture, including interests and previous engagements with different forms of media, can influence a child' critical perspectives on games, new ideas, and their relational positions, a similar approach can be extremely valuable in engaging children in the classroom in challenging power dynamics and positioning themselves as leaders of idea development and change making. We believe that learners in educational spaces would be able to recognise the value of diverse cultural perspectives and appreciate the interdependence that accompanies such recognition.

Commonalities, differences and pluralistic outcomes. The families selected games to redesign based on their shared experiences of playing them. Family members' collective goal was to create a more engaging and relevant game for their family. Our findings illustrate how this approach enable us to we pursue commonalities, differences, and pluralistic outcomes, which are crucial for promoting culturally-sustaining learning in educational spaces. Redesigning games that learners play together can facilitate the emergence of shared design language and mutual understanding. By negotiating ideas within this structure, learners from various backgrounds can also express and apply their distinct ideas, goals, and perspectives stemming from their multiple roles, such as being a student, child, cultural representative, game player, and immigrant (Davies & Harré, 1990).

Game design facilitated family members to cross boundaries between their various life spaces. We propose that learners in diverse contexts can undertake similar work: they can establish links between the game worlds and their own, characterized by inherent multiplicity, foster individual and shared understandings, and imagine new possibilities (Akkerman & Bakker, 2011). We believe that the game redesign process can also facilitate intergenerational meaning-making, as demonstrated in our findings, between teachers and students, which is often a formidable task for educators in the classroom.

Abstract: To support ninth graders to take advantage of the ideas, intuitions, and experiences that contribute to their understanding of climate change, we designed an NLP-based adaptive dialog and tested it in a week-long unit exploring Urban Heat Islands. The dialog's guidance prompts were designed to elicit students' ideas about climate change mechanisms. Students interacted with the adaptive dialog twice during the unit. We scored their initial and revised explanations (after engaging with the adaptive dialog each time) using a Knowledge Integration (KI) rubric. A repeated measures mixed ANOVA revealed that students who initially expressed descriptive ideas often rooted in experience made significantly greater gains during the dialog than those who initially expressed mechanistic ideas. The dialog supported all students to broaden the ideas they considered when exploring climate change. Further, a paired t-test revealed that students made overall gains in KI from pretest to posttest (d=.76).

Introduction

The ideas and experiences students express while reasoning about scientific phenomena are productive and powerful resources for developing integrated understanding (diSessa, 2006; Linn, 2006; Hammer, 2000) especially when they are taken up and built upon by teachers (Fulberg & Silseth, 2022). Students' funds of knowledge (González, Moll, & Amanti, 2005) are grounded in their family culture, daily routines, and community interactions and inform their sensemaking in science classrooms. The initial ideas students hold are often a combination of vague, descriptive, and mechanistic ideas (diSessa, 2006). Research shows that when instruction neglects the ideas students hold while introducing new ideas, students develop a fragmented understanding by either dismissing their own ideas within the school context in favor of what is presented during instruction (Carlone, 2015) or holding both perspectives rather than evaluating and making connections across ideas (diSessa, 2006).

We explore the impact of an adaptive dialog that responds to specific ideas detected in student explanations, mirroring an effective teacher responding to and building upon students' ideas. In particular, this study examines the effect of the adaptive dialog on the learning gains of students who initially express primarily descriptive ideas such as those that are vague and not yet clearly linked to an explanatory mechanism as compared to students who initially express primarily mechanistic ideas. Descriptive ideas are less likely to be taken up and built upon during class interactions (Bang & Medin, 2010) than mechanistic, school-based ideas, which the teacher might more easily recognize as relevant to classroom discussion. We investigate the role of an adaptive dialog that recognizes and builds upon students' descriptive ideas.

Advanced natural language processing (NLP) techniques enable detection of individual ideas in each student's written explanation (Riordan et al., 2022) and have the potential to be embedded within science curricula to help students value and build on their initial ideas. However, a recent review of adaptive dialogs in education, also called chatbots, found that few studies were carried out in K12 classrooms. Further, these studies had negligible learning gains (Wollny et al., 2021). Wollny et al. suggested that the lack of impact might reflect that "chatbot development in education is still driven by technology, rather than having a clear pedagogical focus of improving and supporting learning" (p.13).

We draw on the Knowledge Integration pedagogical framework (KI; Linn & Eylon, 2011) with the aim of designing effective adaptive dialog that builds on students' funds of knowledge to promote development of an integrated understanding of climate change. We investigate the impact of dialogs with guidance that is adaptive to students' distinct initial ideas. KI advocates respecting and building on the diverse ideas each student brings to the classroom. KI recognizes that learners hold varied ideas that reflect their lived experiences. The KI pedagogical model supports students to develop coherent understanding by: *eliciting* and valuing the full range of students' ideas; providing opportunities for students to *discover* evidence in a variety of relevant and meaningful contexts; using evidence to *distinguish* among existing ideas and new ideas; and guiding students to *make connections* among their ideas to form an explanation or argument (Linn & Eylon, 2011).

KI informed the design of both the adaptive dialog and the unit under study. The adaptive dialog is driven by an NLP idea detection model that is trained to identify a wide range of ideas, including ideas rooted in experience, vague ideas, and nonnormative ideas. Adaptive guidance prompts are assigned based on the ideas detected and are designed to elicit further details and reasoning about the ideas students initially expressed. The unit in this study aims to *elicit* students' observations of the causes and impacts of climate change and Urban Heat Islands. It guides students to *discover* new evidence and perspectives. It prompts students to *distinguish* among possible mechanisms that explain climate change and to understand who in their community is most impacted by it. And, it supports students to *make connection*s to explain causes and formulate solutions. In this study we investigate how the design of the unit, including the adaptive dialog, supports students to build on their own ideas to understand the mechanism causing climate change as well as who is most impacted by the dialog.

Methods

Participants

The study was implemented in a suburb of a large Western city in the United States with two ninth grade biology teachers and all of their students. The school is racially diverse, has 26% of students eligible for free or reduced-price lunch and 5% of students are emergent multilingual learners. Only students who completed pretest, posttest, and two full interactions with the adaptive dialogs were included in the analysis (N=70).

Curriculum

David and Mary both taught the Global Climate Change and Urban Heat Islands (UHI) unit to their 9th grade biology students. This unit features interactive models, data visualizations, and mapping activities (Bradford et al., 2022). Students first explore how energy from the Sun is transferred and transformed to heat the Earth. Their ideas and experiences are elicited through activities that ask them to make predictions. They use interactive models to discover ideas about the natural greenhouse effect and then investigate how human activities can amplify the greenhouse effect leading to anthropogenic climate change. Students are then prompted to consider the impact climate change has on people. They are introduced to several youth climate activists from their community and are asked to consider whether marginalized communities experience greater effects of climate change than dominant communities. Students explore the UHI phenomenon through investigations of how different surfaces are heated by the sun. Students deepen their understanding by distinguishing how historical, racist policies, like redlining, contribute to some areas becoming UHIs. Students compare historical redlining maps to present day temperature maps to gather evidence of the impact of redlining.

Pre and posttest assessment

Pretests and posttests were administered to students before and after interacting with the curriculum. Two items determined the pretest and posttest scores used in analysis. The *Coal* item prompted students to explain how increased levels of carbon dioxide in the atmosphere might impact the climate. This item examines students' conceptual understanding of the mechanisms of climate change. The *Impacts* item prompted students to explain how the effects of climate change could impact people and whether or not all people are impacted by these effects in the same way. This item measures connections students make between the causes of climate change and the historical policies that have shaped who experiences the impacts of climate change, such as the effects of UHI. Validated Knowledge Integration rubrics were used to automatically score student responses to each item (Liu et al., 2008). KI scores indicate the degree of integration among normative science ideas that students have in their explanations, without penalizing for vague or non normative ideas. The KI scoring rubric is on a scale of 1-5. The scoring rewards students for connecting their ideas to evidence and does not penalize students for expressing vague or non-normative ideas. A score of 1 or 2 indicates the student has not yet connected their ideas to an explanatory mechanism, while a score of three or higher reflects that students have connected at least one mechanistic idea.

Adaptive dialog idea scoring

The interactive, adaptive dialog occurred on the *Car* item (Figure 1) at two points in the unit: early in the unit after completing a lesson about the natural greenhouse effect, and right before taking the posttest. The adaptive dialog was designed to elicit and build upon student explanations about how the temperature inside a car would compare to the outside temperature on a cold, sunny day. This is an analogy for the greenhouse effect mechanism that drives climate change and leads to rising global temperatures. It asks students to connect the same ideas students use to explain the pre/posttest item *Coal.*

To develop the adaptive dialog, we built a *multi-label* NLP model for idea detection. The NLP model used a *token classification* approach for idea detection (Riordan et al., 2020; Schulz et al., 2018). The model was trained to predict an idea category for each word token in the student response data. Consecutive words with the same predicted idea were treated as an idea *span.* Since ideas can overlap, a given word token can receive more than one idea category prediction. The multi-label idea detection model was trained and validated with 10-fold cross validation for hyperparameter tuning and evaluation. To prepare data to train the model, we first created an idea rubric (Table 1) that enumerates the ideas typically expressed in response to the item, including ideas rooted in personal experience, vague ideas, and non-normative ideas in addition to the ideas that comprise the mechanism targeted by the item (for details see Gerard et al., 2022). We generated a set of 24 ideas for the *Car* item which included nine mechanistic ideas, seven vague or personal experience-based ideas, and eight nonnormative ideas. We then human-coded 793 student explanations by annotating spans of text and labeling them with the corresponding idea. The human-coded student explanations were collected at schools serving similar populations to the school in the present study. Prior to use in this study, the idea detection model was evaluated on word-level micro-averaged F-score (harmonic mean of precision and recall, weighted by frequency of idea category). The overall F-score achieved by the model was .592, in line with similar models developed for challenging idea and reasoning detection tasks (Schulz et al., 2018; 2019).

We also build a KI scoring model (using a KI scoring rubric) for the initial and revised responses to the *Car* item, using 1093 human-coded student explanations. The model achieved a Quadratic Weighted Kappa (QWK) of .889. This indicates a high level of agreement between model and human scoring, exceeding the standard threshold of 0.7 for automated scoring deployment (Williamson et al., 2012).

Table 1
Sample from Car Item Idea Rubric and Adaptive Guidance. The full rubric includes 24 ideas across all KI levels and includes both descriptive and mechanistic ideas.

Item prompt: *On a cold winter day, Akbar is walking to his car that is parked in the sun. His car has not been driven for one week. Does the air inside the car feel colder, hotter or exactly the same as the outside air? Explain.*

#	Idea	KI	Assigned Adaptive Eliciting Guidance in Dialog
2	The car feels colder than outside (DI)	2	Interesting ideas! Can you tell me about how you feel if you are sitting inside a car and the sunlight shines on you through the window?
5	Heat (or cold) is conducted between the car and the surrounding area (DI)	2	You’re right that heat energy is conducted between objects that touch each other. Since the Sun is far away, how can its energy warm the car?
8	The sun warms the car directly (DI)	2	Interesting idea! How does the sun make the car warmer?
15	Solar radiation is transformed into heat energy (MI)	3	I think you're saying that energy from the sun transforms to heat energy in the car. What happens to that heat energy?
18	Heat or infrared energy is trapped inside the car (MI)	3	Can you tell me more about why heat gets trapped in the car but solar radiation doesn’t?

Within the adaptive dialog, the idea detection model was used to detect the ideas present in each response the students provided. After their initial response, students received an adaptive guidance prompt based on the ideas detected (Figure 1). Drawing on the KI framework, prompts were designed to elicit more of the students' thinking about the idea they had expressed. Because multiple ideas could be detected in each student response, we developed a prioritization order for which ideas to guide. We opted to guide detected mechanistic ideas before vague or non-normative ideas. In the dialog interface, students responded to the adaptive prompt and then were given a second, non-adaptive prompt that asked them to share an idea they were unsure about. The second prompt was non-adaptive because we trained the idea detection model on full explanations and had not yet determined how it would perform at identifying student ideas in their responses to the first adaptive prompt. After responding to the non-adaptive prompt, students were asked to revise their explanations.

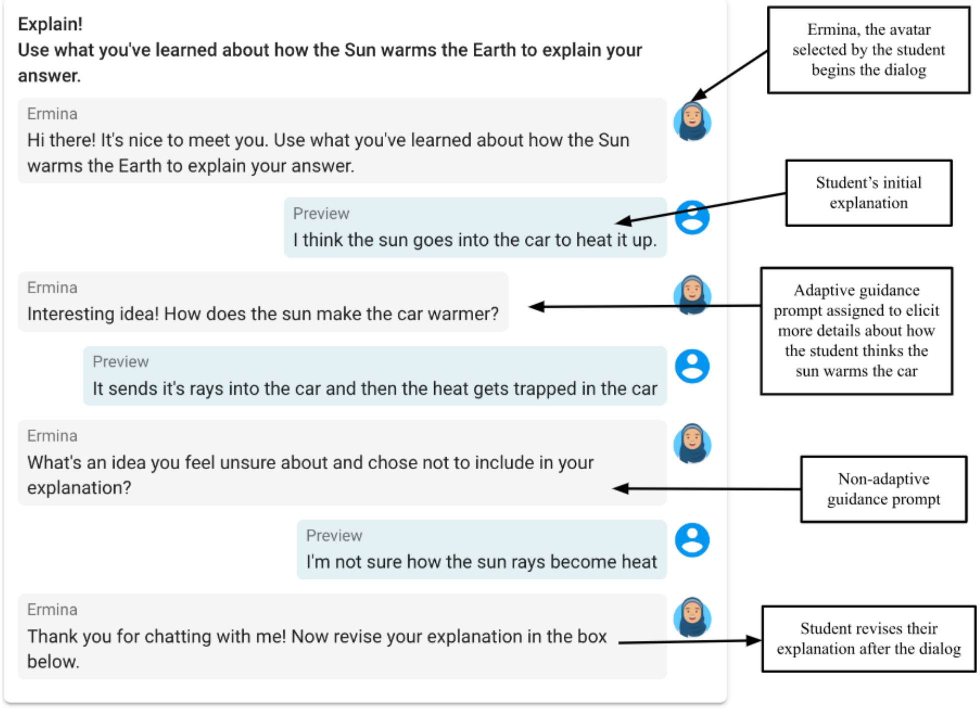
Analysis approach

Descriptive and mechanistic student idea categories

When responding to the Car item, students express a mix of descriptive ideas rooted in everyday experience and mechanistic ideas that are often connected to evidence that they have explored throughout the unit. Because we were interested in how well the unit and dialog supported students to connect their descriptive ideas to an explanatory mechanism, we categorized students based on the kinds of ideas they initially expressed. To assign students to the categories, we considered their performance on both pretest items and on their initial response to the Dialog Item (Car). For each of these items, a score of 3 or more must have at least 1 mechanistic idea connected to evidence, whereas a score of 1 or 2 indicates the use of descriptive or vague ideas not yet connected to a mechanism. We assigned students who had scores of 1 or 2 and not more than one 3 across these items to the Descriptive Ideas (DI) category. We assigned students with at least two scores of 3 or more on each item to the Mechanistic Ideas (MI) category. Thus, students in the DI category started with not more than one mechanistic response across the items. Students in the MI category started with two or more mechanistic ideas. There were 25 students in the DI category and 45 in the MI category.

Figure 1

Example adaptive dialog for the Car item.



Explain!
Use what you've learned about how the Sun warms the Earth to explain your answer.

Ermina
Hi there! It's nice to meet you. Use what you've learned about how the Sun warms the Earth to explain your answer.

Preview
I think the sun goes into the car to heat it up.

Ermina
Interesting idea! How does the sun make the car warmer?

Preview
It sends it's rays into the car and then the heat gets trapped in the car

Ermina
What's an idea you feel unsure about and chose not to include in your explanation?

Preview
I'm not sure how the sun rays become heat

Ermina
Thank you for chatting with me! Now revise your explanation in the box below.

Ermina, the avatar selected by the student begins the dialog

Student's initial explanation

Adaptive guidance prompt assigned to elicit more details about how the student thinks the sun warms the car

Non-adaptive guidance prompt

Student revises their explanation after the dialog

Progress across dialog items

To analyze the impact of the adaptive dialog, we examined the frequency of ideas detected during each round of guidance in each dialog as well as in the revised explanations. We computed the frequency and types of ideas added and pruned between initial and revised explanations for each interaction with the dialog, comparing patterns for DI and MI students. We also use a repeated measures mixed ANOVA to examine the change in students' KI score over *time* (four time points: initial explanation in the first engagement with the dialog, revised explanation after the first dialog, the initial explanation in the second dialog, and final revised response after the second dialog) with student idea category (DI and MI) as a between-subjects factor.

Progress of DI and MI students from pretest to posttest

We assessed students' overall change in understanding by conducting a paired t-test on students' scores on both pretest and posttest items. We computed the gain students made on each item by taking the difference between posttest and pretest scores. We then used a two-sample t-test to investigate whether the gains on either item varied by student idea category, to account for the alignment of the dialog with the *Coal* item and not the *Impacts* item.

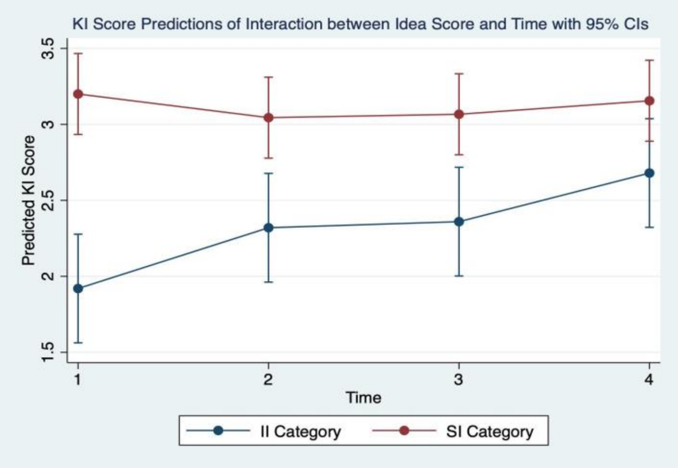
Results and discussion

Progress across dialog items

Across the Dialog items, a repeated measures mixed ANOVA using the Greenhouse-Geisser correction revealed a main effect for both *time* (F(3, 68)=3.41, p=0.022, η^2=0.048) and student *Idea Category* (F(1, 68)=19.8, p<0.001, η^2=0.226) along with a significant interaction between the factors (F(3, 68)=4.51, p=0.005, η^2=0.062). Post-hoc analysis of estimations revealed that DI students made significant gains in KI score at all time points when compared to their explanation at time point 1. The greatest significant difference in KI score for DI students (t(68)=4.17, p<0.001) was between initial explanation (M=1.92, SD=0.75) and final revision after the second dialog (M=2.68, SD=0.80). The KI score difference for MI students was not significant between any time points (Figure 2). Thus, the two interactions with the adaptive dialog on the Car item were more beneficial for DI students than for MI students.

Figure 2

Estimated KI Scores on the Car item at each time point by student Idea Category with 95% CIs



Idea changes during dialog interactions

For both dialogs, students generated ideas in multiple categories (Table 2). We analyzed the overall impact of the adaptive dialog as well as the specific ideas students contributed. We also looked at the ideas generated by students who started with DI and MI ideas.

Advantage of adaptive guidance.

For both dialogs, adaptive guidance elicited more ideas (164) than non-adaptive guidance (52). Specifically, adaptive guidance elicited more mechanistic (99 versus 21) and vague ideas (53 versus 14) than the non-adaptive guidance. Thus, tailoring the first guidance prompt to students' initially expressed ideas motivated them to generate more ideas than did the second, non-adaptive prompt, consistent with prior research showing the value of building on students' prior knowledge and experiences (Zacharia et al., 2015).

Table 2

Frequency of ideas elicited at each round during both interactions with the adaptive dialog. Ideas from the rubric are characterized as mechanistic, vague, or nonnormative. Ideas detected were summed across categories. N=70

Dialog	Round	Mechanistic	Vague	Nonnormative	Total
First Dialog	Initial	89	18	14	116
	Adaptive Guidance	49	26	6	81
	Non-adaptive Guidance	14	9	8	31
	Final Revision	81 (62%)	28 (21%)	22 (17%)	131
Second Dialog	Initial	78	24	16	118
	Adaptive Guidance	50	27	6	83
	Non-adaptive Guidance	7	5	9	21
	Final Revision	103 (65%)	36 (23%)	19 (12%)	158

In both opportunities to engage with the adaptive dialog (Table 2), students in the DI category added more ideas on average from initial to revised explanation than students in the MI category (M=1.08 vs M=0.87 and M=1.2 vs M=1.02). In the first dialog, a greater proportion of these added ideas were mechanistic for MI students (43.9%) than for DI students (33.3%). However, in the second dialog, at least half of the ideas added were related to the mechanism for both groups of students. Specifically, the most frequently added idea during the second dialog was idea 18, the idea that "the car traps heat energy." This is a key part of the mechanism. In both dialogs, students in the MI group pruned more ideas on average than those in the DI category. Additionally, a higher proportion of the pruned ideas were mechanistic for the MI category than for the DI category (Table 3).

Specific changes in ideas

The differences in the frequency and types of ideas that students expressed can explain some of the differences in change in KI score for students in the DI and MI groups. Students in the DI category tended to start with vague or non normative ideas and then integrate mechanistic ideas generated during the dialog into their revised explanations. Students in the MI group tended to start with one or more normative ideas in their initial explanations. The dialog served to elicit additional normative ideas from many of the MI students, however, these students tended to focus only on the new idea in their revised explanations rather than integrating them with their initial ideas.

Table 3

Mean frequency of all ideas (and of mechanistic ideas) that were added and pruned between initial explanation and final revision following interactions with the adaptive dialog.

Dialog	PK Level	Ideas Added/Student	Percent Mechanistic Added	Ideas Pruned/Student	Percent Mechanistic Pruned
First Dialog	DI	1.08	33.3%	0.48	41.7%
	MI	0.87	43.9%	0.82	59.5%
Second Dialog	DI	1.2	53.3%	0.52	46.2%
	MI	1.02	50%	0.88	59.1%

Typical dialog exchanges for DI and MI students were selected from the second interaction with the dialog (Table 4). The DI student initially explains that inside the car is hotter because the sun is "looking right inside" the car. The idea detection model recognizes idea 8, a vague, descriptive idea about how the sun directly warms the car. Based on detection of this idea, the avatar offers an adaptive guidance prompt that asks the student to explain more about how the Sun makes the inside of the car warmer than the outside. The DI student responds to the prompt with idea 18, the mechanistic idea that the car can trap heat energy. In their final revision, the DI student incorporates the idea about the trapping mechanism. The MI student initially explains that solar (electromagnetic) radiation is emitted by the Sun and that some radiation is reflected while some is absorbed. Their explanation also indicates uncertainty about the distinction between solar radiation and infrared radiation. The idea model detects the presence of two mechanistic ideas: idea 13, that radiation comes from the sun, and idea 14, that some radiation is reflected and some is absorbed. Based on the presence of idea 14, the avatar offers an adaptive prompt that elicits additional ideas from the student, namely what happens to the radiation once it has been absorbed. The MI student responds to the prompt with idea 18, stating that some of that energy gets trapped inside the car. In their final revision, the MI student prunes both of their initial mechanistic ideas and expresses idea 18, that the car is warmer inside because it is able to trap heat. Thus, from very different starting points, both the DI and MI students express the same, compelling mechanistic idea.

Progress of DI and MI students from pretest to posttest

On the two pretest/posttest items (Coal and Impacts), students demonstrated significant pretest (M=5.51, SD=1.09) to posttest (M=6.50, SD=1.35) learning gains while interacting with the unit (t(69) = 6.39, $p<0.001$, d=0.764).

Between pretest and posttest, on the *Coal* item, MI and DI students converged on explanations featuring mechanistic ideas about climate change. Each group experienced two interactions with the adaptive dialog that elicited their ideas about the mechanism of climate change. The mechanism students needed to explain the *Car* item used in the adaptive dialogs was the same as the mechanism students needed to explain in the *Coal* item. The DI students showed significantly greater gains (M=0.64, SD=0.91) than MI students (M=0.22, SD=0.95) on the *Coal* posttest item, which targets the climate mechanism (t(68)=1.79, p=0.039, d=0.446). Further, the posttest scores for the *Coal* item were not significantly different between DI and MI students, despite a significant difference at pretest. This suggests that the dialog supported DI students to build upon their ideas to reach the same level of mechanistic explanation as their MI peers.

On the *Impacts* item, which prompted students to connect their understanding of the mechanism of climate change to explain why some groups experience more harmful impacts of climate change than others, there were similar pretest to posttest gains between the MI and DI students. The MI students had significantly higher posttest scores (M=3.49, SD=0.73) on the *Impacts* item than the DI students (M=2.8, SD=0.87, t(68)=-3.55, p<0.001). This result aligns with the lack of attention to policy and social factors in the adaptive dialog. The dialog did not elicit students' thinking about the issues in the *Impacts* item. It is possible that lack of attention to these ideas in the dialog, account for DI students' greater gains and higher average score on the *Coal* item than on the *Impacts* item.

Table 4
Representative examples of the second interaction with the adaptive dialog for students from DI and MI categories. Ideas detected by the model are italicized.

Time	DI Student	MI Student
Initial	It'll be warmer because the *sun is looking right inside the car.*	The *sun uses it's solar radiation to heat the Earth* by infared radiation *getting absorbed into the atmosphere and some reflects off the Earths atmosphere*.
Adaptive Guidance	Can you tell me more about how the Sun makes the inside of the car warmer than outside?	What happens to the energy from the sun when it is absorbed by the car?
Student Response 1	It will be warmer because the *car traps in all of the heat off of the sun*.	Some of the *energy is trapped inside the car* and some is released.
Non-adaptive Guidance	What's an idea you feel unsure about and chose not to include in your explanation?	What's an idea you feel unsure about and chose not to include in your explanation?
Student Response 2	I'm not unsure.	Nothing I'm confident about my answer.
Final Revision	The *car will be warmer* because the *heat from the sun will be trapped in the car making* it warmer than outside.	The *temperature inside the car will be hotter than the outside* because of the *car being able to trap heat* like the Earth does with the sun.

Conclusion and significance

The adaptive dialog shows promise as a strategy for eliciting students' ideas whether they start with descriptive or mechanistic ideas. It seems particularly useful to help students elaborate initial descriptive explanations. We found that students starting with descriptive ideas and starting with mechanistic ideas followed distinct paths during the dialog and achieved similar understanding of the mechanism of climate change by the posttest. The use of eliciting guidance was particularly impactful for DI students, who incorporated new mechanistic ideas into their initial explanations. This aligns with other research that suggests the importance of building on students' funds of knowledge as they construct understanding (diSessa, 2006; Linn, 2006; Hammer, 2000). The eliciting guidance supported MI students to articulate additional mechanistic ideas, which they often prioritized over their initial ideas during revision. Both groups increased their overall KI score at posttest.

The path taken by MI students suggests the potential of leveraging information about the KI score and the presence of multiple ideas when designing and assigning the adaptive guidance prompts. Students who started with one or more mechanistic ideas often articulated additional mechanistic ideas within the dialog. They pruned some of their initial mechanistic ideas to settle on promising final ideas. The KI Framework (Linn & Eylon, 2011) suggests that MI students need further support to distinguish among their mechanistic ideas and connect them into more complex explanations. Future iterations of the dialog could feature new guidance prompts that encourage students to sort out their mechanistic ideas and determine when they apply. This would enhance students' ability to draw connections among their mechanistic ideas to explain the *Car* phenomena.

Although the adaptive dialog was not aligned with the *Impacts* item, students made gains in Impacts KI scores, consistent with the overall focus of the unit. Both MI and DI students made progress in connecting their ideas about the causes of climate change to the social and political reasons that resulted in marginalized communities experiencing greater impacts of climate change. Further research is needed to determine whether an adaptive dialog using an idea detection model for the topics in the *Impacts* item would support greater student learning about the political and social factors that intersect with climate impacts.

Overall, the adaptive dialog was effective at drawing out students' ideas and enabled them to persist in reasoning about their explanations. The wide range of ideas expressed within the dialogs illustrates the value of the unit and dialog design. The dialogs reinforced the classroom culture established by our teacher participants and amplified their ability to both elicit students' descriptive ideas and respond to them.

Musical Agency in Experimental Music Education

Peter J. Woods, University of Nottingham, peter.woods@nottingham.ac.uk

Abstract: Although previous studies have revealed the affordances of experimental music and its subgenres (e.g., noise music) in relation to providing students with access to musical agency, this research often overemphasizes individual capacities for musical performance while ignoring other manifestations of agency. In response, I address the following research question: how do learners in a noise music workshop conceptualize musical agency? To do so, I present findings from comparative case study research into two intertwined noise music workshop series. In analyzing interview data from eight workshop participants, I identify three specific elements of these noise music workshops that participants recognize as contributing to the development of musical agency: permission, accessibility, and relatability. This analysis then expands on previous research into the affordances for musical agency within experimental music and provides a framework for engaging agency in other education contexts as well.

Introduction

Within extant music education research, scholars have routinely explored the role of musical agency in learning processes, here defined as an “individuals’ capacity for action in relation to music or in a music-related setting” (Karlsen, 2011, p. 110). For Sutela et al. (2021), this component of musical knowledge development represents an embodied process that incorporates a student’s ability to make creative decisions, interact with others and express their emotions through music, and be seen as capable musicians themselves. Beyond a focus on the individual musician, explorations of musical agency align with learning sciences research that positions the development of agency as a situated phenomenon through which learning contexts either restrict or enable the inherent agency of learners (see Calabrese Barton & Tan, 2010; Cobb et al., 2009). According to Kuuse (2018), musical agency is “determined by discursive boundaries such as constructions of discipline, empowerment, and space” (p. 151) with conceptions of education praxes and the preconceived notions of genre or musical tradition directly controlling whether students feel empowered to act or make choices within musical contexts.

As an example of this situated framing, music education scholars have routinely highlighted the role of musical agency within experimental music, here referring to Gilmore’s (2014) ideological definition that includes all new musical genres that intentionally break from the tenets of Western music (such as rhythm, pitch, and repetitive structure). In particular, the shift away from traditional music skills and knowledges (such as standard musical notation literacy or instrumental performance techniques) allows musicians of all skill levels to participate in authentic experimental music performance contexts, thus embodying a democratic approach to learning through musical production (Kanellopoulos, 2012; Siljamäki, 2021; Wright, 2019). Experimental music curricula therefore challenge the rigid structures and roles of formal music education, allowing participants to reimagine spaces of learning and, subsequently, the medium through which students access musical agency (Small, 1996).

Yet despite the emphasis placed on musical agency in all processes of learning related to music, music education research (both within and outside of experimental music) has overemphasized forms of agency related to instrumental performance. While scholars such as Kondo & Wiggins (2018) routinely acknowledge that performing, listening, composing, improvising, and theorizing within musical contexts all require agency to some degree, studies routinely focus on the agency learners exercise when playing an instrument without exploring these other musical practices. Building on the affordances of experimental music education to address this oversight, I use this paper to explore the following research question: how do learners in a noise music workshop conceptualize musical agency? Noise music, in this context, refers to a subgenre within experimental music that draws influence from punk, industrial, free-jazz and the mid-century experimental composers (Bailey, 2012) and aligns with constructionist approaches to agentic knowledge production (Woods, 2020). To address my research question, I present findings from a comparative case study of two intertwined experimental music workshop series focused on noise music. Through my analysis, I identify three specific elements of the workshops highlighted by participants that contributed to the holistic development of musical agency: permission, accessibility, and relatability. This analysis both aligns with and expands on previous research into the musical agency of learners and provides a framework for developing student agency in other learning contexts as well.

Methods

To explore the role of student agency within noise music, I draw on a selection of data from a year-long comparative case study (Bartlett & Vavrus, 2016) into two intertwined music series focused on noise music: the Experimental Education Series (EES) and the Noise Knowledge Consortium (NKC). Both events took place at community-based arts organizations in Milwaukee, WI in the United States (EES at the Jazz Gallery Center for the Arts and NKC at Brinn Labs), were free and open to the public, and followed a similar format: featured artists at each event would teach an hour-long workshop related to their artistic practice and then perform at a concert alongside other local experimental musicians. The EES took place once every three months while the NKC occurred monthly. Since each featured artist developed their workshop independently and centered their unique approach to making noise music, the subject matter and pedagogical structure of each event differed. These workshops fell into three broad categories: lectures about the artist's work/creative philosophy (6 workshops), interactive workshops about performance or composition techniques (7 workshops), and hands-on instrument building/music technology demonstrations (2 workshops).

For this particular study, I center my analysis on interview data with eight workshop participants who attended a majority of the sixteen events in the series. Participants initially self-identified as being generally unfamiliar with (but interested in) the genre or novice noise musicians who were interested in developing their musical practice. While all participants had previous experience in other music education contexts, with some having received individual instrument training and others completing general music education courses within formal K12 settings, none had experience with experimental music education explicitly. When joining the study, participants were given the option to use a pseudonym or their own name in publications and all participants chose the latter option except for one (who is referred to by the alias of John A. in this paper). I initially recruited five participants through publicly available social media posts and conducted a series of hour long semi-structured interviews aligned with Siedman's (2005) three-interview structure. This included one interview before the series began, one to two mid-interviews during the implementation year, and one interview after the participant attended their last workshop, all focused on their evolving understanding of noise music and their experiences during the events. Near the end of the study, I enlisted three additional participants who had not responded to my initial recruitment efforts but had still attended a majority of the workshops. Although I only met with each of these additional participants after the workshops had ended, I condensed my semi-structured protocol into one single interview. I also conducted participant observations of all workshops and collected musical artifacts (scores, recordings, etc.) created by the participants, thus producing validity via triangulation of data (Denzin, 2012). Field notes were also used to generate further questions during the semi-structured interviews, creating opportunities for participants to elaborate on (or, potentially, dismiss) moments in the workshops I considered meaningful in relation to learning or embodying musical agency.

To analyze the interviews, field notes, and artifacts, I employed an open and iterative approach to both descriptive and pattern coding techniques (Saldaña, 2015) to explore how participants conceptualized learning within the workshops. In line with Karlsen's (2011) definition of musical agency, I coded excerpts from the interviews where participants described moments of feeling capable of acting or making choices of their own volition, focusing on the elements of the workshop that participants recognized as contributing to this emergent sense of agency. In doing so, I constructed three themes that comprise a shared conceptualization of musical agency: permission, accessibility, and relatability. I describe all three in detail in the following section.

Findings

Permission

Succinctly defining the first theme, Andy de Junco explains that one of his big takeaways was "permission to just make whatever you want, literally whatever you want" within a musical context. Rather than having to conform to a specific set of musical traditions or rules, de Junco saw a potential in noise music to create without restriction and still fit within the genre. For John A., the need for permission relates directly to people's preconceived understanding of what musicians need to make music:

> People [have a] tendency to get caught up in, like, "making music is complex and hard and I can't do it. That will take too much time." Those kinds of things. So making noise music is permission to forget all of that. And that is, to me, what's great about the series.

Importantly, John A. draws a connection between noise music as a context and what happens within the workshops. In his understanding, the value comes from participants gaining exposure to and working within the genre itself. Bill Pariso connects to this framing in a personal moment of gaining permission from the experience:

> It's permission when I see other people do it. I shouldn't have to have that, but for some reason I still do. Like, "this blues guy's career is built on that technique so that means I can't try that," versus Eli [one of the artists] rubbing a coffee cup on top of his guitar. He didn't ask for permission; he just did that and it worked.

Again, Pariso connects this sense of permission to a moment in the workshop and the genre itself, drawing a comparison between understandings of technique (and the implicit inclusion of skill) in noise and blues music.

Accessibility

Beyond an internalized feeling of having permission to make music, the learners in this study also found value in the accessibility of music making tools and practices they experienced in the workshops. In terms of the tools being used, Jack Hietpas recognized this during a workshop on experimental vocal techniques: "Amanda [the featured artist] was encouraging us to explore the possibilities of the voice, this amazing instrument that we all have. It gives people confidence in their own voice. I think that's really powerful." Through this quote, Hietpas not only recognizes the power of gaining confidence in one's voice but speaks to the importance of everyone having the ability to vocalize in the first place (one highlighted by experimental music's shift away from a rigid framing of musical technique). Even when the workshops focused on instruments to which someone might not have immediate access, participants discussed the importance of finding easily accessible instruments. De Junco discusses this theme in relation to a tape loop workshop: "It becomes this thing that I can go out and do now. I just need 20 bucks and I just go out and do this thing and make a ton of them," which sits in opposition to the significantly higher financial hurdles associated with buying or renting many traditional Western instruments.

Beyond the tools, the participants also found accessibility to music making practices themselves important. Hietpas weaves this theme into his discussion of vocal techniques ("exploring the possibilities of voice" instead of having to develop a specific technique through training) while Chris Momsen found a similar connection in learning about composition strategies: "it opened your eyes to something that you maybe hadn't thought of or even would be willing to try. Let's take an everyday occurrence, like taking a shower, and make that an actual performance with a sound component." Momsen, in this moment, learns that the actions he takes on a daily basis (and the sounds they produce) can act as the material for noise music, providing an increased amount of access to music making processes and contributing to a sense of musical agency within composition.

Relatability

Finally, the participants also recognized relatability, or the capacity to see the alignment between their own emergent practice and the work of established musicians, as an important part of developing agency. For Momsen, this relational (and externalized) theme involved seeing a similar compositional approach used by a featured artist:

> It kind of affirmed that what I am doing is not as crazy as it sounds in my own head, that one other person on this planet is following a path that I'm following too. It's an affirmation. It's nice to know you're not doing it wrong because someone else is doing it.

De Junco had a similar reaction to the workshops, asserting that, "it just felt super relatable, because that's how I do it and that's how he does it." For both de Junco and Momsen, the value in these specific workshops did not come from learning some new technique or developing their practice in a new way. Instead, the workshop affirmed their already established approach to music making held value because a veteran artist mirrored their practice in some way. In discussing this theme, Jennifer Zamora differed slightly from Chris and Andy by not fully aligning with the featured artist but still finding enough relatability to feel confident in her practice:

> what I took from that is: I know I could do everything that he did because I've worked with those [programs]. It's like, "I know that. I know how to do that." But I don't do it that way because my brain isn't wired that way.

Rather than comparing her practice with that of the teaching artist, Zamora instead relates to a familiar tool being used and recognizes that she has the skill to create work in a similar fashion (even if she does not want to).

Discussion

In producing the three themes described above, my analysis builds on previous research into experimental music education contexts by attending to underexplored aspects of musical agency beyond instrumental performance, such as composing and theorizing (Kondo & Wiggins, 2018), within noise music. For example, while Siljamäki's (2021) research into vocal choirs reveals how experimental music as a learning context legitimized the use of non-traditional performance techniques, Hietpas' comments on the vocal workshop both reinforce that finding but also acknowledge the importance of positioning the human voice as an accessible and embodied tool in legitimizing musical agency. Described through the lens of this analysis, extant research overemphasizes the notion of permission (and, in particular, permission to legitimately make music without conforming to particular performance standards or techniques) within musical agency (see Karlsen, 2011). While the findings in this study do reinforce the importance of permission, they also acknowledge that enabling access to agency within the workshops also relied on both accessibility to instruments or music making tools and finding relatable practices (including composition processes) with veteran artists. This study therefore aligns with previous research that positions student agency within the interplay between the context and the learner (Calabrese Barton & Tan, 2010; Cobb et al., 2009; Kuuse, 2018). More than just the internal ability to make choices while performing, agency remains intertwined with the people, spaces, and materials that define cultural and learning contexts. Moreover, the positioning of the workshops within the context of experimental music allowed participants to build on the democratic (Kanellopoulos, 2012) and constructionist (Woods, 2020) foundations of the genre as they conceptualized musical agency through this musical tradition. The participants in these workshops therefore distribute the musical agency they experience between themselves, the tenets of experimental music, and other artists. Future research into the agency of learners should therefore explore these themes as a framework for accessing agency within a variety of learning environments. In understanding how different disciplinary contexts (musical or otherwise) either restrict or enable permission, accessibility, or relatability, scholars can trace the affordances for and barriers to developing agency embedded within cultural and educational spaces.

The Impact of Levels of Immersion on Learning: Electrodermal Activity and Eye-Tracking Study

Liat Liberman, Idit Adler, Ilana Dubovi

Tel-Aviv University

Abstract: The current study aims to provide insights into the impact of Virtual Reality (VR) immersion levels on students' learning processes and outcomes. A quasi-experimental design was utilized to compare two conditions: a high-immersive VR simulation using a head-mounted display, and a low-immersive VR simulation using a desktop display. Analysis revealed no significant differences in the perceived sense of presence and in post-test knowledge, regardless of the level of immersion. Analysis of electrodermal activity (EDA) peaks, which indicate cognitive effort, revealed significantly more EDA peaks throughout the learning process with high-immersive VR. Similarly, the results of blink rate metrics, which decrease during cognitive effort, showed significantly fewer blinks for high-immersive VR. Hence, this study suggests that low-immersive VR, which is more accessible in terms of cost and implementation, might demand less cognitive effort and be at least as effective as high-immersive VR in terms of immediate knowledge retention.

Introduction

Virtual reality (VR) provides an authentic and immersive learning experience through simulated reality in computer-generated environments, and is therefore regarded as a productive platform for learning and training (Yu, 2021). VR supports interactive experiences of an alternate reality in which participants are avatars who can move, sense, touch, and act upon simulated computer graphics, supporting the perception that these objects exist. These unique immersive characteristics underlie theoretical VR affordances and are an excellent basis for learning through a constructivist perspective; situated and embodied learning; and experiential learning approaches (Fromm et al., 2021; Matovu et al., 2022). Therefore, VR has been partially adopted in the educational and pedagogical fields. A recent meta-analysis on the effect of VR technology use in education showed a clear benefit of learning with VR for improving learning achievements, interest in learning, and confidence (Yu, 2021). Due to the increased attention accorded VR as a promising educational technology in K-12 and higher education, more research is needed into the various VR immersive affordances that might impact learning.

VR environments can be classified as high-immersive or low-immersive. Slater and Wilbur (1997) emphasized that immersion is a description of the technology's ability to stimulate users' senses via graphics and multiple sensory modalities. High-immersive VR involves high-cost peripheral devices, i.e., a head-mounted display in which a high graphical fidelity screen is mounted in front of one's eyes with separate lenses for each eye and sound is delivered through earphones. By blocking out many visual elements of the real-world environment and inducing sensory stimuli that correspond with the virtual environment, high-immersive VR enables the user to immerse in the virtual environment. In contrast, low-immersive VR is often called desktop VR and takes the form of a window into a virtual world displayed on a computer monitor, where interaction is via a mouse, keyboard, or joystick.

Immersion can induce a sense of presence, i.e., the subjective feeling of being inside and part of a simulated virtual world (Witmer & Singer, 1998). While one can assume that high-immersive VR will induce a stronger sense of presence and better learning outcomes than low-immersive VR, research in this area is inconclusive. Recent studies suggest that although high-immersive VR incorporates more presence, it is also associated with lower levels of immediate knowledge retention, which indicates lower extents of learning (Makransky et al., 2019). In contrast, other studies demonstrated that high-immersive VR is superior to low-immersive VR in knowledge transfer (Han et al., 2022). To this end, this study aims to evaluate how different levels of immersion, low-immersive VR using a desktop display versus high-immersive VR using a head-mounted display, might impact the learning process and learning gains. Since extraneous cognitive processing is associated with learning via immersive virtual environments (Mayer et al., 2022), the current study utilizes a multimodal approach involving measures for capturing learners' cognitive effort, using electrodermal activity (EDA), sensors, and eye-tracking.

Research question

How does the level of immersion, low-immersive VR versus high-immersive VR, impact students' learning processes and outcomes as measured by a presence questionnaire and knowledge test and cognitive effort as measured by EDA and eye-tracking metrics?

Methods

Participants

In total, 52 freshmen nursing students at a university volunteered to participate in the study. Due to technical issues involving data collection (e.g., calibration errors), the data of four participants were excluded, resulting in a final sample size of 47 participants. Due to the nature of the nursing field, globally comprised of a large majority of women, most participants were female (n=40), and the mean age was 24±4.2 years. The study was conducted following the approval of the university's ethics committee (#0001776-3).

Research design and procedure

This study is part of a more extensive study (Dubovi, 2022). This was a quasi-experimental study with two compared conditions: high-immersive VR using an HTC Vive headset, and low-immersive VR using a desktop computer screen. Participants' demographics and pre-post knowledge tests were assessed via paper-and-pencil questionnaires. Following calibrations required to verify that eye-tracking and EDA signals were recorded properly, students were assigned to one of the study's conditions and the learning session with a VR-based simulation was initiated. Eye-tracking and EDA were recorded and real-time analyzed during the entire VR learning experience. Data collection was supported by the iMotions 9.2 Biometric Research Platform. The VR simulation incorporated the architecture of a 3D hospital (Dubovi et al., 2017). Playing the role of a nurse-avatar, participants were asked to learn about medication administration procedures.

Data collection instruments

Content knowledge test

The Medication Administration Test (MAT) assessed nursing students' understanding and practical applications of medication administration guidelines. The test was validated in a previous study (Dubovi, 2022; Dubovi et al., 2017). The test consists of 9 multiple-choice items. Analysis of the MAT using Cronbach's alpha yielded a good internal consistency score of .74.

Presence questionnaire.

The Presence Questionnaire (PQ) was developed by Witmer and Singer (1998) to measure the degree to which a direct interaction with a VR environment gives participants the feeling that the simulation sensations are real. The instrument includes three subscales: (1) Involved/Comparison; (2) Natural; and (3) Interface Quality. The PQ was completed immediately after learning with the VR simulation. The overall internal consistency in the current study was α=.80, similar to previous reports.

Cognitive effort

To evaluate the cognitive effort involved in learning with VR, we used automated continuous eye-tracking and EDA measurements. *Eye tracking*: Smart Eye Aurora hardware was used to collect real-time gaze data at 60 Hz frequency. The extracted metrics were students' blink rates per minute. Researchers have observed that blinking decreases during cognitive and memory processing, suggesting an inverse relationship between task difficulty and blinking; that is, increased difficulty lowers the blinking rate (Martins & Carvalho, 2015). *EDA*: A Shimmer 3 wristband was used to calculate the skin conductance level (known also as tonic level) and a fast-changing component often referred to as the phasic response or the skin conductance response (SCR). A peak detection algorithm and artifact rejection filter were utilized to identify the EDA metrics of EDA peaks per minute (Benedek & Kaernbach, 2010). The mechanism for this is tied to EDA the sympathetic nervous system, which in response to situations that comprise cognitive phenomena immediately activates sweat glands.

Results

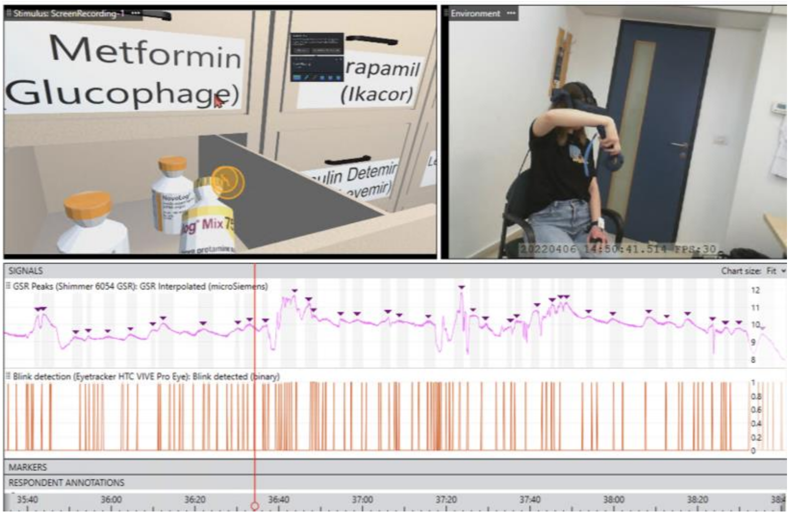
The post-test MAT content knowledge scores were significantly higher than the pre-test scores for both the high-immersive VR (93±11 vs.79±13, paired t=-4.675, $p<0.001$) and the low-immersive VR (92±11 vs.76±14, paired t=-4.927, $p<0.001$). There were no statistically significant differences in students' prior knowledge on the MAT between the two research conditions (unpaired t = -0.701, p = 0.487) as well as for the post-test MAT knowledge level (unpaired t = -0.245, p = 0.808).

Sense of presence within the VR environment is an important parameter of the learning experience. The results showed that the three PQ subscales were comparable between the high-immersive and low-immersive groups: Involved/Comparison (5.2±0.5 vs 5.2±0.6, unpaired t=0.413, p=0.359; respectively); Natural (4.5±1.2 vs. 4.8±1.0, unpaired t=0.902, p=0.243; respectively); and Interface Quality (6.0±1.0 vs. 5.8± 0.9, unpaired t=-0.483, p=0.515; respectively). Subsequently, there was no significant difference in overall PQ between the research groups (5.3±0.6 vs 5.3±0.6, unpaired t=0.048, p=0.860; respectively).

Students' cognitive effort while learning with VR was captured by EDA and eye-tracking metrics of blink rate. When comparing learning with high-immersive VR to low-immersive VR, LMM analysis for repeated measures showed a significant interaction between the type of VR simulation, EDA simulation phase, and peaks per minute (F (5, 39.433) = 5.139, p<0.01). Post-hoc analysis showed that students who learned with the high-immersive VR expressed significantly more EDA peaks per minute for the intro phase (p < 0.05) and for the application of the procedure phase (p < 0.001), than students in the low-immersive VR group (Table 1).

In addition, significant changes in blinks per minute were detected by an LMM for repeated measures analysis across the different VR simulation phases when comparing high-immersive to low-immersive VR (F (5, 44) = 7.817, p<0.001). Post-hoc analysis demonstrated that while learning with the high-immersive VR, students expressed significantly fewer blinks during the follow-up tutorial about the procedure compared to low-immersive VR (Table 1).

Figure 1
Real-time measurement of EDA peaks and blinks rate while learning with the high-immersive VR



Discussion

The main goal of this study was to examine whether the degree of VR immersion can impact learning process and learning outcomes. Our findings show that in terms of immediate knowledge achievements, learning with low-immersive VR was comparable to high-immersive VR. This finding is consistent with previous research (Mayer et al., 2022). Interestingly, our results also indicate that the level of perceived sense of presence was comparable between the study groups. A possible reason for this outcome has been suggested by Steuer (1992), who claimed that presence depends not merely on immersion level but also on its interactivity. It is therefore possible that since the VR simulation in both study conditions was highly interactive and enabled navigation and modification of the virtual hospital environment, it resulted in a high and equivalent sense of presence regardless of the high or low immersion levels of the learning environment. The major contribution of this study is grounded in the incorporation of automated measurements of EDA and eye-tracking to examine cognitive effort within VR environments and adds to the existing literature regarding the differences between high- and low-immersive VR. Our results suggest that learning with high-immersive VR might demand higher cognitive resources, which should be studied further in order to develop instructional approaches to reduce cognitive load and maximize learning. From a practical perspective, we show the educational value of low-immersive VR, demonstrated by our study to be as effective as high-immersive VR. This has notable financial and accessibility implications, especially for schools and students who have no access to costly computer-based VR technologies but can still provide effective low-cost learning opportunities.

Table 1
Changes in the number of EDA peaks and blinks per minute according to the VR simulation sequence phases and research groups

VR simulation sequence phases	GSR per minute Mean (±SD)		Blinks per minute Mean (±SD)	
	Low-Immersive VR	High-Immersive VR	Low-Immersive VR	High-Immersive VR
Intro phase	3.4 (±3.2)	5.3 (±2.3)	18.2 (±1.8)	17.9 (±2.1)
Patient assessment	4.1 (±2.6)	5.2 (±3.1)	17.8 (±1.8)	12.8 (±2.2)
Tutorial about the procedure	2.8 (±2.5)	3.8 (±2.3)	18.6 (±1.9)	14.8 (±2.2)
Application of the procedure	3.4 (±2.9)	7.11 (±3.4)	14.8 (±1.5)	12.4 (±1.7)
Follow-up tutorial about the procedure	3.5 (±2.6)	4.4 (±2.7)	17.8 (±1.9)	11.3 (±2.3)
Sum-up video of the procedure	3.4 (±2.8)	3.8 (±3.0)	19.6 (±2.3)	16.9 (±2.7)

The significant differences between the research groups are highlighted in grey
