In this short conceptual paper, we argue that much of the evidence that has been brought to bear on this debate—and especially evidence used to support the superiority of direct instruction—is in fact irrelevant to the questions about learning and instruction that are of primary interest to learning scientists and that should be of interest to educators more broadly. In this paper, we both critique the current evidential base used to argue for direct instruction and make suggestions for future research.

Clarifying the meaning of inquiry learning

One challenge that bedevils the debate is getting to a shared definition of these forms of instruction (Furtak et al., 2012). We begin by building on new work to clarify what counts as inquiry instruction. Recently, Duncan and Chinn (2021) edited the *International Handbook of Inquiry and Learning*. In their introductory chapter, Chinn and Duncan (2021) synthesized the many approaches to inquiry discussed in the volume and proposed six characteristics that these environments had in common: (1) Students find things out—developing at least some new ideas on their own. (2) They are actively engaged in finding things out by making inferences on their own.

This does not mean that they find *everything* out on their own, but they should work out some significant elements of what they are learning. (3) They use some kind of evidence (which can include empirical data, human testimony, prior experiences, etc.) to develop their ideas. (4) They have epistemic agency, which means they have the autonomy and authority to express their own ideas and develop their own conclusions. (5) There is some complexity in the reasoning involved—that is, the inferences students need to make are not trivial but substantive. (6) Students are engaged in these processes within communities; inquiry takes place in the crucible of social interactions. We would add a seventh commonality: Students are also given various scaffolds and other supports so that they are engaged in guided rather than unguided inquiry.

This analysis, which we refer to as the C&D analysis, has important consequences for how to evaluate and interpret the research base that has been used to try to adjudicate the debate between guided inquiry learning and direct instruction. Specifically, an entailment of the C&D analysis is that much of the research used to support direct instruction has little relevance to the question of whether direct instruction is more or less effective than guided inquiry as a method of instruction. This short paper does not permit an exhaustive re-analysis of the research base that has been used to support claims favoring direct instruction, so we will sketch our fuller analysis.

Limitations of the current research base in evaluating the efficacy of inquiry learning vis a vis direct instruction

In this section, we discuss implications of the C&D analysis of inquiry learning for adjudicating the debate between inquiry learning and direct instruction. Our overarching argument is that many of the studies that purport to address the debate mischaracterize inquiry learning when they set up their experimental conditions. Thus, researchers are not investigating effects of inquiry learning environments at all. We have three main arguments for this position.

First, the C&D analysis emphasizes that existing inquiry learning curricula are fundamentally social. Students engage in inquiry in communities. Discoveries are made within and by communities, not separately by each individual student. But this feature of inquiry environments has an important consequence: It is common in inquiry curricula for students to hear crucial ideas from their classmates instead of inventing those ideas themselves. For example, in a study by Rinehart, Duncan, and Chinn (in preparation; see Rinehart, 2017), students in a genetics inquiry environment collectively invented the core Mendelian idea that every parent has two alleles (students of course used their own terminology), one of which is given to offspring. But it was not the case that every student invented this idea individually. Rather, some students invented the idea, and then as they shared it, and debated it, other students eventually came to endorse and adopt it, as they came to see what it meant and how it best explained the evidence.

In guided inquiry environments, teachers or educational materials may even be the ones to tell students the critical targeted ideas. For example, a teacher might present three alternative models of photosynthesis to students, one of which is the scientifically accepted model, and students work with evidence to determine which is best. This is still inquiry learning because students must work out for themselves what they find most compelling, and they may be asked to further improve the best of the models.

Thus, the core element in inquiry environments is not whether students discover ideas themselves (as opposed to someone telling it to them). In inquiry learning, students often first hear ideas from others. The core element in inquiry learning is that students have the epistemic agency to make sense of the ideas and to decide if they are convinced by the ideas, in light of all the evidence they are considering. This is, of course, like how scientists collectively work; each individual scientist does not invent every idea. Scientists regularly evaluate, investigate, and explore ideas that their colleagues have developed.

Proponents of direct instruction typically misconceive that the core of inquiry environments is that students are *not told* the target ideas. For example, Zhang et al. (2021) praised controlled studies that "have compared teaching involving exploration-based investigations with forms of direct explicit instruction, including simply giving students answers, having students watch demonstrations and listen to explanations, directly reading answers from texts, etc." (p. 1165). Other scholars who have investigated direct instruction have defined the core difference in the same way (e.g., Klahr & Nigam, 2004; Martella et al., 2020). In short, these studies misconceive what the core difference between inquiry environments and direct instruction environments is. Accordingly, most of the controlled studies cited by Zhang et al. (2021) as strong support for direct instruction over inquiry learning simply do not bear on the issue.

A corollary of this observation is that investigations of the effects of inquiry environments need to examine whether students genuinely accept the ideas that they are taught. Given that inquiry environments give students opportunities to choose which ideas make sense and are convincing, measures of the effects of inquiry learning environments should assess the ideas that students really endorse. This requires measures that examine students' responses when they are not simply playing school—responses that reflect real understandings and commitments. Few, if any, controlled studies comparing direct instruction with inquiry learning have included such measures.

A second implication of the C&D analysis raises equally serious objections to many of the studies that purport to contrast guided inquiry with direct instruction. The C&D analysis emphasizes that guided inquiry learning occurs in communities. But when setting up controlled experiments, many studies investigate the learning of individuals alone (e.g., Klahr & Nigam, 2004; Martella et al., 2020). Or, if the researchers do have students work in groups, they do not encourage the kinds of interactions typical of inquiry communities (e.g., Zhang & Van Reet, 2021). These experiments thus compare direct instruction—conceived perhaps fairly as a mainly individual form of learning—with an individual form of discovery that strips away the essential community in which inquiry is supposed to occur. These studies do not speak to whether direct instruction outperforms guided inquiry learning.

By removing the interactions of the community from inquiry learning, these studies block the operation of one of the learning mechanisms posited by many scholars to be central to learning. Specifically, sociocultural approaches to learning emphasize the Vygotskian mechanism that much learning occurs when students "internalize language practices from a social, external plane to an individual, internal plane" (Reznitskaya & Wilkinson, 2015). For instance, students learn to anticipate various counterarguments and to construct better arguments on their own after they have experienced being confronted with similar counterarguments in social processes of argumentation. It is these social experiences that propel growth. Studying inquiry learning without the core driver of carefully curated social interaction is like studying the propulsion of cars that lack engines.

A third important implication of the C&D analysis of inquiry learning for the debate between inquiry learning and direct instruction arises from the fifth criterion, which emphasizes the role of complexity. In inquiry learning environments developed by learning scientists, communities of students typically engage in forms of inquiry that address complex issues and practices (Duncan & Chinn, 2021). For example, students engage in complex practices such as struggling to work out which expert sources are most trustworthy when the experts disagree (Barzilai et al., 2020), determining how to conduct experiments when it is not obvious how to measure outcomes or what variables need to be controlled (Ford, 2005), and how to determine what counts as plants flourishing (Manz & Renga, 2017). None of these practices can be reduced to simple algorithmic rules.

In contrast, many of the studies that contrast inquiry learning and direct instruction focus on very simple strategies that can indeed be reduced to algorithms, such as learning to control variables when there are three or four prespecified variables, most with two prespecified levels each (e.g., Lorch et al., 2014; Martella et al. 2020; Strand-Cary & Klahr, 2008). This can be performed algorithmically. But real reasoning—on topics in history, in science, and in the social world—cannot be reduced to such algorithms. Even if studies were to show that direct instruction can be more effective on these simplistic topics, it would by no means follow that direct instruction is best for learning more complex forms of reasoning. Indeed, Ford (2005) showed that direct instruction on teaching students to control variables promoted performance on assessments that could be solved algorithmically but not on more complex scientific reasoning tasks that required more complex judgments. Thus, a third problem with many studies featured in reviews that appear to support direct instruction over inquiry learning is that they use simplistic, toy tasks that are far from the demands of the thinking needed to thrive in the real world.

Discussion

Based on the C&D analysis of the characteristics of inquiry learning environments, we have argued that the studies that purport to show better outcomes for direct instruction than for inquiry learning are flawed. First, they fail to recognize that "telling ideas" is not the most critical difference between inquiry learning environments and direct instruction, and so experiments that manipulate "telling ideas" fail to capture the most relevant difference—which is the epistemic agency to choose what ideas to accept. Second, many studies test inauthentic forms of inquiry learning environments that strip away essential drivers of learning including social dimensions. Third, many contemporary inquiry learning environments aim to promote complex modes of reasoning and knowledge, whereas many studies contrasting inquiry learning with direct instruction target simple, algorithmic learning goals. These problematic features of many studies call the results of the studies into question.

A number of scholars have commented that the debate between inquiry learning and direct instruction should move beyond declaring which mode of teaching is better, and examine instead which mode is better for which students under which conditions (e.g., de Jong, 2022). Given that shows that students are told many things by many sources in inquiry environments, the critical questions become: What is best told to whom, when, and by whom (de Jong, 2022)? In real instruction, telling students things is constantly interwoven with opportunities for students to think for themselves. What is needed is a better understanding of how to interweave telling and inquiring, and what to tell (and what not to tell) as students are engaged in inquiry. Investigators should shift the focus of research away from broad questions about "which works better?" or "which works better for whom?"—

as if students should spend tracts of time engaged in one or the other. Rather, researchers should ask finer-grained questions about how telling and inquiring should be interwoven from moment to moment to best support learning of content and development of thinking.

Abstract: Community-engaged research partnerships are increasingly used in education research to promote equitable and relevant educational outcomes. One key challenge of such partnerships that is rarely documented is the pre-partnership relationship development phase. This methodological paper reports on the early partnership exploration and formation efforts of an interdisciplinary research team working to build a community-based curriculum materials collaborative for health justice science education in a rural Midwest town. We explicate how we have approached this phase through an epistemological orientation of *desire-centered research* by integrating methods and stances from community-engaged ethnography with commitments from community-based participatory research. We articulate three main activities shaping this phase of work: (1) Learning about communities' well-resourced networks; (2) Progressive refinement of project foci; and (3) Gauging, establishing, and negotiating trust and capacity. Our situated accounting provides an illustration of how interdisciplinary teams might draw from and navigate across multiple methodological traditions in context-specific ways in working towards equity in education research.

Introduction and motivation

Community-engaged research (CEnR) in education can lead to more equitable and relevant forms of research. Importantly, community-engaged research goes beyond identifying partners and instead emphasizes the importance of doing research that directly addresses the needs and well-being of the partnered community (Israel et al., 2013). Building and negotiating trusting relationships with partners is essential, especially given the unequal power dynamics between academic partners and community partners (Wallerstein et al., 2019). However, while there is documentation *that* these relationships are necessary for CEnR partnerships, as well as many tools to guide assessment and evaluation of them (e.g., Boursaw et al., 2021), descriptions of and guidance for how initial relationships come about and develop in the very early stages is relatively absent from this literature (c.f. Parker et al., 2019). These early-stage relationship-formation negotiations are an essential time in which partners establish the norms, structures, and power hierarchies that will shape ongoing project research and design work.

This methodological paper reports on the early partnership exploration and formation efforts of an interdisciplinary research team who came together over a common recognition of the need to conduct community engaged research. Drawing upon our expertise across science education, public health, epidemiology, medicine, and genomic biology, as well as a history of past community-based projects, we are building a community-based curriculum collaborative for health justice science education. We aim to utilize participatory co-design of locally relevant and impactful health justice educational experiences that center students', families', and community-based organizations' deep community knowledge and improve science instruction for students and health outcomes for local communities. Here, we present an illustration of how we have approached early-stage partnership exploration by integrating guidance from ethnographic research traditions (e.g, Mokos, 2022) with community-based participatory research (CBPR) principles including building on community strengths and resources, mutual benefit for all partners, and intentional action to reduce social inequities (Israel et al., 2013).

Methodological orientation: CBPR and desire-centered research

We draw on approaches from community-based participatory research (CBPR), which is broadly used in the health sciences to improve community health outcomes (Brush et al., 2020) and is grounded in a commitment to sharing power with community partners and engaging together in a research process that centers the needs and interests of the communities involved. To inform our early-stage relationship-building phases as community outsiders, we draw upon ethnographic traditions (e.g., sociocultural anthropology; activist and community-engaged ethnographies) that provide methodological guidance around considerations of power and equity, such as balancing the role of key informants with broad community perspectives (McKenna & Main, 2013; Mokos, 2022) and adopting a stance of interpretive reflexivity (Lichterman, 2017).

To epistemologically guide our synthesis of approaches, we draw on Tuck's (2009) call to shift from *damage-centered research*, or "research that operates, even benevolently, from a theory of change that establishes harm or injury in order to achieve reparation" (ibid, p. 413) to *desire-centered research* that aims to capture desire rather than damage by "understanding complexity, contradiction, and the self-determination of lived lives […] by documenting not only the painful elements of social realities but also the wisdom and hope" (ibid, p. 416). In applying a desire-centered epistemology to educational partnership-building, the focus on community thriving allows for complexity and heterogeneity. This has led us to shift from the common question to partners of, "What do you need?" towards questions more like, "What would thriving look like here?" We assume communities' responses will reflect an *assemblage of desire* – a multi-faceted, and sometimes contradictory, collection of values, goals, and imagined possible futures that a community holds (Tuck, 2009) – and aim to have it be the vision that shapes the focus and goals of what a health justice science education collective could be and do.

Context and methods

Description of focal community

This project is situated in the context of "Plainsview," a small community of about 12,000 people near (but distinct from) a major University town in the Midwest United States. Plainsview, while rural in geography, reflects many of the challenges faced by communities experiencing increasing diversification (by which we mean more ethnic, racial, and socioeconomic variety, rather than an increased presence of a single racialized group) and the struggle of communities marked by economic disinvestment. The median income of Plainsview in 2021 was $33,000, and 87% of students in the school district were designated as low-income. Demographically, Plainsview's population as reported on the 2020 Census is 60% white (12.5% Hispanic), 25% black, 2% Asian, 5% other, and 6% two or more races. In contrast, the students in the city's public school system report as 24% white, 30% black, 33% Hispanic, 13% two or more races. The school system often receives low scores on their state report cards. At the elementary and middle school levels, 6% of students received at least a "meets expectations" score on the state's standardized tests. They are currently rated as demonstrating "large gaps" with respect to disparities in academic outcomes across demographic groups. While the teaching staff are highly qualified and well-paid, they do not necessarily reflect the students who they teach: 87% are white, and many do not live in Plainsview but instead commute from the nearby college town or surrounding communities.

The distinct demographic groups in the Plainsview community also have distinct histories. Plainsview has long been a destination for migrant farm workers who travel primarily from the Texas borderlands to work for Monsanto detasseling corn. A strong network of family and community services for migrant families remains active. Gradually, migrant families have elected to stay in Plainsview permanently due to this network, the affordability of housing, and economic opportunities that were available for them in Plainsview. Of course, the Latinx population in Plainsview includes more than migrant farm laborers and their families; for example, there is direct recruitment of Puerto Ricans for factory labor as well as growing Guatemalan and Honduran populations.

The Black community also has a multifaceted history. Some residents have a long history in Plainsview spanning generations. The Black population also gradually grew as major public housing projects in Chicago began closing in the 1990s and early 2000s. Plainsview was a desirable location because of its relatively low crime rate and affordable rental housing. Black residents from other nearby towns have relocated to Plainsview for the same reasons. This varied history brings with it some familiar dynamics: the longevity of presence in Plainsview has sometimes made the concerns of the Black community less urgent to leaders, while the influx of residents from the Chicago projects has at times led to reinforced stereotypes about, and blame for, violence and crime.

Description of the team and history of relationships and work with the community

The current project team includes faculty members and staff who collectively have several existing and successful research-practice partnerships, as well as a wealth of experiences with long-term health outreach organizations. At the same time, the dual pandemics of COVID-19 and increasingly public racial injustice made clear to us the need to build relationships differently with the schools, organizations, and communities with whom we partner for health- and education-related efforts. The first three authors have done the majority of the relationship-building work thus far. The **first author** is a science education scholar whose research interests are in science and science teacher education. She is a white woman from a small town in the Midwest, though not in the same state as Plainsview. While the social and political dynamics of Plainview that have emerged from conversations are eerily familiar, she is also astutely aware of the implications of her "outsider" status within this context. The **second author**, a graduate student and former 6th-12thgrade science teacher, is a Black male and first generation immigrant from the Caribbean. He grew up in a large urban city in the same state as Plainsview. Being a Black man connected to the large nearby University affects conversations in different ways both positively and prohibitively, depending on who is involved. His research is focused on STEM equity and the design of informal afterschool programs. The **third author** is a cultural anthropologist/ethnographer who began carrying out health-related research in Plainsview in May 2020, after the first large outbreak of COVID-19 occurred among (mostly migrant) workers. With other members of the team, she worked to set up COVID testing in collaboration with local politicians and community activists. Also a white woman from the Midwest, she quickly became aware of the suspicions people from Plainsview harbor of university researchers. Most of her previous research has been in Central America.

Research approach: Activities, data collection, and analysis

Over the course of the 2022-2023 academic year, we proposed to engage in three phases of activity: (1) Identifying and assessing partner readiness; (2) Establishment of a collaborative; and (3) Action plan development. This paper presents on Phase 1, which has involved individual meetings and/or information-gathering interviews with leaders at local organizations. To date, we have held informational interviews with 10 individuals representing a range of community organizations and/or leadership or activist roles in the community. We began with existing relationships based on recent collaborations and then asked for additional names at the end of each interview. When we recognized that we were beginning to hear the same few names repeatedly, we explicitly began asking for names of people outside of the local Plainsville "circle of power" (a participant-generated phrase).

To make sense of our data, we debriefed any conversations at weekly project meetings. From these conversations we kept a list of emerging themes related to health and education; notes about social structure and other explicit or implicit political dynamics, including how we wanted to handle them moving forward; and our own individual reactions and reflections. We also kept detailed notes about existing efforts related to health, well-being, and/or education in the community, including how and why they were successful (or not). The first author synthesized notes every 5-6 weeks into a project update. This paper reports on these syntheses.

Findings

We present a description of three key activities shaping our work that we argue characterize the pre-partnership relationship-building phase: **(1) Learning about communities' well-resourced networks; (2) Progressive refinement of project foci; and (3) Gauging, establishing, and negotiating trust and capacity**. Notably, these are re-framings of the goals described in the project proposal for Phase 1, which were originally informed by current literature on establishing community partnerships: (1) Identifying potential connections to community organizations/schools with shared health justice education goals; (2) Identifying the assets and knowledge gaps of respective partners; and (3) Assessing potential for partnership. While these re-framings may seem like semantics, in our case they were the product of continual epistemological and ideological reflection. In the interest of space, we will briefly describe each activity and how the re-framing differs from our original goals.

In our own learning about Plainsview (**Activity (1)**), we identified organizations that had a general health or education component of their mission, then met with them to broadly understand the work they did, their successes and accomplishments, and the challenges and needs they saw. This orientation allowed us to begin to see ***how Plainsview is already a well-resourced network***—even despite its designation as an under-resourced community. Importantly, this "learning about" was deeply informative in terms of the social and political dynamics of the community. As we gained an understanding of these networks and resources, we also gained an understanding of the needs and multifaceted visions for thriving described in relation to them. This led us to *refine our understanding of what a relevant focus on "health justice science education" may look like for Plainsview* (**Activity (2)**). These refinements include (a) an expansive notion of "health" as ***promoting well-being***; (b) the necessity of ***wholistic (and potentially wraparound) programming***; and (c) critical consideration of the ***role the school system plays*** in the community. This has pushed even wider the definitions of "health," "education," and "curriculum" that those with which we began.

Finally, our conversations about "readiness" have been less like an assessment and more like praxis. We describe this praxis in terms of *gauging trust*, or the "dance" between what people say and what we say, how much they are letting us in vs. not; and *considering capacity*, both partners' and ours, for working with uncertainty and building bridges (**Activity (3)**). In terms of trust, a few key dynamics became important in shaping our negotiations. One involved how we talked about our project goals related to justice in a community that leans politically conservative. Early on, several participants asked us what "health justice" meant, admitting they had Googled it before our meeting. Another participant cautioned us that being "too up front" about race and racism might lead people to quietly shut their doors. This raised a central tension that still shapes our work: ***how do we***

maintain a focus on racial equity within a racialized but intentionally "colorblind" community? And ***how should we, as a majority white project team, orient towards these goals of racial equity?*** Relatedly, how much effort and education should we plan to take on in terms of facilitating conversations about the systemic causes of disparities in "well-being," vs. working with groups that already have a deep understanding of those causes?

Our ethnographic-leaning approach also had implications in terms of how we were thinking about capacity. Before beginning conversations about time and funding capacities—more traditional metrics of capacity—we were first developing an understanding of the role(s) that we *could* play in a potential partnership. The relatively powered position we are in as University-affiliated professionals was very clear within these interactions: as we began to ask people to envision what a partnership could look like more explicitly, many responses described us taking on a role as an advocate, often around issues that only tangentially aligned with our areas of expertise. While these requests communicated important ideas about what participants desired, it also led us to reconsider ***how we frame our own capacity for contributions*** and ***how we may need to bound our capacity*** in ways we did not expect.

Discussion and conclusions

This paper has explicated three key activities for early relationship-building efforts in the context of shifting to interdisciplinary, community-engaged research: **(1) Learning about communities' well-resourced networks; (2) Progressive refinement of project foci; and (3) Gauging, establishing, and negotiating trust and capacity.** These activities are distinct from early *partnership*-building activities in that they elaborate what "identifying ready partners" involves when it is guided by specific methodological and ideological commitments. In particular, we highlight how common challenges related to discussions of justice and navigating powered relationships have manifested in this context. Especially as the learning sciences continue to lean into the sociopolitical turn (Gutierrez, 2013; Mendoza et al., 2018), we hope our description of our efforts can serve to de-mystify the process of working to build community-based partnerships and raise critical considerations, especially for scholars who are, like us, relative "outsiders" to the communities with which we partner.

Abstract: A vision of high-quality mathematics instruction is necessary for schoolwide improvement in mathematics. In the context of a research-practice partnership, we used a design-based research approach to create classroom-based immersive learning experiences (CBILE) for school and district leaders to co-construct a sophisticated vision. Qualitative analysis of design meetings and principal interviews explored how CBILE contributed to school leaders' vision. Findings suggest that school leaders' co-constructed vision reflects a negotiation between vision constructs defined by mathematics education research and the situated context of their realities.

Introduction

A shared sophisticated vision of high-quality instruction across a district is important to ensure coherence in professional development and instructional support (Cobb et al., 2020). This study is situated within the context of a research-practice partnership (RPP) (Farrell et al., 2021) focused on schoolwide improvement in mathematics. We examine the co-constructed vision that takes shape among district and school leaders through a classroom-based immersive learning experiences (CBILE).

Principals are important levers in improving student achievement (Grissom et al., 2021). They set schoolwide goals, organize professional learning, and cultivate a culture of teacher collaboration (Supovitz et al., 2010). To foster mathematics improvement, principals must support individual teachers through instructionally focused conversations around mathematics lessons (Grissom et al., 2021). These conversations necessitate content-specific knowledge and a vision for what counts as high-quality mathematics teaching (Schoen, 2010).

As researchers, we draw from existing bodies of literature to support our partners, however, our inquiry process must also attend to the specifics of the context in which our practice partners work. We operated from a vision of high-quality instruction defined by the mathematics education research community (Munter, 2014). We sought to understand how our partners negotiated that vision as ultimately their co-constructed vision will be what informs subsequent school improvement work. This study extends existing literature by exploring how school leaders interpret the notion of high-quality instruction and whether and how it is useful to their priorities. In this paper, we ask: *How did school leaders co-construct a vision of high-quality mathematics instruction through the CBILE? What aspects of this vision are shared with the research community? Which emerge as priorities for school leaders?*

Theoretical framing

Munter (2014) describes vision as the image of what is possible in a mathematics lesson, yet may not be currently enacted. For teachers, a sophisticated instructional vision is related to improved quality of instruction (Munter & Correnti, 2017) and to their knowledge for teaching (Munter & Wilhelm, 2021). Drawing from existing literature on high-quality instruction, Munter suggests a sophisticated vision includes the role of the teacher as a more knowledgeable other who shares authority with students. Classroom discourse should represent a mathematics discourse community. Mathematics tasks should support students in problem solving and the mathematics practices (e.g. generalization). While a principal's vision of mathematics instruction may not need to be the same as a teacher's, they do need enough disciplinary knowledge to support teacher learning and instructional improvement at their site. Without sufficient knowledge, principals give content-neutral feedback to teachers (Rigby et al., 2017). The CBILE were designed as an opportunity for school and district leaders to co-construct a vision of high-quality mathematics instruction by experiencing and debriefing together with the teacher through a series of lessons.

Mode of inquiry

Study context and participants

The RPP is situated in a mid-size district encompassing two cities on the West coast of the United States. The district serves approximately 19,000 students. 46.3% of the population identifies as Latinx and 41.2% identifies as White. While 30.9% of the student population qualifies for free and reduced lunch, the majority of those students are enrolled within schools in one of the two cities.

During the year in which the study took place, the district emphasized building instructional leadership capacity as a means to support their improvement goals. All elementary school principals engaged in monthly learning sessions around the Common Core State Standards in Mathematics which they could draw from in subsequent staff meetings at their site. From this work, a subset of principals and district leaders decided to engage further with the RPP. The practice partners in this group included six principals, an assistant principal, three district leaders and a mathematics coordinator. Five of the six principals lead a Title 1 school. At the time of the study, principals had between one and 16 years of experience in that role, though all were former classroom teachers and previously held other administrative positions. The research team consisted of an education faculty member and two PhD graduate students, all with experience in mathematics teaching and learning in the K-12 setting. Through a series of value mapping and goal setting activities, the RPP established the development of a shared vision of high-quality mathematics instruction among school and district leaders as the goal of joint work, due to the belief that a lack of shared definitions of quality instruction served as an impediment to schoolwide improvement in mathematics. Further meetings defined CBILE as the learning opportunities to co-construct a vision of high-quality math teaching.

Design of classroom-based immersive learning experiences

Four CBILE were designed by one district leader, the mathematics coordinator and the university researchers (the design team). School and district leaders were asked to learn alongside students and the classroom teacher. During the lesson, leaders sat with students to note aspects of their mathematical thinking. This intended to disrupt the leader-as- evaluator structure typical of many classroom observations. The classroom teacher participated in conversations before and after the lesson in order to make visible her instructional decision-making process and to shift the power dynamic between the leaders and the teacher. Additionally, the design team theorized that visits to the same classroom space would support school and district leaders to attend to specific practices rather than superficial aspects of the space (e.g. to attend to how students engage with each other, rather than to how the desks are arranged). Further, school and district leaders would be familiar with students and could see their growth and participation over time.

The mathematics coordinator planned each lesson with the classroom teacher who taught 4th grade. Each session emphasized an aspect of high-quality instruction which was specifically designed into the lesson and the facilitation of the pre- and post- lesson conversations. In between each learning experience, the design team met to incorporate what was learned in the prior session to the next session.

Data and analysis

Audio transcripts and field notes from the CBILE, field notes from design meetings, and artifacts created from both learning experiences and design meetings were used to document what occurred during the CBILE and how they evolved. Audio transcripts of the interviews with the six principals were used to understand their experience and takeaways. Each principal answered the question: *If you were asked to observe a teacher's math classroom for one or more lessons, what would you look for to decide whether the math instruction is high quality?* (Munter, 2014). Follow-up probes were used to expand discourse around each vision dimension. Additionally, principals were given two video clips to watch and were asked if they saw elements in the clips that reflected, or did not reflect, their instructional vision. Finally, principals were asked a series of questions about the CBILE and any connections they made to the work at their school site.

Each design meeting was summarized in an analytic memo. Qualitative coding of principal interviews began with deductive coding using rubrics created by Munter (2014), however emergent codes were recorded and themes summarized in analytic memos. Interrater reliability was established between two researchers. Patterns and themes were discussed with the larger research team. The findings represent themes from the principal interviews that were triangulated with patterns generated from design team meetings.

Findings

Vision grounded in detail

When articulating their vision of high-quality mathematics instruction, principals incorporated substantive details from the classroom space in which they were immersed during the learning experiences. When asked to reflect on how students engage in classroom activity, all principals focused on use of tools (manipulatives, visuals, or mathematical representations) as a means to support problem solving and to show mathematical reasoning. Further, five of the six participating principals detailed the teacher's role in eliciting and responding to student mathematical thinking in language that mirrored what had been observed in the learning experiences. As one principal articulated:

> The teacher is celebrating and recognizing assets in the room…[the] teacher is really thoughtful about who to bring forth in the classroom, to move the whole class, like who, so these students, like there's something I want to get to in my lesson. And these three students…how can I leverage what they have to move the whole class forward on this thing, and definitely the teacher thinking through beforehand, like, these are the ways that kids may do this.

Vision grounded in context

The collaborative, learn-alongside nature of the learning experiences shaped principals' vision construction. As one principal noted, "I thought it was also particularly powerful in hearing from my other colleagues, from other team members, about what they saw that was an example of high-quality instruction, because some of those things are like, oh, I did not pick up on that. So I'm able to pick up on the sharing of ideas around high quality instruction." Others noted that engaging with the teacher unveiled aspects of the lesson previously unknown to them, such as the depth and rigor of the content standards.

Throughout the learning experiences and during the interviews, principals narrated the demands of being both a site administrator and instructional leader within the context of their district. Principals appreciated the opportunity to step out of the rush of their daily work. As one principal explained, the experience allowed leaders to "remove ourselves away from the nuts and bolts and the demands of the school day and just talk about the craft of teaching [which] is incredibly beneficial." Similarly, principals articulated the obstacles they faced to instructional improvement efforts, including pushback from teachers and continued stress from the Covid-19 pandemic. Detailing features of high-quality instruction within the district's context allowed them to create new narratives about what is possible in mathematics instruction given the constraints they faced. Moreover, the CBILE pushed against deficit notions perpetuated in the district context, which can be seen in this principal's comment: "And if we're able to see some wonderful things happening in a classroom, within our district, which is a bifurcated district, and on the side of the tracks, where you might not anticipate the same level of thinking and achievement because of all the other confounding factors. I think it's a pretty good, a pretty good selling point."

Expanding notions of vision

While principals globally praised the experience of participating in the CBILE, tensions emerged that shaped the construction of their vision of high-quality mathematics instruction. The design team conjectured that returning to the same classroom space would support principals in ignoring superficial aspects of instruction and instead attend to the details that mattered. However, this may have caused a tension for principals who are tasked with supporting teachers across a range of grade levels and years of experience. As one principal noted:

> I felt, maybe one of the issues was …, there was a singular focus and maybe a narrow lens on one- on one specific teacher. Right? We went into her class again and again, many times... I think we all agree it's a great classroom, and it's got great rapport. Without looking at a larger, like buffet of different teachers and different styles, I question, well, what else is out there? What other–what other things is a high? Where, what might be some other options out there?

The above quote also reflects questioning that surfaced regarding the forms of high-quality instruction. The four lessons were distinct from each other, though they included classroom routines that were repeated across lessons. While the teacher always started with students seated on the floor engaged in a think-pair-share, the task itself differed based on content and mathematics practice standards. During interviews, principals questioned the forms of instruction more than content specific nuances. It is possible that consistent classroom routines were a limitation of our design, giving the impression that there are only a few forms of high-quality mathematics teaching. However, this design feature surfaced a difference between researchers and leaders' perspectives. For principals, understanding the range of forms of practices became salient to their vision construction, even though the research community prioritizes understanding the function behind those forms (Munter, 2014).

Moreover, while the design of the CBILE intended to focus on specific aspects of high-quality instruction, the conversation went beyond the details of the lesson. District and school leaders asked how to transfer what they witnessed during the lesson to their school sites. During interviews this tension surfaced, as one principal stated:

> Because the teacher shared with us what they were doing, I had an idea of what the teacher's intent was, and an idea of what the teacher was trying to achieve, which standard she was looking at, her level of knowledge in regard to the progressions, she would provide for us an idea of where the kids had been. So, when I came into the class, I had an idea of what, what we might see the kids doing, I definitely felt the freedom and opportunity to look at student work, to talk to students, to get questions answered by the teacher. And I felt like I could hear my colleagues and also hear their concerns, their concerns about how this might look at their school site.

Discussion

When designing the CBILE, we drew from definitions of vision of high-quality mathematics instruction as an idealized classroom space. Our practice partners negotiated that definition within the contexts and realities of their work as school leaders. From a design perspective, this meant that on the one hand, visiting a classroom space and engaging as learners with the teacher provided an opportunity for principals to co-construct a vision of high-quality teaching that included elements recognized by the research community. On the other hand, other aspects, close to our practice partners' priorities, also became salient and expanded our understanding of the intricacies entailed in crafting coherence around instructional improvement across the multiple layers of school systems.

What Does High-Quality Math Instruction Look Like? Elementary School Principals' Noticing and Their Mathematics Instructional Vision

Patricia Fuentes Acevedo, Christina Kimmerling, Rossella Santagata
pcfuente@uci.edu, ckimmerl@uci.edu, r.santagata@uci.edu
University of California, Irvine

Abstract: Mathematics instructional vision and teacher noticing play an important role in high-quality teaching and might be also central for instructional leaders, yet there is limited research on both constructs for principals. In the context of a research-practice partnership focused on mathematics instructional improvement, we investigated the instructional vision and noticing of six elementary school principals. Qualitative analysis of interview responses and video noticing tasks reveals that principals pay most attention to aspects of the teacher's role and classroom discourse. In addition, greater levels of sophistication in their instructional vision are associated with higher sophistication in how principals notice. The results contribute to our understanding of what and how elementary school principals notice and how this relates to their vision of mathematics instruction. We discuss implications for the design of professional development focused on instructional leadership.

Introduction

Research on teacher learning has highlighted both a vision for instructional quality and the ability to attend to and interpret student thinking as important for responsive instructional practices (Munter & Correnti, 2017; van Es, 2011). When considering instructional change in their schools, it is plausible that both vision and noticing are also important components of principals' competence.

Instructional leadership includes the role played by school leaders in supporting teachers to enact high-quality instruction in their classrooms (Hallinger, 2018). The work that leaders do to support teachers' mathematics instructional practices is informed by their vision of mathematics instruction (Munter, 2014). At the same time, principals' noticing has a potentially important role in supporting teachers' noticing and their instructional practices. Even though teacher noticing is a fundamental component of teacher competence (Santagata et al., 2021) and has been studied from different perspectives, little is known about principals' noticing practices. We conjecture that principals' noticing and their instructional vision might be related, hence we ask: *What do elementary school principals notice about mathematics instructional interactions in video observation tasks?; How does their noticing relate to their vision of high-quality mathematics instruction?*

This paper reports on the initial analysis of data collected as part of a research-practice partnership and seeks both to contribute to the limited research on principal noticing (Amador, 2021) and to inform the design of professional development for instructional leaders.

Theoretical framing

Munter and Wilhelm (2021) define instructional vision as the "discourse that teachers or others currently employ to characterize the kind of "ideal classroom practice" to which they aspire but have not yet necessarily mastered" (p. 343). Munter (2014) developed an interview-based instrument, the Vision of High-Quality Mathematics Instruction (VHQMI) instrument, and corresponding scoring rubrics, that seeks to model the developmental trajectories of the instructional vision of educators. The instructional vision characterized in Munter's rubrics derives from decades of research in mathematics education, usually referred to as reform-oriented instruction, which promotes the teaching of mathematics for understanding and sense-making guided by students' mathematical thinking. This is operationalized in three initial dimensions: (1) *role of the teacher*, (2) *classroom discourse*, and (3) *mathematical tasks*. For each dimension, the VHQMI rubrics describe levels of progression ranging from an initial state that does not incorporate elements of reform-oriented instructional approaches to the most advanced level where the teacher is conceived as a knowledgeable other, a discourse community is described, and high-quality mathematical tasks are considered. Munter incorporates *student engagement in classroom activity* as a fourth rubric that emerges from the data collected in his interviews. This rubric only has two levels.

Teacher noticing encompasses the ways in which teachers pay attention to and make sense of what happens in the complexity of instructional situations (Sherin et al., 2011). Reform-oriented instruction in mathematics requires the ability to make decisions based on student thinking, which is a central component of teacher noticing. In her Learning to Notice Framework, van Es (2011) includes a rubric for *how* teachers interpret the events they notice. Considering analytic stances and levels of depth, the rubric characterizes a developmental trajectory of four levels: *baseline, mixed, focused,* and *extended*. Although the original focus of the framework is on students' mathematical thinking, the rubrics have been widely used in several studies and constitute a valuable guiding tool to characterize levels of sophistication of noticing shown by educators when observing a multitude of aspects of instructional interactions in mathematics.

Methods

Research context and participants

During the 2021-2022 academic year we partnered with six elementary school principals who were leaders in schools serving predominantly Latinx students. The leaders had between one and sixteen years of experience as principals and varied previous experiences as classroom teachers. The broader research-practice partnership with the local district aimed to provide tools to leaders so they could better support their teachers' mathematics instruction. Toward the goal of developing a shared vision of high-quality math instruction, principals engaged in four monthly classroom-based immersive learning experiences in a fourth-grade classroom at one of their sites.

Data collection

At the conclusion of the experiences, each principal participated in a semi-structured interview aimed at documenting both their vision of instructional quality and their noticing skills. Principals answered the question: *If you were asked to observe a teacher's math classroom for one or more lessons, what would you look for to decide whether the math instruction is high quality?* (Munter, 2014). They also completed two video observation tasks answering the question *What do you notice in this clip?* Two clips (of 1 min 11 sec and 1 min 06 sec) from a project directed by Kersting et al. (2012) were used. The first clip shows an interaction between the teacher and one student who provides an incorrect answer to a low-cognitive-demand task. The teacher develops a correct solution strategy in the student's notebook. The second clip shows a teacher-led whole-class discussion where one student shares an incorrect answer to a higher-cognitive-demand task. Two other students explain an alternative solution and the teacher facilitates the interaction. Both interview questions were followed up by additional prompts to come to a better understanding of both principals' vision and noticing. The interviews were audio-recorded and transcribed.

Data analysis

Two researchers analyzed qualitatively the interview transcripts, double-coding reliably 20% of the data and holding periodic meetings to discuss difficult cases and come to a consensus. For the responses to the video observation tasks, two rounds of coding were conducted. First, to characterize *what* principals notice, we started with an inductive coding approach. Secondly, the Learning to Notice Framework (van Es, 2011) was used to characterize the level of sophistication of interpretation of the noticed events (i.e., *how* principals noticed). We assigned a score from 1 to 4 (1=baseline, 2=mixed, 3=focused, 4=extended).

Instructional vision responses were coded using VHQMI (Munter, 2014) four rubrics: role of the teacher, mathematical task, classroom discourse, and student engagement. A score between 1 (low sophistication) and 4 (high sophistication) was assigned for each of the dimensions (except for student engagement where the maximum score in the VHQMI rubric is 2). The mean across the four rubrics was calculated by substituting the student engagement score for the score assigned in nature of the talk (a sub-dimension of classroom discourse), following Munter and Correnti (2017)'s methodology. This mean represents the overall level of sophistication of each principal's vision of high-quality mathematics instruction.

Findings

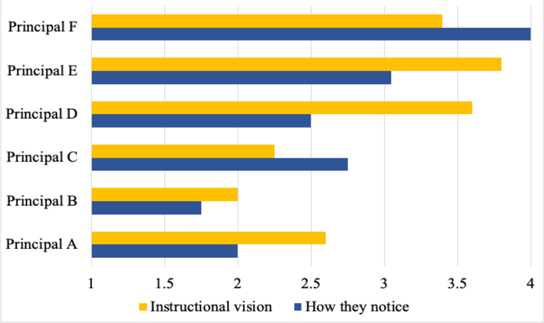
We first report on *what* principals noticed based on their observations of the two video clips. The focus of their noticing could easily be mapped onto three dimensions of Munter's rubrics: role of the teacher, mathematical task, and classroom discourse. Additionally, for the second clip, they also commented on culture and community, a code that emerged from the data. All participating principals made explicit comments about the role of the teacher for the first clip, identifying that the teacher took authorship of the mathematical ideas and did not elicit the student's thinking during the interaction, and the need for the teacher to further probe into the student's thinking. In addition, five principals noticed events related to the nature of the talk. They elaborated on the lack of student mathematical explanations, wondering how much the student did really understand. For the second clip, four principals characterized the role of the teacher as a knowledgeable other or a facilitator, and one of them talked about shared authority. In addition, principals focused on the patterns of the talk: five principals made explicit that it was a whole class/student-led discussion, where students shared their mathematical ideas.

Less attention was given to the mathematical tasks. None of the participants made comments about it in the first clip. In the second clip, only one of the principals noticed the mathematical intention of the task. Aspects of culture and community were highlighted only in the second clip. One of the principals noted that the students' thinking is valued both by the teacher and by students, and three other principals described the videotaped classroom as a space where students feel comfortable sharing their answers and helping their friends.

As mentioned above, we used the Learning to Notice Framework to score *how* principals noticed. We then adopted the VHQMI rubrics (Munter, 2014) to score their vision. Figure 1 reports noticing and vision scores for each principal (from 1 = baseline/low sophistication to 4 = extended/high sophistication), highlighting the association between the two.

Figure 1

Principals' instructional vision and how they notice



To illustrate these findings, we present excerpts from the responses of two principals representing different levels of sophistication. First, for the question about instructional vision, Principal F described an ideal mathematics classroom integrating fundamental notions of high-quality instruction with examples of practices:

> Well, the teacher is recognizing the assets of the students. So the teacher has some way of ideally recording and having a really good idea of what are the assets of the students. What are students able to do in math like, where are they on the progression. (Interview Principal F)

When observing the clips, principal F was able to highlight specific noteworthy events, using them as evidence to elaborate on and make connections to the implications they have for student learning:

> … and then she [the teacher] got it up on the board, she asked students to agree or disagree, which was good, give them opportunity to think through and own their own thinking. And then sure enough, the answer was in the room and kids use the tools. They have like, the one- the last girl talked about pizza, actually. So the pizza is her tool. And so she talks about- like- she had pizza, and sixths versus cutting it in thirds, is going to be much smaller if it's in sixths. (Interview Principal F)

This principal's responses were consistent across the two interview questions. The noticing task prompted an elaboration grounded in evidence from the video clips of ideas he shared about his vision. On the other hand, Principal A provides succinct answers that suggest beginning levels of sophistication. For the instructional vision question, she develops a generic description of her vision that in some passages is based on wonderings. This example is about the teacher's formative assessment practices:

> How's the teacher checking for understanding or changing on the spot if needed? Or bringing in different if it's too much? Or if it's too little? How are they shifting their instruction? (Interview Principal A)

In terms of her noticing, for the same clip principal F commented above, principal A briefly said:

> So that one was more of a student-led discussion. I mean, she [the teacher] wrote the answer in the board, and then there was discussion. (Interview Principal A)

Across both vision and noticing responses for this principal, we observe reference to general ideas (e.g., student-led discussion) without an articulation of the details present in the clip or of principles that guide a vision of high-quality mathematics instruction.

Discussion

Consistent with previous research (Amador, 2021), one of the predominant focuses of principals' noticing was the teacher's pedagogy. Secondly, principals' attention was placed on the students' involvement in the classroom discourse, with details of the mathematical work and thinking. One of the aspects that the principals did not comment on was the quality of mathematical tasks. This was surprising because, although the clips are brief, the task was described by the interviewer before playing each video. As Boston et al. (2017) argue, knowledge regarding the quality of mathematical tasks is essential for principals. These findings thus support the importance of intentionally incorporating in professional development for instructional leaders opportunities to consider the nature of mathematical tasks.

Noticed aspects of culture and community emerged when principals observed the clip that portrayed a whole-class interaction in the more reform-oriented lesson. This is important because high-quality mathematics instruction involves not only aspects of mathematical rigor and attention to students' thinking but also the affirmation of their culture, implementation of inclusive practices, and redistribution of mathematical authority, among other equity-related aspects. We are interested in exploring this further in our future analyses of the data, expanding our perspectives on principal noticing.

While instructional vision is understood as the discourse that is used to describe a dynamic vision of the future in terms of ideal teaching, noticing is a practice that involves attending to details relevant to mathematical learning that are happening moment-to-moment (in a clip or in live instructional situations). Not surprisingly, we found a positive association between the two. A vision for instructional quality is likely framing how principals make sense of what they notice. These findings suggest that creating opportunities to reflect on their instructional vision and refine their noticing practices might be a productive form of professional development for principals to support their instructional leadership skills.

There is No "I" in Beans:
The Complex Organizational Structure of With-ness

Lana Ćosić, Vanderbilt University, lana.cosic@vanderbilt.edu

Abstract: While some learning scientists have begun to explore ensemble learning, the organization of shared activity across people and through time (Ma & Hall, 2018), little is still known about how groups develop the embodied instincts necessary to achieve such coordinated performances. This work explores the patterns and tools of social interaction that emerge in a group of university students learning advanced theatre movement techniques. Through the generative practice of increasingly difficult coordinated tasks (in this case, the act of throwing a sock full of beans in rhythm with each other), students begin to develop an instinct for and awareness of their body in relation to others in time and space. This study has implications for how individuals in groups achieve the embodied intersubjectivity necessary to learn as an ensemble.

Background

In recent years, the learning sciences have begun to theorize beyond the individual learner to include the interactions of such an individual in a group (Goodwin, 2017; Erickson, 2004; Kendon, 1990; Goffman, 1996; Meyer, Streeck & Jordan, 2017). Ensemble learning (Ma & Hall, 2018) in particular has opened the doors for examining how learners coordinate activity in a group that exists not as a collection of individual members, but as a collective *ensemble* that performs as one unit. Many learning scientists have begun to explore the markers of a "successful" ensemble, including the observed qualities of participating in or observing such coordinated groups (Barron, 2003). These are frequently theorized under the umbrella of "group flow" or "intercorporeality" defined as heightened consciousness (also known as *attunement*) emerging from full immersion in a group task (Sawyer, 2015; Stewart, 2010; Meyer, Streeck & Jordan, 2017; Leander, et al., 2023).

However, understanding how a group coordinates its actions can often be obscured by its own complexity, as participation in joint activity may change depending on various contexts or be lost in translation with a researcher who does not belong to the group (Ma & Hall, 2018). Similarly, given that ensemble learning necessarily occurs during group performance of a joint activity, little is known about how groups develop the embodied instincts necessary to achieve such coordinated performances. In theatre (i.e.: the craft, rather than the production of theat*er*), students are unique learners in that they must train themselves to intimately know where their body exists in time and space in order to adjust to the specifications of their role (Suzuki & Steele, 2015). As part of this training, actors practice ensemble-building so that they can prepare to perform coordinated movements with other actors. In a context that allows for the extracted study of the building blocks of *ensemble*, how do learners communicate and adapt their participation in order to achieve attunement?

1	Both hands	Head
2	Dominant hand	Tail
3	Non-dominant hand	Head
4	Non-dominant hand	Tail

Methods

The following described exercise was observed as part of an ongoing ethnographic study of an advanced university theater movement class. During the exercise, 10 participating students were separated by the instructor into two groups of five, each group performing simultaneously. The researcher chose to focus on one group of five due to the vantage point of the camera, though analysis and findings were informed by observations seen in the corresponding group's footage. Interaction analysis (Jordan & Henderson, 1995) of the video data was conducted to reveal patterns of embodied communication. The data was also coded using V-note, a software that can track the duration of interactional events (here, throws and catches).

As a warm-up activity, five students are instructed to pass a sock full of beans in a circle. They are told to say each other's names as they throw the sock and are prompted by the instructor on when to change how they throw and catch the sock. During the activity, the instructor walks around the room observing and reminding the students to "focus on giving and receiving" in order to find their collective rhythm. They perform four rounds, each round increasing in difficulty relative to hand dominance and sock anatomy (see Figure 1).

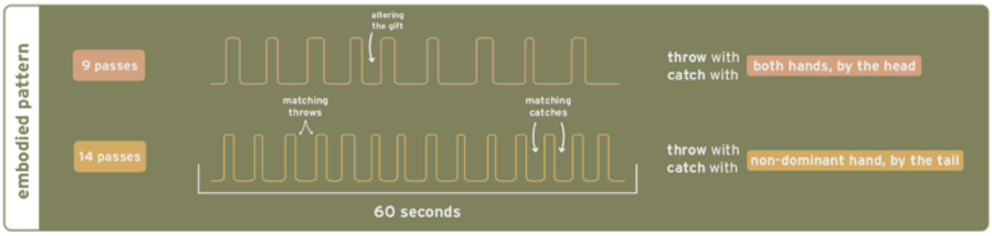
Findings

Overall, qualitative analysis revealed three major findings:

Finding One: As the task became more difficult, the group became more synchronized (see Figure 2). In the first round, where learners throw and catch the sock in a way that allows for the most control (two-handed, by the head), the actors prioritized adding their own flair to how they passed the sock over maintaining the group rhythm. Some actors choreographed unnecessary bows into their catches; others incorporated elaborate spins into their throws. Similar to Ma & Hall (2018)'s observed "tear", these were moments when the embodied flow of the collective was sacrificed. When actors changed the gifted tempo in order to add their own spin on the rhythm (see "altering the gift" in Figure 2) they disrupted the rhythm with which a throw was sent instead of continuing it. Despite the instructor's emphasis on "giving and receiving," these were moments when the actors focused more on "giving" (their contribution to the group) than "receiving" (listening to what the group suggested).

Figure 2

Coded patterns of throws and catches. Here, valleys represent time the sock was held; peaks represent time the sock was in the air; "altering the gift" indicates where a proposed rhythm was changed.

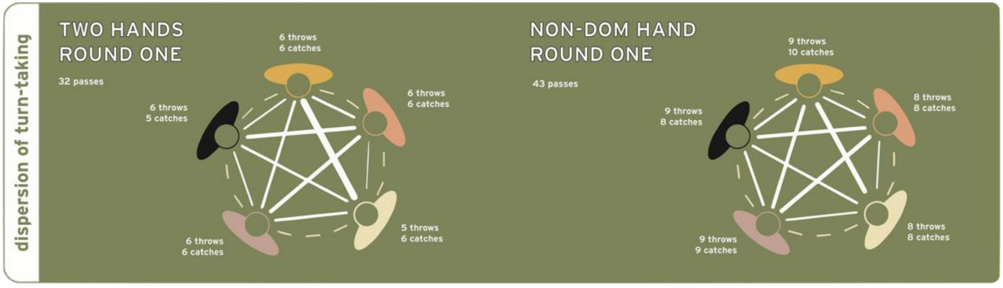


Note: "altering the gift" and "matching throws/catches" are not the only examples represented.

In comparison to the first round, the last round of the activity is much more difficult to execute with intentional control (non-dominant hand, by the tail). In these rounds, participants focused less on individual flair and more on executing the pass successfully, leading to an equal emphasis on the act of "giving" and "receiving." Throwers, less sure of their sock trajectory, entrained their body with the velocity of the sock so as to communicate how they intended to send it to their catcher. Catchers, in turn, entrained with the thrower to articulate how they planned to receive it. This embodied close listening between participants (see: Figure 4a and Figure 4c) allowed pairs to throw and catch with more regularity, as they were able to more clearly replicate the rhythm sent to them. This shifted the focus of participation from an individualized "giving" act to a coordinated *giving-receiving* act that involved both throwers and catchers.

Figure 3

Turn-taking across Round 1 & 3. White line width represents bi-directional throw/catch data.



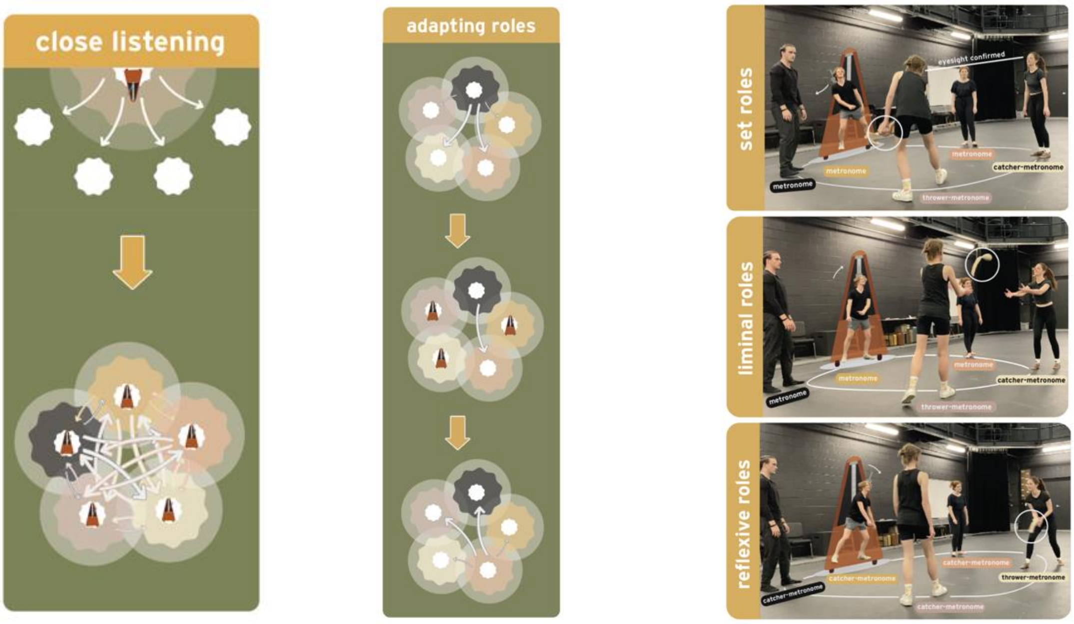
Finding Two: As the task became more difficult, the group shared turn-taking more uniformly across participants (see Figure 3). While the amount of throws and catches was shared well between participants across rounds (visible in the amount of throws and catches in both turn-taking webs in Figure 3), bi-directional throw/catch data revealed more prominent pass-relationships in rounds where participants had more control (two handed or dominant hand). In these 'easier' rounds where hand-eye coordination is less of a concern, actors could control to whom the sock would go, frequently favoring similar pass-relationships.

However, as the task became more complex (introducing non-dominant hand), the pass-relationships appeared more evenly distributed. In these rounds, participants focused less on *to whom* they were sending and instead on *passing* successfully. This required each member to remain in "receiving" mode, attuned to the adapting roles within the group and prepared to flex into what was needed (Figure 4b). This finding revealed a shift away from the group acting as a *collection* of individuals and towards the group as an *ensemble*: rather than determining a singular *who* is giving and *who* is receiving, the participants acted as a *collective* focused on a shared goal of *passing.*

Finding Three: The group achieved a flow state when they inter-determined their tempo based on shared attunement to the rhythm of passes instead of following the tempo set by one person. Rather than a 'conductor' to an 'orchestra' organizational system, each participant became their own metronome attempting to synchronize with other 'metronomes' in the group (see Figure 4a). This role negotiation was supported by the fact that regardless of role prominence in the group (e.g., thrower and catcher could be classically considered 'more prominent'), every actor participated in each exchange by embodying the rhythm of the passes so as to communicate how they all understood the rhythm (see Figure 4c for an example of this *metronoming* phenomenon). The more entrained individuals were to the rhythm of the sock passes– the more *metronome*-like their embodiment– the more responsive to the role outcomes of the activity they were. The more responsive the players, the more stable the group rhythm was.

Figure 4

(a) The interactional practice of close listening. Rather than a conductor model (above), the group regulated their tempo reflexively (below), (b)Embodied role adaption, where actors negotiate being thrower/catcher and continue to support the process by attuning to the sock rhythm, and (c) Example of adapting roles in the activity, including an actor who visibly attunes to the trajectory of the sock in a "metronoming" movement.



(a) (b) (c)

Discussion & implications

The three findings suggest a progression from a group of individuals to an ensemble. As the task became more difficult the group became: 1) more synchronized; 2) more even in their distribution of turns; and 3) more attuned to one another. A discovery like this may feel counterintuitive for actors, given that more skilled performers are often associated with more intentional control over their actions. However, this study demonstrates that in order to become an ensemble, the actors did not relinquish control, they *shared* it: they conducted complex negotiations of tempo through the embodied trajectory of the passed sock. Additionally, this study demonstrates that in order to maintain a successful flow, all participants in the group need to actively participate in those negotiations. It was not enough for a leader to set a rhythm for others to follow– each actor needed to know how to entrain and adapt their personal rhythm in advance of their turn to pass. Unlike collectives where individuals take obvious turns taking the lead, such as in a jazz ensemble, each participant had an equal hand in generating the emergent rhythm of the group. The rhythm arises as an emergent, entangled act where the actions of each part of the collective simultaneously influence the other (Barad, 2007).

Ultimately, ensemble learning and ensemble dynamics are still greatly understudied. While "tears" (Ma & Hall, 2018) in flow can be made visible to outsiders (here, “altering the gift”), how learners move from being a group (a collection of individuals) to being an *ensemble* (a collective, functioning as one unit) is less evident. Through the articulation of how the constraints of a task allowed individuals to transition into a collective “receiving” role with a unified goal, as well as the emergent *metronoming* phenomenon that arises as a result of the achieved flow state, this work attempts to shed light on some of the complex organizational structures in place for role bartering and balancing in small-scale ensembles. While the insights gained from observing students passing a sock full of beans alone cannot speak to all of the challenges that accompany collaborative learning, the understandings gained from how these actors learn to listen to and attune to each other holds great promise for advancing our understanding of ensemble dynamics and learning.

There is much more to group dynamics than how members of a group build on each other's contributions. Transactional accounts of interaction and knowledge building do not go far enough towards developing an understanding of the co-construction and interdependence of turns within an interaction (Erickson, 2004). This work shows that turns (and by extension the content of what we share with others) is also shaped by other people– what Goodwin calls recipient design (Goodwin, 2017). As groups become ensembles, they become attuned to each other and share agency in the construction of shared understandings. At least at the minute scale, it encourages us as learning scientists to expand how we think of participation: as an entangled act of *passing* rather than individual modes of *giving and receiving.*

Perceptions Predict Problem Regulation? The Role of Homogeneous Problem Perception for Successful Regulation in Collaborative Learning

Laura Spang, Martin Greisel, Ingo Kollar

Abstract: Collaborative learning does not always yield positive results. One problem might be that group members have different problem perceptions and fall short in homogenizing them. Yet, little is known whether a homogenous problem perception and an awareness of the homo- vs. heterogeneity of their problem perceptions enhance the regulation process. In this study, *N*=310 pre-service teacher students collaborated online in a problem-based leaning scenario. Afterwards, they answered an online questionnaire to measure their problem perceptions, their awareness of the homo-/heterogeneity of their perceptions, and different indicators of regulation success. Path models indicated that homogeneous problem perceptions enabled regulation success. Learners should thus be scaffolded to achieve homogeneous problem perceptions.

Problem background

Despite its theoretical potential (e.g., Chi & Wylie, 2014), collaborative learning does not always lead to success (Weinberger et al., 2012). One reason is that the collaboration process may be aggravated by a range of problems that need to be regulated by the group (e.g., Järvenoja et al., 2013). To do so, learners first need to identify the problem (Borge et al., 2018). In collaborative learning, though, each group member has their own problem perception, and these problem perceptions may either be heterogeneous (i.e., group members have different perceptions of the current problem) or homogeneous (i.e., group members have the same perception of the current problem). The homogeneity or heterogeneity may affect the regulation process within the group (e.g., Melzner et al., 2020), and thus be decisive for whether the problem is regulated successfully. This paper thus explores how a homogeneous problem perception during collaborative learning influences different learning outcomes.

Problem regulation and homogeneity of problem perception

Problem perceptions of the individual group members may be similar (i.e., homogeneous) or different from each other (i.e., heterogeneous). If all learners believe that a limited productivity is caused by insufficient prior knowledge, they perceive the problem homogeneously. If, however, one group member believes that the unsuccessful learning session is caused by a lack of knowledge, while another group member attributes it to an uninteresting leaning content, the learners have a heterogeneous problem perception, which might hinder the regulation process, as the different group members may use different, possibly incompatible regulation strategies to overcome the problem. A homogenous problem perception, in contrast, might benefit group learning, as the selection of appropriate regulation strategies may be easier (e.g., Borge et al., 2018).

Awareness of a homogeneous problem perception

However, even if group members have the same perception on occurring regulation problems, learners could be unaware of their homogeneous problem perception. The same holds true for learners with heterogeneous problem perceptions. Although one group member might believe that the unsuccessful learning session is caused by a lack of prior knowledge, while another group member may attribute the slow progress to an uninteresting leaning content, both could be convinced that the other group members perceive the situation the same way they do. It is still rather unclear how learners homogenize such a heterogenous problem perception. If, however, learners know that the problem perception differs within the group, they could deliberately try to counteract these heterogeneous perceptions. More specifically, if a learner realizes that his or her own perception is different from the perception of another group member, he or she can initiate regulatory activities to achieve a more homogeneous view (Borge, et al., 2018). Consequently, it seems more likely that learners who are aware of potential discrepancies in the problem perceptions choose regulatory activities to deal with this situation on a group level.

Homogeneous problem perception and regulation success

Homogeneous problem perceptions and awareness of a homogeneous problem perception should increase regulation success (e.g., Melzner et al., 2020), which can manifest in different ways. According to Hadwin et al.

(2018), for example, regulation occurs when learners individually, as well as in interaction with each other, adjust their cognitions, motivations, and/or their emotions. To arrive at successful regulation, a homogeneous problem perception appears to be a necessary precondition. In other words, regulation success would be high if group members successfully solved their problems and improve their learning experience and/or their knowledge gain to a satisfying level. In this paper, we differentiate between four dimensions of regulation success: (a) satisfaction with the group's collaboration process, (b) perceived success of coping with the group's regulation problems, and (c) subjective, as well as (d) objective knowledge acquisition.

Research questions

This paper focuses on the association of (1) actual homogeneity regarding the individual problem perceptions (IPP), and (2) the awareness of the IPPs with regulation success measured by (a) satisfaction with the collaboration process, (b) perceived success of coping with the group's regulation problems, (c) subjective knowledge acquisition, and (d) objective knowledge acquisition.

Since both homogeneous problem perceptions (e.g., Melzner et al., 2020) and an awareness of the group learning process (Borge et al. 2018) seem to be important for group regulation, we hypothesized that homogeneity of IPPs, and accurate awareness of the problem perception within the group would be associated with higher (a) satisfaction with the collaboration process (H1a and H2a), (b) perceived success of coping with the group's regulation problems (H1b and H2b) and, (c) subjective (H1c and H2c) as well as (d) objective knowledge acquisition (H1d, and H2d). For a deeper understanding of the regulation process, we further exploratively analysed video recall interviews, which took place about one week after the group session.

Method

Sample. Initially, N=405 pre-service teachers (M_{age}=20.61, SD=5.01, 77.28 % female) participated. We embedded the study as a learning exercise into the course content of 15 seminars. All students participated on a voluntary basis. N=310 students provided data for the main data collection (t1) and the post-test (t2). N=111 collaborative learning groups from which at least two group members answered the questionnaire were included in the analysis.

Procedure. During the first session, students collaborated in small groups online via Zoom in a problem-based learning scenario in which they had to analyse a case vignette that described a difficult classroom situation. Each group was video recorded. After the group session, participants answered an individual questionnaire. In the second session, one week after collaboration, participants completed a knowledge test. In four groups at least two group members agreed to participate in a post-hoc video recall interview, one week after the knowledge test. During the interviews, we showed each member from the same group one identical video excerpt from their group session and asked them to describe the respective situation and estimate whether they believed their groups members would agree with their problem perception.

Instruments and Analysis. Participants rated the extent to which 33 problems occurred during their collaboration, on a 5-point Likert-scale (3 items per problem, e.g., „Single/multiple group members lacked prior knowledge of the learning content"; on average α=.78). We selected these problems based on prior literature (e.g., Järvenoja, et al., 2013). Then, we calculated the difference of the individual problem ratings of each single group member from the average problem ratings of the rest of the group for each of the 33 problems separately. As a measure of *actual homogeneity of IPPs*, we used the average mean of these differences across all problems and multiplied it by –1 to get a measure of homogeneity instead of heterogeneity. To determine *awareness of homogeneity*, first, participants had to rate their perceived homogeneity of IPPs with six adapted items from Menold (2006; e.g., „I believe that my problem perception is different from the problem perception of the others"; α =.70). Next, we calculated the absolute difference between the z-standardized homogeneity of the IPP and the perceived homogeneity of IPPs and multiplied the score with -1 so that learners whose perceived and actual homogeneity aligned more received higher scores. We determined regulation success with: (1) *satisfaction with the group's collaboration process* which was assessed with five adapted items from Glaesmer et al., (2011; e.g., "I am satisfied with our group work.".; α=.92), (2) *perceived success of coping with the group's regulation problems*, for which we adapted four items from Engelschalk et al. (2016; e.g., „My group managed to successfully solve the problems that arose during group work."; α=.93), (3) *subjective knowledge acquisition* which was measured by 9 adapted items from Ritzmann et al. (2014; e.g., „I have the impression that my knowledge of Piaget's/Selman's/Kohlberg's theories has increased. "; α=.94), and (4) a multiple-choice test consisting of 36 statements (1 point for each correct answer) to assess *objective knowledge acquisition*. For analysis, we used the manifest scale means of the self-report measures and the percentage of correct answers for the multiple-choice test in addition to the homogeneity variables described above. We calculated a path model (see Figure 1) with a maximum likelihood estimator using lavaan version 0.6.11 (Rosseel, 2012*)*.

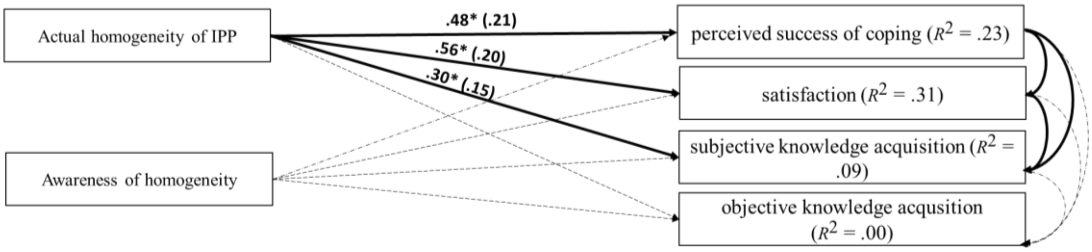
Results

Path model

The path model revealed that actual homogeneity of IPPs significantly predicted satisfaction with the collaboration process, perceived success of coping with the group's regulation problems, and subjective knowledge acquisition (see Figure 1). However, it did not significantly predict knowledge acquisition (H1d). Awareness of homogeneity neither predicted satisfaction with the group learning process, perceived success of coping with the group's regulation problems, subjective knowledge acquisition, nor objective knowledge acquisition (H2a-2d).

Figure 1

Path model with homogenous problem perception, awareness of homogeneity and regulation success



Note. Presented are only significant standardized coefficients (standard errors) *$p < .001$.

Interviews

For a deeper understanding of our results, we analysed two interviews of a group in which the group members had a rather heterogeneous problem perception based on the actual homogeneity of IPPs.

Excerpt from interview with group member A

> I: Then I would like to ask you: Describe, what just happened.
> L: I think we were unsure what exactly the task was, so we were unsure where to start working, how we could divide the group work, because we had no idea what exactly the goal was. (…)
> I: What do you think how the others perceived the situation? Do you think that their perception coincided with yours?
> L: Yes, I think so. Otherwise, somebody would have said something or helped me, or said whether we have to do it like this. But I think we as a group were on the same page.

Excerpt of interview with group member B

> I: How would you evaluate this situation?
> L: I think I evaluated it a little bit negative, because I had the feeling that the others had no real interest. (…) But I did not know, how to get these concerns across to the others or how to talk to them, to engulf them into a conversation that continues.
> I: Do you think that the other group members perceived the situation like you?
> L: I can imagine that it differed because everyone has different views and backgrounds, and I can only guess what they thought by the way they acted, but it is also possible that it is completely different.

Summary

The problem perception of the group members clearly differed. A mentioned that the group was unsure what exactly the task was. B, in contrast, expressed that the other group members did not feel like doing something. B realized that there might have been heterogeneous problem perceptions. However, he or she was still unsure how to regulate this situation. The group reported low regulation success compared to the overall sample (perceived success of coping with the group’s regulation problems: *M*= *3.42, SD* = 1.63, satisfaction with the group’s collaboration process: *M*= 3.40, *SD*=1.20; subjective knowledge acquisition: *M*= 3.00, *SD*= 1.20).

Discussion and practical implications

As expected (e. g., Melzner et al., 2020), actual homogeneity of IPP was associated with satisfaction (H1a), perceived success of coping with the group's regulation problems (H1b) and self-reported knowledge acquisition (H1c). Consequently, educators should develop ways to support groups in how to reach a homogeneous problem perception. However, instructors should consider that awareness of the homogeneity of the problem perception did not correlate with regulation success (H2a-2d). This finding indicates that even when learners are aware of their heterogenous problems perception, they might not try or be unable to regulate discrepancies and develop a homogeneous perception. The interview data supports this assumption. Here, even though a group member knew that the problem perception within the group was heterogeneous, he or she was still unsure on how to deal with this situation. Consequently, group members should not only be made aware of their different perceptions, but also be supported to achieve homogeneity. Potential support options might combine group awareness tools with prompts (e.g., Schnaubert & Bodemer, 2018).

Limitations and outlook

Analysis of video recordings might uncover the extent to which learners engaged in knowledge generating activities (e.g., Chi & Wylie, 2014) and consequently might explain why homogeneous problem perceptions did not significantly predict knowledge acquisition (H1d). Video analysis might also investigate if homogeneous problem perception indeed leads to a more coordinated selection and use of suitable strategies. Despite these limitations, our study helps to understand problem regulation and how it should be supported.

Middle School Learners’ Uncertainties and Their Triggers During Collaborative Engineering Design Tasks

Navneet Kaur, Indian Institute of Technology Bombay, navneetkaur@iitb.ac.in
Chandan Dasgupta, Indian Institute of Technology Bombay, cdasgupta@iitb.ac.in

Abstract: Uncertainty experiences are crucial for solving collaborative engineering design problems. They shape the teams’ design trajectories and affect their uncertainty management approaches. In this paper, we investigate the types of uncertainties that learners at the middle school level experience while they collaboratively solve an engineering design problem and examine how these uncertainties are triggered. We analyzed learner interactions of five teams of sixth and seventh graders from two different studies and identified seven types of learner uncertainties. We also found that the process of *Noticing* is central to learners’ uncertainty experiences and is triggered by various external cues or situations.

Introduction

Research has shown that when learners are exposed to uncertain situations, it provides them opportunities to develop problem-solving skills and acquire new knowledge (Manz, 2018). However, in the case of open-ended problem-solving situations that are collaborative in nature, such as engineering design, knowledge is often unclear, ambiguous, and constantly changing. Making decisions in such cases and dealing with the complexities of collaborative contexts can become challenging, especially for young learners (Dym et al., 2005). Previous work also shows that learners are not always driven to ‘learn’ when they face uncertainty and usually fail to acknowledge the need to address them (Kaur & Dasgupta, 2022). Therefore, it is crucial to comprehend learners’ uncertainties since they reflect the most significant issues they encounter and also shape their interactions.

Even with a growing emphasis on engaging young learners in ill-structured problem-solving, we have little understanding of what kind of uncertainties learners experience and what processes lead to those experiences (M. E. Jordan & McDaniel, 2014). Developing scaffolds to engage learners in uncertainty management productively requires a deeper understanding of what questions or issues matter to learners and how different factors influence them. We can leverage learners’ uncertainty experiences and orient them in productive directions only when we understand their inherent nature and how they emerge during learner interactions naturally. Therefore, in this paper, we tap into these issues and investigate the following research questions: What type of uncertainties do learners experience? And how these uncertainties are triggered during a collaborative engineering design activity.

Method

To answer our RQs, we analyzed learner interactions of five groups of middle school learners. The data came from two studies where groups solved an engineering design problem given to them. In the first study, two groups of seventh-grade learners (Group A (2 participants) and Group B (3 participants)) designed a cleaning robot while optimizing the design cost using the LEGO Mindstorms^{TM} kit during a one-day study conducted in a workshop mode. The second study was conducted with three groups of sixth-grade learners (Groups C (4 participants), Group D (3 participants), and Group E (4 participants)) who designed a balloon-powered toy vehicle with the objective of maximizing the distance. This was an in-class study spread over four days (1 to 1.5 hours each day) conducted in a large public school in India. Along with two primary observers (who are also the authors of the paper), teaching assistants from the same department were also present in both studies to handle the logistics and also mentor teams from time to time.

The data analysis started by identifying the uncertainty instances where learners externalize their uncertainties. These expressions were captured using a coding scheme by Jordan et al. (2014), which uses markers like hedges, probabilistic statements, and non-verbal indicators. A total of ninety-four instances were identified and analyzed from the two studies combined. The data analysis process was inductive, and we used interaction analysis methods (Jordan & Henderson, 1995). To interpret types of uncertainties, we asked ourselves: What aspects/issues concerning the content-related or interpersonal uncertainties do learners experience? Following the inductive coding method, we started labeling the identified uncertainty instance with short text segments explaining what the uncertainty is about. We then combined the overlapping and redundant themes into categories, finally refining them into broad themes describing the types of uncertainties expressed by learners.

To understand how uncertainties are triggered, we asked the following questions: What situations or cues lead to learners expressing uncertainty? And What factors influence learners’ uncertainty experiences? We prepared detailed descriptions of related learner interactions for each uncertainty instance to trace critical moments and situations connected to how uncertainties are triggered. Along with the uncertainty episodes, we also analyzed the neighboring events to make sense of processes that led to learners experiencing different types of uncertainty.

Initially, three researchers independently analyzed Team A episodes, followed by extensive discussions to resolve discrepancies in the initial findings. The codes and descriptions were then iteratively refined through elaborate discussion sessions among the three researchers while simultaneously analyzing data from the remaining teams.

Findings and discussion

In this section, we will first discuss the types of learner uncertainties identified in our data. Next, we describe how these uncertainties emerge while learners collaboratively resolve the design problem.

Types of learner uncertainties during collaborative engineering design activities

We found that learner uncertainties during a collaborative engineering design activity can be categorized into broadly seven themes (T1 to T7) as described below:

Uncertainty pertaining to problem definition (T1)

Learners experience uncertainty related to understanding and redefining the problem parameters. For example, this may include clarifying the objectives that they need to fulfill, identifying constraints that must be met, and defining functions that their design should be able to perform. For example, in the excerpt below, we see that a participant from Team C expresses her uncertainty about whether the *"looks"* of the vehicle matter (line 1) and whether it should be included as an objective to fulfill (line 3). The other participant also related it to the client's expectations (kids as end users) and acknowledged it as an essential design aspect (line 2).

1 Pooja: Does looks matter?
2 Krish: It is a toy for kids. Looks will matter.
3 Pooja: We have to decide if it is one of our goals to make it beautiful. Will we get extra credit for that?

Uncertainty pertaining to the conceptualization of solution (T2)

Most learner uncertainties are about conceptualizing the solution-related aspects. For example, this includes understanding the required domain concepts, coming up with alternatives, selecting appropriate materials, deciding the shape and structure of their designs, and choosing optimal options.

For example, in the case of Team B, while exploring the materials kit, a participant, Shilpa, expressed uncertainty about using different cleaning materials provided to them. She suggested an idea about how to use a cleaning mop. This was followed by a discussion about different possible alternatives for placing the materials, where another participant, Karan, added to her idea and suggested an alternative placement option. Finally, Shilpa suggested finding and using a *"broom"* like material to swipe away the dry waste.

Uncertainty during troubleshooting an issue (T3)

Many uncertainties are experienced when learners troubleshoot issues during the prototyping phase. These uncertainties are usually triggered when learners struggle to determine the causes of failed trials or make sense of unexpected or contradictory outcomes.

For example, in an episode from Team A, the team faced uncertainty regarding why their robot was not moving as expected. A participant, Sneh, expressed his uncertainty by writing it on a post-it note, saying, "*Why is it acting like a horse?*" as their robot moved with breaks and jerks. They had made earlier attempts to resolve this issue by making several changes to the program code; however, they were unsuccessful in correcting it.

Process-related uncertainty (T4)

Learners also express uncertainties when they do not know how to proceed further. These are uncertainties about what steps they should take next, both with respect to resolving the uncertainty and making progress in the overall design process. For example, in the example discussed in T3, when the participants could not resolve the issue they were facing, Sneh felt uncertain about what they should do next. Additionally, the repeated unsuccessful attempts, and another participant, Aditi's action of abruptly dismantling their current design made him feel confused and panicked. This further added to his uncertainty about what steps to take next to resolve their uncertainty.

Anticipatory uncertainty (T5)

Learners also anticipate future events, especially feeling uncertain about the expected outcome of their actions, decisions, and uncertainty management approaches. They specifically wonder whether they will be able to complete on time, if they will perform better than other teams, and whether their plans will work out as expected. For example, the following expressions from different participants indicate learners' uncertainties about the future: *"What if we do not complete on time?"; "Do you think our car will be the fastest?"*; *"It isn't easy. Will we be able to make it?"*; "*I am not sure if this will work out."*

Reflective uncertainty (T6)

Learner uncertainties can be reflective in nature, where they contemplate their present or prior actions to resolve their doubts and confusions. In these cases, learners may express uncertainties related to the propriety of their decisions, whether they are on the right track, and if and how they should regulate their actions.

For example, in the case of Team C, the team reflected on the previous experiments they performed to test which nozzle straw to use and expressed their uncertainty about changing their strategy. This initiated a discussion where participants reflected on why their earlier experiment failed. For example, Krish said, "*We were testing it without attaching everything. That is why it did not work. How did you decide then?*" Then they discussed how they should regulate their approach to deciding which nozzle straw to use. For example, Pooja suggested, "*Let's ask sir which one to use.*" And Krish recommended completing the construction of the vehicle first and then testing each straw one by one.

Relational uncertainty (T7)

Learners sometimes express uncertainties regarding their own and peers' roles in uncertainty management. For example, learners can experience uncertainties about what actions or behaviors are expected from them (by their peers or teacher/mentor) in a situation of uncertainty, how other team members perceive them, or uncertainty about their own or their team members' roles and positioning in the team.

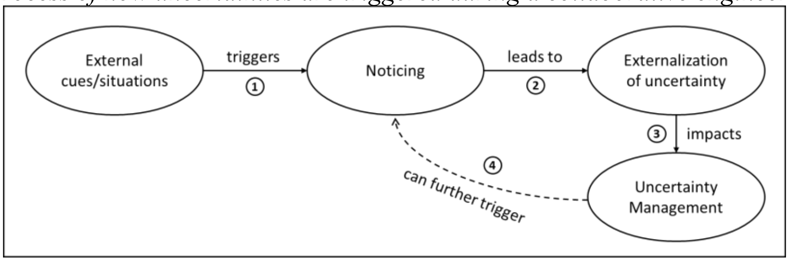
For example, in the case of Team E, one of the participants, Shreya, kept expressing her uncertainty about why her teammates were doing everything alone and how she should participate in the problem-solving tasks. For example, she repeatedly asked them why they were not *"turning around"* and doing things *"together."* When they did not listen to her, she finally asked them if they would ever include her in the decision-making process.

How are learner uncertainties triggered while they solve an engineering design problem?

While analyzing data to understand uncertainty triggers, we found that the *Noticing* process mediates uncertainty experiences. Particularly, we observed the following relationship trail*: The external cues/situations trigger the Noticing of critical information leading to the experience and hence externalization of uncertainty.* This process often impacts what type of uncertainties learners experience and how they respond to them. We show these connections through a schematic representation in Figure 1 and elaborate on its components below:

Figure 1

Process of how uncertainties are triggered during a collaborative engineering design activity



Noticing means actively selecting and interpreting relevant information in a situation (Lobato et al., 2012). Our analysis shows that *specific external cues or situations often trigger Noticing* while learners collaboratively solve a problem *(connection 1 in figure 1),* leading learners to externalize the uncertainties they experience *(connection 2 in figure 1)*. In our data, these cues majorly included – (a) Materials and artifacts, b) Peers' actions, (c) Mentor's intervention, and (d) Unexpected or contradictory outcomes.

In both studies, the teams spent a large chunk of their time dealing with uncertainties that concerned the *materials provided to them*. These were – *How to select and use the cleaning materials for building the robot?*

(Study 1) and *Which one of the three different-sized straws to use as a nozzle for building the balloon-powered toy?* (Study 2). Materials provide a good starting point for teams to begin thinking about how to solve the problem. Therefore, in all the teams, we saw that the moment teams are given the materials kit, they divert all their attention to it.

The relational uncertainties are usually triggered when learners notice oddities in their *peer's actions and behaviors.* For example, in Team E, Shreya noticed that her teammembers Kartik and Sehaj are not including her in any discussions or decision making and even ignoring her suggestions and inputs. This led her to express her uncertainties regarding her role in the team and her doubts regarding how her teammates position her.

Learners' uncertainties are also influenced by *how a mentor intervenes* during learner interactions. For example, in the case of Team C, we found that the questions posed by the mentor, where he asked a team member about the justification for a decision he made on behalf of the team and then doing careful counter questioning on his responses, acted as reflective prompts for the team. It enabled them to notice the gaps in their knowledge and realize the need to gather more information. However, there were also cases where the mentor's intervention was not fruitful. For example, in the case of Team B, even when the mentor asked learners to "*discuss," "think about,"* and *"pay more attention to"* how to optimize cost and simultaneously build a sturdy robot, team members ignored these suggestions. They kept thinking about how their robot should look better than the other team.

The other prominent factors that triggered most uncertainties were *unexpected or contradictory outcomes* or *failure during the prototyping and troubleshooting phases.* Such situations initiate conversations among team members where learners reflect on their actions or decisions (T6), identify knowledge elements needed to troubleshoot issues (T3), or even wonder about process-related uncertainties (T4).

There were also situations where *Noticing* was not directly triggered due to any external cue but rather resulted from the uncertainty management processes where learners strived to maintain uncertainty. This happens when learners engage in deep discussions to resolve uncertainty. This is because expanding on different aspects of uncertainty makes the interconnected issues more visible. In such cases, managing uncertainty triggers noticing and hence results in the externalization of connected important uncertainties *(Connection 4 in figure 1).*

We found that different situations trigger different learner responses to uncertainties. For example, situations of failure can cause learners to notice important variables they need to test to resolve the issue (uncertainty related to troubleshooting). In the same case, learners may notice that they may not be able to resolve the issue due to a shortage of time, causing them to experience anticipatory or process uncertainties. These different situations impact how learners respond to uncertainty, i.e., the strategies they use to deal with it, as represented by *connection 3 in figure 1.*

Conclusion

The findings give us insights into different learner uncertainties and factors triggering *Noticing* when middle school learners engage in a collaborative design activity. The analysis showed that learners could perceive the same information differently and do not naturally notice relevant details by themselves. Therefore, learners should be scaffolded in a way that they not only notice what is critical for their problem but also find it meaningful.

“It Was… Frustration That I Inflicted on Myself Because I Wanted to Know”: An Elementary Preservice Teacher’s Vexation About Responsive Teaching

Ruveyde Asli Kaya, Sherry A. Southerland, Jennifer Schellinger
rkaya@fsu.edu, ssoutherland@admin.fsu.edu, jls09h@fsu.edu
Florida State University

Abstract: There is a growing consensus on the significance of tailoring instruction mindful of students’ resources, which is known as responsive teaching. When encountering such student-centered pedagogies, teachers often express vexations - feelings of concern and discomfort. This case study surfaces one elementary preservice teacher’s (PST) vexations as she was sensemaking about responsive science teaching during a science methods class when her vexations became the *disciplinary substance* of the instruction. We described an iterative cycle of vexations, starting when this PST was positioned to wrestle with figuring out phenomena for herself. As she worked through these vexations, she began recognizing her resources and reflecting on her past experiences and realized how “*powerful*” her learning experience was, which resulted in additional vexations yet a shift in her perspective towards science.

Introduction

The recent reform in science education presents a vision for science learning in which students develop science proficiency by figuring out phenomena from the physical world. This requires them to draw on their resources (meaning their prior knowledge and experiences) to connect with scientific concepts through discursive practices and to negotiate their ideas with peers. While students are expected to wrestle with why and how questions when they are situated as sense makers, teachers need to attend to and pursue students' ideas and experiences and tailor their instruction accordingly. This is called “responsive teaching” (Hammer et al., 2012; Robertson et al., 2016). A growing body of research suggests that novice teachers often express concern and discomfort – which may signify the presence of *vexations* in this study -- when encountering this unfamiliar approach (Jaber, 2021; Radoff, 2017; Robertson & Atkins Elliot, 2020). The term *vexations* refers to feelings of discomfort, bother, or unease as learners engage in the learning process when something does not make sense or the learner identifies an inconsistency in their knowledge (Jaber, 2021; Odden & Russ, 2019). When the notion of vexations is applied to understanding teacher learning, we begin to see that teachers often face ambiguities and uncertainties when engaging in a new pedagogical approach. These vexations emerge when teachers try to reconcile the norms of traditional instruction with their attempts to be responsive (Robertson & Atkins Elliot, 2020; Robertson & Richards, 2017). While much of this work has emerged in secondary and post-secondary science classrooms, less is known about the vexations experienced by elementary preservice teachers (PSTs) as they make sense of responsive teaching.

The role of vexations

Scholars argue that vexations can be critical sensemaking moments when learners experience and then work through conflicts in their learning (e.g., Jaber, 2021; Jaber et al., 2022; Radoff et al., 2019). From the asset-based perspective, when teachers are engaged in *responsively facilitated scientific inquiry* and provided spaces to articulate their vexations and share and interact with peers, vexations are found to function to trigger or sustain sensemaking and evolve into productive resources to gain perspective and sensemaking about responsive practices (Gray et al., 2021; Jaber, 2021; Radoff, 2017; Robertson & Richards, 2017; Smith & Southerland 2007). In this study, we examine a PST’s sensemaking process about responsive science teaching, which surfaced her vexations. Moments of vexation are identified as instances when PSTs articulate uncertainty and ambiguity, problematize knowledge or experience, raise a question, and construct meaning, often accompanied by a display of affect (Jaber, 2021; Robertson & Richards, 2017).

Methods

The data for this study are drawn from a science methods course in an elementary education degree program in which elementary PSTs engaged in a series of scientific investigations, video case study analyses, and discussions centered on responsive teaching pedagogies. During the investigations, PSTs were presented with a phenomenon and encouraged to make observations, create models, and ask questions to surface their ideas and experiences. PSTs were left with their lingering ideas between classes (~2 days) to provide them with time and space to wrestle with their ideas about the phenomenon. In tandem, the PSTs explored a series of video case studies in which elementary students work to explain scientific phenomena. The PSTs answered questions focused on their ideas about the substance of students' sensemaking and the instruction that allowed for the elicitation of that sensemaking.

Participant: Harper

Using a case study approach, we focused on the experiences of one Black woman, Harper (a pseudonym). At the outset of the class, she expressed to the teacher "I hate science. No disrespect, ma'am". Her openness in sharing her views, questions, and feelings made her a particularly informative participant, as it was evident that she consistently tried to work through her vexations by actively participating in discussions. In addition, she often provided cues to her thinking by using her gestures (e.g., facial and body) animatedly. For instance, when offering her ideas to the class, she often used her hands to express frustration and her face (e.g., smiling or frowning) to indicate when she was satisfied or dissatisfied with an idea. The shift in Harper's expressions toward science and science teaching was distinct as the weeks progressed.

Data and analysis

Data were drawn from classroom recordings, class artifacts (e.g., discussion board posts and exit tickets), and interviews. After collecting the participant's consent to the study, we focused on observation and in-depth data collection to understand the focal participant's vexations in a targeted way. The first round of data analysis was to examine available data sources for Harper to tag data that suggested possible movements of vexation. For this, we searched for when she problematized any experience or practice which did not make sense to her (i.e., raised a question or expressed uncertainty and ambiguity) and/or displayed an affect, such as confusion, frustration, discomfort, or excitement (Allen & Penuel, 2015; Jaber, 2021; Radoff et al., 2019; Robertson & Atkins Elliott, 2020; Robertson & Richards, 2017). Harper's vexations were then tracked, to see whether they were surfaced during her learning process again or how these vexations shifted over time and across activities. This led us to identify whether there is a pattern in the vexations of Harper. For example, in one of the initial reflections, Harper noted '*Thinking back over the week, my thinking about science was challenged because I realized that science is way more than just book work and worksheets'*. Here, Harper was expressing a '*challenge*' about science learning from textbooks and worksheets which we tagged, then sought related moments in different data sources following weeks to see whether Harper mentioned about the challenge again or made a connection with a past experience or if this idea caused a vexation for Harper during sensemaking about responsive teaching. So, all data were tagged for any evidence about questions or affective displays that included confusion, excitement, anxiety, or uncertainty.

Findings

Reflecting on her initial experiences in the class, Harper described the way she engaged in scientific investigations in the science methods class (e.g., figuring out a scientific phenomenon) as different from her past science experiences. She noted that she had not been situated as a "*science thinker*" in her prior science learning experiences. As she was reflecting on these different ways of engaging in science, she described how the early activities in the methods class had been frustrating as she was asked to sit with her scientific uncertainties, she said:

> So I felt like I was giving too much time on [these ideas]. So I was just like, 'Okay, I'm done. The answer is what it is.' ...It was really like self-frustration that I inflicted on myself because I wanted to know. Why? Like, why is this answer wrong? What? What? ...It was like a self-inflicted quit. I had to quit [thinking about these things] because I was overthinking it way too much like more than what it was.

Harper's vexation was evident that she was "*frustrated*" and "*challenged"* during her wrestling with lingering uncertainties about scientific phenomena, which transformed into a "*wanting to know"* perspective that sustained Harper in sensemaking she found herself *working on something far way too long* and *analyzing the wrong answer even though she knew the right answer*.

As Harper continued to work through these vexations, she regularly drew upon her everyday knowledge to connect with the science content. She shared her experience of leaving a container in a microwave and the heat impact on the change of shape, or she described physical change by drawing on her observations of "*steam filling up the bathroom*" and "*floors feel wet*" another time. In another lesson, Harper and her cohort were figuring out the melting time of an ice cube suspended in tap water versus salt water. As the instructor was pressing for students' explanations using their own words rather than striving to use scientific vocabulary, PSTs were animated in this exploration talking over one another and indicating confusion about the ideas being explored. In Harper's reflection the following day, she noted:

> The most challenging part to me was understanding density! This was a struggle for me because the only instances I could think of density were in the aspect of a thickness (a cake and hair extensions). This frustration!... I didn't fault my learning. Rather, it made me want to keep going. It felt like I was almost there, but there was something that I was missing…

In this excerpt, Harper discovered that she had everyday resources she could use in sensemaking. While she came into the class thinking that science was not her "*strong suit*", later in the semester she noted, "*I know more about science than I thought*!" There was evidence that Harper worked through these science vexations outside the class. Instead of *"quit(ting)"* as she said before, she wrote, "*I have been talking about the ice phenomena since Thursday to both my family and coworkers."*

By engaging in the class and the realization of her own resources, Harper started to problematize her past learning experiences and distinguished affordances of responsive teaching based on her past experiences. She described just "*learning different concepts*" in the past and saw her past experiences as a "*waste of her time*" because she engaged in learning material to *"just pass the course".* She added "*You read passages and answer questions...nothing that requires thinking."* This resulted in her distaste for science, "*I hated science because I was never taught properly"*. She expressed, *"If I would have had a more interactive and thought-provoking science experience, I would be able to further expand on my ideas about things a lot more…That's something that this class has helped me do--explain my reasoning, …. Now I'm able to do like more explanation and put more thought into it".* Through reflecting on her past and current experiences in the class, she realized that "*Science is way more than just bookwork and worksheets*" instead recognizing and embracing some responsive moves such as giving students the "*floor*" for sensemaking. *"[Responsive teaching] gets students thinking. But it doesn't give any answers"* and appreciating students' different ideas "*..all answers are good answers. That's a that's a really, really big thing that I learned…. [that] as a teacher we need to accept all students' answers, even if they're maybe not right".* Toward the end of the semester, she continued *"I feel like being a responsive teacher is the only option like. That's the only way that you're going to be an effective teacher".* In her last exit ticket submitted before her teaching in the field placement she wrote: "*…I came to the realization that maybe I don't hate science after all…. I was just hating the manner it was being presented before".*

Discussion

This work illustrates a preservice teacher's vexations as she experienced responsive science teaching as a learner and as she considered it as a teacher. Harper was vexed by authentic experience- being presented with a scientific phenomenon and figuring it out herself- and then she started to recognize her resources and how "*powerful*" her learning experience was, which made her reflect on the past science learning experiences and caused some vexation relatedly. When Harper was given the floor to speak up through different spaces, her vexations surfaced which positioned her to realize that her past experiences conflicted with her current experiences, that this realization led her to sense make the affordances of responsive teaching practices.

PSTs can feel vexed when encountering student-centered pedagogies (Jaber, 2021) because these pedagogies are counter to the ways that they have been taught (Cohen & Ball, 1990). These vexations may be precursors to PSTs considering student-centered pedagogies in their future teaching when they are positioned to explore the power of these ways of learning (Jaber, 2021; Jaber et al., 2018, 2022).

Conclusion

This research speaks to a gap in our understanding of PST's sensemaking about responsive teaching and the role that vexations play in that sensemaking. Being mindful about presenting a case study, Harper's sensemaking process and emerging vexations shed light on how these vexations influenced the beliefs of oneself, science, and science teaching, which allowed her to juxtapose traditional and student-oriented pedagogies and also on that possible ways to support PSTs' engagement in the teacher education programs by recognizing their vexations and providing spaces to articulate and sit with these vexations (Robertson & Atkins Elliot, 2020; Robertson & Richards, 2017).

Quickstart Spaceship Programming for Developing Physical Intuition and Connecting it to Propositional Physics Knowledge

Jacob Kelter, Amanda Peel, Bradley Davey, Michael Horn, Uri Wilensky
jacobkelter@u.northwestern.edu, amanda.peel@northwestern.edu, bradleydavey2026@u.northwestern.edu,
michael-horn@northwestern.edu, uri@northwestern.edu
Northwestern University, Center for Connected Learning and Computer Based Modeling

Abstract: Decades of research reveals that students enter physics classrooms with non-Newtonian intuitions that are difficult to change. We present a "quickstart" blocks-based programming environment in which students program the engines of a spaceship to navigate it to a new location. We then present a theoretical framework and analysis methodology combining student-produced computational artifacts with interaction analysis to investigate student learning in the environment. Preliminary results from a case study analysis of two students shows that through the programming task they align their intuitive mental models with Newtonian physics, and then by answering questions about the computational model afterwards, they were able to connect these intuitions to propositional physics knowledge.

Background

Decades of research shows that students enter the physics classroom with non-Newtonian intuitions and that changing these intuitions is difficult (e.g., Clement, 1982; diSessa, 1982; Halloun & Hestenes, 1985). To help students develop Newtonian intuitions we designed a spaceship programming microworld. A microworld embodies some domain of mathematics or science in a computational environment which students explore (Papert, 1980). A very early class of physics microworlds used the "Dynaturtle", a computational Newtonian object that students interact with by applying virtual "kicks" (diSessa, 1982; Papert, 1980). This early work showed that naive non-Newtonian physics intuitions are difficult to change but that playing Dynaturtle games can help. We build on this work by constructing a spaceship programming microworld in which students program the engines of a spaceship to turn on and off using programming blocks in a "quickstart programming environment" (Wagh & Wilensky, 2018). The programming blocks in a quickstart environment represent important concepts or mechanisms in a science domain rather than low-level computational primitives, enabling students to learn about scientific phenomena through programming without needing any prior programming experience. Two broad Constructionist learning principles embodied in the design are that (1) constructing an external "public entity" facilitates constructing mental knowledge structures (Papert, 1991) and (2) thinking and talking about one's activity aids learning (Harel & Papert, 1990). The microworld and domain-specific programming blocks are implemented with NetTango Web (Horn et al., 2020), a block-based interface to the agent-based programming environment NetLogo (Wilensky, 1999) that makes it easy for students to construct a public artifact, in this case, the program for the spaceship. The design also encouraged students to work in groups and discuss their problem solving.

In analyzing student learning we build on research focusing on the convergence of two collaborators' understanding (Roschelle, 1992). We combine this with the frameworks of mental models (Gentner & Stevens, 1983; Johnson-Laird, 2010) and representational redescription (Karmiloff-Smith, 1992; Taber, 2010) to analyze the convergence and divergence of two students' understanding. In our usage, a mental model (MM) is a dynamically constructed mental representation of a situation which can be "run" to make predictions. According to the representational redescription hypothesis (Karmiloff-Smith, 1992), children (and perhaps adults) develop increasingly explicit representations throughout development that enable increasingly flexible behavior. On this view, the representation a person initially develops to enable "behavioral mastery" in a domain is not replaced. Rather, representations are *redescribed* at more explicit levels. We assume that student MMs can contain multiple types of representations at different levels of explicitness.

Following the Constructionist stance that a person's mental models are intimately linked with the external artifacts they construct, we analyze the alignments and misalignments between students' MMs and the computational model (CM) underlying the spaceship programming task. Using these frameworks, we aim to answer the following research question in future work: *How did students' MMs diverge and converge with each other and ultimately come to align with canonical physics knowledge embedded in the spaceship programming microworld?* The goal of our analysis method is to understand both what learning happened and how.

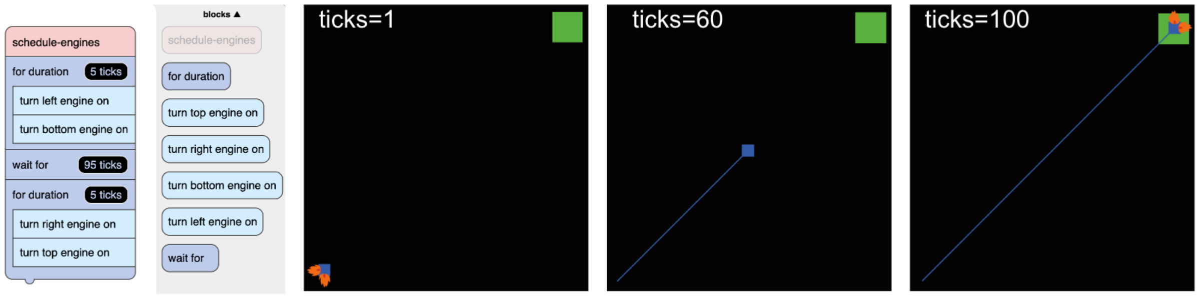
Methods

Software and task design

Students are given the task of programming the engines of a spaceship to reach a target square. They are encouraged to work in pairs to facilitate learning through discussion. In the microworld, the spaceship is visualized as a square with an engine on each side. Figure 1 shows the visualization along with a potential solution to get the spaceship to stop on the green square. The pane to the left shows the block-based programming environment. Learners drag blocks from the gray "blocks" area to program the pink "schedule-engines" procedure. In this case, the spaceship's bottom and left engine are scheduled to turn on for five "ticks" (the standard unit of time in NetLogo). Then the spaceship "waits" for 95 ticks without any engines on. Finally, the opposite engines are turned on for an equal amount of time to bring the spaceship to a stop. The blue line traces the path of the spaceship. This "diagonal" solution requires the fewest number of blocks, but many other solutions are possible. The next three panes in Figure 1 show the spaceship at the beginning, middle, and end of its journey with this block configuration.

Figure 1

A solution to the spaceship programming task.



```
schedule-engines
for duration 5 ticks
  turn left engine on
  turn bottom engine on
wait for 95 ticks
for duration 5 ticks
  turn right engine on
  turn top engine on
```

Data collection

Data was collected in an AP physics A course in large public high school in the midwestern United States. Every block configuration (schedule-engines procedure) that each student tried was logged. Additionally, we recorded audiovisual data for the focal pair of students in this study, Kate and Jay, as they worked through the problem. Each student had their own laptop but they worked together.

Analysis methodology

We began qualitative analysis by transcribing seven minutes of audiovisual data of two students from a larger corpus. Next, a team of three researchers analyzed the video and transcript. We iteratively watched and segmented the video into 24 episodes of coherent joint and individual activity, each roughly 15-20 seconds in length. We summarized the result of each episode in terms of the students' problem-solving approaches and their understanding of the computational model and its latent physics concepts. Next, we deductively coded each episode for *convergence* or *divergence*. During this process we recognized and inductively coded emergent moments of *alignment* and *misalignment* between the two students' mental models (MM) and the computational model (CM). We present these deductive and inductive codes in Table 1. After coding the episodes, the first author wrote a narrative description of the episodes interleaving parts of the transcript (including students' computational blocks) with analysis. Other authors read this narrative description and any disagreements were discussed until agreement was reached. The combination of audiovisual data and a record of the students' computational blocks provides a rich combination for characterizing students' learning processes and trajectories.

Table 1

Deductive (convergence) and inductive (divergence/alignment) coding scheme

Code	Description
MM convergence	The two students' MMs converge
MM divergence	The two students have different MMs
Blocks convergence	The two students set up the same programming blocks and parameters
Blocks divergence	The two students set up different programming blocks and/or parameters
Alignment	When a student's MM agrees with the CM
Misalignment	When a student's MM does not align with the CM

Example analysis

Thirty seconds after starting the activity, with the blocks in their default starting position, Kate realized they could move the ship diagonally. They *converged* on this with a brief exchange:

Figure 2

Initial convergence excerpt

Kate (0:30): We only have to use certain engines (makes a triangle gesture with both hands together)
Jay (0:35): Wait what do you mean?
Kate (0:36): Go diagonally
Jay (0:37): Ooh yes. Okay, I want to see how far
Kate (0:42): How much does a tick go?
Jay (0:43): Yeah. Okay, I'm gonna do just "bottom" (engine) for one tick.

Kate's blocks	**Kate's MM**	**Jay's blocks**	**Jay's MM**
 schedule-engines for duration 1 ticks	Go diagonally❼ only certain engines	 schedule-engines for duration 1 ticks	Go diagonally❼ only certain engines

It is important to note that Kate initially uses a triangular hand gesture and only then uses the words "go diagonally" to clarify. This indicates she first developed an explicit but non-verbal MM and only afterwards redescribed it in words. At this point Kate and Jay's MMs have *converged* on the idea to "go diagonally". Despite this, Jay decided to start by turning on just the bottom engine for one tick. After setting up the blocks and running the model, Jay saw that the ship did not slow down or stop after the engine turned off and concluded, "So, it looks like there's no friction. That's useful," and then they both laughed. Their shared laughter might suggest that Kate and Jay had converged on an understanding of "no friction," but when Kate ran the model herself for 30 seconds, it is clear there was actually a *divergence* between their mental models and a *misalignment* between Kate's MM and the CM:

Figure 3

Divergence and misalignment excerpt

Kate (1:52): Why does it keep going? Oh it's "for duration" // wait // Or, you have to stop it? It will just keep going?
Jay (2:05): Yeah, yeah

Kate's blocks	**Kate's M**	**Jay's blocks**	**Jay's MM**
 schedule-engines for duration 1 ticks turn bottom engine on	Ship will keep going❼ unclear why	 schedule-engines for duration 1 ticks turn bottom engine on	Ship will keep going❼ no friction

After running the model herself Kate got confused as to why the spaceship did not stop on its own, revealing the *misalignment* between her MM and the CM. She quickly realized that it will "just keep going" but phrased it as a question to Jay for confirmation. After his confirmation, we can infer that her MM was *aligned* with the CM in that the spaceship will not stop on its own, but it is not clear if she had connected this to the physical concept of "no friction" as Jay had. Based on her later reactions, she probably had not.

Preliminary results

Due to space restrictions, we are unable to present a full case study here. However, preliminary analysis shows Kate and Jay progressively *aligned* their mental models (MMs) with the computational model (CM) embedded in a physics microworld. At times their MMs and programming blocks *diverged* from one another, but ultimately, they *converged* on both a shared solution to the spaceship programming task and a shared MM of why the solution works. In answering subsequent questions in the assignment, they linked the behavior of the model to canonical physics concepts such as force, acceleration, and inertia, helping them connect the non-verbal understanding they gained from interacting with the microworld to more formal physics concepts, including previously disconnected propositional knowledge.

Discussion and future work

The spaceship programming activity helps students develop physics understanding, because there is immediate feedback if the spaceship does not move or stop as they expect given the sequence of programming blocks. This creates a feedback loop which allows the student to iteratively refine their MM of the situation to align with the physics embedded in the microworld. Working in pairs, students discuss their activity and can learn from each other both through spoken interactions and through sharing their computational artifacts. The block-based programming activity additionally gives students experience with a simple form of programming and computational thinking (CT), aligning with current science standards. Incorporating CT into physics also expands participation and advances equity in CT, because a much more diverse set of students take physics courses compared to dedicated courses on computer science (Wilensky et al., 2014).

The block-based programming activity advances a methodological contribution of relating students' MMs to their programming blocks. The full record of a student's block-based program gives insight into the student's learning trajectory, because the state of their program often reflects their MM. When paired with video data, we have shown it is possible to construct a narrative that accounts for the dynamic *alignments* and *misalignments* between students' MMs and the CM as well as *convergences* and *divergences* between the two collaborating students' MMs. These theoretical constructs and methods can be used to understand students' learning trajectories and patterns of collaboration. Future work will present full case studies of student learning using the theoretical frameworks and methods presented here.

Abstract: Building causal knowledge is critical to science learning and scientific explanations that require one to understand the how and why of a phenomenon. In the present study, we focused on writing about the how and why of a phenomenon. We used natural language processing (NLP) to provide automated feedback on middle school students' writing about an underlying principle (the law of conservation of energy) and its related concepts. We report the role of understanding the underlying principle in writing based on NLP-generated feedback.

Introduction

Understanding cause-and-effect relationships is an essential part of reasoning about scientific phenomena and writing scientific explanations. At the core of this process is learning underlying principles that explain observed/identified relationships (Russ et al., 2008; Vieira et al., 2019). This contributes to "a clear conceptual understanding of the principles and theories, plus the knowledge of how to apply these principles to a different context" (Vieira et al., 2019, p. 203). For example, when experimenting with a roller coaster simulation, students may be able to identify that a car's motion will be sustained through the remainder of the ride when the initial drop height is higher than a subsequent hill. However, they may not be able to explain why this is so, particularly when they do not understand the underlying principle.

In this study, middle school students learned about the law of conservation of energy (LCE) and its associated concepts and relationships (e.g., potential energy, kinetic energy, total energy), and received automated feedback through natural language processing (NLP) on their writing about the principle and related concepts. Our research questions were:

1. How does students' early understanding of an underlying principle (law of conservation of energy) relate to their writing about the principle and related concepts?
2. How does students' understanding of the underlying principle relate to feedback effectiveness (evidenced in the quality of the revised essay)?

Conceptual framework

We constructed the conceptual framework of the present study based on literature recognizing intuitive knowledge (diSessa, 1988, 2018), intuitive theories (Gopnik, 2012), and intuitive explanations (Keil & Wilson, 2000) as part of a pathway toward scientific theory and scientific explanations. We acknowledge the importance of mechanistic reasoning (Carmichael et al., 2010; Russ et al., 2008; Vieira et al., 2019) in scientific explanations in that it enables one to understand underlying principles. Given that scientific explanations describe the how and why of a phenomenon based on scientific facts (Osborne & Patterson, 2011), covariational reasoning, which identifies cause-and-effect relationships without the why, is not sufficient. At the same time, we value the learning process that includes covariational reasoning and even perceptual explanations, especially considering that causal knowledge involves both scientific and intuitive theories (Gopnik, 2012). The conceptual framework guides us to attend more to the process of "reconciling theory with experience of the natural world" (Furtak et al., 2010, p. 177). We conceptualize automated feedback from NLP in the present study as a scaffold for students to translate between underlying principles and experience during the reconciliation process.

Method

Two eighth-grade science teachers and their 138 students from a mid-sized, US Midwestern city participated in this study. The study was conducted during a three-week, design-based physics unit focused on energy conservation and transformation, where students were invited to design a roller coaster using what they learned about physics. During the unit, students participated in five virtual labs using a roller coaster simulation, answered questions after each lab, and wrote and revised two design essays. The initial design essay (Essay 1) was to explain how height and mass affected the amount of energy there was in their roller coaster system, as well as how the LCE could be used to explain transformations. This initial essay was sent to our NLP technology, called PyrEval, to automatically assess students' essays for feedback, which students could later use to revise their ideas. Students then learned about how height and mass affected speed. Students then wrote their second design essay (Essay 2), building on the ideas in their initial essay, using the feedback from PyrEval. Automated feedback was generated through the NLP technology that detected four main content units in students' essays: one was about LCE and the other three were about related concepts (i.e., height and energy; mass and energy; initial drop in relation to hill height). Based on the presence or absence of each content unit, the feedback was given to either acknowledge their inclusion of the content unit or prompt them to explain the missing content unit. For example, students who did not explain LCE but explained other related concepts in their Essay 1 were asked to elaborate on their current explanation in connection with LCE.

Data for this study consisted of students' written responses from short answer questions about LCE after labs and for their design essays. Two researchers independently coded 15% of all students' responses and achieved an Intra Class Correlation value of .947, which is considered excellent (Cicchetti, 1994). All discrepancies between raters were resolved through discussion.

Findings and discussion

RQ1: How does students' early understanding of the underlying principle (LCE) relate to their writing about the principle and the related concepts?

We sorted students into four groups depending on which of the early short answer questions about LCE they answered correctly. We also categorized Essay 1 into four explanation patterns depending on which of LCE and related concepts were explained. We then ran a Fisher's exact test. Table 1 lists all groups and patterns.

Table 1
Early Understanding Groups and Essay 1 Explanation Patterns

Early Understanding of the Underlying Principle: Answers to the first and second lab questions about LCE		**Essay 1 Explanation Patterns:** Explanations of LCE and related concepts	
Group A (n=29)	Correctly answered the first and second lab questions	**Pattern 1** (n= 70)	Wrote about LCE and at least one of the related concepts
Group B (n=23)	Correctly answered only the first lab question	**Pattern 2** (n= 4)	Wrote about LCE
Group C (n=32)	Correctly answered only the second lab question	**Pattern 3** (n=51)	Wrote about at least one of the related concepts
Group D (n=54)	Did not answer either question correctly	**Pattern 4** (n=13)	Wrote neither

Fisher's exact test results showed that there was a statistically significant association between students' early understanding of LCE and their Essay 1 writing quality (two-tailed, $p<.001$). Observed frequency table (Table 2) shows that among students who answered both lab questions about LCE correctly (Group A), 65.5% explained LCE and at least one related concept correctly in Essay 1. Among students who answered one of the lab questions about LCE correctly (Groups B and C), 65.6%-73.9% explained LCE and at least one of the related concepts correctly in their Essay 1. Among students who were not able to answer any of the lab questions about LCE correctly (Group D), only 24.1% explained LCE and at least one of the related concepts correctly in Essay 1, but 64.8% explained at least one of the related concepts correctly in their Essay 1. The results also show that it was possible to write about related concepts without understanding the underlying principle. For example, one of the related concepts that students were expected to write about in their essays was the initial drop height of the roller coaster being higher than the subsequential hill that they designed to get the car to travel to the end of the roller coaster. That is, without understanding of LCE, cause-and-effect relationships were discoverable on the simulation and the data summary table without knowledge of underlying principles. Such phenomenological explanations (Furtak et al., 2010) written by students in Group D are not deficits within our conceptual framework. They are the opportunity for the process of reconciling underlying principles with data to begin. These students received automated feedback on their Essay 1 asking them to write about LCE.

Table 2

Observed Frequencies of Essay 1 Explanation Patterns per Early Understanding Group

	Pattern 1 LCE and related concepts	**Pattern 2** LCE only	**Pattern 3** Related concepts only	**Pattern 4** No LCE and no related concepts
Group A	65.5% (n=19)	0.0% (n=0)	24.1% (n=7)	10.3% (n=3)
Group B	73.9% (n=17)	4.3% (n=1)	8.7% (n=2)	13.0% (n=3)
Group C	65.6% (n=21)	9.4% (n=3)	21.9% (n=7)	3.1% (n=1)
Group D	24.1% (n=13)	0.0% (n=0)	64.8% (n=35)	11.1% (n=6)

Note. Output in each cell indicates percentage within each early understanding group.

RQ2: How does students' understanding of the underlying principle (LCE) relate to feedback effectiveness (evidenced in the quality of the revised essay)?

We categorized Essay 2 into the four explanation patterns as in the first Fisher's exact test and used the same early understanding group data. We then ran another Fisher's exact test and found a statistically significant association between students' early understanding of LCE and their Essay 2 writing quality (two tailed, p<.001) (Table 3).

Table 3

Observed Frequencies of Essay 2 Explanation Patterns per Early Understanding Group

	Pattern 1 LCE and related concepts	**Pattern 2** LCE only	**Pattern 3** Related concepts only	**Pattern 4** No LCE and no related concepts
Group A	72.4% (n=21)	0.0% (n=0)	20.7% (n=6)	6.9% (n=2)
Group B	65.2% (n=15)	0.0% (n=0)	21.7% (n=5)	13.0% (n=3)
Group C	81.3% (n=26)	6.3% (n=2)	12.5% (n=4)	0.0% (n=0)
Group D	37.0% (n=20)	0.0% (n=0)	57.4% (n=31)	5.6% (n=3)

Note. Output in each cell indicates percentage within each early understanding group.

Overall improvements in writing quality were visible in that more essays included correct explanations of both LCE and related concepts (Pattern 1), and less essays included no correct explanation of LCE and/or related concepts (Pattern 4) in Essay 2 than Essay 1. Automated feedback that prompted students to write about LCE when other related concepts were explained without explaining the why, beyond referring to their simulation data as reasons, may have helped students connect concrete experiences (from the simulation) to LCE. These findings also suggest that early understanding of LCE could be impactful, but based on Group C who showed the largest increase in Pattern 1, a longer process of reconciling theory with data may have been even better.

The overall improvement in explanation patterns hinted that the feedback given between Essay 1 and Essay 2 may have played a positive role. We ran a repeated measures ANOVA to see if there was a statistically significant difference in writing quality scores between Essay 1 and Essay 2. The results showed that Essay 2 was significantly better than Essay 1, F(1, 134) = 22.96, p<.001. The effect size was medium (Cohen's d = .42). Furthermore, the improvement from Essay 1 to Essay 2 differed depending on the explanation patterns that the students included in Essay 1, F(3, 134) = 101.77, p<.001, Cohen's d = 1.5. That is, the improvement from Essay 1 to Essay 2 shown among students who included explanations of only LCE (Pattern 2) in Essay 1 was significantly larger than the improvement shown among the students who included explanations of only related concepts (Pattern 3) in Essay 1. Feedback worked better among those who understood and wrote about the underlying principle (LCE) than those who were able to write about one or more of related concepts but without the underlying principle. The effect size was large (Cohen's d = 1.5).

We also ran linear mixed effect models using the lme4 R package (Bates et al., 2014) to see further about the relations between students' understanding of the underlying principle and their revised essay, with other possible predicting variables for the revised essay quality. Table 4 lists the output of mixed effect model analysis with Essay 2 writing quality as a dependent variable. We included fixed effects of early understanding group, Essay 1 explanation pattern, Essay 1 writing quality, NLP accuracy, Essay 1 revision, and engagement. We also included in the model teacher and class clustering factors as random effects to control for the potential impact of the teacher and class variance. The model specification was as follows: Essay 2 writing quality ~ early understanding group + Essay 1 explanation pattern + Essay 1 writing quality + Essay 1 revision + engagement + (1|Teacher) + (1|Class). There were two significant predicting variables at .05 significance level: Essay 1 writing quality (ß=0.87, p<0.0001) and Essay 1 revision (ß=1.12, p<0.0001). While there were still indirect effects of early understanding and Essay 1 explanation pattern reported above, only these two variables were direct predictors for Essay 2 writing quality. This means that students' revised essay quality was better when they revised their Essay 1 as per automated feedback. It seems intuitive that their revised essay quality was better when their first essay quality was already better, but this finding also suggests that the automated feedback did not ask students to revise their essay when unneeded. Also, the finding that their revised essay quality was better when revisions were made according to the automated feedback suggests that the positive impact of automated feedback on improving writing quality. Especially considering the improvements reported above including more Explanation Pattern 1 in Essay 2, the findings demonstrate a unique potential contribution of PyrEval to science learning and writing as a scaffold for students' translating, connecting, and reconciling between theory with experience (diSessa, 2018; Furtak et al., 2010; Puntambekar & Goldstein, 2007). This will in turn contribute to knowledge building that recognizes possible interplay between intuitive explanations and scientific explanations and value the role of intuitive explanations that can be leveraged through automated feedback scaffolding toward scientific explanations.

Abstract: Algorithmic thinking is the process involved in formulating a problem which can be represented by computational steps. We investigate the impact of students' perspective-taking during a mixed reality embodied activity and how the emergence of a blended perspective mixing agent and global perspectives has the potential to improve learners' algorithmic thinking by concretizing the computational steps.

Introduction

Algorithmic thinking is a cornerstone of programming and computational thinking (CT), that allows one to solve problems effectively across contexts (Shute et al., 2017; Grover & Pea, 2013). Algorithms are sets of precise steps commonly used in computational settings. Developing expertise in creating algorithms require planning, writing, and debugging processes. Algorithmic thinking can be challenging for novice programmers due to its abstract nature (Yadav et al., 2017). The use of embodiment to concretize abstract principles in computing education, shows promising results both for CT and STEM and deepens the understanding of the purpose of computing (Sung et al., 2017). In this paper, we investigate the impact of embodied activities in GEM-STEP (Generalized Embodied Modeling - Science through Technology Enhanced Play), a mixed reality environment, designed to encourage learners to take a first-person perspective while modeling. Specifically, we ask: How does perspective taking mediate the creation of algorithmic solutions in embodied modeling?

Background

Algorithmic thinking and embodiment

Computing education, particularly CT, is becoming increasingly important as technology is becoming more integrated in everyday lives and most fields. CT is broadly understood as a "universal attitude and skill set" that "involves solving problems, designing systems, and understanding human behavior" (Grover & Pea, 2013). Shute's et al. (2017) definition emphasizes that CT can be expressed through thinking and acting, and is exhibited using specific skills, including decomposition, abstraction, debugging, iteration, generalization, and algorithm design. Other researchers claim algorithmic thinking is a particularly hard task (Yadav et al., 2017).

A growing body of CT research highlights activities that involve the use of gestures to represent the abstract concepts associated with CT (Wang et al., 2021; Danish et al., 2020). Agent-based modeling also focuses on the benefits of body syntonicity: the connection learners make when imagining themselves as agents in a programming environment leveraging embodied roles or movement (Papert, 1980).

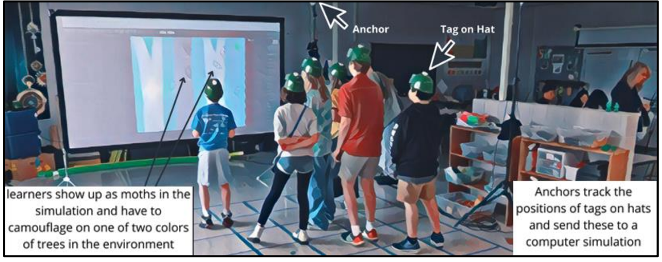
Perspective taking within modeling

The embodied or syntonic connection that learners make with computational agents can support them in leveraging new perspectives to explore ideas. Scholars use viewpoints to delineate learners' perspectives: agent perspective (i.e., ground-level, or first-person agent) focus on individual contribution to the system; global perspective (i.e., top-level, or aggregated observer, with a third person or bird's eye viewpoint) focus on how the broader system-view affects the individual. Although it is a hard process to move between agent and global perspectives, moving between perspectives supports deeper and more complex reasoning (Lindgren & DeLiema, 2022).These benefits are further extended in embodied contexts. When the physical and symbolic worlds blend, it creates an in-between space where learners can reason about ideas and experiences, described as liminal blend. Such liminal blends help to concretize abstract concepts through perspective taking (Enyedy et al., 2015).

Methods

This study focuses on a group of 6 learners (1 Female & 5 Males), in a fifth-grade classroom in a southern middle school during 3 days (90 minutes) of a 9 day intervention. The curriculum leveraged the anchoring phenomenon of peppered moths to explore camouflage and adaptation. We focus on an activity that aimed to enhance students' CT, and specifically algorithmic design. This GEM-STEP model allows learners to control virtual moths by moving around the room, using tracking tags. The color of each moth was unknown to the group. The goal was to camouflage by matching their moth's color to one-of-two tree colors within 30 seconds (see figure 1). A match-meter goes up if a learner stands on the right color of a tree, and down if the learner moves elsewhere. The CT goal of the model was to develop a strategy for a Binary Matching problem through an embodied solution. Finally, as a group activity, this activity required students to collaborate to successfully design and enact the algorithm in the model. After the group participated in the embodied activity, we asked them to develop a strategy for a new group to be successful. The goal was to help learners shift from being agents in the model to taking a global perspective to make sense of and explicate the mechanism of the algorithm. To support learners, we asked series of questions: 1) ‘What are the different situations you could be in? What is your position? What are the different actions that you can take?’, 2) ‘When you played, how did you decide what to do?’ and 3) ’How would you explain to another group how they should act in this activity?’ (Zipitría, 2018). The learners created a paper-based artifact to represent their strategy. After completing their own artifact, the group tried another group’s strategy.

Figure 1
Group activity in the GEM-STEP mixed-reality system



In prior work (Ayalon et al., 2023), we identified the development of algorithmic solutions by comparing the learners’ movement in the environment before and after a discourse on their strategy. Here, we focus on the hands-on activity designed to support the development of algorithmic thinking. Specifically, we examine the ways that students extend their embodied experiences through perspective taking as they negotiate and create an algorithm. Using Interaction Analysis (Jordan & Henderson, 1995), we developed a coding scheme (see table 1) to identify the perspective taken: Agent, Global and a novel perspective which we called *blended perspective*. The coding scheme considers ways in which learners may be taking perspectives both verbally and through gestures. When learners used the pronounce “I” to describe individual strategy or “you” to describe a single other, we coded it as an agent perspective. When learners used the pronounce “it” or “YOU” to describe a plural other or a generic moth, we codded it as a global perspective. We coded for a blended perspective when learners expressed ideas that leveraged both agent and global perspectives together. Specifically, when the following three events occurred: (1) talking about individual and group strategy in the same sentence, (2) talking about one moth while using hand gestures to refer to the entire system and, (3) switching the use of the word “You” & “YOU”.

Table 1
Framework of discourse analysis about perspectives’ indications (color coding for table 2)

Agent Perspective	Global Perspective	Blended Perspective
Individual strategy	Group strategy	Both individual and group strategy
One particular moth	All moths	Agent perspective dialog combined with Global perspective hand gestures
Limited, first-person view	Top down, bird's eye view	
"I" & "You"	A generic moth ("It" & "YOU")	"You" & “YOU”

While pronouns alone are not inconclusive evidence for perspective taking, triangulated with additional verbal and interactional cues they provide reliable indicators of a given perspective. Nevertheless, we acknowledge the limitations of this approach that integrates these observations with learner gesture, content of speech, and patterns of engagement.

Findings

The perspectives are expressed in three phases: the first round of the model, during the hands-on activity, and last round of the model. Below, we provide an overview of the learning trajectory while uncovering the perspective taking that occurred during the hands-on activity, focusing on blended perspectives in algorithmic design. During the hands-on activity, the facilitator prompted a discussion, asking learners to consider the different positions they may take in the model. The learners had a gradual shift in perspective taking, as learners first shared perspectives across agent and global perspective then began to blend these as the strategy was concretized. Ahead (see transcript in table 2), we explore how this blended perspective emerged in three ways.

Table 2

Transcript of group discussion between learners guided by the facilitator.

	All pseudonyms were selected by the learners, see color coding in table 1		
1	**Swaggy Muffin (SM):** Yes it's the way you can successfully do this, look at it, right?	12	**SM:** Two on each tree
2	**Crazy Wolf Love Pizza (CWLP):** Look at the match-meter is it right? Are you a match? Yes.	13	**PX:** Yeah, you're just two on each tree
3	**Facilitator:** But you have six moths that you need to look at, [at] the same time as the match-	14	**SM:** You're just look and see if you//
4	meter, how can you do it?	15	**PX:** //Faster in a//
5	**Luke (L):** You can do it like- you can do it like one or like two at a time maybe and go on a tree	16	**L:** //If you think about it, if all going on a tree//
6	and see if two matches go up.	17	**SM:** //It might be a bit faster, it's all
7	**Facilitator:** Okay, so you go, [by what] you suggest. Before PX suggested one by one	18	**L:** //Going on a tree it would be confusing. //
8	and you suggest[ed] let's do it two by two.	19	**PX:** If we go on one tree//
9	**L:** Like the whole group	20	**SM:** //How about//
10	**ProfessorX (PX):** Or three	21	**L:** //And then it would be confusing on what's not the match. Yeah.
11	**L:** Like the whole group? Like two on each tree		

First, as learners began to discuss their strategy efficiency, they would shift between expressing ideas on the individual and group strategy. For example, in line 2 of the transcript, CWLP says "Look at the match-meter is it right?" expressing a blended perspective when he refers both to another learner's ("Look") while talking about a generic moth in a global perspective ("it"). Another example are lines 16-18. In line 16, L is explaining what will happen "if all [group] going on a tree" (global perspective). He expresses a group level strategy when SM adds to it (line 17), expressing that "it might be a bit faster" to send multiple moths to trees than their strategy so far. L shifts back into the agent perspective when in line 18 he suggests that going all at once might be a bit confusing, reflecting that he is embodying the individual moth in the strategy. In both examples, the learners shifted between agent and global perspectives to balance goals of efficiency with simplicity in agent rules.

Figure 2

On left, hand gestures used during the group discussion expressed in lines 3-4 of Table 2. On right, hand gestures used during the group discussion expressed in lines 13-14 of Table 2.

Second, we observed that both learners and the facilitator expressed first person perspective in their speech while expressing global perspective in their gestures (i.e. motioning with their hands to create the borders of trees). In one example, PX and SM explore together the idea that learners could walk in pairs to discover matches more efficiently (lines 12-15). In the brief interaction, SM first repeats a suggestion made by another student "two on each tree", without use of pronouns which suggests a more global perspective. PX contributes by agreeing and repeating the idea but adding "you're", which centers the learner using an agent perspective (line 13). Adding to PX's statement, SM then begins to describe, from an agent perspective, what two moths at a time would physically do in the model (looking at the match-meter), "you're just look and see if you". As they both use the agent perspective to explain the strategy, they gesture with their hands, indicating trees in the model and the match-meter (see figure 2). From this shared communication and set of gestures, PX determines that this strategy is "faster" than if they go one by one (line 15, 19). In this example, learners used their embodied experiences and an agent perspective to make sense of a global strategy, which they expressed through gesture.

We observed a third expression of blended perspective, when the learners used the word "you" while discussing strategies (lines 1-5, 7-8, 13-14, 16). The conversation shifted frequently between you as one moth or a player to YOU as the group or a general moth, reflecting a potential comfort between the shifts in agent to global perspectives. Moreover, "you" (you & YOU) was often a bridging pronoun that was used by students to shift between perspectives. For example, CWLP refers to both agent and global perspectives of 'you' as a moth by asking "are you a match?". While asking another learner to identify their state, his word choice of "a match" indicates a bird's eye view of the model; rather than 'are you matching', he asks the learners to attend to the match-meter. Throughout the discussion, learners continued to center themselves within the strategy and the designed algorithms, even while attending to global perspectives or outcomes of the system.

Discussion & conclusion

In the study, we explore the impact of multi perspective-taking, using embodied activities, to enhance the development of algorithmic approach in the scientific context. The activity supported learners to switch from an agent perspective when they played in the mixed reality embodied simulation, into a global perspective, when we invited them to think of a strategy. The expected behavior could have been that the students will switch from agent to global perspective or maybe switch back and forth, However, analyzing their interaction revealed that the students were able to hold both agent and global perspectives **at the same time** and created a blended perspective. We argue that the embodied activity helped to concretize the abstract components of the activity and allowed a glimpse inside the algorithm. Moreover, a significant aspect of their learning was due to the invitation to think globally about the group's strategy, and the creation of *blended perspective*.

We suggest that this coordinated embodied activity while changing between agent and global perspectives has the potential to improve the efficiency of learners' algorithms and support abstract concept-learning by concretizing them. The use of the body improves performance by taking a blended perspective, a space where learners can act simultaneously as a group and as individuals. We suggest that further research is needed on methods to design activities that encourage the blended perspective. In addition, another aspect of future work should test learners' algorithmic thinking assimilation over time.

Abstract: We explored how Natural Language Processing (NLP) adaptive dialogs that are designed following Knowledge Integration (KI) pedagogy elicit rich student ideas about thermodynamics and contribute to productive revision. We analyzed how 619 6-8th graders interacted with two rounds of adaptive dialog on an end-of-year inventory. The adaptive dialog significantly improved students' KI levels. Their revised explanations are more integrated across all grades, genders, and prior thermodynamics experiences. The dialog elicited many additional ideas, including normative ideas and vague reasoning. In the first round, students refined their explanation to focus on their normative ideas. In the second round they began to elaborate their reasoning and add new normative ideas. Students added more mechanistic ideas about conductivity, equilibrium, and the distinction between how an object feels and its temperature after the dialog. Thus, adaptive dialogs are a promising tool for scaffolding science sense-making.

Introduction

Students develop everyday ideas about heat and temperature. Instruction can help them connect their normative and mechanistic ideas to gain coherent understanding (diSessa, 1988). During instruction, students distinguish between heat and temperature; explain when and why materials feel hot or cold; connect how materials feel to their measured temperature; sort out heat flow from cold flow, and grapple with the process of thermal equilibrium (Donnelly et al., 2015; Lewis & Linn, 1994). They can form powerful explanations while distinguishing among everyday ideas (Sandoval & Millwood, 2005). We draw on Knowledge Integration (KI) pedagogy to support the process of eliciting student explanations, encouraging students to discover additional ideas, guiding students to use evidence to distinguish among their ideas, and asking students to reformulate links among their ideas (Linn & Eylon, 2011). We studied how an adaptive dialog (Fig. 1) based on an idea detection model informed by Natural Language Processing (NLP) facilitated student ability to make productive revisions of their explanations of thermodynamics. We build on prior research demonstrating ways to promote productive revision with NLP tools (Gerard & Linn, 2022). In this paper, we investigate: How do two rounds of adaptive guidance support students' science learning? How do students from different grades, gender, and prior thermodynamic experiences respond to the adaptive dialog?

Methods

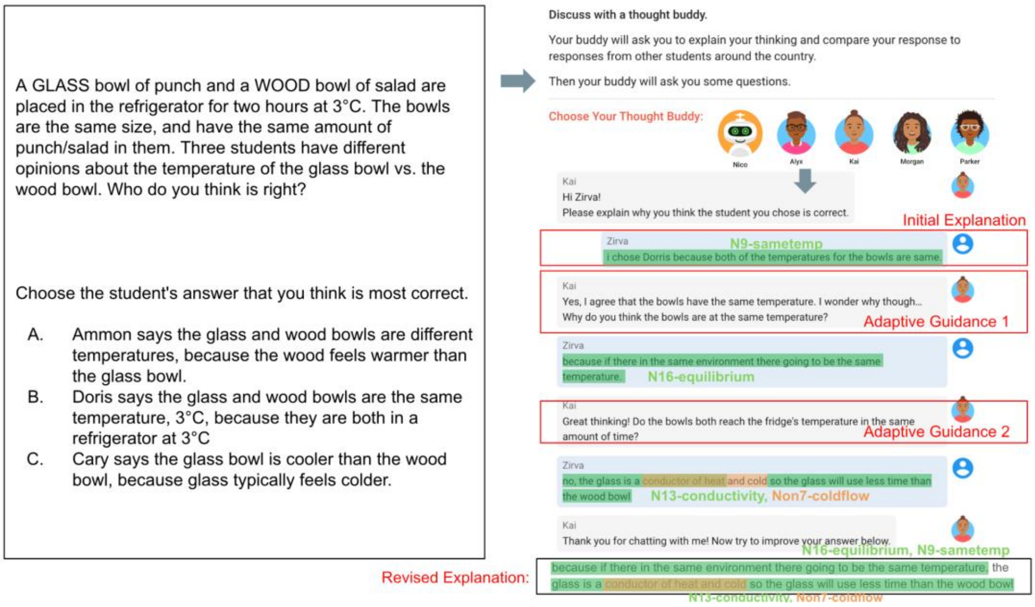
Participants

The 619 middle school students (72 6th graders, 323 7th graders, 224 8th graders) were taught by 11 teachers from 4 public schools. Among the students, 42.97% were female-identifying, 48.95% were male-identifying, 2.10% were non-binary, 5.98% preferred not to answer. Overall, 55.6% were monolingual English speakers and 49.1% had parents who speak another language at home. The idea detection NLP models were trained on student written explanations in English from a sample with similar demographics.

Adaptive guidance design

We embedded the NLP adaptive dialog in an end-of-year inventory using an open-source Web-based Inquiry Science Environment (WISE). The inventory elicits explanations for topics students studied during the year. We designed the dialog to promote productive revision of the initial responses. We report on the revisions students made to the *Bowls In A Fridge* item about thermodynamics (Figure 1). Students first select the answer they think is most correct, then engage in a dialog with a virtual *thought buddy*.

Figure 1
Example adaptive dialog with idea detection NLP model (detected ideas shown: e.g. N9-sametemp =normative idea 9-two bowls at same temperature, Non7-coldflow=non-normative idea 7-absorb coldness.)



A GLASS bowl of punch and a WOOD bowl of salad are placed in the refrigerator for two hours at 3°C. The bowls are the same size, and have the same amount of punch/salad in them. Three students have different opinions about the temperature of the glass bowl vs. the wood bowl. Who do you think is right?

Choose the student's answer that you think is most correct.

A. Ammon says the glass and wood bowls are different temperatures, because the wood feels warmer than the glass bowl.
B. Doris says the glass and wood bowls are the same temperature, 3°C, because they are both in a refrigerator at 3°C
C. Cary says the glass bowl is cooler than the wood bowl, because glass typically feels colder.

Discuss with a thought buddy.

Your buddy will ask you to explain your thinking and compare your response to responses from other students around the country.

Then your buddy will ask you some questions.

Choose Your Thought Buddy:

Kai
Hi Zirva!
Please explain why you think the student you chose is correct.

Initial Explanation

Zirva
i chose Dorris because both of the temperatures for the bowls are same.

N9-sametemp

Kai
Yes, I agree that the bowls have the same temperature. I wonder why though...
Why do you think the bowls are at the same temperature?

Adaptive Guidance 1

Zirva
because if there in the same environment there going to be the same temperature.

N16-equilibrium

Kai
Great thinking! Do the bowls both reach the fridge's temperature in the same amount of time?

Adaptive Guidance 2

Zirva
no, the glass is a conductor of heat and cold so the glass will use less time than the wood bowl

N13-conductivity, Non7-coldflow

Kai
Thank you for chatting with me! Now try to improve your answer below.

N16-equilibrium, N9-sametemp

Revised Explanation: because if there in the same environment there going to be the same temperature. the glass is a conductor of heat and cold so the glass will use less time than the wood bowl

N13-conductivity, Non7-coldflow

NLP Idea detection model and KI scoring model

For idea detection, we developed and applied an NLP model using a *token classification* approach (Riordan et al., 2020). For KI scores, we updated a validated NLP model for the initial and final explanations (Liu et al., 2016). KI scores reward students for linking ideas and evidence, in this case, linking their science knowledge about thermodynamics in explanations of complex situations. There are 5 levels of KI scores, the higher the KI score is, the better that students can integrate and link their science knowledge. To develop both of the NLP models we collected over 1000 student responses to the target question, in prior research, from five schools. To update the KI model, two researchers reached inter-rater reliability above Cohen's Kappa 0.85, and then scored the remaining items. To build the idea detection model, researchers collaboratively scored and labeled ideas until they achieved inter-rater reliability above Cohen's Kappa 0.85. The researchers identified 14 distinct ideas expressed by students in their explanations, including normative, non-normative and vague claims and reasonings. The *multi-label* idea detection model achieved an overall micro-averaged F-score of 0.68. When the rule-based adaptive guidance detected multiple ideas in a student explanation, it was tailored to encourage the student to elaborate their reasoning for one of them. In order to honor the students' reasoning and evidence, we prioritized the ideas as the following sequences: 1) non-normative reasoning; 2) vague reasoning ideas; 3) normative reasoning; 4) normative claims; 5) non-normative claims. The resulting labeled dataset was used to train separate idea detection and KI scoring NLP models.

Data analysis

We chose Cumulative Link Mixed Models (CLMM) to analyze KI scores because students are measured repeatedly before and after the dialog and our KI scores are not normally distributed. We modeled four factors: Dialog effect (initial explanation before dialog, revised explanation after dialog), gender (Female, male, non-binary, prefer not to answer), grade (6, 7, 8), and prior experience with the thermodynamic WISE unit (Yes, No). We chose to include prior experience with the Thermo WISE unit because the unit features simulations aligned with our inventory item. We did not test the interaction between grade level and the WISE unit because only grade 6 and 7 students had the opportunity to study the Thermo WISE unit. We used Generalized Estimating Equations (GEE) with Poisson regression with repeated measures for the idea counts. We used GEE with binomial regression with repeated measures for each single idea.

Results

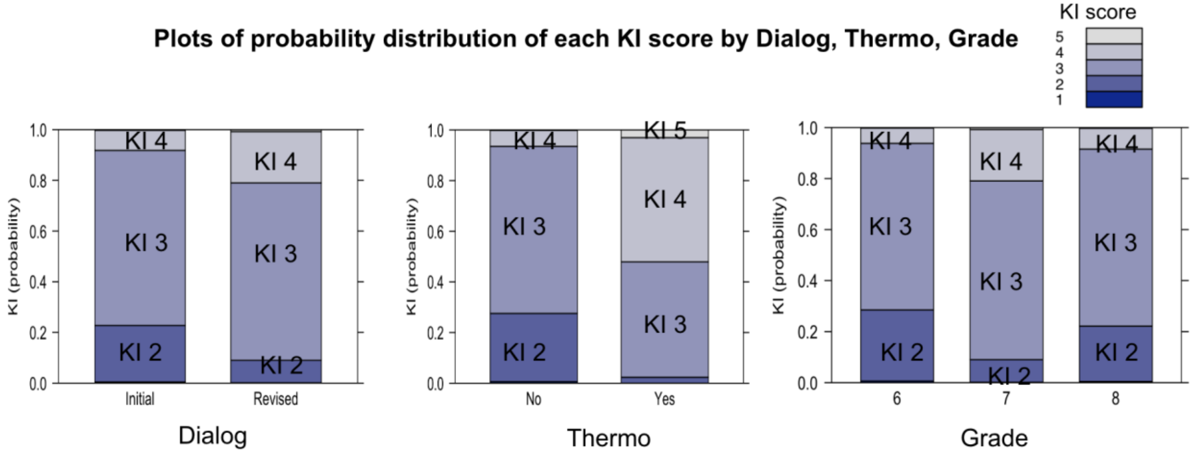
1. Do students integrate their ideas as measured by their KI scores?

Students' revised explanations (M=3.15, SD=0.97) were more integrated than their initial explanations (M=2.85, SD=0.98) across all grades, genders, and students' previous unit experiences. For 6th and 7th graders, students who had studied the unit (M_{6Y}=3.31, SD_{6Y}=1.02; M_{7Y}=3.64, SD_{7Y}=0.99) achieved higher KI scores than those who had not (M_{6N}=2.25, SD_{6}=0.46; M_{7N}=2.94, SD_{7N}=0.89). In a related study of this corpus, students from monolingual and multilingual backgrounds made similar KI gains (Holtmann et al., 2023).

Using CLMM, we found that NLP dialog, grade, and prior Thermo unit experience all have significant impacts on the model fit (AIC=2969, p<.001). After controlling other variables, for the dialog, students have higher predicted cumulative probability of revised KI scores compared to their initial scores (β=1.09, p<.0001, Fig. 2, Dialog). This means that students are more likely to link normative, relevant ideas after they received the NLP adaptive guidance. After controlling for other variables, students who studied the Thermo WISE unit before received higher cumulative KI scores than students who did not (β=2.76, p<.0001, Fig. 2, Thermo). After controlling for other variables, Grade 7 students had higher cumulative KI scores after the dialog compared to Grade 6 (β=1.39, p<.01, Fig. 2, Grade). The differences between grade 7 and 8, and 6 and 8 are not significant.

Figure 2

The probability distribution of each KI score by dialog, Thermo WISE unit experience, and grades



2. How does the NLP dialog elicit ideas?

2.1 Total number of ideas elicited

Using GEE, we found that students are 1.2 times more likely to express more ideas for their revised explanations than for their initial explanations (Wald=30.21, p<.001). Students expressed more normative ideas (Wald=19.22, p<.001), and more vague ideas (Wald=7.35, p<.01) at their revised explanation. Revised explanations had slightly and not significantly fewer non-normative ideas. Adding gender, prior thermo experience, and grade into our model, we found that students who studied the Thermo WISE unit expressed significantly more ideas (Wald=33.19, p<.001), more normative ideas (Wald=7.31, p<.01) and fewer non-normative ideas (Wald=5.85, p=0.016) than those who did not study the unit. 7th graders expressed more ideas (Wald=13.24, p<.001) and more normative ideas (Wald=6.15, p=0.013) than 6th and 8th graders. Since thermodynamics is often taught in 6th grade, our 7th graders have the most recent experience. Female students expressed more ideas (Wald=34.62, p<.001, Cohen's d = 0.1), especially more vague (Wald=20.67, p<.001, Cohen's d = 0.29) and non-normative ideas (Wald=15.59, p<.001, Cohen's d = 0.19) than male students. The effect sizes of these idea differences are small, and the KI score for gender is not significantly different. This aligns with the previous research showing that women compared to men, have slightly better performance on verbal tasks (Hyde & Linn, 1988) and that differences between genders in science are small and declining (Linn & Hyde, 1989).

2.2 Integrating individual ideas

The ideas that students integrated, after controlling other variables, include conductivity (92% more likely; Wald=26.63, p<.001), "feeling is not the actual temperature" (60% more likely; Wald=5.27, p=0.022), and equilibrium (37% more likely; Wald=4.52, p=0.034). The changes in other ideas were not significant. 7th and 8th graders were more likely to add conductivity compared to 6th graders ($Wald_7$=18.75, $Wald_8$=12.62, p<.001). Students who studied the Thermo WISE unit compared to those who did not, were more likely to add conductivity (Wald=24.06, p<.001) and equilibrium ideas (Wald=36.16, p<.001). Among the three significantly integrated ideas, based on the odds ratios in the GEE model, the conductivity idea is most likely to appear when students revise their ideas, followed by the "feeling is not the actual temperature" and equilibrium idea. The equilibrium idea is the least likely to emerge during the dialog and without instruction, consistent with its complexity for middle school students (Lewis & Linn, 1994).

3. How do two rounds of adaptive guidance work?

Two rounds of adaptive guidance helped students distinguish their ideas from everyday observations and to continue adding mechanistic ideas to explain thermodynamics. In the first round, 56.06% of the students dropped vague and non-normative ideas; 31.99% added new normative ideas and 38.77% of students added another normative idea to their previous response. For specific guidance, compared to prompts that ask broad and general questions, we found that prompts that ask students to explain specific mechanisms work well. For instance, students' explanations are 41.24% irrelevant vague ideas for the prompt to idea *Non3-onebowlcolder* ("*I see, you're saying the bowls have different temperatures. What affects the temperature of the bowls in the fridge?*"). They either have very broad associations like "Refrigerators cool the bowls through evaporation", or have a vague and general answer like "fridge/bowls/the stuff inside", or have responses like "idk what you're talking about". In contrast, 31.67% of students expressed N13-conductivity evidence after they received a prompt to idea *V6-bowlmaterial* ("*Yes, wood and glass are very different materials! Thinking about heat energy, what are glass and wood good or bad at doing with heat energy?*").

Conclusion

Consistent with the KI pedagogy, this study illustrates that students have more ideas than they initially express and that when they are supported to follow the KI process with adaptive dialogs, they form more coherent and sophisticated explanations. Specifically, this study shows that the NLP adaptive dialog can elicit a significant number of ideas including normative ideas without further instruction. Further, the NLP dialog can help students revise explanations to achieve a higher KI score. This holds across 6th, 7th, and 8th graders whether they have prior thermodynamics WISE experience or not. Using the KI pedagogy to design the adaptive dialog facilitated this progress (Gerard & Linn, 2022). Rather than correcting students, the adaptive dialog supported them to analyze their own reasoning and the evidence underlying their perspective. This spurred many students to sort out their ideas and engage in refining their explanations. Next steps include continuing to partner with teachers to refine the dialog so that it focuses students on identifying evidence they need to sort out their ideas in adaptive dialogs and with peers.

“For the First Time in a Long Time, …”: Teachers’ Transformative Agency During the Creation of a Professional Community

Yeliz Günal Aggül, Boğaziçi University, yeliz.gunal@boun.edu.tr
Diler Öner, Boğaziçi University, diler.oner@boun.edu.tr

Abstract: The goal of this study is to support a group of mathematics teachers in creating their professional community under a non-profit organization in Turkey and to examine how teachers exercise collective transformative agency in this community-building process as they engage in mediating tools and activities. Analysis of the data collected during this ongoing project reveals that when teachers are provided with mediating tools, activity structures, and discursive practices that provide enough space, time, and support to face the contradictions in their activity system, they begin to see their power to transform their practices and the system in a positive way. This becomes the first step in designing a sustainable community by teachers.

Introduction and purpose

Teacher communities have long been recognized for their value as learning environments in which teachers can seek professional learning in agentic ways and develop collective solutions for their problems of practice (Palincsar et al., 1998). On the other hand, research on teacher communities has revealed that these communities are not effective by itself and that opportunities to learn in teacher communities vary according to the conceptual resources teachers draw on and a shared sense of what is possible (Horn & Kane, 2015). In this study, we argue that in order to support teacher communities to expand the opportunities to learn in them and also ensure their sustainability, different from the mainstream focus on the development of knowledge and skills in teacher education designs, teachers’ agency should be the ultimate learning goal (Haapasaari & Kerosuo, 2015).

This ongoing study follows the participatory design research (PDR) paradigm in Learning Sciences to support a group of mathematics teachers in designing their professional community under a non-profit organization in Turkey called Teachers’ Network, which promotes teacher empowerment by supporting teacher solidarity in communities. The method of formative interventions (Engeström, 2016) is put into practice, and how participants exercise agency while designing their community through this intervention is examined. As a specific form of PDR, formative interventions include mechanisms to support practitioners’ collective agency in both facing the paralyzing disturbances in their activity system and designing and implementing novel solutions (Engeström, 2016). In line with this, in this study, community building is interpreted as a problem-solving process in which the activity model of the community is designed as a solution to teachers’ common problems of practice.

Theoretical framework and research question

The method of formative interventions is organized based on the steps in the expansive learning cycle (Engeström, 2016) and the methodological tools that Vygotsky (1997) employed in his double-stimulation experiments. In formative interventions, it is expected that expansive learning would emerge in a cyclical manner through specific epistemic or learning actions (Engeström, 2016). The expansive learning process is mediated by two types of artifacts: the “first stimulus,” which helps practitioners face the contradictions in their activity, and the “second stimulus,” which is put into action to design a novel solution (Engeström, 2016). Transformative agency is considered the main learning outcome, which “goes beyond the individual as it seeks possibilities for collective change efforts” (Haapasaari et al., 2016, p. 33). Through analyzing conversational data, Haapasaari et al. (2016) came up with six types of discursive manifestations of transformative agency in a formative intervention. These are: *resisting* the change, new suggestions or initiatives; *criticizing* the current activity in a change-oriented way to identify the problems; *explicating* new possibilities or potentials in the activity relating to past-positive experiences; *envisioning* new patterns or models in the activity; *committing to taking actions* and *taking consequential actions* to change the activity.

Unlike conventional applications of formative interventions, in which practitioners from the same organization collectively transform their work practices, in this study, we used this method to support a group of experienced teachers working in different schools, levels, and cities in Turkey to design their community model under the Teachers’ Network. The activity system that these teachers share is the mathematics education system in Turkey, which is highly centralized with a Ministry of Education, a common curriculum, and high-stakes testing for high school and university enrollments. Within the boundaries of this project, the transformation in this activity system is interpreted as follows: the collective activity model that participants design will offer a local solution for the identified contradictions in the system, which prevent the country’s mathematics teachers from improving their practices and solving their crises in their classrooms. This local solution, produced by the participants and concretized as the community's activity model, will be generalizable in the sense that it will have the potential to spread among other teachers in or outside the network in similar or hybridized forms (Engeström, 2009).

The overarching research question of this study is "How does a group of teachers who teach at different schools design their professional community during a formative intervention?" This paper answers the following sub-research questions specific to the first phase of the study: 1. How did the mediating tools and activities support teachers in identifying the common contradictions in their activity system? 2. What types of expressions of transformative agency emerged as teachers exercised expansive learning actions?

Data sources and analysis

Because of this study's interest in discursive expressions of transformative agency expressed in practitioners' conversations and written artifacts, this paper primarily draws on video recordings of eight online or hybrid community meetings that lasted between 129 and 172 minutes, artifacts (reflection papers, the "our problems" map) produced by the participants, and post-first phase interviews that mainly aimed to understand teachers' experiences with the first phase of the intervention. For analysis of the meetings, we have focused on topical interaction episodes to identify the collective achievement of transformative agency during conversations and speaking turns within them. The data were analyzed against the above-mentioned theoretical framework following the abductive analysis approach (Timmermans & Tavory, 2012). The selected quotes were translated from Turkish to English by the authors. Pseudonyms for all participant names have been given.

Findings

Two transformative agency expressions —criticizing and envisioning— have been identified from the analysis of the data collected during the first phase of the study, which aimed to support teachers in identifying the contradictions in their activity system that gave rise to paralyzing disturbances in their activity system (Engeström, 2016).

Achieving change-oriented criticism: "As we researched the causes, causes of the causes, …"

In Turkey, the centralized exam system is mostly seen as the fundamental problem that keeps teachers from creating meaningful and engaging learning environments for their students. This is because, in this eliminative system, the common belief is that students should do a lot of math exercises instead of getting deeper into the mathematical ideas at a slower pace to be successful at the exams. Teachers mostly believe that it is their responsibility to "show and tell" how to solve a variety of problem types that may be asked in these exams. Even though teachers are eager to make their classrooms more engaging for their students by designing and implementing alternative activities, they cannot sustain such classroom environments. This dilemma makes them feel paralyzed since the examination system is a major systemic problem that they are not able to overcome. On the other hand, this dominant discourse hides other structural and cultural problems that are obstacles, but that teachers can produce solutions for if they face them. In this study, as teachers engaged with tools and activities to identify their common contradictions, they collectively achieved change-oriented criticism by seeing alternative explanations for their dilemmas, which paved the way for them to "break away from the given frame of action and take the initiative to transform it" (Virkunnen, 2006, p. 49).

In the first meeting of the community, we discussed teachers' problems through the question, *"What do you think about the problems of mathematics teachers in Turkey?" "What are the obstacles that prevent teachers from teaching in a way that they idealize?" "Under which conditions do you feel yourself in a double bind?"* This discussion has been analyzed and transformed into an interactive map by the first author, utilizing a dynamic collaborative working space that has been revised and worked on by community members at different stages of the phase. Participant teachers mentioned various problems that prevent them from performing their ideal practice; however, centralized exams dominated the discussion. For that reason, "centralized exam system" was located as a major title in this map, which was named "Our Problems Map." Throughout the following four sessions, to trigger teachers' questioning action, the book *The Teaching Gap* (Stigler & Hiebert, 1999), which compares mathematics teaching practices in three countries (Germany, Japan, and the USA), and the accompanying lesson videos provided the first stimuli. The community read the book part by part, wrote reflection papers, and discussed it along with various activities that helped them identify their common problems. In the eighth session of the first phase, which included the discussion on the short clips of previous sessions to clarify the problem situations, the community was invited to reconsider the "centralized exam system" title on the "Our Problems Map" based on a prominent finding of this analysis: neither their reflection papers nor their session discussions talked about centralized exam systems different from the first meeting of the community. The first author (YGA), who conducted the sessions, initiated the discussion by saying:

> YGA: When I watched six sessions… -the book may not have led us to discuss the exam- but while we were discussing the book, we continued to discuss our own problems and questions, and the exam was almost never pronounced. What do you think when you re-evaluate it - should it continue to be a main topic [on the map]?

Defne responded to this conversation, and other community members continued it. The following collective discussion represents how transformative agency was achieved in the community and how mediating tools and processes supported teachers in developing an alternative perspective for their problems of practice.

> Defne: During this process, I realized that, yes, this [centralized exam] is one of our problems; but that's not the problem we should have taken on in the first place. The problem we need to take first is the teaching method. How are we going to teach this [mathematics]? How should mathematics be taught? I think we have to move forward beginning here…

> Açelya: When we started this process, it was a period when the stress and pressure of LGS [High-school enrollment exam] were felt very intensely by teachers in every school, and naturally… we thought of this as the primary problem situation, but then we read, thought about, and discussed... As we researched the causes and causes of the causes and examined them, we concluded that the real problem is not the exam but the mathematics teaching or the curriculum/framework.

> Yonca: I think in a similar way as Defne and Açelya. At first, I thought that the exam system was a very big problem, but as time went on and our studies increased, I saw that there was actually a serious problem in mathematics teaching … and here the exam system turned into a very, very small building block of this big picture for me…

> Lale: I thought we could relate the exam system there as a sub-title as the [systemic] problems under the Ministry of Education... It is no longer a situation that directly affects our practice in the classroom, at least after understanding the book. It seemed to me that it could turn into something that we can solve by ensuring [students'] deeper learning. For example, as my colleague Yaprak said, everyone thought it was the exam system at the beginning; it seemed like a big problem, but as I read it, I had started thinking in the same way. You know, the exam system is a small part of it; actually, the thought has settled [in the community].

As a result, the community decided to include the "centralized exam system" as a sub-problem category on their map. Seeing centralized exams as the most prominent systemic problem was preventing teachers in the community from proposing any meaningful solutions to the crises they were experiencing in their practices and in the system, making them feel powerless. *The community identified many aspects of their cultural codes regarding "mathematics teaching and learning" and the lack of a robust curriculum to transform these codes as the fundamental problem, which changed their perception of what is possible, supported their transition to the possibility discourse, and expanded their collective zone of proximal development* (Engeström, 2007; Horn & Kane, 2015).

Envisioning: "For the first time in a long time, I can think of so-called extreme ideas."

As teachers broadened their perspectives about the problems of the current mathematics education activity system that prevent them from improving their practice and making mathematics classrooms more engaging, they started to see their power in controlling their teaching practice, and the community started to have a different function for them: a place that guides and informs their imagination (Cole, 2019), a place where they can realize their dreams. Another transformative agency indicator, envisioning, emerged in the community as the intervention opened a space for them to be the "designers of their own futures" (Gutiérrez et al., 2016, p. 276) and supported them during the process of expansive learning as the community and researchers were learning *what was not yet there* (Engeström, 2016, p. 9).

During the post-first phase individual interviews, the first author asked questions to help teachers reflect on their experiences throughout the first phase. Defne answered the question, "Do you think there was room for your opinions and contribution in this study?" by stating that this study accomplished more than that:

> Definitely… I keep coming up with ideas, ideas, ideas, and maybe, you know, extreme ideas... For the first time in a long time, I can think of ideas you can call crazy … I think it [the study] is a catalyst that reopens my imagination or my creativity. This made me extremely happy... I reproached the environment and society, "How, how did they kill my creativity?" But it's nice … to be able to say, "Yes, I can do those so-called crazy ideas here, and from here [the community], I can get support, we can feed each other, and we can do it together."… It feels safe to be able to think about it. (Defne, post-first phase individual interview)

She continued sharing her reasons that she started to dream again with the community: *the quality of the things we were doing in the process made her think this way, which was not the case at the beginning; some decisions that the community made nourished her dreams.* The decisions that Defne referred to were those the community made at the end of the first phase as actions that the community could take to understand the roots of teachers' common problems and to design local solutions. Some of the ideas that emerged during this meeting were these: they could contact people who were in charge of the mathematics curriculum development and ask their questions; design the community's principles and orienting framework for teaching by reading scientific resources; model, implement, and disseminate a collective instructional design activity that could support the development of a teaching culture among mathematics teachers in the country. These decisions could be made by the researcher as "design elements" of a professional development program as a response to the teachers' needs that researchers determined at the beginning of the process. However, this would not support the collaborative design of a sustainable community model that teachers own and in which they could pursue their professional learning in agentic ways.

Conclusion and significance

This study reveals that when teachers are provided with appropriate mediating tools that help them question their practices and with activities and discursive practices that provide enough space, time, and support to face and analyze the contradictions in their activity system, they develop alternative perspectives in understanding their transformative power in influencing their practices and the system. In this way, they develop their community together with its novel practices and its artifacts as a solution to these contradictions. We conclude that participatory design research is fundamental so that practitioners experience transformative agency and a door for a sustainable community is opened.

Diaries and Digital Artifacts: Investigating Teens' Daily Experiences Through User-Shared Images

Vanessa P. Dennen, Florida State University, vdennen@fsu.edu
Lauren M. Bagdy, University of Georgia, lauren.bagdy@uga.edu
Stacey A. Rutledge, Florida State University, sarutledge@fsu.edu

Abstract: This study explores the effectiveness of collecting digital artifacts from teens, specifically photographs and screenshots of their daily lives, to help better understand their online and offline experiences. When debriefed in interviews, these user-shared images led to rich conversations about the teens' experiences. Participants alternately sought to document their activities or provide specific evidence they thought would interest researchers. This data collection approach holds promise for phenomenological and case study research, documenting learning events and experiences in settings and at times when a researcher's presence may not be feasible or welcome.

Introduction

As a researcher, it is not always possible to be present and directly observe a phenomenon, especially when that phenomenon occurs at unscheduled times or is naturalistically distributed across parts of life. For example, while much learning research is situated in formal class settings that researchers can access, many learning activities occur in other locations, including at home and in virtual spaces. It is not always feasible or even appropriate for researchers to be present and observe these activities directly. Experience sampling techniques are one way to capture moments *in situ*, documenting some aspect of a participant's life as it happens (Christensen et al., 2003) without the researcher needing to be present.

Teenagers are a population that can be challenging to research with authenticity. Social media and related online social spaces (e.g., networked gaming) provide teens with multi-purpose spaces for engaging in various activities. A recent Pew survey found that teenagers aged 13-17 most frequently listed connections/socialization and information/learning as their primary reasons for using social media (Anderson et al., 2022). Teenagers transition between online and offline life, and in and out of school settings in a fluid manner, with friendship and peer groups connected across contexts (Dennen et al., 2020; Rutledge et al., 2019). Adults may be present in these offline settings but are generally not welcome in or privy to activities in online environments.

Experience sampling has captured elements of the teenage experience in other studies. In particular, teens' experiences have been documented using brief surveys throughout the day, focusing on feelings and activities (Pouwels et al., 2021; Siebers et al., 2022). Other studies have used diaries to collect experience data, with video diaries preferred over text-based ones due to the relative ease of recording (Debbag & Fidan, 2020). Photographs are another option for documenting experiences, allowing researchers to see through the lens of a participant (Zirkel et al., 2015). In the era of smartphones and social media, screenshots also can capture an individual's experiences in the online world.

Purpose, research questions, and context

This exploratory study aims to investigate the effectiveness of user-shared images as a form of experience sampling, considering the value of this data collection approach for enhancing qualitative research methods such as phenomenology and case study. In both methods, interviews, and observations are expected forms of data collection, and together can be used for triangulation, strengthening a study's trustworthiness. Whereas interviews elicit stories, memories, and positions through the participant's lens, observations capture *in situ* events through the researcher's lens. However, in some research contexts, observations may not be practicable. For example, studying the online worlds of minor children can be fraught with practical and ethical issues (Dennen & Rutledge, 2018). Thus, we propose media diaries as a means of accessing direct glimpses of the participant's online (or offline) worlds, through their unique lens and with their full awareness. The research questions guiding this study are:

1. What was the volume and frequency of digital image sharing among participants?
2. How did the digital image diaries help answer the original study's research questions?
3. How did these digital image diaries enhance follow-up interviews?

Contextually, this study examines participant digital artifacts from a study about the intersection of teenagers' online, offline, and school lives (Dennen et al., 2021a, 2021b; Dennen et al., 2022). In this larger study, teenage participants were asked to document their experiences via photos and screenshots in a diary format. The study's research questions focused on digital school-based, informal, and incidental learning experiences during the first year of the COVID-19 pandemic when teenagers – a population already prone to heavy online activity levels – found themselves increasingly dependent on digital means of socialization and learning.

Method

Participants

The participants in this study are 29 teenagers who completed both years of a two-year study of their daily experiences and learning activities both on and offline. The researchers' Institutional Review Board approved the study. All participants provided consent if over 18 or assent along with parental consent if under 18. This paper focuses on data from Year 2 of the study, when the participants ranged in age from 13 to 19. There were 15 female and 14 male participants who completed the study in Year 2. Participants were offered an incentive in the form of a $100 gift card for each year they participated in the study.

Data collection and analysis

In the larger study, data collection during each year entailed participating in an initial interview of approximately 45-60 minutes, followed by a week of maintaining a video diary and a final semi-structured interview in which the diaries were debriefed. During Year 2, the focus of this study, a digital image component was added to the video diaries. Specifically, teens were asked to share up to three photos characterizing their day during each day of the video diary process. Participants were required to complete at least five diary entries during the week.

The daily diary procedure involved accessing a survey via a link. Participants were prompted via a daily text message. The diary survey began with a set of questions each day, including what social media tools they had used that day, what online activities they had engaged in, their happiness, and how much time they had spent on school activities, online, and with friends. These questions collected structured data across days and participants and helped cue participants' memories about relevant details of their days. After completing these questions, participants were prompted to upload photos and videos. Videos were shot selfie-style, with participants directly addressing the camera and recounting their day in 3-5 minutes.

Data analysis for the first research question involved inventorying and counting each participant's photo submissions. To address the second research question, we coded each image by type and content. Finally, to address the third research question, we explored four participants as brief cases. We selected the cases for the diversity of image type and content as well as the number of photos submitted.

Findings

Volume and frequency of photo sharing

All but one participant shared photos or other digital images as part of their diary submissions. That participant also did not record his own image on his video diaries, instead placing his phone on a table and simply recording audio. He was open and loquacious during interviews but reticent to share visuals. Across the other participants, contributions ranged from a low of 1 photo / 1 day (2 participants) to a high of 21 photos / 7 days (1 participant). The average number of photos per participant was 11, with female participants sharing more photos (mean=14) than male participants (mean=10).

Images as data source

Most participants shared a combination of original photographs and screenshots, each comprising close to 45% of the overall shared images. However, it is worth noting that although original photos and screenshots were shared with similar frequency, the proportion varied by participant. Additionally, 46% of the participants shared selfies, although – with one exception – selfies did not comprise the majority of a participant's photos. Topically, the photographs that participants shared were diverse in content. Many photos documented specific activities, such as submitting an assignment, working on homework, watching TV, or even getting a COVID vaccine. Screenshots similarly documented schoolwork, but also captured what the participants were searching for and seeing online. Screenshots documented hobby-related learning, current events (especially COVID and mask-related information), what the participants posted online, and things they found humorous. As a data source, the images gave the researchers an authentic look at what was otherwise merely described during interviews.

Shared images and follow-up interviews

During the second interview, participants were presented with a slide show of their images from the diaries and encouraged to discuss the content and the stories behind the images with the researcher. In many instances, the discussion of photos led to a deeper conversation about topics related to the photos, although this differed by interviewer. Some interviewers probed more than others, whereas others simply asked for a brief explanation of each image and then swiftly moved to the next. It also differed by participant. Unsurprisingly, participants who shared more images also had more to talk about across the images. Participants who shared fewer photos seemed less engaged overall and were more likely to report that they simply forgot to take photos. In this sense, however, taking more photos did not appear to be about actually having more going on in one's life, but rather having a stronger desire to engage in conversation about what was going on in one's life. Some participants were documentarians, photographing the places they visited and the things they ate during the week. During interviews the photos prompted stories, much like someone might share their vacation photos. Others appeared to seek out images to share with their interviewer specifically. For example, one participant mentioned to her interviewer in the first session that she felt bad when she spent too much time on TikTok and got the "TikTok stop guy" suggesting that she take a break. Her interviewer was unfamiliar, and she purposefully sought to capture a screenshot to share it during the second interview.

Case 1: Celine and a life lived offline

Celine, a 16-year-old girl, was not enamored of online life and indicated during interviews that she strongly preferred to just participate in activities in person and real time. Although she had a smartphone and social media accounts, she used them sparingly and mostly to support promoting her skills as an equestrian in the hopes of being noticed by a college scout. She spent substantial time riding and caring for her horse at the stables. As she documented her week, all 20 of the images she shared were photographs of locations she visited. In addition to photos of horses, she shared photos from her babysitting job and events she attended with her friends. Nowhere in her photos was anything that hinted at smartphones or social media.

Case 2: Charles, the aspiring filmmaker

Charles, a 16-year-old boy who wants to be a filmmaker, primarily shared Letterboxd screenshots. He spent substantial time on Letterboxd, writing film reviews and compiling lists of films. During the second interview, Charles indicated that he had purposefully created screenshots to show the interviewer specific examples of how he uses Letterboxd. He was eager to discuss these images during the interview.

Case 3: Cameron, a teen with a plan

Cameron, a 16-year-old boy, shared nine photos across multiple days. Collectively those photos told two stories. First were photos documenting a surprise birthday party he was throwing for his mother. He documented packages that arrived in the mail, tables being set up for the party, and getting his schoolwork done so he would have time to focus on the party. The latter photo, which included his computer screens, led to an in-depth discussion of how he has set up his school workspace for remote learning and what he does about school when there are Internet problems. Cameron's photos also documented his new hobby, creating t-shirts with heat-press designs. He had just received the heat press, which was shared in an unboxing photo, and shared screenshots documenting how he was using online videos to learn how to operate it.

Case 4: Briana and her online life

Briana, a 15-year-old girl, primarily shared screenshots from TikTok and Instagram. She was heavily interested in documenting things she saw online for later reference. For example, she captured Starbucks' secret menu, commenting that she is not allowed to have Starbucks during cheer season, but she saved it in her notes on her phone so she could remember it. She also shared a post of a giant knitting project, sharing that she was not actually doing it but would like to. She also shared memes and quotes because she found them funny and wanted the interview team to laugh as well. Each image that Briana shared led to a larger conversation that provided insights into her interests and her thoughts.

Discussion and conclusions

These findings show how experience sampling with digital images can effectively elicit data from participants, enhancing data collection for case study and phenomenological research approaches. Nestled between two interviews, a period of visual documentation encourages participants to share images that capture daily experiences and the phenomenon of interest to the researchers. In this study, participant-generated images allowed the researchers to see through the participants' eyes, prompting rich stories and conversation during an otherwise largely unstructured interview. In practical terms, the nearly ubiquitous nature of mobile phones makes experience sampling relatively easy to accomplish (Xie et al., 2019), and this study demonstrates how photos might be used to capture data instead of survey items. Although we did not prompt participants to take photos at specific times of day, mimicking the *BeReal* app, that is an alternate approach that could be taken.

This study shows how user-generated images help researchers see a phenomenon through the participants' eyes, which provides a valuable vantage point when studying all manner of learning. It was situated in the context of everyday life, with participants free to choose which activities they would (and would not) capture and share. Amid the mundane and special events that teens documented were images that captured moments of formal, informal, and incidental learning. This research approach could just as easily be used in a more structured context, encouraging learners to document learning processes during small group work or while doing homework.

It's a Little Frustrating, but Fun: Supporting Novice Programmers' Learning Through Unscaffolded Problem-Based Designs

Sagun Giri, Penn State University, sqg5512@psu.edu
Gabriela Richard, Penn State University, grichard@psu.edu

Abstract: Past efforts to teach novices programming through pair programming and project-based learning utilizing different "low floors, high ceilings and wide walls" platforms have been successful. Building from related work, we propose that Productive Failure-based learning designs can also be an effective approach to supporting youth and novices when learning programming and fundamental computational concepts. We report on findings from an online synchronous remote workshop, which occurred during the COVID-19 pandemic, and was designed to support participants in federal programs for low-income families. Participants engaged in code debugging without scaffolding followed by a consolidation phase. Findings show the effectiveness of PF design in application accuracy of some computational concepts however persistent struggles with complex concepts such as conditionals and operators. We identify the need to design structured support structures in PF designs to manage failures, improve problem-solving approaches and generate optimal solutions.

Background

Programming is a useful and necessary skill for a technology focused workforce. However, learning to program is a difficult task for novices. Novices face difficulties in understanding and applying fundamental programming concepts. They are plagued by recurring bugs, syntax errors and code smells (Fraser, 2021). Novices also develop "bad" debugging practices by trying to solve buggy code through brute force, adding high frequency errors and fixating on first solutions without conducting detailed error location or hypothesis testing (Chmiel & Michael, 2004). Various efforts have been made to facilitate learning and address the difficulties faced by novice programmers in formal and informal education. Novice-friendly programming platforms with "low floors, high ceilings and wide walls" (Resnick, et al, 2009) such as Alice, Scratch and Blockly were developed. Additionally, instructional approaches such as pair programming (Umpathy & Ritzhaupt, 2017) and constructionist gaming (Kafai, 2006) have been shown to facilitate novice programming.

We argue that using "Productive Failure" (PF) pedagogical design can also be an effective approach to support novices learning and understanding of fundamental computational concepts (Kapur, 2008). The design and implementation of this study is also in line with this year's theme around building knowledge and sustaining community. We report on a DBR mixed methods study conducted with 10 high school students – all of whom participated in federally funded programs for low-income families - who engaged in a 3-week high school workshop, which was re-designed to occur remotely online due to Covid-19. Implementation of the curriculum followed the Productive Failure learning design where in Phase I, students generated multiple solutions to coding problems without scaffolding and direct instruction, and Phase II consisted of facilitator feedback and discussions of optimal solutions. Our guiding research question is: How do productive failure designs support learners' understanding of computational concepts when working with open-ended debugging problems?

Methods

Research design

A convergent parallel mixed methods research design was used to carry out this study (Creswell & Plano Clark, 2017). Qualitative and Quantitative data were collected concurrently, independently analyzed and results were interpreted together. A Design-Based Research framework (Sandoval & Bell, 2004) was selected to design and implement the debugging mini curriculum leveraging Productive Failure Design. Three iterative cycles have been completed, and the current study represents the second iterative cycle.

Setting and participants

The productive failure-based activity (herein termed "debugging mini curriculum") was implemented as a 3-week online synchronous "Coding, Game Design and Problem Solving" workshop in the fall of 2021 as part of a federal TRiO-supported after school program for high school students from low-income families from urban and rural communities in the Northeastern United States. The workshop was conducted twice a week for two hours via Zoom with one primary instructor (Author 1) and a TRiO assistant. Google Chromebooks were delivered to all so that they could participate. Ten students (7 girls, 3 boys; 6 Latinx, 2 Asian, 2 Black) between 15-18 years old (10-12th grade) consented, 9 of whom had no prior experience with programming and Scratch.

Curriculum design

The debugging mini curriculum was developed over two iterative cycles of the DBR project. Individual lessons were based on *Debugems* (Griffin, Kaplan, & Burke, 2012). Programming problems were presented as buggy games that participants had to troubleshoot to play. Faulty code was strategically placed within the problems and had a range of features including missing blocks (e.g., initialization, conditionals, and operators), containing incomplete object-oriented code on Sprites, or comprising erroneous sequences. A narrative was provided as a fun backstory for the challenges along with a task list. The curriculum consisted of 5 units with 14 debugging problems targeting fundamental computational concepts: U1= Sequences; U2= Events & Loops; U3= Conditionals & Parallelisms; U4= Operators & Data; U5= Combination (design game).

Implementation

Implementation of the curriculum followed Kapur's (2008) Productive Failure design. Phase I, which consisted of "Exploration and Solution Generation," involved exploring block-based programming through Scratch tutorials. Students then worked individually on generating multiple solutions to each debugging problem without scaffolding and direct instruction. Phase II consisted of guided "Consolidation and Knowledge Assembly" where Author 1 compared student generated solutions with an optimal solution and provided feedback on students' understanding as well as accurate examples of applications of computational concepts.

Data sources

We examined four primary types of student data. Students completed online pre-post surveys scored on a 6-point Likert scale (1=Strongly Disagree to 6=Strongly Agree), which consisted of items from previously validated instruments: (a) Problem Solving Inventory (PSI), a = > 0.80 (Heppner, 1988), (b) Attitude Scale of Computer Programing Learning (ASCOPL), r = 0.671, n= 476 p< 0.001 (Korkmaz, & Altun, 2014) and (c) Computer Programming Self Efficacy Scale (CPSES), α= 0.95; r = 0.966, n = 233, p<0.0 (Kukul et al. 2017). The survey assessed participants' problem-solving abilities, attitudes towards programming, programming self-efficacy and confidence. Think Alouds were administered during Phase I and II to examine conceptual and procedural understanding. Online semi-structured interviews were administered after each session to understand students' debugging processes, moments of failure and learning. Student generated solutions and their artifacts (games) were also analyzed to provide insights into the trajectory of students' applications of computational concepts.

Data analysis

The Wilcoxon signed-rank test was used to analyze pre-posttest changes in the discrete quantitative survey data, as it is suitable for non-normal distribution samples and accepted in peer-reviewed publications for small N samples. For the qualitative data, interaction analysis (Jordan & Henderson, 1995) was used to unpack discourse on failure mediated learning. We selected, coded, and analyzed prominent interactions during Phases I and II, focusing on participants' explanations. Initial codes and axial codes were informed by Litts et al's (2016) four stage coding process focused on identifying instances of debugging challenges, types of challenges and strategies used to resolve problems. Case studies were then created to understand the specific aspects of Productive Failure design that supported learning. Artifact analysis was conducted in conjunction to track students' iterative attempts and changes throughout the debugging curriculum.

Findings

Quantitative findings

A Wilcoxon Matched Pairs Signed-Ranks Test indicated that post-test scores were statistically significantly higher than pre-test scores z = -10.52, p < 0.001, r = 0.35 with medium effect size (r > 0.3). In particular, Computer Programming Self Efficacy (CPSES), z = -9.25, p < 0.001, r = 0.58, statistically significantly increased with a large effect size (r > 0.5), indicating improvements in students' confidence and perceived ability to program (Table 1). Similarly, participants' computer programing attitudes measured by ASCOPL, z = -4.83, p < 0.001, r = 0.28 (moderate effect), and participants' problem-solving confidence as measured by PSI, z = -2.12, p = 0.034, r = 0.11 (small effect) were statistically significantly higher. However, participants' "Approach Avoidance Style" (PSI subscale) was not statistically significant, z = -1.00, p = 0.317, r = 0.07 indicating that some participants may have shown a tendency to avoid as opposed to fully examine or troubleshoot problems at the end of the workshop.

Table 1
Wilcoxon signed-rank test results (α = 0.05)

	Pre(median)	Post(median)	*p* (2-tailed)	*z*	*r*
All Items	4	5	**< 0.001**	-10.52	**0.35**
ASCOPL	4	5	**< 0.001**	-4.83	0.28
CPSES	2	5	**< 0.001**	-9.25	***0.58***
PSI	4	5	**0.034**	-2.12	0.11
PSI--Emotion	3	4.5	**0.004**	-2.90	**0.37**
PSI--Avoidance	4	4	0.317	-1.00	0.07
PSI--Confidence	5	5	**0.001**	-3.20	0.28

Qualitative findings

Two case studies were created and analyzed to understand aspects of Productive Failure design that supported improvements in programming self-efficacy and application of computational concepts.

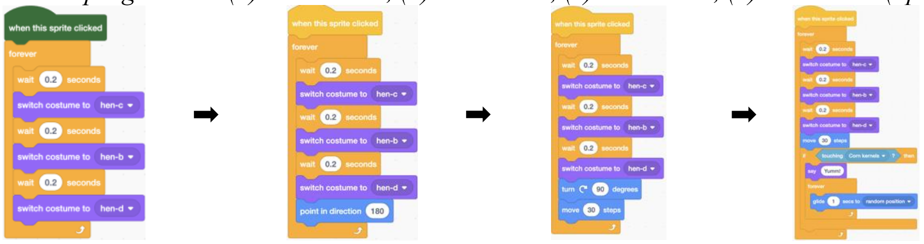
Case I: Learning through trial and error

During the Solution Generation phase on Day 2-5, students were encouraged to apply prior knowledge, informal heuristics, and any debugging strategies at their disposal to generate solutions. In the absence of direct instruction and prior programming experience, trial and error became the prominent informal heuristics applied. In one of the think aloud exchanges during the activities, Jamarcus (Latinx, 16 yrs., 11th grade), explained that he used trial and error to debug a problem where they had to get the chicken sprite from its coop to the corn kernels and around the farm (See Figure 1). By trying out different codes, he "knew what it did, where to put it and how [to use the] code block later" indicating that trial and error could be effective for exploratory learning. Later, during the interview, he expanded on this further.

> **Author 1:** So, how did you get to the right solution? How did you think about it?
> **Jamarcus:** Well, basically, I did trial and error. Basically, I found out the things [codes] that didn't work, so that when I found the glide button it solved my problem, because then I could have him move around...
> **Author 1:** Right! Talk to me about trial and error. How did that help you?
> **Jamarcus:** It's a little frustrating, but it's also fun, you know? Sometimes it's kind of disappointing, but I just have to keep trying cause every time I tried a code, I learn something. I knew what it did, where to put it and how I can use that [code block] later.

When working through the problem, Jamarcus generated 3 solutions first adding "Point in direction 180" which changed the sprite direction without moving it (Figure 1, b), then adding "Turn 90 degrees clockwise" and "Move 10 steps" which rotated the sprite on the same spot due to the "Forever" loop (Figure 1, c). In his third attempt, he got the sprite to the corn and around the farm by combining motion, conditionals, and loops (Figure 1, d).

Figure 1
Jamarcus's progression: (a) Given code, (b) Iteration 1, (c) Iteration 2, (d) Iteration 3 (optimal)



(a)

```
when this sprite clicked
forever
  wait 0.2 seconds
  switch costume to hen-c
  wait 0.2 seconds
  switch costume to hen-b
  wait 0.2 seconds
  switch costume to hen-d
```

(b)

```
when this sprite clicked
forever
  wait 0.2 seconds
  switch costume to hen-c
  wait 0.2 seconds
  switch costume to hen-b
  wait 0.2 seconds
  switch costume to hen-d
  point in direction 180
```

(c)

```
when this sprite clicked
forever
  wait 0.2 seconds
  switch costume to hen-c
  wait 0.2 seconds
  switch costume to hen-b
  wait 0.2 seconds
  switch costume to hen-d
  turn ↻ 90 degrees
  move 30 steps
```

(d)

```
when this sprite clicked
forever
  wait 0.2 seconds
  switch costume to hen-c
  wait 0.2 seconds
  switch costume to hen-b
  wait 0.2 seconds
  switch costume to hen-d
  move 30 steps
  if touching Corn kernels ? then
    say Yumm!
    forever
      glide 1 secs to random position
```

While Jamarcus found trial and error "frustrating" and "disappointing" at times, he also described it as "fun" and useful for his learning. However, he was especially persistent and resilient as a learner, so trial and error may have presented him with perceived benefits in ways it did not for others.

Case II: Changes in debugging strategies through facilitation

Facilitator feedback during the Consolidation phase was designed to support code optimization and accuracy by encouraging student reflections on their solutions and changes in their debugging strategies. One of the participants, Safiya (Latinx, 15 yrs., 10th Grade), explained in her interview how facilitators' feedback contributed to changing her debugging strategy from trial and error, "trying different blocks" to forward reasoning (or, in her words, "looking at the code and the problem and figuring out what blocks were missing"). When debugging this problem, she was trying to get a dog sprite to say "Come back" on through a loop sequence if the dog touched the butterfly sprite. However, she placed a Sensing Boolean block "touching Butterfly1" inside the "Forever" loop without the "If-then" conditional and was "confused" as to "why certain blocks didn't go together." After Author 1's feedback, that only container blocks (such as "If-then") can house sensing blocks, Safiya examined her entire code. She debugged the problem by adding in the missing "If-Then" container and placing the "touching Butterfly1" inside it along with the say "Come back" block. In a later interview, she expanded on her process.

> **Author 1:** How did you go about solving these problems? …
> **Safiya:** I got confused on what the task was and why certain blocks didn't go together. I tried different blocks, but it didn't work to just add the blocks while ignoring the hints and goals. But I got help with it and understood how to do it. Some solutions that worked were looking at the code and the problem and figuring out what blocks were missing instead of just trying different blocks.

Discussion

Findings show that well-designed and reinforced PF learning designs can enhance learners' comprehension and future troubleshooting efforts, despite introducing frustration and complexity. Students showed improvement in their interest, willingness to program, and self-efficacy in applying computational concepts. However, while some students mitigated their difficulty when confronting challenges, others lacked confidence in their programming and debugging abilities and tended to avoid challenges. The case studies shed light how different strategies or scaffolds can benefit different students. Ongoing work aims to find optimal ways to support novice learners in their understanding, awareness of their learning, and confidence over time.

Moreover, the workshop also provided initial insights into the effects of the pandemic and remote learning on vulnerable learners. However, future work is needed to explore how different designs can facilitate meaningful learning and community building for marginalized learners. Furthermore, the small sample size calls for larger studies, and additional research is needed to examine the effects of online and face-to-face learning interventions.

Abstract: Design is not neutral. Making explicit the design assumptions that drive our work is essential toward designing for culturally sustaining/revitalizing futures. In this short paper, we share our development of a community-driven design process that supports our collaborative work of inviting Tribal families to share and preserve cultural knowledge through building relationships with the land. Specifically, we present a case study to illustrate the design process and reciprocal relationship that we cultivated between Tribal Elders and University designers. As a team, we collaboratively designed a series of learning guides to share the Tribe's culture with families. We characterize the community-driven design process with four design waves: sharing, interpreting, learning, and reflecting. This design process invites a slow, rhythmic, and intentional knowledge exchange. Our work contributes theoretical and practical understandings of community-driven design as a process to sustain/revitalize culture.

Objective

Designers hold exceptional power to invite or disinvite certain knowledge and values. Thus, *who* designs matters, *what* is designed matters, *how* it is designed matters, *why* it is designed matters, and *when* it is designed matters, especially in the context of designing for culturally sustaining/revitalizing goals (McCarty & Lee, 2014). Scholar, who labor in this area, highlight the importance of making explicit the assumptions driving our design work; for example, Bang and colleagues explicate the reality that "what is good, right, true, and beautiful" (Bang et al., 2016, p. 29) is rooted in cultural, historical, and political knowledge and values. Therefore, it is necessary to disrupt who designs learning environments and technologies by redistributing power from education researchers and designers to local communities.

As designers, Indigenous peoples have been actively reclaiming *who* designs by centering the uses of digital and original technologies on "meaningful community-driven goals" (Bang et al., 2013, p. 707). These goals disrupt colonizing purposes of technologies and repurpose them to assert self-determination through language revitalization and cultural preservation. By pursuing meaningful community-driven goals, communities become designers and redefine what it means to create with technology through rich innovations at the intersection of learning and culture (Bang et al., 2013).

In this paper, our team explores our development of a collaborative design process that supports the goal of sharing and preserving knowledge between and within Indigenous communities and families. As Indigenous and non-Indigenous researchers, designers, and educators, we specifically investigate: *how do we employ a community-driven design process to create learning guides for Indigenous families to build relationships with the land?* Specifically, we share our collective analysis and reflection on our design process, which led to the identification of four design waves: sharing, learning, interpreting, and reflecting. Our work contributes practical and theoretical understandings of community-driven design led by a Tribal Nation.

Background

In our work, we take a culturally sustaining/revitalizing approach (McCarty & Lee, 2014) to support and develop our relationship with the land. Culturally sustaining/revitalizing approaches emphasize understanding and conceptualizing educational practices specific to Indigenous learners. Culturally sustaining/revitalizing pedagogies are deeply rooted in recognition of Tribal sovereignty by pushing for the decolonization of learning (e.g., McCarty & Lee, 2014). These stances inform our work to center *relationship with the land* as a way to sustain and revitalize cultural identities. Thus, we understand our relationship with the land as fundamentally cultural. How people relate to land and nature is socially constructed and varies across cultures (e.g., Medin & Bang, 2014). Relating with the land is highly integrated and, in some cases, synonymous with culture. Thus, we need to restore our relationship with the land to sustain and revitalize culture.

Community-based approaches to design

As a field, the learning sciences is rich with seminal work around collaborative design processes that include designing *with* rather than *for* communities. In our work, we are heavily shaped by a community-based design research (CBDR; Bang et al., 2016) approach. Specifically, CBDR involves "design efforts that work from within the "ongoingness" of communities" (p. 11) and is characterized by axiological innovations that occur as a result of three interrelated design commitments: critical historicity, intergenerational learning, and transforming institutional relations (Bang et al., 2016). This orientation to design recognizes the historical, cultural, and political nature of partnering with Indigenous communities and embraces the need to invite community-wide and intergenerational participation. Since community-based efforts are often characterized by various levels and forms of community participation, we use *community-driven* in our work to clarify the Tribal Nation's sovereign role across our research and design efforts. As a team that includes non-Indigenous researchers, our stance on CBDR is characterized by a TribalCrit (Brayboy, 2005) orientation toward partnering with tribal communities: respect and reciprocity in relationships, self-determination, and sovereignty.

Methods

As part of a multiyear critical ethnographic study, we present in this paper an intrinsic case study (Stake, 2008). Through developing the case, we seek to better understand the design process and reciprocal relationship that developed between Tribal Elders and University design researchers, who collaboratively designed a series of learning guides to engage families in building relationships with the land. Given the iterative and multiyear nature of our approach, participants varied over the course of the design process. The bulk of the design work happened between Joaquin (pseudonym to maintain anonymity), a Tribal Elder and designer, and Author 1 (Kenden Quayle) & Author 3 (Breanne Litts), two University design researchers. The process also included other Tribal Elders and University-affiliated Indigenous and non-Indigenous design team members.

Data collection and analysis

To construct the case presented in this paper, we draw on *personal communication* between Tribal Elders and University design researchers, *design artifacts* developed throughout the process, *fieldnotes* that were collaboratively written every week, and *analytic discussions* across the entire project team. We employed a collaborative and reflexive meaning-making analytic approach to construct cases by triangulating (Creswell, 1998) interpretations and claims across partners, perspectives, and documentation. Joaquin's analytic insights are integrated into this work as transcriptions of data analysis meetings. In addition, University design researchers drafted a re-telling of our collective insights, and Joaquin reviewed these re-tellings before submission.

Findings

While analyses are ongoing, we present four waves of a community-driven design process: sharing, interpreting, learning, and reflecting. Here we share one moment between Joaquin and Kenden to illustrate how our design team employed community-driven design.

Sharing

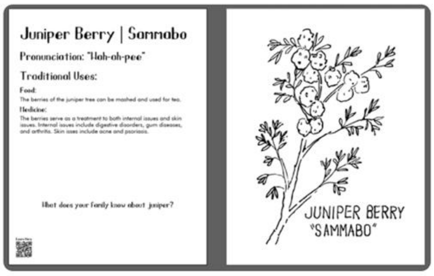
Building a relationship based on trust and reciprocity with community partners prompts the possibility of sharing. Thus, a community that shares ideas, designs, and knowledge is a key marker of a community-driven design process. In our case, the trust cultivated within the multiyear partnership made space for Joaquin to openly share a vision and plan for a Tribal Plant Guide, which included Shoshone words and his knowledge of plants. Part of the trust-building process includes only capturing what is explicitly permitted for research. Due to the confidential nature of this initial exchange, we do not have details of it captured as data. This level of confidentiality was maintained throughout the design process: nothing was shared with additional team members or beyond until Joaquin said it was the appropriate time to do so.

Interpreting

Interpreting often followed sharing because the design process allowed space for each designer to assess individual understandings of the knowledge that was shared. Interpreting occurred any time there was a meaning-making opportunity to understand cultural knowledge. Joaquin guided this wave with what he called "hints." By this, we mean that questions and unknowns were not answered hastily or entirely; instead, the team was invited to interpret their own meaning. In one example of interpreting through hints, after reviewing the first iteration of the Tribal Plant Guide, Kenden suggested to Joaquin that we include pronunciations for the Shoshone words in the guide. Though Joaquin agreed this would be helpful, rather than offer the pronunciations himself, he encouraged Kenden to sound out each word by herself first and then share the results with him. This prompted an active exchange of interpretation. Here is an exchange from 01/07/2022 that serves as an illustrative example:

> Kenden: "Does sammabo mean berries? For the berry side should it say sammabo instead of waapi?"
> Joaquin: "Ok lets put Juniper Berry under Sammabo like [where] Juniper under Waapi take out ok"
> Kenden: "Alright! Like this?" [see Figure 1]
> Joaquin: "Yes Kenden that's grt8 but pronunciation is Sammabo not Wah-ah-pee that's the tree itself other than that grt8 good work Kenden THANK YOU much"
> Kenden: "thank you for catching that! I will fix it! I think that is all I have for you today! Thank you!!"
> Joaquin: "Kenden grt8 this plant book will help the youth know more about how we used the things in nature and what we named them in Shoshone language thanks again Kenden"

Figure 1
Juniper Berry "Sammbo"



Juniper Berry | Sammabo

Pronunciation: "Wah-ah-pee"

Traditional Uses:

Food:
The berries of the juniper tree can be mashed and used for tea.

Medicine:
The berries serve as a treatment to both internal issues and skin issues. Internal issues include digestive disorders, gum diseases, and arthritis. Skin isses include acne and psoriasis.

What does your family know about juniper?

Learning

Learning served as a rhythmic knowledge exchange between Joaquin and Kenden to check in with their interpretation results. When developing the Shoshone pronunciations, Joaquin learned how to think about designing for learning in this written format and Kenden learned the Shoshone language and pronunciations. As time went on, many of the knowledge exchanges over Slack started to include knowledge beyond the Tribal Plant Guide, such as greetings and sign-offs. As an example, consider this Slack exchange from 01/23/2022:

> Joaquin: "Kenden Aishen AI has line under like Daigwade for thank you"
> Kenden: "Hi [Joaquin], sure thing, which book can this be found in?"
> Joaquin: "No book just letting you know how to say Thank you – Aishen"
> Kenden: "That's great, Aishen! (with a line under the ai) 😊"

Another important aspect in designing the learning guides involved relating with the land by learning directly from the plants and nature. Joaquin explains this process: "you know when you're doing this, you have to go out and find some of those plants. But then when you've found them you can put a lot more detail in them... When you have that, I guess I call it hands on contact with the things that you are interested in, you have a better way of being able to learn" (Reflective Conversation, 07/14/2022). In this iterative rhythm, we gain knowledge slowly.

Reflecting

Because this was an iterative process marked by the careful sharing, interpreting, and learning, there were moments between exchanges that allowed space for reflection. These spaces for reflection characterize the reflecting wave of community-driven design. For example, in one exchange, Joaquin continued researching the plants and shared via email on 12/10/2021 that he found a Shoshone name for a plant that was not currently included in the guide:

> Joaquin: "Good day (tsaaN da bai) Kenden one change a better name for horse tail Sebu so scratch out Isayugip thank you Kenden... Kenden one more change mountain mahogany name Tonambe I didn't have name before now I do"

Allowing this time is a critical characteristic of community-driven design, as Joaquin explains, "And then what was good was being able to edit, editing. Going back to refine everything. Having the ability to do that and not say, 'well, we're just gonna give you this much time, we need to have it out.' Because when you're ready and you say okay let's do it now, then all of a sudden something pops up." (Reflective Conversation 07/14/2022). The wave of reflecting remained unconstrained to allow everyone however much time and space needed to consider and (re)consider the guides and generate more sharing.

The process enacted with the learning guides

The waves of the community-driven design process that shaped the creation of the learning guides are reflected in the product of the guides themselves. Joaquin explains the goal of the Tribal Plant Guides: "so doing that coloring book, that was the whole idea was to get the youth and others interested in wanting to know more and to use them." (Reflective Conversation 07/14/2022). Everything included in and left out of the guides was intentional, as the guide serves as a starting point for the facilitation of Tribal members' relationship with the land. Joaquin takes the same "hint"-based approach in his design of the guides: "so, when people look at that book, they can also go further because we don't want to give them all the stuff when you're trying to use a guidebook, to give them all the information. They still need to find out a lot on their own, and it makes it better for them." (Reflective Conversation 07/14/2022). These goals of sharing, interpreting, learning, and reflecting manifested in the guide with a space for people to add their own knowledge by asking: "what does your family know about [particular plant]?". It is important to acknowledge how the waves of community-driven design are embedded in the product (i.e., the learning guides) of the process, because it further demonstrates the importance of *who* designs and *how* design happens.

Significance

The cadence embodied by the community-driven design process is unique, as it invites a slow, rhythmic, and intentional exchange of knowledge through four waves: sharing, interpreting, learning, and reflecting. Of special importance is how Joaquin and his vision led the entire process. Unlike standard Western design processes, which are often characterized by discrete steps and strict deadlines, the community-driven process is centered on trust and relationships. Community-driven design is, instead, characterized by meaningful community-driven goals – or "what is good, right, true, and beautiful" (Bang et al., 2016, p. 29). If we take seriously goals toward culturally sustaining/revitalizing design, we must also consider what forms of process will support these designs and accept that these forms will invite new rhythms of knowledge exchange.

Abstract: Assessments are an integral part of academic environments and provide key insights on students' learning and the efficacy of pedagogical practices. In this work, we introduce the development process of a novel research-based assessment - the Thermal and Statistical Physics Assessment (TaSPA), for undergraduate physics courses. We elucidate leveraging of existing theoretical and design frameworks in the development of TaSPA, and how the interplay of these frameworks addresses some of the shortcomings of contemporary assessments. Unlike most of its counterparts, TaSPA focuses on providing actionable feedback for instructors to modify their courses. The current work represents a paradigm shift in how assessments are envisioned and designed by the discipline-based education research community.

Introduction

Development and dissemination of research-based assessments (RBAs) in higher education – commonly referred to as "concept inventories" – has attracted substantial traction in the physics education research community. The development of an RBA typically involves creating assessment items on a target domain (often based on the insights obtained from student interviews), and validating the items in terms of their content and the intended measurement. The assessments are then administered (usually in pre- and post-format), and students' scores are interpreted to gauge their learning along with the efficacy of relevant teaching and learning environments. However, researchers and practitioners have noted the lack of clarity for instructors in interpreting students' sores to make effective course modifications (Madsen et al., 2016).

In the current work, we elucidate the process of an RBA under development - the Thermal and Statistical Physics Assessment (TaSPA), which provides actionable feedback for the instructors based on their students' responses. When available, instructors will be able to use the TaSPA portal by selecting a set of valued learning goals from a list. Through a web-link accessed by an email, students can take the TaSPA online. After a stipulated time, instructors will receive a report on their students' performance along with actionable feedback (if required) about how they can modify their courses to better support their students' learning.

In the rest of this manuscript, we address the research question: *How can we develop a research-based assessment that provides actionable feedback for instructors to support their students' learning?*

Theory-of-action for TaSPA

The process of assessment design typically involves articulating the measurement argument, i.e., what the assessment intends to measure, and the mechanism through which this measurement occurs (Kane, 2013). The measurement arguments assume significance as they communicate what the education research community considers important to assess, and can influence instructors on guiding the everyday activities in classrooms.

For the current work, we consider assessments also as "instruments of change" rather than solely as "instruments of measurement". This paradigm shift then requires us to replace the measurement argument with a "theory-of-action" - an explicit argument on how the assessment brings about the intended change in an individual or an institution (Bennett, 2010). A theory of action entails articulating the components of the assessment, the change the components intend to produce (intended effects), and the mechanism which facilitates this change. Our intended effects correspond to shifting the emphasis of our classrooms from pure conceptual understanding to application of students' existing knowledge in making sense of novel contexts. The assessment components include assessment tasks and feedback reports. Instructors taking up the generated feedback and making relevant course modifications correspond to the mechanism through which our assessment components lead to the intended effects.

Three-Dimensional Learning

Educators have emphasized the need to shift the focus of academic learning environments from “knowing” to “doing” science (Harris et al., 2019). Three-Dimensional Learning (3DL) is the design framework which promotes the spirit of “doing science” by characterizing students’ learning across three “dimensions”. These include (i) *Scientific Practices* - the activities through which scientists generate new knowledge (e.g., constructing explanations), (ii) *Core ideas*- the key disciplinary concepts which provide organizational structure for students’ existing knowledge (e.g., energy), (iii) *Cross-cutting concepts*- the concepts which have applications across multiple scientific disciplines (e.g., cause and effect). While this framework was initially proposed for the K-12 education system, researchers have argued for its relevance to the college level (Laverty et al., 2016). We adopt this framework in design of our assessment tasks.

Self-regulated learning

The notion of learning as it relates to assessment scores has traditionally been focused on students learning. Here, we also position instructors as learners, or, more specifically, as self-regulated learners who seek to modify their pedagogical practices to better support their students' learning. Self-regulated learning (Butler & Winne, 1995) is a meta-cognitive activity in which learners regulate aspects of their thought processes, motivation, and behavior during learning. This can include: actively monitoring progress towards goals; consistently analyzing strategies employed in pursuit of the set goals; managing emotions, etc.; and responding to external feedback. Effective feedback, particularly external, has been considered as a catalyst in accelerating and providing necessary impetus for self-regulated learners in making progress towards their goals. Sadler (Sadler, 1989) put forward three features of external feedback that are effective at assisting self-regulated learners in their progress towards the set goals. These include clarifying: (i) the desired performance, (ii) the current state of the performance, and (iii) opportunities to close the gap between current and desired performance. We adopt these features in the design of our external feedback to instructors.

Development of TaSPA’s assessment components

Below, we briefly articulate the development of our assessment components by leveraging the frameworks discussed above. The development of the components 1-4 are strongly influenced by Harris et al. (Harris et al., 2019) and a detailed discussion on the contextual adoption can be found in (Rainey, Jambuge, et al., 2020) and (Laverty et al., 2022).

1. Articulating learning performances.

Learning performances (LPs) are assessable statements formed by blending scientific practices, core ideas and cross-cutting concepts, and reflect what students should know and be able to do with that knowledge (Harris et al., 2019). The focal content areas of our LPs are drawn from Rainey *et al.’s* survey (Rainey, Vignal, et al., 2020) documenting the conceptual ideas valued by instructors who have taught thermal/statistical physics courses across the United States. Below is an example of a learning performance with the scientific practice **“Constructing Explanations”,** the core idea “Energy”, and the cross-cutting concept “*Cause and effect”*.

> **Generate an explanation** about *the mechanism by which the temperature does (or does not) change* with heat flow into or out of a system informed by the process undergone and ambient conditions (e.g., pressure, temperature).

2. Generating knowledge-in-use tables.

The next step involves articulating the (i) *knowledge, skills, and abilities* required to demonstrate proficiency in addressing the learning performance, (ii) the corresponding *evidence statements* (ESs) in students’ work, and (iii) the *task features* which can engage students in the targeted scientific practice, core idea, and cross-cutting concept. The organization of these elements in a tabular form is referred to as the “knowledge-in-use” table.

3. Developing assessment tasks.

The task development begins by identifying a context which addresses each of the elements in the Knowledge-in-Use table and developing an open-ended task. This task is then piloted to undergraduate physics students, and their responses are analyzed through the lens of the evidence statements. The student responses assist in the development of a coupled multiple-response (CMR) version of the task (Wilcox & Pollock, 2014).

4. Designing rubrics.

Rubrics translate students' responses to the tasks into scores which in turn are interpreted with respect to ideal outcomes. Our rubrics reflect the evidence provided in students' responses demonstrating the extent to which they have achieved the given learning performance. We characterize students' responses into "Met" (strong evidence), "Partially Met" (weak evidence), or "Not Met" (no evidence) reflecting their extent of meeting the learning performance. The task development and the rubric design often occur simultaneously to ensure coherence in capturing relevant evidence for students' proficiencies. Every response pattern to tasks is associated with a rating characterizing the aforementioned proficiency levels.

5. Generating feedback reports.

Our feedback embodies the effective principles as specified in the "Self-Regulated Learning" subsection. Accounting for the instructors' diverse classroom practices, the feedback refrains from providing specific, prescriptive approaches. Instead, we focus on the nature of opportunities that students can be provided with, to better support their students' learning. However, the ways of operationalizing these opportunities are left to the instructors.

The process of generating feedback involves interpreting individual students' responses with regard to evidence statements and making inferences about the class' performance. Every rating of the rubric accompanies a feedback statement which specifies the desired performance, students' current performance, and the opportunities which can bridge the gap between the desired and the current performance (if required). For our example, if we have weak evidence of students demonstrating proficiency in meeting the learning performance (proficiency "Partially Met"), our feedback will look like:

Students were asked to:

- Identify relevant processes and conditions that influence temperature changes.
- Describe the physical mechanism justifying why heat flow does or does not change the temperature.

The TaSPA:

- Provided evidence that your students identified relevant processes and conditions that influence temperature changes.
- Provided evidence that your students partially accounted for the mechanism justifying why heat does or does not change the temperature of the system.

Students could benefit from more opportunities:

- To explore the physical mechanisms through which the heat flow into or out of the system affects its temperature.

This feedback structure was designed with attention to both simplicity and actionability. However, as the feedback will be delivered online, we plan to build in options for instructors to get more fine-grained suggestions if they are interested.

Intended effects of the TaSPA's feedback

Assuming that instructors find our generated feedback clear and actionable, they would then initiate changes in classroom instruction that could result in improved student learning. Going back to TaSPA's theory-of-action, our first intended change would be on students' learning on the valued LPs. Since the generated feedback is rooted in evidence statements, which are in turn derived from the learning performances, any uptake of feedback is also expected to result in students' improved learning on the corresponding learning performance.

Conclusion

We present a broad overview of the development process of a novel research-based assessment - the Thermal and Statistical Physics Assessment and providing actionable feedback for instructors. Our work presents a paradigm shift in how RBAs are envisioned and designed by the discipline-based education research community. We have presented our "theory-of-action"- an explicit account of how our assessment can bring about an intended change by shifting the focus of our classrooms from "knowing" to "doing" science.

Furthermore, in order to get instructors' perspectives on our feedback statements, ten faculty members who were teaching or had recently taught thermal and statistical physics at various institutions across the United States were interviewed. The interviews mainly revealed an overall positive response on the learning performances reflecting the viability of scientific practices, core ideas, and cross-cutting concepts for undergraduate level. In addition, every faculty member considered a different learning performance as important, thereby reinforcing the need for a design feature allowing instructors to select valued assessment objectives.

As for the future work, theoretical underpinnings in translating and interpreting the individual responses to the class' results are being explored. We are also in the process of piloting the entire exercise of our assessment administration, starting from instructors choosing learning performances to getting actionable feedback based on their students' responses at numerous undergraduate institutions in the United States. The assessment will be available to the public in 2024.

Abstract: Developing knowledge of others' cultures is essential to cultural competence. To join scholars and educators who have varied approaches to engaging students with culture in formal learning settings, as a team of Indigenous and non-Indigenous researchers, educators, and designers, we designed a series of interdisciplinary, land-based curricular units to bring Native cultural perspectives into sixth-grade classrooms. This short paper focuses on the research question: how does sixth graders' knowledge of Native cultures and Native Americans change through engaging with culturally centered curricular units throughout a school year? We share three learning paths that illustrate sixth graders' movements in understanding. The learning paths provide insights into how sixth graders develop a closer psychological distance to culture, particularly Native cultures, as they actively negotiated their prior understandings with their culturally centered classroom experiences. This work contributes new insights into how youth learn in a culturally centered context.

Introduction

In the face of persistent attacks on culturally based education in K-12 classrooms in the United States, we join scholars who advocate for the need to center culture in learning (e.g., Nasir et al., 2020). Among the myriad of rich and fruitful approaches to engage young learners in culture, we focus on the opportunity to develop youths' cultural competence in the classroom (Keengwe, 2010). The core components of cultural competence include developing an awareness of culture (one's own and others) and the use of knowledge and skills (such as perspective taking and ethnocultural empathy) for effective and respectful cross-cultural interactions (Tehee et al., 2020). Moreover, there is a critical need for accurate and culturally sustaining representations of Indigenous cultures in K-12 classrooms (e.g., Sabzalian et al., 2021). Thus, as a team of Indigenous and non-Indigenous researchers, educators, and designers, we collaboratively designed culturally centered curricular units, particularly focused on representing Indigenous perspectives in the classroom, throughout a multi-year research partnership. In this paper, we are guided by the research question: *how does sixth graders' knowledge of Native cultures and Native Americans change through engaging with culturally centered curricular units throughout a school year?* In prior years, we observed that students' relationship and distance with other cultures change as they developed more cultural knowledge. Thus, in this analysis, we empirically investigate this observation. Findings provide insights into how youth develop a closer psychological distance (Medin & Bang, 2014) to Native cultures through engaging with culturally centered learning activities.

Literature review/relevant works

Teaching culture in K-12

Teaching cultural knowledge in a formal learning setting can be challenging, especially in the current socio-political landscape. Formal learning environments are often assumed to be acultural spaces even though they operate on a set of norms rooted in the dominant culture (Bang et al., 2012). Moreover, some argue for a distinction between "cultural knowledge" and school or domain knowledge, despite the reality that all knowledge is cultural (Nasir et al., 2008). From this stance, our inquiry is informed by a culturally disruptive pedagogical approach alongside place- and land-based approaches to learning. Culturally disruptive pedagogy focuses on the disruption of privilege, especially Whiteness, by making the socializing of Whiteness visible and disrupting hegemonic cultural norms (San Pedro, 2018). Informed by the culturally disruptive approach, we intend to make Western culture visible in the sixth-grade curriculum by introducing Native American cultural knowledge. In our design and implementation of sixth graders' curricular units, we adopted place- and land-based approaches that attend to "constructions and storying of land and repatriation by Indigenous peoples, documenting and advancing

Indigenous agency and land rights" (Tuck et al., 2014, p.13). As part of the curricular activities, we designed place-and land-based experiences for sixth graders to engage with Native cultures.

Relating with others' cultures through developing cultural knowledge

In this study, we examine the different paths of how sixth graders develop knowledge of Native American cultures as the processes of how their psychological distance (Medin & Bang, 2014) to Native cultures change over time. Psychological distance refers to the degree of subjective relatedness to an event or person across different kinds of distance, such as time, space, and personal identity (Trope & Liberman, 2003). Furthermore, researchers have identified the home-field disadvantage (Medin et al., 2010) that shapes our interpretations of cultural groups other than our own. The home-field disadvantage describes two models that are particularly relevant to this paper. We, first, tend to take different cultures as marked while our own culture as normal or "unmarked." We also tend to assume substantial homogeneity of other cultures while viewing heterogeneity in our own culture group (Medin et al., 2010). We intend to identify sixth graders' learning paths from how their understandings of Native cultures change along the two threads Medin and colleagues (2010) introduce: (1) marked vs. unmarked culture; (2) homogeneous vs. heterogeneous culture. We trace these tensions in our analysis.

Methods

The work we share here is part of a broader multi-year study investigating how youth develop relationships with culture. In this paper, we draw on data collected during the 2019-2020 school year at an experiential learning school in a predominately White community in the Mountain West. Participant demographics are representative of the student demographics of the school are 86% White, 5% Multiracial, 6% Hispanic, 1% Black or African American, 2% Asian, 1% American Indian or Alaska Native, and 0% Native Hawaiian or Other Pacific Islander. We conducted interviews across three timepoints: beginning, middle, and end of the school year. Our analysis focused on 105 interviews with the 39 sixth graders, ages 10-12, with parent/guardian consent and who assented to research. Participants chose their pseudonyms. The interviews capture how students' understandings of Native cultures and Native Americans shifted over time, particularly with two foci: (1) whether students understand Native cultures as marked or unmarked and (2) whether they regard Native cultures as homogeneous or heterogeneous. In our analysis, two researchers coded interviews using descriptive and in vivo codes (Saldaña, 2009) to develop a codebook that captured shifts in students' descriptions of Native cultures. Researchers conducted thematic coding around two forms of representation (historical and modern) and students' levels of understanding (i.e., misunderstanding, no knowledge, basic understanding, high-level understanding, and advanced-level understanding). We then traced individual students' changes across the school year.

Findings

Findings provide insights into students' diverse learning paths toward developing cultural competence. We identified three learning paths in knowledge development that supported students' movement in understanding Native cultures over the year. We characterize these learning paths in terms of scope, depth, and perspective, which include: (1) deeper nuanced understanding, (2) growth in modern understanding, and (3) awareness of limitations of personal understanding.

Deeper nuanced understanding

Over the course of the school year, students developed more detailed and nuanced knowledge about Native cultures. At the beginning of the school year, students often described limited or overgeneralized knowledge about Native cultures. Take Mandy's reflection as an example: "I know they [Native Americans] were very resourceful with what they had, and they, like, they were very strong and with their tribe, and they traveled long distances with and, um, yeah, so" (Mandy, Interview, Time 1). In this response, Mandy shared how she felt like she didn't know much about Native people. In her attempt to describe Native Americans, Mandy used the past tense and described Native Americans as “resourceful”, “strong”, and “traveled long distance”. However, towards the end of the year, Mandy showed a development in the understanding of Native people. Mandy demonstrated this change by sharing how she had learned a lot about the Navajo tribe and their culture:

> "Um. We learned a lot about, like, the, like, the Navajo tribe, and, like, the, um, like, the-their culture and that was really cool. Um. We also learned a lot about, like, the, um, like, cave paintings and all the paintings that the Navajo tribe did. And, yeah, we also learned about, like, I think, different animals and plants that were there that was part of our science. And, like, looking at stars” (Mandy, Interview, Time 3).

Instead of talking about Native culture in general, Mandy specifically described what she learned about the Navajo tribe and their painting, which is part of the field trip experience where she also learned about animals, plants, and stars. Across the year, students demonstrated growth through nuanced understanding by recognizing the unique Tribal communities in their local context, sharing personal experiences with stories learned from local Tribal Knowledge Holders, and highlighting the range of values and cultural practices that exist across Tribal communities. This learning path toward deeper nuanced understanding also demonstrates the process of starting to acknowledge heterogeneity (Medin et al., 2010) in Native cultures.

Growth in modern understanding

Students' deeper and more nuanced understanding was paired, in part, with their growth in modern understanding. A persistent misconception among students was that Native Americans are historical and ancient people who do not live in the same modern world students live in today. Over the school year, though, students grew in their understanding of Native Americans as modern and contemporary people with rich historical and ancient roots. For example, at the beginning of the school year, Ted's knowledge of Native culture centered on the use of "flint." Ted shared that "like, the way that they did stuff, like, a lot of Native Americans, they, Native American tribes, they … they, uh, like, used flint a lot" (Ted, Interview, Time 1). Ted not only used the past tense when describing his knowledge of Native Americans, but also showed historical knowledge about the flint tool that he gained from a book. Toward the end of the school year, Ted shared a more contemporary perspective of Native Americans:

> "Oh, um, hmm…I think I…I think I understand the cultures that live around here in Utah and in the, in the states around Utah. I think I understand them a little bit better because we went down there, and we saw a bunch of their cultural…or a bunch of that culture's um…yeah. We learned about that specific culture. And I'm sure that the other cultures…or the other, uh, native tribes that live in Utah and around Utah, I bet that if I went to their to places that have cultural significance to them, I would learn a lot about them, and I would appreciate that more" (Ted, Interview, Time 3).

Here Ted describes Native Americans as modern people and recognizes that land and place have specific cultural significance in Native cultures due to both past and present connections. He particularly highlights how the cultural experience of visiting southern Utah contributed to his growth in modern understanding. Similar to Mandy in the previous example, Ted also demonstrated the awareness of Native culture as plural rather than homogenous (Medin et al., 2010), which reveals the interdependence of these forms of knowledge shift.

Awareness of limitations of personal understanding

Students' knowledge of Native cultures shifted as they became aware of the limitations of their personal understanding of Native Americans, which they demonstrated as a reflection of their learning. This awareness was largely prompted by contrasting their prior personal understandings with new knowledge and experiences they were exposed to over the school year.

In this process of deepening nuanced understanding and growing in modern understanding, students often shared their developing awareness of the limitations of their personal understanding of Native Americans and Native cultures. Quentin grappled with this shift in his reflection at the end of the school year:

> "Um. I, well, when before when I thought of Nat-Native Americans, I more thought of, like, um, tribes living in the woods or living in, um, like, not living in a normal house. I thought of them, like, building their own houses and doing a – hunting themselves and some of them still do, but, um, they-a lot of them also just live in a house and that's just their religion and their same, but they still do the same stuff as us. Well, like, live in the same, um, spaces as us and eat some of the same food as us but still eat, like, um, don't go - some of them don't go hunting, and, to get food, and, like, before I kind of thought of them, like, living in the woods and, um, stuff like that. But, now, I, um, realize that they can have that, um, uh, culture and religion, but still, like, live and-and have the same lifestyle as us" (Quentin, Interview, Time 3).

In this reflection, Quentin addressed limitations of his previous understanding of Native culture, especially regarding how Native people live today and how they might engage in cultural activities. This critical reflection led to Quentin's developing self-awareness of the limitations of his personal understanding of Native people. This process not only results in a more nuanced and modern understanding but also shares a "now I realize" moment as an acknowledgment that his previous personal understandings were inaccurate. In addition, Quentin developed a closer distance to Native cultures as he negotiated with his own culture as unmarked (Medin et al.,2010), particularly while thinking about place and food as cultural. This learning path shows Quentin's engagement with his own understanding reflectively as well as their awareness of the limitation of understanding other cultures from a distanced view.

Discussion and conclusion

In this short paper, we share three interdependent learning paths to illustrate how sixth graders develop knowledge of Native cultures throughout a school year. Along these three learning pathways, we identified an overarching trend toward developing more cultural awareness and understanding. Initially, many students began the year with stereotypical and historical perspectives of Native Americans and Native cultures, which revealed as marked and homogeneous understandings. Over the school year, students demonstrated growth in more accurate historical understandings and deepening of contemporary understandings of Native cultures and Native Americans, which manifested as more unmarked or relatable and heterogeneous understandings. The three learning paths we highlight demonstrate sixth graders' processes of developing understandings of cultural others as they build relationships with Native cultures and Native Americans through being on their land and hearing from Native people. Students developed a closer distance to Native cultures as they moved away from seeing Native cultures as marked and homogenous toward unmarked and heterogenous (Medin et al., 2010). These insights contribute new understandings of how youth develop cultural competence and what and how students learn through culturally centered learning experiences.

Developing Medical Educators' Adaptive Practices Through Training in Learning Sciences and Design

Catherine C. Chase, Stanford University, cchase@stanford.edu

Abstract: Effective educators are adaptive, but adapting is challenging. We designed and implemented an intervention to train medical educators in teaching strategies from the learning sciences plus design processes to support them in adapting their instruction. In follow-up interviews, educators reported high rates of transfer and adaptation one and a half years later. Our work contributes new measures of transfer and adaptation, and a successful intervention model for disseminating learning science practices beyond K-12 contexts. Design process training may have enabled educators to adapt learning science content for their personal teaching contexts while encouraging them to be open to change and growth.

Introduction

An effective educator is *adaptive* (Darling-Hammond & Bransford, 2005), meaning they can transfer teaching practices learned in one situation to another, and they can change their teaching practices in response to new student needs or situational demands. Moreover, an adaptive educator is willing to try new practices when old practices fail. Research suggests that adaptive teaching can boost learner achievement (Hattie, 2009).

However, adapting is difficult in many contexts and domains. Years of research have demonstrated that transfer is challenging for most learners, and some have argued that meaningful transfer rarely occurs (Schwartz et al., 2005). It is also difficult for learners to resist routine behaviors and try a new way of doing things, as research on "set" effects and "functional fixedness" has clearly demonstrated (Schwartz et al., 2005). Adaptivity is often a challenge for teachers as well. For example, Hoffman & Duffy (2016) observed elementary literacy teachers over a 9-year period and found they seldom changed their instruction, often sticking to preset scripts.

In this paper, we describe research on an intervention that was explicitly designed to promote the development of adaptivity in medical educators. We view educator adaptivity through the framework of adaptive expertise (Hatano & Inagaki, 1986). Adaptive experts can adapt to the demands of a novel situation by engaging in several *adaptive practices*. They can (1) transfer their knowledge across contexts, (2) let go of old ways that are suboptimal and change their practices, and (3) seek out opportunities to learn and grow (Schwartz, Bransford, & Sears, 2005). While we did not study experts per se, we use this framework to explore the development of adaptive practices in medical educators.

To promote medical educators' adaptive practices, we taught them teaching strategies culled from the learning sciences in concert with a creative design thinking process that focused on adapting instruction for learner needs and contexts. While professional development programs often train teachers on teaching strategies, they rarely pair it with this kind of process-based instruction.

Design thinking is a set of processes and practices, derived from traditional design fields, that yield creative solutions to complex problems (Cross 1982). The crux of design thinking is that it is human-centered, which means that its major goal is to design for a human need. Instead of starting with a technological solution, the designer begins by investigating users' needs through interviewing and observation. Subsequent prototype testing and user feedback allow the designer to iterate towards a meaningful solution (Buchenau & Suri 2000). In short, design thinking provides a process for adapting to learner needs and revising one's design based on learners' feedback. As such, we believe it is particularly well-suited to helping educators adapt.

The learning sciences & design training program for medical educators

In this study, oncologists with an interest in education participated in a series of four 1-2 day training workshops, interspersed throughout the year. During these workshops, we taught medical educators 15 evidence-based strategies culled from learning sciences research: self-explanation, elaboration, generation, worked examples, contrasting cases, observation, feedback, deliberate practice, reward, reducing cognitive load, learning-by-teaching, just-in-time telling, question-driven learning, and providing constructive and interactive activities (strategies were derived from Schwartz, Tsang, & Blair, 2016). While learning sciences research has infiltrated the K-12 educator space, it has not gained much traction in other circles where it could provide great value. In particular, medical instruction suffers from an over-dependence on passive forms of instruction and factual, rote learning (McCoy et al., 2018), which runs counter to learning science recommendations.

In addition to learning science strategies, we taught a creative design process with two stages: 1) identifying learners and their needs and 2) developing and iterating on prototypes that address the learners' needs. In stage one, designers gather information about how learners engage in a learning task through interviews, observations, surveys, and other research methods. The goal is to understand what currently works and does not work for most learners in a particular context (i.e., the learner's needs). Designers in stage two construct multiple prototypes based on learning science strategies that address the needs they identified. The combined steps of creative ideation and iterative prototyping are practices that encourage designers to build out novel solutions that are refined specifically in response to feedback from learners.

Participants learned both the design & learning sciences content by doing design (Darling-Hammond et al., 2015). Participants worked in small groups to complete several "mini" design challenges before completing a longer, final design challenge. Examples included such diverse activities from designing a math lesson for a first grader to redesigning the format of a conference workshop.

In this paper, we evaluate whether teaching this combination of learning sciences and design processes promoted the development of medical educators' adaptive teaching practices. We focus on measuring two key aspects of adaptivity: (1) transfer of learning science strategies and design processes to participants' personal teaching contexts, and (2) other adaptive practices such as changing instruction and engaging in new learning.

Methods

Participants

Oncology faculty applied to participate in the program and were selected based on merit. All 12 participants of the program were solicited for the interview study, but only 8 were able to participate.

Interview and coding

Interviews were conducted with program participants about 1.5 years after completion of the program. The 45-minute semi-structured interviews were conducted by the first author on Zoom. Interviewees were asked to share an instructional experience they had designed or modified after completing the training program. This paper focuses on their responses to 5 core interview questions: (1) Describe the instructional experience you created and the context for which it was designed or used. (2) Describe how you applied or adapted learning science concepts within this experience, if at all. (3) Describe how you used a design thinking process to create this instructional experience, if at all. (4) How does this instructional experience differ from the types of experiences you designed prior to participating in this program? (5) In what ways do you feel your teaching, instructional practices, or instructional design processes have changed because of your participation in this program, if at all?

Responses to questions were analyzed to examine our three categories of interest: transfer of instructional practices, changes to old instructional practices, and engaging in new learning. We then conducted open coding to create subcategories that exemplified the ways in which participants engaged in these adaptive practices. In addition, new unexpected categories emerged, such as broader changes to the teacher's sense of self and dissemination of the training program content to others. Two coders independently coded all participants' data for the categories in Table 1. After two rounds of coding, good reliability was achieved (kappa > .7). All disagreements were discussed and adjudicated.

Table 1

An Overview of the Coding Categories Used in Analyzing Participant Responses

Category	**Subcategory**
Transfer of Instructional Practices	*Application of a Learning Science Strategy in a specific activity/context*
	Application of a Design Process in a specific activity/context
Change to Instruction	*Less didactic* and more interactive instruction
	Simplify presentation of content (to reduce learners' cognitive load)
	New objectives/goals (for learners)
Changes to Individual	*Affective change* (growth in confidence, awareness)
	Growth as a teacher/learner (developing new perspectives, honing practices)
	Becoming part of a *community* of medical educators
New Learning	*Explicit learning* (reading education literature, taking a course in education)
	New educational work (educational committee work, editing an educational journal)
	Prospective learning (specific future learning goals and plans)
Dissemination	*Dissemination* of LSSs and DPs to other faculty, fellows, or residents

Results

Transfer of content

Participants engaged in a sizeable amount of substantive talk about the learning science strategies and design processes they were applying (see Table 2). On average, participants uttered 13 talk segments describing the application of learning science strategies (LSS) in their home teaching contexts and 12 talk segments on the application of design processes (DP). In addition, participants applied both of the DPs and an average of 7.5 different LSSs (out of the 15 they were taught) in their home teaching contexts. This is reasonable, given that we taught them a large set of LSSs with the intention of giving them a choice in adapting the strategies that are most appropriate for their contexts. Finally, participants described applying what they learned from our training in an average of 5 different contexts (e.g., teaching patients, designing medical school courses, presenting at conferences, mentoring residents, parenting, etc.). In fact, several participants reported transferring LSSs to quite distal contexts. For example, one participant applied LSSs to help her study for courses in her Masters program. Another critiqued the pedagogy in her child's school from a learning sciences perspective. All together, these data paint a picture of impressive transfer of both learning sciences and design content to a variety of contexts.

Table 2
Medical Educators' Transfer of Learning Science Strategies (LSS) and Design Processes (DP)

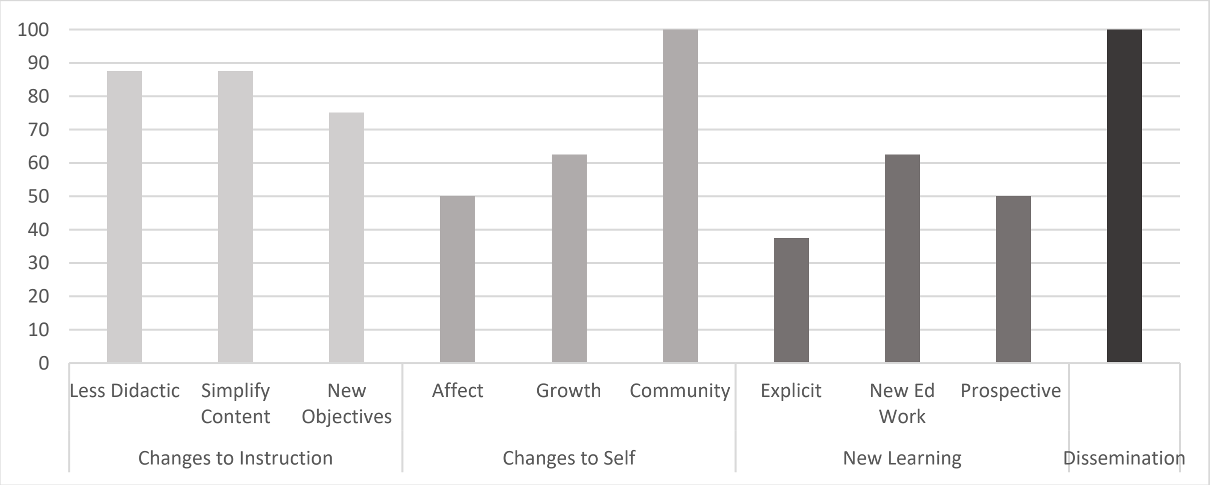
	# of LSS Application Talk Segments	# of LSSs Applied	# of DP Application Talk Segments	# of DPs Applied	# of Contexts Applied
Mean	13.1	7.5	12.3	2.0	5.1
Range	7-24	6-9	5-24	(no range)	3-7

Other adaptive practices

Participants also demonstrated significant engagement in other core adaptive practices, as shown in Figure 1. 100% of the interviewees described making changes to their instruction as a result of the program. Subcodes for types of instructional changes provide a window into the types of changes participants made to their instruction. 88% of participants made their instruction less didactic and more active and interactive. 88% streamlined the content they delivered to learners to avoid cognitive overload. Finally, 75% adopted new objectives for the learners they were teaching. For example, some participants reported a marked pedagogical shift from training students to remember facts and procedures to developing their critical thinking and transfer abilities.

In addition to changing their instruction, 100% of participants described changes to their broader sense of themselves as teachers. 50% reported affective changes, such as gaining awareness of and confidence in their teaching abilities. 63% described how they had grown as a teacher or learner. For example, some reported that their teaching had become more "organic and conversational," while others identified changes to the way they critiqued colleagues' lectures and presentations. 100% described how they became part of a larger community of medical educators and the myriad benefits this provided.

Figure 1
Percent of Medical Educators who Engaged in a Variety of Adaptive Practices



All but one participant (88% of the sample) described engaging in new learning in order to adapt. 38% of participants engaged in explicit learning, such as reading the medical education literature or attending professional development workshops. 63% took on new educational work that would continue to develop their expertise in education. For example, participants often took on educational leadership roles at their institutions (e.g., Associate Dean of Graduate Medical Education), joined education committees in oncology organizations, or volunteered to design new curricula. Finally, another 50% of participants had specific plans and goals around future learning they would undertake to improve their teaching.

It was surprising for us to learn that participants in our program were also helping others to adapt their teaching by disseminating the learning science content we had taught them. In fact, 100% of participants described disseminating learning science strategies to other medical educators. Several participants described teaching our learning science content to residents or fellows. Some participants designed instructional modules around the learning sciences strategies for an oncology website. One participant applied learning science strategies to redesign the whole feedback system for fellows at her hospital and trained 167 oncology faculty to use it.

Discussion

Effective educators are adaptive – they can flexibly adapt their practices for various learners and learning contexts and try new ways of teaching when old ways fail. However, being adaptive is challenging in any domain, and educators are no exception. Further, many professional development opportunities yield disappointing results, where educators fail to apply what they have learned in real-world settings.

In this paper, we describe an intervention that was explicitly designed to promote medical educators' abilities to adapt the learning science content we taught them. Medical educators reported fairly extensive transfer and adaptation one and a half years after the conclusion of our intervention. While our study was not designed to reveal which specific components of our intervention facilitated transfer and adaptation, we speculate that integrating design thinking was critical to the program's success. Design thinking may provide a process to supports educators in adapting their professional training for their personal contexts.

Another contribution is the development of new measures of transfer and adaptation. We used interview methods to uncover the unexpected and individualized ways and places where educators chose to apply their learnings, rather than assuming beforehand how and where they would adapt. In addition, our work provides an example of a successful intervention that promoted the dissemination of learning sciences research beyond K-12 education to medical education.

This research is not without limitations. Future research could gather causal evidence of the impact of our intervention, collect data on the interaction of learning science strategies and design processes, and create a design-focused training intervention for K-12 teachers.

Online Arts and Design Studios and Experiential Learning: A Review of Literature

Zi Lin, Yumiko Murai
anna_lin_3@sfu.ca, yumiko_murai@sfu.ca
Simon Fraser University

Abstract: In traditional arts and design studio education, experiential learning plays a crucial role. COVID-19 quarantine orders forced studio education into online spaces, challenging instructors' capacity to provide experiential learning. This literature review uses the seven key features of experiential learning by Moon (2004) to explore how experiential learning is supported in virtual arts and design studios. This paper asks how virtual arts and design studios leverage learning and communication technologies in online instructional and learning experiences. Our findings from articles published in the last 10 years highlight that a variety of factors influence the virtual studio teaching and learning experience, including digital literacy, course design, instructional adaptations, and sociocultural interactions. Implications and practical recommendations for researchers and educators who design virtual arts and design studio experiences are also discussed.

Introduction

In arts and design studio education, experiential learning processes play a crucial role (Senbel, 2012; Sutherland & Jelinek, 2015; Köylü, 2019). Arts education requires "time, studio space, and a context for self-directed learning" (Mottram & Whale, 2001, p. 98), and close interactions and feedback on students' artwork (Fleischmann, 2019). During processes like sketching, collaborating, critiquing, and engaging with art-related objects, art studios allow students to gain aesthetic knowledge through sensory triggers and sense-making (Sutherland & Jelinek, 2015). Experiential learning in studio education emphasizes constructing knowledge based on practical, observational, and reflective experiences; its key characteristics are sense-making processes and continually modified interactions (perception, cognition, and behavior) between self and environment (Beard & Wilson, 2006; Kolb, 2014). Kolb's (2014) experiential learning theory identified a spiral process with four linked elements: "concrete experience, abstract conceptualization, reflective observation, and active experimentation" (Kolb, 2014, structural foundations of the learning process, para. 8). Drawing from Kolb's learning spiral and diverse literature on experiential learning, Moon (2004) posits seven key features of experiential learning: "1) is not "being taught"; 2) happens through direct experiences; 3) is an empowering way to gain knowledge; 4) involves reflections, 5) involves actions (making, doing, experimenting); 6) involves mechanisms of feedback, 7) includes a formal intention of learning" (p. 120) (see Table 1).

Table 1
Experiential learning features used for evaluation. (Wording modified by the authors for clarity).

	Features	Description
1	Experiential learning is not through "being taught"	It is about not merely the instructional process, but also guidance for what should be learned.
2	Learning happens through direct experiences	The material of learning is from experience.
3	Experiential learning is an empowering way to gain knowledge	Consider the overall functioning of an individual, including emotional, intellectual, and sensory aspects.
4	Experiential learning involves reflections	A deep approach to learning links new learning materials with previous experience and knowledge.
5	Experiential learning usually involves actions	Environment provides opportunities for teachers/students in active phases of learning (making, doing, experimenting).
6	Experiential learning involves mechanisms of feedback	Offer feedback that summarizes the learning outcomes.
7	Experiential learning includes a formal intention of learning	Deliver learning activities consciously and with specific intentions.

COVID-19 quarantine orders forced studio education into virtual spaces, posing challenges and affecting learning and instructional experiences. For instance, online studios differ from physical studios when it comes to sensory triggers and sense-making processes. While recent lifting of restrictive measures prompted many arts and design studios to return to on-site learning, online studios will remain a viable course delivery alternative because of recent acceptance and implementation of distance and hybrid learning strategies (Ceylan, Şahin, Seçmen, Somer & Süher, 2021). It is therefore necessary to review empirical studies of online studios to gain a deeper understanding of how experiential learning theories are supported and how pedagogic design strategies can be applied in online arts and design studios.

Research questions

To sustain the value and essence of studio education in virtual environments requires technology integration and experiential learning experiences in online studios. This literature review explores course delivery approaches and experiential learning theories reflected in online arts and design studios, and asks the following research questions: (1) What are the learning technologies and strategies used in online art and design studio classes? (2) How are experiential learning experiences supported in online arts and design studios?

Methods

In our literature review, we analyzed articles published over the past ten years (2011-2021); using a two-stage selection approach. We conducted the initial keyword search in 15 popular journals specifically associated with arts and design education, and the second keyword search within more comprehensive databases (JSTOR, ProQuest, ERIC) to identify existing research on online studios not covered by the specialized journals. The selection of these databases was based on wide use and inclusion of comprehensive art and education-related articles. Each of the selection stages involved two screening phases, conducted October 2021. Keywords included “Online Art Studio” OR “Distance Art Studios” OR “Online Education Art Studios” OR “Virtual Online Art Education” OR “Online Design Studios” OR “Distant Design Studio.” Disciplines were limited to Arts and Humanities, and Education. We limited our keywords search to title and abstract, and to peer-reviewed journal articles published in English. As a result, we identified 691 journal articles on the first screen phase through title and abstract review. In the second phase, we found 11 articles that met the inclusion criteria. We assessed experiential learning affordances in these articles to identify the presence of the seven experiential features (Moon, 2004) of online learning.

Results

The instructors of online arts and design studios integrated synchronous (e.g., Zoom, Microsoft team, and Blackboard), asynchronous (e.g., itslearning), social media (e.g., YouTube, Vimeo), geolocational (e.g., Google Earth), and communication tools (e.g., WhatsApp) in their teaching. Commonly reported benefits of online arts and design studios in these papers included flexibility (e.g., review of course materials at preferred time and location) (Marshalsey, 2020; Fleischmann, 2019), capacity to support in-depth learning (e.g., review recording) (Ceylan et al., 2021; Alawad, 2021), possibility to save travel time and reduce late arrival (Alnusairat et al., 2021; Alawad, 2021; Marshalsey, 2020; Fleischmann, 2020), reduction of energy consumption from campus utilities (Alnusairat et al., 2021), and opportunity for global collaboration (e.g., specialists located in geographically diverse locations) (Varma et al., 2021; Makemson, 2021).

The articles pointed to several challenges of online arts and design studios. Firstly, the online studio lacks a sense of belonging (e.g., distant feelings) (Marshalsey, 2020; Alawad, 2021). Secondly, working in an online studio may lead to cognition issues (e.g., difficulty focusing on video content) (Fleischmann, 2019; Fleischmann, 2020; Marshalsey, 2020). Thirdly, online studios may lack instructions and mediation tools. Makemson (2021) proposed that online studio learning requires less cognitive load and centers attention when learners have experience with a digital platform; a lack of prior knowledge may demotivate students, affecting their learning (Amro, 2021; Marshalsey, 2020). Further, because textures, materiality, and scale of art and design are difficult to display through digital formats (online images, videos), studio classes needing special resources and experimentations cannot be fully transferred into an online format.

Our study gathered student and instructor feedback from selected articles and investigated their match/mismatch with Moon’s (2004) seven experiential learning features. Two studies fulfilled the first criterion, *experiential learning is not through “being taught”* (Alnusairat et al., 2021; Makemson, 2021). Participating students stated online arts and design studios enabled them to conquer weaknesses and fears: “I bec[a]me more responsible about my design, as online learning gave us the opportunity to rely more on ourselves” (Alnusairat et al., 2021, p. 229). Makemson (2021) explained that technology-mediated tools and interactive digital platforms would facilitate students’ self-navigation of knowledge without teacher intervention. For the second criterion, *experiential learning happens through direct experiences*, one study thoroughly reflected the theory of experiential learning (Amro, 2021), finding that participating instructors encouraged students to connect their direct experiences and feelings of the pandemic to their design projects. In the end, the creativity in those projects exceeded teachers' expectations (Amro, 2021). Two articles fulfilled the third criterion, *experiential learning is an empowered way to gain knowledge* (Amro, 2021; Fleischmann, 2020). In Amro's (2021) study, teachers recognized students' emotional states within online contexts. To motivate and help students overcome negative emotions, teachers changed methods of teaching and communicating using digital tools. However, Fleischmann (2020) found students "need physical classes to motivate [themselves]" (p. 46). Those students emphasized that taking classes on-site enables them to stay focused and self-disciplined. For the fourth criterion, *experiential learning involves reflections*, some participants in the articles believed physical studio classes provide better interaction for students to become "reflective practitioners" (Fleischmann, 2020, p. 49); while others believed easy and flexible communication and collaboration in online studios would facilitate student reflections on peer feedback (Fleischmann, 2019). For the fifth criterion, *experiential learning usually involves actions (making, doing, experimenting)*, some studies noted that physical studios easily provide opportunities for unstructured activities, whereas this can be difficult for online arts and design studios (Ceylan et al., 2021); others found students' unwillingness to share their work with groups online may diminish learning outcomes in the long run since they have fewer opportunities to practice (Fleischmann, 2019). For the sixth criterion, *experiential learning involves mechanisms of feedback*, authors commented that some students preferred not to take design online because it was hard to keep up with content; however, physical studios allow iterative in-person interactions and fortuitous encounters (e.g., non-visual cues), two crucial elements for studio education (Varma et al., 2021). Other students appreciated the speed of communication and feedback received from the online studio (Fleischmann, 2019). For the seventh criterion, *experiential learning includes a formal intention of learning*, the articles revealed mixed results. Some studies revealed intentions of learning were missing: in on-site studios, these are usually presented at the beginning of the year (Alnusairat et al., 2021), while other studies stated their virtual studio posted a pre-planned assessment sheet online and presented it during a synchronous meeting (Fleischmann, 2019).

Discussion & conclusion

This literature review explored technologies adopted in online studio classes with student and teacher perspectives and reviewed how the seven experiential learning features (Moon, 2004) were supported in selected articles. Examining these articles through a lens of experiential learning theory, we found that a significant portion discussed student learning outcomes, student and teacher perspectives about key components of studios (iterative feedback, interactions and collaborations), and motivational aspects in online studios. Teachers and students offered mixed feedback about their online studio experiences. For example, Alawad's (2021) study found that freshmen in design majors prefer online over on-site learning compared to their senior peers. However, Amro's (2021) study found that freshmen experienced a higher level of anxiety due to inexperience with online creative and communication technologies, and that more fourth-year students preferred to continue their studio courses online. Studies also found that students who offered positive feedback about online learning usually already had previous online or blended learning experiences (Fleischmann, 2019).

Overall, online technology has permanently changed the way design and art education is taught through studio-based learning; and the advancement of digital technologies and networks has accelerated the transfer of knowledge from master to apprentice (Dreamson, 2020). However, the review of articles in this study indicated that the use of fully online studios is still in the testing phase and that digital literacy plays an important role in the experience of students and teachers in online studios. Online studio educators are exploring and experimenting with instructional technologies to replicate the sense-making, sensory trigger, and collaboration experiences that may occur naturally in on-site studios. To facilitate this process, teachers would benefit from implementation standards and guidelines based on experiential learning theory. Further, training for instructional technology prior to modification of the course would assist teachers in establishing online space that cultivates a collaborative culture and enhances sense-making experiences. Additionally, positive learning and teaching experiences are not based merely on the particular type of instructional technologies, because "technologies themselves do not determine social behaviors" and interactions (Smirnov, Easterday & Gerber, 2018, p. 593), one of the core characteristics of studio experiential learning. Studio experiences can be influenced by how course modules are designed (e.g., the length of an online video, the speed of feedback for students), how teachers manage classes (e.g., how teachers consider students' emotional factors, adaptations of teaching styles in virtual environments), and sociocultural interactions between teachers and students facilitated by educational technologies (e.g., the formation of a learning community and culture online). One study, for instance, included partial instruction through pre-recorded video lectures, and reported that students found it challenging to engage and learn without immediate feedback from instructors (Fleischmann, 2020). Another study revealed that one fifth of participating students found it difficult to express their ideas through digital tools without manual drawing or physical materials, while two thirds of students found online communication difficult and felt teachers disregarded their mental health

(Alnusairat et al., 2021). These students' reflections suggest that even though digital technology enabled virtual studios (e.g., pre-recorded video lectures, distance communication), its complexities present additional challenges to instructors, including how and when to use these technologies. Instructors should make informed decisions regarding which parts of the courses can be delivered via pre-recorded videos (e.g., where less feedback and interaction are required), which time is optimal for providing virtual support, and which types of web-based activities and platforms should be established to facilitate peer-support and virtual collaboration. When designing online studio pedagogy, instructors should consider technologies that facilitate self-exploratory learning, student motivation, and reflection during and after class. Future studies should further explore how the interaction of online communication technologies and instructional design can best support the social and cultural experiences of online studio learners.

Identity Play: Nonlinear and Agentic Aspects of Middle School Youths' Self-Making

Heidi B. Carlone, Vanderbilt University, heidi.carlone@vanderbilt.edu
Alison K. Mercier, University of Wyoming, amercier@uwyo.edu

Abstract: Identity development has been described as a process of *identity regulation*—structural arrangements that act to govern and shape people's identities—and *identity work*, which includes people's responses to identity regulation. While identity regulation emphasizes structural aspects of self-making, and identity work emphasizes a structure/agency dialectic, we consider a third construct called *identity play*, which emphasizes the agentic, nonlinear aspects of self-making. This is a grounded study of youths' identity play as they engaged in out-of-school, integrated STEM programs focused on environmental problem solving across three years. We outline features of identity play, illustrate what characterized it, and resources youth leveraged to do it with the cases of Mirabel and Josue.

Introduction

In schools, growth and learning are often considered with a measurement paradigm that assumes linearity. Educational research can also be guilty of this– from scores on standardized tests to measurements on Likert scale surveys, success is often defined with descriptors like *more*, *better*, *stronger*, and *higher*. Even a sociocultural lens implies that increased access, opportunities, and engagement will more likely lead to fuller participation and learning (Wenger, 1998). Qualitative and design-based studies of learning can also invoke a traditional growth paradigm, framing problems with scarcity or deficit lenses and positioning educational interventions as *fixing problems*. The assumption is that as participants experience a successful design or intervention, they develop "more"—e.g., more facility with a learning community's practices, have more knowledge, and/or are more affiliated with a learning community. We can apply this critique to our own work. This study takes a different approach. We studied middle school youths' identity development over two to three years as they participated in out-of-school learning focused on environmental problem solving. As we tracked their identity work over time, we noticed their identity work as playful, unpredictable, and nonlinear. This paper presents a grounded theory of STEM *identity play* to understand youths' self-making that occurs in nonlinear and less directional ways. The work builds on scholarship in organizational studies that introduced identity play (Ibarra & Petriglieri, 2010). Our research questions include: How do youth engage in identity play? What resources do they draw on to do so?

Conceptual framework

Wayfaring

Wayfaring informed our understanding of the nonlinear nature of identity play (Ingold, 2007). Wayfaring is the idea that experience is a journey that moves along paths of travel. A person travels these paths in starts and stops, "moving hither and thither" (p. 81), pausing here and there, before moving on with "no beginning or end" (p. 167). In this view, a journeyer travels lines that are "winding and irregular" (p. 81), revisiting old paths, looping into paths not yet traveled, all the while paying attention to their environment. While the middle school youth did not show such free-wheeling wayfaring, we were inspired to think of their engagement over time as experimental and less constricting than science that is more narrowly construed. Normative views of disciplinary identity development implicitly draw on milestone metaphors, which distort the adaptation, flexibility, and diversity of the ways youth grow, learn, try on and try out ways of being (Gallacher, 2017). Wayfaring is juxtaposed with the notion of transport, which is traveling from point A to point B. A wayfaring adolescent engages their environment and charts their own paths, emphasizing more agentic and playful imagery, and respects youths' individuality.

Self-making

We view the endeavor of identity development as "self-making" because it emphasizes the active processes of becoming somebody in and across settings as well as the multi-pronged nature of identity development. Self-making has also been used by Bruner (2001), but in a different way than we use it here. Identity studies have largely emphasized two primary elements of identity development– identity regulation and identity work. *Identity regulation* emphasizes structural and sociopolitical dimensions of self-making, or the parameters that shape meanings of legitimacy, competency, and belonging (Alvesson & Willmott, 2002). In other words, identity regulation is about the disciplining of subjects (Foucault, 1977). *Identity work* comes about when people navigate structural constraints of a setting, institution, or discipline (Varelas et al., 2015). The more tightly guarded the boundaries of the insider identity, the more challenging the identity work, especially for Black, Brown, and Indigenous youth (McGee, 2020). The focus on the structure/agency dialectic in identity studies emphasizes self-making as a negotiation between self-authoring and others' positioning. Identity work recognizes the struggle to become someone. We came to understand *identity play* as emphasizing the more agentic side of self-making, enacted for different reasons, prompted by different kinds of activity, and involving different kinds of negotiations (Table 1). In analytically separating identity work and identity play, we do not claim that identity play does not involve structural dimensions, nor do we claim that identity play happens without identity work. We argue that the identity play lens helps us see and understand the youths' self-making differently than if we considered identity play as a part of identity work. Identity play is a process involving: 1) playful self-discovery in trying on new performances and narrations of self; 2) imaginative engagements that deviate from expectations or self-understandings (Fachin & Davel, 2015); 3) exploration of possible selves (Markus & Nurius, 1986).

Table 1
Identity Work Versus Identity Play

	Identity Work	Identity Play
Purpose/ Telos	To be considered competent in a group; to belong; directed towards more central participation	To pursue individual curiosities; just for fun; nonlinear and wayfaring (Ingold, 2007); not always predictable or sticky
How	Engagement and proficiency in social practices deemed relevant for membership	Working in new spaces and/or outside of one's comfort zone; horizon-expanding
Negotiations	Negotiation of prior/desired selves with governed self; can be contentious, a struggle	Loosening up of pre-conceived notions of self; can be scary, joyful

Methods

BRIDGES focused on environmental problem solving for middle school youth in the southeastern United States. The program's framework highlighted the multifaceted nature of STEM and youths' identities. We considered multiple ways to engage environmental problems which included: altruism, conservationism, investigating, inventing, tinkering, and designing. We used these categories for curricular design and as a research heuristic. We introduced the terminology to youth as STEM profile categories; we gave them multiple opportunities throughout the program to name and discuss their affiliation using these categories. The categories were not used to stamp youth with labels. We used them fluidly to build a common vocabulary. As Wenger (1998) explained, some reification is necessary to narrate and reflect on one's own identity development. BRIDGES consisted of Saturday Academies, a Summer Institute, and after-school STEM clubs. Forty middle-schoolers participated in two or more BRIDGES programs. Twenty-one identified as female, 19 identified as male. Fourteen youth identified as Black, 10 as Latinx, five as multiracial, and 11 as white. We describe cases of Mirabel and Josue because their cases illustrate different ways of engaging identity play, and their social positioning differed.

We interviewed youth at the end of each BRIDGES program and then one or more years after their last participation. We took fieldnotes, video recordings, and audio recordings during all BRIDGES activities. Interviews included a card sort that asked youth to identify their affiliation STEM profile categories during BRIDGES activities. Following the creation of radial graphs (Figure 1), we analyzed video and interviews with Mirabel and Josue, coding for identity play using markers outlined in Table 1. These data allowed us to focus on youths' narrated identity play and identity play in practice. Informed by grounded theory (Charmaz, 2014), we created assertions which we tested out with additional empirical data through saturation.

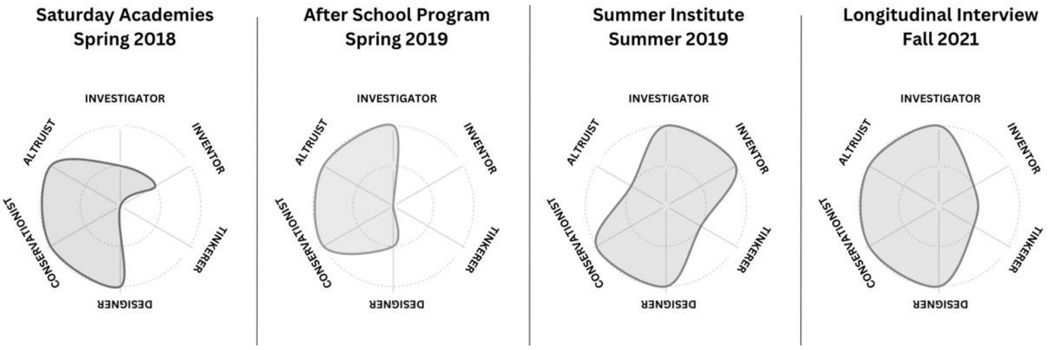
Findings

Mirabel

Mirabel had an easy, kind, joyful, confidence about her—she was outgoing, upbeat, and presented herself as comfortable in most social and academic settings, with peers and adults. Mirabel was academically successful; she skipped eighth grade so that she would have access to more academically challenging courses. Mirabel nearly always engaged fully in activities; she used opportunities she was given to perform herself in multifaceted ways. Socially, she could be silly, mature, serious, fun-loving, and kind. Using the STEM profile categories as markers, she consistently affiliated as a conservationist, usually an altruist and designer, only sometimes and somewhat an inventor and tinkerer, and affiliated as more of an investigator over time (Figure 1). The radial graph depiction is simply *beginning* evidence that there was some unpredictability happening with her self-making over time, which we explored further with analysis of interviews and video.

Figure 1

Mirabel's Identity Play Over Time



Note. The graphs depict how Mirabel narrated her affiliations with the STEM profile categories, in interviews, over time. Points on the outside of each graph indicate those she narrated as "very much like me," middle points are "somewhat like me," and the graph's center indicates "nothing like me."

When Mirabel discussed what she liked about BRIDGES, she described a version of wayfaring: "You never knew what you were going to do next….it was always just so exciting and so surprising… it was so diverse, so beautiful. It was so inspiring… a new way of looking at STEM every day." Her quote indicates going with the flow, with no immediate goal or purpose other than to enjoy. As indicated by wayfaring, she attends to and appreciates the journey. The unknown was not anxiety-producing, but exciting.

She enjoyed discovering new things about herself, demonstrating a typical purpose for identity play. For example, Figure 1 indicates a growing and shrinking affiliation with inventor. She viewed the makerspace in the Summer Institute a place to try out her inventor self. With friends, she developed an app to "help visitors in the park" by providing "information and presentation ideas about what to wear and even what to do if you find something dangerous" like poison ivy, ticks, and venomous snakes. Two years later, she reflected on how she "grew into" being more of an inventor in the makerspace. "I had a lot of fun with that, being an inventor. I did a lot of that that week...I had to create solutions and fix problems." It was perfectly fine with her that the inventor identity did not necessarily stick over time: "Even if [inventor] didn't become my big one, I got more into it." Unlike identity work, which can be higher stakes, she playfully tried out her inventor self.

Mirabel leveraged several resources to engage in identity play without visible constraint or struggle. She had a comfortable social position in BRIDGES; peers liked and respected her and often followed her lead in trying new things. This was an identity-affirming space. She leveraged comfortable identity performances when trying out new identity performances. For instance, her consistent affiliation with the altruist and conservationist categories ("I was already a person who cared about people and the environment") may have been a resource to persist with engaging with the invention and tinkering while developing the app. This activity also involved a lot of investigation. When working in the makerspace, she asked to go on nature walks with peers and a naturalist to explore the park so that she could recognize dangerous flora.

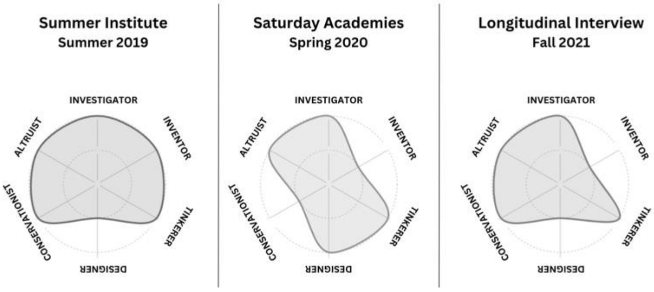
Josue

Josue was jolly, affable, and good-natured, describing BRIDGES as "a fun production." A self-identified Latino male, he described himself as "the volunteer guy" and "the social guy" who was open to anything new. "It was part of me that said, 'Try everything.'" Josue was not self-conscious— "It don't matter what people think." Figure 2 shows Josue consistently narrated himself as a tinkerer and altruist and sometimes as a strong conservationist, designer, and investigator, and inventor. All his interviews emphasized BRIDGES's influence on his love of and curiosity about animals in their natural habitats, helping peers, trying out new things, and having fun. He positioned Dr. M., a herpetologist, as his "best friend during that camp." He went with Dr. M. on optional field studies in afternoons and later arranged a visit to her property with his family during salamander mating season.

He explained BRIDGES as a good fit for "people who haven't done lots of things, people who need bonding with people" and "scared people who need to conquer their fears," which points to the horizon-expanding spaces we created for youth to try out new ways of being. In interviews, Josue talked at length about his learning, details about his experiences, and supplied multiple examples of each identity category and the ways he "got to be" an inventor, investigator, and so on. He appreciated an activity where youth chose "identi-beads" to represent their engagement because "the beads were a reminder of how you can be different things every day." Identifying his first frog call and catching a toad, he said, was "where my life really actually changed a little." His interviews and his uninhibited engagement were replete with examples of identity play. Resources that encouraged his identity play included: 1) embodied learning—like a frog peeing in his hand, the night hike, and holding a toad "turn into memories you…keep forever"; 2) his desire to try anything; 3) his affiliation with Dr. M.; and 4) his lack of self-consciousness—"A STEM-Y person doesn't care about getting dirty… just goes out there and tries."

Figure 2

Josue's Identity Play Over Time



Significance

First, identity play is an expansive construct. While our data show that we cannot expect identity play in spaces that are not also identity affirming, they also demonstrate the value and productivity of identity play. Second, the construct of STEM identity work has been dominant in science education, include our own scholarship. Identity work emphasizes the dialectic between structure and agency, often directed toward understanding the ways youth "become scientific." While our data clearly show the importance of context (structure) in prompting identity play, a focus on identity play allows us to pay attention to youths' multi-faceted, unpredictable, playful selves when they work beyond their comfort zones. Considering identity through a playful lens, one that highlights self-discovery rather than goals and endpoints, gives the field a nuanced and fluid account of self-making.

Abstract: This paper presents preliminary findings of a phenomenographic study on a youth forum on intangible cultural heritage (ICH) in Luang Prabang (LPB), Lao People's Democratic Republic. Youth members participated in workshops for finding community-centred innovations for ICH. They formed a community of practice (CoP), collaborating closely with local cultural bearers. Preliminary phenomenographic findings of their collaborative learning experience presented in an outcome space reveal that youth members can be motivated to safeguard threatened cultural practices. Mapping the qualitatively different ways in which youth members experience learning about safeguarding ICH makes this study relevant for understanding a youth's participation in a CoP involving ICH.

Introduction

The inscription of Luang Prabang (LPB) as a United Nations Educational, Scientific and Cultural Organization (UNESCO) World Heritage site initiated a tourism boom that threatens its cultural heritage (Dearborn & Stallmeyer, 2009). Efforts to preserve tangible heritage sites at the expense of neglecting cultural practices or living heritage bear the risk of turning heritage sites into spaces devoid of their original social and cultural significance (Reeves & Long, 2011). Safeguarding intangible cultural heritage (ICH) has social benefits for communities, e.g., some cultural practices can enhance an individual's sense of belonging and identity (Shaharuddin et al., 2021). Maintaining and revitalising cultural expressions in LPB upholds the cultural identity of its inhabitants. This paper presents preliminary qualitative research findings on a 2.5-month-long youth forum in LPB, implemented by the United Nations University Institute for the Advanced Study of Sustainability in collaboration with UNESCO Bangkok and the Traditional Arts and Ethnology Centre (TAEC). The forum was designed to engage youth members on the human-centred design process in combination with ICT, offering sessions on ICH, design thinking, digital storytelling, and research ethics. This paper aims to 1) provide a phenomenographic analysis of the collaborative learning experience of one youth group and its selected culture bearer, and 2) present their experiences in an outcome space that illustrates the structure of the varied qualitative categories of description. It is guided by the research question: How can the empirical collaborative learning experience of youth members in a community of practice (CoP) on ICH be represented in a phenomenographic outcome space?

Literature review

Living cultural heritage can be defined as "the practices, representations, expressions, knowledge, skills … that communities, groups and … individuals recognise as part of their cultural heritage" (UNESCO, 2020). Thus, communities are integral in safeguarding local ICH. The theorisations offered by Wenger and Lave on CoPs will be applied as the general theoretical framework for the present study because it explains the structuring elements of social learning systems. Learning in a CoP is inherently social. Learners absorb and become absorbed in the culture of practice, which increasingly provides them with occasions to make the culture of practice their own (Lave & Wenger, 1991). Wenger and Snyder (2000) define CoPs as "groups of people informally bound together by shared expertise and passion for a joint enterprise" (p. 139). McKellar and colleagues (2020) argue that extra-organisational CoPs have not received much evaluation attention from scholars. Additionally, several studies point out that the participants of a CoP are instrumental in an assessment. For Mbassegue and Gardoni (2018), participants are core elements in terms of evaluating the outcomes of a CoP because it is the participants who generate knowledge. The benefits of a CoP can be described as an impact on participants, so frameworks to assess CoPs must favour the participants' points of view. However, the individual level as a unit of analysis presents a gap because methodological processes to assess CoPs have not taken individuals into account sufficiently. Jang and Ko (2014) stress that an individual member can significantly influence an organisation, e.g., when a member's unique knowledge enters the knowledge repository of a CoP. Moreover, the sense of identity of participating individuals is a critical factor for a CoP to reach maturity (Boughzala & Bououd, 2011).

For Wenger, learning takes place in the interplay between the ‘competence’ established in the community and the ‘experience’ of an individual. “Learning … is an interplay between social competence and *personal experience*” (Wenger, 2000, p. 227). Furthermore, CoPs “grow out of a convergent interplay of competence and *experience* that involves mutual engagement” (Wenger, 2000, p. 229) where practitioners of a CoP share an experience. Similarly, for Lave, learning is neither purely subjective nor purely within social interaction. Instead, “learning is recognised as a social phenomenon constituted in the experienced, lived-in world” (Lave, 1991, p. 64). Therefore, the individual experience of youth members participating in a CoP for ICH safeguarding is the entry point of the present study. We ask: What are the youth members’ experiences participating in a CoP and learning from a culture bearer in LPB? We hypothesise that examining these experiences will contribute to crucial knowledge about subjective concepts and understandings of youth members on learning ICH in their local community. A qualitative phenomenographic analysis is deemed an appropriate methodology for the present study because 1) it analyses the learning experience of the youth members with a culture bearer of their community, presenting their qualitatively varying experiences as categories of description, and 2) it allows said categories of description to be presented in an ‘outcome space’ that illustrates how individual categories are related to each other. Outcome space is a product of phenomenographic study. It is a “complex of categories of description comprising distinct groupings of aspects of the phenomenon and the relationships between them” (Marton & Booth, 1997, p. 125).

Methodology

Youth forum design

Twenty-five youth members between the ages of 14 to 31 took part in the youth forum, which consisted of hybrid workshops on weekends, and had a total of 41 hours. The youth members formed five groups, carrying out project group work, research, and fieldwork on weekdays. Each group selected a cultural practice and sought a 'culture bearer'. Here, ‘culture bearer’ refers to a person who is deeply knowledgeable about a particular living heritage, and has mastered its expression through many years of practice. The groups collaborated closely with their selected culture bearer(s) by researching their ICH; leading discussions on issues affecting its vitality; video recording interviews with the culture bearer; and designing an innovative solution to support or revitalise the ICH with the feedback and approval of the culture bearer. Final presentations included: 1) a documentary-style video to showcase their group’s working process; 2) introducing an innovative solution for their ICH.

Data collection and analysis

In total, twenty-four participants took part in a semi-structured post-interview. This is an analysis of the answers provided by five youth members of the “Elephant group” to a specific question of the post-interview protocol. The group was chosen because of the cultural practice they selected. Among the four living heritages of the forum, the oral practice of recital reading represented the most threatened one: Due to weakened practice and transmission, extremely few cultural bearers are left. Youth members remain anonymous, and all names are pseudonyms. Group members were: Mandis (F), Faani (F), Vandi (F), Sonbha (M), and Somchai (M). The analysed question of the interview protocol is: “What did you learn from your culture bearer, or what did they learn from you in the past two months in this forum?” Their responses were transcribed, translated from Lao into English, and subsequently analysed following the phenomenographic approach to find the qualitatively varied ways of experiencing a given phenomenon (Ornek, 2018). This approach draws on the assumption that “each phenomenon, concept, or principle can be understood in a limited number of qualitatively different ways” (Marton, 1986). The collected data was analysed iteratively to identify and describe ‘categories of description’ (Ornek, 2008). For presenting the results in an outcome space, the categories of description were set in relationship to one another to illustrate their structural relationship. Research shows that the outcome space can be structured, e.g., through diagrams, tables, or illustrations, depending on how the categories' relationships are mapped out (Han & Ellis, 2019). This study’s outcome space is represented below in Figure 1.

Findings

Members of the Elephant group did not know each other before joining the forum. They discovered that traditional LPB recitation was rare: “it was only in old videos, and not many people knew it, so we decided to choose it” (Somchai). They scouted for a recitation culture bearer, but most lived far away. Vandi asked her father, who suggested “Auntie Khamyai” from nearby Don Mai village. The youth members reported the threats to be the diminishing interest of younger generations and misunderstanding of its content and meaning, which consists of advice and instruction about the roles of husbands and wives. The group decided to use social media as a tool for awareness raising. Three categories of description emerged from the iterative coding of the interviewees’ answers.

Lack of interest of youth members

Faani reported that the culture bearer "was very happy that we were interested in recitation and interviewed her *because there were not many people interested in it, particularly young people,* who had less interest in this practice." Similarly, Somchai mentioned that many students were unaware of this cultural practice.

Self-awareness about new knowledge and reflection on the culture bearer's new knowledge gained

All group members talked about learning something from Auntie Khamyai, with variations about what new knowledge was acquired. For example, Mandis, Faani, Sonbha, and Somchai related their new learning to Lao culture, history, and recitation techniques. Sonbha gave a representative sample: "We learned background and history, skills and techniques of the recitation. Auntie Khamyai also told us that there are many cultures or songs … that are new knowledge for us." Vandi reported learning about the resilience of the culture bearer to keep practising recital readings, saying: "I learned from Auntie Khamyai that she always believed in and had a passion for this culture and that it could turn into a job. So, I learned that we shouldn't leave our passion and belief." Additionally, three youth members reflected on what they believed Auntie Khamyai learnt from them. Two mentioned her learning as being related to social media, whereas a third generally spoke about having conveyed to her the ways of thinking of young people.

Aims after the youth forum

Interestingly, three youth members revealed their plans to visit Auntie Khamyai after the conclusion of the youth forum. Two explained their plans to spread information to raise awareness. Sonbha specifically mentioned using social media platforms: "we plan to post it on social media sites like YouTube and Facebook so that not only Laotians but people around the world will see it."

Discussion and conclusion

In the outcome space, the relations between the categories of description can be interpreted as causal, where one category causes the existence of the other (see Figure 1). For example, reading the outcome space can begin with the category "Lack of interest of youth members". The disinterest of younger generations caused the Elephant group to select this ICH practice. Learning from the culture bearer made them realise their own lack of knowledge and identify what new knowledge they gained. Three of five group members perceived the culture bearer to have also learned from them. This collaborative learning motivated the youth members to continue advocating for raising awareness on recitations even after the forum, to counteract the lack of youth interest. This causal relation is illustrated as a circle arrow process (see Figure 1).

Figure 1

Circle Arrow Process Illustrating the Outcome Space

Phenomenographic data of the Elephant group has implications for understanding how youth members experienced collaborative learning of ICH in a CoP at an individual level. All group members reported having experienced a learning gain. The fact that the categories of description can be set in a structure of causality suggests that some youth members can be driven to learn about a cultural practice despite its low vitality. For example, the lack of interest among young generations challenged the Elephant group to learn more about a little-known cultural expression in their community. Rather than being put off by this cultural knowledge gap among their peers, they were compelled to know more about it and spread awareness. Their interviews revealed that: they learned more about recital readings during the youth forum; they realised that also they lacked knowledge about it; they set new knowledge in the context of their local community history, thereby identifying with it and appreciating it as new knowledge about their language and culture; they perceived their interactions as teaching the culture bearer as well. These experiences motivated them to pursue awareness-raising activities among others.

For the Elephant group, participating in a CoP involving ICH was a possibility to learn about a little-known living heritage of their community. The group's individual members are core elements of the CoP and are directly impacted by their participation. Phenomenographic insights into their qualitatively different experiences represent a unit of analysis of the CoP at an individual level. Summarised in an outcome space, these experiences imply that the low vitality of a cultural practice is not necessarily a barrier to youth members' attempts at safeguarding a cultural practice. It is empirical evidence that youth members can be driven to safeguard ICH among their peers if their experiences in the CoP: enhances their sense of local identity; leads them to recognise the value of cultural knowledge; results in collaborative learning between themselves and a culture bearer; challenge them to find innovative solutions. Methodologically, the present study shows that phenomenographic insights into an individual's experience in a CoP involving ICH contribute to understanding how CoPs can enhance collaborative learning for a cultural practice, especially those threatened by weakened practice and transmission.

Abstract: This study takes advantage of advances in Natural Language Processing (NLP) to build an idea detection model that can identify ideas grounded in students' linguistic experiences. We designed adaptive, interactive dialogs for four explanation items using the NLP idea detection model and investigated whether they similarly support students from distinct language backgrounds. The curriculum, assessments, and scoring rubrics were informed by the Knowledge Integration (KI) pedagogy. We analyzed responses of 1,036 students of different language backgrounds taught by 10 teachers in five schools in the western United States. The adaptive dialog engages students from both monolingual English and multilingual backgrounds in incorporating additional relevant ideas into their explanations, resulting in a significant improvement in student responses from initial to revised explanations. The guidance supports students in both language groups to progress in integrating their scientific ideas.

Introduction

Students develop heterogenous, valuable, evidence-based, and fragmented ideas from experiences in their family, culture, and daily routines (diSessa, 1988). Research shows that students are more likely to develop coherent understanding and appreciate the relevance of science to their lives when their ideas are respected (e.g., Basu & Calabrese-Barton, 2007; diSessa, 1998, Linn & Eylon, 2011). In particular, the rich ideas and arguments of students from non-dominant linguistic backgrounds are often overlooked or rejected (Bang & Medin, 2010). This research is a partnership with teachers and schools that serve students from varied linguistic groups. We take advantage of advances in Natural Language Processing (NLP) to build an idea detection model that can identify ideas expressed by students from distinct linguistic backgrounds (Lison et al., 2020).

Prior research shows that human guidance using dialog structures supports students to use strategies to discriminate between ideas and develop coherent and accurate scientific explanations (e.g., Chi et al., 2017). Research using web-based classroom instruction has demonstrated the benefits of adaptive knowledge integration guidance for strengthening students' science explanations (Gerard et al., 2015). Engaging students in explaining scientific phenomena in familiar contexts, encourages them to connect their ideas from prior experience with ideas from science instruction. Yet, ensuring that instruction responds to the varied ideas students develop about familiar contexts requires diligence. Using NLP idea-detection models embedded in a web-based inquiry environment, we identify the science ideas each student expresses and engage the student in an adaptive dialog. An avatar encourages each student to analyze the evidence underlying their detected idea, generate new ideas to deepen or refine their initial ideas, and integrate their ideas into a revised explanation (Linn & Eylon, 2011). The curriculum, dialog, assessments, and scoring rubrics in this study were informed by the Knowledge Integration (KI) pedagogy (Linn et al., 2014). We investigate whether adaptive, interactive dialogs similarly support monolingual English and multilingual students to revise and improve their science explanations. We examine the effectiveness of the idea detection rubrics for helping students' build on diverse everyday experiences. We study how the dialogs support each student to develop their understanding of scientific phenomena. Specifically, we ask, how does an adaptive dialog based on an NLP idea detection model, impact monolingual English and multilingual students?

Methods

Participants

We analyzed responses of 1,036 students taught by ten teachers in five schools in the western United States. Students were in 6th (20.3%), 7th (38.4%), and 8th (41.3%) grade. Students who reported that they speak mostly or only English at home were categorized as "monolingual English speakers" (58.1%). Students who reported never speaking English, mostly not speaking English, or speaking both English and another language at home were categorized as "multilingual speakers" (41.9%). The data do not include information about specific languages.

KI diagnostic inventory

Students explained scientific phenomena while responding to a diagnostic inventory featuring KI items: short essay explanation items that require students to connect multiple ideas, along with an adaptive dialog. The four items elicit student ideas about science concepts they will learn in the following months; items are situated within contexts familiar to the students. The KI scoring rubric rewards students for connecting their ideas with evidence and increasing the coherence of their explanation. The items and the KI scoring rubric for the explanations were validated in prior research and showed no bias for language status (Boda et al., 2021). This was the first test of the effectiveness of the NLP-based idea detection models and designs of the adaptive dialogs.

To build the idea guidance dialog, we identified the rich ideas students develop during their daily experiences and created a rubric with high human inter-rater reliability (Riordan et al., 2020). We designed dialog prompts aligned with each detected idea (see Bradford et al., 2022). The prompts were intended to encourage students to rethink their response and deepen their explanation. Specifically, (a) students write an initial explanation; (b) an NLP scoring model assigns a score based on a 5-point KI rubric; (c) the idea detection model identifies the ideas expressed in the response; (d) the students receive a prompt designed to encourage them to explain an observation or a mechanism based on the KI score and the idea(s) detected; (e) students revise their response; (f) steps *d* and *e* are repeated; (g) students write a final explanation for the initial prompt. We analyzed students' initial and final revised explanations.

NLP model validation

Prior to deployment in classrooms, we validated the human-machine agreement performance of the KI scoring and idea detection models on previously collected data from middle and high school classrooms. The KI scoring models were evaluated on quadratic weighted kappa (QWK), while the idea detection models were evaluated on word-level micro-averaged F-score (harmonic mean of precision and recall, weighted by frequency of idea category) (Table 1). All KI scoring models achieved greater than 0.8 QWK, showing high agreement with expert raters. The idea detection models' performance ranged from 0.59 to 0.82, indicating that the difficulty of modeling human-annotated ideas varied greatly by item (cf. Schulz et al., 2018).

Table 1
Human-Machine Agreement Results for the KI Scoring and Idea Detection Models across Items

Model	Metric	Thermodynamics	Photosynthesis	Climate Change	Sound Waves
KI Scoring	QWK	.809	.936	.889	.833
Idea Detection	F-score	.666	.819	.592	.763

Analysis

For all analyses, we use the software *R*. Missing data are handled by multiple imputation (Rubin, 1987) using the *R* package "mice" (van Buuren & Groothuis-Oudshoorn, 2011). In case of missing data, fifteen values are estimated. All results are pooled by Rubin's rules (c.f. 1987) using the *R* package "eatRep" (Weirich et al., 2022). To analyze differences between initial and revised ordinal scaled KI Score we conduct a non-parametric Wilcoxon signed rank test in both groups. We used a logistic regression to model students' increase in KI Score as a binary outcome indicating if they improved or not. We test whether language background is a predictor for the outcome controlling for school, grade, and parents' language at home.

Findings

Impact of dialog on KI score

The adaptive dialog leads students to add more relevant ideas resulting in a significant improvement in student responses from initial to revised explanations across all items. We confirmed the similarity of the response patterns for each item, before aggregating the analyses across all items. From initial to final explanation, the proportion of students at KI 1 and KI 2 level decreases, while the proportion of students on KI 3 and KI 4 level increases, in the total sample and among multilingual and monolingual English speakers. We observe similar KI score transitions from KI level 1 to KI level 2 or KI level 2 to KI level 3, for both multilingual and monolingual English speakers (Figure 1). Most of the students at KI level 1 move on to KI level 2 in both groups. Around one fourth of the students manage the transition from KI level 2 to KI level 3 or even KI level 4 at the end of the adaptive dialog; the majority of the remaining students at KI level 2 stay at that level. Likewise, the majority of students in both groups who started at KI level 3 remain at this level. Proportionally, slightly more students from the monolingual English-speaking group make the transition to KI level 4. A few differences in idea frequency emerged (Table 2).

For the multilingual group, the initial KI score mean is $M = 2.29$ ($SD = .75$) and the mean of the revised KI score is $M = 2.50$ ($SD = .77$). For the monolingual English speaking group, the mean of the initial KI score is $M = 2.36$ ($SD = .75$) and the mean of the revised KI score is $M = 2.57$ ($SD = .77$). The results of the non-parametric Wilcoxon signed-rank test indicate a significant difference in median between the initial and the revised measurement points for multilingual ($W = 101413.2$, $p < .01$) and monolingual English speakers ($W = 58747.73$, $p < .01$). This implies that both groups show a significant improvement in the median KI score. In a logistic regression, we test if the improvement in KI score is associated with students' language backgrounds controlling for school, grade, and parents' language at home. Students' language backgrounds do not predict the gain in KI score suggesting that they are independent of language background ($\beta = .09$, $p = .51$).

Figure 1

KI Level Transition (across all Items) – According to Students' Language at Home

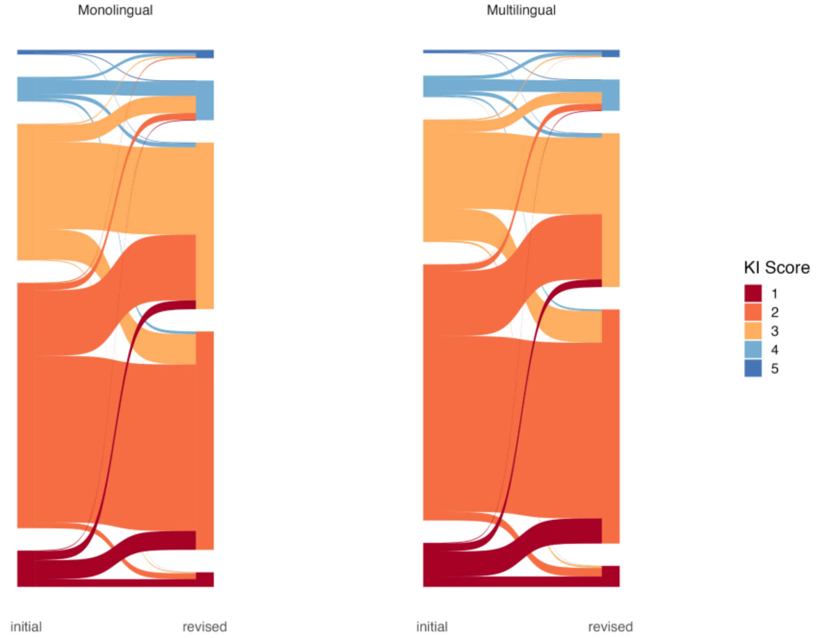

Table 2

For Each Item, the Idea with the Most Discrepancies between both Language Groups

Item: Idea	Initial Ideas	Added Ideas	Revised Ideas
Thermodynamics: cold flow	$W = 78267, p < 0.05^1$	$W = 60680, p = 0.14$	$W = 74097, p = 0.49$
Photosynthesis: animals use the sun's energy	$W = 99244, p = 0.11^1$	$W = 79444, p = 0.20$	$W = 93915, p = 0.73$
Climate Change: metal attracts heat	$W = 94721, p = 0.24$	$W = 81954, p = 0.07^2$	$W = 95976, p = 0.28$
Sound waves: sound travels same speed in water/air	$W = 98132, p = 0.52$	$W = 85744, p < 0.05^2$	$W = 96480, p = 0.17$

Note. ¹ more common for monolingual English speakers; ² added more often by multilingual English speakers.

Ideas detected

Additionally, we investigate differences between the ideas that are mentioned by students from both language backgrounds before, during, and after the adaptive dialog. Overall, the adaptive dialog elicits additional ideas and increases distinguishing of ideas in both groups. For four ideas (across the four items), we find trends or significant differences, using two sample Wilcoxon tests (Table 2). Two ideas were initially expressed more frequently by monolingual English speakers; two ideas were added more frequently by multilingual English speakers. Results for idea revision reveal convergence for language groups across the adaptive dialog, so that revised responses have similar idea frequencies.

Conclusion

The adaptive dialog supported both monolingual English and multilingual speaking students to progress in science sensemaking. We found no indication of possible language bias in the idea detection rubric and the adaptive dialog based on NLP. The adaptive dialog appears to help students of both language backgrounds use their own ideas as a starting point for generating additional ideas. It motivates each student to converge on a more integrated perspective. Thus, our results build on previous findings showing that eliciting ideas can result in greater learning gains than increased review (e.g., Karpicke & Roediger, 2008). Further, the study adds to prior research on student learning in science among multilingual speaking students (Lee & Buxton, 2010). Students of both language groups benefit from personalized scaffolding when engaging in sense-making around language rich (revising explanations, engaging in dialog), contextually familiar, and open-ended problems.

Characterizing Stakeholder Change Agency During Expansive Learning Processes

Susannah C. Davis, Vanessa Svihla, Madalyn Wilson-Fetrow
scdavis@unm.edu, vsvihla@unm.edu, mefetrow144@unm.edu
University of New Mexico

Abstract: Research on change efforts in higher education highlights the importance of change teams having sufficient authority to bring about the change they envision. This paper employs an activity-theoretical framework for organizational change known as expansive learning, along with theory on agency and intersectional power, to examine how faculty exhibited change agency in dialogue in observational data from an engineering department undergoing a major reform project. We analyzed discourse from audio-recorded faculty meetings and workshops within this six-year change project to characterize change agency in talk. Findings highlight the importance of meeting stakeholders where they are, acknowledging and legitimizing their concerns, sharing agency with them, articulating potential control, and inviting them into the effort in ways that suggest ownership. This study extends previous work on expansive learning by illuminating discursive practices that can further joint object-oriented activity in ways that foster stakeholder agency.

Background and purpose

Institutions of higher education face a variety of pressures for change, ranging from external accountability to increasing justice, equity, diversity, and inclusion. Over the past decade, much attention has focused on organizational change efforts in higher education, including those funded by the NSF Revolutionizing Engineering Departments (RED) program. Related research highlights the importance of change teams having sufficient authority to bring about the change they envision (Doten-Snitker et al., 2021; Kang et al., 2020), as well as the capacity to recognize and contend with ways that structural and normative power relations are reproduced (Collins & Bilge, 2020; Kellam et al., 2021).

We drew from a conception of organizational learning based in activity theory known as expansive learning (Engeström, 1987; Engeström et al., 2007; Engeström & Sannino, 2010) to examine how faculty involved in one RED project situated in a large, public, Hispanic-Serving Institution expressed agency in discourse during the change process, and how their expressions of agency were shaped by structural, cultural, normative, and interpersonal power relations. Findings highlight the importance of meeting faculty where they are and collaboratively moving the work forward by explicitly placing agency with stakeholders in the change process.

Theoretical framework

To explore faculty agency during organizational change, we bring together theory on framing agency, intersectional power, and expansive learning. An intersectional approach to understanding power relations suggests that power is distributed across structures, cultures, disciplinary norms, and interpersonal factors (Collins & Bilge, 2020). We intersect this complex, dynamic conception of power with theory about agency, including material agency. While classical conceptions of agency highlight dialectic tensions between human agency and structures that constrain such agency (Giddens, 1984; Sewell, 1992), more recent theory highlights the situated nature of agency, in which some decisions are consequential (Svihla et al., 2021). Rather than humans and structures in opposition, this conception of agency highlights how agency is distributed and negotiated across humans, structures, and materials (Eglash et al., 2020).

To consider how agency and power relate to organizational learning processes, we draw from expansive learning, based in cultural-historical activity theory (CHAT; Engeström, 1987, 2001; Engeström et al., 2007). Expansive learning is an iterative, evolving process of development in which interdependent elements of an activity system (e.g., rules, tools, community, division of labor) are re-mediated through collective activity in order to better serve the *object*, or collective motive, of activity (Engeström, 1987). CHAT highlights the role of historically-laden tensions within and between components of the activity system, known as contradictions, in driving change and learning (Engeström, 2001). These contradictions manifest through disturbances, conflicts, or double binds in the activity system (Engeström & Sannino, 2010). Development and learning occur as individuals and groups attempt to resolve contradictions through the development of new tools, practices, or social relations aimed at better aiding an evolving object. These developments and new practices lead to changes or expansions of the object through *expansive learning*.

In this paper, we attend to faculty's *change agency*, or agency aimed at shifting structures, norms, and practices towards the object of expansive learning. Boreham and Morgan (2004) identified dialogue, carried out within relational practices, as the fundamental process of expansive learning. We consider how faculty's change agency was exhibited in dialogue in observational data from an engineering department undergoing a major reform project, guided by the following research question: How do faculty exhibit change agency in dialogue during expansive learning processes?

Methods

The study takes place within the context of a RED project situated in an engineering department at a large, public, Hispanic-Serving Institution. Both authors were members of the change team, though neither are engineers. To examine faculty change agency, we selected data from a large corpus of qualitative data collected over six years, including more than 80 hours of transcribed audio recordings of interviews and faculty meetings and workshops, involving 20 faculty. We selected data with attention to contentiousness and disagreement, as contentiousness and disagreement seem to be markers of power differentials as experienced by the participants. We focused primarily on interactional data (e.g., faculty meetings and workshops) in order to characterize change agency in dialogue.

We analyzed transcribed data using the framing agency coding toolkit (Svihla et al., 2021), a discourse analytic approach adapted from past studies of how agency shows up in talk (Kanopasky & Sheridan, 2016). This approach focuses on how forms of speech, especially the subject and verb, express or mitigate agency. First person subjects show higher agency than third person. Verbs may suggest no, potential, or full control. As a sociocultural approach (Gee, 2014), we considered what and whom individuals expressed agency over or assigned agency to as they attempted to further particular organizational changes.

Results and discussion

To explore change agency within dialogue, we analyzed interactional data from transcribed faculty meetings and retreats to highlight what change agency might look like as it plays out. The vignette highlighted in Figure 1, which takes place during a faculty meeting near the beginning of the RED team's change effort, involves members of a change team who, at that point, did not share a common understanding of the object of expansive learning, including the change strategies they would employ to reach that object. Lin (names are pseudonyms), in the role of engineering education researcher, had developed the project's core curricular approach with Arun, the department leader. The change team planned to thread design challenges through core engineering courses, with teams of faculty, students, the engineering education researcher, and other partners collaborating across power differentials and employing an asset-based orientation to develop the design challenges. At this point in the project, while Arun was occupied during design challenge planning processes, Park stepped up to support the effort by meeting with students on the design challenge planning team.

In this vignette, Park raised concerns about the students' capacity to contribute to the development of the design challenge, taking a deficit-oriented approach to the students' contributions despite change goals emphasizing an asset orientation. In voicing this concern, Park displayed a lack of control ("what needs to be emphasized"), offloading agency onto the course content in ways that reinforced cultural norms about the role of students. Rather than forcefully countering Park, Lin and Arun met Park's concern with verbs showing potential control (e.g., might, going to, could). Lin, who held some power as an expert on learning, which was mitigated by their status as a non-tenured woman who was not an engineer, worked to recast the role of the student to align it with the planned change strategy. Next, Arun articulated what he thought was an assumption about the roles of students that Park held, which Park confirmed. This apparent openness seems counter to models of change that emphasize the importance of forming shared vision (Kotter, 1995). Arun made a discursive move to express sharing Park's concern (using "we,"), though Park's concern was counter to the specific strategy of engaging students for their perspectives and interests. Arun then took collective responsibility for the issues Park brought up ("We may not have been… successful in finding the right students in year one."), explicitly assigning Park agency in addressing this issue ("Well, you're going to develop the next one.").

Rather than directly confronting Park's concern as "wrong" or against the goals of the change project, Arun used his power as department leader to employ Park's concern in the service of moving the collective work forward. Arun employed a form of change agency by meeting Park where he was at that moment and encouraging development from that current place. By feigning shared ownership of Park's concern, Arun acknowledged the realness of the concern, then suggested that both the faculty collectively and Park specifically could address this challenge moving forward. By working with Park in a way that recognized Park's motives and aligning his responses with those of others involved in expansive learning processes, Arun demonstrated relational agency (Edwards, 2010). Arun capitalized on his power as department leader to discursively legitimize Park's concern, then worked to create an organizational narrative (Davis, 2022; Edwards, 2010) that attempted to move Park and other faculty in the room to expand the object of activity collaboratively by making specific suggestions of what "could" happen to address this concern moving forward (e.g., "This problem can be revisited with far more complexity in [junior classes] or later". Arun placed agency and autonomy with faculty in this process ("… We could build up or dispense with it and move on to something else. That's really up to each class."). Finally, Arun invited other faculty to engage in the joint work of expansive learning ("Now we really throw it open to everybody to say, how can your research be integrated into undergraduate education?").

Figure 1
A vignette from early in a change project. In the transcription, we used dashes to indicate pauses, all caps to indicate emphasis in the audio file, […] when part of the transcript was removed for clarity, brackets to help clarify statements, and // to indicate overlapping talk.

High agency marker. First person singular subject
Shared agency marker. First person plural subject
Framing agency marker. Verbs show potential control
Low agency marker. External person/object subject
Low agency marker. Verb indicates lack of control

Park: So, I express a couple of concerns about, so number one is the students that we are hiring to accomplish to develop these challenges. I- I- I—a particular student came into my office, [and] it seems he's essentially parroting what I told him to when it comes to the phase change and what needs to be emphasized, simply experiments that I suggested. And he had absolutely NO idea how to solve transient heat transport problems. um so not that we were expecting that from 101 students, uh, the student had no idea what their key problems were and if the students were actually helping them design, um, rather reducing the complexity of that problem to match the understanding of sophomores and freshman year students, I think there is, there's a lapse there's- I want to express that concern um.
Lin: I will say that the student point of view is also very important, having the students on the team, because they're able to tell us what kinds of things they know, what kinds of things were hard for them in the classes they've taken very much like the peer learning facilitators. They're also going to tell us if something seems interesting to them, it's the kind of thing that's come up in classes. What other classes they might've taken that this would have been beneficial for. Um, and so that point of view, that expertise they bring was actually a really //.
Arun: // I think what Park's concern is, I know what you're expecting is that the students who helped design this challenge should have a high level of understanding of the subject so that they know it fully. And then they'll simplify it down to//
Park: // Distill it
Arun: to freshmen level Right.
Park: yes
Arun: That's what we'd like to see now we may not have been done have been successful in finding the right students in year 1. Well, you're going to develop the next one. This is a good point.
Park: ALSO And then the second point that I was going to make is this will be much more appropriate for [a junior course] then perhaps even 101.
Arun: Yeah. So we're going to scratch the surface. […] This problem can be revisited with far more complexity in [junior courses] or later. So the idea is this is not the end of this challenge. This challenge could become far more sophisticated and we could build up or dispense with it and move on to something else. That's really up to each class. […] Now we really throw it open to everybody to say, how can your research be integrated into undergraduate education?

Significance and implications

Arun's response to Park's concern is characteristic of change agency. This single vignette of a contentious moment early in the project is not sufficient, on its own, to encapsulate how faculty exhibit change agency in expansive learning in what has become a very successful change effort. However, we argue that it does highlight key elements of change agency: as meeting others where they are, sharing agency with them ("we"), using potential control verbs (can, could, might, etc.), acknowledging and legitimizing their concerns, and inviting them into the effort in ways that suggest ownership.

In processes of expansive learning, contradictions unsettle existing practices and potentially motivate and guide re-mediation of the activity system in ways that further collective learning and development. However, contradictions do not necessarily lead to expansive learning; expansive learning cycles may be broken or abandoned (Engeström et al., 2007). Engeström and colleagues (2007) found that there were times when efforts to "bridge" the discontinuities leading to "breaks" in a cycle of expansive learning were successful in continuing organizational development towards an expanding object, while at other times these attempts were not successful. In these cases, expansive learning processes were abandoned and an alternative object was embraced. Research on organizational change from an activity theory perspective often ignores or underspecifies the important role and contribution of individual learning, identity, agency, and motivation (Billett, 2006; Edwards, 2010; Engeström & Sannino, 2010). This study expands on the important but undertheorized role of individuals and relational practices within processes of expansive learning (Boreham & Morgan, 2004; Engeström et al., 2007). In our data selection, we looked for contentious moments that illuminated contradictions between existing aspects of the activity system and the object of the change project. In this vignette, we saw such a contentious moment and the ways in which change team leaders addressed a concern counter to the goals of the project. Their discursive moves, which both legitimized the faculty member's concern and fostered stakeholder agency and ownership in moving the change project forward, offer a new glimpse into relational practices that help bridge discontinuities in expansive learning (Davis, 2022).

We recognize these discursive markers as potentially necessary but not sufficient ingredients for fostering agency within expansive learning. However, this analysis highlights possibility for both research and practice in attending closely to dialogue, the fundamental process of expansive learning (Boreham & Morgan, 2004), in considering faculty's change agency.

Generative and Hindering Roles of Student-Material Intra-Actions in a University Makerspace

Abstract: As design-based and construction-oriented maker activities are increasingly integrated into formal education, it has become important to better understand how materials and tools contribute to student learning. This study analyzed intra-actions between students and materials in a university makerspace during a graduate summer course. Incorporating constructionist and posthumanist perspectives, the study aims to understand how materials and tools 'co-contribute' to student engagement and learning. Conducting diffractive reading of student journals and reflections, we illustrate how materials in the makerspace intra-acted with students both constructively and counter-productively for their engagement and learning.

Introduction

The last decade has seen increasing recognition that design-based, construction-oriented creative activities, often referred to as 'making' or a maker approach, have numerous educational advantages for learners (Blikstein, 2013; Sheridan et al., 2014). This maker approach to learning is guided by constructionism, which considers learners most effectively construct knowledge by making sharable and personally meaningful artifacts (Harel & Papert, 1991). Constructionism posits that materials play a significant role in learning experiences by working as "objects-to-think-with," which Papert defines as objects representing ideas and understanding that learners physically manipulate, reconstruct, and refine through social interaction.

As maker approaches to learning are implemented broadly in both in- and out-of-school contexts in K-12, a number of higher education institutions have also started to adapt to hands-on, skill-oriented, project-based instruction and introduce university-wide makerspaces as part of their infrastructures (Wilczynski et al., 2017). Makerspaces are resource-rich environments that invite individuals to make, tinker with, and collaborate on projects and activities using a variety of materials and tools, including digital technologies and fabrication tools (Blikstein & Krannich, 2013). In higher education institutions, a makerspace is usually open to the entire community of the university and aims to allow students, faculty, and staff across disciplines to collaborate, tinker, teach, and learn in a shared environment. Previous research exploring maker learning in higher education has shown the impacts of makerspaces on learning and examined a variety of tools and technologies that could be incorporated into classes taking place in makerspaces (e.g., Tomko et al., 2021). Despite the growing literature in the field, few empirical studies show how tools and materials in university makerspaces contribute to learning opportunities. Investigating the workings of tools and materials in the educational process can highlight how makerspaces provide opportunities for students to engage in a creative construction process that contributes to their learning.

Theoretical background: Constructionism and posthuman perspectives

A growing number of educational research on making and construction has explored the application of the relational materialist perspective (Hultman & Taguchi, 2010) and posthumanist perspective (Barad, 2003) to gain further understanding of the role of materials and surrounding environments in educational environments (e.g., Keune & Peppler, 2019; Kumpulainen & Kajamaa, 2020). These perspectives look at "non-human forces" (Hultman & Taguchi, 2010, p.526) such as physical manipulatives or physical environments as equal participants in the process of learning. Keune (2022) claims that posthuman perspectives can expand the constructionist view of learning by (1) looking beyond the human and non-human binaries, (2) considering how material contributes to knowledge creation, and (3) explicitly focusing on ethics and multiplicity. Keune describes how "posthumanist perspectives make it possible to see how material directs bodies to produce the domain phenomena that a constructionist lens captures (p. 9)." Inspired by this premise, this exploratory study applied Keune's approach to incorporate constructionist views of learning and posthumanist perspectives to understand how university makerspaces co-generate or hinder learning for students. The research question guiding this study was: how do materials actively contribute to student engagement and learning in the summer graduate course? This paper contributes to the growing body of work exploring the role of materials in constructionist learning environments and also to an emerging understanding of how university makerspaces enhance student educational experiences.

Methods

We employed a diffractive analysis approach (Mazzei, 2014; Murris & Bozalek, 2019) using two theoretical orientations, constructionism and posthumanism, to gain an in-depth understanding of how materials 'co-contribute' to student engagement and learning in a graduate course hosted in a university makerspace.

Context, participants, data collection

This study was conducted during a 13-week graduate-level summer course in a faculty of education on maker pedagogy taught by the first two authors and assisted by the third author. Nine graduate students participated in this study. One student in the course participated entirely remotely. This course met three hours a week at a makerspace in a university library. The course covered both theoretical and practical aspects of maker education: the first half of each session focused on a discussion of reading assignments, and the second half was dedicated to hands-on mini projects using a variety of different materials each week: including cardboard and other traditional craft materials, sound, animation, coding, digital fabrication, biomaterials, and virtual materials.

The data collected for this study comprised an online web survey about students' making experiences, students' lab journals, and transcripts from the final reflection of the semester. Students were asked to keep a digital lab journal throughout the semester in a format they preferred (e.g., slide shows and blogs) to keep track of what they did, what they observed/learned, and what they reflected upon after each class. For the final class, students showcased their projects in a public exhibition. We then conducted a whole group reflection on the semester and takeaways from the activities, which we recorded and transcribed for further analysis.

Analysis

In this study, we engaged in diffractive reading of the research data (Mazzei, 2014; Murris & Bozalek, 2019) to understand how students and materials/environments around them intra-acted over the semester and the consequences of the intra-actions. Diffractive reading is a method to examine data from multiple perspectives "through, with, and in relation to each other to construct a process of thinking with the data and with the theories" (Mazzei, 2014, p.744). Like water waves diffract and go in different directions as they intra-act with each other, the approach aims for the expansion of thoughts and knowledge rather than drawing consolidated conclusions. To this end, the researchers of this study closely read the data with and through two theoretical perspectives, i.e., constructionism and posthumanism, to understand the multiplicity of the phenomena. Two of the authors repeatedly read the data, with two theories in mind, each created analytical memos as they discovered the moments of student-material intra-actions. The first author then diffractively read the two memos to combine and organize the findings in their entirety and all authors discussed to refine the findings for clarity.

Findings

Our diffractive reading of the data enabled us to capture the intra-action between students and materials in the makerspace contributing to student discovery and generation of creative ideas, spontaneous collaboration, engagement in deeper thinking, and learning beyond class sessions. On the other hand, the analysis revealed that the intra-actions also limited student engagement by discouraging them from continuing certain actions, assimilating their ideas with their peers' ideas, terminating deeper and critical thinking, and not attracting them enough to continue exploration beyond the class activities. Below, we showcase a few examples and summarize the major findings, to illustrate the ways in which material intra-actions contributed to student participation and learning in both constructive and counter-productive ways. All participant names are pseudonyms.

(1) Unexpected discovery ⇔ Discouragement over unexpectedness

One of the most interesting findings was how many students learned something new about the material characteristics and tool functions through intra-acting with materials. In particular, they gained sensitivity to materials around them when what they worked with reacted in ways contradictory to their expectations or plans. For instance, Cynthia participated in a scribbling machine activity where students created motored scribbling machines using recycled materials and toy motors and described, "[after some struggles] I ended up just connecting the marker directly to the motor and started to see some success." Her intra-action with the LEGO material made her realize that her original plan would not work, allowing her to discover a simpler structure to make the machine work. While such dissonance between material affordances and student expectations or plans contributed to discoveries and a deeper understanding of the characteristics of materials and tools for many students, the gap between what they anticipated and the feedback they received from the materials also led to frustration and the termination of activities. For instance, Janice described her experience with a video-sensing function in a visual coding platform Scratch, "Every time I tried to adjust my webcam transparency settings, the screen would go blank … eventually I just stayed away from that button," implying that contradictory material feedback can have a strong discouraging impact on student activities.

(2) Conditioned collaboration ⇔ Peer assimilation

Another major observation was that many students collaborated with one another out of necessity demanded by the materials at hand. For example, working on stop-motion animation, Polly pointed out that collaboration with her peers was inevitable because all physical materials needed to be constantly moved around to create an animation. Janice also noted that a chain reaction activity—where each group made sure their parts were physically connected and worked with other teams' parts—required careful coordination between the teams. These student-student interactions helped students like Janice to make meaning out of their experiences from the feedback they received from other students on the part that they created. However, several students noted that seeing and learning about other physical examples drew them to choose similar ideas or restricted their imagination in coming up with new ideas. While many of them described that they resisted the temptation, it is worth noting how the materials played a role in encouraging students to work together, yet may have contributed to the assimilation of ideas among them.

(3) Material-inspired thinking ⇔ Material-constrained thinking

Materials often inspired project ideas and deeper thinking for students, especially when they were contextualized in stories or particular conditions. For example, Skye described his experience in the stop-motion animation project, "the concept of personifying objects … made the project easy to imagine." The material he chose as the main subject in their animation inspired the animated story they eventually created. Janice also mentioned the experience during the stop-motion animation, "the yarn comes into frame [and] makes the whole storyline work." The cat character that they created—inspired by a spherical yarn ball—provoked much affection for the character and helped them come up with an interesting storyline for the animation. These examples illustrate that materials inspire creative ideas through their affordances, appearances, and textures helping students make connections with their personal experiences and knowledge. However, we also documented instances when materials or tools constrained what students were able to envision and realize. For instance, when Simon worked on a project using Scratch, he described how "thinking (for a desired action) was as the coding blocks/resources allowed." That is, he recognized that he was constrained by the tool to envision what could be done for his project. Furthermore, Janice suggested how materials were destructive to her thinking process, explaining that she experienced "idea fog" during the chain reaction activity: "I wonder if going to the materials table first is detrimental to the brainstorm process." These examples show how intra-action between materials and students can cause students to focus on the material experiences without taking the opportunity for meaningful knowledge building. Interestingly, some students tried to resist being overly involved in material experiences by setting their own constraints and goals for their activities. For example, Cynthia noted that she actively avoided obvious materials and challenged herself by repurposing unexpected materials available in her environment. These proactive strategies by the students are worth noting to be further examined to enhance material experiences for educational purposes.

(4) Motivation to learn beyond classrooms ⇔ Not enough enticement

The materials inspired students to continue their learning outside the classrooms if they were strongly motivated to interact with the material or tool. Cassandra noted that creative experiences with materials in the classroom provided her with introductory skills and prompted curiosity about the other types of materials that she did not get to interact with during the course. She reflected on the soundscape activity, describing how the interaction with sound and tools made the activity "certainly become feasible" for her, which encouraged her to explore the topic further after class. This highlights that the interaction with materials provides not only resources and skills to continue learning in the contexts outside the classroom but also confidence and mental accessibility to do so. Unsurprisingly, not all activities inspired the same level of motivation or accessibility that would prompt students to continue them beyond this course. For example, Simon noted that he planned to use a laser cutter outside class time to further his final project but had to give up on the idea due to a lack of convenient availability, and potentially also a lack of motivation to make it happen.

Implications

Several implications for university makerspaces can be drawn from this study. First, the material table where the instructors provided various materials played a key role, enabling students and materials to have meaningful relationships and intra-actions. However, since our analysis also noted the potential for too much or too early material intra-action to distract students from meaningful reflection and knowledge building, the timing and ways in which the material table is used in the educational activities need to be carefully chosen. Second, the tool and material affordability, availability during students' schedules, and instructions for students to learn to use the materials and tools were key aspects of makerspace infrastructures that led to intera-actions that inspired new discoveries and understandings. When students find that tools or materials are inaccessible, the resulting tendency is a loss of motivation, lack of deep engagement with the subject, or worse, total elimination of the tools and materials from their learning experiences. The instructors and makerspace facilitators should carefully design the infrastructure and use of materials and tools to ensure they are available for students at all skill levels. Lastly, our study highlighted that this different makeup of activities impacted the ways in which students were able to interact with materials and tools in the space, influencing the discoveries, motivation, and deep thinking students were able to engage in through the activities. While university makerspaces are often open-ended, program-agnostic spaces, activities should be designed so that students can gain the skills they need, and explore ideas for the project.

This study was limited by the data we were able to collect during the course. Future studies should consider video analysis of the activities, which is a method commonly used for posthumanist research studies. This study also highlighted how different materials impacted students' learning experiences in distinct ways. Future studies can explore how different material affordances lead to different relationships that students have with materials and each other, and open up different opportunities for engagement and learning.

Elementary Teachers’ Endorsement of Deficit Discourses About Mathematics and the Relative Risk of Educational Racism and Sexism

Erik Jacobson, Indiana University, erdajaco@indiana.edu

Abstract: This study explores the prevalence of deficit and anti-deficit discourses among elementary teachers in the US and their relationship to racist and sexist beliefs about mathematics learning. By combining attribution theory and equity scholarship, the research investigates the endorsement of these discourses through survey data. Findings reveal that both deficit and anti-deficit discourses are common among teachers and strongly related to the endorsement of racist/sexist and anti-racist/anti-sexist statements about mathematics learning. Surprisingly, belief in innate mathematical ability is associated with greater endorsement of anti-racist/anti-sexist educational statements, while belief in educational opportunity is not significantly associated with lesser endorsement of racist and sexist statements. The study emphasizes the need for teacher education to address these tangled discourses and suggests that anti-deficit discourses alone may be insufficient to dismantle deficit discourses in mathematics education.

Introduction

Teachers in the US often use deficit discourses when discussing mathematics education. These discourses are comprised of both seemingly neutral and clearly problematic ideas that shape thinking about math ability (Adiredja & Louie, 2020, p. 42). Researchers studying equity in mathematics learning have used interviews and classroom observations to demonstrate the racist and sexist function of ostensibly neutral discourses (Jackson et al., 2017; Martin, 2009; Shah, 2019). In this study, I combine attribution theory from cognitive psychology with equity scholarship as a lens to identify and quantify the prevalence of seemingly neutral deficit discourses. Through survey data and quantitative techniques, I explore their relationship to racist and sexist statements about math learning. This large sample, quantitative approach has the potential to inform teacher education and policy change in new ways.

Background and conceptual framework

Research suggests that merely having good intentions is not enough for equitable instruction (e.g., Rubie-Davies et al., 2006). Teachers' beliefs about the sources of racial and gender differences in math outcomes, or attribution beliefs, may influence their follow-through on equity intentions. Students' learning opportunities are connected to teachers' sense of efficacy which can vary by student (Schwab, 2019). Thus, a teacher’s attribution beliefs shape a student’s opportunities to learn via teaching self-efficacy. Teachers with genetic attribution beliefs may be less motivated to offer instructional support, as they believe struggles result from innate ability beyond their power to change. In contrast, teachers with educational attribution beliefs, who attribute struggles to insufficient learning opportunities, are more likely to adapt or increase instructional interventions.

Deficit discourses in mathematics education connect two types of deficits: students' academic shortcomings and deficiencies within students, their families, or their culture (Adiredja & Louie, 2020). These discourses often overlook students' existing knowledge and the impact of learning opportunities and social contexts on students' struggles or success. The first type of deficit, "narratives about what counts as mathematics," is based on conceptions of mathematics as objective and universal (ibid, p. 43). These conceptions establish standards that can emphasize students' shortcomings rather than their strengths. The still common but debunked view of mathematics learning as a linear process (Blanton & Kaput, 2005) also contributes to this deficit view. The second type of deficit, "narratives about students from marginalized groups" (Adiredja & Louie, 2020, p. 43) includes narratives about deficits in ability, intelligence (Leyva, 2016), culture (Solórzano & Yosso, 2002), and personal effort (Oppland-Cordell, 2014). These narratives focus on individuals membership in marginalized groups, attributing underachievement to the group rather than external, sociohistorical factors such as learning opportunities. Addressing these discourses may help promote more equitable and inclusive mathematics education.

Teachers' beliefs about students significantly influence their judgments and classroom organization (Reyna, 2008). Attribution theory examines how individuals attribute behavior to internal or external causes (Graham, 2020). Teachers often possess attributional biases (Bertrand & Marsh, 2015), and tend to attribute student failure to factors internal to students and external to themselves (Kulinna, 2007). Research further shows that teachers' attributions relate to student variables like gender and race (e.g., Espinoza et al., 2014). Three kinds of attribution beliefs are genetic determinism (Keller, 2005), social determinism (Rangel & Keller, 2011), and school meritocracy (Wiederkehr et al., 2015). Genetic determinism (BGD) posits that innate biological traits primarily shape individuals (Keller, 2005), and is associated with stereotyping and prejudice. Social determinism (BSD) suggests that social factors permanently mold an individual's character (Rangel & Keller, 2011) and is linked to negative stereotyping and prejudice. Belief in school meritocracy (BSM) maintains that school success depends on effort (Wiederkehr et al., 2015), and is related to social inequality legitimization.

I introduce the term "attributions of mathematical excellence" to characterize deficit discourses in mathematics education and make two key contributions. First, it highlights the prevalence and insidious nature of positive language in describing what counts as mathematics. This conceptual stance supports the methodology of examining teachers' implicitly held beliefs through coded, identity-neutral language, which echoes narratives about students from marginalized groups (Louie et al., 2021). The second contribution is to focus on the attributions that underlie deficit discourses, leveraging social psychology research to distinguish different types. Teachers' beliefs about the sources of unequal outcomes in mathematics education are consequential, as certain beliefs may reinforce racist and sexist outcomes, while others could help disrupt them. Notably, anti-deficit attributions of mathematical excellence recognize the role of schooling and its social and historical context in shaping student outcomes. This perspective suggests that anti-deficit attributions can create space for teachers to engage in anti-deficit noticing, which deliberately challenges deficit discourses and intentionally elevates the humanity, intelligence, and mathematical abilities of marginalized people in routine instructional interactions (Louie et al., 2021).

In this study, I focus on genetic and educational attributions of mathematical excellence and address the following research questions.

1. How common are deficit discourses—and anti-deficit discourses—about mathematics? How commonly do teachers endorse explicitly racist and sexist statements—and anti-racist/anti-sexist statements—about mathematics learning?
2. How are identity neutral deficit discourses (and anti-deficit discourses) related to analogous racist and sexist statements (or anti-racist, anti-sexist statements) about mathematics learning?
3. What is teachers' risk of endorsing racist or sexist genetic statements (or anti-racist or anti-sexist educational statements) about mathematical learning relative to their identity neutral attribution of mathematical success to innate ability or to education?

Methods and procedures

The study involved 313 participants, including 223 practicing teachers and 90 preservice teachers from a midwestern state, who were predominantly white (96%) and female (89%), reflecting the regional demographics of elementary teachers. Participants answered 64 survey items across four attribution categories, with each category containing eight pairs of identity-neutral items and identity-specific items expressing racist, sexist, anti-racist, or anti-sexist attributions (Jacobson et al., 2022). Participants rated the truth of each attribution on a 7-point scale from 1: Completely true to 7: Not at all true. Responses were dichotomized into endorsement (1-5) and non-endorsement (6-7). The survey was administered online via Qualtrics, and participants received gift cards as an incentive. Data collection concluded after a two-week period, with two follow-up email reminders sent. All participants provided informed consent, and the study was approved by an Institutional Review Board.

Relative risk, a technique borrowed from medical sciences, was used to analyze the survey data. Exposure was operationalized as a teacher's endorsement of an identity-neutral genetic attribution statement, indicating exposure to the corresponding deficit discourse. The consequence was the teacher's endorsement of an explicitly racist or sexist statement. The same interpretation was applied to teachers' endorsement of an identity-neutral educational attribution statement (exposure to anti-deficit discourses) and endorsement of an anti-racist or anti-sexist statement (consequence).

Findings

To answer the first research question, I examined the distribution of endorsement for each attribution item. All but one of the identity neutral genetic items were endorsed by a majority of participants, with endorsement ranging from 52% to 77%. Endorsement of the last item was 38%. By contrast, the identity specific genetic items were endorsed by a minority of participants, with endorsement ranging from 13% to 43%. All the neutral educational items were endorsed by most of the participants, with endorsement ranging from 79% to 88%. Similarly, all the identified educational items were endorsed by most participants, with endorsement ranging from 50% to 80%.

Thus, endorsement of either the genetic or the educational items was not uncommon for participants in this sample, whether the items were identity neutral or identified.

For the second research question, I computed the relative risk of a teacher endorsing the identified item given their endorsement of the neutral item in each item pair. For example, teachers who endorsed the identity neutral item (*I think that basic genetic differences determine to a large degree who becomes a professional mathematician.*) were 2.49 ($p < .0001$) times as likely to endorse the identified genetic attribution (*I think that basic genetic differences explain why there are far more male than female mathematicians.*) than others. In a second example, teachers who endorsed the identity neutral item (*In my view, students who excel in mathematics usually have more educational opportunities than students who do not excel in mathematics*.) were 1.86 (p = .0019) times as likely to endorse the identified educational attribution (*I believe that Asian students who excel in mathematics have more educational opportunities than students from other groups who do not excel in mathematics.*) than others. Across the seven genetic attribution item pairs, the relative risk of endorsing the identified item was always statistically significant ($p < .01$) and ranged from 1.90 to 10.67. Across the seven educational attribution item pairs, the relative risk of endorsing the identified item was always statistically significant ($p < .01$) and ranged from 1.73 to 3.05.

For the third research question, I used the median to summarize each teacher's endorsement ratings for the educational and genetic items. This enabled me to compute the overall relative risk based on summaries of both kinds of item in each attribution category. Teachers with median endorsement of identity neutral educational items (anti-deficit educational discourses) were nearly eight times as likely (p < 0.001) to endorse identified educational (antiracist) statements. Teachers with median endorsement of identity neutral genetic items (genetic deficit discourses) were more than 12 times as likely (p < .0001) to endorse identified genetic (racist and sexist) statements. Teachers with median endorsement of identity neutral educational items (anti-deficit educational discourses) were 12% more likely to endorse identified genetic (racist and sexist) statements, but this relative risk was not statistically significant (p = .3824). Teachers with median endorsement of identity neutral genetic items (genetic deficit discourses) were 25% more likely (p = .0044) to endorse identified educational (antiracist) statements.

Discussion

This paper uses survey methods to explore the prevalence of elementary teachers' deficit discourses about innate mathematical ability and anti-deficit discourses about the central role of educational opportunity in mathematical success. I also examined the risk of endorsing racist and sexist statements about mathematics learning relative to these deficit and anti-deficit discourses. The findings show that (1) deficit and anti-deficit discourses are both common, (2) deficit and anti-deficit discourses are strongly related to the teachers' endorsement of racist/sexist and anti-racist/anti-sexist statements about mathematics learning, respectively, and (3) deficit and anti-deficit discourses are distinct from each other in the sense that belief in innate mathematical ability is counter-intuitively associated with a greater endorsement of anti-racist/anti-sexist educational statements and that belief in educational opportunity is not significantly associated with lesser endorsement of racist and sexist statements about mathematical ability.

Attribution beliefs provide a useful lens for analyzing deficit and anti-deficit discourses in mathematics education. The first finding confirms the pervasive nature of both genetic and educational attributions for mathematical success. The methodological choice of using two versions of the same attribution statement (which differed only in whether race and gender were explicit) highlighted the strong relationship between common place, often unquestioned "threads" of discourse about mathematics ability and the more obviously problematic, explicitly racist and sexist "strands" that together make up deficit discourses in mathematics education. From a theoretical perspective, these results make plausible the claim that these apparently separate discursive elements are not actually distinct but are "tangled" together to form discursive "webs" that are challenging to navigate or extricate (Adiredja & Louie, 2020). The results also provide a sobering implication for teacher education: participating in both deficit and anti-deficit discourses evidently does not cause an internal contradiction for many teachers. If teacher education is going to unravel the webs of deficit discourses, anti-deficit discourses alone are likely an insufficient tool to dismantle deficit discourses.

Detecting Patterns of Constructed Collaborative Novelty in Online Discourse in Knowledge Building Communities

Guangji Yuan, Nanyang Technological University, Singapore, guangji.yuan@nie.edu.sg

Abstract: Investigating how students collaboratively advance online discussion has much value in understanding the mechanisms of novelty. Extending creative discourse by broadening adjacent novelty with new ideas is an essential benchmark to expand the community's knowledge in a knowledge building community. This study aims to continue the investigation of the mechanisms and novelty momentums behind the discourse in students' knowledge building online discussion, with a new novelty framework to understand students' collaborative discussions. Results show a promising understanding of the discussion patterns from this new perspective.

Introduction

Novelty is a crucial element in advancing the field of knowledge to make breakthroughs. In recent decades, the novelty has been investigated from individual to collaborative levels. A new trend in understanding novelty is the social process developed by transitions between persons sharing a context that technology can support (Bereiter & Scardamalia, 2014; Slotta et al., 2014). The study of novelty expands from both eccentric personalities to a competence that can be learned and developed over a life span (Romero et al., 2012) with the support of technology. The concept of novelty is receiving growing attention in Computer-Supported Collaborative Learning which is often defined as "new and not resembling something formerly known or used" (Merriam-Webster, 1991). While the collaboration format also reveals a significant increase in creativity. For instance, collaboration in design, where collaborative stimulation (prompting, seeding, clarifying, and correcting) occurs while designing entities or questions, stimulating the generative cognitive process. Moreover, it has been shown that collaborative stimulation for seeding and correcting could result in the most significant increase in the novelty of design entities (Sauder et al., 2013). While aggregate and process models provide valuable insights into collaborative creativity, they also have limitations. One limitation of aggregate models is that they tend to focus on the individual characteristics of team members rather than the social and cultural context of collaboration. This may overlook important factors such as power dynamics, group norms, and social identity that can impact creativity in a collaborative setting. On the other hand, process models may oversimplify the complex nature of collaboration by reducing it to a set of discrete interactions. This may overlook the role of context and the non-linear nature of collaboration, where creativity can emerge from unexpected sources and pathways. Our research question asks: what patterns of students' online knowledge building discourse are based on novelty analysis?

Novelty framework:

We created a novelty framework (2021, Yuan et al.,) and analyzed idea novelty based on the content of students' online posts that contained unique and relevant information extending their current understanding. The analysis led to a refined coding scheme that includes six dimensions (main categories). The quality of each type of new contribution was further assessed based on three levels: 0-not new and not substantial, 1: new but not substantial, 2: new and substantial. The levels are determined in a temporal context based on how a specific note compares against the previous notes. Thus, the code of 0 does not mean that note has no rich formation, but it indicates that no new information is provided in that specific note compared to the previous posts under a measurement dimension. Below we explain each dimension.

A) New concept

Definition: In this framework, the new concept is defined in three aspects: 1) adding new topics that have never appeared in the discussion before; 2) adding to or expanding a piece of information on an existing topic/theme; 3) adding different opinions to show alternative thinking. If a note qualifies any of the criteria, we further determine its level of substance; otherwise, we code it as 0.

Substantial or not: We define a note as substantial when it adds detailed information about the topic/theme/concept or it contributes to progress in explaining the topic. We define a note as 0 when it contains only several words or repeated information.

B) New connection

Definition: The new connection is defined as 1) connecting a new conceptual construct to an existing conceptual construct; 2) adding a new connection between two new/existing conceptual constructs that has not been shown before.

Substantial or not: A current note is substantial when it adds an essential connection between two new or existing conceptual constructs with a sufficient explanation. If the connection is only about two concepts briefly, or simply mentions the concept, or if no further explanation is provided, we code it as not substantial.

C) New rise-above

Definition: The definition of new rise-above is: 1) it has a new integration of the previous information at a new/higher/finer level, which means that the note contains synthesized ideas without redundancy; 2) the note adapts to the changes of the progressive set of ideas.

Substantial or not: When the current note shares a higher-level of understanding about the learning concept/topic, or makes a comprehensive integration of the previous information, or summarizes the previous discussion at a higher level with sufficient information, it will be counted as substantial.

D) New question

Definition: The definition of a question is quite clear when the note proposing a new question(s) starts with what, why, how, when, or do, as a sentence starter indicating it is a question.

Substantial or not: A substantial question should: 1) ask a new open-ended question with deeper insights; 2) ask several questions with detailed information. If the question only contains a few words or closed-ended questions, it counts as not substantial.

E) New source

Definition: A note shares non-redundant resources, such as books and websites.

Substantial or not: When a new resource type is shared with links and other explanations, or a summary related to the current topic, it will be counted as 1. If a new resource type is shared with only a link, without any explanation, it will be counted as 0.

F) New context

Definition: This column focuses on whether a new learning environment is mentioned or a different context is connected or compared to the previous concept.

Substantial or not: The new note will be counted as substantial when a new learning environment or context is mentioned/connected/compared with the same discussion topic and with detailed explanations.

Method

Contexts

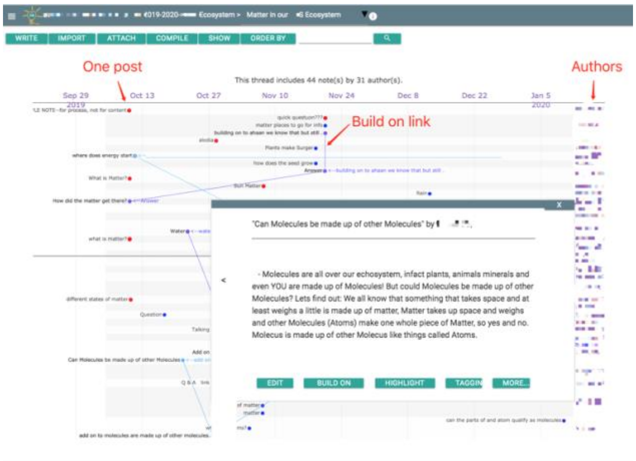
This study was conducted during two consecutive school years (2018-2019 and 2019-2020) at a public elementary school in the Northeastern U.S. Each year, four Grade 5 science classrooms participated—each of two experienced teachers taught in two classrooms. The participants were 163 students, 84 in the first year and 79 in the second year. Students of each year studied ecology from September to December. Their science learning was implemented using a knowledge building pedagogy (Bereiter & Scardamalia, 2014) supported by a collaborative online platform, Idea Thread Mapper (ITM, Zhang & Chen, 2019). Each year, the class began with a set of kick-off activities (e.g., schoolyard observation of living and non-living things) that triggered student interest in the unit topic. Students generated initial questions and shared them in the classroom and online conversations. They had face-to-face metacognitive meetings in classrooms, where they collaboratively built on ideas, explored problems, reflected on collective idea progress, and identified knowledge gaps for further study. They continued the collaborative conversation in ITM (Figure 1). As students expanded questions about overarching inquiry goals (e.g., the interaction of living and non-living things), teachers added wondering areas (overarching question or branch of inquiry) with temporal idea threads in ITM. The online discourse was organized in the idea threads. In each idea thread, students posted a series of notes (discourse entries) addressing a topic of inquiry and built on ideas in the notes connected by links. Students were encouraged to participate in the collaborative discourse in any wondering areas based on their interests. They used multiple resources, such as books, websites, and online videos, and conducted hands-on observations.

Data sources and analysis

The data source was students' notes in ITM over the two school years. In total, we collected 899 notes with an average of 38.62 words per note. A combination of qualitative analysis methods was used to investigate students' online discourse aligned with their face-to-face work over time, which was to develop and test an analytic framework for measuring students' idea novelty, A grounded theory approach (Strauss & Corbin, 1998) was conducted for identifying various creative input types concerning prior and subsequent discourse entries. The authors of this paper read and reread the ITM notes in the context of the classroom inquiry to learn the overall progress of students' ecological understanding and idea creation. The developed coding scheme was employed to conduct content analysis (Chi, 1997) for analyzing the notes and characterize the types and levels of creative contributions involved. To further understand how the community build-on notes relate to the novelty, researchers coded 184 notes from 9 views which contain more than 10 notes, and used Epistemic Network Analysis (Shaffer et al., 2009) to find the relationships among the 6 novelty coding schemes.

Figure 1

An example of Idea Thread in ITM. Each dot represents a post (note), and a line linking two posts shows a build-on response.



This thread includes 44 note(s) by 31 author(s).

"Can Molecules be made up of other Molecules" by [redacted]

- Molecules are all over our echosystem, infact plants, animals minerals and even YOU are made up of Molecules! But could Molecules be made up of other Molecules? Lets find out: We all know that something that takes space and at least weighs a little is made up of matter, Matter takes up space and weighs and other Molecules (Atoms) make one whole piece of Matter, so yes and no. Molecus is made up of other Molecus like things called Atoms.

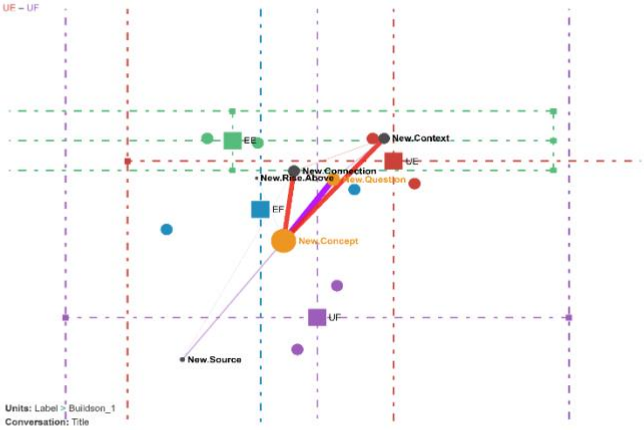
Results

RQ: What patterns of students' online knowledge building discourse are based on novelty analysis?

To understand the pattern of students' online discourse in the six novelty dimensions, researchers conducted an Epistatic Network Analysis based on the novelty coding.

Figure 2

Build-on notes only: plot Unelaborated Fact. The New Question and New Concept show a correlation of 0.85.

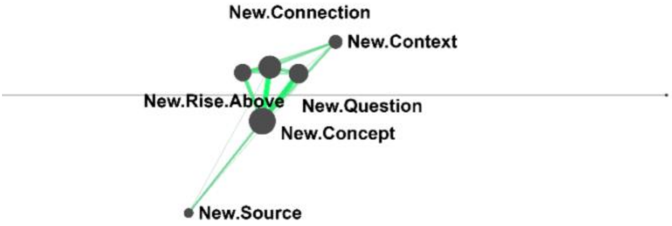


The results of the Epistemic Network Analysis show that among the build-on notes, the cluster of the most frequently contributed note indicates the quality of *Unelaborated Fact*. The connection between New

Question and New Concept shows a correlation of 0.85, which means that students tend to post a simple note with questions and new concepts to extend the conversation at the basic level. However, three coding pairs show a close connection within the cluster of the highest-quality notes (Elaborated Explanation). The New Question and New Concept with a correlation of 0.46, New Concept and New Connection (0.46), and New Concept and New Rise-above (0.36), in dictating the multiple aspects students contribute to extending the conversation at a deeper level.

Figure 3

Build-on notes only: plot notes of Elaborated Explanation, the correlation between the New Question and New Concept is 0.46, New Concept and New Connection (0.46), New Concept and New Rise-above (0.36).



Conclusion

This study implied a new novelty analytic framework in a new dataset, which was applied to understand the temporal patterns and progress of students' idea development in the online discourse of knowledge building communities. The Epistemic Network Analysis reveals patterns of students’ novelty contribution during online discussion. Researchers and educators may use this analytic framework to investigate students' collaborative discourse in a way that captures the progressive changes of students' novel contributions. This analytical framework may also serve as a foundation for creating classroom rubrics and generating formative feedback on students' collaborative discussions.

Supporting Diversity, Equity, and Inclusion Through Productive Disciplinary Engagement and Expansive Framing

Abstract: Productive disciplinary engagement (PDE) and expansive framing are among the most widely used educational design principles grounded in situative theories of cognition. Because they insist that learners "problematize" content from their own perspective, these principles are compatible with contemporary "asset-based" efforts to support diversity, equity, and inclusion. This paper systematically reviews scholarship advancing that claim. The reviewed body of work shows how educational practices that sustain the unique competencies of historically marginalized groups can also support "generative" learning that transfers readily and widely to dominant *and* non-dominant contexts for learning, achieving, working, and living.

Introduction

How People Learn II (NASEM, 2018) argued that education should be "relevant and responsive to the languages, literacies, and cultural practices of all students" (p. 137). As a consensus report, however, *HPL II* endorsed these asset-based approaches to diversity, equity, and inclusion (DEI) without detailing how they might look in practice. This paper explores one promising strand of DEI scholarship based on design principles developed by Randi Engle (1965-2012) and colleagues for *productive disciplinary engagement* (PDE) and *expansive framing*. While their initial work did not address DEI directly, several scholars (including Engle herself) acknowledged that potential and began exploring ways to pursue it. This paper systematically reviews the body of research applying PDE and expansive framing to matters of equity.

Engle and Conant (2002) introduced PDE as a situative framework for characterizing sustained student inquiry and debate. They proposed that four "guiding principles" help foster PDE: *problematizing content, conferring students authority*, *holding students accountable*, and *providing relevant resources*. Engle (2006) further analyzed the PDE data to consider *generative* learning that transfers readily and widely. She argued that transfer would be more likely when learners establish *intercontextuality* between the learning and transfer environments. Transfer is further supported by positioning students as *authors* of disciplinary ideas, participating in a broader intellectual conversation that extends over time (see also Engle et al., 2012).

Expansive framing may enhance PDE and vice versa. For instance, building students' authority is central to both frameworks. Further, problematizing topics often entails *transferring in* knowledge from out-of-school; problematizing also entails seeing a topic's wider import. Seen together in this light, the two frameworks align with asset-based approaches that "support young people in sustaining the cultural and linguistic competence of their communities while simultaneously offering access to dominant cultural competence" (Paris, 2012, p. 95). Subsequent work on PDE and expansive framing has taken up this pursuit to make learning environments more culturally *relevant* (Ladson-Billings, 1995), *responsive* (Gay, 2000), and *sustaining* (Paris, 2012).

Method

As part of a larger systematic review, we used Google Scholar to identify 2714 publications (as of June 2022) containing the terms "productive disciplinary engagement" or "expansive framing" or citing Engle's scholarship. Two team members independently coded each publication as unpublished/irrelevant/inaccessible (450), not in English (287), passing reference to Engle's work (800), supporting reference (803), not peer-reviewed (177), or include (197), with an interrater agreement of 78% (Cohen's kappa = .72). Publications marked for inclusion engaged substantively with PDE, expansive framing, or both. We determined that 32 of these focused on DEI. One reviewer then further coded these 32 publications for the features and categories described below.

Findings

Most of the included publications (23) concerned PDE, while nine concerned expansive framing. School levels included secondary (19), elementary (7), postsecondary (5), and multiple grades (1). Academic disciplines included science (13), mathematics (9), composition (3), engineering (2), computer science (1), and multiple (4).

Most of the publications (24) reported research conducted in the USA, while three were from Norway, and one each were from France, Sweden, South Africa, South Korea, and international.

Our review further revealed that the research fell into four categories. The first of these, *using PDE principles to engage marginalized students*, we omit here due to space limitations and refer interested readers to Freedman et al. (2023). Studies in this category used the PDE principles to aid and empower students from historically oppressed communities, usually in the context of mathematics education. The studies left unexplored, however, whether all students benefitted equally from these learning opportunities.

The second category of work, *confronting inequitable access to PDE*, took up this latter issue. Engle et al. (2014) re-examined the original PDE data to determine which students were contributing to discussion and why. The resulting *influence framework* explained students' differential engagement using five socially negotiated components: *degree of influence, merits of arguments, intellectual authority, access to the conversational floor*, and *access to interactional space*. The framework explained why one male student won over most peers to his position despite making the weakest arguments. Langer-Osuna (2016) likewise showed how a teacher positioned one math student as the intellectual and directive authority at the expense of another, leading the one to accept the other's flawed ideas as correct. In a subsequent review, Langer-Osuna (2018) noted that students often position each other as high or low authority based on racialized and gendered scripts. Shah and Lewis (2019) showed how, even within participant structures designed for equity, more competent or self-assured students can still marginalize peers—in this case, by telling a computer programming partner exactly what to do.

Other studies in this category include Zuiker et al. (2016), who used elements of the PDE framework in concert with complexity theory to explain how a collaborative group grew dysfunctional. The students positioned one student as holding far more authority and accountability than the others, resulting in a group-level pattern of "orienting to the leader" (p. 86). Conversely, Han and Gutierez (2021) used the PDE framework to show how a passive female science student came to experience curiosity and joy as she grew more confident in her abilities and accepted by her groupmates. Finally, Haverly et al. (2020) used the framework to examine how novice teachers can make space for "equitable sense-making" (p. 63). They suggested that teachers need more support to avoid mistaking problematizing for confusion or misunderstanding, especially with marginalized students.

In summary, these studies identified factors that either undermine or support equitable access to PDE, offering a corrective to work that tracks engagement only at the group level. But these studies (and those in Category 1) focused on accessing dominant cultural forms—not on elevating the status of other ways of knowing.

The third category of scholarship, *widening PDE to include cultural and community knowledge*, aimed to expand the meaning of "disciplinary." Thompson (2014), for instance, refined a Lunchtime Science (LS) intervention for minoritized female students. The program combined the PDE principles with identity work that involved "laying stories alongside curriculum" by asking students "who I am and who I am becoming…in order to build a sense of belonging" (p. 404-405). While passive in their regular science courses, most became passionate and productive during LS as they brought in community funds of knowledge. For example, four girls "described how their LS experiments were fueled by unanswered health-related questions in their families" (p. 422).

In a similar manner, Agarwal and Sengupta-Irving (2019) offered new themes of *epistemic diversity* and *historicity & identity*, asking "what knowledge is and who has claims over it to broaden the normative perspectives on disciplinary learning" (p. 350). With their new framework, *Connective and Productive Disciplinary Engagement* (CPDE), they argued that *problematizing* ought to involve analysis of sociopolitical controversies and the use of alternative epistemologies (e.g., Indigenous, feminist, etc.). CPDE expanded *authority* "by inviting [students] to draw on their history of experiences with disciplinary ideas beyond school" (p. 354). CPDE expanded *accountability* to include a broader array of people and ideas to whom students should be responsive. Jordan et al. (2021) drew on the CPDE framework in a project where Latino/a students designed a community-based solar energy innovation. The authors concluded, "problematizing is unlikely to induce grappling with deep disciplinary uncertainties; the emotional demands of risky design work may not be sustainable without the commitment and identity inherent to real work with real consequences" (p. 251). Suárez (2020) likewise expanded the PDE framework to study translanguaging in STEM, while Brodie et al. (2021) expanded it to study mathematical sensemaking about the COVID-19 pandemic.

In summary, this third set of studies widens the definition of "disciplinary" to include knowledge derived from the worlds that marginalized students inhabit. Doing so seems a promising way of "sustaining the cultural and linguistic competence of their communities" (Paris, 2012, p. 95). Short of considering expansive framing and transfer directly, these interventions likely fostered intercontextuality by helping students find personally relevant connections across school, home, and community. Supporting our core argument, the resulting learning should therefore transfer more readily to those non-dominant contexts, in addition to more dominant contexts.

The fourth category of scholarship, *using expansive framing to define diverse transfer contexts*, addressed this matter more directly. Like Category 3, these studies expanded the nature of disciplinary knowledge.

But they were more explicit in defining transfer contexts that derived from students' lived experience with oppression, conflict, and activism. McCoy (2017), for instance, applied expansive framing in college composition, where students were writing for social justice (e.g., from a Black feminist perspective). McCoy (2020) later presented additional writing prompts that might create "pathways for successful knowledge transfer from the learning environment of the classroom to the learning environment of the street" (p. 28). Coupled with McCoy's (2021) extensions of Engle et al.'s (2012) five explanations of transfer, this work offers a compelling example of promoting transfer to both dominant and non-dominant contexts.

In the same vein, Doucette et al. (2022) described an *underrepresentation curriculum* that used expansive framing to "develop intercontextuality and make connections between the context in which [students] are learning and the communities in which they live" (p. 303). Curricular units set the stage for talking about equity, questioning scientific objectivity, and engaging in social action. Harris et al. (2020) studied efforts to expansively frame youths' participation in "citizen science" efforts where they gathered data "nested" in actual scientific investigations. Finding that these framing contexts were invisible and/or unbelievable to some participants, the authors offered strategies to overcome such impediments. Several studies conducted in Norwegian classrooms highlight additional challenges teachers and students face in drawing on cultural and communal knowledge to support learning (Rocksén & Olander, 2017; Silseth, 2018; Silseth & Erstad, 2018; Wiig et al., 2018).

In summary, as compared to PDE, fewer studies extended expansive framing to support DEI. But we find such studies crucial because of their explicit attention to *transfer*. For schooling to carry meaning beyond the classroom, the material explored must resonate with students' cultural and communal knowledge—and strike them as relevant to those communities' past, present, and future.

Conclusions and next steps

We conclude that these four categories of studies document a range of consequential efforts to apply Engle's ideas in support of DEI goals. More than just providing instruction that is culturally *relevant*, this work uses PDE and expansive framing to sustain (i.e., transfer) the ways of knowing present in historically marginalized communities, while also providing access to disciplinary discourses associated with power and prestige. We also see potential for synergy across the four categories. Widening disciplinary knowledge (Category 3) naturally frames learning more expansively (Category 4), making transfer more likely to both dominant (Category 1) and non-dominant contexts, with the caveat that unequal access (Category 2) makes this work challenging.

One goal of our systematic review was to locate traditionally "rigorous" applications of Engle's ideas to DEI. Most of the corpus fell short of this mark. Of course, we acknowledge that DEI scholars often rely on interpretive methods and many question the generalizability of experimental designs and the validity of externally developed tests. Admittedly, we find ourselves conflicted in this regard. Our main goal, however, is providing a useful starting point for others wishing to continue this important line of work. The scholarship reviewed here suggests that PDE and expansive framing hold great potential for pursuing diversity, equity, and inclusion.

High School Students’ Evidentiary Reasoning in a Hominid Evolution Lab

Shuangting Li, Purdue University, li2954@purdue.edu
Ala Samarapungavan, Purdue University, ala@purdue.edu
Kari Clase, Purdue University, kclase@purdue.edu
Stephanie Gardner, Purdue University, sgardne@purdue.edu
Nancy Pelaez, Purdue University, npelaez@purdue.edu

Abstract: NGSS calls for engaging disciplinary core ideas in the practice of science learning. This study explored high school students’ evidentiary reasoning in a two-week hominid evolution laboratory investigation. Students compared morphological characteristics and age data for a set of hominid skulls and constructed a phylogenetic tree from the data representing hominid evolution. The study interviewed twenty high school students (sixteen 9th graders and four 12th graders) to understand their evidentiary reasoning in human evolution context. The results suggested that students used multiple lines of evidence to support their claims. However, students showed limited understanding of the constraints of evidence. The research suggests a need to help students understand the boundedness and limitations of inferences from evidence through laboratory inquiry.

Problem statement

Students’ ability to reason with evidence is an emphasis in modern science education. Next Generation Science Standards (NGSS, 2013) provide guidelines for three dimensions of science learning, “disciplinary core ideas,” “crosscutting concepts,” and “science and engineering practices.” Standards related to each dimension are specified for grade bands and content areas of science. A key aspect of science that is emphasized across scientific practices, such as explanation, argumentation, inquiry, and modeling, is reasoning with evidence.

Sandoval (2003) defines *evidence* as data that is connected to a knowledge claim through explanation or argumentation. Building on these ideas of evidence, the Conceptual Analysis of Disciplinary Evidence (CADE) framework elaborates on the relationships between evidentiary reasoning and disciplinary knowledge through cycles of inquiry (Liu et al., 2022; Samarapungavan, 2018). This short paper aims to understand students’ learning about biological evidence from their reflections on their work in the hominid evolution lab. There are two main research questions in this study: 1. How did students use skull data from their laboratory investigations to support conclusions about hominid evolution? 2. More broadly, how did students describe the relationship between evidence and scientific knowledge?

Methods

Table 1
Interview Questions by Theme

Theme	Interview Questions
1. Use of skull data to support conclusions about hominid evolution	Q1 What did the data from your laboratory tell you about human evolution?
2. Broad understanding of the role of scientific evidence in building scientific knowledge	Q2. Do you believe that data from fossil records can provide evidence for ancestral relationships among species? Q3. How did working on these tasks affect your understanding of the role of scientific evidence in relation to biological knowledge?

The data source was from an NSF-funded project to study students’ understanding and use of biological evidence in laboratory investigations (Samarapungavan et al., 2017). In this laboratory, students measured and compared various dimensions of a set of hominid skulls (e.g., morphological and age data) to construct an evolutionary tree showing the common ancestry and divergence of the hominid species they had investigated. The hominid skulls used in the investigation were life-size replicas of skulls in the Smithsonian collection.

Students also had access to skull dating data as well as biogeographical data (e.g., regional distribution of food sources). Students' evidentiary reasoning about data was scaffolded with written prompts helping them connect content knowledge about evolution to the data. Twenty high school students (sixteen ninth graders and four twelfth graders) were interviewed after task completion to interpret evidence for evolution and discuss their understanding of the relationship between evidence and theory. Qualitative content analysis was used to analyze students' interviews (Chi,1997). Table 1 categorizes the interview questions by the two key themes related to our research questions (see above): (1) use of skull data to support conclusions about hominid evolution and (2) understanding of the role of evidence in a scientific investigation. Tables 2 and 3 show the coding of student responses for the two themes related to our research questions. To establish coding reliability, the interviews of a subset of five randomly selected students (two twelfth graders and three ninth graders) were coded by an additional independent coder. The interrater agreement was 93%. Disagreements were resolved by discussion.

Table 2
Coding Scheme by question for Theme 1 with response examples

Questions	Codes	Response Examples
Q1. What did the data from your laboratory tell you about human evolution? Q2. Do you believe that data from fossil records can provide evidence for ancestral relationships among species?	Only describe data collected from the laboratory.	*"… we measured like the distance between the eyes for the skulls and the length of the canine teeth . . ."*
	Only state a conclusion; do not explain how data provide evidence for the conclusion.	*"… [evolution process is] not a straight line, there are other species [that] branch off, go distinct."*
	Connect data on changes in one trait to a conclusion about evolutionary change.	*"I feel like skulls get bigger because human skull[s] [get] bigger when they are older, like brain sizes."*
	Draw on varied data about how changes across multiple traits support conclusions about evolution over time.	*"As the skulls came to more recent, different data [is] like differ, so as they got more recent, the forehead is a way bigger. They canine gets smaller. All of these is new. … "*

Table 3
Coding Scheme by question for Theme 2 with response examples

Questions	Codes	Response Examples
Q3: How did working on these tasks affect your understanding of the role of scientific evidence in relation to biological knowledge?	Assert that biological knowledge is based on evidence: no elaboration.	*"Evolution is real, there is evidence for that. Biology changes … We have evidence. Based on evidence, we have conclusions and facts."*
	Illustrate how evidence is used to support conclusions with examples from laboratory activity.	*"Working in the laboratory . . . [has helped me to] get in [the] mind of biologists. It helped me to look at and identify different features; like I had my hypothesis, what the order would be, and just working … [on the] laboratory help[ed] me identify what the order actually was by looking at key differences."*
	Discuss uncertainty and limits of evidence and how institutional/communal processes of verification and feedback contribute to the growth of knowledge.	*"A lot of times, they have to take different [pieces of evidence] because in our laboratory, we only have the head; we weren't able to look at the entire body. Scientists should work [with] what they have and what they are given..."*

Key findings

Table 4 shows students' performance interpreting the relationship between evidence and conclusion. Most students are able to use multiple lines of data to support their evidentiary reasoning about the relationship between evidence and their conclusion. The performance of twelfth graders is better than ninth graders. For example, in response to the question, "What did the data from your laboratory tell you about human evolution?" one student said, "*It showed that possibly the diet changed, the size of the canines, was not as large as time goes on... the crests are disappearing as strong as jaws. The size of the brain is increasing means they are increasingly intelligent as well. They can get an idea of how they changed from the beginning to where we are now.*" Students not only looked at the change in physical features but also biogeographical factors such as changes in food sources.

Table 4

Results for theme 1 reflections on the skull evolution laboratory

Theme 1 codes	9th grade	12th grade	Total
Describe one piece of data from the laboratory but do not explain how it provides evidence of evolution.	3(18.8%)	-	3(15%)
Describe a conclusion about evolution such as the branching of new species from a common ancestor but do not explain how the laboratory data provide evidence for the conclusion.	4(25%)	-	4(20%)
Connect data on changes in one trait to a conclusion about evolutionary change.	3(18.8%)	1(25%)	4(20%)
Draw on varied data about how changes across multiple traits support conclusions about evolution over time.	6(37.5%)	3(75%)	9(45%)
Total	16(100%)	4(100%)	20(100%)

Note. Fr. = frequency

However, with regard to our second research question, students had difficulties understanding the role of scientific evidence in developing biological knowledge. For example, Table 5 showed the result indicating that only 15% of students understand the role of uncertainty and boundedness of evidence in the development of knowledge.

Table 5

Results for theme 2 Broader understanding about the role of evidence in science investigation by grade

Theme 2 codes	9th Grade Fr. (%)	12th Grade Fr. (%)	Total Fr. (%)
No answer	1 (6.25%)	-	1 (5%)
Assert that biological knowledge is based on evidence: no elaboration.	9 (56.25%)	2 (50%)	11 (55%)
Illustrate how evidence is used to support conclusions with examples from the laboratory activity.	4 (25%)	1 (25%)	5 (25%)
Discuss uncertainty and limits of evidence and institutional/communal processes of verification and feedback.	2 (12.5%)	1 (25%)	3 (15%)
Total	16 (100%)	4 (100%)	20 (100%)

Note. Fr. = frequency

Directions for future research

The study results suggest that engaging students in authentic inquiry practices grounded in disciplinary knowledge enhances evidentiary reasoning and helps students use multiple lines of evidence to build biological knowledge. Hogan and Maglienti (2001) suggest that using multiple lines of evidence is critical for novice learners working toward scientists. However, many students need help considering the limitations of the evidence. Duncan et al. (2022) argued that science education should prepare students to evaluate the evidence critically in this complex real world. The scaffolded guiding questions could be applied to help students think about the limitations of evidence in future study and practice.

Computational Thinking Practices at Play in an Early Childhood Microworld

Paul N. Reimer, AIMS Center for Math and Science Education, paul@aimscenter.org
Hannah Smith, Worcester Polytechnic Institute, hsmith2@wpi.edu

Abstract: Recently there has been increased interest in exploring computational thinking (CT) concepts and practices in preK-12 teaching and learning. Few studies, however, have explored how CT learning experiences are implemented in play-based early childhood classrooms. The current study explored the design and implementation of a hands-on and play-based microworld in preschool classrooms. Framed in the context of a professional development program with Head Start educators, we designed an activity to engage preschoolers in designing and building mazes for a bristlebot bug to navigate. We collected data in the form of classroom observations, teacher surveys, and interviews. Findings showed that children engaged in CT practices as they collaboratively designed and modified paths for the bug to travel. These findings suggest that microworlds with carefully chosen physical objects may give preschoolers opportunities to develop CT practices while experiencing the benefits of free and collaborative play.

Introduction

Research has suggested that engaging young children in computational thinking (CT) can lead to positive attitudes toward computing and the development of CT skills (Israel et al., 2015). Studies have shown that some of the core concepts of CT such as sequencing, algorithmic thinking, and debugging may provide children unique opportunities to apply their creativity and problem solving skills (Bers et al., 2014; McCormick & Hall, 2022). CT experiences have also been shown to help young learners develop both social and motor skills as well as increase competency in other academic subjects (Hunsaker et. al., 2019).

Studies have focused on identifying the essential elements of CT for teaching and learning within the elementary grades (Yadav, Hong, & Stephenson, 2016), as well as teachers' conceptions of developmentally appropriate CT instruction for young children (Rich, Yadav, & Schwartz, 2019). However, more work is needed to adequately examine the opportunities for CT in play-based early childhood classrooms (McCormick & Hall, 2022). This is especially important, given that efforts to articulate developmentally appropriate practices for learning suggest that young children should "engage in sustained play, investigation, exploration, and interaction with adults and peers" (NAEYC, 2009, p. 18). Play-based learning environments are well-suited to provide opportunities for CT practices such as those outlined by Brennan and Resnick (2012): (1) being incremental and iterative, and (2) testing and debugging. In their recent review, however, McCormick and Hall (2022) found that few studies have examined children's free play with CT tools. Given that many early childhood educational programs view children's play as an essential component of development and learning, more research is needed on children's play-based CT experiences. The present study seeks to understand the potential of play-based CT experiences to support young children's engagement with computational thinking practices.

Theoretical framework

Play-based CT experiences draw on the affordances of play-based learning that offers children opportunities to explore materials, repeat ideas, and follow emergent goals. Vygotsky (1978) proposed that in play, children develop their own rules and norms as they negotiate their actions based on situational constraints, such as limits imposed by physical objects or environments. Play provides opportunities for children to voluntarily engage in activity, encounter constraints, and resolve them in playful and imaginative ways. Guided play (Weisberg et al., 2016), as a middle approach between didactic instruction and free play, suggests that adults can actively and intentionally support children's learning through co-play, questioning, and reflecting with children during play. Guided play centers children's agency and interest in the play experience, while offering teachers opportunities to advance learning goals.

We also draw on interactive constructionist microworlds (Papert, 1980) as contexts for offering children play-based opportunities to develop computational thinking practices. "A microworld, like a playground, is a subset of reality that presents itself with structures carefully chosen to encourage children to encounter a particular set of powerful ideas" (Bers, 2020, p. 34). We see potential for microworlds with physical objects to align with play-based early childhood environments as they allow children to explore freely, follow emergent goals, test and repeat their ideas, and problem solve.

Methods

This study is part of a larger professional development (PD) project that introduced preschool educators to play-based activities to support their own developing understanding of CT. In turn, educators then implemented and adapted these activities in their Head Start classrooms with preschoolers (ages 3-5). For this study, we explored how one of the activities—a designed microworld—engaged preschoolers in two CT practices proposed by Brennan and Resnick (2012): (1) being incremental and iterative, and (2) testing and debugging. In this paper, we describe the design and implementation of the microworld and report initial findings from our implementation.

Setting, participants, and professional development

A total of 26 Head Start preschool teachers and teacher-assistants participated in the PD project. These educators teach a total of 131 preschoolers in eight classrooms, each classroom having between two to four teachers.

We organized the PD into five modules, with each module spanning one month of the calendar year and focusing on a different theme: patterns, spatial communication (including directional language), movement, board games, and programming robots. Each module included a two-hour PD session, follow-up classroom coaching, and activities for classroom and home use. In each module, teachers and children were encouraged to use natural, intuitive, and play-based ways to explore ideas.

The microworld activity described in this study was nested in the robots module and was centered around a bristlebot bug. The bristlebot is a simple robot that uses a vibrating motor and rubber bristles to move around in a bug-like manner and is confined to the environment in which it travels. The microworld environment for the bug is created as a maze with various construction materials such as blocks, DUPLO bricks, cardboard tubes, clear tubes, and other found objects. Teachers first explored the microworld and bristlebot bug during the two-hour PD session before implementing the activity in their classrooms. Throughout the month, teachers encouraged children to explore the bristlebot bug and use the construction materials to create a maze for their bug (See Figure 1). Children programmed the bug by designing physical constraints; as children modified the constraints, the bug's movement changed.

Figure 1
Opportunities for Constructive Exploration within the Bristlebot Bug Microworld

Data sources and analysis

We collected data in the form of written PD reflections from teachers, notes from classroom observations, photos and videos of children's activity, and teacher interviews. We used interpretivist methods to understand how teachers and children engaged in CT practices when exploring the microworld. We then used thematic analysis to code and categorize children's activity.

Findings

Our findings are organized around children's use of CT practices when exploring the microworld, including how they playfully engaged with the bug and the environmental materials. We also describe what teachers noticed about children's activity and their own facilitation through the lens of one participating teacher's observations.

As children were introduced to the bristlebot bug, they quickly became acquainted with the bug's movement. When holding the bug in their hands, children were delighted with the quirky and unpredictable movement. When placed on the table or the floor, the bug quickly moved in random directions, with children often trying to corral the bug with their hands. The other materials available to children, such as wooden blocks, were then introduced by teachers as potential environmental constraints or boundaries that could guide the bug's movement (See Figure 2).

Figure 2
Physical Materials Provide Movement Constraints

In creating their mazes, children engaged in *incremental and iterative* activity as they began to assemble materials to guide the bug (Table 1). They found that certain materials were helpful in moving the bug in a straight direction forward, while other combinations of materials allowed for right or left turns. In one instance, a group of four children connected tubes sequentially to provide a long path for the bug. In doing so, they explored the potential of narrow paths to guide movement toward a desired location. Wider spaces, in contrast, allowed for random movement and turn-arounds (this type of movement seemed more "buglike" and delightful to children). During their play, children engaged in spatial communication and dialogue as they explored what materials to use to accomplish their goal. Teachers noticed that children incrementally tried things out based on their ideas, then adapted their constructions based on their experiences. Teachers also encouraged children to attend to the physical resources in their planning, such as suggesting that children make the bug travel according to the directional arrows marked in the half-tube shown in the lower right corner of Figure 2.

Table 1
Correlation of Bristlebot Bug Microworld to CT practices (Brennan & Resnick, 2012)

CT Practices	Evidence from Children's Activity	Evidence from Teacher Interviews
being incremental and iterative	Children designed mazes for bugs in parts, adding sections onto existing structures and adapting existing mazes based on evidence from prior mazes	"I just put the materials out, and I just left them there… and said, 'How are we going to do this?' you know, instead of constructing it for them…and they were like, 'Well, we could do this, and we could,' it was like, it just stimulated their brain to figure it out." "Um the children also, too, they would always bring in different supplies, 'Well, let's try this,' you know, 'well let's try that,' um, so they have their own ideas, and brought in their own ideas and experiences, too."
testing and debugging	Children tested how various materials affected the bug's movement and fixed existing problems; for example, when the bug's path was interrupted between tubes, children used painter's tape to connect tubes	"They will set up like, different toys, put it around there, and just put the bugs, the hex bugs, and see if they are going through, or are they going into the tube, or they can't escape from the table when they put a toy blocking it like a maze." "A little girl came up and said, 'We can do races with those tunnels, with the bugs,' you know, and so that was interesting. She came up with that, 'so we could make a maze on top of the tunnel, and, um, we can see if the bugs can go through.'"

A second CT practice observed was *testing and debugging*. This practice was evidenced when children were pursuing particular goals and their constructions did not work exactly as intended. For example, when children wanted to see how far they could make the bug travel, they arranged a path with materials, released the bug to travel the path, collected the bug, rearranged or modified the path, then rereleased the bug. Other small groups of children worked through trial and error efforts as they created races with other bugs.

Discussion and implications

Our findings suggest that the designed microworld engaged young children in computational thinking practices as they programmed their bug through the physical construction of a microworld maze. In contrast to CT robotic experiences which require a programmer to direct a robot by telling it how to move, the bristlebot bug microworld required children to introduce environmental constraints. We suggest that the microworld served as a rich playground for the merging of computational thinking practices with play-based learning affordances; for example, our findings showed numerous instances of children's playful repetition as a catalyst for *incremental and iterative* maze construction. In addition, children's pursuit of emergent goals led to cycles of *testing and debugging*. For teachers, the microworld provided opportunities to engage with children during play in ways that supported children's iterative processes and constructions.

One particular line of research worth pursuing further involves the careful selection of physical materials within the microworld. Because the bug microworld engaged children in hands-on play with physical materials only, we are interested in examining the role of these materials themselves as action-oriented substructures. Rather than using symbolic features such as arrows to communicate commands, the physical materials themselves became associated with actions: the clear or cardboard tubes caused straight and efficient movement; "L" shaped constructions made from DUPLO blocks caused turns; "U" shaped corrals constrained the bug but allowed for exit; square shaped configurations constrained the bug indefinitely. As such, the physical materials of this particular microworld show promise in serving as intermediary bridges between the physical and symbolic. Other materials may provide for additional variations to maze construction, such as inclines and declines.

Our future work will continue to examine the designed features of this microworld, as well as others, to help us further understand the opportunities young learners have to engage in CT practices in play-based learning settings.

Using Social Network Analysis to Evaluate the Functioning of a Class With Multiple Collaborating Groups

Brayan Díaz, Cesar Delgado, Collin Lynch, Kevin Han
badiaz@ncsu.edu, cdelgad@ncsu.edu, cflynch@ncsu.edu, khan6@ncsu.edu
North Carolina State University

Abstract: This study uses Social Network Analysis (SNA) to evaluate the Communities of Practice (CoPs) formed around a multidisciplinary graduate course in which students work in small teams to complete a class project. Each team has an assigned subtask for the larger project. Students must collaborate within teams to produce their designated component and coordinate across teams to integrate the larger project. Coordination and communication within and across teams were done through the Slack platform. We analyzed messages sent on Slack via SNA, allowing us to evaluate the class participation, communication, and interaction. In this analysis, we identified the three types of group-group interactions described by CoP theory: overlaps, boundary practices, and peripheral connections. We also used the message dates to analyze how group-group interactions and communication changed throughout the course. Researchers can use this methodology to analyze and evaluate courses with multiple collaborating groups and instructors to monitor and improve their classes.

Introduction

In order to pursue a successful STEM career, it is necessary to develop not just technical skills but organizational skills such as collaboration and communication (World Economic Forum, 2017). However, gaps persist between industry expectations and students' skills upon graduation, leading recent graduates to experience frustration, nervousness, and anxiety when entering the professional world (Kolmos & Holgaard, 2019).

In response to this need, we analyzed an existing STEM course: Design of a Robotic Computer Vision System for Autonomous Navigation (RCAN). In contrast to many courses, this one is designed to emulate a professional environment. Students in this course work in teams to develop subcomponents of a larger robotic platform. The students must collaborate within their team on their assigned task and coordinate across teams to integrate the larger project. Social network analysis (SNA) offers a suitable methodology to evaluate intra- and inter-group collaboration and it has been applied successfully to assess interaction and participation within CoP or highly collaborative environments (e.g., Williams et al., 2013; Ma et al., 2019)l; among educational researchers (e.g., Queupli & Muñez-García, 2018); and in teaching-focused communities (Ma et al., 2019), among others. In the present context, the students communicated using the Slack platform which offers a natural medium for our analysis. Our work is grounded in the CoP theory and uses SNA methodology for our analysis.

Background

Theoretical framework: CoP theory

Wenger developed the idea of a community of practice as a group of people who share purposes and methods, which emerge from the needs of a context, with the negotiation of shared meaning and forms of participation, including tools, symbols, concepts, procedures, criteria, etc. (Lave & Wenger, 1991; Wenger, 1998). The CoP framework has been successfully applied in different settings including cross-institution communities (e.g., Kirkman et al., 2013) and informal educational contexts (e.g., Kim et al., 2020). However, few studies have used this theoretical framework to develop or research experiences in a classroom context in part because there are limited strategies for evaluating the practical impact or group structure (McKellar et al., 2011; Díaz et al., 2022a), and existing methods rely on qualitative methods and are extremely time-consuming.

Social Network Analysis (SNA)

Social network analysis is a quantitative analytical technique commonly used in education to analyze and visualize communication networks or group environments (Cela et al., 2015). SNA allows us to capture the interaction, communication, and support that occurs within and across teams by representing the communication structures as graphs where individuals or groups are represented as nodes and the edges between them represent communicative acts, exchanges, or other implicit or explicit social relations. A literature review of SNA in higher education noted that: “We need to study and test the roles of committees and other meaningful subgroups” (Kezar, 2014, p.112).

Answering that call, our research examines the following research questions using the data from the RCAN course:

1. How did students communicate within and across groups?
2. How did the class communication patterns change during the semester?

Methods

Context and setting

The course was taught in the Spring 2017 semester at a large public research university in the Southeastern USA. Twenty-six students were assigned to seven teams by the instructor based on their preferencesEach team was charged with developing one subcomponent of the robot. The SLAM teams were devoted to machine vision, and included the two monocular vision teams SLAM-A and SLAM-B and the stereo vision team SLAM-S. CTX teams focused on context awareness to facilitate navigation. The HARDW team was responsible for the robotic parts, sensor control, and computer integration, and the CONTROL team was responsible for the path planning and navigation of the robot.

Data sources

Students in the course were required to communicate primarily through Slack. At the beginning of the course, the instructor created eleven default channels: seven single-team channels; one channel for the entire class (GENERAL); one for team leaders (TEAMLEADER); one to facilitate the communication among the SLAM teams (SLAM-OVERVIEW), and one between the CTX teams (CONTEXT AWARENESS). Direct messages were discouraged by the instructor and students were guided to use the public channels as much as possible.

Data analysis

We downloaded all of the public messages as transcripts in JavaScript Object Notation (JSON) format using object literals of JavaScript. The downloaded messages record all of the information within a server, including when they were sent, who sent them, what channel they were sent to, and whether the messages were the start of a conversation or a reply. Using a combination of Neo4j (https://neo4j.com/product/bloom/), Cypher (openCypher, 2017), and Python we can create complex queries for the database and extract knowledge about how team members communicated. We generated descriptive statistics for the messages sent by each student within their group and to other groups. We generated graphs showing the social network using Gephi (https://gephi.org/).

Results and discussion

How did students communicate within and across groups? (RQ1)

Students sent a total of 5,969 messages. 72% of the messages (4,269) were exchanged within team channels, and 28% across teams. This suggests that tasks involving internal teamwork - setting up the team's designated subcomponent - required more frequent discussion and likely more effort than cross-team coordination tasks.

The teams that had the most frequent internal communication were SLAM-B (1,350 messages) and SLAM-S (914 messages). By contrast, the HARDW team had the fewest messages both within and outside their team; this finding aligned well with observations by the instructor and interviews with class participants (reported elsewhere) that the team was isolated and not very responsive to other groups.

To shed light on cross-team interaction, we generated network graphs with each team channel as a node and cross-team messages as directed arcs with direction indicating the sender and recipient of the messages (Fig. 1b). To facilitate interpretation we only show connections with five or more messages. The thickness of the arcs is proportional to the number of messages sent. Purple outlines show areas of greatest interaction across teams.

The strongest connections were between teams with similar tasks and who used similar instruments: the CTX cluster at the top and the SLAM cluster at the bottom left. The CTX cluster includes the single-team channels CTX-A and CTX-B and the ContextAwareness channel. The SLAM cluster includes SLAM-A, SLAM-B, SLAM-S, and the instructor-created channel for communications coordinating these three groups, SLAM-OVERVIEW.

Consistent with CoP, we identified the connections within the CTX cluster and within the SLAM cluster as "overlap" connections, which are generated when teams share similar objects, challenges, and procedures within their communities. The SLAM teams, for example, are jointly in charge of designing and implementing the robot's vision system. They have common goals and tools but also some differences, e.g., lasers vs. cameras for object detection. When designing a course with intra- and inter-group cooperation, having similar learning objectives and common tools across teams will ease coordination.

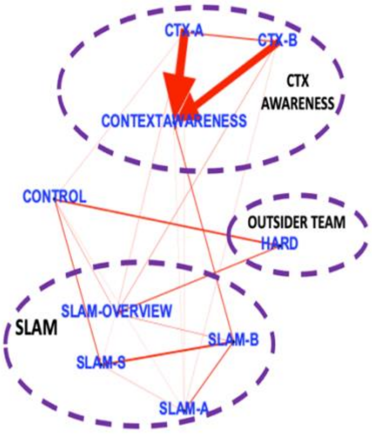
Figure 1

(a) Distribution of Messages Sent by Teams During the First and Second Part of the Class and (b) SNA of Connections Across Teams, Showing Areas of Greatest Interaction

	Part 1				Part 2			
TEAM	Within	Across	Ratio*	Total	Within	Across	Ratio*	Total
CONTROL	302	80	3.78	382	171	201	0.85	372
SLAM-A	103	34	3.03	137	69	152	0.45	221
CTX-A	158	133	1.19	291	219	218	1	437
SLAM-B	502	111	4.52	613	848	172	4.93	1,020
HARD	317	45	7.04	362	178	80	2.23	258
CTX-B	120	94	1.28	214	368	151	2.44	519
SLAM-S	420	95	4.42	515	494	134	3.69	628
TOTAL	1,922	592	3.25	2,514	2,347	1,108	2.12	3,455

*Ratio was calculated as Within/Across messages.

(a)



(b)

The arcs *across* the SLAM and CTX clusters reflects "boundary practice" connections. This type of connection is established between communities engaged in different but connected activities. The CONTROL team has a peripheral connection with the CTX and SLAM teams. Connections of this type develop when the CoPs increase the permeability of their groups to allow a selective exchange of information. From the teacher's perspective, these results were expected and aligned with the tasks developed in the CONTROL team.

Finally, our network diagram shows that the HARDW team was an "outsider", with comparatively low participation and communication. The class was not designed to have an outsider group, so this represents a challenge for the project and instruction. Recognizing outsider teams with a practical methodology like SNA on Slack data will allow teachers to design timely interventions fostering greater participation by students and teams.

How did the class communication patterns change during the semester? (RQ2)

For this analysis, we divided the messages into two sections. The first section was from the start of the class to the first trial of the integrated robot, during Week fifteen of class, and the second was from after demo 1 to the end of the class. Figure 1 a) shows the distribution of messages by team sent within each section.

More messages were exchanged in the second half of the course than in the first (3,455 vs 2,514). In both halves of the course, intra-team communication was more frequent than inter-team communication, but the proportions varied. In the first part, 76% of messages were within a single team, and in the second part, 68%. These results were expected since, at the beginning of the semester, the students were primarily working to solve challenges as teams. As the course progressed, however, integration of the components became an essential task.

Interestingly, the participation patterns of the teams were broadly similar in the two periods analyzed. The teams that exchanged a greater number of messages in the first half of the course were the same ones that had a greater exchange of messages in the second half. One major difference between sections of the course was that the communication was more diverse and evenly distributed in the second half. If SNA analyses had been conducted while the course was being taught, it would have provided valuable diagnostic information to the instructor. For example, the instructor could have intervened to elicit greater integration with the HARDW group.

Conclusions

To prepare students for a professional career, we must improve their preparation in communication and collaboration. To that end, we designed and implemented a course requiring intra- and inter-group collaboration course. The scarcity of tools available for the practical, real-time evaluation of CoP functioning led us to use the quantitative tool of SNA based on Slack messages. Applying CoP as a lens to interpret the results of the SNA allowed us to understand what kind of connections were developed between the teams and how the course functioned in general. Separating the data by date also allowed us to analyze whether and how the communication patterns changed across the semester. Our research introduces a general methodology which can be used by instructors to evaluate their class communication; diagnose specific issues such as isolated teams or uncommunicative individuals; and assess the fit to formal theories of team organization such as CoP. This in turn can support better classroom practices and timely interventions to allow the participation of all students and the appropriate development of collaborative skills. Finally, knowing the patterns of participation of the teams within the class will allow the instructor to design new or modified tasks for each team that allows generating team inter-dependency, supporting equitable participation for all.

Limitations and future work

The primary limitation of this work is that it takes place within a single course and was not evaluated across multiple classes. An additional limitation is that we were not able to capture the in-person interactions that took place in the classroom. While the classes were of fixed duration and were focused on seminars not team communication it is possible that some relevant communications were missed. We are researching subsequent iterations of this course, as well as other graduate engineering courses, in order to generalize our findings.

Designing for and Characterizing Critical Navigation of Disciplinary Values in an Undergraduate Computational Biology Course

Sugat Dabholkar, Julia Gouvea, Lawrence Uricchio
dsugat@gmail.com, julia.gouvea@tufts.edu, lawrence.uricchio@tufts.edu
Tufts University

Abstract: We describe a process of designing for equity-oriented learning outcomes in an undergraduate computational biology course. Our focus is designing for critical navigation of disciplinary values. We build on prior work that has articulated how mismatches between students' identities and disciplinary values create barriers to full participation. We describe how in our work our orientation towards equity evolved to include how navigating disciplinary values could not only support students in envisioning themselves as part of the discipline but could also function to allow students to consider the processes through which disciplinary values change, including the possibility of their own participation in resisting established disciplinary ideas and norms. We use conjecture mapping to trace the emergence of a conjecture related to critical disciplinary navigation and analyze students' responses for evidence of how they identified and navigated disciplinary values in one focal assignment.

"I hope one day I can [be] someone who can share and show the power people of all walks of life have in science. In the paper, I thought it was really interesting how they discussed the potential evolutionary basis of the heteronormative and patriarchal Euro-American cultural norm and how this is viewed as the natural order which I think brings out more questions and shows some biases."

Introduction

In this quote, from a response to a "spotlight" assignment in an undergraduate computational biology course, a student describes how cultural norms shape knowledge construction in a disciplinary community. The student references the work of Monk and colleagues (2019) who argue that the long-standing assumption that different-sex sexual behavior, as opposed to same-sex sexual behavior, is the ancestral condition for animals is rooted in heteronormative and patriarchal Euro-American cultural norms. The student uses this example to illustrate "the power people of all walks of life have in science" and position themselves as hoping to contribute to such efforts.

The inclusion of spotlight assignments was part of an effort to design an undergraduate computational biology course to support learning outcomes that would enhance equity in students' learning and participation. In prior work, spotlight assignments have been used to counter stereotypes and to support students from marginalized groups to see themselves as possible participants in scientific fields (Schinske et al., 2016). In this paper, we describe how some of these assignments, which we call *resistance* spotlight assignments, functioned to support the process of critical disciplinary values navigation. We describe how this mediating process emerged from equity-oriented conjecture mapping. We then present an analysis of students' responses for evidence of how they identified and navigated disciplinary values in one focal resistance assignment to address the research question: *What are the ways in which a resistance spotlight assignment mediated students' critical navigation of disciplinary values?*

Theoretical framework

Disciplinary learning can be understood as a process of becoming enculturated into a community of practice (Lave & Wenger 1991). In STEM disciplines, the process of gaining entry into these communities has not been equitable (e.g., Garrison, 2013). Students belonging to minoritized groups continue to experience barriers to participation in STEM learning spaces and ultimately in STEM careers. One barrier to equitable and full participation centers on interactions between students' identities and values and what they perceive to be valued in legitimate disciplinary participation (Margolis, J. & Fisher, 2002; Nasir, 2012; Vakil, 2020). Whether or not they are made explicit, disciplinary communities are governed by sets of values that specify the conditions for successful entry and participation. Disciplinary values describe the sanctioned disciplinary practices (e.g., use of computational tools,), forms of participation (e.g., authorship in peer-reviewed publications, podcasts), ideas (e.g., objectivity, complex systems theory), and relationships between the discipline and society (e.g., the use of technology for social good). A perceived mismatch between students' and disciplinary values can position students as outsiders and discourage them from disciplinary pursuits (Vakil, 2020). Even for those students who do persist, disciplinary values may function to put constraints on both participation and identity (e.g., McGee & Martin, 2011).

In considering how to design a course that can engage undergraduates in critical navigations of disciplinary values we build on Vakil's (2020) idea of *disciplinary values interpretation*—a process by which students reflect on the values of a disciplinary domain, as well as who they are and might become in that domain. Vakil's analysis featured students' sense-making about the dynamics of how disciplinary values are negotiated and shaped in disciplinary communities and students' identification with available roles in those communities. We use the term *critical disciplinary values navigation* to extend from this work and emphasize designing for disciplinary learning that allows students to not only gain entry to participation in disciplinary communities *as they are*, but also affords them with the agency to *reshape disciplinary values and participation* towards equity and justice (Calabrese Barton & Tan, 2020).

College students are at a critical juncture in their learning as they are preparing to transition from classroom learning to learning in disciplinary spaces, academic or otherwise. For these students the need to anticipate and prepare to navigate their own participation in disciplinary communities is critical.

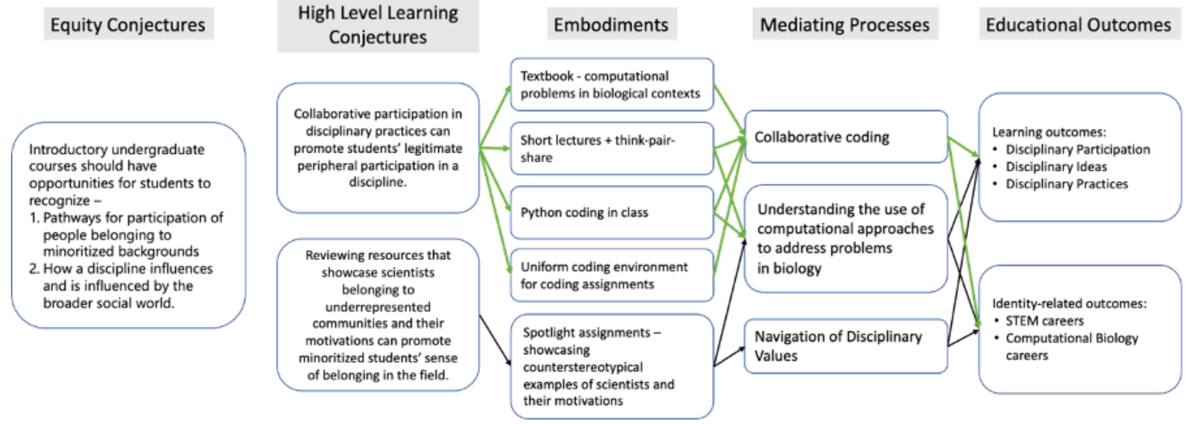
Research context and methodology

The CompBio (pseudonym) course was designed and taught by Author 3 in the Fall of 2021 at a university in the United States. Reported demographics at the university is 46% non-male and 47% non-white students. Less than one-third of students responded to demographic survey which makes it impossible to report on the course participants demographics. However, field observations indicate that the course demographics were roughly similar to university demographics. A significant aspect of the course design was a series of twelve required "spotlight" assignments that featured the computational research of diverse scientists, as well as those scientists' experiences with racism and sexism, and ethical dilemmas in the academy. For each assignment, students reviewed academic papers, interviews, podcasts, or other materials and wrote an open-ended one-page reflection on these materials. In this paper, we focus on a resistance spotlight assignment that featured the work of evolutionary biologist and ecologist Dr. Amika Kamath (Spotlight AK). Students read the research article, 'An alternative hypothesis for the evolution of same-sex sexual behavior in animals', co-authored by Monk, Kamath, and others (2019), and listened to a podcast in which Kamath recounts her experience as a woman and feminist scholar in the field of ecology and evolutionary biology. Kamath describes how she drew on her training as a biologist and feminist to challenge established ideas about animal behavior rooted in patriarchal logics. The prompt asked students to write about what they found interesting, what they learned about the subject matter, or insights into the motivations of people that do computational biology.

Equity conjecture mapping

Author 1 and Author 2 designed an equity conjecture mapping interview protocol (Lee et al., 2022) to interview the course instructor (Author 3) and constructed a conjecture map (Sandoval, 2014). The interview included questions about expected course outcomes and how the instructor expected design choices, related to curriculum and tasks, participant structures and classroom interactions, would produce those outcomes. The instructor was interviewed twice to capture his evolving understandings of the course design and outcomes. We coded interview responses and organized them into an equity-oriented conjecture map (Figure 1).

Figure 1
Conjecture map of the CompBio course.



An initial conjecture map based on the instructor's interview revealed two paths intended to support equitable participation in computational biology: 1) Learning to use computational approaches to solve problems in biological contexts (Figure 1, Green arrows), and 2) Learning about practices and participation of scientists from underrepresented communities(Figure 1, Black arrows). In this paper we focus on Path 2, which uses spotlight assignments to support students' disciplinary values navigation, a process that we conjecture can ultimately impact outcomes related to both learning how to participate in the discipline and identity development. The initial high-level learning conjecture for this path was inspired by claims by Schinske and colleagues (2016) that spotlight assignments can counter disciplinary stereotypes. The path was revised to include the instructor's intention to include examples of resistance work by scientists that could stimulate interest in the field, particularly for students from marginalized groups. The instructor's revised design conjecture can be stated as, showcasing examples of scientists belonging to underrepresented communities who challenge the norms of the field would lead to students' critical navigation of disciplinary values.

Critical disciplinary values navigation in student responses

We (Authors 1 and 2) used a combination of deductive and inductive coding (Miles et al., 2018) to analyze the written responses to spotlight assignments for consented students (n = 24). Using a deductive coding approach, we first coded all the responses for six categories: Connections to Prior Lived Experiences, Personal Participation, Disciplinary Sense-making, Disciplinary Practices, Disciplinary Values, Critical Considerations of Power and Privilege. This first round of coding allowed us to identify disciplinary values and their co-occurrence with other themes.

We further inductively coded identified parts (n = 56) in students' written responses that were about disciplinary values. For this second round of coding, we generated five categories of themes that corresponded to disciplinary values in student responses. These categories were: Objectivity and Bias Avoidance, Diversity, Resistance to disciplinary ideas, Resistance to cultural norms, and Social Implications. Seven instances in student responses did not fall into any of these themes. The combination of deductive and inductive coding was instrumental in the development of themes. For example, *critical* navigation of disciplinary values emerged from co-occurrences of Disciplinary Values and Critical Considerations of Power and Privilege.

Findings

We analyzed student responses to Spotlight AK. All the student responses to the assignment were coded positive for *disciplinary values* by both coders. This means that all the students who submitted their written responses engaged with navigation of disciplinary values to some extent. We present two examples of *critical* disciplinary values navigation (critical DVN), which we operationalized as students' reflections on values of a disciplinary domain that considered dynamicity of disciplinary participation (changes in who gets to participate and how) from an equity and justice perspective.

Valuing resistance to social norms to strengthen objectivity

The following response is an example of a student navigating how 'objectivity' and 'resistance to social norms' were perceived as disciplinary values in connection with Dr. Kamath's work.

> *"By presenting a shifted lens through which to explain the prevalence and patterns of SSB [same-sex sexual behavior] and DSB [different-sex sexual behavior], Kamath shows how science can be improved when its practitioners try to question dominant social norms and their effects on previous scientific research and theory. The same principle is clear in her talk: how people interpret the world cannot be fully 'objective' but is influenced by their different identities and places in it. Realizing this is good for both science and society."*

In this quote, the student is claiming that both objectivity in science and impacts on society can be improved when scientists actively question the role of social norms in upholding disciplinary knowledge claims.

Valuing diverse perspectives to remove bias

In the response below we see a student articulating the value of diverse perspectives in science.

> *"The first step [in removing bias] is including a diverse range of people in the science community, because as Ambika Kamath mentioned in the podcast, people will approach topics differently based on their prior experiences. To acquire the most accurate and diverse bank of scientific knowledge, it is crucial to have researchers with different backgrounds included, as everyone will bring a different viewpoint to the table."*

In this quote, the student is recognizing how diverse backgrounds bring diverse perspectives that ultimately improve science by removing bias.

Discussion

One possible function of design features such as spotlight assignments is to showcase the works of people belonging to underrepresented groups with the aim of helping students from minoritized populations “see themselves” as possible participants in the discipline (Schinske et al., 2016). In our work, this initial conjecture was revised and expanded to include cases of how practitioners of the field can engage in resistance work. Challenging ideas and practices rooted in patriarchal, heteronormative, Eurocentric logics is an important part of rightful participation in the discipline (Calabrese Barton & Tan, 2020). We have called this process *critical disciplinary values navigation*.

Our findings from the analysis of student responses the Spotlight AK support the design conjecture that this assignment supported students’ critical DVN and contributed to emerging justice-oriented understandings of disciplinary participation. Students interpreted disciplinary values, such as objectivity, and also navigated understandings of how those values are enacted in disciplinary practice. Students’ critical DVN included identifying where a problem is located related to a value (e.g., objectivity is difficult to achieve) and how it can be addressed by another disciplinary value such as resistance to cultural norms, or inclusion of diverse perspectives.

Overall, we argue that the opportunity to review works of scholars belonging to underrepresented groups that challenge established ideas and unjust social norms (Resistance Spotlights) can provide new resources for critical DVN that can ultimately have significant implications for how students view their participation and their possible futures within the discipline of computational biology. This process entails grappling with questions such as: *How have disciplinary values been shaped by cultural/historical processes? Which values are up for negotiation? By what processes can disciplinary values change? What are the implications of different disciplinary values for participation, knowledge building, and societal impact? What might be my role/responsibility in shaping disciplinary values?* This research contributes to questions about supporting identity development and challenging inequity in education and has implications for ethical theories of learning.

Probabilistic Motivation Profiles and Student Behaviors in Log Data

Gahyun Sung, Harvard University, gsung@g.harvard.edu

Abstract: Motivation is a multi-faceted construct that has complex relationships with behavior. To better understand student motivations in a large introductory statistics course, we cluster different aspects of student motivation and investigate their link to observed student engagement in an online textbook. A soft clustering method reveals three distinct motivation profiles in students: reluctant, motivated, and confident. Membership in the confident group is associated with GPA and financial difficulties, but not with engagement metrics that reflect student choice, such as time spent. Contrary to the simple hypothesis that better motivation will lead to higher engagement, students with "reluctant" and "motivated" profiles seem to spend similar amounts of efforts for course preparation but spend less of it progressing with learning, and more time struggling.

Introduction

Numerous theories link learner motivation to engagement, a precursor to successful learning (e.g. Elliot & Harackiewicz 1994; Ryan & Deci 2000). While studies have utilized self-reports to empirically establish the link between motivation and adaptive student behavior (e.g., Hendy, Schorschinsky & Wade, 2014), self-reports can be biased and may be prone to recall error, particularly when probing low-level behaviors. Thus, an alternative method of inquiry for computer-assisted learning environments has been to take advantage of the digital log traces that occur with student activities (e.g. clickstream) to track their behavior (e.g., Xu & Yang, 2016; Schoor & Bannert, 2011).

The current study adopts this approach to study a context where motivation is expected to vary, and is crucial for success: a large introductory statistics course where college students engage with an online textbook in a self-directed manner. Motivation is operationalized using the expectancy-value theory of motivation (Eccles et al., 1983), which has been previously successfully applied in the context of learning analytics for the goal of finding student profiles, in studies such as Schumacher & Ifenthaler (2018) as well as Templaar and colleagues (2018).

Two methodological considerations are made in response to calls for change in associated fields: the use of a person-centered approach in motivation profiles, and the use of engagement metrics that go beyond click counts. The use of a person-centered approach in estimating student motivation have been increasingly endorsed by researchers as a way of allowing how patterns of variables related to motivation have an intricate relationship with one another at the level of the individual (Linnenbrink-Garcia & Barger, 2014). The use of more sophisticated log data metrics that measure engagement and student learning behavior in ways other than summative count has been raised time and again, such as in Knight & Shum (2017), Lodge and Lewis (2012), and Fincham and colleagues (2019).

With such considerations in mind, we hope to answer the following research questions:

1. What types of distinct student motivation profiles exist in an introductory statistics course?
2. Are the probabilities of belonging to a certain motivational profile impacted by student factors, namely gender, race, GPA, and economic hardship?
3. Do the ways in which students engage with course material differ by motivational profile?

Setting and data

Log data was collected from an online textbook used in a large introductory statistics class in a U.S. research university with a highly competitive undergraduate program. The online textbook was a central component in the course. Students learned the material by working through assigned chapters in the textbook every week before coming to lectures. The log data includes all student interactions with textbook elements, such as reading material, graphics, videos, R coding exercises, and formative assessment questions. Our data comes from 166 students who filled out the pre -course survey, and did not drop out of the course.

The survey data used to create motivational profiles comes from the pre-course survey. The survey contained various demographic questions, as well as a combination of validated measures for the estimation of expectancy, value, and cost from two instruments (Kosovich, et al., 2015; Gaspard et al., 2017). To create a more holistic, person-centered motivational profile, we utilize additional survey questions relevant to discriminating different student motivations for taking a statistics course: the level of self-reported prior experience in statistics, and the level of self-reported intent to persist in statistics learning.

Methodology

Motivational profiles were created by combining confirmatory factor analysis (CFA) with gaussian mixture modeling (GMM). First, confirmatory factor analysis was applied to the previously described survey items to create composite scores. Five factors were created: expectancy, value, cost, prior experience, and intent (to persist in statistics). Model fit indices largely indicated that the CFA had acceptable fit (χ^2=539.481, $p < 0.001$; CFI = 0.830, RMSEA = 0.084, SRMR = 0.077). Then, the resulting factors were normalized and used to create GMM-based student motivation clusters. GMM is a “soft” clustering method, i.e., a probabilistic model that assigns a student a probability of belonging to a certain cluster. Compared to “hard” clustering methods such as k-means clustering, it provides a better theoretical fit in cases where students do not belong to clearly discrete groups. A three-cluster model was chosen based on elbow graphs of fit statistics (AIC, BIC).

Parallelly, the following week-level metrics were created from the log data to understand student behaviors expected to co-vary with motivation: time spent, ratio of questions that the student ultimately did not get correct despite unlimited tries, ratio of questions never attempted, ratio of attempts correct to total attempts, and ratio of time spent on the due date (i.e. cramming) to total time. These metrics attempt to measure not only the amount of effort or engagement the student put forth in a particular week, but also the way in which this time was spent: was a student’s time on the textbook spent fruitfully progressing through the material, or spent making wrong attempts, or rushing to finish work? That is, might student motivation profiles be related to not only the amount of effort, but also the ways in which this effort is expended?

While three distinct clusters are described, subsequent analysis uses a binary variable for membership in the most advantageous cluster, termed the “confident” group (described further in the next section). This is to account for strong class imbalance – the smallest cluster, while mathematically and theoretically distinct, was approximately 1/10 of the size of the “confident” group. Two types of analysis are performed on this binary profile. First, we test whether different student factors, namely race, gender, GPA, and economic hardship, are associated with “confident” group membership. Then, behavioral metrics are connected to this binary variable using linear mixed models (LMM), a generalization of linear regression that allows modeling of random effects of correlated clusters (Byrk & Raudenbush, 1987). Since we have multiple datapoints from each student, and multiple datapoints from each week, LMMs allow us to explicitly model these effects for a less biased estimate of main effect sizes. Lastly, given the importance of prior academic history in determining motivation and student behavior, we introduce prior GPA (a binary variable, 3.5- and 3.5+) as a control variable in LMM analysis. Identical models without the control variable showed the same trends.

Results

RQ1. Student profiles in an introductory statistics course

Our first research question asked whether there are distinct motivation profiles in this introductory statistics course. The results of cluster analysis showed the emergence of three distinct clusters. Based on the inspection of variable distributions, we respectively term them the “reluctant”, “motivated” and “confident” groups. As seen in figure 1, the reluctant group is characterized by a low level of intent to persist in statistics, low expectancy for success, and low value for the course, despite having some prior related experience. The motivated group stands out most for their lack of prior experience, yet they expect to do better than the reluctant group and value the class more, as well as having a higher intent. Lastly, the confident group has the highest intent, level of prior experience, expectancy, and value. The reluctant group includes 12 students, while the motivated and confident groups each consist of 59 and 95 students.

Figure 1

Factor distribution for reluctant, motivated, confident clusters

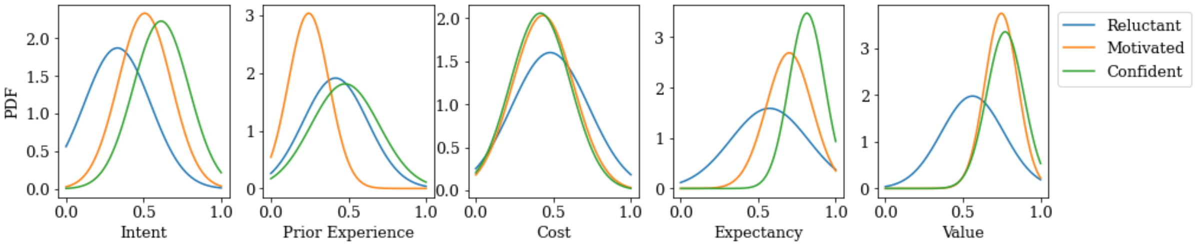

Table 1

Factor means for reluctant, motivated, confident clusters

	Intent	Prior experience	Cost	Expectancy	Value
Reluctant	0.33	0.42	0.48	0.57	0.56
Motivated	0.51	0.24	0.43	0.70	0.75
Confident	0.61	0.48	0.42	0.81	0.77

RQ2. Student factors influencing probabilities of profile membership

Next, turning to our second research question, results of contingency analysis showed that group membership is not statistically significantly associated with either student gender or race; however, they were significantly associated with prior GPA (less or more than 3.5; $\chi^2(1) = 8.039, p = 0.004$) and economic hardship (level of economic hardship reported: high, medium, low, none; $\chi^2(3) = 9.527, p = 0.023$). In the contingency table below (table 2), actual counts are accompanied by expected values in parenthesis. The table indicates that lower GPA students, and students with high- and medium-levels of financial difficulty tend to belong less than chance to the confident group.

Table 2

Contingency table between student factors and motivation clusters.

	GPA		Economic Hardship			
	3.5-	3.5+	High	Medium	Low	None
Confident group	**32 (44)**	132 (125)	**13 (18)**	**46 (51)**	56 (44)	60 (61)
Other groups	52 (40)	104 (116)	22 (17)	52 (47)	31 (42)	59 (58)

* Number in cells indicate observed count (expected count)

RQ3. Connection between student motivation profiles and learning behavior

The LMM regression results showed somewhat surprising results. Many metrics did *not* have a statistically significant association with “confident” group membership. The time spent on the textbook, the ratio of questions never attempted, and ratio of time spent cramming all had statistically nonsignificant associations. However, the ratio of correct attempts to total attempts, and the ratio of questions given up differed between the confident group and other groups. Table 3 summarizes the LMM regression results for these two metrics for which there were significant results. Belonging to the “confident” group was on average associated with a 5-percentage point increase in the ratio of correct attempts, and a 7-percentage point decrease on the ratio of questions never answered correctly, or given up, even after controlling for student GPA.

Table 3

Results of LMM regression analyses

	M1: Ratio of correct attempts	M2: Ratio of questions given up
Belonging in “Confident” group	.05 *** (3.544)	-.07 *** (-4.212)
GPA less than 3.5	-.07 *** (-4.60)	.11 *** (5.728)

*** $p < 0.001$; Satterthwaite approximations used for calculation of t-statistics (in parentheses)

Discussions and conclusion

Our results reveal three distinct profiles of student motivation in taking this introductory statistics course: the reluctant group sees lower value in the course and the subject despite some prior experience, the motivated group is new to the field but has high expectations for the course and for their own performance, and the confident group is surest of their success and the relevance of this course, and has highest prior experience. Bringing contextual information into the model allows us to create realistic profiles that more holistically capture the types of student motivations for taking an introductory STEM course.

These motivational profiles are shown to be related to self-reported student GPA and economic hardship. While these results are hardly surprising, it does bear note that gender and race, influential factors known to be related to motivation in STEM, lose significance in this relatively homogenous population while economic hardship retains its influence, speaking to its salience and perseverance as a barrier to academic success.

Lastly, regression results show that having a "confident" motivation profile at the start of the course may be less related to how student *decides* to engage in course preparation. That is, the time they spend, the questions attempted, and the way they divide the time throughout the week are all choices students autonomously make. Conversely, the ratio of correct attempts, and the ratio of questions given up, both indicators of the quality of experiences a student had during their engagement, differ by motivational profile. While further analysis is needed to fully understand this different experience, it seems that students with the "reluctant" and "motivated" profiles spend similar efforts for course preparation but spend less of it progressing with learning, and more time struggling with the material. This disproves the simple hypothesis that "better" motivation leads to higher engagement; rather, it seems that these holistic motivational profiles are correlated with student resources beyond their willingness to put in effort, which lead to different experiences in the course, despite their best intent.

Future work will focus on creating more sophisticated engagement metrics, making the next natural connection between engagement and performance, and then testing a larger model that includes motivation, engagement, and performance. Ultimately, we hope to understand how students that enter a STEM classroom with different types and levels of motivation engage in learning based on their process data, for the end goal of tailoring feedback for students based on both their motivation and observed engagement.

Re-Mediating Technology-Facilitated Embodied Activities at a Summer Camp for Youth With Disabilities

Morgan Vickery, Indiana University, moravick@iu.edu

Abstract: This paper describes the implementation of technology-facilitated collective embodied modeling activities at a reverse-inclusion summer camp for children with moderate/severe disabilities impacting communication. Video data of camper interactions, paraprofessional debrief audio data, and researcher field notes were analyzed revealing three barriers to participation unique to children with disabilities in embodied learning activity design: (1) issues of abstraction/overstimulation, (2) needs for control/routine/choice, and (3) limited motivation for collaboration. Each of these barriers is conceptualized as dis/enabling elements of the activity design and informed a set of re-mediations in the activity design.

Introduction

For children with disabilities, embodied learning activities can be sites of pressure, stigma, distress, and shame . Technology-mediated embodied environments in particular are often designed with an able-bodied, neurotypical user in mind. In the learning sciences, there is a lack of research discussing the unique needs and barriers experienced by users with disabilities in these spaces. In this work, I argue that the design of technology-facilitated embodied learning environments should first and foremost prioritize the well-being, dignity, and comfort of learners as a prerequisite to disciplinary outcomes as I investigate the following research questions:

1. What barriers to participation do young learners with moderate-severe communication disorders experience in mixed-reality collective embodied learning activities?
2. How can mixed-reality collective embodied learning activities be re-mediated to reduce these barriers?

Theoretical framework

In the learning sciences, embodied cognition scholars have long positioned the human body as a resource for learners to engage in individual and collaborative meaning-making (Nathan, 2021). However, limited attention has been given to how embodied activities place unique demands, pressures, and messages onto learners and produce settings where attention and value are allocated to those bodies which perform within the strict range of abilities, skills, and characteristics required to succeed (Fitzgerald, 2005).

Activities that explicitly draw attention to learners' bodies in this way often reinforce unattainable traits (i.e. whiteness, motor competence, masculinity, neurotypicality, heterosexuality, etc) as acceptable, desirable, and achievable (Fitzgerald, 2005). Critical disability scholars have sociopolitically contextualized the barriers experienced by learners with disabilities, calling for the organization of learning spaces by focusing on mediation and artifacts such that "we can intentionally organize classrooms to help teachers learn to engage in reflective practices that shift away from static notions of race, culture, and ability" (Connor et al., 2016, p. 108). The concept of "mediation" here is drawn from technology design-oriented work, relying on activity theoretical and phenomenological perspectives (Kaptelinin, 2015). In this work, 'mediational means' include the structures, processes, tools, and scaffolding which shapes how 'subjects' (i.e. campers) pursue their 'objects' within the larger activity system. Further, 're-mediation' becomes a sociocultural approach through which learning ecologies can be socially reorganized and redesigned towards the enabling of learners and shifts how local interactions occur between learners; "[re-mediation] is not simply about changing infrastructure, but changing it so that it can be used to achieve particular political ends[…] for the goals of social justice and equity" (Jurow et al., 2019, p. 83).

Here, 'equitable participation' is utilized as a 'canary in the coal mine' to indicate when re-mediation of the activity system is necessary, with the analytical focus on which particular elements of the activity design are causing some break in the learning ecology. How 'in/equity' is operationalized is highly variable depending on the context; 'seeing' in/equities in the participation of participants requires unique insight into the social infrastructures, histories, and practices of the camp community. In this study, I leverage these perspectives to 'stress test' a series of technology-facilitated embodied learning activities within a reverse-inclusion summer camp context to identify those design aspects which are disabling for non-neurotypical populations and re-mediate the designs accordingly. This study is yet one piece in ongoing efforts to disrupt the hegemonic, ableist narratives, structures, and practices reinforced in western educational settings.

Methods

Camp Comrade is an annual reverse-inclusion (Baker, 2015) day camp in a small Midwestern city directed by a university-affiliated team of speech therapists to service local children (n=27) aged 5-12 with moderate-to-severe disabilities impacting communication and a group of invited 'peer models' (n=10). Over four (video recorded) days, groups of campers and staff participated in multiple 20-minute activities using the GEM-STEP system (GEM-STEP, 2021) with the objective of fostering social competencies and interactions between youth. GEM-STEP is a mixed-reality embodied learning environment through which students' physical movements are tracked via either a system of 'tags' and motion-tracking 'anchors' or an iPad 'character controller' and mapped to a digital avatar displayed on a projection visible at the front of the room. Students' movements then enable them to interact with virtual elements and characters alongside their peers within a hybrid physical and virtual space (see Figure 1).

Figure 1

The projected simulation (a), campers using the GEMSTEP system (b), and room layout (c)

(a) (b) (c)

Four audio and video sources of each activity session, researcher field notes, and audio recordings of paraprofessional debriefs for each activity session were analyzed using Jordan and Hendersons' (1995) guidelines for Interaction Analysis, user experience (UX) design methodologies such as affinity diagramming and solution prioritization, and Sandoval's (2014) conjecture mapping schema. Events were repeatedly watched with attention towards moments of trouble and/or repair within interactions, shifts in camper participation, instances of camper frustration or apprehension, engagement in social competency practices as identified by paraprofessionals. I also engaged in a series of qualitative validation procedures throughout the data collection and analysis processes including member-checking (with paraprofessionals and other camp staff), peer debriefing and collaboration with other researchers, and disconfirming evidence (Creswell & Miller, 2000).

Findings

I describe three barriers to participation experienced by elementary-aged children with moderate/severe communication disorders in technology-facilitated collective embodied modeling activities. For each set of barriers, I provide a description of how these barriers manifested during the GEM-STEP activities at Camp Comrade and a set of proposed design re-mediations lightly modeled after Sandoval's (2014) embodied conjecture mapping approach.

Barrier 1: Abstraction and overstimulation

While campers were often eager to participate, video data and paraprofessional debriefs revealed signs that campers could become overstimulated including (a) frustration around the state of their avatar due to confusion around the causes of these state changes, (b) maladaptive/destructive behaviors, and emotional breakdowns, and (c) behavioral indicators of discomfort (i.e. abrupt movements, repetitive gestures, closing eyes, covering ears, etc.) as noted by paraprofessionals. Traditionally, such expressions of frustration, traumatization, aversion, and anxiety could be interpreted by facilitators as acts of noncompliance and thus, something to be corrected and punished (Goodwin, 2020). Rather than attributing them to the individual and 'correcting' the behavior via individual intervention or conditioning (as is typical of those who rely on medical models of disability), these expressions were interpreted as signals of some disabling factor being present within the activity design thus prompting re-mediation.

For children with particularly high environmental needs (i.e. for environments to be literal, clean, organized, and in line with expectations) activity designs needed to be proactive in their preparation, protective and sensitive to students' sensory triggers, and accommodating of in-the-moment changes as these triggers are revealed. These insights prompted the generation of several design re-mediation options; these solutions varied in scope, technical difficulty, time required to implement, and anticipated immediate payoff for campers and were prioritized accordingly. Solutions that offered a high value to campers were feasible over the course of 2-3 days and a relatively low-technical/financial burden were applied during the latter half of the implementation and were evaluated and reviewed by paraprofessional experts during daily debriefs.

Table 1
A table of proposed design re-mediations to address issues of abstraction and overstimulation

Design Re-mediation	Conjecture
Physically marking virtual positions on carpet	Decreases the level of abstraction between the virtual and physical worlds; improves accessibility of embodiment tasks for campers with spatial / visual / visual processing impairments
Removing superfluous visual elements from projection interface; optimize iPad UI	Lessens effort required for campers enter & participate in system; minimizes breaks in distraction, decision paralysis, and distress for campers with attention challenges & sensory-sensitivities
Activating 'guided access' on iPads (limits functionality)	Minimizes off-task behaviors & need for staff-intervention / supervision
Providing fidgets; Introducing a 'break time' gesture (ASL)	Provides non-destructive outlet for campers to express distress or anxieties; redirects maladaptive behaviors
Replacing the screen with higher-contrast, larger projection; reposition / lower	Improves accessibility, visibility, and salience of simulation events and avatar states; lessens burden for connecting to avatar; improves size-inclusivity of system
Frequently resetting simulation rounds (automated looping)	Minimizes visual clutter and lessens effort required to monitor one's avatar

Barrier 2: Desire for control, routine, and choice

Within the video data, several moments featured children engaging in antisocial behaviors such as yelling, crying, and instigating conflict with other campers. While these episodes lessened as the campers became more familiar with the activities, paraprofessional debriefs clarified how many of the children had a high needs for particular task structures; these needs varied from the need to have control over events/actions, for the activity to follow a predictable and consistent routine, and to have opportunities for choice. This insight informed the following set of design re-mediations:

Table 2
A table of proposed design solutions to address issues of control, routine, and choice

Design Re-mediation	Conjecture
Offering additional character-control options (wearables, holdables, staff as proxies)	Enables campers the opportunity to opt-in to different modes of participation requiring varying degrees of movement, contact, communication, and attention
Presenting choices to individuals instead of the large group via pointing/gestures/AAC	Provides campers time & space to consider options, communicate their choice as preferred, and receive an appropriate response from facilitators
Daily visual schedules; GEMSTEP-specific token boards	Illustrates expected activity flow and schedule to preempt any breaks in routine; provides an (optional) visual set of guidelines/actions as a response to campers' paralysis/overwhelm using the sandbox task structure
Aligning GEMSTEP activities with camp themes/topics	Maintains cohesion, consistency, and predictability of GEMSTEP activities within the context of campers' entire camp sessions
Pre-training facilitators to use a common set of signs (ASL), gestures, and vocabulary	Standardizes facilitator awareness of many campers' preferred mode of communication; streamlines decision-making and needs articulation
Resetting individual avatars without resetting the entire simulation	Minimizes the degree that each individual avatar's progress and state is dependent on others; minimizes disruption to other campers in-simulation goals

While the outcomes of these re-mediations varied for each individual, simply recognizing and validating certain camper's needs for control over their environments allowed facilitators to more effectively and compassionately validate their frustrations and redirect any aggressive behaviors as evidenced in the video and debrief data.

Barrier 3: Motivation for collaboration

A core objective for camp staff and activity designs was to support inter-camper communication and relationship-building; midway through implementation after many technical barriers had been addressed, we noticed how campers often opted to act independently while using GEMSTEP as opposed to initiating collaborations. Furthermore, camper goals and motivations within the simulations often didn't align, and the aforementioned barriers to communication made it difficult for campers to identify and work toward a common goal. Conversations with camp leadership and paraprofessionals generated the following re-mediations:

Table 3

A table of proposed design solutions to address issues of low motivation for peer collaboration

Design Re-mediation	Conjecture
Peer & counselor modeling; graduated prompting/scaffolding	Normalizes bodily movement and promotes campers "joining in" on playful activities; provides a live model for campers to imitate; enhances group cohesion; provides increasing levels of support as needed to complete the task
Implementing a 'buddy' iPad system	Encourages campers to engage in synchronous collaboration, negotiation, turn-taking, and communication to achieve 'success'
Identifying/prescribing dyad & group-level collective goals	Directs campers towards pursuit of common goal; lessens need for camper agreement over misaligned-yet-rigid individually-defined goals
Pre-training facilitators to use a common set of signs (ASL), gestures, and vocabulary	Standardizes facilitator awareness of many campers' preferred mode of communication; streamlines decision-making and needs articulation; limits miscommunication and conflict

Discussion and conclusion

While learning scientists often emphasize designing for collaboration, I argue that the third collaboration-oriented barrier only became visible due to the efficacy of our adjustments addressing the other two barriers. These re-mediations represented a pivotal shift in the rapid iterative design process; it was only after the earlier barriers associated with abstraction, overstimulation, control, routine, and choice had been addressed that barriers to higher-level interactional and collaborative objectives could be considered. In other words, by designing for participants' comfort via the removal of barriers to participation, opportunities for meaningful collaborative meaning-making were 'unlocked.'

This work represents one step towards efforts to not only acknowledge and design for often marginalized students, but shift how the contributions of students outside the 'norm' are valued and legitimized in educational spaces. By critically examining where learners may encounter such barriers to participation, we shift the responsibility for (non)participation away from individuals and onto the activity design itself. By embracing these reflexive design practices in our work, we might conduct transparent, equitable research that is and offer an education that does not come at the expense of learners' comfort, dignity, and humanity.

Teaching Artist Perceptions of Anti-Racism in an Out-of-School Time Theatre Programs

Kailea Saplan, Katherine E. Norman, Molly Mattaini
saplan@wisc.edu, knorman4@wisc.edu, mattaini@wisc.edu
University of Wisconsin-Madison

Abstract: This paper reports findings from a pilot study that used qualitative surveys to examine how Teaching Artists (TAs) in one Out-of-School Time (OST) theatre organization defined and enacted anti-racist pedagogy. We report on two domains of action TAs described when defining anti-racism and three tactics they used to apply anti-racism to their programs. This paper represents a necessary step towards developing research-based recommendations for arts programs grounded in anti-racism; it also offers preliminary conceptual frameworks for understanding and studying how educators approach anti-racist pedagogy writ large.

Major issues addressed

Teaching artists (TAs) – who have expertise in both the teaching and practice of one or several artforms – are increasingly responsible for providing youth with arts education in the United States as positions for full-time arts teachers in schools have declined (Rabkin, 2012). TAs tend to operate Outside-of-School Time (OST), offering programs through community-based education spaces (Baldridge et al., 2017), private youth arts companies, or artist-in-residence programs. Often, the programs TAs offer are considered valuable and virtuous, because they provide an opportunity to engage young people who might otherwise have no access to formal arts education. Arts learning environments have been conveyed as safe spaces for youth with identities that are marginalized by systemic oppression (Chappell & Cahnmann-Taylor, 2013; Hanley, 2011), and TAs have been charged with acting as change agents in these spaces to empower youth artistically and emotionally (Fitzhugh & LaPadula, 2004). There is, however, little empirical research regarding TAs' confidence, capacity, and preparedness to help youth navigate issues of social injustice in equitable ways.

To be sure, there are countless examples in literature where youth have engaged critically and creatively in OST arts-centered spaces (e.g., Barniskis, 2012; Solomon et al., 2022). However, TAs are rarely emphasized in such examples, and many of the programs reported on in literature are led by researchers, leading one to question whether these examples are the exception rather than the rule across OST arts programs. Furthermore, literature that does directly examine educator attitudes towards race and anti-racism comes predominantly from traditional school settings (e.g., Philip, 2011; Vaught & Castagno, 2008), which have different affordances and challenges than OST arts education spaces, and different practical implications. In this pilot study, we aim to address the paucity of literature on theatre TAs specifically, by directly eliciting their perspectives on anti-racism in OST drama education. The following research questions directed this study: (1) How do teaching artists conceive of anti-racism broadly and in theatre education spaces? (2) How do teaching artists' conceptions of anti-racism align with self-reports of their application of anti-racist pedagogy? This work represents a necessary step towards developing research-based recommendations for arts programs grounded in anti-racism, and it offers preliminary conceptual and methodological frameworks for understanding and studying how educators approach anti-racist pedagogy writ large.

Anti-racist pedagogy and teaching artists

Today, extant literature that takes a critical perspective on race in education is vast, with work in educational ethnography (Fordham, 2016), sociology (Kao & Thompson, 2003), psychology (Lomotey-Nakon, 2018), and curriculum and pedagogy studies (Ladson-Billings, 1995; Paris & Alim, 2017). The notion of anti-racist pedagogy comes from this scholarship; it generally refers to an approach to education that requires ongoing awareness of power and racial dynamics within a learning setting, the inclusion of course content and materials that both recognizes racism and does not ignore or tokenize the perspectives of people of color, and the employment of teaching practices that disrupt uncritical assumptions on race, achievement, learning, and authority (Kishimoto, 2018). However, the majority of scholarship in this area is focused on formal school environments. Although educators in informal learning spaces can and do draw from this literature, they must make sense of how this work applies to their learning context. TAs in informal arts learning spaces find themselves with even less support.

Arts programs are often deemed safe, empowering spaces for youth with marginalized identities, and in turn, TAs are considered capable guides who help youth navigate social injustice by engaging in creative and artistic expression. In reality, TAs are not always prepared to support students most affected by educational and societal injustice. Despite an idealistic narrative about the power of youth engagement in the arts, in practice, TAs "may be entering teaching opportunities largely unprepared to engage with youth and organizations in this capacity" (Hager, 2010, p. 117). There is no uniform education or training process for TAs that can guarantee their engagement with culturally relevant or anti-racist pedagogy. And, as with any OST organization, deficit-based perspectives on youth have the potential to filter into TAs' work and impact the ways they engage diverse populations of learners (Baldridge, 2014). In this study, we asked TAs working in OST theatre and drama settings to examine their own teaching - their areas of confidence and discomfort, and their narratives about their own practice - in order to begin building a base of literature about TA perspectives on anti-racist pedagogy, which can become a foundation for future research-based recommendations.

Methods

This pilot study asks: (1) How do teaching artists conceive of anti-racism both broadly and in theatre education spaces? (2) How do teaching artists' conceptions of anti-racism align with self-reports of their application of anti-racist pedagogy? We invited TAs (N=12) affiliated with a youth theatre organization to respond to an online, short-answer survey. The anonymous online format encourages honesty in responding to a potentially sensitive topic (Deckman, 2017).

The survey consists of definition-based questions and practice-based prompts. The definition-based questions elicit TAs' understanding of anti-racism in society broadly and within drama education specifically. Our understanding of anti-racist pedagogy comes from the critical tradition of educational scholarship described earlier; however, we also recognize that the term "anti-racism" has both academic and colloquial meanings. To capture a wide-range of conceptualizations of anti-racism, we designed the survey questions to be open-ended, and prompted TAs directly to define "anti-racism" in their own words. In the practice-based prompts, we asked TAs to share a story about a time when they successfully applied anti-racist pedagogy, and a time when they either felt uncertain about how to enact anti-racism or failed to successfully enact it. We asked for specific moments so our analysis could be grounded in concrete examples, and encouraged TAs to write in narrative form so they might include relevant context (e.g., setting, relevant characters, etc.). The survey also included basic demographic questions, so we could connect TAs' responses to their self-reported identities.

We approached data collection and analysis through a qualitative phenomenological lens (Creswell & Poth, 2018), and constructed our understanding of the data through themes that emerged from, and were anchored in, the lived experience shared by our participants. Survey responses were analyzed through a multi-step qualitative coding process: in-vivo coding of the data, a memoing process, and then a detailed conceptual and dramaturgical coding phase. In-vivo codes were derived from the specific and direct words and actions of the participant. The prioritization of the actual words and physical actions of the participants makes in-vivo coding particularly useful in generating codes for understanding teachers' experience and expertise within their classrooms. The middle-step, which occurred concurrently across both the initial and secondary coding phases, consisted of generating meaning-making memos to make sense of, explore, and expand on emerging themes in the data. Throughout the memoing process, the research team met to challenge each other's perspectives on the meaning of the data by discussing any discrepancies.

The final step involved identifying patterns and emergent themes in the data which led to generating conceptual codes for the definition-based data and dramaturgical codes for the story-based data. Dramaturgy in theatre focuses on clarifying and understanding the entire dramatic composition; this includes not only the text, but also the Setting, the Objectives and Obstacles that impact the characters, the Tactics characters use to achieve their Objectives (e.g., Cattaneo, 2021). Dramaturgical coding applies conventions from dramatic literary and performance analysis to the story data (Saldaña & Omasta, 2017). Aligning our methodological design across study content, analytical approach, and intended audience allows us to bridge the expertise of the study participants, researchers, and intended audience in order to better communicate the study's findings.

Major findings

Definitional data: Anti-racism as epistemic and pragmatic action

In the definition-based questions, we asked TAs to indicate whether and where they encountered the concept of "anti-racism," to describe in their own words the meaning of anti-racism, and to explain what anti-racism in drama education means to them. In congruence with a recent review on counter-deficit literature in educational research (Kolluri & Tichavakunda, 2022), TAs conceptualized racism as *ideological*—an internalized personal belief at the individual level, or shared racial attitudes at the collective level, and *structural*—material barriers to opportunity and resource disparities that fall along racial and socioeconomic lines. TAs described *anti-racism* with verbs like “promoting,” “dismantling,” “recognizing,” “challenging,” and “listening,” implying action against racism in both its ideological and structural forms.

Our analysis identified two types of anti-racist action in TAs’ survey responses, which correspond with the ideological and structural concepts of racism. The first related to challenging one’s own biases, learning about systemic oppression, and unlearning prejudiced ways of thinking and being. The second related to creating material and generating structural changes in society. We found that these two types of actions resembled Kirsh and Maglio’s concepts of *epistemic actions* and *pragmatic actions* (1994) in embodied cognition, so we re-analyzed the data using these concepts as etic codes to confirm their relevance, and adapted them into *epistemic anti-racist action* and *pragmatic anti-racist action*. Epistemic anti-racist actions are external actions that are performed to change one's cognitive state (e.g., observing and naming microaggressions enacted by ourselves and others). They represent “actions designed to change the input to an [individual’s] information-processing system” (1994, p. 541). Pragmatic anti-racist actions are actions that create “transformations in physical or social space,” performed to change the external world or to bring one physically closer to a goal, even if the goal is to instigate an internal shift in *someone else’s* mind (1994, p. 515). Pragmatic actions can look like changing policies, advocating for others, or critiquing racist media.

The idea of employing reflection and action in dismantling oppressive systems is not new; scholars and activists have asserted the importance of reflection and action in anti-racist work, and have connected them through the concept of *praxis* (for examples, see Freire). Additionally, research has addressed the value of habit-breaking practices to combat internalized implicit race bias (Devine et al., 2012), and teacher sensemaking about racism is well documented (Philip, 2011; Pollock et al., 2010). However, to the best of our knowledge, this specific cognitive framing as a categorization of anti-racist actions is a novel contribution to the field, one which is related but subtly distinct from conceptualizations of anti-racism in the broader public discourse (i.e., individual prejudice vs. institutional racism: Kishimoto, 2018; self-awareness vs. structural awareness: Vaught & Castagno, 2008).

Story data: Dramaturgical analysis and common tactics

The narrative prompts asked TAs to tell stories of successes and failures/uncertainties in the classroom. Through dramaturgical coding, we identified three common Tactics TAs reported using to enact anti-racist classroom practices. These Tactics were largely related to the textual materials TAs used as the centerpiece of a drama classroom, and included: (1) *Naming/ Discussing* problematic elements in materials; (2) *Rewriting/ Replacing* problematic elements in materials; and (3) directing *Student Driven Creation* instead of relying on potentially problematic pre-existing materials. The most significant finding from this phase of analysis is that all three Tactics emerged in TAs stories as examples of perceived success and of perceived uncertainty/failure.

Naming/Discussing emerged in stories about identifying and making space for conversations about racist content in the theatre canon within drama education classes. When TAs provided examples of successfully using this tactic to enact anti-racism, they described actively confronting the history of certain texts or lyrics with their students. Examples of failure typically emerged in stories about avoiding these topics; TAs reported avoiding these discussions due to feeling unqualified to lead such discussions or trying to manage white students’ discomfort. When TAs relied on *Rewriting/Replacing* as a Tactic, they would not only identify racist material in the canon, but then also remove, rewrite, or replace it with new text. TAs expressed uncertainty about the effectiveness of this tactic when they weighed the relative value of naming harmful language with students and recruiting student participation in the rewriting process in contrast to removing harmful language outright. We recognize the *Naming/ Discussing* and *Rewriting/Replacing* Tactics as reactive, meaning they were actions taken in response to pre-existing canonical dramatic materials. The third common Tactic sidestepped the racism inherent in the canon by relying instead on Student Driven Creation. Success stories for this Tactic described students taking agency over their own art-making and generating work from within their own perspectives. Moments of failure with this Tactic were those in which students created work based on content and contexts with which they were already familiar, and in doing so, perpetuated racist stereotypes. The challenge of this Tactic lies in TAs being able to balance the value of Student Driven Creation with productive and safe boundaries, while also helping guide students to new or different understandings and perspectives.

Conclusions and implications

Although our pilot study includes a small sample size, it has provided rich data to build on in future research. The study illustrates that even when TAs voice uncertainty around implementing anti-racist pedagogy, their responses reveal thoughtful reflection and awareness that can be strengthened and translated into more concrete action with more professional support. TAs’ definitions of anti-racism were already grounded in action, namely epistemic and pragmatic anti-racist actions. Though more research is necessary to refine these actions into complete conceptual frameworks, they already offer a common language with which scholars, organization leaders, and TAs alike can discuss possible approaches to anti-racist pedagogy.

Additionally, TAs reported three common Tactics which they used to enact anti-racism in their classroom. These Tactics will likely look familiar to TAs in other theatre organizations; naming them explicitly is a crucial step to enable TAs to think critically about their anti-racist practices and question whether their Tactics are having the impact they want. Moreover, the fact that these tactics emerged in stories of both success and failure/uncertainty suggests there is no single "correct" approach to enacting anti-racism in drama education. Rather, the success or failure of a tactic depends on the specific situational context. By exploring and reporting on how TAs currently understand anti-racist practice, we have begun building a body of literature on anti-racist pedagogy that applies to the highly specific context of OST drama education. Additionally, we offer the *epistemic* and *pragmatic anti-racist action* as a preliminary conceptual framework for describing educators' approach to anti-racist pedagogy writ large, and we encourage scholars to employ dramaturgical coding as a method for analyzing educators' anti-racist practices and communicating to an arts educator audience.

Appearing and Disappearing in the Data: Emotional Configurations Within Children's Data Modeling Practices

Kathryn Lanouette, Megan Church, Courtney Maynard
lanouette@wm.edu, mrchurch01@wm.edu, cbmaynard@wm.edu
William & Mary

Abstract: Data modeling is a central science knowledge building practice, entailing amplifying and reducing the world across inscriptional forms. Recent research in science education has elevated how emotion is integral to science knowledge building practices, yet emotion emergent *within* young people's data construction and critique processes remains less understood. In this study, we present findings from a multi-week 5th grade science and data science curriculum. We describe how emotion was often emergent as aspects of the ecological system were made more or less visible - by the data form's structure as well as by the activity structure. We focus in depth on one illuminating case were children falsify their data, detailing how emotion, sensemaking and modeling practices were co-emergent. Building on existing scholarship in data feminism, our findings suggest that transforming the world into data is an inherently emotional endeavor, in turn entangled in young peoples' sensemaking with and about data.

Introduction

Inherent to western science is the process of amplifying and reducing the world (Latour, 1999), moving away from the immediacies of the moment towards varying degrees of abstraction, standardizations and calculations through modeling pursuits and practices. Existing work in Science and Technology Studies (STS) and Feminist Data scholarship has illuminated how data intensive practices are inextricably enmeshed in emotion, whether intentionally repressed or openly embraced (D'Ignazio & Klein, 2020*;* Kennedy & Hill, 2018). Yet to date, there has been limited research on emotion *within* modeling, particularly at the intersections of emotion, data and science sensemaking in K-12 contexts.

In light of calls for enacting more expansive, equitable and meaningful modeling practices in science education (Schwarz et al, 2021), this proposed manuscript seeks to illuminate how emotion is integral to practices of data construction, interpretation and critique, in turn shaping children's sensemaking about interrelationships in socio-ecological systems and the data itself. In this analysis, we focus on children's engagement in collaboratively constructing multiple data visualizations with their schoolyard data: a bar chart of earthworm counts, a two-way table of invertebrate sketches and tallies, and an interactive digital GIS map involving multiple organisms and data formats. We ask, how do children navigate this inherently emotional process of amplifying and reducing the world?

Emotion and data modeling in science and science education

Existing scholarship has documented the longstanding bifurcated depictions of emotion as separate from data modeling and sensemaking in science, part of broader dichotomizing separating rationality, mind and objectivity from emotionality, body and subjectivity (e.g., Haraway, 2020). Such dichotomizing functions to perpetuate social political narratives of science as a dispassionate discipline, where data are merely extracted, transformed and distributed anew around the world. Recent research in science, math and data science education has increasingly elevated the emotional and situated dimensions inherent to data modeling and sensemaking across science, math, and data science disciplines (e.g., McGowen & Bell, 2022; Kahn et al, 2022). Yet much research in this area still focuses on emotion *about* existing data forms (e.g., empathy towards organisms from causal modeling, anger when looking at a particular data visualization), or alternatively, centers around designing data activities and visualizations to deliberately elicit specific emotional responses (e.g., Kennedy & Hill, 2018). As a result, less is known about emotion emergent *within* the data construction and interpretation process, particularly for younger learners newer to these enculturated practices as they build and discuss their data.

Theoretical frameworks

We draw on situated, socio-cultural frameworks to understand how emotion and data modeling are central to science practices. Emotion is understood as emergent *within* science practices, inseparable from social, conceptual and epistemic threads of disciplinary practice (Jaber & Hammer, 2016). Emotion plays a dual role, simultaneously *in/ as* practice, wherein emotion configures and is configured by disciplinary practices (Vea, 2020). Drawing on Latour (1999), we understand western scientific knowledge building practices as inscriptional movements away from locality, particularity, materiality and multiplicity towards increasing forms of standardization, calculation, compatibility and relative universality. We understand young peoples' data practices as intersecting constellations of personal, cultural and sociopolitical layers shaping their sensemaking (Lee, Wilkerson & Lanouette, 2022).

Research context and design

This study is part of a larger multi-year design-based research project that aimed to support expansive science and data science teaching and learning in late elementary school contexts (Lanouette, 2022; Lanouette, Van Wart, & Parikh, 2016). Central to the project design was collectively constructing and visualizing data about their schoolyard together as a whole group, to intertwine children's embodied, historical and material connections in a local socio-ecological system ecosystem in their sensemaking of aggregated data visualizations. Across the multi-month curriculum collaboration with an US elementary public school, a 5th grade class created, constructed and explored patterns in their data in analog and digital forms to better understand who could thrive in their schoolyard, providing multiple opportunities for collectively building and interpreting increasingly complex data forms.

Data sources specific to this analysis include three whole class sessions where multiple data representations were collaboratively constructed, including a bar chart of earthworm counts, a two way table of all invertebrates observed and counted, and an interactive map that included children's data on invertebrates, soil conditions, and schoolyard activities. These three class sessions were selected because they engaged children in physically constructing and interpreting varied aggregated data, involving three different data visualization forms that amplified and reduced varying aspects of the system. In each of these class sessions, video recording from several angles were collected, along with researcher field notes and student/ teacher paper artifacts.

Analysis

We examined how emotion was emergent and entangled within children's constructing, interpreting, and critiquing data visualizations across three different class sessions, accomplished through successive waves of coding video (Derry et al, 2010) using MAXQDA. In the first pass, we focused on children's concurrent sensemaking with and about their data (e.g., coded as *Sensemaking with data*: exploring what earthworms need to thrive, talking about how other invertebrates and kids' movements impact presence of certain plant and animal species, coded as *Sensemaking about data*: noting covariate relationships, attending to outliers, documenting absent or incomplete data). In the second pass, we focused on instances where aspects of the schoolyard socio-ecological system were amplified and reduced, encompassing instances where aspects of the data were shifted towards materiality, locality, and multiplicity or towards standardization, relative universality and calculation (coded as *Appearing/ Disappearing*, drawing on Latour (1999, pg. 71). This code included instances where children were constructing different categories of invertebrates (e.g., roly-polies, centipede), transforming their sketches and tallies into sticker dots representing earthworm counts, or removing layers of data from the interactive maps, bar charts or two way tables. It also included dimensions of the data visualization itself, when the form amplified or reduced particular dimensions (e.g., obscured locality, demanded homogenous categories within set columns, obscured children's names). In the third pass, we focused on *multi-modal expressions of emotion* (Jaber & Hammer, 2016), including verbal reference (e.g., "I just love finding animals!"), paralinguistic markers (e.g., rising accent, pitch, volume, speed), and multimodal expressions (e.g., shared smile, crossed arms, eye rolling). Combined, this multi-phased video coding resulted in identifying entanglements of emotion and data sensemaking alongside instances of appearing and disappearing in the broader modeling activities supported by the data form itself and the class activities.

Findings

Given space limitations, we share one illustrative case involving children collectively building a bar chart together of earthworm counts in their schoolyard. The class session was structured to support insights into what earthworms might need to thrive, in relation to soil conditions, site locations, and children's daily rhythms and routines in the schoolyard. Children use different colored sticker dots to refer to their sampling site's general location - green for the garden area and yellow for the small pond area. We selected this instance because it entailed multiple expressions of emotion and multiple amplifications and reductions.

As children slowly begin building the bar chart though, one pair (Elena and Brian) decide to falsify their data, elevating their tallies just enough to ensure they have the highest earthworm counts among the whole class (21½ worms, despite recording 15 and 15 ½ in their field notes). At the same time, other groups with low and mid-level counts accurately report their data and notably, other groups with zero counts did not share their findings at all or reluctantly with flat expression, given that there is no place for their zeros to go on the bar chart. We draw on adapted Jeffersonian transcription methods (Jefferson, 1984) to capture multi-modal emotional expression.

Ms. A: Brian, come on up, you can build it. Elennnnaa.

Elena: *(quickly making eye contact with Brian while staying seated)* We have 21!

Brian: *(standing up, looking down at Elena)* What?!

Elena: (*rising to her knees*). Yeah (*exhales*). 15 in the garden and 6 in the [pitfall trap] cup. We count it as 21.

Brian: (….) NO, let's just … No, we added those!

Elena: No! It was 15½ so like 16. And then I found other cups, remember? Other worms in the cup. That makes 21!

Brian: (*smiling at Elena*) So 21½?

Elena: (*smiling at Brian*) Yes!

Brian: (*talking to Ms. A*) Can we have like three of them (*referring to the sticker sheets*)?

Brian: *(turning pack to Elena).* But like we already recorded it as 15!

Elena: *(now coming up to standing).* No, it's okay! Let's put it as 21½…It doesn't even go up to 21! (*in a loud voice, raising arm is an upward sweeping motion, Figure 1*).

Figure 1

(a) Elena's arm rising (left) and (b) Elena shouting 21 and a half (right)

Pairs continue adding their stickers, with children counting out loud as they place stickers and coordinate keeping their tallies in the column with their name. After about 30 seconds, Elena and Brian now begin adding their tallies.

Elena: (*walking toward chart)* Are we supp::osed to use 21 stickers? I need to put my name down!!(*holding a marker*) ... I'll do Elena and Brian!

Elena: Brian! We are right here (*pointing to their column*).

Brian: Here? We found a half!

Beatrice: (*crouched low):* You should really start at the bottom because we are all measuring from the top [referring to the ordering of sticker dots on the bar chart].*(Elena and Brian begin placing their stickers onto the chart.)*

Beatrice: Brian, why are you starting at the top?

Brian: 21 and a ½! (*smiling wide*)

Elena: 1,2,3,4,5,6,7,8! (pause) 9,10,11, 12. … Brian, why are you putting them up there?

Brian: We meet in the center!

Elena: *(walking her fingers in marching pattern up the chart*): 1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16, 17! *(stretching word)* 18, um 19.

Brian: Wait you did it wrong?

Elena: Twenty!!

Ms. I: Woah you guys, look at the bar chart!

Elan: I know, like in ten minutes it has grown by tens. (*more children are looking at the bar chart, with just Elena and Brian still standing placing their last stickers on the chart*).

Ms. I: I know…

Group: Oh wow! What the heck?!

Elena: 21… 21 and a half! *(Hands raising up)* 21 ½ (*even louder, with smile forming and arm swinging across her chest, see Figure 1b)*

Brian: (*smile forms*)

Mark: Wa:::it! *(springing up and walking up to the chart from back of rug)* Is this also like invertebrates too?

Beatrice: No, Mark! it is JUST earthworms (*shouting out from back of the rug*).

Mark: Then why is that 21?! (*pointing at the chart*).

Elena: 21 and a ha::lf. We found half a worm! (*walking back towards the rug, smiling spreading*).

Mark: You found 21 worms?! (*louder, eyebrows raised).*

Elena: Yes, 21 worms and a half (*louder*). Right there (*quieter, pointing towards the bar chart*).

Brian: The fraction is important (*smiling)*.

Over the course of several minutes, as they make their way up from the rug toward the bar chart, with expressions of celebration and smiles increasing as their tallies grow bigger - numerically and physically, Elena and Brian falsify their data. We see emotional expression related to personally showing up in the data itself, from ensuring their column has their name on it to increasing their data to have the most in the class. We posit that the class activity structure of collectively aggregating pairs' data as a whole class and having earthworm tallies grouped by children's names amplified the personal, numerical and comparative aspects of modeling activity. At the same time, the structure and history of the bar chart form itself, emphasizing counts and comparison over locality and multiplicity, further amplified showing up and becoming visible in the data. As such, Brian and Elena's engagement in the data modeling practices entail dynamic emotional configurations (Vea, 2020), entangling what tallies children report and how publicly they announced and defend their results to the group. Additional analyses are underway to follow other children's' emotional expressions and data sensemaking within this bar chart class session, often of markedly varied emotional expression as they report different numerical tallies (e.g., having zero or low counts) making them less visible in the aggregated data display. We are also analyzing emotional configurations across different data forms that amplify and reduce aspects of the socio-ecological system, including interactive GIS maps and two way tables.

Conclusion

Preliminary findings shed light on how emotion emergent *within* young people's data modeling pursuits can be integral to practices of data construction, visualization and critique. At the same time, findings also point to the importance of attending to the historical relationships that shape children's data modeling pursuits, illuminating how the data forms themselves and children's own histories with the data transformation process are also dynamically configuring and reconfiguring emotion, science sensemaking and disciplinary pursuits.

Self-Regulated Learning Through Online Formative Assessments: The Effects of Assessment Frequency and Participation on Student Performance

Abstract: Using online formative assessments, students can monitor their learning and find strategies to attain their self-regulated learning (SRL) goals. However, as formative assessments are often optional and ungraded, some students may not be motivated enough to participate in such assessments. In this study, we argue that the frequency and stakes (i.e., optional vs. required) of formative assessment can influence the interplay between SRL and student performance. Using data from multiple offerings of an undergraduate course, we investigate the role of formative assessment frequency and participation rate in predicting students' course performance. Our findings showed that student performance and participation in the required formative assessments were more predictive of their course outcomes. Furthermore, increasing the frequency of formative assessments did not improve student performance.

Background of the study

With the rise of digital technologies, today's educators (e.g., K-12 teachers and university instructors) use online formative assessment to monitor the students' learning progress and provide them with immediate feedback (Bulut et al., 2022). Online formative assessment can help students develop their capability for self-regulation learning (SRL)—the process of how learners use their meta-cognitive skills together to identify learning goals, monitor their own learning, and regulate their cognitive skills to reach the learning goals (Zimmerman, 2002). Although formative assessments promote student reflection on learning by developing students' self-evaluative capacities (Hawe & Dixon, 2017), within the higher education context, it is still not clear when and how formative assessments can help students improve their SRL skills. In this study, we argue that providing more formative assessments and making them optional (i.e., giving students more freedom in regulating their learning) could influence the interplay between formative assessment and SRL. This study examines the effect of frequency and stakes of formative assessment on students' academic performance as measured by their final course grade. We compare results between two sections of the same asynchronous undergraduate course. These two sections differ in terms of formative assessment frequency (i.e., administered weekly vs. after every lecture) and stakes of formative assessment (i.e., optional vs. ungraded mandatory participation). In this study, we argue that providing more formative assessments (i.e., increasing the amount of formative feedback students can receive to monitor their learning) and making formative assessments optional (i.e., giving students more freedom in regulating their learning) could influence the dynamic relationship among formative assessment, SRL, and student learning.

Literature review

Abney et al. (2017) showed that students' participation in low-stakes formative assessments (i.e. ungraded or optional) could be accounted for by students' approach to learning, such as fear of failure and perceived value of the assessment. Similarly, Jones and Korula (2021) found that student perception of their own assessment preparedness is an important predictor of participation in optional and ungraded formative assessments. In addition, self-directed students who perceive that questions in optional formative assessments are relevant and challenging are more likely to participate in the assessment and achieve better final exam performance as opposed to less motivated students (Brazeal & Couch, 2017). The aforementioned findings support that student participation in formative assessments largely depends on student characteristics.

As a core component of student achievement motivation, goal orientation can also be used to explain students' participation in non-mandatory formative assessments (Chazan et al., 2022). According to Elliot and McGregor's (2001) 2 × 2 achievement goal framework, student achievement goals can be characterized by two dimensions, valence (i.e., approach and avoidance) and goal definition (i.e., mastery and performance). The goal definition dimension focuses on students' learning motivations (increasing personal competence vs.

outperforming peers), while the valence dimension describes students' behaviors driven by either their desire to pursue success (approach motivation) or to avoid negative outcomes (avoidance motivation).In achievement settings, mastery-oriented students tend to seek feedback and thus are more willing to participate in formative assessments because they believe that formative assessments enable them to reflect on their learning and improve their performance (Dijksterhuis et al., 2013). Similarly, Yan (2018) found that mastery goal orientation can positively predict students' feedback-seeking and self-reflection behaviors, while performance goal orientation negatively affects such behaviors. More recently, Kaur et al. (2017) found that formative assessments are more favored to mastery-oriented students than performance-oriented students because, for mastery-oriented students, a formative assessment is perceived as the opportunity to improve their understanding of course content and thereby motivating them to participate in assessments for continuous feedback on their learning. On the other hand, performance-oriented students demonstrated the greatest interest in the grades but the least interest in the received feedback about their learning progress (Kaur et al., 2017).

Research method

Data source

Data for this study came from two sections of an undergraduate course designed for pre-service teachers enrolled in the Elementary and Secondary Education programs at a Canadian university. The first section (n_1 = 123) was taught by Instructor A during the Fall 2021 semester, while the second section (n_2 = 119) was taught by Instructor B during the Winter 2022 semester. Due to the public health restrictions taken during the COVID-19 pandemic, both sections were delivered online and asynchronously. The instructors followed the same curriculum, shared the course materials with students via the same Moodle-based LMS throughout the semester, and used identical course assessments (two midterms and a cumulative final exam). Both instructors also shared online quizzes as formative assessment tools. Multiple-choice items were auto-scored within the LMS, while the answer key for short-answer items was shared with students upon completing each online formative assessment. The LMS recorded all student activities, including assessment results and timestamps for each student activity.

At the beginning of the semester, both instructors explained the main rationale behind formative assessment clearly: these ungraded assessments were designed to help students gain experience and improve their skills to obtain better grades in the midterm and final exams. Students were allowed to complete each formative assessment as many times as they wanted. The accuracy of students' responses to selected-response items and their percent-correct scores were displayed after each quiz attempt to provide students with feedback on their performance. However, the two sections differed based on how online formative assessments were utilized by the instructors. At the beginning of each week, Instructor A posted learning materials for two lectures (e.g., lecture slides, pre-recorded lecture videos, etc.) and an online formative assessment via the LMS. In contrast, Instructor B posted a formative assessment after each lecture. This led to Instructor B having twice as many formative assessments (N = 10) as Instructor A.

Data analysis

We extracted features from the LMS data focusing on formative assessment behavior and course performance. Specifically, we retrieved the first midterm, second midterm, and final exam scores of students for each section. Then, drawing upon previous studies, we extracted features focused on formative assessment behavior, including the average first attempt score (i.e., the mean of formative assessment scores based on students' first attempt), the average score based on all attempts across the available formative assessments, and the frequency of formative assessment attempts for each formative assessment (i.e., how many times students participated in each formative assessment). Since we analyzed the course performance on all three summative assessments (i.e., midterm and final exams), we extracted formative assessment features pertaining to each exam separately. Using the extracted features and students' exam performance, we ran three multiple regression models (i.e., one for each summative assessment) for each section to understand which features predicted the students' performance. This helped us evaluate the unique contribution of each feature to predicting and evaluating student performance. All analyses, including data cleaning procedures, were completed using the R programming language (R Core Team, 2022).

Results

Both instructors completed four weeks of lectures (two lectures per week) before the first midterm. Thus, Instructor A had two formative assessments, whereas Instructor B had four formative assessments before the first midterm exam. In Table 1, The top part presents the multiple regression results for both sections using the formative assessment features extracted from the quizzes before the first midterm. For the class of Instructor A where participation in formative assessments was required, we found that the first attempt score ($b = 0.27$, $p < .05$) and the frequency of attempts for the first formative assessment ($b = 0.85$, $p < .05$) were significant predictors of the first midterm scores. Also, the model showed explained almost 50% of the variability in the first midterm scores. However, the same model for Instructor B only explained about a quarter of variability in the first midterm scores. Similar to Instructor A, first attempt scores ($b = 0.12$, $p < .05$) were a significant predictor of the midterm scores, whereas, unlike for Instructor A, the frequency of attempts to the last two formative assessments ($b = 0.81$, $p < .05$ and $b = -0.84$, $p < .05$) significantly predicted the midterm scores.

Table 1
Regression Analysis Results for Predicting Midterm 1 Scores for Instructors A and B

Adjusted R^2	21%				17%			
Overall Model Fit	$F(4, 115) = 8.671$*				$F(6, 93) = 4.325$*			

Note: *$p < .05$. b and β the unstandardized and standardized regression coefficients, respectively *SE*: Standard error. Frequency of attempts (1) to (4) refers to participation in the first to fourth formative assessments taken before each midterm exam.

Two interesting patterns deserve to be scrutinized in Table 1. First, participation in the first and last formative assessments in Instructor B's class was negatively associated with the midterm scores. This result is likely to be a consequence of the non-mandatory nature of formative assessments in Instructor B's class. Instead of participating in formative assessments regularly and monitoring their performance, some students (especially those with lower midterm scores) took the last formative assessment repeatedly before the first midterm exam to better prepare for the midterm exam. Second, there are differential effects of formative assessments in predicting students' midterm scores. In Instructor A's class, mandatory participation in the first formative assessment seemed to be a significant predictor, whereas in Instructor B's class, optional participation in the third and last formative assessments was significantly related to students' midterm performance. The bottom part of Table 2 shows the regression results for the second midterm exam. None of the formative assessment-related features significantly predicted the second midterm scores for Instructor A and Instructor B. This was primarily because most students performed very well in the second midterm exam, leading to a highly skewed distribution with low variance.

Table 2 presents the regression results for the final exam. For Instructor A, the model explained 25% of the variability in the final exam scores, whereas for Instructor B, the regression model explained only 2% of the variability in the final exams scores and the overall goodness of fit was not significant. For Instructor A, the frequency of attempts to the formative assessment ($b = 3.32$, $p < .05$) was a significant predictor of the final exam scores, even though the scores in the formative assessment were not a significant predictor. This finding suggests that participation in online formative assessments, but not their scores, could be a key factor in explaining which students are preparing better for the final exam. In contrast, the attempts for the first and second formative assessments in Instructor B's class were not significantly related to students' final exam scores.

Table 2

Regression Analysis Results for Predicting Final Exam Scores for Instructors A and B

	Instructor A				Instructor B			
	b	*SE*	β	*t*	*b*	*SE*	β	*t*

Frequency of attempts (2)	-	-	-	-	0.25	1.02	0.04	0.25
Adjusted R^2	25%				2%			
Overall Model Fit	*F*(3, 105) = 13.1*				*F*(4, 76) = 1.486			

Note: *$p < .05$. *b* and β the unstandardized and standardized regression coefficients, respectively *SE*: Standard error. Frequency of attempts (1) to (4) refers to participation in the first to fourth formative assessments.

Discussion

Our results emphasize the predictive utility of online formative assessments in predicting student achievement. This predictive utility seems to increase when online formative assessments are deemed mandatory. Also, increasing the frequency of online formative assessments does not necessarily lead to better student outcomes, suggesting the need for using fewer but more meaningful assessments. Our findings suggest that providing students with feedback through formative assessments can help them regulate their learning and formulate more effective learning strategies to obtain better course grades (Hattie & Temperley, 2007). Also, making the formative assessments required could motivate students to participate in the formative assessments regularly throughout the semester. Although scores from formative assessments may lose their predictive utility over time, students' participation behavior in formative assessments could still inform the instructors about who is likely to be successful in the course.

Which Way is Up? Orientation and Young Children's Directional Arrow Interpretations in Coding Contexts

Abstract: Many coding environments for young children involve using navigational arrow codes representing four movements: *forward, backwards, rotate left, and rotate right*. Children interpreting these four, seemingly simple codes encounter a complex interaction of spatial thinking and semantic meaning. In this study of how children interpret directional arrows, we found that they interpret each of the arrows as encoding many meanings and that the orientation of the agent plays a critical role in children's interpretations. Through iterative rounds of qualitative coding and drawing on two examples, we unpack some common interpretations.

Introduction

There has been a push to make computer science education equitable for all students. However, as mentioned in the call for proposals for the ISLS 2023 conference, things that are argued to be more inclusive for many learners have also been shown to disadvantage many others. Sometimes our designs for learning are messy, and as learning scientists, we need to take a step back and try to disentangle the complexity and engage in sensemaking about how learners are interpreting and interacting with our designs for learning and the materials that are meant to support them. Such is the case for the present study. In this paper we explore how young children interpret and interact with the materials we designed to teach and assess their understanding of computational thinking (CT). Like many researchers in early childhood, we use coding as a context to promote CT (Wang et al., 2021). Most coding environments for pre-literate children use navigational codes that are represented through arrows: *forward*, *backward, rotate left,* and *rotate right* (Clarke-Midura et al, 2019). While the idea of using arrows to represent movement may seem simple, it is challenging for young children. The navigational arrow codes are a whole new symbol system they need to make meaning of. It requires understanding what each arrow instructs the agent to do, that one arrow only produces one discreet movement, and that each arrow always produces the same movement but depends on the agent's orientation. In this paper we theorize about the complexity that two codes: *forward* and *rotate left* and how the orientation of an agent affects children's interpretations of the two codes as they engage in tasks designed to assess their understanding of CT. Our inquiry is guided by the following research questions: *How are children interpreting the arrows? How does the orientation of the agent affect children's interpretation of the arrow codes?*

Background and context

The present study has roots in Papert's (1980) Logo Turtle Geometry where the turtle became a virtual computational agent for children to connect with abstract ideas like angles and navigation in a concrete way through "body syntonicity." Reasoning about an agent's orientations, locations, and navigation in space involves spatial thinking. The National Research Council (NRC) defined spatial thinking as comprised of three elements: concepts of space, tools of representation, and processes of reasoning (NRC, 2006). Children first develop spatial orientation concepts in relation to their own position in space and later develop external based reference systems using landmarks outside themselves (Sarama & Clements, 2009). Yet, few studies have systematically investigated the complexity of spatial orientation in children's understanding of CT.

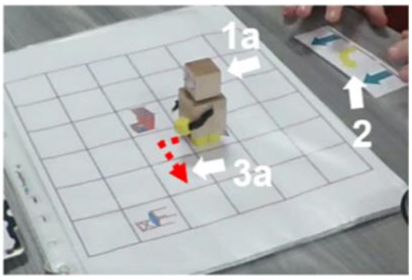
Research design and methods

Task and materials

We designed two tasks that are identical except for the starting orientation of the agent. In both tasks, children were asked to enact a sequence of codes, *forward, rotate left, forward*, that were provided to them in the form of arrows (see Figure 1). Children were instructed to physically move a tangible agent on a 6x6 2D grid. In Task A, the agent shares the same orientation as the child, while in Task B, it is oriented 90 degrees to the left.

Figure 1

Set up for Task A (left) & Task B (right)

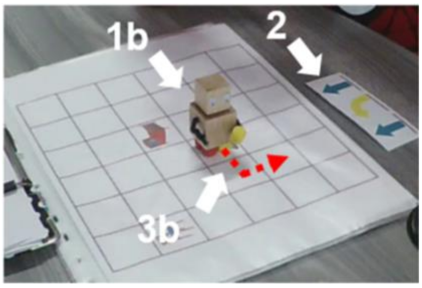


1a: Agent's orientation same as the child's perspective.

1b: Agent's orientation 90 degrees to the left from the child's perspective.

2: Program to enact: FLF

3a & 3b: Expected path the agent will travel if all codes are enacted correctly



Sample and data sources

This research is part of a larger project that is operationalizing CT in early childhood and developing curricular tasks and a performance assessment (Clarke-Midura, et al, 2021a). Data come from video of 146 children aged 5-7, spread across five elementary schools in the western United States, solving the two tasks described above.

Data analysis

This analysis started with *a priori* codes that were developed from a previous analysis where we observed how four groups of children (n=16) interpreted the *rotate left* and *rotate right* arrows during a curriculum enactment with different materials but similar navigational codes (*forward, backward, rotate left, rotate right*). In the present study, as we coded the new video data, we modified and refined the codes as new types of arrow interpretations emerged. The codes were cross-checked with each other and with the data from the previous analysis. We compared codes, identified interpretations that appeared frequently or with more clarity, and could be differentiated from each other. This allowed us to create categories and identify themes. We engaged in selective coding, where we refined, solidified, and clarified codes and categories until we reached saturation.

Results

Various interpretations of forward and rotate left

In our context, a *rotate left* arrow makes the agent stay in the square and rotate 90 degrees to the left and a *forward* arrow makes the agent move one square forward *from the agent's perspective.* However, children interpreted the *forward* and *rotate left* arrows in various ways. We identified four *forward* arrow interpretations and five *rotate left* arrow interpretations. The various interpretations indicate that some of the children did not attach one fixed meaning to an arrow and, as a result, each arrow had the potential to do everything.

Figure 2

Children's Forward Arrow Interpretations

	Spin to face this way	Slide sideways	Curve this way	Rotate and slide this way
Definition	Reorienting the agent to share a child's perspective	Moving the agent one square above without reorienting the agent to face forward	Making the agent curve to the square above	Rotating the agent face forward and then travel to the square above
Visual illustration				
Figure 2 shows that children used *forward* arrows to do things other than moving the agent to an adjacent square. They assigned two distinct movements, rotating the agent while staying in the square and moving one square forward to one *forward* arrow. They enacted both movements either as one fluid movement by making the agent curve one square in the direction of the arrow (*curve this way*) or as two distinct movements (*rotate and slide this way*). Children sometimes enacted the *forward* arrow as *slide sideway* by moving an agent one square forward when the agent's orientation is different from the direction it travels. In this case, children attached the correct movement (sliding one square) to the *forward* arrow; however, they did not take on the agent's viewpoint when moving it.

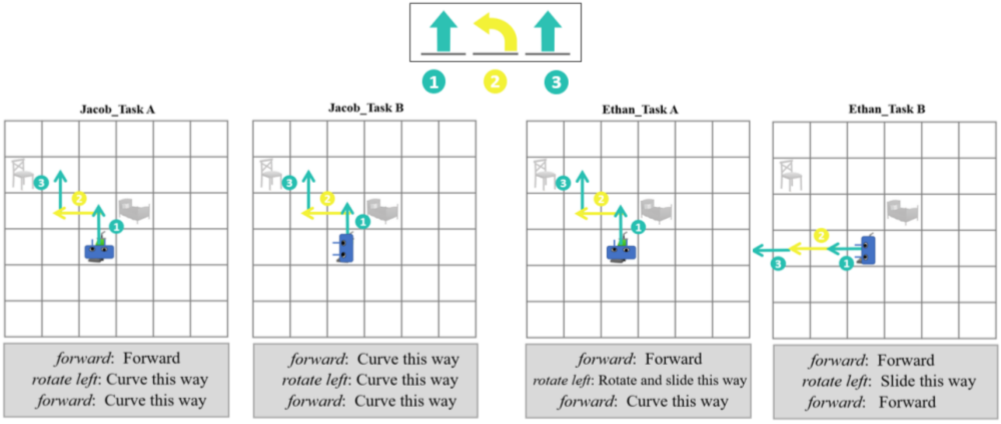
Figure 3
Children's Rotate Left Arrow Interpretation

	Slide this way	Slide sideways	Curve this way	Rotate and slide this way	Slide this way and rotation
Definition	Moving the agent one square in the direction of the arrow	Moving the agent one square to the left without reorienting the agent	Making the agent curve to the square on the left	Rotating the agent face to the left and then travel to the next square	Making the agent travel one square and then rotate it to face to the direction of the arrow
Visual illustration					
Children used *rotate left* arrows to make the agent move in ways other than rotate 90 degrees to the left (see Figure 3). Some children interpreted the *rotate left* arrow by enacting two moves: first rotating the agent 90 degrees to the left and then sliding it to the next square (*rotate and slide this way*). Sometimes they combined rotation and sliding by making the agent travel in one fluid movement (*curve this way*). When the agent's orientation was facing left (the same as the arrow's), some children enacted the *rotate left* arrow as if it were a *forward* arrow, by moving the agent to an adjacent square without reorienting it (*slide this way*).

How orientation affects interpretation

Figure 4 presents visual representations of two children's enactment of Task A and B, Jacob and Ethan. The arrow direction represents the direction the agent was facing at the end of each code enactment.

Figure 4
Jacob's and Ethan's Arrow Interpretation



Example 1: Jacob

In task A, where the agent shares Jacob's orientation, he enacted the *forward* arrow correctly. However, the enacted the *rotate left* and last code, *forward*, incorrectly. In Task B Jacob enacts both *forward* arrow codes by making the agent curve to the square above. Even though the agent shared his orientation when he enacted the second code, *rotate left* in both tasks, he enacted it by making the agent curve to the square on the left.

Example 2: Ethan

Ethan enacted the first *forward* arrow correctly in both tasks. In task A, even though the agent shared his orientation when he enacted the second code, *rotate left* he enacted it by rotating the agent to face the left and travel to the next square. In task B, he enacted the left rotation by moving the agent one square in the direction of the arrow (to the left). In Task A, Ethan enacted the second *forward* arrow as *curve this way* yet in Task B, he enacted the second *forward* arrow correctly.

Analytic findings

Using the symbolic system of navigational arrows to sequence and enact codes requires understanding *code-to-movement correspondence*, that each code (arrow) makes the agent do a single discreet movement; and *agent-orientation correspondence*, which means codes always produce the same movement but depend on the agent's orientation. We observed various interpretations that violated these rules; the most common example is using a *rotate left* arrow to do *curve this way*. While the orientation of the agent did affect children's interpretations, their interpretations were not consistent. Some children used the same arrow differently in the same program.

Previous studies have characterized the ways children have difficulty determining spatial orientations other than their own (Sarama & Clements, 2009) including in the context of coding with robot coding toys (Wang et al., 2022; Clarke-Midura et al., 2021b). Our findings align with these studies in that they show how not being able to take on the perspective of the agent is associated with mistakes and incorrect use or enactment of codes. Besides perspective taking, arrow interpretation is influenced by the directional relationship between the agent's orientation and the arrow's. When the agent's orientation is the same as the direction of the arrow code to enact, even if children shift their perspective to the agent's, they may still interpret an arrow's meaning other than it is supposed to be. When the agent is facing an orientation different from the orientation of the arrow code to enact, a child may reorient the agent to the direction of the arrow before any further enactment. In our study, many children look only at the tile and see the *forward* arrow is oriented "up" as depicted in the tile and then move the agent to the direction of the arrow, regardless of its orientation and position on the grid. While using arrows to represent navigation may seem like a simple design idea, our findings illustrate how the arrows caused confusion for children.

Conclusion

In this study, children acted as surrogates by moving a physical agent to solve CT tasks on a two-dimensional grid through arrow-by-arrow enactment. This is a promising context for young children to learn spatial thinking and computational thinking skills. However, the variety of arrow interpretation indicates that tasks situated in this context are also difficult for young children. Children need to coordinate multiple representations and meanings, such as the agent's orientation in relation to the symbolic representation of the arrow's orientation on the code tile, and the position of the arrow tile to the child's orientation. When designing learning and assessment environments for early childhood CT, we need to be aware of how the designs and materials intersect and influence children's spatial thinking skills. This study contributes to our knowledge of the intersection between syntonic learning, spatial thinking, and computational thinking in early childhood.

How Off-Duty Data Scientists Did Math for Civic and Social Good

Vien Nguyen, Reed Stevens
viennguyen2026@u.northwestern.edu, reed-stevens@northwestern.edu
Northwestern University

Abstract: This paper presents an ethnographic case study of a team of off-duty data scientists who electively made a new mathematical metric to address a problem with one of their city's key public services. This case study offers an image of an environment that was organized to allow participants to pursue two opportunities by doing math — one was to help potentially improve a public service in the near future and the other was to become better data scientists. The case material offers ideas for designing mathematical learning environments that might similarly offer young people opportunities to learn to do math for social good and to advance their broader interests and concerns (Stevens, 2020).

Introduction

Schools teach students the subject of math, hoping students will carry it into their everyday lives. We need to understand the actual and possible relations between school math and the math that is done outside of school (Stevens et al, 2016). Learning Sciences researchers have shown that people in everyday life are motivated to do math that is fitted to the criteria that they themselves define for success in their daily lives, whether in leisure or work contexts (Lave, 1988; Stevens & Hall, 1998). Recent studies have examined a number of contexts, where the math involved has negative consequences for society, math that is both biased and hidden within an unseen algorithm (O'Neil, 2017; Noble, 2018). A very different genre of study documents examples of math that is done for civic and social good (Esmonde, Curnow & Riviere, 2014; Taylor & Hall, 2013). As we see it, our study contributes to this emerging genre — we tell the story of one team of volunteers who made a new mathematical metric to address a problem with a key public service in their city.

This case study offers an image of an environment that might offer ideas for making math more meaningful for young people in school. Schools find it difficult to motivate children to do math (Boaler, 2000). In contrast, the participants in this case study were motivated to do and learn math in their work; so much so that they did it late at night after long hours working at day jobs in data science. The volunteers organized an environment that offered at least two opportunities — one was to use math to help potentially improve a public service in the near future and the other was to learn skills relevant to their careers as data scientists. The participant's motivating environment might offer, we argue, ideas for reconstructing educational experiences in school (Stevens et al, 2016; Stevens, R., Davey, B, & Nguyen, V., in preparation), to offer children opportunities to do math to advance social good as well as to advance their own interests and concerns (Stevens, 2020).

Research context, data collection, & analytic framework

Civic Technology Volunteers (CTV) is a non-profit organization located in a very large midwestern city. CTV is run by volunteers who come every week after working day jobs as data scientists. The CTV volunteers use publicly available data to build technology applications and present them to a public audience of news media channels and nonprofits. We focused on a project called "Phantom Buses", one of many at the CTV. We conducted ethnographic participant observation (Emerson, 2001) with the Phantom Buses team starting in June of 2022. The first author attended the weekly team meetings held on zoom and face to face, participated in the team's Slack communication platform, read the team's software repository, and conducted semi-structured interviews to understand the project activities outside of the weekly meetings. To date, we have collected approximately 45 hours of video data, 5 hours of interview data, and 30 pages of field notes.

The first author watched the videos after every data collection session, made content logs (cf. Jordan & Henderson, 1995), and generated analytic memos. Our analytic framework falls within the learning sciences and cognitive tradition of problem-solving. In particular, we followed the distributed cognition approach in which an analysis follows how people and tools are coordinated across time and space to solve a problem (Hutchins, 1995). This case study involved a phase of problem solving that is often left out of problem-solving studies — the problem finding phase (Getzels, 1979). The problem-solving in this case study also involved a process called *drawing things together*, whereby disparate data is gathered into one place then transformed into one synoptic representation which is made as strong and complete as possible for an anticipated contestation (Latour, 1987). In the next section, we present the product of our analytic work: an analysis of the chronological set of events from our ethnographic record.

Data and analysis

Lilah finds the problem of Phantom Buses and pulls together a team to address it

Buses are an important part of city transit infrastructure; many bus riders rely on buses every day to get to places of work or to medical care. Since the COVID-19 pandemic, city bus riders have noticed that bus service has seemed especially unreliable. Many bus riders have experienced a situation where the schedule published by the municipal transit association (MTA) claims a bus is coming, but none shows up; that bus is a “phantom bus.”

One of the members of CTV, Lilah, closely followed and read social media stories and online forums where citizens reported their experiences with phantom buses. Lilah heard that some citizens were so frustrated that they had tried to alert the MTA of these phantom buses, but that the MTA dismissed their pleas. Lilah heard that in the upcoming months there would be a public hearing at City Hall where city officials, and citizens would meet to discuss their concerns with the MTA. Lilah began to think of ways to help citizens convince the MTA, in this upcoming encounter, to acknowledge the problem of phantom buses and to fix it. Lilah’s idea was to make a data representation of phantom buses, then give it to citizens who could present it at the upcoming public hearing. Lilah searched around and found two relevant datasets. One dataset consisted of the set of locations and times at which all buses operated by the MTA were scheduled to arrive at their stops, called the “schedule dataset”. The second dataset consisted of real-time live data from the Global Positioning System tracker hardware that is on every MTA bus, called the “real-time dataset”. Lilah’s idea was to characterize the phantom bus phenomenon by quantifying the discrepancies between scheduled and actual service levels. Lilah had found a problem, which Getzels (1979) aptly described as a critical but overlooked part of problem-solving.

Lilah brought the problem of phantom buses to the CTV and pulled together a team to address it. Lilah hoped that other CTV members might share enough of her concerns about this key city transit system, and also share interest in expanding their data science repertoires, that they might want to join the team. Three other CTV members joined. The team divided their labor (Hutchins, 1995; Stevens, 2000) according to each member’s distinctive competencies and interests in learning new data science skills. Then the project work began in earnest.

The team draws together data and transforms it into a strong synoptic math metric

To convince the MTA at the upcoming public hearing to fix the problem of phantom buses, the team would have to *draw together* the disparate data into one compelling synoptic representation of the problem (Latour, 1987). To start, the team had to gather raw data from both the public “real-time” and “schedule” datasets and store it in one place. Storing the data in one place would require Lilah to find a data storage service and to write a kind of computer program that she had never written before (FN, 6/02). Lilah took this opportunity to learn. She selected a data storage service that she was curious about but had never used in her day job as a data scientist. She wrote the new computer program and revised it until it reliably aggregated the two datasets (FN, 6/14). Having gathered the data into one place, the team was ready for the next step — deciding on a way to quantify phantom buses.

The team set out to find a way to quantify the phantom buses phenomenon that would expose two aspects of the problem at once — its pervasiveness and its distribution across the city. The team insisted on seeing the distribution because they suspected that phantom buses were most concentrated in neighborhoods in the South and West, which historical records showed were chronically neglected by the city. The team wanted to be ready to argue, at the upcoming public hearing, that the MTA should focus its resources on fixing phantom buses in those neighborhoods, if indeed their analysis showed that they were most affected by the problem. With this in mind, the team decided to quantitatively represent the phantom buses phenomenon as a metric consisting of the ratio of actual to scheduled trips. Then, the team had to decide between two ways of aggregating the data — by stop or by route. The team decided on the latter, because it offered a practical advantage for the upcoming contestation. The MTA had control over the staffing by route but not by stop. Therefore, in the upcoming hearing at City Hall, it would be easier for the team to ask city officials to compel the MTA to increase its staffing on specific routes than at particular stops. The team had found a way to quantify the phantom buses phenomenon. But the team was still not yet ready for the anticipated contestation.

If the team was going to present their metric at the upcoming public hearing, they still had yet to do the work of calculating it. The two datasets contained so much data that the team had to write separate computer programs to calculate the numerator and denominator (i.e., actual vs. scheduled). This was no easy task, but the team persisted out of their desire to both use the metric for the upcoming contestation and to learn to write new kinds of programs. To calculate the numerators, the team taught themselves to work with a number of libraries in the Python programming language in order to transform a metaphoric mountain of geo-spatial latitude and longitude data of the real-time locations of the buses. Calculating the denominators was not easy either, because it required the team to convert the schedule dataset, which was encoded in an idiosyncratic data format that only the MTA used, into a more standard one to match the format that the numerator dataset was expressed in. Then, having separately calculated the numerators and denominators, the team wrote a third computer program to combine the two. This computer program contained a line of code which read g = trip_count_rt / trip_count_sched, which is equivalently expressed in shortened form as g = r / s, where for a given route, g stands for the ratio of phantom buses for that route, r stands for the number of actual real-time bus trips, and s stands for the number of scheduled bus trips. From this computer program, the team created a data table showing the metric computed for all of the buses in the city (FN, 7/18). A few rows are depicted in Figure 1(a). The leftmost column, highlighted in yellow, showed that phantom buses were concentrated in the South and West of the city. The team had represented the pervasiveness and inequitable distribution of phantom buses.

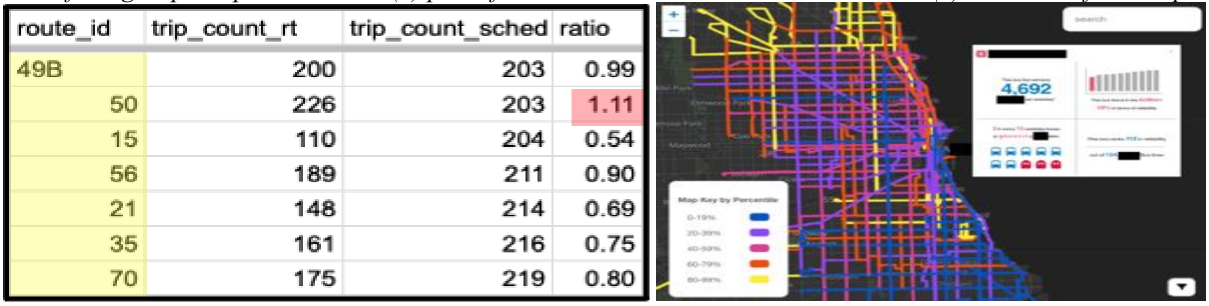
The team needed the metric to be strong for the anticipated contestation with the MTA at a City Hall Transit Hearing. But team member Diego noticed a potential problem that called the metric's strength into question. The problem was that some of the routes had ratio metrics with values greater than one. One of these ratios is highlighted in red in the rightmost column of Figure 1(a). For any such route, this would mean that there were more actual trips than scheduled trips; this would indicate *surplus* buses, rather than phantom buses. The team worried that the MTA might challenge the ratios above one as faulty, if they did not represent a *fact* of reality but rather were an *artefact* of a poor algorithm (Latour & Woolgar, 2005). The team members went to great lengths to figure out whether their computations were indeed incorrect. Lilah inspected her prior code and noticed that it was "double-counting" numbers, and that this was ultimately rooted in a tricky data architecture problem involving what the team called "non-unique identifiers" (FN, 10/4). The metric was not yet strong enough for an anticipated contestation with the MTA at City Hall.

Diego then proposed an idea for revising the metric so it could not be dismissed so easily by the MTA. Diego's idea was to calculate the ratio metric in a coarser time window than it had been calculated before (daily rather than hourly). Diego then wrote new code, which generated data tables based on his newly calculated metrics. The team then double-checked the new code to ensure that its architecture addressed the issues that had plagued the old code, and that the resulting new ratios were plausible when considered together as a whole distribution. After these revisions, most of the numbers were lower than they were before, indicating even more phantom buses than the prior round of calculations had identified. The team had now eliminated a problematic artefact in their metric and had enhanced the quality of the evidence about the phantom buses problem, aligning nicely with Latour's description of making a representation stronger for its uses in future anticipated contestations.

The final step in the team's process involved the team transforming Diego's data table to produce a final synoptic map visualization of the metric, pictured below in Figure 1(b). As of this writing, the team has shared the map of the metric with citizens via social media, along with a supplementary written report detailing the methodology the team used to make the metric and the team's software repository of computer programs. Citizens can now testify before City Hall to get city officials to persuade the MTA to fix the problem of phantom buses, especially in neighborhoods most affected. To summarize, the team had listened to citizens' experiences with phantom buses, found a problem (Getzels, 1979), quantified the pervasiveness and inequitable distribution of that problem, then drew together and transformed data into a synoptic representation — they had turned the question of Phantom Buses into a fact (Latour, 1987). As of this writing, we don't know if the team, or the citizens with whom they shared their metric, will succeed in the upcoming contestation with the MTA at City Hall. But if Latour's conceptual model is as apt as we have found it in this case, they were as prepared as they could be.

Figure 1

Two of the group's representations, (a) part of a data table with the initial metric, and (b) the team's final map



route_id	trip_count_rt	trip_count_sched	ratio
49B	200	203	0.99
50	226	203	1.11
15	110	204	0.54
56	189	211	0.90
21	148	214	0.69
35	161	216	0.75
70	175	219	0.80

Discussion

This case study is one of a small but growing number of examples of a new genre of math that is done for civic and social good (Esmonde, Curnow, & Riviere, 2014; Taylor & Hall, 2013). Our community can make use of more such examples, to show learners that math is not just a tool of the powerful (Noble, 2018; O'Neil, 2016).

This case study speaks to learning issues at both the collective and the individual levels. At the collective level (Hutchins, 1995; Stevens, 2000), the team learned how to take a *question* about a potential civic problem and turn it into a *fact* that documented that problem. The team learned something that was not known before and now could be 'taught' to others. At the individual level, each project member took opportunities to become better data scientists. For example, Lilah identified a mistake in her code and revised it with Diego's help.

In addition to the value of this case study as basic research on mathematics and data use in the wild, it also might suggest ideas for motivating young people to learn math. In school that motivation is hard to find and when it is found it is often better characterized as what psychologists call extrinsic rather than intrinsic. Students often do math for the benefits that high grades in math courses bring (Boaler, 2000). In contrast, the Phantom Buses members did math for free and without 'credit', volunteering after working all day in math-heavy data science jobs. A constant refrain math teachers everywhere hear is "when are we ever going to use this". This case suggests that learning environments that provide analogously consequential problems as those found and solved by the Phantom Buses team could mean a real answer to that question, with the added benefit that young people might not see only see that math has a meaningful use, but one that can make the world a better place.

Abstract: In this paper, we report a systematic review of the literature on teacher professional development (PD) focused on antiracism and ask the following questions: *(1) what are the assumptions about race and racisms embedded within PD designs? and (2) what is the relationship between PD design features and outcomes for teachers (e.g., development of antiracist dispositions and practices)?* We reviewed research that is explicit about the design of PD for teachers' development of antiracist praxis with particular attention to how PD designs are conceptualized, and how they facilitate changes in teacher practices. We found that many PD interventions did not connect their designs to cultural-historical conceptualizations of race, and even fewer made empirical claims about changes in teacher practice as a result of PD.

Introduction

In the wake of George Floyd's murder (E. Hill et al., 2020), a national reckoning about systemic racism awakened school leaders and policymakers across the U.S. to the fact that racism is real, alive, and thriving (Madkins & Nazar, 2022). The recognition that there was a need to create professional learning opportunities for teachers that were serving a growing population of minoritized learners, intensified *professional development* (PD) efforts – defined as bounded, organized activity for teacher learning – in public schools to confront racism and learn, now colloquially termed, *how to become an antiracist* (Kendi, 2019).

While the energy for anti-bias and antiracist teacher PD has somewhat dwindled after the U.S. protests of 2020, the urgency for a radical transformation of *teacher learning*–the developmental learning process bounded within and outwith PD–has never been more necessary. The cumulative impact of historical inequities on opportunities to learn, along with existential threats that disproportionately impact communities of color (e.g., Covid-19 and climate change), means that status-quo public education does not simply reproduce racial structures, but can exacerbate inequalities in realms beyond education.

Schools have simply been too effective at reproducing inequitable educational outcomes for black, indigenous, and other children of color (BIPoC) in the U.S. These patterns are a byproduct of the everyday ways in which structures of domination on the basis of race (Omi & Winant, 2014) shape inequitable opportunities to learn, and are by no means a reflection of minoritized students' inherent ability to learn. Teachers, embedded within these systems, invariably participate in maintaining a racially unjust status quo, regardless of whether they are cognizant of the ways in which they do (Milner, 2017). Teachers *could*, however, be marshaled as critical players in the process of reimagining schooling–reconfiguring the educational processes that create meaningful outcomes for children of color, in the near term (i.e., opportunities to learn), as well as far (i.e., possible futures).

In this paper, we focus on envisioning what it takes for teachers to learn how to reimagine and refigure educational processes they orchestrate through teaching practice in service of the growth of BIPoC youth. We seek to surface how PD designs for antiracism help teachers grow in ways that, generatively, lend themselves to the creation of healthful learning spaces for minoritized children to grow and thrive in the near term (and have the potential for longer-term impacts on children's possible futures). We report a systematic review of the literature on teacher PD and ask the following questions: *(1) what are the assumptions about race and racisms embedded within PD designs? and (2) what is the relationship between PD design features and outcomes for teachers (e.g., development of antiracist dispositions and practices)?* We review research that is explicit about the design of PD for teachers' development of antiracist, equitable, and culturally relevant praxis. In this review, we consolidate PD design features that yield teachers' expansive learning about equity, justice, and antiracist praxis. Our goal is to 1) synthesize the current state-of-the-art on PD for antiracism, 2) identify design features of PD that lend themselves to teachers' expansive learning around antiracism, and 3) to identify the gaps in the literature on supporting deep and sustained conceptual transformation around race/racisms that could be embodied in teaching practices that work towards fundamentally antiracist ends for BIPoC students.

Methodology

Situating antiracist professional development in cultural-historical contexts

We conducted a synthetic review of literature on teacher PD focused on *antiracism*. We define *race* as social-cultural construction of *racial meanings* (real or imagined attributes used to classify people) (Omi & Winant, 2014). These signifiers "inform practices, and shape institutions and communities, demarcate social boundaries, and organize the distribution of resources" (Omi & Winant, 2014, p. 125). *Racism*, then, is the production or reproduction of "structures of domination based on racial significations and identifiers" (Omi & Winant, 2014 p. 128). In schools, this process of production/reproduction can occur at the macro-level through structures such as school funding (explicit systems of unequal and inequitable distribution of resources to public schools that serve particular communities), at the meso-level through systems such as tracking (a system of sorting children by perceived ability levels in schools, which in the U.S. disproportionately places BIPoC youth in low and remedial tracks); and the micro-level instructional decisions (e.g., how teachers teach children in low and remedial tracks, such as lowering the cognitive demand of instruction). In other words, the consequences of racism in schools and teaching are inequitable opportunities to learn, which in the U.S. have materially and disproportionately harmed BIPoC children and youth.

Therefore, we understand antiracist teacher PD as designs for teacher learning that seek to develop teachers' conceptual understandings about race/racisms, as well as pedagogical practices that fundamentally resist the reproduction of the racial meanings that shape education equities for BIPoC youth. More specifically, we view antiracist teacher professional learning in terms of human development as situated within cultural historical activity systems (Engeström et al., 1999). In this sense, we attend to several features of designs for PD: 1) mediational tools for sensemaking around race/racisms and antiracism, 2) implicit and explicit articulations of the nature of race/racisms with particular attention to its cultural-historical formation, systems of power, and hierarchical systems; 3) implicit/explicit theories about how teachers learn. Next, we examined the relationship between these design features on the outcomes of PD interventions. Our goal is to consolidate the evidence, in terms of designs for teacher learning that support teachers' generative growth in dispositions and practices that yield healthful learning spaces for BIPoC youth.

Review methods

We conducted a database search in ERIC that focused on three broad components: 1) teachers, 2) antiracism, and 3) professional development. After removing duplicates, a total of 1470 articles were identified. We used excluded articles that did not meet the following criteria, 1) description of K-12 PD design centered around antiracism, 2) was an empirical study, and 3) BIPoC students were identified as beneficiaries of growth in teacher learning. Studies were excluded if they were evaluation studies or doctoral dissertations. This resulted in 31 articles that were decomposed to analyze features of the interventions (e.g., mediational tools, conceptualization of race/racism, duration, frequency, iteration, situativity, roles of teachers/PD providers, intended outcomes, reported outcomes, and evidence of outcomes). In this paper, we focus on the 14 studies that documented evidence that teachers' shifted in dispositions or practices.

Findings

Gaps in cultural-historical articulations of antiracism

From the cultural-historical perspective on antiracism and learning we utilized to conduct this review, we observed gaps and variations in the ways they conceptually framed antiracism. We found that almost half of the studies, which all explicitly articulated goals to change teachers' practices towards antiracist ends, did not define or frame antiracism in ways that acknowledged how racism shapes power in the learning environments, is systemic, or historical in its formation. In other words, many of the studies were striving to advance teachers' antiracist practice but did not fully acknowledge the cultural-historical nature of racism. Not fully conceptualizing the nature of the phenomena raises questions for whether an intervention could be fully efficacious.

Six out of the 14 manuscripts that shared a goal for change in classroom practices did not offer any cultural-historical framings of antiracism. Many of the studies (K. D. Hill, 2012) conceptualized antiracism from a perspective of culturally-relevant pedagogy (e.g. Ladson-Billings, 1995), which in its original formulation, includes calls for educators to support the development of "critical consciousness" in teachers. However, a common theme in the studies within this category was that they focused on supporting teachers' development of pedagogical practices but did not link these practices to broader, sociocultural practices and structures of racism. Other articles in this category (e.g. Katz et al., 2010) limited the scope of teacher learning to derivative models of culturally relevant pedagogy, such as multicultural education, focusing on increasing representation in the classroom in which cultural markers of particular groups (e.g. historical figures) were integrated into classroom teaching.

Of the eight studies that did frame antiracism in terms of systems, power, and history, only two conceptualized antiracism in terms of all three of these aspects of a cultural-historical framing of racism/antiracism (Seglem & Garcia, 2015; Shah & Coles, 2020). These studies were explicit about how learning environments were shaped by racialized power dynamics and the nature of systemic racism as a historical process. These studies connected all three aspects of this frame to the PDs they designed and implemented. The remaining six articles touched on one or two dimensions of racism/antiracism and made explicit design connections (e.g., engaging teachers in discussions of Critical Race Theory as a mediational tool for sensemaking about systemic racism). For the purposes of this paper, we examined these eight articles further to investigate the evidentiary base for how PDs constructed through these framings of antiracism accomplished their stated goals for changes in teacher practice.

Deepening the connection between antiracist frames and empirical outcomes

Based on the articles reviewed, there is a need for more research to provide strong evidence on how PD designs focused on antiracism can promote changes in teacher practice. Of the eight articles that explicitly framed antiracism from a cultural-historical perspective, we found that half had made evidentiary claims about changes in teacher practices resulting from their participation in formal teacher learning (Brown & Weber, 2016; Irby, 2018; Johnson, 2011; Villavicencio et al., 2020). One study examined the effects of the pre-service teacher professional learning design on “racial noticing” in the classroom and found that while teachers developed anticipated conceptual understandings in pre-service methods classes, such conceptual learning did not translate to classroom practices during student teaching in the classroom (Shah & Coles, 2020). The other three manuscripts did not examine how their professional learning designs impacted classroom practice.

The small number of articles that connected cultural-historical perspectives on race to their PD designs and observed changes in teacher practice suggested designs were successful in changing teacher practices. However, we view a need to expand the evidentiary basis of the studies that connect features of PD designs for antiracism with teacher practices. One article examined teachers’ use of school disciplinary data through ethnographic methods and observed changes in the ways teachers collaboratively engaged in sensemaking on school disciplinary data (Irby, 2018). Brown and Weber (2016), through a case study of two pre-K and kindergarten teachers who participated in PD designed to incorporate culturally-relevant pedagogy into classroom activities, found that lessons designed in this PD context were implemented in the two teachers’ classrooms. Similarly, through a case study of two middle school science teachers, Johnson (2011) found that the two teachers who participated in a PD to incorporate aspects of culturally-relevant pedagogy into their classroom practice did in fact implement classroom practices intended to better serve Hispanic students in their classes. Villavicencio and colleagues (2020), reporting on a PD organized by the Center for Racial Justice in Education to, “provide opportunities for educators to examine how racism manifests in their schools and develop policies and practices that are grounded in racial justice”(P.2), found through a case study of two school sites that while staff in both schools developed shared language regarding racial justice and implemented them into organizational change plans, only staff in one school implemented those plans.

Discussion and implications

Designs for learning inherently make conjectures about how people learn, and a robust conjecture attends, intentionally, to these processes by designing features (tools, tasks, discursive practices, participant structures) that help to mediate learning processes towards an intended outcome (Sandoval, 2014). In this review, we found that few PD designs interrogated the nature of racism/racisms as historical and cultural practices, in order to support teachers’ learning about how to embody antiracism. The findings also highlight that designs that engaged teachers in sensemaking around the cultural-historical dimensions of race and racisms, reported outcomes of transformation in teachers’ practices towards antiracism.

The implications of these findings highlight the need for research and PD practices focused on supporting teachers in using their agency to resist normative forms of activity that ignore the historicity of race and racism while serving to uphold extant hierarchies and systems of oppression and power, as it is precisely these norms that over time have material consequences for BIPoC children and youth. Thus, we conclude that designs for teacher learning around antiracism must attend to the nature of race/racisms–social processes that are tacit yet ubiquitous– and attend to how to develop teachers’ critical consciousness, and how to develop teachers’ agency to utilize emergent conceptual change around the phenomena of race/racism to transform praxis. The nature of racism as a wicked problem means that there is a need for design logics that can help to make visible to teachers the ways in which hidden and socialized ideologies shape teaching and learning, and its consequences (Lee et al., 2022). In addition, there is a need for design logics that can see themselves as sowers of seeds of resistance to ubiquitous and normative, activities, tools, and ideologies that reproduce racism.

Spatial Reasoning and Debugging With Lego Structures

Sezai Kocabas, Yi Zhu, Laura Bofferding
Skocabas@purdue.edu, Zhu966@purdue.edu, Lbofferd@purdue.edu
Purdue University

Abstract: Our study builds upon K-2 students' early block building experiences and the increased importance of fostering computational thinking skills, especially debugging. We had 12 K-2 students debug a Lego structure by finding and fixing differences between a given and target structure. Half of the students worked with red Lego bricks only while the other half worked with various colors of bricks. We analyzed the type and order of errors they fixed and their process for debugging. Misplaced Lego bricks on the plate were the most difficult for students to find and fix.

Introduction

With the increased focus on computational thinking, considering how students use computational thinking skills (e.g., debugging) across non-programming domains such as block building is important (Barr & Stephenson, 2011). In block building, debugging can involve identifying and fixing differences between two structures (Kocabas et al., 2022), a type of change detection task (Rensink et al., 1997; Shore et al., 2016). In recent research, K-2 students built a vertical Lego structure. They were then told to find and fix differences between their completed structure and a modified one using a building manual (Kocabas et al., 2022). The students successfully engaged in debugging using strategies similar to those in programming. However, students who used a grayscale manual (as opposed to color) identified fewer differences, and the symmetrical features of the vertical structure played a role in their debugging (Kocabas et al., 2022). Students' efforts to build the original structure may have aided their efforts to debug it. In this study, we expand on prior findings by investigating students' spatial thinking as they debug a combination horizontal-and-vertical structure when they did not build the original structure. Our research questions include the following: How do students debug a multi-colored versus a red Lego structure when referring to pictures of the target structure and a video of the structure being composed? (a) Which bugs do students fix and in what order? (b) What debugging strategies do students use?

Spatial reasoning and change-detection framework

Spatial visualization skill is "…generating and manipulating mental images of two- and three-dimensional objects, including moving, matching, and combining them" (Clements & Sarama, 2009, p.110; see also intrinsic spatial skills, Newcombe & Shipley, 2015). Children ages 5-8 (similar to our participants) develop from being able to slide, flip, and turn shapes (sometimes in the wrong direction) to being able to use mental images to predict the results of moving shapes (Clements & Sarama, 2009). Further, they develop from *local framework users* that can interpret "objects' positions relative to landmarks" (p. 118) to being able to interpret locations based on coordinates (Clements & Sarama, 2009; see also extrinsic spatial skills, Newcombe & Shipley, 2015). If the landmarks are not obvious, K-2 students might struggle to place blocks along the forward and backward dimension in relation to those landmarks (e.g, Kocabas et al., 2022). Block building activities support these spatial reasoning abilities (e.g., Brosnan, 1998; Casey et al., 2008), part-whole reasoning (Casey et al., 2008), and visual-difference recognition.

Two types of visual change-detection tasks include identifying differences after sequentially seeing two versions of a scene (e.g., Shore et al., 2006; Stieff et al., 2020) or seeing two versions of the scene side-by-side (see "Hidden Pictures" tasks, https://www.highlightskids.com/games). Fewer elements in the scene or central errors make differences easier to spot (Rensink et al., 1997; Shore et al., 2006). Additionally, while deleted objects are the hardest to detect, changes in object position and orientation are easier to spot than changes in color (Rensink et al., 1997; Shore et al., 2006). In contrast, visual changes such as color on digital molecular representations were easier to detect than other changes such as spatial grouping for undergraduate students (Stieff et al., 2020). Debugging is a critical process in programming and non-programming activities such as puzzles or block building (Bofferding & Kocabas, 2021; Ahn, et al., 2021; Caeli & Yadav, 2020). However, in change detection debugging tasks with a Lego structure, students were most likely to find errors at the top and bottom of a vertical structure, along with differences in orientation and placement. Errors in the middle of the structure were hardest to find (Kocabas et al., 2022). They also used spatial thinking techniques like visualization and rotation and similar debugging strategies as in programming (Kocabas et al., 2022; Murphy et al., 2008, see Table 1).

Methods

Participants and setting

In this exploratory study, we recruited four kindergarteners, four first graders, and four second graders from an afterschool program at a Montessori school in the midwestern United States. During each session, students met with one of the researchers one-on-one in a classroom. As students worked with the Lego bricks, we used two cameras to record their work from the front and back of the structures.

Design

The data comes from the third out of three sessions of a larger project. During this session, we gave students an already-built Lego structure (randomly assigned to using multicolored or red bricks) and asked them whether they would like to use the pictures or video to debug the six bugs in the Lego structure (see Figure 1A & 1B). They could switch between these media whenever they wanted. As they debugged, we asked students questions about where they were looking in the picture or video, how they identified erroneous bricks, and how they knew how to fix errors. We also gave some hints (e.g., “A structure was placed in the wrong spot on this green plate.”) if the students were stuck or feeling frustrated. We analyzed how students debugged the six bugs on the Lego structure in the third session of the project. We first identified which bugs each student debugged and explored the sequence of debugging among the bugs. We also identified if they introduced a new bug when debugging. Then, we coded the students’ debugging process based on programming and block debugging strategies (see Table 1; Kocabas et al., 2022; Murphy et al., 2008, see also Bofferding et al., 2022).

Table 1
Description of Program Debugging Strategies and Potential Application to Block Debugging Strategies

Debugging strategy	Programming description	Finding bugs in block structures
Tinkering	Students randomly making changes; multiple changes at one time.	Students play with the blocks, randomly adding or removing pieces to see the result.
Tracing (top-to-bottom or bottom-to-top)	Students follow each line of code and match it with the result, reasoning forward or backward.	Students start at the top or bottom of the structure and match it sequentially with the steps in building the structure.
Pattern matching	Students just know what is wrong or recognize the problem based on past experience.	Students notice a difference by looking at the overall structures. They may move their eyes back and forth to similar parts of the structure and picture to notice what has changed.
Rebuilding	Students scrap the code and reprogram from the beginning.	Students take apart the structure and rebuild it using the target structure by using the manual.
Understanding the Structure	Students reason about how the code works and the problem.	Students turn the physical structure or take apart parts to see how they are put together.

Results

Bugs and order

Overall, students who debugged the multicolor structure found roughly one more bug on average (M=5.25, Mdn=5.75) than students in the red structure group (M=4.17, Mdn=5). All students found and fixed Bug5, which involved rotating the eye, making it the easiest bug. In fact, three students in the multicolor group and four students in the red group found it first. Students were less successful at fixing the rotation issue with Bug4 with only nine students doing so (and it was often the fifth bug they found). Therefore, although students could rotate bricks (Clements & Sarama, 2009), identifying the differences in orientation was easier when the brick had a distinct feature. Students who did not find rotation Bug5 first often found the missing piece instead (Bug2) or fixed the piece with an incorrect thickness (Bug1). Eleven students (six multicolor, five red group) found Bug2, followed by nine students (five multicolor, four red group) who fixed Bug1. The difference between groups increased for correcting Bug3 on the staircase; five students from the multicolor group fixed it, while three students from the red group did so. Students in the multicolor group not only had to fix the block from a 2x3 to a 2x4, but they also had to change the color. While these students noticed both parts of the bug (if they found the bug), one student noticed the change in color later.

Even though the video showed Bug6a and Bug6b first, most students fixed these errors last (if at all), and most students needed the hint that one of the structures was put in the wrong place. Once they figured out that the tree was in the wrong place, five students from the multicolor group and four students from the red group fixed Bug6a, which involved adjusting the tree structure outward (from three to two studs from the edge), farther away from the staircase structure. Four students from the multicolor group and only two students from the red group also fixed 6B by adjusting the structure inward (from four to six studs from the edge).

Debugging strategies

Groups used similar debugging strategies and referred to the video and pictures of the final structures to varying extents. Two students only relied on the pictures to debug, six students started with the pictures and then switched to the video to help them as needed, and four students started with the video and then switched to the pictures as needed. No students only used the video to find the differences, but all of them turned the structure at some point to understand the structure and check for differences. Only one first grader used a rebuilding strategy (see Figure 1C) when trying to correct differences in a chunk. She fixed Bug2 and Bug3, but then later removed the front arch with tower and the staircase that led from it. She re-placed Bug1 (placing the thin piece back) but put it back in the wrong place as she attempted to recreate the staircase. Further, she did not space the stairs correctly as she rebuilt, so the placement of her fixed Bug3 ended up in the wrong place. She did not replace the front arch and tower (including the fixed Bug2) before deciding to be done. All other students fixed bugs by removing the pieces directly around the bug and placing them back immediately. As the students corrected the Lego structure, they employed pattern matching and tracing strategies while moving between the pictures and the video. Additionally, each student utilized the understanding of structure strategy by turning the structure to identify any differences. Nonetheless, in some cases, specific students chose to look at the structure from different viewpoints instead of turning it. When fixing Bug6a and Bug6b, students usually counted the studs on the base (Figure 1D), and only one second grader counted the studs on blocks in her process to fix Bug3.

Incorrect pieces: Bugs 1 and 3, **Missing pieces:** Bug 2, **Incorrect orientation:** Bugs 4 and 5,
Incorrect placement: Bugs 6a and 6b

Discussion and significance

Unlike in previous change detection tasks with Lego structures, we organized the structures horizontally. Although Bug5 was shown third, students were most likely to fix it first, easily turning the eye. This result suggests they could anticipate the rotation and that pictures on the bricks made them central to the Lego scene. It took longer for students to notice orientation Bug4 compared to Bug5, further suggesting that students might easily notice spatial bugs involving orientation when some visual feature makes it stand out more (Stieff et al., 2020). Contrary to traditional change detection tasks where identifying missing elements are hardest (Rensink et al., 1997), identifying the missing brick (Bug2) was one of the first two bugs students noticed, similar to prior Lego debugging results (Kocabas et al., 2022), even for five students who were only looking at the images. Changes in block size (Bug3 on the stairs) were harder for students in the red group to notice; students in the color group might have found this bug easier to find because it was also in a different color. Future explorations should determine if pairing bugs could make them more salient to students.

Interestingly, changes in placement (Bug6a and Bug6b) took the longest for students to find and were hardest (with many needing hints). Therefore, placement bugs on the Lego plate appear to be more difficult to detect than placement bugs on a structure (Kocabas et al., 2022). Students had an easier time detecting differences in placement when the tree structure needed to be shifted away from another structure as opposed to shifted to the right in relation to a structure, suggesting the saliency of proximity to landmarks (Clements & Sarama, 2009; Newcombe & Shipley, 2015). In addition, students counted the studs on the base to identify and fix the placement errors. Having more parts of the block design placed horizontally (as opposed to vertically), may have encouraged some students to use mathematical concepts such as counting and helped move them toward seeing the Lego plate as a form of a coordinate system made up of the studs. Future work could further explore factors that encourage students' use of the Lego plate as a coordinate system versus proximity to other landmarks when placing pieces.

For debugging, the findings were consistent with previous studies that block play can engage children in debugging in early years of education. Compared to our previous analysis where students debugged *after* building a structure (Kocabas et al., 2022), none of the students completely started over building from the beginning and followed along with the video to build the corrected structure. In fact, only one student completely removed a chunk, and that student had difficulty putting it all back together. Building a structure first may help students' rebuilding; whereas fixing one structure at a time may have been easier given the several parts of this design.

Abstract: Identity and intersectionality must be foregrounded in design interventions for computing and STEM education. In this paper, our research team presents findings from a sports and technology intervention we developed with the culturally responsive computing framework. We implemented the intervention in a local summer program for young Black boys entering grades 3-8. Data were collected and analyzed from caregiver interviews. Findings suggest that youth recognized relationships between digital technologies and sports, and conceptualized more expansive ways for technology to mediate their sports interest. The interviews also revealed the need for greater intentionality in facilitating family engagement.

Introduction

Learning Sciences literature on the relationship between sports and technology highlights approaches to engaging minoritized youth in CS-STEM (STEM and computer science) learning experiences by situating them in athletics (Drazan et al., 2017; Jones et al., 2020). Efforts for disciplinary learning that introduce or expose the CS-STEM practices and knowledge within non-traditional learning contexts – while reinforcing youths' cultural practices and knowledges – can enable minoritized youth to recognize CS-STEM within their interests. We present findings for an intervention on sports and wearable technologies at Brothas Camp, a summer program for Black boys in elementary and middle school. We engage the following research question in this study: What do conversations at home reveal about CS-STEM interest development for youth that are exposed to sports technology through a sports camp?

Positionality statement

Responding to the charge that Vakil et al. (2016) gave academic researchers to "critically examine the role that race, racialization, and power play across the arc of DBR [design-based research] projects" (p. 205), we acknowledge here our diverse positionalities. All the authors of this paper are People of Color. The fourth author is a Black male engineer who plays sports to this day and who facilitated our sports technology curriculum. Our first and third authors facilitated several of the sessions and played sports in their youth. They were able to provide context where necessary, expanded on the youths' ideas, and teased with them. One of the authors is also a former teacher who leveraged her blackness when interacting with youth and camp staff. Although our second author did not interact with the camp, she was integral to the data analysis and writing the findings. We also acknowledge our outsider relation to Brothas Camp. None of us grew up in the city where Brothas Camp took place, and our intervention pushed into the camp, which kept us relatively separate from the camp community.

Literature review

Disciplinarity (in learning, practice, and identity) can function as a means for excluding and othering. Research on CS-STEM interest development (Wang et al., 2017; Dou et al., 2020) and the "identity turn" in CS-STEM education (Shaw & Kafai, 2020) has noted how existing identities should be foregrounded in interventions for broadening participation. Many of these research efforts address stereotypes, such as the notion of CS-STEM as acultural, apolitical, and decontextualized, and CS-STEM identity as "singularly-focused," "asocial," "competitive," and "male" (Lewis et al. 2016). However, exposure to computing content that engages participants in larger critiques about a technology's purpose, potential, and impact tends to be more interesting to minoritized youth (Margolis et al., 2015; Webb et al., 2012; Vakil & Ayers, 2019). Research on "practice-linked identities" (Nasir & Hand, 2008; Nasir & Cooks, 2009), "practice-linked learning and environments" (Jones et al., 2020), and "everyday learning" (Philip & Azevedo, 2017) demonstrates the need for broadened access to disciplinary resources for diverse learners.

Culturally responsive computing (CRC; Eglash et al., 2013; Scott et al., 2013) is a pedagogical framework for computing education that uses culturally-responsive values to validate learner interests, identities, and cultures. The framework includes several important tenets. Tenet 1 sets the expectation for youth use existing tools innovatively and construct artifacts that represent big ideas, irrespective of prior knowledge or exposure;

Tenet 2 supports unique learning contexts where youth explore a technology's capabilities, consider their limitations, and transform them; and Tenet 3 attends to learners' identities and the importance of intersectionality in helping youth understand the multiple dimensions of self. By engaging in critique and interacting with tools, youth in CRC learning environments realize their identities in relation to power and become empowered to actively resist these dynamics. Tenet 4 describes the role of digital technology in equipping youth to reflect on and reimagine their identities through counternarratives and counternormative images. Tenet 5 invites youth to reappropriate disciplinary and research practices to dismantle systems and empowers their communities. Importantly, CRC affirms the critical role that caring adults such as parents and community members have in guiding and advocating for youth.

Design of intervention

Brothas Camp (renamed for anonymity) was a summer program that offered Black boys in grades 3 through 8. Camp sessions for elementary students occurred separately from the middle school students, and youth within each session were organized by their grade levels. The Brothas Camp designers incorporated several communal aspects to instill pride and promote camaraderie. Staff members and college mentors – all Black men – were affectionately referred to as "brothas," and the group became "my family". Our work with Brothas Camp provided youth the opportunity to explore, de-settle, and reconcile their relationship with athletics and CS-STEM.

Contextualized learning opportunities for CS-STEM provide alternative conceptions of what computer science is to youth who do not selectively engage in CS-STEM activities (Drazan et al., 2017; DiSalvo et al., 2014) or who do not benefit from "preparatory privilege" (Margolis et. al, 2015; Isaac & Gardner-McCune, 2021). Such activities can essentialize dominant epistemologies, which for our American context meant (whether intentionally or unintentionally) requiring participants to forsake their identities to develop CS-STEM identities and practices. Our intervention exposed youth to sports wearables while attending to both their heritage culture (blackness) and vernacular culture (sports) (Eglash et al. 2013). Similar to other sports technology interventions, learning was situated on the court and field to connect these sites of sports practice and activity to CS-STEM experiences involving wearable physical computing kits. We conducted three 45-minute sessions with middle school youth and four with elementary school youth. Middle school youth completed activities for track and field with pedometers and smart watches, soccer activities with micro:bit microcontrollers, and basketball drills with sensor-enabled basketballs. Elementary school youth engaged with the same activities for track and basketball, and also drew their dream sports technology.

Methods

Some qualitative and quantitative data – including youth drawings – were published in the Wallace et al. (2023) study. For this paper, we focus on qualitative jottings and interviews with youth's caregivers. Members of the research team engaged in participant observation, recording jottings about the implementations and youth insights. These data helped support our sensemaking around youth experiences with the design intervention. We include data from three semi-structured interviews conducted with caregivers after Brothas Camp. The interview protocol focused on: what the child shared with family members regarding their camp experience; the child's interests in sports and how they engage with or build digital technologies; impressions of the child's relationship with school and extracurricular activities; and suggestions for program improvements. The Brothas Camp director recruited caregivers to participate in the interviews. Caregivers completed an intake process form and consented to participating in the study. Interviews were audio-recorded and machine-transcribed with a web conferencing platform. Transcripts were then corrected by the authors and reformatted for analysis.

The first and second authors coded short passages within the transcript to identify speech related to how caregivers described youth interactions with the sports-technology intervention and their perceptions of the technologies. These codes referenced parent wording. The second iteration of coding looked for instances of youth's connections between sports and technology. We used Braun and Strauss' thematic analysis (Vaismoradi et al., 2013), to find thematic codes within the data by identifying, analyzing, and presenting those themes. These more detailed codes were grouped into categories: at-home connections to technology and sports, building community, and academic and athletic identities.

Findings and discussion

In all three interviews, at-home connections between technology and sports emerged from interactions around smartwatch technology. The interviews revealed how conversations from the camp made it home, and how the families structured communication around the day's events. Youth brought up ways that this technology could track heart rate, step counts, and sleep. Parents immediately recognized their youths' excitement with these technologies and mentioned nuances around their talkativeness. One youth used the tech to regulate their physical movement with the hourly reminders. Another one enthusiastically compared the features of their smartwatch with the features of their parent's smartwatch, and they explored the system in a way that the parents had not done themselves. A third child was passionate about sound engineering and wanted to explore ways to connect to this technology. Even so, there was difficulty in remembering events when not explicitly prompted to recount them. One caregiver remarked, "He mentions some of these things, but because I didn't have a reference point for them, you know, when I'm like, 'How is camp? What was your favorite thing?' I don't think he used these exact words." Caregivers recommended that discussion prompts and general information be shared in future implementations to reinforce learning at home.

The interviews were an opportunity for caregivers to address the scholar-athlete identity. They wanted to expose their Black boys to opportunities beyond being "just an athlete" so they see themselves as knowers and practitioners at the intersection of technology and sports. They also noted identities outside the scholar-athlete that connect sports to technology: "...my son loves sports, right? But I want him to be both an athlete and a scholar. And so, there are so many jobs that are within sports that kids don't see outside of the athlete. Somebody who tracks all this stuff as a statistician…Because he's really interested in that. So if I can keep him engaged in this way, he'll see different avenues". Involvement also meant helping their youth navigate the difficulties of discrimination and intersectional spaces. As one parent called out: "He's just not really into sports like that…and you know that's something that all Black boys are supposed to do." This parent stated that they manage the societal expectation for Black boys by validating their child's desire to do whatever activities they enjoy. There are stereotypes around athletic identity and academic acumen, which they referred to as, "this challenge of being able to bring that athletic identity to the academic space without being stigmatized." The families relayed the importance of having affirming spaces that promote possibilities and choice for Black boys when raising them in environments that can be unwelcoming. All three praised the Brothas Camp's emphasis on fostering brotherhood. One caregiver stated, "I'm super excited for him to be in this space of Black joy…everybody looks like me".

Our intervention for Brothas Camp introduced the youth to CS-STEM and to the technology community within sports. Yet, identities are not developed from exposure alone. For youth to conceptualize a CS-STEM identity will require multiple and sustained opportunities for practice and collaboration with caregivers and communities. We designed the intervention with CRC in mind, but connected learning presents an additional framework for facilitating these family engagements in more intentional ways. According to Ito et al. (2013), "Connected learning is realized when a young person pursues a personal interest or passion with the support of friends and caring adults, and is in turn able to link this learning and interest to academic achievement, career possibilities, or civic engagement." Caregivers' desires for deeper discussions with youth reinforced to us the importance of family engagement in sustaining culturally-responsive learning.

Limitations

Relationship dynamics between researchers and those involved in the research are fragile due to race and power (Vakil et al., 2016). For this study, we interviewed caregivers instead of the learners themselves. We wanted to preserve the sanctity of the Brothas Camp community since the activities of Black boys are already heavily surveilled and critiqued in society. Though well-intentioned, this did make data analysis challenging. For instance, our data collection methods prevented us from making claims about the youth participants' CS-STEM identity development. We also do not present the "authentic voice of Black boys" (Coleman, 2016). Nevertheless, caregiver interviews provided us with insights into their thinking and suggestions for extending learning at home.

Conclusion

As an endeavor in culturally-responsive computing (CRC), our sports technology intervention expanded the Brothas Camp youth participants' conceptualizations of CS-STEM. Exposure to various technologies within the sports context created new opportunities for youth to reflect on technology through conversations at Brothas Camp and at home. Several youth also got the chance to ideate future innovations in sports technologies. While we were able to note changes in youths' perceptions of sports and technology, it is unknown what effects the intervention had on their identities, and to what degree. Consequently, future directions for this project include: designing interventions that shift CS-STEM interest in middle school students, communicating our programming to families to extend its effects to home, and considering thoughtful data collection methods that attend to researcher and educator goals while also attending to the interests and concerns of minoritized youth. Our recent research (Wallace et al., 2023) found that CS-STEM interest increased for the elementary school students, which aligns with the current literature. Facilitating family engagement could support CS-STEM identity development, in addition to providing more data on the ways in which caregivers guide youth to connect sports and technology. We envision environments where youth learn to code on the court and on the field, allowing their passion for sports to support the development of new interests and identities. These explorations will certainly require envisioning more creative data collection methods.

Ideologies of Place and Reasoning About Space With Maps

Maximilian Sherard, Southern Methodist University, msherard@smu.edu

Abstract: Contemporary research in the learning sciences has illuminated the central role that ideologies play in reasoning. I extend this research by investigating how ideologies of *place* mediate reasoning about *space* when people use maps. Using map-reading frameworks and critical discourse analysis, I traced how one student, Aaron, drew on ideologies about various neighborhoods to read and interpret patterns within maps of Austin.

Introduction

Mapping is a form of spatial thinking which involves defining, orienting, and representing objects in space (NRC, 2006). Research about how people reason with maps has taken a variety of perspectives. From the cognitive perspective, psychologists have identified a foundational set of spatial thinking skills which all people develop to reason with maps (e. g. Uttal, 2000). From the cultural perspective, anthropologists have described the complexity of practices that different human groups have developed for reasoning with maps (e.g. Hutchins, 1995).

However, maps are not objective representations of space and reasoning with maps is not solely a cognitive or cultural phenomenon. Rather, reasoning with maps is intimately entangled with broader issues of power and dominance (Scott, 2008). Using maps to reason about space also involves thinking also about *place*. Place is a geographical construct which describes the socially shared meanings about who or what activity is natural within a particular space (Cresswell, 1996). Place is where “geography and ideology intersect” (Cresswell, 1996, p.1) and supports people in “seeing, knowing, and understanding the world” (p.16). Therefore, reasoning with maps is simultaneously a cognitive, cultural, *and* political achievement.

This paper investigates the entanglement of ideologies of place and reasoning about space with maps. I examined a group of preservice teachers as they used maps to learn about the geographic and political causes of urban heat island effect in their local city. The primary research question guiding this project was: *how do ideologies of place mediate reasoning about space with maps?*

Conceptual framework

To theoretically guide this work, I drew on three bodies of literature: First, I drew on Rubel et al. (2017) to conceptualize how people reason with maps. Reasoning with maps involves five related practices: (a) reading a map (interpreting the symbolic components of the map); (b) reading within the map (comparing places within a map); (c) reading beyond the map (identifying spatial patterns); (d) reading behind a map (interpreting causes of a spatial pattern); and (e) entering a map (collecting new data for a map). I used this framework to trace how preservice teachers reasoned with maps of their local city to learn about urban heat island effect.

Second, I drew on Hall (1996) and Philip (2011) to conceptualize ideologies. Ideologies are the “mental frameworks – the languages, the concepts, the categories, imagery of thought, and the systems of representations – which different classes and social groups deploy in other to make sense of, define, figure out and render intelligible the way society works” (1996, p. 26). I used Hall and Philip’s conception of ideology to identify ideological talk that occurred alongside reasoning with maps.

Third, I drew on Cresswell (1996) to conceptualize ideologies of place. Ideologies of place are collections of social meanings which are attached to spaces. Cresswell specifies four axiomatic elements of a place ideology: (a) classifying place – naming a place and defining its spatial extent; (b) differentiating place – describing how one place is distinct from others; (c) naturalizing place – specifying what people, objects, or organisms are ‘normal’ in a place; and (d) place as practice – specifying what actions are or ‘normal’ in a place. I used Cresswell’s four elements to describe instances where people drew on ideologies of place to reason with maps.

Context, participant, and data sources

This research was conducted in a secondary STEM teacher education course. I investigated a 6-lesson series where the course instructor and six preservice teachers used maps to investigate the causes of urban heat island effect in their local city, Austin, Texas. This study focused on one student from the class: Aaron (a psuedonomy). Aaron is a White, cis-gender, male STEM preservice teacher. He had lived in Austin for over 20 years and had many things to say about places in Austin. Many of Aaron’s remarks regarded the nature of certain neighborhoods in the city, the types of people who lived there, and his perceived history of each place. To examine how Aaron’s ideologies of place mediated reasoning with maps, I collected video recordings of all classroom activity, artifacts that students used or created, and wrote field notes for each day.

Data analysis

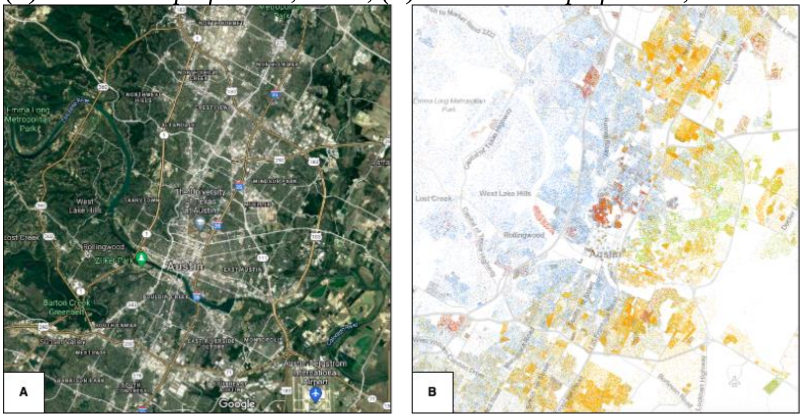
In a forthcoming manuscript, I detail my analysis of the entire 6-day lesson series. In this manuscript, I focused on the first day when Aaron and his classmates used two maps to learn about urban heat islands in Austin, Texas: a satellite reference map a race-dot thematic map. I began by extracting and transcribing any instance when Aaron reasoned out loud using one of the three maps. To understand how Aaron's ideologies of place mediated his ability to reason with maps, I proceeded through three analytical passes with the data:

First, I used Rubel et al.'s map reading framework to analyze how Aaron reasoned with each map. I read the transcripts, viewed the video footage, and tagged moments when Aaron engaged in one of the five map-reading practices. This allowed me to see the coarse practices Aaron used to read maps of Austin. Second, working with Hall's conception of ideology and Cresswell's four elements of place ideology, I searched each instance for ideological remarks made by Aaron. I read the transcripts and tagged any remarks which classified places, differentiated places, naturalized places, or associated places with certain practices (Cresswell, 1996). This allowed me to render initial understandings of the various place ideologies which Aaron drew upon to reason with each map. Third, I used tools from sociosemantic analysis (van Leeuwen, 1993) to probe these instances further to see how Aaron represented the people, materials, and actions associated with urban heat island effect. This allowed me to further clarify the various ideologies of place which Aaron dew upon to make sense of maps of Austin.

Results

I present two episodes to illustrate how Aaron drew on ideologies of place to reason with maps. In the first episode, I examined how Aaron interpreted patterns in a satellite map of Austin (Figure 1, A). In the second episode, I examined how Aaron interpreted patterns in a thematic map showing the racial make-up of Austin (Figure 1, B).

Figure 1
(A) Satellite Map of Austin, Texas; (B) Race-Dot Map of Austin, Texas



Episode 1: Satellite map of Austin

The first episode occurred while students were discussing a satellite map depicting the center of Austin (Figure 1, A). The course instructor (KB, a pseudonym) began *reading the map* for students: identifying points of interest (the university, a major shopping mall), identifying major boundaries (the river and two highways), and clarifying the color schemes ('lighter areas' on the map were concrete and the 'darker areas' as on the map were nature). Finally, she asked students to reflect on differences they saw on either side of I-35, one of the two major highways that bisects the city into East Austin and West Austin. Aaron was the second student to respond, and said:

1.1	Aaron	Honestly it's what we would consider the slums = Or you know when I first came here that
1.2		area was kind of the slums of Austin = You hate to put it that way but it was (.) .hhh Yeah
1.3		that = Yeah that is where you had built up areas = but it's where it's where the poorest =
1.4		those were the poorest neighborhoods right in the area you are pointing to right now (.) .hhh
1.5		east of 35 right ne- right east of downtown

In this response, Aaron *read within the map* a variety of important spatial patterns. He named East Austin as 'the slums', located poor neighborhoods within East Austin, and described it as 'built up.' Immediately after, KB and a student (Elias, a psuedonym) responded to Aaron's classification of East Austin as 'the slums':

2.1	KB	Historically these are (*tracing cursor, more slowly, over the East Austin area*) (.) uhh (.) yes
2.2		like a lower:: uhh (1.0)
2.3	Elias	SES
2.4	KB	Ye:ah (.) .hhh Um all along the east side of 35 (traces cursor up and down on East side of
2.5		map) (.) and now- I mean now what you seeing = and this isn't really part of the
2.6		conversation of our unit = but what you are seeing (traces cursor over East 7th street, West
2.7		to East, then draws circle within East Austin) is around here now is a lot of gentrification
2.8		going on (.) in Austin (.) taking advantage of those low property (.) um (.) values (.) Uh but
2.9		(.) yes (.) historically we've got lower (cursor moving randomly, on East side of Map) (.)
2.10		people who are in a lower SES class living east of 35 and more expensive property on the
2.11		west (cursor moving randomly, on West side of Map) (.) and particularly as you get closer
2.12		and closer to Mopac (traces cursor on Mopac, back and forth, North to South) (.) your prices
2.13		are going way up(.)

The course instructor responded first by tracing her cursor over the East Austin neighborhood while pondering a different word to describe the area. She began to *read within the map* by saying that East Austin is a "like a lower::" but trailed off. Elias completed her effort to *read within the map* by saying "SES" (socioeconomic status). The course instructor followed up, *read behind the map,* and said three new ideas: First, she explained that East Austin is presently undergoing a process of gentrification. Second, she indicated that 'historically' East Austin had been the primary place of residence for 'lower SES class.' And finally, she continued to explain that 'historically' there was a pattern where property cost increased as you moved from east to west across the city, "particularly as you get closer and closer to Mopac" (2.13-2.14).

I interpreted this interaction as ideological because it involved negotiating various *classifications* and *differentiations* of East Austin. Aaron began by classifying East Austin as 'the slums' and justified this based on his personal experience having lived in the city for many years. He differentiated it from other parts of the city by explaining that East Austin had 'built up areas' and is the part of the city where the 'the poorest neighborhoods' were present. This can be contrasted by imagining areas of the city with less 'built up areas' or 'richer neighborhoods.' He closed his remarks by re-affirming the location of 'the slums' as being "east of 35" and "right east of downtown." In response to Aaron, KB and Elias provided an alternate ideological framing of East Austin. Together, they re-classified East Austin as 'lower SES' rather than 'the slums.'

Using tools from sociosemantic analysis, we can see important ideological differences in how Aaron represents two groups of spaces/people: East Austin and 'the public consensus.' East Austin is referenced by Aaron's use of two pronouns (it and that) (1.1, 1.3) and a definite article and noun (that area) (1.4). By using these words, Aaron circumscribes East Austin into a single entity which can be classified and differentiated. This is what van Leeuwen (1993) refers to as the *spatialization*. Spatialization is a representational strategy where a group of people is represented by the place/space they live in. By spatializing a group of people, a speaker can attribute qualities or actions to a space rather than to the people who live in the space.

The public consensus is referenced by Aaron's use of the pronouns 'we' and 'you' (1.1). Aaron began by saying 'it's what *we* would consider the slums' (1.1). Shortly after, he says '*you* hate to put it that way but it was' (1.3). Both 'we' and 'you' are what van Leeuwen refers to as *generalization*. Generalization is when a speaker does not refer to specific people in the real world, but instead refer to abstract or hypothetical groups. I interpret these generalized 'we' and 'you' to represent some form of 'public consensus.' Eliciting a public consensus to justify classifying East Austin as 'the slums' is an ideological strategy which made Aaron's remarks seem natural. This is a hallmark indicator that ideological geographies are being established through talk.

Episode 2: Racial map of Austin

The second episode occurred while students viewed and discussed the race-dot map (Cable, 2013) Austin (Figure 1, B). The Race-Dot Map is a thematic map which uses data from the 2010 census to visualize one dot per individual within the census block group they live in. The course instructor began again by *reading the map* for students (explaining the symbols). The course instructor then asked for students to make connections between the satellite map and the race-dot map. Drew responded first, followed by the course instructor and Aaron.

3.1	Drew	There's like (.) you can clearly see I-35 (.) um and to the left um it's all White or Asian
3.2		American and to the right its all Black or Latinx so [like] and that very clearly like (.) that
3.3		racial divide happens to also be like the divide between the left side of I-35 on this map is
3.4		way more green than the right side.

3.5	KB	[Yeah]
3.6	KB	Indeed ((knowing and formal tone))
3.7	Aaron	There is a strong correlation between uh identification and SES sorry but that's how I see it

Drew began by *reading the map* (identifying I-35), *reading within the map* (explaining patterns from the race-dot map), and *reading beyond the map* (making connections to the previous Satellite Map). Using the categories from the map, Drew explained that west of I-35 the dots were primarily representing White and Asian American people, and East of I-35 the dots were primarily representing Black and Latinx people. Drew then connected this to the previously established pattern that west of I-35 has more trees or is "way more green" (3.5). The course instructor agrees briefly by saying "indeed" (3.6) in what I interpreted to be a formal and 'knowing' tone, as if Drew explained the pattern KB was hoping to see. Aaron followed Drew's remarks by *reading beyond the map*, to explain a correlation between identification and SES. He closed his remarks by apologizing for this idea.

In this short sequence, a variety of ideological moves were made. Drew began by drawing upon the I-35 boundary to classify the city into two regions, East and West. Then, Drew used the dot colors to differentiate East and West by describing the general composition of racial groups in each area. Despite there being many boundaries between racial groups on this map, the boundary of I-35 was repeated as an important line to differentiate the city. Finally, Drew made a connection between the racial compositions and the previously differentiated pattern of West Austin having more greenery than East Austin. Aaron's response layered new ideological meanings onto the pattern which Drew established. Aaron explained that there was a correlation between identification and income level. Although Drew didn't mention income, it seemed Aaron was referring to the conversation moments before where the course instructor and Elias re-classified East Austin as 'lower SES'. Aaron then drew a connection between the racial divide along I-35, and the perception that East Austin is lower SES and West Austin is higher SES. With this remark, Aaron further differentiated East Austin as lower SES, with primarily Black and Latinx residents, and having less greenery than West Austin.

By drawing on sociosemantic analysis, we can further see the ideological nature of Aaron's portrayal of East Austin. Aaron began his remark with the verb phrase "there is." Sociosemantic anlaysis refers to this as an *existential* process, where the speaker is bringing something into existence that needs no further justification. The use of the phrase "there is", naturalizes the statement that follows: racial identification and SES are correlated. Aaron goes on to complete his sentence by saying "sorry but that's how I see it" (3.9). I interpreted the use of apology here to indicate that Aaron believed this fact to be true, although potentially uncomfortable or even controversial for the class to hear.

Discussion

In summary - through interactions with his classmates, two maps of Austin, and the course instructor – Aaron read the map, read within the map, and read beyond the map while drawing on an ideological geography of Austin. This ideological geography classified East Austin as 'the slums', differentiated it as being a low SES area, with less tree cover, and primarily Black and Latinx residents. He naturalized these statements by evoking public consensus with generalized phrases such as "It's (East Austin is) what *we* would consider the slums." This research demonstrates the necessity for examining the relationship between ideologies of place and reasoning with maps.

Abstract: Artificial Intelligence (AI) has increasingly become a ubiquitous face in our daily lives. Following this trend, many organizations and educational researchers started fostering AI education at the K-12 level. Yet, there is less knowledge about the impact of curriculum interventions on students' self-efficacy. In order to understand K-12 students' AI learning and interests, it is critical to examine their self-efficacy. This paper examines high school students' self-efficacy in machine learning practices before and after participating in a technology-enhanced AI curriculum intervention for three weeks. We analyzed students' pre- and post-questionnaire responses to investigate the impact of the AI curriculum intervention on students' self-efficacy. Our analysis revealed that students' self-efficacy toward text classification tasks significantly increased after they completed the AI curriculum activities. Additionally, we found that students' characteristics in terms of their interests and engagement in the activities played a critical role in their self-efficacy.

Introduction

Artificial Intelligence (AI) literacy has become a necessity for a data-savvy workforce. Therefore, introducing AI literacy at an early age is significant to prepare youths in AI-related fields. Particularly, K-12 is a critical stage for young people to develop foundational knowledge and interest in AI-related careers. Currently, much has been known about AI education at K-12 is related to how to support students' understanding of the AI implications from social, technical, cultural, and ethical perspectives (Ali et al., 2019). However, only a few studies emphasized the impacts of AI education on high school students' confidence. As an illustration, Chua et al., (2019) organized a pilot program to support high school students' data science knowledge. In this pilot study, students worked on five different curriculum modules and explored Data Science concepts such as data visualization, probability in ML, and Webscraping with Python. This study showed that students developed an understanding of basic concepts and became more confident in explaining these concepts. Yet, these kinds of studies are limited to explaining K-12 students' confidence in specific domains, especially in ML, since the training mostly focuses on a broader conceptual understanding of Data Science.

While efforts to integrate AI into K-12 classrooms have been ongoing, less is known about the impacts of AI curriculum interventions on students' self-efficacy in ML practices. Examining K-12 students' self-efficacy is critical to understand their achievements, motivation, and interests in learning AI concepts. Therefore, there is still a need for empirical studies on how AI curriculum activities help students to gain confidence in ML practices. Thus, the purpose of this study is to examine high school students' self-efficacy in ML practices before and after they experienced technology-enhanced AI curriculum activities. Specifically, this study aims to address the following research questions: (1) How does students' self-efficacy change after participation in technology-enhanced AI curriculum activities? and (2) With regard to changes in self-efficacy in machine learning, which type of students can be identified, and what are their individual characteristics?

Theoretical framework

Influenced by behavior, cognition, and the environment, self-efficacy is the belief in one's capabilities to perform a task. "Self-efficacy beliefs determine how people feel, think, motivate themselves, and behave" (Bandura, 1994, p.1). At the core of Bandura's (1986) Social Cognitive theory (SCT), self-efficacy engages in a "triadic reciprocal causation model in which the behavior of a person, the characteristics of that person, and the environment within which the behavior is performed are constantly interacting," (Van der Bijl & Shortridge-Bagge, p.9, 2002). Bandura (1994) asserts high self-efficacy with a greater interest in various careers and believes those use self-improvement to master the skills to achieve career pursuit. The tasks and activities that improve self-efficacy rely heavily on educators to create learning environments conducive to developing cognitive skills (Bandura, 1994). Studies showing improved self-efficacy used specific tasks like extensive teacher-supported scaffolding (Jin et al., 2021), collaborative pairs of the same gender (Wei et al., 2021), and explicit instruction of concept mapping (Boroumand et al., 2021). For example, Konak (2018) evaluates High School students' self-efficacy after participating in a K-12 cybersecurity program that combined hands-on experiences with collaborative and inquiry-based strategies through a pre-and post-survey. This week-long program included heavy skill-based scaffolding before the problem-solving activity. In this study, they found that active experimentation components of the hands-on activities helped improve self-efficacy in problem-solving. Over the last two decades, there has been considerable research on K12 teachers' self-efficacy. However, the literature is sparse for studies on self-efficacy in K12 students in the STEM fields but even less for AI Education. Most studies focus on high school and college students in Science and Math. Hence, in this study, we address the critical gap in the literature by examining self-efficacy in K12 AI Education for students after completing technology-enhanced curriculum activities.

Methods

This study was conducted in the context of a high school Journalism classroom in a public school in the Northeastern United States. The class included twenty-eight students; however, eight students did not complete the data collection process. Therefore, in this research, we only included the data from twenty students; nine Black/African, four Hispanic, five White/Caucasian, one other, and one prefer not to answer. Fourteen of the students were female and six were male. At the beginning of each class, the teacher introduced key concepts in the StoryQ AI curriculum (Chao et al., 2022) and asked students about their thinking of these concepts. Multiple sources of data analysis, including pre-and-post surveys, pre-and-post knowledge assessments, video recordings, interviews, and activity-specific questions were collected. In this particular study, we only used students' data from pre-and-post surveys and activity-specific questions. The pre-and-post surveys were identical and had sixty-four questions that included five constructs: thoughts about AI, current understanding of the roles and responsibilities of AI developers and users, understanding of knowledge and skills required to develop AI, interests in AI, and self-efficacy. Since this research aims to investigate students' self-efficacy before and after they completed the AI curriculum activities, we mainly focused on the self-efficacy construct in the survey. While developing self-efficacy items, we examined the validated surveys around the STEM self-efficacy literature like the STEM career motivation scale (Shin et al., 2016). Two researchers examined these surveys and developed thirteen self-efficacy items on a 5-point Likert scale (1- strongly disagree; 5- strongly agreed) related to the curriculum content. After the self-efficacy items were created, the research team was invited to test these items and give feedback. After several iterations, the items were finalized. While interpreting the reliability, DeVellis (2021) suggested that if a coefficient is between 0.70-0.80, it is "respectable", and if it is above 0.80, it is accepted as "very good" for an instrument. We checked the reliability of the items in the pre-survey ($\alpha = 0.94$) and post-survey ($\alpha = 0.93$). To address the first research question, paired t-tests were performed to analyze differences between pre-and post-survey responses. We used SPSS to analyze all the data. To address the second research, we identified three students with regard to the changes in their self-efficacies and presented their characteristics as cases. We specifically investigated three types of students; (1) started with low self-efficacy and ended with high self- efficacy, (2) started with high self-efficacy and ended with low self-efficacy, and (3) did not have a change in their self-efficacy. After we identified these students, we explored their activity-specific responses. In each curriculum activity, students answered open-ended and multiple-choice questions. We followed exploratory analysis to gain a deep understanding of their characteristics and learning progress throughout the activities. We analyzed the open-ended questions by following open-coding strategies (Williams &Moser, 2019). After the first round of analysis, the research team discussed the sub-themes related to each case and finalized the findings. We used pseudonyms for the participants while presenting the findings.

Findings

A paired-sample t-test was conducted to compare the high school students' self-efficacy in ML practices before and after students experienced the AI curriculum activities. Mean values for the 13 self-efficacy statements varied between 2.29 and 3.35 in the pre-surveys and between 3.39 and 4.06 in the post-surveys on the five points Likert scales (1Strongly Disagree to 5 Strongly Agree) (see Figure 2). Overall, we found a significant improvement in students' self-efficacy from pre-survey (M=2.66, SD=0.85) to post-survey (M=3.70, SD=0.54), (t (18) =4.82, $p < 0.001$). Suggesting that completing the AI curriculum was related to an increase meaning scores of students perceived/reported self-efficacy. When we closely examined each self-efficacy item, we saw that the largest increase was observed in an item that asked about students' confidence in training a computer model to classify text. On the pre-survey, 58% of the students (n=11) indicated less confidence or neutral (selected "disagree" or "neutral" to the statement), whereas, on the post-survey, 74% of the students (n=14) demonstrated high confidence in the statement (selected “agree” or “strongly agree”). This shows that the curriculum implementation helped students to become more confident in ML practices, in particularly developing ML models for text classification tasks. On the other hand, the least increase was observed in an item that asked about students’ confidence in completing a new course unit related to AI and ML. In the pre-survey, students were mostly neutral or slightly disagree with this statement. When we examined their post-survey, we found that they kept the same attitude in the post-survey. This demonstrates that students might not see the similarities between text-classification tasks and other ML topics like image recognition or speech recognition. Therefore, they might not feel confident in completing a new ML course.

After we explored the changes in the students’ self-efficacy, we explored students’ characteristics to gain more understanding of similarities and differences. We investigated their responses to the activity-specific questions as well as their survey responses. We followed the thematic exploratory analysis to identify patterns between the students’ self-efficacy levels and their activity progress. Firstly, we identified students who started the curriculum activities with a low self-efficacy level and ended with a high self-efficacy level. Lindsey was a 12th-grade, female, White/Caucasian student who had generally moderate positive attitudes towards AI but was also suspicious about the impacts of AI on jobs in the United States. She was familiar with AI technologies around her. When we investigated her responses to the activity questions, we found that her completion rate was 88%. In according with her completion rate, her interest in ML tasks might be increased and this might also lead to an increase in her self-efficacy. Additionally, when she was working on Activity 6, she indicated that working as a group was the most effective strategy to understand ML concepts. The peer interaction while completing the ML tasks might also be another factor that affects her self-efficacy. Put differently, she might feel more comfortable asking questions and/or sharing her ideas while working with her classmates and this might help her self-efficacy. Secondly, we also investigated students who had higher self-efficacy before the curriculum activities but ended with lower self-efficacy after completing the activities. We saw that only two students out of twenty were applied to this situation. In regard to their completion rate and the changes from pre-to-post-survey, we decided to examine one of the students closely. Diego was a 12th-grade, Male, Hispanic student who heard of the term AI through online magazines and TV shows. Even though he stated a slightly positive attitude toward AI, he mentioned no interest in AI when it came to sharing his emotions and feelings about this term. His overall completion rate was 70% but when we closely examined his responses to the activities, we saw that his completion rate in the ML activities (e.g., Activity 6) was quite low. For example, he only responded to fourteen questions out of thirty-eight in Activity 6. He might have some challenges to continue answering the questions. Finally, to gain a deeper understanding of students’ self-efficacy and their learning progress, we investigated students who did not show more than a 10% difference from pre-survey to post-survey. We identified two students who had a 0.08 difference between the mean of the post-survey self-efficacy items and the mean of the pre-survey self-efficacy items. One of the students stayed neutral in both the pre-survey and post-survey while another student felt strongly confident in her ML practices in both surveys. Thus, we mainly focused on the student who generally stayed neutral on the self-efficacy items. Destiny was an 11th-grade, Female, Black/African student who heard the term AI through movies, TV shows, and social media. Before the curriculum activities, she was slightly positive toward the impacts of AI on people’s lives and neutral in terms of her emotions and feelings related to AI. Her completion rate of the activities was 78.3%. When she was working on the ML activities, she indicated her enjoyment in working with others. She completed the majority of the work in the ML activities and demonstrated an understanding of ML concepts, including building ML models, identifying useful features, and explaining why a feature has a large influence on a model’s performance. Yet, her mean score of self-efficacies did not show a significant difference from the pre-survey to the post-survey. When we closely examined her response to each self-efficacy item, we saw that her self-efficacy showed an increase in three items that were related to explaining the text-classification concept. On the other side, she was less confident in completing a new course unit on a type of classification model (e.g., image recognition or speech recognition). She might find those new concepts more complex than text classification, therefore, she might not feel confident about that.

Conclusion

With the developments in AI technologies, there have been numerous calls to engage K-12 students in AI education. In spite of ongoing efforts to integrate AI into K-12 classrooms, little is known about the impacts of AI curriculum interventions on students' self-efficacy. This study aims to fill this gap by exploring high school students’ self-efficacy in ML practices before and after they completed technology-enhanced AI curriculum activities for three weeks in the context of a Journalism classroom. Additionally, this study also investigates high school students’ characteristics while completing the activities regarding to the changes in their self-efficacy levels. The results of this study demonstrated that students’ self-efficacy in ML practices increased significantly after they completed the AI curriculum activities. In particular, after the curriculum intervention, students became more confident in feature engineering tasks related to ML practices. On the other side, this study showed that students needed further training and reinforcement to feel confident in completing a new ML course, including new ML concepts like image or speech recognition. In accordance with the literature, our approach to teaching AI and ML concepts through hands-on learning practices was promising to support high school students' self-efficacy in ML practices. Drawing on the SCT perspective, these hands-on experiences provided mastery-level experiences in ML practices. Students were able to practice ML concepts through three different curriculum lessons. These might help them gradually develop a high level of self-efficacy throughout the curriculum activities. Additionally, when we closely examined students' characteristics, we found that students' completion rate in the activities, peer interactions among them, and initial interests in ML practices can be predictors for their self-efficacy in ML practices. In line with other studies, our findings demonstrated the importance of students' active participation and initial interests in completing learning activities. Many studies showed the significance of understanding self-efficacy in designing scaffolding learning tasks and activities. The findings of this research can inform AI curriculum developers and researchers in designing and developing AI curriculum intervention in high school classroom settings. Our work contributes to the AI education field by demonstrating a way to integrate an AI curriculum into non-STEM classrooms to foster K-12 students' self-efficacy in ML.

Authentic Invitations: Offering Girls of Color Voluntary, Contextual, and Responsive Opportunities to Develop Computing Identities

Patricia Garcia, Laura-Ann Jacobs, Melissa Perez
garciapg@umich.edu, lxjacobs@umich.edu, perezme@umich.edu
University of Michigan

Abstract: Broadening participation in computing requires a deeper understanding of how to support girls of color in developing computing identities, or views of themselves as active participants within computing. We propose the concept of *authentic invitations* as a promising avenue for supporting girls of color in developing computing identities. To illustrate the three proposed dimensions of an authentic invitation, we highlight the experiences of Deandra, a 16-year-old Black girl who participated in an informal computing program for girls of color hosted in public libraries. Our findings show how offering voluntary, contextual, and responsive invitations to participate in computing can support girls of color in authoring computing identities that integrate their social and personal experiences.

Introduction

Opportunities for girls of color to meaningfully participate in computing continue to be inequitably distributed in K-12 education (Garcia, et al., 2020). When girls of color do have access to computing education, they often face racialized and gendered stereotypes that position them as lacking motivation and unable to master challenging course content (Allen & Eisenhart, 2017). In this paper, we examined how informal computing programs can design nurturing learning spaces that proactively dispel stereotypes and foster positive computing identities, or views of oneself as an active participant who can contribute and belong within computing (Mahadeo et al., 2020). We propose the concept of *authentic invitations* as a promising avenue for supporting girls of color in developing computing identities that are grounded in their lived experiences. We conceptualize an *authentic invitation* as an offer to participate in learning that is 1) voluntary and not mandated; 2) contextual and not conditional; and 3) responsive and not dismissive of girls' past, present, and future selves. To illustrate the three proposed dimensions of an *authentic invitation*, we highlight the experiences of Deandra, a 16-year-old Black girl who, while pregnant and working a part-time job, participated in an informal computing program for girls of color hosted in public libraries. Ultimately, we argue that providing meaningful connections between girls' lived experiences and computing identities can result in broader and more inclusive conceptions of what it means to participate in computing, especially in ways that extend beyond academic performance and career goals.

Conceptual framing: Authentic invitations to author a computing identity

Our work draws on disciplinary identity models that explain how learners develop feelings of recognition, interest, and capability within disciplines (Mahadeo, et al., 2020). The process of "authoring" a disciplinary identity involves performing behaviors, actions, and speech that are valued and recognized by peers and educators (Johnson et al., 2011). Students can be positioned by educators and peers in specific ways based on their race, gender, class, and the context (Allen & Eisenhart, 2017). These positionings can influence how they author their identities and come to imagine their future as active experts in science fields. We examine how girls of color develop computing identities, which describes the extent to which a learner identifies as a "computing person," within the context of an informal computing education program (Rodriguez & Lehman, 2017). Prior conceptualizations of a computing identity typically involve performing behaviors that are recognized as related to the discipline of computer science, such as learning to program (Harrington et al., 2019). Instead of developing a performance-based computing identity model, our work examines how *authentic invitations* to participate in a learning environment that equally values personal meaning making and computing skills impacts the development of computing identities among girls of color. Our conceptualization of an authentic invitation is informed by community-based practices that acknowledge that "transformation occurs through choice, not mandate," that community building supports "people to participate and own the relationships, tasks, and process that lead to success," and that invitations are "the call to create an alternative future" (Block, 2008). Based on these community-based practices, we describe an authentic invitation as one that is 1) voluntary and not mandated; 2) contextual and not conditional; 3) responsive and not dismissive of girls' past, present, and future selves. Thus, invitations to learn should support student agency (voluntary), consider obstacles to participation (contextual), and provide opportunities for girls of color to thrive on their own terms (responsive).

Research design

The study context is an informal computing program hosted at a library in an urban city in Southeast Michigan, USA. The curriculum consisted of twenty hours of activities that introduced girls to computer programming using an Arduino, an opensource microcontroller. While we evaluated the curriculum effectiveness, we do not present those results in this paper. The program enrollment was capped at 10 girls per implementation. Recruitment was conducted by librarians who hosted “open houses” and focused on recruiting girls, ages of 13-16, who identify as Black, Latina, and Native American. Two researchers attended each program session and collected field notes and audiovisual recordings of participant artifacts such as group projects and expressive artwork. Three members of the research team analyzed the data using an inductive coding process and collaboratively conducted thematic analysis. The analysis process included cross-checking interpretative claims using data triangulation that converged information gathered across the textual, audio, and visual forms of data.

Findings

Rather than report a summary of whole group experiences, we focus on the experiences of one participant to present a unified account of how authentic invitations can influence the development of a computing identity. Deandra was chosen as the exemplary narrative because her experiences exemplify the construct of interest in a particularly interesting manner given her initial reluctance to participate in the program, her decision to complete the program twice, and her life circumstances. While her experiences may not be “typical,” exemplary narratives can still be used to understand a wide range of developmental processes because they represent the upper ends of development and allow for the inclusion of detail, context, voice, and emotion (Bronk, King, & Matsuba, 2013).

An introduction to Deandra

At the time of the program, Deandra was a 16-year-old Black girl who worked at a local doughnut shop and attended the program in her work uniform since she started her work shift shortly after each session. She participated in two full implementations of the program (40 hours total); first in the summer of 2019 and again in the fall of the same year. While Deandra demonstrated her interest in the program by adjusting her work schedule, she also positioned herself as someone who was “too cool” for the program. During her first experience participating in the program, Deandra positioned herself as someone who was mainly interested in the program because of the “snacks” and was not afraid to announce “I ain’t doing that” when asked to participate in an activity. Although Deandra publicly dismissed most of the program activities, she attended while pregnant, chose to return for a second implementation, and ultimately accepted invitations to participate in computing.

Authentic invitations as voluntary: Deandra becomes “good at this type of thing”

Deandra arrived late during a session when the girls were learning to use an Arduino because she had been experiencing morning sickness. The librarians invited her to participate in the session but did not mandate her participation. When she realized how far along the other girls were on the project, she used humor to deflect from her nervousness. She peered over girls’ shoulders to look at their projects and when she saw fumes rising from the soldering iron one of the girls was using she exclaimed, “Oh no! I’m not doing that!” Deandra chose not to participate and spent the remainder of the session sitting at a table with her head down. She was never asked to leave, and she was never chastised because the invitation to participate was always voluntary and not mandated. At the end of the session, the librarian, Sarah, encouraged her to return, “I hope you feel better. See you tomorrow!” Deandra did return the next day. She boisterously grabbed an Arduino and began joking again when Sarah invited her to learn how to integrate a photoresistor with the Arduino. “Oh no no no,” she said as she proceeded to grab all the materials she needed to complete the project. Sarah laughed at her feigned trepidation as she helped Deandra get settled. By the end of the session, Deandra had learned to use variables to store the resistance value of a photoresistor (int sensorValue = 0) in the Arduino Integrated Development Environment. After successfully getting an LED to respond to changes in light using the photoresistor, Deandra proclaimed, “I’m good at this type of thing!” While it may seem counterproductive to accept Deandra’s refusal to participate, respecting her decision underscored the voluntary nature of the authentic invitation to learn new computing skills and highlighted her ability to have control over how and when she wanted to learn.

Authentic invitations as contextual: Deandra becomes a “veteran”

When Deandra enrolled in the program, she arrived with her grandmother, sister, and cousins. Before Deandra’s grandmother signed her up, she asked Sarah, “Is it okay if one of them is pregnant?” Although we had not planned for meeting the needs of a pregnant participant, the invitation we offered to participate in computing was contextual and not conditional. We worked with the librarians to consider the context of Deandra’s specific life circumstances and agreed to find ways to support her participation by accommodating her doctors' appointments, the physical demands of pregnancy, and her evolving familial relationships. As previously described, Deandra did not always feel well enough to participate. She struggled with morning sickness, swollen feet, and headaches. She also balanced her work and doctors' appointments with her program participation. While participating in computing was a valued program outcome, the librarians accepted that Deandra could not always participate and continued to communicate their investment in her success through persistent and consistent academic and emotional support. After several sessions, it became clear that the program served as a refuge for Deandra. During an activity that introduced girls to the concept of an algorithm using dance steps, Deandra shared that she "loved coming here because at home everyone is focused on the baby." She also later shared that learning new things helped her stop worrying about "drama" with her family. The program offered Deandra a safe space to learn new computing skills and a refuge from the evolving context of her life and family relationships. When the next program implementation began in the fall, Michelle, one of Deandra's cousins enrolled but Deandra did not show up. Sarah asked Michelle to encourage Deandra to return, "Next time you see Deandra, let her know we miss her, and we hope she comes with her baby." Michelle responded, "Is that allowed? Can she bring her baby?" Deandra did show up during the next program session and she lovingly showed off her baby, "His stomach is so big but then he has these little chicken legs." The librarians and researchers took turns holding the baby while Deandra participated in the program activities. As she participated, Sarah positioned Deandra as a leader with prior experience. Deandra also positioned herself as a "computing person" by offering to help "newbies." When a new participant struggled, Sarah said, "Well it's a good thing Deandra is here. She is a veteran. She can help you." By describing Deandra as a "veteran," Sarah positioned her as knowledgeable and skilled and acknowledged her as someone capable of continued participation in computing.

Authentic invitations as responsive: Deandra becomes a member of the group

Deandra struggled to form relationships with other girls in the program and tended to stay near her cousins. After Deandra refused to participate in an icebreaker designed to build trust between participants, Sarah shared her frustration, "Deandra refused to get up for the icebreaker. She just did not want to engage at all. It made it awkward and weird for the other girls. Everyone felt it." Deandra and her cousins also giggled when other girls showed excitement over completing computing activities, which caused the other girls to feel self-conscious. Deandra's behavior was a clear violation of the shared norms the girls had collaboratively created, which included "Be kind and respectful to others." Part of being responsive and not dismissive of girls' sense of self involves having them honestly examine their attitudes and beliefs about themselves and reflect on how those attitudes and beliefs influence their intrapersonal relationships. Sarah reminded Deandra that it was important to "build each other up" and asked her why she was behaving "outside of the boundaries" the group had agreed upon. After reflecting on her behavior, Deandra explained that she was just "messing around" and agreed to be more mindful about how her behaviors affected others and asked to be held accountable if she lost her "filter." Deandra's commitment to change was tested during the next program session when she told a member of the research team, "You're big." The researcher replied, "Oh, you mean like fat?" Deandra tried to play the comment off as a joke, but the researcher held her accountable, "If in the next few hours you feel like you want to apologize to me for that, I'm here to hear you. Just anytime, I do expect it though." Within a couple of minutes, Deandra apologized, "I have no filter. Yeah, I'm sorry." Over time Deandra began to interact with the other girls, entering the space within the agreed community norms. Sarah described the change she saw in Deandra, "She started feeling more trusting and she started making more positive comments to the other girls by the end of the week. She was receptive because I think she felt safe and felt accepted by us." By supporting personal reflection on past and future behaviors, Sarah's invitation to continue participating was responsive to Deandra's sense of self. She left the possibility open for Deandra to change her behaviors in the future.

Discussion

By allowing program participation to be voluntary and not mandatory, Deandra was free to refuse our invitation to learn new computing skills. Accepting Deandra's refusals required reframing how non-participation was viewed in the program and it pushed us to consider how an invitation to participate could be authentically voluntary and still supportive of girls' personal and academic growth. Deandra taught us that an authentic invitation must support and not suppress opportunities for decision-making and agency throughout the learning process, even if the decisions do not always align with the goals of the program. An approach that treats the invitation to participate in computing as a voluntary decision may help support the development of more agentic computing identities that allow girls to see themselves as having choice and control over how they use computing skills in their lives. In our program, an authentic invitation also meant encouraging girls to bring their whole selves to the learning environment. The invitation to participate in the program was not conditional and did not require the girls to leave their multiple identities, prior experiences, and personal lives at the door. Deandra and her cousins openly talked about their families, crushes, and worries - all while participating in computing. Respecting the context of Deandra's life circumstances and inviting her to bring her home life into the learning environment, such as welcoming her baby, resulted in her continuing to show up to the program. She participated in the program on her own terms and authored a computing identity that aligned with her life circumstances. Finally, by making space for girls to reflect on their academic and self-growth, we were responsive and not dismissive of girls' past, present, and future selves. For Deandra, the process of authoring a computing identity involved using humor to persist through computing activities that made her feel nervous. The librarians were responsive to Deandra's mode of identity work and invited her to participate in computing in ways that felt comfortable for her. The librarians were also responsive to Deandra's future self and worked with her to author a computing identity that could include her baby. Yet, an authentic invitation also included challenging Deandra to change behaviors that were comfortable but detrimental to forming positive relationships with other girls. The librarians supported Deandra in developing a computing identity that included views of herself as "good" at computing, integrated her life as a mother, and laid the foundation for positive peer relationships.

Conclusion

In this paper, we present the concept of *authentic invitations* as a promising avenue for supporting girls of color in developing computing identities. We acknowledge that analytically focusing on one participant limits the extent to which readers can understand the variety of experiences that girls could have in these programs. However, we posit that Deandra's exemplary narrative helps illustrate the upper ends of identity development and demonstrates the potential of using authentic invitations to foster computing identities among girls of color. Future work will focus on developing more formalized roles for returning participants and examine how serving as a near-peer mentor influences their development of a computing identity. By illustrating how authentic invitations can be used within an informal computing program, we contribute a greater theoretical and empirical understanding of how girls of color author computing identities and offer our approach as an avenue for expanding narrow performance-based computing identity models in ways that account for girls' lived experiences.

Community Cultural Wealth in Latinofuturism: Leveraging Speculative Fiction for STEM + Arts Asset-Based Pedagogies

Santiago Ojeda-Ramirez, R. Mishael Sedas, Kylie Peppler
sojedara@uci.edu, rmsedas@uci.edu, kpeppler@uci.edu
University of California, Irvine

Abstract: In this conceptual paper, we present our work in progress towards the theorization and operationalization of an asset-based pedagogy for STEM + Arts content infused with the aesthetic and speculative fiction movement of Latinofuturism. As Latine scholars, we aim to contribute to the education field with an alternative approach to support the Latine population who is still disproportionately underrepresented in the STEM fields. Through our review of the literature and media, we use the theoretical framework of Community Cultural Wealth, specifically its six forms of capital, to examine Latinofuturism as a genre that can connect STEM + Arts themes with Latine culture through speculative practices. We propose that asset-based pedagogies situated in Latinofuturism aesthetics provide emancipatory opportunities for Latine to dream and think beyond the current barriers of access to STEM + Arts and create a new STEM culture *for* and *with* Latine.

Introduction and background

Our pluralistic world is more connected than ever, and so is the opportunity to exchange ideas and to collaboratively work to address, solve, or even improve the situation of complex challenges that affect us all. Such unprecedented and complex "wicked problems" (Rittel & Webber, 1973) include global pandemics, severe issues to our food systems due to climate change, systemic racism, wars, and their humanitarian and economic ripples, among many other issues. As education practitioners and researchers of increasingly pluralistic and interconnected societies, we need to reflect on our pedagogical practices and ensure we adequately support learners within our spaces. In this conceptual paper, we present our initial work towards the theorization and operationalization of an asset-based pedagogy for STEM + Arts (1) content infused with the aesthetic and speculative fiction movement of Latinofuturism. Through the theoretical lens of Community Cultural Wealth (Yosso, 2005), we examine Latinofuturism and show its leveraging potential to encourage Latine learners to participate, expand their cultural practices, and enrich the STEM + Arts disciplines while contributing to the solutions and improvement efforts of our 21st-century complex challenges.

The underrepresentation of Latine in STEM education

The increase in the racial and ethnic composition of the population in our countries and classrooms is evidence of the expansion of pluralism of ideas, and it is an opportunity for education researchers and practitioners to embrace and nourish marginalized Students of Color (2) with unique cultural practices and strengths. For instance, from the latest data collection in 2019, more than half (52%) of all public elementary and secondary school students in the U.S. attended schools where Students of Color made up 50% or more of the total enrollment (NCES, 2022). Also, the most recent census data in the United States showed that the Latine population (i.e., Hispanic and Latina/o) comprises 19% of the total population in the United States, becoming the largest minority (U.S. Census Bureau, 2020).

However, some minorities are excluded and underrepresented in the Science, Engineering, Technology, and Math (STEM) fields. The Latine population is one of them who are still disproportionately underrepresented in STEM classrooms and workplaces. In fact, Latine youth face numerous barriers to entering and participating in the STEM fields. Several explanations of these barriers point to the nature of school curricula and structural and cultural factors, such as curriculum not culturally relevant but designed for the majority white middle-class; lack of funding to pursue a college education; difficulty in adapting to the culture of STEM college classrooms; and unnecessary rigor within competitive, exclusionary, and elitist environments (González et al., 2005; Chapa & De La Rosa, 2006; Flores, 2011; McGee, 2020). Therefore, new curricula, pedagogies, and educational environments that invite, embrace, and nourish Latine culture are more paramount every day.

The asset-based framework of Community Cultural Wealth

Some educational institutions have operated under the deficit view model towards minorities, treating these marginalized populations as lacking abilities and possessing deficits that need to be addressed by pouring knowledge into their empty minds. We can resist and eradicate this damaging worldview by changing our mindset to embrace the cultural practices and strengths these populations already possess and incorporate them into our learning environments. This has been the aim of the strength-based and *asset-based pedagogies* tradition. This tradition has been advanced by many scholars, such as the work of Funds of Knowledge by Luis Moll and Norma González; the Third Space by Kris Gutiérrez; Culturally Relevant Pedagogy by Gloria Ladson-Billings; Community Cultural Wealth by Tara J. Yosso; and Culturally Sustaining Pedagogies by Django Paris and H. Samy Alim. We specifically inform our conceptual work with the theoretical framework of Community Cultural Wealth (CCW; Yosso, 2005).

The asset-based framework of CCW is a critical race theory approach to recognize and acknowledge the strengths of Communities of Color toward social and racial justice. CCW focuses on *wealth*, defined as the historical accumulation of resources and assets to resist forms of oppression (Yosso, 2005). In her work, Yosso (2005) challenges the assumption that Students of Color come to school with cultural deficiencies, but she calls to value and embrace their prior experiential knowledge and cultural practices from their home and their communities. In order to accurately inform our conceptual paper, we include here the definitions of each of the six not mutually exclusive or static forms of capital that nurture this community cultural wealth (Yosso, 2005): **(1)** *Aspirational capital***,** defined as the "ability to maintain hopes and dreams for the future even in the face of real and perceived barriers" (p. 77). **(2)** *Linguistic capital* refers to "intellectual and social skills attained through communication experiences in more than one language and/or style" (p. 78). This capital also includes communication abilities via music, visual art, and poetry. **(3)** *Familial capital*, the "cultural knowledge nurtured among *familia* that carry a sense of community, history, memory, and cultural intuition" (p. 79). **(4)** *Social capital* alludes to "networks of people and community resources for instrumental and emotional support" (p. 79). **(5)** *Navigational capital, "*skills of maneuvering through social institutions" not created with minorities in mind (p. 80). And **(6)** *Resistant capital*, which is 'knowledge and skills fostered through oppositional behavior that challenges inequality'(p. 80).

From our literature reviews and other studies in progress, we have found that the particular aesthetic movement called *Latinofuturism* (Merla-Watson, 2019) employs speculative fiction to imagine new possibilities and futures while displaying evidence of all of the six capitals of CCW. In the following sections, we refer to each of the above definitions to show how CCW is present in Latinofuturism and why it can be leveraged to center Peoples of Color in their own learning and teaching. This theoretical move has the potential to empower Peoples of Color to reimagine the irrelevant pedagogical standards designed for the dominant population.

Latinofuturism

Speculative practices, dreaming and thinking beyond the present social and technological realities and future-oriented, is a powerful form of resistance and agency against inequity. Speculative fiction, an umbrella term that includes the genres of science fiction, fantasy, and horror, has been used by critical pedagogues to reimagine our present, or as Thomas (2013) put it, for "reading and rereading, writing and rewriting the world" (p. 4). Thomas & Stornaiuolo (2016) describe this practice, *restorying*, as using new media tools to reimagine the world and retell popular stories by changing to an alternate identity, time, place, mode, perspective, or metanarrative. Learning scientists have used speculative practices and their potential to empower youth, especially from minoritized communities, to engage in constructing and thinking on meaningful and more equitable futures (Holbert et al., 2020; Mirra & Garcia, 2020).

Latinofuturism, describes a broad range of Latine speculative aesthetics produced by creators of Latine origin (Merla-Watson, 2019). This speculative form of fiction denotes Latine aesthetics of various media, drawing inspiration from Afrofuturism and focusing on topics such as *indigenismo* (indigenous cultures), *mestizaje* (interracial mixing), and *coloniality* (dominant/dominated), which question narratives of progress and technological advancement (Merla-Watson, 2019). However, it is still a matter of discussion if Latinofuturism should include indigenous-futurism from the Indigenous Peoples of Mesoamerica and Latin America. Latinofuturism sees Latine people not as passive consumers of the speculative but as creators that repurpose speculation towards emancipatory ends (Merla-Watson, 2019). The work of Sedas et al. (forthcoming) on everyday ingenuity as a culturally-relevant practice of engineering of some Latine participants provides a concrete example of how we envision Latinofuturism to be integrated into a STEM + Arts asset-based pedagogy.

Community Cultural Wealth in Latinofuturism

To evidence how each of the six forms of capital that nurture CCW are displayed in Latinofuturistic media, we present evidence from comics, art installations, and video games (Figure 1). **(1)** *Aspirational capital***.** In Latinofuturistic speculation, creators imagine futures, materialities, and possibilities for themselves to generate new worlds (i.e., worldmaking). For example, in *"Puerto Roboto"* (Santiago & Reyes Rico, 2021), the author dreams and creates a futuristic world where Puerto Rico is the "global center of robotics, engineering, and new technology." **(2)** *Linguistic capital.* In *"Children of the sea"* (Pueyo & Luis, 2021), a character finds a prayer to the goddess Lemanjá which is written in Portuguese, as well as many signs and writings as part of the comic. Students could use their own linguistic resources and mother tongue to restory STEM + Arts practices and include multilingual elements in their artifacts, also to access artistic references in many languages. **(3)** *Familial capital* connects with Latinofuturism as it includes inquiry on the past, heritage, and history. In Latinofuturism, family history, knowledge, and practices are brought to dialogue with STEM + Arts practices. For example, in "*Día de la vida*" (Pérez & de la Torre, 2021), memories and stories of the past come alive through holograms that emulate dead family members. **(4)** *Social capital.* As Latinofuturism centers Latino communities as protagonists, students could cultivate and foster their relationships. In *'Aztech: Forgotten Gods'* (2022), an indigenous-futuristic video game, the character is seen supported by other members of the community. Many of the challenges in the game are solved through the community's wisdom and resources. **(5)** *Navigational capital* appears in Latinofuturistic stories and aesthetics, as they often include narratives of challenging and reimagining social institutions. In "Espiral" (Manzano, 2021), the main character learns to navigate a complicated diplomatic negotiation and succeeds due to his kindness and through promoting intercultural exchange between future Latin America and space. Lastly, **(6)** *Resistant Capital* is broadly depicted in Latinofuturistic artifacts as its main themes are migration and coloniality. Engaging with and producing Latinofuturistic media includes reflecting on historical inequalities that the Latine diaspora has faced and also how Latine people have continued to resist. For example, in *"Walk on Water"* (Guadalupe Maravilla, 2019), futuristic *coyotes* (people smugglers) resignify immigrant labor; they use futuristic vacuum cleaners and sounds to "clean" the space of New Yorkers Political phobias and blockages (Ramirez, 2021).

Figure 1
Community cultural wealth in Latinofuturistic media (see endnote 3).

Aspirational capital in 'Puerto Roboto'

Linguistic capital in 'Children of the sea'.

Familial capital in 'Dia de la familia'

Social capital in 'Aztech: Forgotten Gods.'

Navigational capital in 'Espiral'

Resistant Capital in 'Walk on Water' .

Towards an asset-based pedagogy situated in Latinofuturism

We have shared our theoretical considerations on how situating STEM + Arts pedagogies within the aesthetics of *Latinofuturistic* movement may provide a nourishing learning environment since these aesthetics display the six forms of capital denoted in CCW already present in Latine populations. Providing latine youth with these opportunities may constitute an example of much needed culturally relevant STEM curricula that invite Latine to participate while embracing and celebrating their cultural backgrounds. Asset-based pedagogies infused with Latinofuturism may present opportunities for Latine to engage with STEM + Arts practices while *restorying* their past, present, and future narratives in these fields. Our present and future work includes a systematic literature review of empirical studies that describe the use of Latinofuturism in such asset-based pedagogies and also concrete examples of how Latine youth bring their community cultural wealth to reimagine STEM education that is relevant to them and their own communities and cultures.

Endnotes

(1) We use the term “STEM + Arts” instead of the “STEAM” to symbolically give the Arts its place as equal to the other disciplines and signal the implicit trouble of the STEAM construct, as explained by Mejias and colleagues (2021).

(2) The National Center for Education Statistics uses the designation of “Students of Color” to those who are Black, Hispanic, Asian, Pacific Islander, American Indian/Alaska Native, and of Two or more races.

(3) Power and Magic Press, Publisher of “MAÑANA: Latinx comics from the 25th Century,” granted written permission to use figures in this educational publication.

The University of Texas at Austin

Wonhee Hwang, Seoul Metropolitan Office of Education, gml24160@gmail.com

Abstract: Within computer science (CS) education, physical computing has emerged as a tool for designing learning environments where children can learn computer science and increase their identification with and interest in computer science. Here, we report findings from our examination of students' identity work based on their participation in an 18-week after-school club in a Korean elementary school focused on physical computing with four sixth-grade students. In analyzing multiple observational data sources (e.g., video recordings, interviews), we highlight how a focal student authored himself as an expert and a club leader. Our findings show the importance of an interest-based learning environment for identity development.

Introduction

Science, Technology, Engineering and Mathematics (STEM) education and learning sciences scholars have demonstrated the importance of examining identity processes that occur across K-12 learning environments (Bell et al., 2017). Azevedo and Mann (2022, p. 179) define identity work as "the interactionally achieved, historically and contextually situated process" of "actively authoring him/her/theirself as a particular kind of individual" and others' positioning of that person. This work occurs over time and across settings as individuals engage more deeply in communities of practice (Lave & Wenger, 1991). Informal STEM settings may offer fewer limitations than traditional schooling contexts for designing student-led learning environments centering on children's interests—important instructional design principles that can foster interest-based engagement and identity development. Here, interest-based engagement in practice refers to "self-motivated, often self-guided, short- and long-term participation in the fabric of activities that make up the practice" (Azevedo, 2013, p. 464). Individual interests are linked to cognitive, social, cultural, and material dimensions, and establishing environments where interests can take root and grow is key to instructional design (Azevedo, 2013).

Physical computing (Blikstein, 2013; Kalelioglu & Sentance, 2020) emerged as a tool to support children's engagement in CS learning and increase their identification with and interest in CS while helping us understand humans' interactions with digital environments. Physical computing can 1) promote creativity and engagement, 2) deepen students' understanding of and interest in CS, and 3) enhance their computational thinking skills (Blikstein, 2013; Kalelioglu & Sentance, 2020; Przybylla, 2015). The physical computing device is a "programmable tangible that would bring programming to the physical world" (Blikstein, 2013, p. 173). An example of using physical computing in practice is the BBC micro:bit, a microcontroller with many features (e.g., LED lights, programmable buttons, sensors), used in this study as a tool to support students' interest-based engagement and elaborate on the role that tools, artifacts, and materials play in learning (e.g., Saxe, 1992).

We examine how four sixth-grade students' identities developed through an interest-driven physical computing project over 18 weeks, given that human behavior is best understood by tracing its change over time (e.g., Saxe, 1992). Drawing upon sociocultural theories of learning (Lave & Wenger, 1991), we unpack students' identity work by situating physical computing in a student-centered interest-driven learning environment. We view learning as a contextual and social phenomenon acquired by engagement in a community of practice (Lave & Wenger, 1991) and examine how a focal student, Song, became a leader of a collaborative project and authored himself a CS expert. We ask, how did interest-driven physical computing influence Song's identity work over time? Using observational data sources, we discuss how the design of the learning environment supported his increased interest in and identification with CS. We also highlight Song's identity work related to being a club leader and CS expert, including his deepened participation in CS learning activities, and personal growth, contributing to the literature related to CS identity development.

Methodology

Study context and data collection

The study context was the Bright Computing After-School Club at J Elementary School, located in a low-middle income school district in Seoul, South Korea. In the club, students typically learned how a small media station is operated and how to utilize digital tools (e.g., computer, camera, streaming equipment). The study participants were four 12-year-old sixth-graders (one female, three male students) and the club teacher, Ms. Han, a Korean woman in her late twenties who taught the students science during the school day and worked with them in the club. Students voluntarily participated in the club and shared an interest in learning technology and a desire to experience digital devices. Most students had less than six months of learning experience with introductory-level CS elementary education, while Song had more than 2.5 years of experience; none had prior experience with physical computing. All students had experience using a block-based programming language (e.g., Entry, Scratch), but stopped other CS activities because they did not enjoy teachers' unidirectional instructions.

We desired to foster a learning environment where students could pursue their own interests without fear of being assessed for correctness. Author 1 came up with the idea for redesigning the club, the research plan, and met weekly with the teacher to assist. Students were given space to work on their projects and resources, including smart tablets, BBC micro:bit boards, computers, and crafting materials (e.g., paper, scissors, glue). Ms. Han had limited familiarity and expertise in CS, so there was little teacher intervention; students primarily used resources (e.g., YouTube videos) to teach themselves and support their learning. Researchers examined student learning activities over 18 weeks and collected five data sources: video recordings of students participating in the club; the teacher's reflective diary documenting both science classes and the after-school club; student artifacts; student and teacher interviews; and notes from weekly meetings with the teacher. We video-recorded each session and documented the specifics of individual students' activities in and beyond the club. Ms. Han kept a reflective diary with rich records of daily teaching reflections from each science class and after-school club session. We collected any artifacts students produced as part of their physical computing projects (e.g., micro:bit electric guitar, micro:bit digital pet). After 18 weeks, when the project was complete, Authors 1 and 3 conducted semi-structured interviews with each student in Korean (30 minutes each) and translated transcripts into English. Interview questions were designed to elicit information about students' activities at the club, classroom work, family life, and other learning environments. We also asked follow-up questions to gain clarity about their artifacts, perceptions, and visible and salient behaviors in video recordings.

Data analysis

This study is part of a larger, ongoing design-based research project (Barab & Squire, 2004) combining case study methodologies (Yin, 2012). This approach includes ethnographic mapping of themes and description via participant observation, collection of artifacts, production of a detailed reflective diary (Geertz, 1973), and video-based interaction analysis (Jordan & Henderson, 1995), enabling a focus on the macro-, meso-, and micro- systems shaping student activity and learning. To understand students' identity processes over time, the first author open-coded transcripts from video recordings, interviews, teacher's reflective diary and examined student artifacts (Miles et al., 2018). We segmented instances of video recordings and performed interaction analysis to identify and describe occurrences of identity work in the classroom (Jordan & Henderson, 1995). The data was holistically analyzed through the lens of sociocultural theories of learning (Lave & Wenger, 1991), examining how they were positioned to engage in specific kinds of activities over time, the types of persons associated with that work, and the self-reflection and social recognition work that developed over time (Jordan & Henderson, 1995). We layered this analysis with analytic memo writing (Emerson et al., 2011). From these analyses, we selected Song as a focal student. His identity work was most prominent in the data sources (e.g., video recordings, teacher's reflective diary), providing detailed evidence to develop an account for his identity work. We selected instances of the focal student's identity work related to authoring himself as a particular kind of individual, relating these to the instances of recognition by the teacher and peers.

Results

Song's identity work toward becoming a club leader

We present results from Song's identity-building efforts. Before initiating the club, data sources (interviews with Song and Ms. Han, teacher's reflective diary) revealed Song was generally quiet and disengaged in overall school activities. In his interview, Song mentioned his parents' divorce and implied that it had an impact on his life. Initially, Song's position relative to the other three club members was clearly peripheral, as he hardly spoke or communicated with them. Although none of the students had prior experience with micro:bit, over the course of 18 weeks, Song developed a reputation as an expert on digital devices and coding among the club members, identifying him as the member most skilled with computers and occasionally asking him for help.

Considering Song's identity work relative to the club's internal group structure and functioning, it was evident that Song had become the club's leader. In asserting his position, he would "teach [peers to] do something" (Excerpt from Song's interview) and enthusiastically seek resources for what his peers would appreciate and find easy to try out together. He said, “We are friends. We’re the same age. It’s not about teaching from the teacher. It’s about playing together. I wanted the kids to look at this side, the computer, with more interest. I looked for things they might like.” There was a virtual group chat space where club members and teachers interacted. The children asked questions when they had difficulties with physical computing tasks outside of the actual club space, and Song responded to those questions. Even his daily displays of closeness and affection for computing (based on video recordings) seemed to reaffirm his standing. We interpret these actions as Song’s work to maintain his identity and position as the club’s leader and author himself as an expert in computers.

Song’s identity work as the club’s leader was accompanied by his demonstrations of knowledge that hinted at his familiarity with and expertise in the field of computing. Although Ms. Han’s role was primarily as a supervisor, she also publicly asked Song a few times to help others who were struggling, such as when students were having problems connecting micro:bit to the computer or when the codes would not work, thus reaffirming his primary authority over the club activities. His power and authority appeared to stem from club members’ and Ms. Han’s recognition of Song’s prior experience with computers and digital devices.

Song gaining confidence and strengthening relationships with family and peers

Song’s gained power and authority also had influences on his daily school life. Clearly, there has been a change. Whereas he had been very quiet and disengaged in class prior to the club, Song became attentive, enthusiastic, and very talkative by the end of the after-school club. The following excerpt from the individual interview demonstrates who he is becoming: “Well, you know, I taught them [peers] do something. I was looking for what they would like, and I tried to find things that they would like and that would be easy for them. You know, I’m not typically the type of person who takes the lead. [Interviewer: But aren’t you the class president right now?] That's right. Ha ha! That’s because [when we were working on the micro:bit project], I realized I could help them and guide and lead them. So, I got that bit of leadership and learned about being a leader, and this time I ran for class president. [Interviewer: The confidence started with the micro:bit?] Ha ha! [nodding and acknowledging]

Song had developed such specific forms of participating in and contributing to the club. Song developed close personal relationships with peers through club activities. Over the course of 18 weeks, four club members collaboratively created their own digital pets and electric guitars using micro:bits through a series of trial and error and struggling moments. When they succeeded in creating a working micro:bit guitar, for instance, they were all full of enthusiasm and stated that they now want to try building other things using the physical computing device. For example, Song was particularly interested in designing and building a face recognition device that opens the door as the next step in applying his knowledge. He wanted to improve the security of the club’s physical space by installing the device in the club room entrance, which would prevent non-affiliated individuals from entering the after-school program classroom. He reported gaining confidence through club activities, and as a result, he even ran for and was elected class president. Song reported that his personal relationship with his dad had also gotten better. He said that, with coding as a mediator, he was better able to comprehend his father’s work. He mentioned that his desire to learn about computers was influenced by his father, who is a computer engineer. Song said, “I felt interested to see my father do it [coding]. I started to learn coding on my own because I thought it would be fun for me as well.”

Song authoring himself as a CS expert

Song claimed that he began coding at an early age and began learning block-based programming language independently in first grade. For third grade, he attended an after-school computer program. He added, “I joined [the program] a bit late. But they [friends] were already pretty good. [Interviewer: Coding?] Yes. That made me want to win them. Since then, I've been learning on my own after school... Then, when I was in 4th grade, the program disappeared because of COVID, so I went to it for about a year or two.” Song said that he hopes to be a video creator and keep engaging in technology-related work in the future. He recalled that he had edited videos as a hobby since kindergarten: “I filmed a video of me playing with a toy with my friend and uploaded it on YouTube. I edited it with my phone.” His identity-building efforts were strongly tied to his own views on digital devices and technologies. The following interview excerpt displays one portion of Song authoring himself as a CS expert: “It’s [computer] my life… Before my dad bought me a computer, my father and I used to share one. I was only four years old when I first used a computer… But then I did some pilot things. Since then, I've been more interested. But now I'm also very interested in hardware, not just computer software. Assembling and stuff like this… My computer broke down once before. It won’t boot. But I saw on YouTube that you could take out some kind of RAM and put it back in. So, I took out the RAM and put it back in. From then on, I was more curious. [Interviewer: What grade were you in?] I was in 4th or 5th grade, so from then on, I became more fully immersed in it and I did it all night long. 48 hours really... I studied Python for 48 hours.

Discussion

As researchers in the learning sciences, we are interested in advancing the field's understanding of how learning environments can shape identity work, especially in CS educational settings. Identity work happens across settings and time and in relationships with others as individuals engage more deeply in communities of practice. This work can be supported when students have interest-based engagement and their learning is supported by material infrastructure (Azevedo, 2013; Saxe, 1992). To this end, we analyzed data from sixth-graders' participation in the Bright Computing After-School Club for 18 weeks. This learning environment was designed to foster students' interest and identification with CS using a physical computing tool (i.e., micro:bit). We highlighted how Song authored himself as a CS expert and club leader and how others positioned him as such within and across learning environments. Since club activities centered around physical computing, students' identity work was often accompanied by displays of knowing and learning of computing concepts. We discovered that Song's identity work is inextricably intertwined with the knowledge he acquired independently, out of his own curiosity and for his own amusement (Azevedo & Mann, 2022). Song continuously took action to maintain his identity and position as the club's leader. His identity work was also related to others' recognition which, as a result, helped increase his confidence and strengthened his relationships with family and peers. Song "being a leader of the club" stretched across settings and contexts and was expanded to "being a class president" and "having a more intimate father-son relationship" as he engaged more deeply in the club. Song's position in relation to the other three club members was peripheral at first, but his participation grew into forms that were more central to the functioning of the club and even outside the club. Our findings build upon and extend prior research in CS educational settings that suggests physical computing can promote creativity and interest in CS (Blikstein, 2013; Kalelioglu & Sentence, 2020; Przybylla, 2015). Further, our work demonstrates the value of an interest-based physical computing learning environment for promoting students' interest in CS and deepening engagement, which supports their identity work. Such an environment and the tangible tool provided students with the opportunities to better imagine what they wanted to create, and to design and produce artifacts in the actual world that reflected their own interests and identities. Students' interests in CS increased as they connected it to their specific interests and the computing project they desired to undertake. Students' identity work was influenced by the design of the club, which provides opportunities to pursue their interests, interact with others, overcome struggles, reaffirm their own standings, and maintain their identities and positions. Moreover, interactions within and beyond the club revealed social group dynamics rich in identity work from all club participants; thus, we will further investigate all students' identity work in our future study.

Live Zoom Room: Understanding How Young People Build Joy and Connection Online

Jiyoung Lee, Erin Riesland, Katie Headrick Taylor
jiyoungl@uw.edu, erinsage@uw.edu, kht126@uw.edu
University of Washington

Abstract: In online learning through Zoom, focusing on joy has been a useful strategy to resist deficit narratives about youth of color during the Covid-19 pandemic. To better understand designing and facilitating joyful STEM learning, we explore unique interactional phenomena in "Live Zoom Room," an online, out-of-school cooking program, World through Food. We performed interaction analysis on video data to identify semiotic resources and themes that contributed to joyful moments. Findings revealed that participants drew from common sets of tools and resources to cook and communicate through Zoom and improvised while doing so. These resources allowed participants to be themselves online, and to build on each other's actions, forming a foundation of joyful STEM learning experience.

Introduction

The COVID-19 pandemic and closure of educational spaces forced youth and educators to reconsider the ways we learn together in space and time. As a result, educators in schools and out-of-school-time (OST) programs redesigned their curricula to deliver content via various video-assisted online learning platforms like Zoom. Adapting to Zoom posed unique challenges to project-based, STEM OST learning programs because the activities and projects often required special tools and materials provided by the program on site. Learning on Zoom posed other challenges, too, due to digital fatigue and emotional distance for learners and facilitators (Toney, Light & Urbaczewski, 2020). However, moments of great joy and happiness also occurred on Zoom that sustained participants through the pandemic. Joy and happiness have been framed as responsive actions to unpleasant situations to change perspectives (Adams, 2022; Lu & Steele, 2019). These responsive actions are useful as resistance strategies against a dominant white narrative that positions youth of color as lesser than, lacking cognitive and emotional abilities.

To understand how we can better design and facilitate moments of joyful learning over live Zoom sessions, we need to identify such moments and understand what makes them joyful for young people. We identify and analyze interactions using a "Live Zoom Room" (LZR) practice in which analysts collaboratively view video of learning over Zoom, over Zoom. LZR allows us to understand the unique semiotic resources involved in understanding joyful STEM learning online. We identify *substrates* (Goodwin, 2018) of joyful STEM learning--the semiotic fields of resources that Zoom offers (e.g. video, audio) for participants to operate on, to build from, and to modify actions. We ask: how do young people (and adult facilitators) draw from resources in Zoom, and build on each other's embodied interactions through Zoom to create a shared meaning of joy in STEM learning?

Conceptual framework

A substrate is a symbolic or semiotic resource that serves as a "point of departure for transformative operations that create new action" (Goodwin, 2018, p. 32). We position Zoom as a set of semiotic resources that organizes and transforms participants' interactions and sense-making processes. Zoom interactions are unique in that they occur in real time, but at a spatial distance. In our study, participants were often observed interacting with the technology in semiotically transformative ways where the resources of Zoom became points of departure for new actions to unfold. Zoom's ability to support the real-time unfolding of semiotic actions contributes to the joyful "liveness" of the Zoom learning environment.

Liveness is made possible through a sense of immediacy which occurs through moment-to-moment interactions. Immediacy results in a sense of presence, made possible when the distance between embodied experience and live experience is diminished to the point where mediation becomes invisible (Davis, 2012). We look to Zoom as the mediating technology that enables participants to engage in co-operative embodied interactions that accumulate and transform at a distance, and in real time. It is important to note that these in-the-moment interactions at a distance are made possible by the technology of Zoom, which is not neutral nor evenly distributed across hardware and connection (Eubanks, 2018).

When we use technologies, they reshape how we experience the environment, thus reorganizing the relationships between people and the environment (Verbeek, 2005). In our study, this meant how participants created and experienced joy was shaped by the kinds of relationships they had with Zoom technology. To better see this unfolding relationship, we draw upon Ihde's theory of human-technology relations as an analytical lens through which to understand the *substrates* that are produced. Ihde's human-technology relations are highly context dependent; we adopt and adapt two relations in this study: 1. *alterity relation* and 2. *embodied relation* (as cited in Verbeek, 2005, p.127).

First, *alterity relation* concerns how humans are "related to or with a technology" (Verbeek, 2005, p.127). It often refers to the ways in which humans use or interact with a technology to do a certain task. *Embodied relation* is the mediation of those technologies which transform a user's actional and perceptual engagement with the world (Verbeek, 2005). In the context of Zoom-human relations, *alterity* and *embodied* relations are not always clearly demarcated, and they are always in motion together. This is because we use Zoom to communicate and relate to other people; we usually do not connect directly, and only to Zoom. For example, if a youth prefers using audio, they are relating to a part of Zoom technology to communicate in a specific mode. Thus, when we describe participants' propensity to draw from particular resources in Zoom (e.g. using chat), we refer to this as *embodied alterity relation*. We reserve *embodied relations* for instances where participants' field of perception, or bodily actions are mediated via Zoom. We use *alterity* and *embodied relations* as helpful lenses to examine how people use Zoom resources and build their own *substrates.*

Study context

STUDIO is a research practice-partnership between the University of Washington (UW), and a community-based organization (CBO) located in a mixed-income, public housing community in a city in the Pacific North West region. STUDIO is a collaborative effort to create and facilitate STEM, project-based curricula that serves middle and high school youth of color from local immigrant and refugee families through a learning community (Herrenkohl et al., 2019). Researchers, CBO staff collaborate with youth and work with undergraduates who serve as mentors to youth by participating in 2-2.5 hours of weekly program activities. STUDIO considers youth, families, and undergraduate students as co-designers and facilitators of OST curriculum that we describe and analyze below. During the early months of the COVID-19 pandemic, STUDIO responded by designing an online STEM-based cooking program called *World through Food*. The curriculum took place between September and December of 2020 and aimed to bring participants together to cook, explore STEM concepts embedded in cooking, and support one another. The CBO staff and researchers purchased and delivered ingredients to youth's homes weekly before each Zoom session. All activities took place over Zoom once a week for two hours synchronously. Video recordings of these Zoom sessions were then collected and analyzed (Jordan & Henderson, 1995). The first author identified segments of videos that indicated joyful learning, and these were then co-viewed by a team of researchers to identify key semiotic resources, themes, and substrates (Goodwin, 2018).

The vignettes below were from the first day of *World through Food* when youth and facilitators made Dalgona coffee, a drink trending on Instagram in 2020. We observed that youth and facilitators had different ways of engaging with resources in Zoom. Although youth talked more over time, their preferences toward using distinct Zoom resources largely stayed the same. This prompted the authors to analyze the Zoom video data from the beginning more closely, and thus use the vignettes from the first day.

Findings

Although facilitators and youth have a similar range of resources, we observed that each individual participant had specific preferences toward certain sensory modalities such as audio and chat. These specific *embodied alterity relations* that individual participants formed with Zoom affected how participants embodied themselves online, and built upon each other's actions to create *substrates* of joyful STEM learning. Youth had control of turning on and off different Zoom functions (e.g., muting themselves, turning off their camera) with the exception of recording, setting up breakout rooms, and muting the audio of other participants; only the host had control over these functions. The authors chose to focus on audio and video in this study because these were the most often exhibited communication preferences. We describe how these preferences were used in Zoom by youth to joyfully connect and communicate using vignettes below.

1. Max's embodied alterity relation: Creating moments of joy through video and audio

In the short exchange between Lucy, Max and Jiyoung, youth created moments of laughter and joy as they built on each other's actions using video and audio to compare foam to prepare for drink making. Max was making his drink using cocoa powder because he had made Dalgona coffee in a previous session and he was wondering whether cocoa powder and milk were easier to foam up than the coffee blend.

01 Max: Lucy, is it supposed to be not that hard to do?
02 Lucy:*[[she smiles]]* It's already thick in consistency so, it depends on what you want.
03 Max: Mine is just, *[[Max shows his bowl upside down in front of the camera]]* hahaha
04 Lucy: Same. *[[Lucy shows her bowl upside down as well]]*

05 Jiyoung: Magic hands! Coco team.
06 *[[Max puts the bowl upside down over his head]]*
07 Jiyoung: Mine looks like this *[[putting her whisk up on the screen, and a blob of coffee mixture falls down]]*
08 Max: You have to whisk it more.
09 Jiyoung: I guess *[[She speaks with a playful inflection and facial expression]]*
10 Max: Arm strength, Jiyoung! This is your workout.
11 Jiyoung: hahahaha

In line 03, Max enacted stickiness of the mixture by putting his bowl upside down and holding it in front of the camera, showing that the mixture was thick enough to stick to the bowl. Then, he started laughing out loud as if the mixture's stickiness was intriguing and amusing. His preference of using audio and video together, his particular *embodied alterity relation* with Zoom, supported him to embody his sense of humor by creating a moment of levity and joy in the group as well as to communicate the status of his cocoa drink. Max's actions became a *substrate* when Lucy mimicked his motion by showing her bowl in an upside down position and smiling (04) (See Figure 1). Jiyoung followed this chain of *substrates*, and modified it by showing her own mixture and adding a lighthearted comment, "magic hands"(05). Although they were making their drinks from different ingredients, they all were using the same tools, whisks and bowls that allowed them to enact similar actions. Max encouraged Jiyoung to keep whisking and made an joke about exercising (10). Max's joke was a response to her comment, "I guess" with a facial expression that expresses a bit of protest (12). When Max noticed that she, a facilitator, was complaining about whisking, he encouraged and made fun of her at the same time; he transformed whisking into a visible arm workout. This short interaction ended with Jiyoung laughing out loud; Max, Lucy and other participants smiling together. In this sense, this *substrate* is an example of how Max embodied his sense of humor through audio and video, and how moments of joy can be shared in Zoom rooms.

Figure 1
Lucy puts her bowl upside down like Max did with his bowl.

Although Max was apt to use his microphone and camera to communicate, he rarely did so by adjusting his body positions to show what he was doing to other people. He would sometimes disappear from the video frame to help his brother Alan with cooking. The lack of bodily reconfiguration contrasted with how facilitators adjusted their body to maximize visibility will be addressed in vignette 2. This pattern of video use showed us that Max was less concerned with how he appeared on Zoom screen, rather he cared more about communicating that he was participating along with other people in the Zoom room.

2. How facilitators support youth and how youth reciprocate with joy

This vignette illustrates how facilitators use different kinds of bodily configurations to effectively teach, over Zoom, a new practice. Below, we describe how facilitators built on each other's actions to support youth in whisking, an important step in creating foam in Dalgona coffee by mixing instant coffee powder and water. When the participants started the activity, two facilitators, Lucy and Jiyoung took the lead in instructing what and how much of each ingredient were needed. To make sure their voices were picked up by the microphone, and their hands were visible by the camera, facilitators centered their bodies in front of their laptops. Jiyoung further demonstrates this intentional bodily positioning to effectively communicate within the Zoom room.

Figure 2
Lucy, Jiyoung, and Cathy model whisking for youth in the live Zoom room.

Jiyoung showed how to whisk by moving her hands and arm left and right, and explained verbally, "There are different ways to whisk, I usually go left and right like this, that puts a lot of air into it. Go left and right really fast." Further, when she noticed that her hands were not visible on the camera, she raised her bowl, angled toward the camera and whisked in the air, a quite awkward body position for the whisker (see Figure 2). If she did not have to show the youth how to whisk through the camera, Jiyoung would have put the bowls down on the countertop for more stability. This kind of intentional use of camera and reconfiguration of body position is what we mean by Zoom mediating our *embodied relation* with the technology.

Jiyoung's whisking motion was quickly adopted by Lucy and Cathy right after Jiyoung lifted her bowl. Like Jiyoung, Lucy raised her bowl in front of the camera. Cathy modified her action by lowering her camera lens so that viewers would be able to see her bowl and whisk on the table (see Figure 2). While they are building on each other's actions in close succession, other participants started changing their whisking motion from swirling to quick left and right turns. One youth, Moshin, gave us a verbal response, "That's actually a good idea! I am seeing some bubbles." In Zoom, where facilitators' bodily sensations are limited for checking on youth, Moshin's comments provided facilitators a sense of relief and joy as their effort to support youth was reciprocated. The joy is apparent in Jiyoung when she smiled and replied to Moshin with encouragement, "Yes, go Moshin!" The *substrate* that Jiyoung presented by reconfiguring her body in front of the camera was modified by Lucy and Cathy to teach youth how to whisk more effectively. When Moshin took up this *substrate* with his joyful approval, the facilitators' *substrate* became not only a resource to teach but also to express joy in striving to reach a shared goal of making a delicious coffee.

Conclusion

Across two vignettes, we presented how youth and facilitators drew from resources in Zoom to build on each other's actions to create shared joyful moments. There are three critical aspects of *substrates* of joy that we attend to: 1. Similar sets of resources involved in cooking and communicating, 2. Synchronicity of participation, and 3. Immediacy of actions. As participants tried to learn and teach how to use whisks, they paid attention to each other's ways of using Zoom's resources; they created a series of visual and auditory substrates to communicate. Because participants had a similar set of tools and materials, and engaged in the same activity at the same time, they could inhabit similar actions, and thus be able to build on each other. Further, substrates were available for a short period of time, pushing participants to react immediately and improvise. While doing so, they added their own sense of humor, and they responded with appreciation and approval, making moments of joyful STEM learning possible. Educators interested in creating joyful online STEM learning environments should design common activities that engage similar sets of tools and materials for each participant, and ensure access to the resources available on Zoom that creates a foundation for building actions together.

Expansive Framing for Citizen Science: Use of a Facilitated Online Platform to Connect Current and Future Teacher Practices in STEM

Rebekah Jongewaard, Michelle Jordan, Steven Zuiker, Carlos Meza-Torres
rjongewa@asu.edu, michelle.e.jordan@asu.edu, steven.zuiker@asu.edu, cmezator@asu.edu
Arizona State University

Abstract: Engaging pre-college students as consequential contributors to socioscientific endeavors requires teachers to shift their pedagogical approaches to encompass more expansive views of community, learning goals, and student roles. Drawing on ecological perspectives, teacher professional development can support expansive shifts by fostering connections across contexts, including links between current and envisioned practices. In a summer PD program designed to promote adoption of pedagogies for citizen science, we used a facilitated online learning platform to support teachers in enlisting resources across contexts to expand their perspectives of what is possible for their practice. This design-based research project used qualitative methods to explore whether and how teachers' projective posts more expansively framed their practices relative to practices they initially described.

Introduction

In a world increasingly affected by climate change and the misconceptions surrounding it and scientific fields in general, it is vital to equip teachers to prepare students with skills and dispositions to become active and ethical participants in STEM fields. There is a need for teachers to enact innovative pedagogies that support consequential and connected learning in STEM instruction (Jordan et al., 2021). Such approaches require K-12 teachers to take complex approaches to disciplinary content and pedagogical practices. Example approaches include place-based citizen science and community-centered engineering, each oriented towards students being recognized as rightfully present members of their classrooms and broader communities (Calabrese Barton & Tan, 2019). Effective professional development (PD) experiences for such pedagogies necessitate intensive commitments of time and collaborative energy, often among teachers and facilitators who are dispersed across physical distance. Online learning platforms can facilitate continuing PD in distributed learning communities across temporal, geographical, and institutional space (MaKinster et al., 2006).

We report on a hybrid PD program designed to support classroom enactments of innovative STEM instruction through school-based citizen science (CitSci) focused on testing a novel solar energy innovation. Through an ongoing program, teachers participate in the cocreation of a network of researchers, community experts, and K-12 students contributing to sustainable and equitable community-centered energy transitions. Here, we report on STEM teachers' participation in the online connected growth platform designed to support the development of a networked community of teachers distributed across schools, districts, and cities. The facilitated platform aims to engage teachers in learning and contributing to the pedagogies envisioned for K-12 STEM students in the CitSci program. The purpose of this study is to explore ways the platform supports teachers in expanding their pedagogical practices to include new perspectives on community, educational goals, and student roles that are vital to consequential and connected learning in STEM (Jordan et al., 2021).

Literature

Shifts in pedagogies and content knowledge are harder for teachers to make than are changes to discrete classroom behaviors (Desimone & Garet, 2015) and yet these types of deep changes are necessary to engage students in consequential STEM learning. Adopting new approaches requires reflecting on and shifting "habitual and socially reinforced ways of thinking about schooling" (Priestley et al., 2015). We see teacher learning through an ecological perspective that suggests PD opportunities should enable teachers to agentively connect new concepts with past, present, and future visions of their practice, across multiple settings, and with a diversity of resources including other teachers' wisdom and support. Learning is thus conceptualized as stretching across multiple scales of social influence and time, enlisting interconnected relationships, experiences, and tools as resources for sensemaking (Ehrenfeld, 2022).

When teachers have the opportunity to connect multiple resources from across their lives, in essence, to "expansively frame" (Engle et al., 2012) their learning in terms of its relationship to their current practices, past PD, lived experiences, and imagined future practices, they can better make decisions for agentive action in practice (Priestley et al., 2015). Teachers who learn in community are more likely to incorporate pedagogies presented in PD programs into their practices (Penuel et al., 2007). Benichou et al. (2022) and Stephens et al. (2022) reported on researcher-practitioner collaborations in which participation in PD fostered teachers' expansive framing of their own and their students' learning. This expansive framing led to enhancement of practice through greater understanding of and engagement with the PD concepts and aims.

Online platforms show promise for facilitating teachers' expansive framing and professional growth in community even when not co-located (MaKinster, 2006; Andrews et al., 2019). The platform used in this study, Journey.do, brings together expansive framing and ecological perspectives motivated by the idea that growth occurs when learners see their context-of-use as consequentially connected to the content and context of learning (Barab et al., 2019). On Journey.do,, teachers can share stories that recruit their experiences, beliefs, values, goals, and expertise as resources for making sense of new concepts (Jongewaard et al., 2021).

Method

This design-based research (DBR) study addressed the question: *How and to what extent do teachers' projective story posts more expansively frame their future practices relative to posts that describe their current practices?*

Participants and context

Participants in this first design cycle of a multi-year DBR study (Barab & Squire, 2004) included 9 STEM teachers (experience ranged from 1 to 10+ years) in a 6-week (~100 hour) PD program co-designed by researchers located in a southwestern US desert. Three teachers taught high school (earth systems, chemistry, botany), two middle school (STEAM, science), and four elementary (3rd-5th).

The PD context of this study was a summer program that engaged teachers in co-developing and instantiating Agrivoltaic (agri-PV) CitSci as an innovative pedagogy. School-based CitSci provides opportunities for students to engage with professional researchers and other community members through authentic science practices (Bautista-Puig et al., 2019). *Citizen science* is a viable instructional strategy for engaging students in scientific argumentation and investigations, (Phillips et al., 2019). Nonetheless, we join others in calling for CitSci pedagogies to go beyond data collection to include students in all phases of knowledge generation (Morales-Doyle & Frausto, 2021), and taking action on data they and others collect (Harris et al., 2020). *Agrivoltaics* is a relatively new area of research that couples agriculture with solar energy production in order to grow food across more of the year, generate multi-uses of land to decrease social conflict, and conserve water. Early results suggest that agri-PV shows particular promise for desert climates, like the study setting. Thus, the agri-PV CitSci PD sought to prepare teachers to engage their students in investigative research at campus-based agri-PV sites through collecting, analyzing, interpreting, and sharing data with university researchers, and also with K-12 co-lab members across campus sites. With this long-term agenda in mind, teachers came together to learn about agri-PV, work in teams to design and test agri-PV CitSci tools and protocols, and co-develop CitSci curriculum. Through our PD design, the co-designers sought to promote teachers expansively framing their pedagogical practices in order to expansively frame youths' science engagement (Benichou, 2022). Specifically, we focused on fostering teachers' expansive framing of (a) community (b) learning goals, and (c) student roles, because these elements are required for successful enactment of the agri-PV CitSci program.

This study's design intervention built on Journey.do's ecological design to create online modules to structure individual and collective growth and support teachers' expansive framing of their practices relative to agri-PV CitSci. Each Journey.do module has a 4-phase engagement cycle: 1) Connect, 2) Grow, 3) Apply, and 4) Inspire. When teachers begin a module, they view the rationale and learning goals for the module, set by the program designers. In the Connect phase, teachers read stories by members who have already completed the module, written in response to a prompt that asks them to reflect on their current practice or to envision enactment of the module concepts in their future practices. The member just starting the module responds (i.e. "connects") to stories with emojis or comments. Responses to stories give participants a chance to support each other and use each other as resources when envisioning their own practices. In the Grow phase, members encounter the module's informational content that invites them to become authorities on the module concepts, expanding and deepening their disciplinary and pedagogical content knowledge. Subsequently, participants move to the Apply phase where they write their own story posts. Through storytelling, participants enlist their experiences, beliefs, and hopes as resources to develop expanded visions of what their practice might become. The prompts promote links between (a) past, current, and future practice, (b) partnerships in and out of classrooms, and (c) goals for students as learners and as contributors. In the final phase, Inspire, participants submit their story for publication; others can create a thread of responses.

Data collection and analysis

Teachers were asked to complete 8 1-to-2-hour Journey.do modules in total, 4 before and 4 during the six-week PD. Altogether, the teachers shared 44 story posts averaging 230 words each and generated 144 responses.

Analysis for this study was limited to the story posts. Qualitative analysis entailed iterative rounds of deductive and inductive processes. Grounded in our belief that consequential and connected learning requires expansive views of *community*, *learning goals*, and *student roles* (Jordan et al., 2021), three researchers first worked independently to deductively pre-coded the stories for description of these concepts (Ravitch & Carl, 2019), followed by collective negotiation. We then honed our understanding of these three concepts within the context by inductively identifying sub-themes within the data (e.g., community within school, community beyond school, student contributions), looking across the coded data within and across posts, to collectively characterize distinct orientations toward community, goals, and roles. Viewing each teacher's collection of coded data through the lens of expansive framing (Engle et al., 2012), and comparing across teachers, we determined that there was a spectrum of framing along which some teachers viewed their practice more expansively than others. We clustered the teachers in 2 groups: 5 initially viewed their practices related to community, goals, and roles more narrowly, 4 viewed their practice more expansively, with an understanding of community extending beyond the classroom, goals for learning expanding past content mastery, and vision of student roles as agentive contributors. We then compared each teacher's stories of current practices with their stories of projected practices to interpret shifts in how they expansively framed. We limit reporting of findings to 6 focal teachers who contributed the highest number of posts: 3 from the "narrow" and 3 from the "expansive" clusters.

Findings

In each of the 6 focal teachers' posts, we saw more expansive framing of at least one aspect of their practice. Teachers varied in the extent to which the practices were expanded as well as in which of the 3 areas were expanded. In the cluster of those who initially expansively framed their practices, teachers continued to expand and deepen their visions of what could be, with concrete ideas for steps they would take. Those whose initial practices were more narrowly framed connected new concepts with their current practices, but also expanded in ways that suggested qualitatively different orientations to community, learning goals, and student roles.

Among the three teachers whose practices were initially less expansive, one teacher's shift was especially noteworthy. Sam began the program confident in their pedagogical approaches, which they described as "innovative, research-based instructional methods." However, their view of community was limited to students in the classroom as they participated in the "collaborative spirit of science." Sam's during-summer stories maintained a value on collaboration, but also expanded to propose partnerships with community members outside of their school. For instance, they wrote about a potential partner at an organic farm, saying, "we can enter into a reciprocal relationship" leading to the "creation of a generation of young people who can, through their own work, proliferate the core principles upon which [the owner] herself operates." Building on their current idea of students working toward common goals, Sam envisioned a community expanded by the inclusion of experts where learning and contributing are reciprocal, and relationships over time push shared goals towards fruition not just for a school year, but across generations.

Another teacher, Penny, whose view of community, goals, and roles were relatively narrow in earlier entries, showed expansion of student roles. In describing her prior work with the school garden, Penny described her students as "helpers." After learning about citizen science on the platform, Penny showed a view of students as contributors to scientific endeavors: "We are *all* researchers and can benefit science." Penny wrote that she was inspired by student-created art in one of the other teachers' gardens to solicit student art for her school's garden. While the shift is subtle, we see that through interactions with other teachers and new concepts encountered on the platform, she began to expand roles for students beyond helpers to partners with their own voices. In her existing practice, a third teacher, Liz, positioned students as contributors to the class's learning through conversations about phenomena she chose for the class to study. Her prospection of the garden expanded on agency in student roles, envisioning art students collaborating with physics students to design a fountain and describing students as having "options for what is grown and what questions are asked."

In the cluster of teachers whose practices already expansively framed community, goals, and roles, two teachers envisioned even more community connections and listed concrete ways their students could become more consequentially connected with community members and scientific projects. Val already had 2 years of experience working with agri-PV geared toward consequential and connected learning. Her projective stories intermingled plans for changes to the school gardens, with ideas for a year of garden-based community interactions in which students led tours, shared produce, and forged relationships with other organizations. Like Val, Mark's practice already positioned students as agentive contributors to a community beyond the classroom. His current stories focused on student belonging and identity as science caretakers of the school's gardens. His projective stories envisioned possibilities for his students to go beyond being science learners to being citizen scientists doing "real research", starting with the agri-PV beds and then to "scale up" to a project benefiting butterfly migration. A third teacher in the more expansive cluster expanded her view of what it meant for students to be climate action advocates. Bella told current stories of students creating ways to raise their schools' awareness about endangered species. After a PD module about justice in STEM, her prospection expanded student influence to the surrounding community and to complex issues of inequitable access to green technologies. For these 3 teachers, expansive framing of practice in relation to community, learning goals, and student roles was not new, but their stories revealed a strengthening and further expansion of pedagogies.

Discussion

By designing invitations to connect current practices with envisioned ones, online modules can support teachers in framing their practice more expansively whether they are strengthening already expansive views on community, goals, and roles or moving from narrow perspectives. Future research will explore if and how enactment of innovative pedagogies is supported through continued opportunities to share reflective and projective stories of practice as teachers attempt to enact their envisioned agri-PV CitSci pedagogies. Ongoing study of the agri-PV CitSci network and Journey.do will look at future cohorts as well as follow teachers and their online interactions into their school year implementation to learn more about the ways networked communities on learning platforms can support connected and consequential STEM pedagogies.

Preparing Students for a "Post-Truth" World: The Epistemic Unfriendliness of Science Curricula

Clark A. Chinn, Hera Kalu-Mamji, Brydie Boyle
clark.chinn@gse.rutgers.edu, hkalu@scarletmail.rutgers.edu, bab341@scarletmail.rutgers.edu
Rutgers University, New Brunswick, NJ

Abstract: The contemporary information society is "epistemically unfriendly"—that is, it is rife with often confusing, conflicting information that varies dramatically in quality. To prepare students for the epistemic unfriendliness of the contemporary world, it is vital that students be exposed to some of this unfriendliness in school so that they can learn to cope with it. But to what extent do existing curricula expose students to epistemic unfriendliness (e.g., various kinds of poor evidence, various kinds of trustworthy sources, etc.)? Using the Grasp of Evidence framework to guide our analysis, we provide a preliminary analysis of the extent to which five selected researcher-developed science curricula expose students to epistemic unfriendliness. Our results to date indicate that students may get relatively few opportunities to engage with poor evidence and sources on the dimensions of evaluation, integration, and lay use of evidence.

Introduction

In the contemporary information society, people find themselves in an "unfriendly epistemic environment" (Chinn et al., 2021). By this, we mean that the information world is rife with confusing, conflicting information that varies dramatically in quality, yet it is difficult to determine which sources and information are trustworthy and which are not. In this world people often encounter evidence, but the evidence is frequently of low quality or cherry picked. To find out what is accurate, citizens need to become adept at negotiating this unfriendly epistemic environment. In contrast, schools typically present students with epistemically friendly, even sanitized environments (Chinn et al., 2021; Duncan et al., 2018). Evidence is typically simple and straightforward. Exposure to biased or inexpert sources can be rare, and controversies are often avoided (Hess, 2009). In such environments, students will have little chance to learn how to deal with poor evidence, weak arguments, misleading sources, and other unfriendly features of the so-called "post-truth" world. An overly friendly epistemic environment will not prepare students to distinguish between accurate information and misinformation, good and poor evidence, sufficient and insufficient evidence, and trustworthy and untrustworthy sources. It is vital for students to be exposed to some of these unfriendly elements in school so that they can learn to cope with them.

Goals and theoretical framework

This project appraises the extent to which selected science curricula incorporate features of epistemic unfriendliness. We have chosen to focus on science curricula because many of the issues that citizens encounter in the digital world (e.g., COVID-19, the safety and efficacy of vaccines, climate change) are scientific issues and require that people come to grips with scientific evidence and scientific sources of information. Accordingly, the eventual goals of this overall project are to examine a wide range of science curricula to see how well they prepare students to grapple with the epistemic unfriendliness of the digital world related to scientific issues—that is, to what extent these curricula incorporate elements of poor scientific evidence and trustworthy scientific sources so that students learn to deal with them. Which forms of unfriendliness are and are not incorporated?

How can we conceptualize curricula in order to analyze how "epistemically unfriendly" they are? The Grasp of Evidence (GoE) framework developed by Duncan et al. (2018) provides a useful tool for this analysis. In this section, we provide a brief overview of the GoE framework, noting how it can be applied to analyze the degree to which learning environments incorporate various dimensions of unfriendliness. In the remainder of the paper, we will report on our work to date to apply this framework to analyze science curricula.

The GoE framework is grounded in Ford's (2008) notion of *grasp of practice*, which conceives scientific practice as encompassing both construction and critique of scientific knowledge. A grasp of practice involves both the ability to engage in the practice and to reflect on it metacognitively. The GoE Framework (Duncan et al., 2018) applies these notions to practices of evidential reasoning. They posit that there are five dimensions involved in reasoning about evidence. We use four of their dimensions as most relevant to our analysis:

- *Evidence evaluation* involves examining the methodological qualities of the procedures used to generate scientific evidence. This can involve identifying methodological strengths and weaknesses related to (a) what kind of comparisons are made (if any) and the extent to which these comparisons could be confounded, (b) issues of sampling such as sample size and representativeness, (c) appropriateness of data collection procedures, (d) the validity and reliability of measures, and (e) the appropriateness of the generalizations made. A curriculum that prepares students for features of epistemic unfriendliness encountered out of school will expose students to evidence that is poor (as well as good) along these various dimensions.

- *Evidence interpretation* involves appraising the strength of evidence in supporting and contradicting various alternative explanations. Evidence interpretation includes consideration of issues such as (a) the relevance of the evidence, (b) how comprehensively the evidence supports the model, (c) the directness of the support, and (d) whether evidence can be used to confidently rule out certain explanations. In epistemically unfriendly environments, students should encounter evidence that is strong and weak along these various sub-dimensions.
- *Evidence integration* moves beyond one or a few pieces of evidence and considers the role of larger bodies of evidence. In many situations, scientists make judgments based on large bodies of evidence, not just one or a few studies only. Yet students may seldom be exposed to syntheses of research (reviews, meta-analyses, etc.) as opposed to single studies. Larger bodies of evidence can vary from highly consistent (e.g., evidence on climate change) to highly unsettled (e.g., evidence on many issues in the early days of the COVID-19 pandemic). Scientists consider whether discrepancies can be resolved through identifying critical differences among studies (e.g., differences in procedures, study quality, etc.). It may be valuable to weigh whether there are different lines of evidence available. Science curricula should expose students to the challenges of reasoning about these larger bodies of evidence, not just one or a few pieces of evidence.
- *Lay use of evidence* takes account of the fact that proper appraisal of scientific evidence often requires a great deal of disciplinary expertise. Laypeople cannot be expected to have the rich disciplinary knowledge of experts (Osborne & Pimentel, in press). With bounded disciplinary knowledge, people must often defer to experts who have the detailed technical knowledge to make sense of evidence in a field (Bromme & Goldman, 2014). This means that science students need to learn to consider which sources to trust, and how to identify good and bad sources like those in the real world. In order to appreciate a wide range of criteria for determining source trustworthiness (e.g., expertise, bias, benevolence, integrity, track record), they need to be exposed to sources that violate these criteria as well as sources that meet them (Chinn et al., 2021). Students should consider how certain practices of venues such as editing, fact checking, and peer review can influence trustworthiness. They should grapple with challenges of identifying and weighing the degree of expert consensus on topics of interest.

This brief overview highlights the various ways in which the GoE framework can serve as a guide to examining dimensions of epistemic unfriendliness. Next, we describe our method for analyzing curricula, and we present our first efforts to apply this framework in an analysis of five inquiry curricula in science.

Method

Guided by the GoE framework, we developed a coding scheme to code curricula according to whether they had students consider unfriendly facets of evidence. Coded facets within each of the four dimensions captured the facets summarized in the previous section, along with additional facets laid out in the full GoE framework (Duncan et al., 2018). Table 1 presents a selection of these categories. (We have chosen a subset of all categories to present in this paper due to space limitations. Our full analysis contains additional categories, most of which encoded facets of unfriendliness that did not appear in any of the analyzed curricula.)

As a first step in assaying our coding scheme, we selected five researcher-developed curricula to analyze. We chose to analyze influential contemporary science curricula developed by researchers because these seemed to be the curricula most likely to present a wide range of complex challenges to students. The analyzed curricula were substantive lessons/units spanning at least multiple weeks. Our plan in the full project is code over 30 curricula; the choice of these five to begin with was arbitrary. In this preliminary analysis, we analyzed these curricula: (1) BioGraph (Yoon, 2022). We examined 5 lessons on biological systems for high school students. (2) IQWST (Investigating and Questioning Our World Through Science and Technology). We chose 11 lessons on heredity and natural selection (Krajcik et al., 2013). (3) PRACCIS (Promoting Conceptual Change and Reasoning in Science) (Rinehart et al., 2016). We chose a unit on cell organelles to analyze from this model-based inquiry curricula for middle-school students. (4) PUM (Physics Union Mathematics), an ISLE (Investigative Science Learning Environmental) based physics curriculum for high school (Etkina et al., 2021). We selected the Physics II dynamics unit. (5) WISE (Web-based Integrated Science Environment) (e.g., Linn & Eylon, 2011). Current online WISE curricula include many units across all grade levels; we focused on a set of chemistry units for middle school.

For each curriculum, we obtained online or published materials detailing the analyzed units. We used these as the basis for coding the curricula, augmented by reading published articles and chapters describing the units and their use. We acknowledge that coding other units might yield different results, and in ongoing work, we will analyze additional units for each selected curriculum. We developed codes through extended discussions among the authors, achieving concordant objectivity through iterative cycles of joint deliberation (Douglas, 2009).

Table 1

Percent of the five selected curricula (for selected lessons) that incorporated each category of unfriendliness for students to consider when making judgments (cognitive engagement) and reflecting (metacognitive engagement)

GoE Dimension	Category	Brief explanation	Cognitive	Metacognitive
Evidence Evaluation	Comparisons and confounds	Students weigh possible confounds between conditions that could impact conclusions or consider the presence or absence of comparisons when drawing conclusions.	20%	0%
	Sampling	Students weigh challenges of considering smaller or larger samples and/or the representativeness of samples when making judgments.	20%	0%
	Measures	Students consider the validity and/or reliability of lower as well as higher quality measures.	20%	0%
	Generali-zation	Students consider whether over- or under-generalizations to findings have been made when developing models or explanations.	0%	0%
Evidence Interpretation	Contrary evidence	Contrary or anomalous evidence are considered to rule out an explanation or drive revision of an inadequate explanation.	80%	60%
	Strength of evidence	Students weigh stronger or weaker evidence along subdimensions such as the degree to which evidence is diagnostic, direct, and/or comprehensive.	20%	20%
	Effect sizes or degree of fit	Students weigh evidence that varies in effect sizes (e.g., considering how to interpret studies with small effect sizes versus large effect sizes)	0%	0%
Evidence Integration	Quantity of evidence	Full bodies of evidence are considered (not just one or a few selected studies) to reach conclusions.	0%	0%
	Reconciling discrepant evidence	Students reconcile conflicting bodies of evidence along dimensions such as evidence quality, evidence strength, and evidence details.	20%	0%
	Synthesis reports	Students weigh reviews of evidence (e.g., meta-analyses and other reviews), not one or a few individual studies.	0%	0%
	Lines of evidence	Students consider how more versus fewer lines of evidence bear on conclusions.	20%	0%
Lay use of evidence	Source trustworthiness	Students consider source trustworthiness when making decisions and grapple with sources that vary in quality.	20%	0%
	Source criteria	Students use criteria such as expertise, bias, integrity, etc., to evaluate poor as well as good sources.	20%	0%
	Consensus	Students encounter variation in the extent of expert consensus on issues and must weigh this in their conclusions.	0%	0%

When coding the curricula, we assigned two codes for each category (i.e., two codes for each row in Table 1). To begin the process, we perused the set of lessons for each curriculum to scrutinize the range of evidence and sources that students worked with across all the student tasks. We next scored the level of cognitive engagement with each category. This referred to whether students needed to consider better and worse evidence or better and worse sources (as relevant to the category) and to use this information to reach conclusions at least one time within the analyzed set of lessons. If so, the unit received a score of 1; if not, a score of 0. For example, in the category *sampling* within the evidence evaluation dimension, we scored a 1 if students encountered too-small as well as good sample sizes, or unrepresentative as well as representative samples, and needed to consider these issues when developing models or reaching conclusions. Second, we coded at the *metacognitive* level. Curricula were assigned a 1 if students reflected metacognitively on the corresponding feature of unfriendliness at least one time in the analyzed set of lessons. Otherwise, curricula were assigned a 0. For example, in the sampling category, curricula were assigned a 1 if students were prompted to explicitly reflect on and discuss sample size or sample representativeness and the problems posed by too-small or unrepresentative samples. If there was no explicit discussion or reflection on sample size or representativeness, curricula were assigned a 0.

Results

Table 1 summarizes results for selected coding categories with a brief description of the meaning of each category. We report the proportion of curricula that scored positively for each category. The main findings are: (1) Cognitive engagement with epistemic unfriendliness in the analyzed categories was, overall, rare in these units. (2) Evidence interpretation was the dimension that most often incorporated epistemically unfriendly features, but only in presenting students with contrary or anomalous evidence that students needed to use to revise explanations or to rule them out. (3) There were fewer opportunities for students to grapple with the integration and lay dimensions. Students seldom needed to consider more than a few pieces of evidence, and they seldom considered sources at all, let alone poor sources. (4) Most evidence presented was to be considered as methodologically good by students; discussions of evidence quality were not common. (5) Even when cognitive engagement with epistemically unfriendly features was present, metacognitive engagement was usually absent.

Percentages indicate the number of curricula that scored a 1 for the analyzed sequence of lessons, divided by 5 (the number of curricula scored).

Discussion

This paper has reported on the first steps of a project to analyze researcher-developed science curricula according to how effectively they expose students to the various categories of epistemic unfriendliness found in the contemporary information society. We have demonstrated the viability of using the GoE framework to perform these analyses. This report is, of course, only an initial foray into affordances of research-based science curricula. Further analyses will enrich our findings and, no doubt, identify additional curricula that take interesting approaches to introducing various categories of epistemic unfriendliness to curricula.

Our preliminary findings suggest that curricula should do more to introduce various categories of epistemic unfriendliness to science classrooms. In the units analyzed, students had few opportunities to engage with the kinds of epistemic unfriendliness that they encounter in the digital world out of school, particularly with respect to evidence evaluation, evidence integration, and lay use of evidence. There were even fewer opportunities to discuss these challenges metacognitively, despite the value of metacognitive discussion for supporting productive cognitive engagement (Barzilai & Zohar, 2014). We encourage developers of curricula to incorporate opportunities for students to reason about poor and weak evidence, insufficient evidence, and less trustworthy sources and to reflect metacognitively on these reasoning challenges. We also encourage activities that engage students in metacognitive reflections of evidence and sources of varying quality.

Humanizing College Student Success: The Role of Brave Space, Validation, and Social-Emotional Competencies

Abstract: Higher education inequities are caused by multiple factors within and beyond the classroom; yet, notions of college student success beyond course grades in formal classes are understudied. Using a sociocultural framework called the zone of proximal self, the purpose of this study is to deepen understanding of how to advance equity in informal learning settings such as counseling and advising spaces. This paper presents three forms of effective equity-oriented and relational practices, drawing from two contrasting student cases from a study of 50 students at a public four-year U.S. institution. The cases highlight how counselors' creation of a brave space, validation, and support for social-emotional competencies can enhance students' pathways towards their possible selves in humanizing, relational ways. These findings illuminate how the ZPS framework can offer broader ways to examine college student success by including students' personal and professional achievements across formal and informal learning environments.

Introduction

When discussing challenges with persistence and retention in higher education, there exists a greater need to theorize the complex relational dimensions that support how students adapt and thrive. There are multiple factors that may contribute to a holistic understanding of declining performance, persistence, and retention rates within and beyond classrooms, such as students' lack of clear future goals, a sense of uncertainty, and poor integration with the college community (Sithole et al., 2017). Frameworks in the learning sciences such as the learning humanities framework have shown the importance of equity-oriented relational practices for students' persistence in STEM through mentorship (Herrenkohl et al., 2019). Equity-oriented interactions in mentorship, counseling, and advising settings are critical in supporting students' holistic navigation of higher education, but are understudied or traditionally measured in terms of academic metrics such as GPA (Swecker, Fifolt, & Searby, 2013). Therefore, this study reimagines college student success through a framework called the zone of proximal self, which foregrounds relational practices in supporting student's learning across formal and informal spaces.

The zone of proximal self framework

The zone of proximal self (ZPS) offers a framework to examine college student success through relational practices that can improve students' pathways towards their personal, professional, and academic goals. ZPS is the distance between a learner's current and possible selves that can be bridged with the support of individuals and resources. ZPS extends Vygotsky's (1978) zone of proximal development from a focus on children's academic problem-solving to considering college students' pursuit of their possible selves (i.e., the imagined selves they want to become and feared selves they are afraid of becoming) across a wide learning ecology (Markus & Nurius, 1986; Barron, 2006). By using the ZPS framework to examine sociocultural practices within settings such as counseling and advising, this study contributes to nuanced understandings of college student learning and development as a cultural process (Rogoff, 1995; Nasir et al., 2006).

Methods

This paper reports a qualitative case study designed to define equity-oriented, relational practices within ZPS for college students from first-generation, low-income, and minoritized (FLM) backgrounds. Therefore, this paper addresses the following research question: What practices from advisors and counselors do students from FLM backgrounds describe as supporting their college success? To answer this question, this study employs Merriam's (2002) case study methods by being 1) particularistic with student-counselor interactions, 2) descriptive with student examples, and 3) heuristic with dimensions of effective practices.

The study includes 50 undergraduate students from a large public university on the US West Coast. A majority of the participants were first-generation (74%), women (74%), and Latinx/Chicanx (52%). Students were recruited from federally-funded TRIO programs such as the Educational Opportunity Program (EOP) and the

Student Support Services (SSS) Program. Students met virtually with a counselor, advisor, or mentor figure at pre-, mid-, and post-semester time points over 14 weeks in spring of 2021. Students completed three diary entries, three surveys, and one post-interview. Professional and personal goals were assessed in an open-ended question of “What are your [professional/ personal] goals?” followed by a 1-7 Likert-scale response item. This study focuses on two students for the case analysis. The interviews were qualitatively coded using a mix of deductive and inductive coding via the Dedoose software. For internal validity and reliability, the study triangulates data from interviews with diary entries and survey data. Thick descriptions of cases are provided for external validity.

Findings

Equity-oriented and relational counselor practices

The creation of a brave space, validation, and support for social-emotional competencies emerged during thematic coding as the main categories of equity-oriented and relational practices. The creation of a **brave space** category includes practices such as *sharing experiences* and *vulnerability*, *creating a welcoming environment*, *understanding a person holistically*, *relating personal experiences*, *establishing a working partnership*, and *expressing low and high arousal positive emotions*. The second category of **validation** includes practices of *validating strengths and continuous growth, validating negative emotions and experiences*, and *validating decision-making processes*. The third category of **social-emotional competencies** includes practices of *encouraging self-awareness, promoting self-management, and advancing relationship skills.*

Contrasting cases of brave space, validation, and social-emotional competencies

Using identical surveys, we measured students’ change scores from pre- to post-study on their personal and professional goals. We examined their change scores for these goals to examine their progression towards their possible selves. One student from each of the low- and high-progression categories were selected as a pair of contrasting cases, August Mohammed and Celeste Rodriguez. August reported low progression in professional, personal, and academic goals from the beginning to end of the study, while Celeste showed the opposite, a high progression in all her goals over time.

Low progression towards goals in the zone of proximal self: August Mohammed

August Mohammed’s story reveals a tale of a low progression in the ZPS framework, in which he did not feel he was effectively supported by individuals and resources in his learning ecology. August identifies as a man and comes from a mixed-race background that is “mixed Brown, White, and Black.” Coming to the university at a young age, August was 18 years old at the time of the interview and was a fourth-year student in college. For this study, August met with a college advisor for all of his meeting sessions.

Lack of a Brave Space and Vulnerability. During his interview, August described the practices he wished his college advisor engaged in with him during their meeting sessions. In particular, August felt a need for his college advisor to be more transparent, direct, and honest with him. When asked about the importance of this directness, August explained:

> … if the [college advisor] can honestly speak their mind about what they've seen in the past or their feelings or something that they've experienced in a very direct way, that can give a lot of clarity rather than having to dance around an issue and not wanting to express what they think.

August did not feel that his college advisor was honest with him or provided relevant knowledge for his life goals. In other words, he did not feel that the counselor *shared experiences or embraced vulnerability*, which were important practices for creating a brave space. August’s experience with his college advisor resulted in him feeling a sense of depersonalization, in which he stated that, “If you talk to [a college] advisor, even for an entire year, they don't actually know you…They know what you tell them and not necessarily how you feel about something. They might have their own inherent biases.” August’s words reveal that a brave space was not created during the session, since he felt that no matter how many times he met with his advisor, they would never really know who he was, and they judged his goals and his ideas for achieving them.

Lack of Validation in Decision-making. Additionally, August felt that his college advisor did not understand how his backgrounds and interests led to his aspirational goals. In his interview, August began to talk about his college advisor and then generalized to academic advisors broadly on campus:

> It's hard to go to any academic advisor and explain a more nuanced issue to them. Even though a lot of students have a lot of the same problems, if you have a different outlook on life or a

> different background or personal feelings towards something or aspirations, again, it's harder for them to understand why you want to do something differently.

In other words, August did not sense that his college advisor was *validating his decision-making processes*, especially as they related to his personal interests and background. Instead, he felt that his college advisor, as mentioned previously, held certain biases against the decisions he was making.

Lack of Support for Social-emotional Competencies. Finally, August did not describe his college advisor providing support for strengthening his social-emotional competencies. On the other hand, he wished that his advisor was able to work on something more concrete with him during the session to help him navigate his various interests in the future. In his first diary entry, August wrote: “I’m trying to figure out my life and my plan. I’m kinda lost.” In his interview, August shared wanting strategies and support from his advisor:

> I think a concrete plan would reflect coming up... having a solution for not knowing what I want to do, specifically in tone with me. Figuring out specific avenues that I can approach in order to either figure out what I want to do that might fit all my needs rather than just saying, ‘You'll figure it out. It'll take some time, or you can try to look at different fields’

As shown in the quote above, August felt frustrated with the lack of support and organizational brokering from his advisor. Taken together, a traditional approach to examining August’s success, or lack thereof, may focus on the decline in his academic performance throughout the semester. However, a ZPS lens draws attention to the conditions that he experienced, including counseling and advising practices that did not address his needs.

High progression towards goals in the zone of proximal self: Celeste Rodriguez

In contrast to August, Celeste Rodriguez’s narrative highlights a high progression in ZPS that was created by her counselor despite the challenges she faced. Celeste identifies as a woman and comes from a Latinx cultural background. She is the first in her family to go to college. For her first meeting session, Celeste met with a college advisor, but Celeste also met with EOP counselors for her second and third meeting.

Presence of a Brave Space. In her interview, Celeste provided detail on how an EOP counselor was able to enact a brave space during their meeting sessions through relational practices that contributed to creating *a welcoming environment* and *understanding her holistically as a person*. In her own words, Celeste revealed:

> It's always like, ‘Oh, hi, how are you?’ and very genuine and very kind, which is something that's really important to me because I think that a lot of my questions have to do with not just about myself, but also about my family, because I don't do anything without, I wouldn't say without my family, but without thinking about my family. And so I think family is such a huge, important part of me. Like I said, my uncle went to jail and my mom had COVID, and other things. And I think these are important factors for people to understand why I'm choosing to go in a specific way.

In her explanation of how her EOP counselor created a welcoming environment, Celeste highlighted consideration of her learning needs, family, and home context when understanding her motivations for her future goals.

Validating Decision-making. In a similar vein to understanding Celeste’s family and cultural background, Celeste described how her counselor manifested validation through *validating her decision-making* processes related to her family. In her diary entries, Celeste wrote: “She always listens to my entire story so she can give advice before cutting me off, she asks if something sounds good and if not she offers other options.” When probed about this entry in the interview, Celeste shared how the counselor explicitly listened to her interest and needs and validated the decisions that she felt were important for her future goals:

> I feel like sometimes when I go ask for an advisor I need help, as soon as I start talking and someone recognizes a problem, they want to offer advice. But sometimes that doesn't even seem like a problem to me. I remember going to [an advisor] one time and saying that I wanted to decrease my units because my uncle had gone to jail and they said something along the lines of, ‘Oh, well you already made it into [this college]. The best way for you to take care of your family is to take care of yourself first.’ And I understand, and I get where they're coming from, but that's not the issue that I needed help with. And so I appreciate that [this EOP counselor] listens to what I have to say before giving me advice on problems that she thinks are the problems.

In her description of her interaction with the EOP counselor, Celeste highlighted how the counselor validated what she perceived are problems in her life. Most importantly, the counselor's validation came from a place of active listening and understanding of Celeste as a person, which are actions that August did not perceive in his interactions with a college advisor.

Practices for Supporting Social-emotional Competencies. Focusing again on the same EOP counselor, Celeste further mentioned how the counselor was able to support her social-emotional competencies related to relationship skills for her professional career. Specifically, Celeste described her counselor as a broker:

> So, well, first she gave me [a career counselor]'s email and it was pretty easy to schedule a meeting with [the career counselor], but also she told me about the work that they do, and some of the questions I can ask, which I think is really helpful because sometimes I know I need the help, but I don't know what to ask because I don't even know where to start. […] I have really good experience in my field, but some of my work experience started when I was in high school and I was doing retail jobs and stuff like that. So [the counselor] also said that I should ask [the career counselor] some of the questions on how I can implement that.

As Celeste's quote foregrounds, the counselor not only helped Celeste make the connection with a career counselor, but also supported her in making this connection by describing how to interact with the career counselor. Moreover, her counselor recognized the wealth of experiences Celeste gained in high school and encouraged her to leverage her strengths in future meetings with the career counselor. This support and advice are in contrast to the experiences that August faced in interactions with college advisors, where he felt that his experiences were looked down upon or disconnected from his future possibilities. In sum, traditional approaches might capture how Celeste was able to achieve her academic goals in college and persist at the institution. However, a ZPS lens provides greater understanding into how Celeste's counselors acted as organizational brokers to support her social-emotional competency of *relationship skills* and cultivating a network of support.

Discussion and conclusion

This paper offers a ZPS framework highlighting three equity-oriented, relational practices that institutional figures can use to support college student success in humanizing ways that recognize their academic, social, emotional, and basic needs. Themes across student interviews and in-depth contrasting cases further provide practical significance into supporting a brave space, validation, and social-emotional competencies. Moving forward, there is an opportunity for future research to 1) broaden measures of college student success and 2) work in partnership with institutional figures to examine how relational practices impact students' pathways and possible selves. The hope of this paper is to reframe college student success holistically as an act of humanization to increase equity.

A Temporal Toolkit for Analyzing Agency in Open-Ended Work

Kimberly Sheridan, George Mason University, ksherida@gmu.edu
Xiaorong Zhang, George Mason University, xzhang31@gmu.edu

Abstract: Open-ended work provides opportunities for learner agency. We pose a temporal toolkit for analyzing how learners express their agency and for how others support this agency. Drawing on Emirbayer & Mische (1998) conception of agency as temporally embedded, we track how learners' decisions and actions in the present, are informed by habitual past resources, and projective futures. Using examples from two domains (a theater improvisation exercise and a parent-child circuit design project) we apply temporal dimensions, processes and linguistic markers to provide analytic description on how agency is expressed and supported.

Introduction

Agentive action in the world involves a kind of time travel: to make decisions and execute actions in any *present* moment, we continually revisit our *habitual past* selectively attending to recognize relevant types of experiences, knowledge and resources to inform our actions, and imagining and improvising to select possible *futures* to move towards. Emirbayer & Mische (1998) argue that this temporal embeddedness is the characteristic feature of human agency.

In many educational situations, students' agency is highly constrained. Relevant past resources are provided and future goals are identified. Teachers seeking to support students' agency within these constraints may offer choices, encourage students to find personal connections and interests to the identified problem, and provide explanations about their decisions (Stroet et al., 2013). However, in open-ended work, such as in art and design, students often have latitude in finding a problem to work on, choosing how to approach it, and revising throughout the process (Gravel & Svihla, 2021; Sawyer, 2018; Sheridan et al., 2022,). To do so, they mine relevant past experiences, knowledge and resources and recombine possibilities for future directions.

We outline a temporal framework and methodological tools for qualitative analysis of agency in open-ended creative work. Prior analyses suggest the temporal frame gives insight into teacher scaffolding of learner agency in visual arts (Sheridan et al., 2022). We build on this work through analytic description of examples in two additional open-ended learning areas, a theater improvisational exercise and a parent-child design project to consider how these tools can provide insight into how and when learners are operating agentively and how dimensions of agency are scaffolded in diverse learning situations.

Temporal toolkit for studying agency

We draw on Emirbayer & Mische's (1998) theoretical frame of agency as inherently temporally embedded. As we make decisions and take actions in the present, we are informed by our habitual *past*, yet also oriented toward the future to imagine alternatives (p. 963). Emirbayer's & Mische suggest each temporal dimension involves sub-processes that reflect how agency is expressed (Table 1).

Table 1
Temporal dimensions of agency and sub-processes in Emirbayer & Mische's 1998 framework.

	Habitual Past	Practical-Evaluative Present	Future Projective
Processes	Selective attention Recognition of type	Problem Characterization Decision-making Execution	Symbolic recombination Narrative construction

To draw on habitual past resources, we employ *selective attention* to identify relevant aspects of prior experiences and *recognition of types* to identify "typical patterns of experience" from our past (p. 979). The projective future employs the sub-processes of *symbolic recombination*-- using existing resources in new ways-- and *narrative construction*, creating stories and making meaning about possible futures. Both the habitual past and the projective future inform how we *characterize problems* in the present, make *decisions* on how to proceed, and *execute actions* as part of present practical-evaluative agency.

Tracking temporality of agency

These temporal dimensions (habitual past, practical-evaluative present and projective future) can serve as an organizing structure for qualitative data analysis. In what follows, we apply the temporal frame to a theater improvisation exercise and then to a family co-design activity to illustrate how agency is enacted, distributed and supported in a given activity. We then discuss how functional linguistic markers can aid in analysis.

Temporal dimensions of agency in theater improvisation exercise

For improvised scenes in theatre classes, students are provided initial constraints within which they are encouraged to experiment and explore. Teachers scaffold this process, emphasizing more generalized concepts such as how to quickly establish a setting or scenario, how to elaborate on another's contribution, and how to explore and experiment to find dramatic and comedic potential in a scene as it evolves. A temporal lens on agency helps us understand how and when students express their agency in this open-ended problem, and how teachers strategically support dimensions of student agency.

In Table 2, we track temporal dimensions of agency in a group improvisational exercise. When high school students were prompted to improvise a cafeteria scene, they responded by carrying imaginary cafeteria trays, walking and talking as a group about their classes, imagining seeing new characters to gossip about, each responding dynamically to new concepts others introduced. The teacher paused their activity, saying, "You cannot enter the cafeteria with your tray. You have to like *establish your space*, so use your imagination!" In their next iteration, the students show a more elaborated sense of setting: they walk in, obtain imaginary cafeteria trays, go in the food line. One student then takes on the role of cafeteria worker, creating new possibilities for interactions.

Table 2

Temporal embeddedness of agency an improvisational theatre exercise

	Habitual Past	Present Practical Evaluative	Future Projective
Students initial response to prompt	Draw on memories of cafeterias, improv concepts	Decide to use imaginary props (trays, shared table), move in a group to a table,	Imagine new possibilities in response to each other (e.g. gossip about imagined characters).
Teacher scaffold	Prompts for nuance "You cannot enter a cafeteria with your tray," reminds of concept "establish your space"		
Student revisit prompt	Draw on more specific processes in cafeteria (how you enter, obtain trays and food, varied roles)	Student actions establish the space of a cafeteria (e,g,entering the cafeteria, going through line).	Students imagine possibilities for diverse roles and interactions (e.g., student becomes cafeteria worker)

This analytic description suggests students express broad agency across all three temporal dimensions in both iterations. They drew on relevant *habitual past* resources from their memories of cafeterias and their knowledge of improvisational techniques (e.g., pantomime with imaginary props to signal space and action, introduce new ideas and characters to propel the story forward, elaborate on what others have contributed) to *characterize the problem* and make *decisions* in the present. Each also needed to continually re-imagine the *projected future* of where the scene was going based on the actions and contributions of others.

The teacher uses minimal scaffolding, but her brief interjection directs students to reconsider their broader set of *habitual past* resources of processes connected to cafeterias promoting *recognition of type* of the disciplinary concept of "establishing space." This informs students' *practical-evaluative present* of how they *characterize* the problem and make *decisions* and *actions*. This re-characterization invites new *narrative construction* and *symbolic recombination* of *projected futures* connected to diverse roles and settings in the cafeteria. Thus the teacher's intervention briefly supports *habitual past*, but students readily use that information to return to expressing agency independently across the three temporal modes.

Temporal dimensions of agency in a family making workshop

The dynamic iteration across temporal dimensions of agency is seen in other open-ended work. Here, we use the temporal frame to understand how agency is distributed and supported in a workshop facilitated by a maker educator, where a 7 year-old boy and his mother, after using circuit blocks to learn about how circuits work, are now co-designing and building their own circuit- powered creation (Table 3).

Table 3
Tracking temporal dimensions of agency in a family making workshop

	Habitual Past	Practical-Evaluative Present	Future Projective	General Encouragement
Child's initial response to prompt	Draws on prior knowledge of rockets. Uses skills from circuit activity.	Decides to make a rocket, draws plans, builds and assigns tasks to mother.	Imagines flight of rocket (e.g. "Let's go with 2 engines, the ceiling is not that high")	
Mother's response		Mother executes actions assigned by son (e.g. cutting thick materials)		"Oh it can fly? Oh my goodness, that's going to be good."
Child Stalls/Frustrated with project		Rocket unable to fly, characterizes problem: "It's too heavy to fly." Stops project, upset.		Mom sympathizes, acknowledges his disappointment.
Educator's prompts	Suggests habitual strategies (change outputs, materials as inspiration).	Agrees that motors are not powerful enough to fly.	Suggests alternatives (launch a propeller? make something new?)	
Child restarts project		Decides to build a flashlight with new materials. Then revisits his rocket project.	Invents new possibilities for "abandoned" rocket—a "tickler," a "bug distracter".	

In this family pair, the child strongly expresses agency across the temporal dimensions: he *decides* what they will build (a rocket), draws the plans, discussing prior knowledge of boosters and engines. He instructs his mom to *execute* specific actions such as cutting out parts according to his plans. Much of his mother's support focuses on following his directions and general encouragement—when her son says he's building a rocket that will fly she responds: "Oh it can fly? Oh my goodness that's going to be good." As he looks up, *projecting the future* flight of the rocket, he *decides* "Let's go with 2 engines, the ceiling is not that high." They build a model that resembles his plans, but after testing he *characterizes the problem* "It is too heavy to fly." He abandons the project, sadly tearing up paper into small pieces. His mom sympathizes, acknowledging his disappointment.

Noticing his frustration, the educator first supports his *present-practical evaluative* agency by agreeing with his *characterization*, subtly shifting focus by elaborating that these motors, rather than his design, weren't powerful enough for flight. She scaffolds the *projective future* dimension of agency by *symbolically recombining* alternatives on his existing design, asking "Maybe you can make something else fly or flutter from it?" He rejects this. She later draws on a more general principle, or *recognition of type* "I wonder if a way to make yourself less frustrated is to put all of this aside and think about a different output…one thing I do is I go look at my materials." Here, she draws on a *habitual past* strategy for responding to design setbacks. She points to a table with materials he could use to change the output and offers support for a new projective future: "Can you make something cool with lights?" He initially rejects all suggestions, but after a few minutes says, "Maybe I could make a …" and goes over to the materials and finds materials to quickly build what he first calls a flashlight, but then later says it is "another kind of rocket" that he's later going to add fins to. He then revisits his first rocket, *symbolically recombining* and *narratively constructing* new possibilities for it, such as calling it a "tickler" then touching his skin with the moving motor to test it. Later he says it is a “bug distractor” to keep insects away. The *projective future* seems an important dimension for sustaining and expressing his agency after frustration.

Tracking agency linguistically

Both temporality and agency are expressed through the content of speech, and in underlying grammatical structures (Konopasky & Sheridan, 2016; Sheridan et al., 2022). For instance, a study comparing two groups of students on a making task with circuits found that students who participated in an open-ended making task used more linguistic markers of agency—such as personal pronouns and material and mental verbs-- to describe their work than students who followed more structured instructions (Konopasky & Sheridan, 2015).

Grammatical forms can serve as indicators of the temporal dimension of agency, and thus support analytic description of temporal dimensions. For instance, the projective future is often expressed by a modal verb indicating possibility (e.g., could, may, might), with its sense of tentativeness further marked with “maybe.” (e.g., the child says “Maybe I could…” as he’s thinking of new designs). The present-practical evaluative may be framed in the present tense (“It’s too heavy to fly”) or marked by modals of obligation when characterizing the dimensions of the problem, (“You need to…”). Habitual past resources may be objects within these sentences, identifying resources to inform decisions and actions in the present, or to be recombined in the projective future.

Educator language also shows patterns in how they support agency—for instance, the theater teacher uses a modal of obligation “You have to-like-*establish your space.*” to re-characterize the problem, referencing a habitual past resource. Educators often soften their directions on open-ended tasks, often by posing advice as a question or mitigating it with a “maybe” when offering a projective future idea (e.g.,“Maybe you can make something else fly or flutter from it?”). Similarly, educators may highlight the learner’s agency by downplaying their own authority, giving directions from a personal perspective, (e.g., “I wonder…”, “one thing I do…”. These patterns mirror findings in studio arts class where teachers typically use language to highlight student agency, such as by posing their own advice as questions or from a personal point of view to consider rather than an instruction (Sheridan et al., 2022; see Konopasky & Sheridan, 2016 for a full account of linguistic markers of agency).

Conclusion

Understanding how agency and scaffolding of agency is temporally embedded allows us to see the past resources and potential futures individuals are drawing on to inform their present decisions and actions. These tools also allow us to examine how agency is distributed between learner and teacher or among collaborators, including tracking who poses relevant past resources, who recognizes relevant types, who characterizes the problem, makes decisions, takes actions, and who poses and interprets potential futures for the project. In open-ended work, tracking the temporality of this agency helps us understand the resources learners draw on, the possibilities they imagine, and how these shape their evolving characterization of the problem and their decisions and actions in the moment.

Preschoolers' Embodied and Shared Self-Regulation Through Computational Thinking

X. Christine Wang, Virginia J. Flood, Grace Yaxin Xing
wangxc@buffalo.edu, vflood@buffalo.edu, yaxinxin@buffalo.edu
Graduate School of Education, State University of New York at Buffalo, USA

Abstract: Despite shared characteristics and developmental significance of self-regulation (SR) and computational thinking (CT) in young children, existing research mainly focuses on the positive correlation between these two while neglecting the underlying processes of influence. To fill this gap, we examine how preschoolers are engaged in *embodied* and *socially-shared* SR through CT with a tangible programming toy in teacher-guided small groups. Through interaction analysis, we show how a teacher and preschoolers leverage embodied knowledge together and with a tangible programming toy to successfully engage in *focused attention* and *inhibitory control*, two key components of SR. Our findings challenge and expand the existent conceptualization of children's SR as individual and confined to the mind, and illustrate how embodied and collaborative CT activities in early childhood are generative occasions for SR.

Introduction

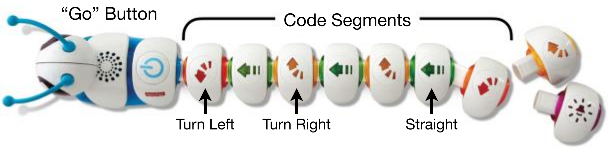
Self-Regulation (SR), the ability to regulate and control cognition/emotions/behaviors to achieve goals, entails basic executive functions (EFs) including working memory, focused attention, and inhibitory control as well as higher-level EFs including reasoning, problem-solving, and planning (Diamond, 2016). As a burgeoning area of practice and research in early childhood, computational thinking (CT) typically encompasses planning, critical thinking, and problem-solving skills (Bers et al., 2022). Both SR and CT are empirically proven to be positively related to young children's social adjustment and educational outcomes (Bers et al., 2022; Diamond, 2016). Given the positive association between CT and SR (e.g., Arfé et al., 2020; Di Lieto et al., 2017), it would be advantageous to co-develop SR and CT in early childhood. However, little is known about how *social, interactional processes* in CT activities can support young children's SR.

To address the gap, we examine how preschoolers engage in embodied and shared SR through CT with a programming toy in teacher-guided small groups by employing a *we-syntonicity* framework (Wang, et al., 2021). Papert (1980) defined *body syntonicity* as the identification and resonance between learning tools and learners' "sense and knowledge about their own bodies" (p. 63), while *ego syntonicity* is the identification and resonance between learning tools and learners' "sense of self as people with intentions, goals, desires, likes, and dislikes" (p. 63). The "we-relationship" proposed by the phenomenologist Schutz (1967), a reciprocal embodied experience of togetherness resulting from bodily co-presence and close attunement with others, extends our understanding of how body/ego syntonicity can be achieved *on a social plane, collectively as a group.* The group, as a collective, can form a shared understanding together – a *we-syntonicity* – based on ego and body syntonicity with the learning tool (e.g., a tangible programming toy).

Methods

Our study is part of a larger investigation examining young children's CT learning at a preschool in the US using a programming toy (Fisher-Price's Think and Learn Code-a-pillar, see Figure 1) whose body segments can be programmed for varied movements. Twenty-two children and two teachers participated in the study. Guided by teachers, children worked with the Code-a-pillar (named Rapunzel) in small groups once or twice a week (average 15 minutes per session) for over 12 weeks. All sessions were video recorded, creating a corpus of about 15 hours.

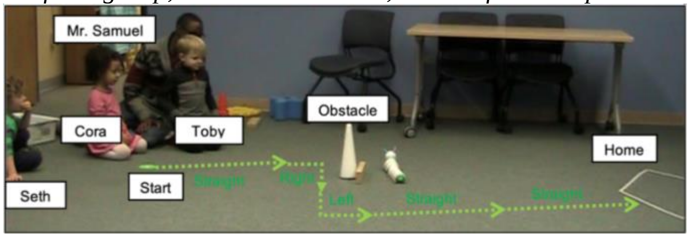
Figure 1
Code-a-pillar (named Rapunzel)



We conducted multimodal microanalyses of small groups navigating the "Obstacle Challenge" informed by Interaction Analysis (Jordan & Henderson, 1995). In each case, we examined how participants (including

Rapunzel) use multimodal resources (e.g., speech, whole body movement, gesture, gaze, etc.) to coordinate their activity to complete this challenge and achieve associated regulatory functions.

Figure 2
The focal group, the obstacle course, and the final completed route



In this study, we focused on a group led by Mr. Samuel, a teacher with 7 years of experience, working with three 4-year-old students, Cora, Seth, and Toby, to navigate a route (see Figure 2). The chosen excerpts from this session demonstrate how the group utilized shared body/ego syntonicity with the toy Rapunzel and among each other (we-syntonicity) to exhibit two forms of collective self-regulation: focused attention and inhibitory control, within the context of CT practices. We created detailed transcriptions of two excerpts using conventions adapted from conversation analysis: degree signs for quiet speech (°°); capitals for louder speech; question marks for rising intonation (?); colons denote elongated syllables (::); double paratheses for actions/body movements; braces for analyst comments or descriptions ({ }); and square brackets show overlapping actions or speeches ([ ). Embodied actions are illustrated using screenshots; co-timed speech is outlined with boxes.

Findings and discussion

Focused attention through we-syntonicity

Figure 3
Embodied/shared attention regulation

Screenshot A
Screenshot B

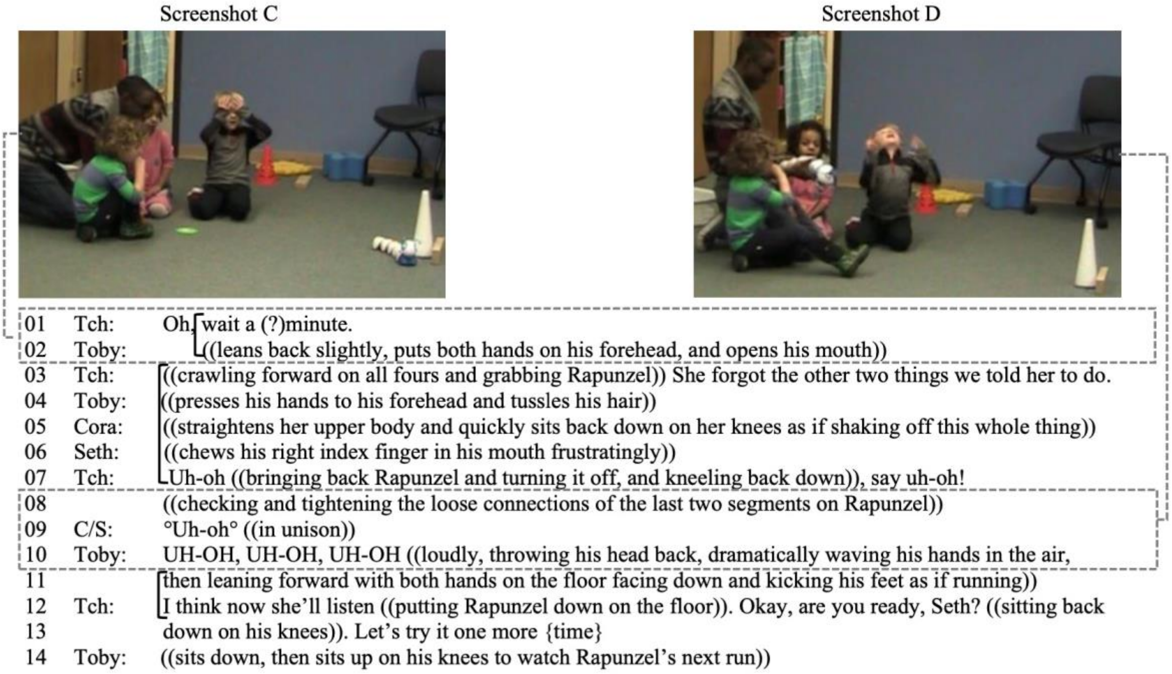
01 Seth: ((looks down and plays with the "straight" segment in his hands))
02 Tch: Do you think she should start [by turn::ing ((holding Rapunzel in his right hand while manually steering
03 Rapunzel to turn left on the floor))
04 Seth: [((looks up to the right at Stanley briefly and look back at the piece))
05 Tch: Is it a good way? Is it gonna get her home if we turn first ((pointing his left hand
06 at Rapunzel's home to his left while holding the "left turn" segment that children attached initially))
07 Cora: [((bends and leans forward to look in the direction of Rapunzel's home))
08 Toby: [((turns right to look at Rapunzel's home and shakes his head quickly))
09 Tch: No. What- Which way should we start heading first? ((pointing his left hand at Rapunzel's home again))
10 Toby: ((shaking his head several times)) Straight and tur::n! ((flapping his hands in midair excitedly))
11 Tch: Maybe a straight and turn, maybe! ((raising Rapunzel in his right hand and taking off a "left turn"
12 segment children attached earlier)) So let's try that.
13 ((looking up at Seth)) Seth, you have a straight in your hand. Can you add the straight on? ((putting
14 down Rapunzel, placing it in the middle of the circle and angling its tail directly in front of Seth))
15 Toby: ((Sits up on his knees and moves to the right))
16 Seth: ((looks up and then back at his hands, scooches over slightly right toward the circle while holding
17 forward the "straight" segment in the right hand))
18 Tch: [We will try a straight and then a turn.
19 Toby: [((excitedly turns his body right and moves over on his knees to face the obstacle))
20 Cora: [((sitting up excitedly)) Now …{inaudible}
21 Seth: [Mmmm ((bending over forward and attaching the "straight" piece to Rapunzel while holding her head))

In Figure 3, Mr. Samuel and the children were working to debug and figure out the solution to their first failed run, which they attached two left turns and Rapunzel ended right in front of Cora's feet. While Mr. Samuel, Cora and Toby were discussing Rapunzel's next steps (lines 2-3 & 5-12), Seth was playing with a spare, unattached coding segment (line 1). The spatial-orientational pattern in Screenshot A shows Seth outside the group, with his attention diverging from the group's. Inside the joint transactional space marked by red lines, Mr. Samuel, Cora, and Toby's attention – as evidenced by their gaze and body posture – were jointly focused on Rapunzel as they discussed her desired movement (lines 2-3, 9-11) and her goal of going home (lines 5-8). In line 13, Mr. Samuel explicitly invited Seth to rejoin the joint space by asking him to add the straight segment he had in his hands. Subsequently, the group adjusted their bodies/positions to integrate Toby into the space: Mr. Samuel placed Rapunzel in the center directly in front of Seth to reinforce his verbal invitation (line 14), Toby moved to the right to create an opening (line 15), and Seth responded by scooching into the space and offering the straight segment (line 16-17). As a result, the group formed a new joint space incorporating Seth, marked by the green lines in Screenshot B. In this newly formed space, joint attention was re-established and all four participants worked together to re-direct Rapunzel to her home (lines 18-21).

Directing and managing one's attention is an important basic executive function and foundational SR behavior (Diamond, 2016). Without focused attention, learning would not be possible. As illustrated above, Rapunzel constituted an anchor for attention in the center of their joint transactional space figurately and literally. By taking up Rapunzel's needs and goals of going home (ego-syntonicity), the children eagerly coordinated and directed their attention towards her (body syntonicity). When such focused attention broke as shown in Screenshot A, the group worked to repair and restore the space to include everyone as shown in Screenshot B. Although the teacher played a more explicit role in directing/managing their attention to Rapunzel, the children also supported each other in their embodied positionings to reform joint focused attention. Toby's move to the right created a critical opening to allow Seth to join and form a new "o-space" and rejoin the group's joint focused attention on Rapunzel. In other words, embodied attunement among the children and awareness of each other's body/position, a form of we-syntonicity, also supports the formation, maintenance, and repair of their joint focused attention.

Inhibitory control through we-syntonicity

Figure 4
Embodied/shared inhibitory control



Screenshot C

Screenshot D

01 Tch: Oh, [wait a (?)minute.
02 Toby: [((leans back slightly, puts both hands on his forehead, and opens his mouth))
03 Tch: [((crawling forward on all fours and grabbing Rapunzel)) She forgot the other two things we told her to do.
04 Toby: ((presses his hands to his forehead and tussles his hair))
05 Cora: ((straightens her upper body and quickly sits back down on her knees as if shaking off this whole thing))
06 Seth: ((chews his right index finger in his mouth frustratingly))
07 Tch: [Uh-oh ((bringing back Rapunzel and turning it off, and kneeling back down)), say uh-oh!
08 ((checking and tightening the loose connections of the last two segments on Rapunzel))
09 C/S: °Uh-oh° ((in unison))
10 Toby: UH-OH, UH-OH, UH-OH ((loudly, throwing his head back, dramatically waving his hands in the air,
11 [then leaning forward with both hands on the floor facing down and kicking his feet as if running))
12 Tch: [I think now she'll listen ((putting Rapunzel down on the floor)). Okay, are you ready, Seth? ((sitting back
13 down on his knees)). Let's try it one more {time}
14 Toby: ((sits down, then sits up on his knees to watch Rapunzel's next run))

As Figure 4 began, Rapunzel executed only first two of four attached code segments and stopped prematurely. Mr. Samuel was surprised by this (line 1) and made a light-hearted observation (line 3). In response, the children used embodied displays to show their disappointment and frustration (lines 5-6) and Toby's was particularly intense (line 2, Screenshot C). Noticing this, Mr. Samuel orchestrated a collective vocalization of this emotion, "uh-oh" to verbalize and label the felt tension (line 7). Toby took up the suggestion, saying "uh-oh uh-oh uh-oh" loudly while throwing his head back and waving his hands in the air (line 10, Screenshot D) and then leaning forward with both hands on the floor facing down and kicking his feet as if running (line 11). After the physical display and using a shared word to describe the embodied display ("uh-oh"), the children quickly resumed the task with Mr. Samuel (lines 12-14).

This excerpt illustrates the group's collective effort to regulate their emotional reactions and achieve inhibitory control in responding to Rapunzel's premature stop at the obstacle. Inhibitory control, a central component of executive function, involves the ability to inhibit automatic but incorrect responses or to resist interference from distracting stimuli (Diamond, 2016). Difficulties or challenges in a task can cause young children's distress and frustration to overwhelm them, which can then lead to giving up on the task (an ineffective response). Mr. Samuel prioritized managing emotions and inhibitory control as a group, and appealed to children's body/ego syntonicity with Rapunzel by offering a relatable explanation ("She forgot the other two things we told her to do") and helped them label and vocalize their embodied feelings ("Uh-oh" like Rapunzel might have responded). While the children's initial emotional response was intense, their strong empathy with Rapunzel's goal of getting home without crashing into the obstacle (body/ego syntonicity) and the opportunity to express and label their responses to frustration together (we-syntonicity) allowed them to take a pause, process their shared visceral emotional reaction, and recover quickly. Through their body/ego syntonicity with Rapunzel as well as we-syntonicity with each other, the group effectively engaged in embodied/shared inhibitory control.

Conclusion

Our close examination demonstrates that preschoolers leverage their sense/knowledge of their own body/self and attunement with Rapunzel and with each other to engage in rich self-regulatory actions through CT practices with a programming toy in a teacher-guided small group. Children's embodied SR through body/ego syntonicity with Rapunzel is closely intertwined with their embodied attunement with each other (we-syntonicity), and thus *socially shared* and *distributed* (see also Danish & Enyedy, 2020). Their shared body/ego syntonicity with Rapunzel motivated such we-syntonicity, which in return allowed the group to collectively regulate their attention and inhibitory control. These findings lend support that SR, especially in early childhood, should be viewed and examined as embodied as well as social/situated in nature, with implications for the identification and measurement of SR. Our study also lends support to some of the suggested mechanism between CT and SR: joy and sense of belonging derived from CT activities, active engagement with CT, and characteristics of robots that help children to learn to wait and focus (Arfé et al., 2020; Di Lieto et al., 2017). Our we-syntonicity framework captures these potential pathways between CT and SR and provides a useful approach to employing CT practices to support SR in practice.

“Accessibility is Important to Everybody”: Unpacking Students’ Understanding About Accessibility

Victoria C. Chávez, Northwestern University, vcchavez@u.northwestern.edu
Sarah Van Wart, University of North Carolina Asheville, svanwart@unca.edu

Abstract: Existing research on accessibility in computing courses identifies barriers and practices for teaching web accessibility, but little work has been done to leverage students’ acquired understanding of accessibility as a meaningful topic of study. In this paper, we use students’ assignments to offer insights about what students take away when they learn about web accessibility. Our analysis begins to unpack how students recognize the importance of accessibility, the affordances they associate with it, as well as a considerable willingness to implement accessibility features beyond minimum requirements.

Introduction

From a website’s inaccessibility preventing the purchase of necessities such as food (“Another Big Win in the Domino’s Pizza Accessibility Saga,” 2022) to it inhibiting the completion of a job application (Cahalane, 2018), web accessibility is a social justice issue. Existing work on accessibility in web development courses tends to focus on instructional approaches (e.g., Baker et al., 2020; Putnam et al., 2016; Rosmaita, 2006; Shinohara et al., 2018; Wang, 2012). As such, students’ understandings of accessibility are often considered in relation to course or instructor evaluation, rather than its own meaningful topic of study. Research that centers student perceptions and understandings of accessibility provides meaningful insights into structural barriers impacting students’ understanding of accessibility, and how instructors and institutions might design courses and programs to better support students’ cultivation of accessibility practices (Alonso et al., 2010; Cao & Loiacono, 2021; Conn et al., 2020). Additionally, more research in this area could help expand the conversation around student motivations for learning accessibility (Conn et al., 2020; Putnam et al., 2016; Wang, 2012). Contributing to this important and needed area of research, this paper, which is part of a larger study of accessibility teaching and learning, seeks to answer two research questions: 1) What affordances do students associate with accessibility? In other words, how do students begin to identify all that accessibility offers, and 2) To what extent did students take up supplementary opportunities to implement accessibility features?

Course context

This study was conducted in a large web development course offered as an elective in the Computer Science (CS) department of a large private university in the U.S. The course has an average enrollment of about 150 students ranging across years in the CS major and enrolled students have taken at least two prior programming courses. The course is broad in scope and covers a variety of front-end (i.e., user-facing aspects of a site) and back-end (i.e., components required for dynamic features and functionality of a site) topics. Students work on developing full-stack applications (i.e., websites requiring both front-end and back-end development) and assignments build on each other to create an Instagram-like web application. Assignments consist of labs which are graded pass/fail based on effort and homework assignments are graded on a point-scale according to each assignment’s corresponding rubric. Accessibility is embedded in over half of all lab and homework assignments.

Data and methods

The data used for this paper consist of the submissions for three course assignments. Lab 1 is the first assignment students complete in the course and is designed to help them set up their development environments while offering a brief HTML and CSS introduction. Homework 2 and Homework 4 both focus on creating an Instagram-like web application using different technologies: server-side templating and client-side templating, respectively. The three assignments are representative of various accessibility-related tasks including reflections, accessibility testing, and accessibility feature implementation. The data from the three assignments was analyzed using a combination of open coding as well as summative statistics.

Open coding for RQ1: Affordances associated with accessibility

To answer RQ1, we analyzed the responses to two open-ended reflection questions, one from Lab 1 and one from Homework 4, asking about the importance of accessibility. In Lab 1, students responded to “Why, and to whom, is accessibility important?” while in Homework 4, the prompt asked “Do you think that designing for accessibility also improves the usability of the site for all users? Why or why not?”. We grouped the student responses for both questions and free coded for topics.

Summative statistics and open coding for RQ2: Supplementary opportunities

For RQ2, we analyzed implementation details for Homework 2 and Homework 4, which both offered opportunities for students to implement accessibility features beyond what was required to receive credit. In Homework 2, we asked students to “Download the WAVE Extension using either Firefox or Chrome, and use it to generate an accessibility report. Correct as many accessibility errors as you can. Then take a screenshot of your final accessibility report.” We also asked students “What corrections did you have to make?”.

The WAVE Browser Extension (WebAIM, n.d.-a) is a tool that provides information regarding the accessibility of a webpage by displaying accessibility errors, warnings, and features. Students can click on any of these messages to get more information about what it means and, if it is an error, how to address it. WAVE reports return counts for various categories of issues, including (1) “errors” – indicating failure to include essential accessibility markup tags and attributes in the code, (2) “color contrast” – indicating that the color choices interfere with readability, and (3) “alerts” – indicating potential accessibility issues. We manually extracted the total counts from each student’s submitted screenshot and used Microsoft Excel to automatically calculate and plot five number summary statistics to assess the distribution of each. Furthermore, we compiled all the possible errors for each category (see WebAIM, n.d.-b) and assigned codes to the ‘alert’ category. We used the coding scheme from this list of possible alerts to code students’ responses of what corrections they made.

In Homework 4, students were asked to implement three accessibility features that enable users relying on assistive technology to interact with a web application without using a mouse: basic keyboard navigation, screen-reader friendly toggling behaviour, and change of focus for a modal. Students were also given the opportunity to implement an additional feature for extra credit, namely, allowing the ‘Escape’ key to trigger the closing of the modal while preserving the appropriate keyboard focus. To facilitate grading, students were asked to self-report whether they implemented the extra credit feature. As such, we read through student’s submission comments and counted how many of them implemented the extra credit feature.

Findings

What affordances did students associate with accessibility?

One salient theme that emerged from the open coding of students' responses to Lab 1 and Homework 4 was that accessibility benefits everyone— including the students themselves.

Accessibility benefits everyone

Across the responses for both assignments, 62.5% of students wrote about accessibility being beneficial for all users of a website. Below we include an illustrative student response from each assignment:

Lab 1:	“Accessibility is important to everybody. Accessibility dictates the usability of applications across populations, and it is to our advantage that applications are widely available. In addition, a large percentage of the population requires accessible interfaces.”
Homework 4:	“Designing for accessibility does improve the usability of the site for all users. The screen reader components don’t necessarily impact all users, but many may want the option to use the keyboard instead of the mouse only.”

Additionally, 74% of student responses included an example to elaborate on or justify how or why accessibility benefited everyone. Some examples shared by students in Lab 1 included: “Making a website accessible may also benefit everyone (e.g., closed captioning used in a crowded bar)” as well as “ [Accessibility] leads to better designs and more readable code, and it makes using the site easier and more pleasant for everyone”, and some examples from Homework 4 consisted of: “I think all users can benefit from things like alt text (i.e., your browser might be slow one day and images don't load properly)” as well as, “although someone is able to use a mouse, it’s just easier given a situation where they would want to tab through the site instead. Another example is color contrast, where although a user might not be colorblind, having a well-contrasted site would just be more visually pleasing.”

Accessibility is relatable

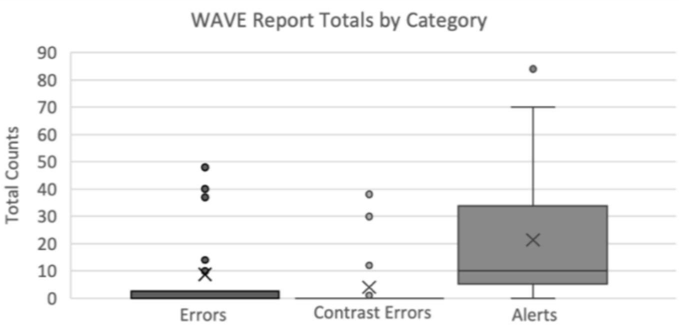
Across both assignments, 20 unique students shared examples of accessibility being beneficial to everyone. Of those, 40% of them gave examples from their own experiences navigating websites using accessibility features. For example, one student shared "it was really easy to just hit enter twice to open and close the modal (and test modal functionality), rather than clicking the "view more button" and then the "close" button. I believe tabbing (and using the enter or space key) can be a useful tool for anyone." In identifying the ease of use that accessibility features— such as tabbing— can provide, students unlock a novel way of navigating and interacting with the web. Interestingly, half of the students who shared similar examples explicitly described these examples as stemming from testing the accessibility features they had implemented for their assignments.

To what extent did students take up supplementary accessibility opportunities?

Students implemented accessibility features beyond those required for credit, which is a strong indication that students *want* to implement accessible websites and when given the appropriate tools, will do so. When given the opportunity to implement an additional accessibility feature for extra credit in Homework 4, over half of all students (54%) implemented it. Implementing the extra credit feature was worth an additional two points for an assignment graded out of 40 points.

Furthermore, in Homework 2, most students corrected all 'errors' and 'contrast errors', while many corrected 'alerts', when the prompt asked for them to "correct as many errors as [they could]". As Figure 1 demonstrates, Homework 2 errors and contrast errors were both tightly grouped around zero, demonstrating that a majority of students were able to correct simple accessibility errors such as empty fields, non-descriptive links, missing alt-text, and low contrast, among others (see WebAIM, n.d.-b).

Figure 1
Student WAVE Report Totals by Category



Despite not being grouped near zero, about half of all students had 10 or fewer alerts. This is likely an indication that students *chose* to address the alerts they received from WAVE, despite not being required to do so— a theory supported by 60% of student reflection responses for this assignment mentioning specific types of alerts they addressed. This evidence suggests that students were motivated to address as many issues as they felt they had the skills to do.

Discussion & implications

As evidenced in this paper, there is incredible richness in how students are taking up the value and importance of accessibility. However, existing research on accessibility focuses on pedagogical practices, interventions, and course design and evaluation (see Baker et al., 2020; Lewthwaite & Sloan, 2016; Nishchyk & Chen, 2018 for in-depth literature reviews on these topics), with little attention given to students' thoughts and practices regarding accessibility. Importantly, while existing work on teaching about accessibility highlights students' and web developers' lack of interest (Putnam et al., 2016) and their disregard for the importance of accessibility (Conn et al., 2020; Putnam et al., 2016; Wang, 2012), the findings presented here offer insights into the many ways in which students value accessibility, and how willing they are to go above and beyond minimum requirements of assigned accessibility implementation. This finding is not only encouraging for instructors who may be feeling discouraged about teaching the topic, it also highlights the need for better understanding how educators can enable and motivate students in this area. For example, while conducting the analysis across student responses for Lab 1 and Homework 4, we noticed a considerable difference in the number of students who recognized accessibility as important and beneficial for all users in each assignment (Lab 1: 36%, vs. Homework 4: 89%). It is unclear how much of that recognition came from the positive bias in the wording of the Homework 4 question as opposed to students' learning through the course (the assignments were even weeks apart). Understanding whether this discrepancy was due to student understanding fomented through the course overall (i.e., students learned to recognize that accessibility benefits everyone) or through the question's positively biased wording (i.e., question wording helped surface students' underlying understanding) could impact course design to better foster this learning. Relatedly, understanding whether the ambiguity of asking students to "correct as many errors as [they] can" helped motivate students to address more errors than they would have had they been given a specific threshold, could also help frame assignment question design. Lastly, while it is encouraging that students appreciated the added value of accessibility as benefitting all users, it is important that students recognize that accessibility primarily impacts how users with disabilities navigate the web and a site's conveniences for abled users must not undermine its access and functionality for disabled users.

We also extend our deepest gratitude to all the students in the Intro to Web Development course.

“Wait, Wait, Go Back”: Investigating Social Supports for Homework During Do-Design Sessions With Teachers

Paul Hatch, University of Illinois Chicago, USA. phatch2@uic.edu
Joseph E. Michaelis, University of Illinois Chicago, USA. jmich@uic.edu

Abstract: Teachers use interpersonal classroom skills to support their students’ learning in the classroom, but homework is done in isolation without the affordances of classroom interactions. Here we investigate how a homework tool could empower teachers to utilize their interpersonal classroom skills and provide new ways to support students outside of the classroom. Through three phases of interviews and co-design, we co-designed software for teachers to create their own robot-assisted homework activities. We found that teachers' existing expertise initially led to wrong assumptions about the tool but after viewing an exemplifying stimulus they shifted their mental model of the tool and of homework in general. These findings can help understand (1) how pedagogical expertise may hinder utilization of new tools, and (2) how a catalyst may shift existing perceptions and facilitate the use of new paradigms to support student learning.

Introduction

Teachers utilize *interpersonal classroom skills* to facilitate meaningful social learning for their students. These socially situated interactions can foster interconnected understanding of content and deeper learning through a process of co-construction of knowledge (Miyake & Kirschner, 2014). However, teachers cannot apply these crucial interpersonal classroom skills to learning activities outside the classroom, such as homework which is typically undertaken in isolation. Some existing technological approaches can be effective in supporting social interactions during learning and offer automated differentiation to support students’ comprehension and problem solving. But these often require teachers to adapt their pedagogical approaches to the needs of the software which rarely allows the teacher to utilize their existing classroom interpersonal skills or tailor their supports to connect to students' individual and collective experiences. There is therefore a need for software that shifts the paradigm of homework to align with classroom practices, thereby empowering teachers to use their existing interpersonal classroom skills to provide meaningful connections to the material and support deeper learning. Our goal is to facilitate this change in homework paradigms by co-designing an authoring tool for middle school science teachers to provide rich socially interactive guidance to students working at home with a social robot.

Theoretical framework

Teachers guide students’ acquisition and integration of domain knowledge by utilizing **interpersonal social skills** to co-create knowledge between teachers and peers (Miyaki & Kirschner, 2014; Cress & Kimmerle, 2018). Teachers actively support their students’ socially situated learning by responsively attending to student questions and misconceptions, prompting verbal reflections on learning, and adapting content to student’s learning preferences (Kucirkova, 2021; Walkington & Bernacki, 2021). To scaffold complex concepts and texts teachers also rephrase or simplify content and use interpersonal and informal language closer to students’ discourse and receptive vocabulary (Bernacki, 2021). Such socially interactive learning is particularly critical for science learning where the focus is on generating deep knowledge through collaboration and discussion (NGSS, 2022).

Homework is a valuable instructional tool that can enhance students’ learning, have a positive influence on students’ academic achievements, especially when connected to classwork and tailored to students’ individual needs (Cooper, 2015, Rosario et al., 2019). While many teachers are aware of the need for social guidance in the classroom, students are left to complete homework as an isolated activity. Teachers also believe students face issues of inequity in time, technical resources, and support outside of the classroom, which has led to a reduction of assigning homework (Hatch & Michaelis, 2021). Given these challenges to providing at-home learning, it is important to bolster the use of homework by facilitating teachers to integrate their interpersonal social skills.

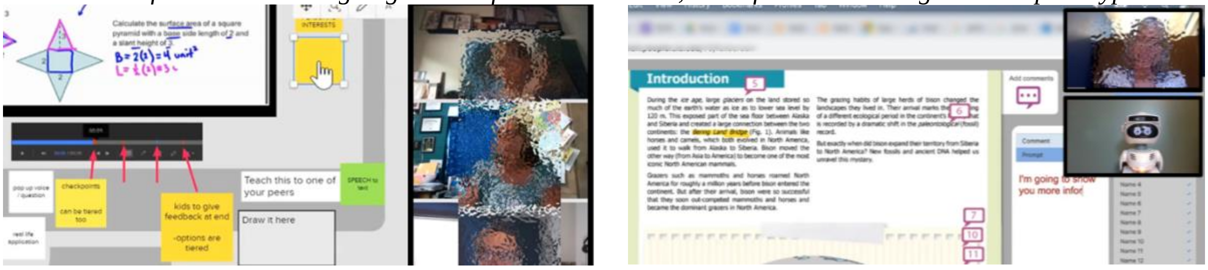
Social robots are becoming more affordable for at-home and classroom use and have the potential to transform isolated activities such as homework into socially interactive experiences and facilitate higher levels of engagement, thus promoting learning and interest (Balpaeme et al., 2018, Michaelis & Mutlu, 2018, 2019).

Earlier research in this study showed that science teachers felt current online learning options do not adequately support socially interactive approaches to learning (Hatch & Michaelis, 2021) and explored the co-design of a homework authoring tool (Hatch & Michaelis, 2022). We now apply a different lens to the teachers’ viewpoints as they developed over time across the research. Specifically, we examine how to empower teachers to use their existing interpersonal skills to support students' at-home learning with a social robot: (RQ1) How do teachers' perspectives differ on ways to support their students' learning in the classroom and in homework? And (RQ2) how do teachers' current pedagogical practices impact their application of a new educational technology?

Method

This study stretches over three phases of participatory research with middle school science teachers to elicit their perspectives on providing classroom and homework guidance using a social robot. First, we elicited their perspectives in 1-hour interviews (n=12) on how they currently provide guidance in the classroom and on how they approach homework. We then populated an online whiteboard 'Mural' with a range of digital features based on their views on how they provide guidance to reading assignments. In groups of 2 or 3 (n=7) the teachers then used these digital features to co-design an online tool to meet their needs while we guided and captured the discussions via Zoom (see Figure 2). Teachers indicated their preferences and discussed their reasoning around the features they chose and the layouts they created. These co-designs became the basis for a subsequent working prototype which we then tested (n=13) teachers' use of it to provide support to students doing homework with a social robot. The teachers could add either questions or prompts, 'annotations', to a reading homework article and we explained how these annotations would eventually be voiced by a social robot at home with the student. The 'Misty II' robot used in prior research (Michaelis & Mutlu, 2018, 2019) was also visible to them via the online Zoom window. After the teacher's first or second annotation, the robot voiced the annotations as it would at home with the child. We then asked the teachers to share their thoughts about their impression of this, before prompting them to continue annotating. The locus of this study is not on the eventual student-robot interaction - the focus of previous work (Michaelis & Mutlu, 2018, 2019) - but on how the teachers' pedagogical expertise shapes how they grapple with a software that presents a new way of interacting with students. All three phases were conducted online using Zoom from which we analyzed the captured video and dialogue using a Thematic Analysis approach (Braun et al., 2018) to inductively construct semantic codes and organize the data into major latent codes. We then co-constructed emergent themes through iterative discussion based on meaningful patterns in the data.

Figure 2
Screenshots of teachers co-designing desired features in Mural; and of a teacher using the later prototype.



Findings

We found two major themes across the three phases that pertains directly to our research questions: (1) Teachers feel the lack of interpersonal supports limits the impact of homework and (2) Viewing the robot's interactions appeared to shift teachers' perspectives on the homework activities.

Teachers described classroom activities as rich interpersonal exchanges where they are able to actively guide and respond to their students' learning. Homework was described as an extension of the classroom where students can deepen their understanding of the topic. Many teachers said they use homework as a structured test of their students' understanding upon which to build in classroom activities. However, they also told us they minimized homework as they are not able to provide the kinds of social supports they do in the classroom and expressed frustration at not being able to immediately address issues and questions as they would in person.

When teachers were asked to annotate the homework reading using the working prototype, their initial approach appeared to align with how they had described homework in the preceding interviews. A high majority of the annotations were formed as questions to test the students' understanding of the material, formulated in concise and *formal* language. However, after seeing the robot enact their initial annotations, many teachers appeared to second-guess their original approach and made immediate changes to their original annotations or started new ones that use a *conversational* or socially rich language. Teachers' new annotations appeared to be less like formal test questions and closer to how the teacher would use interpersonal language to support their students' learning in the classroom. This change in the way they phrased annotations seemed to be aligned to teachers accounting for the student's perception of the robot as a social interlocutor, and teachers spoke about how they viewed the robot as a teacher at home with the student. The teachers' later annotations included ways to prompt verbal reflections, bring emphasis to specific content, and rephrase or simplify complex vocabulary. Many teachers described their later annotations reflected the style of speech they would use in the classroom and greatly expanded the types of annotations to include comments, exclamations, and humorous quips. For example, one teacher's annotation guides the students' attention to a picture, by having the robot say, "Hey take a look at this. Wait, wait, go back, look at that picture again" (Teacher#5), where both content and style appear to be unique to the affordances of social interaction.

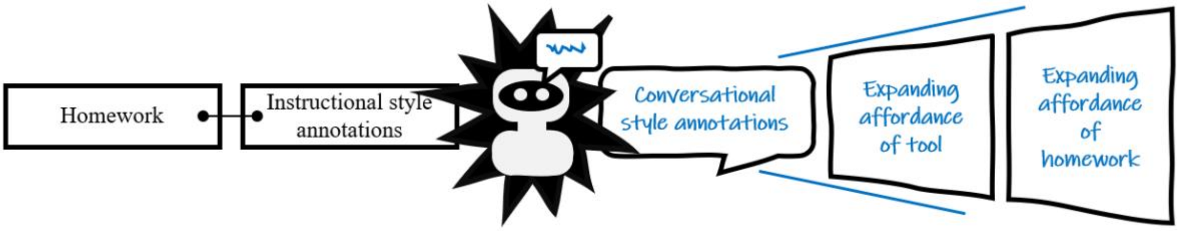
In sum, teachers' initial annotations were instructional prompts and formal questions which seemed to be relate to their pedagogical experience with *homework*, but hearing the robot speak those annotations appeared to demonstrate how impersonal those prompts were and inspired the teachers to then create annotations that reflect the interpersonal dialogue they use in the *classroom* to connect with and motivate students.

Discussion

At the start of this study teachers described how they utilize their interpersonal skills to socially support their students' learning in the classroom, which contrasts to how they described their approach to homework. However, after hearing the robot say their annotations, the teachers explained -and demonstrated- how they could utilize the robot's social skills to support homework in ways similar to how they described supporting student learning in the classroom. Teachers saw this as an opportunity to facilitate meaningful social learning through homework and thereby attend to student questions and misconceptions, prompt verbal reflections on learning, actively support engagement, and engage with students in relatable ways (Kucirkova, 2021; Walkington & Bernacki, 2021). Their approach changed from preparing homework as an isolated, unsupported task (Cooper, 2015) to preparing it as a new way of interacting with the student and facilitating meaningful social learning (Miyake & Kirschner, 2014).

We also consider that seeing the robot enact their homework annotations may have been a critical catalyst to shift the teachers' mental model of homework activities away from their existing construct of homework, only after which were they able to use their interpersonal classroom skills to augment the homework. The teachers in this study did not immediately use the robot's social capabilities, despite knowing that their annotations would be voiced by it. Every teacher in the study started by creating annotations that resembled traditional homework questions and prompts. We believe it may be that teachers' mental model of the homework activity was initially framed by their prior experience in assigning homework, despite this platform's addition of the robot technology. This mental model appeared to be challenged at the very moment the teachers heard and saw the robot vocalize their annotation. It seems the juxtaposition of the instructional-style writing appeared inappropriate as dialogue and brought their attention to the new *social* purpose of the annotation. The experience appeared to act as a catalyst to abruptly shift the teachers' mental model from a homework paradigm to that of a *classroom paradigm*. This shift in perspective allowed them to tap into their interpersonal classroom skills and create homework activities that mimic student-teacher classroom interactions, rather than a student-paper interaction paradigm. Thus, experiencing the robot enact the annotations seemed to be a critical catalyst for reshaping teachers' understanding of the purpose of the annotations, and shifted their mental model of the affordances of the homework.

Figure 1
It appeared a catalyst was necessary to shift teachers' mental model from a homework paradigm to that of a classroom paradigm and expand their perception of what they could achieve with homework through the tool.



Our study echoed current theory on how complex and challenging homework can require substantial guidance which teachers and parents are often unable to provide (Cooper, 2015). Building on current theory around how social robots provide these important supports (Michaelis & Mutlu, 2019; Balpaeme et al, 2022), we provide a way for teachers to provide robot-student homework interactions that utilize their interpersonal classroom skills, crucial for creating meaningful connections to the material and supporting acquisition of deeper learning (Miyake & Kirschner, 2014). We also build on existing theory by demonstrating how a catalyst can shift teachers' mental model and thus enable them to draw from existing skills and experiences.

Learning Scientists often engage in changes to teaching practices, therefore consideration of teachers' difficulties in adopting change is essential. Our findings show that it may be important for researchers to find the right *catalyst* to help shift a mental model to take full advantage of innovative new tools. In this study, the teachers' typical instructional style of writing seemed to jar with the spoken voice of the robot, thereby acting as a catalyst for a mental model shift in which they realized the social affordances of the robot. This may suggest that a mental model of an existing teaching practice can be shifted by creating a form of cognitive conflict between old and new paradigms, thereby necessitating the teacher to actively make a change of approach to resolve the issue. Once the mental model has been shifted, the teacher may be able to freely apply their existing expertise within the new paradigm rather than be limited by the constructs of the old one.

Conclusion

In this study, we found how teachers' existing pedagogical expertise with homework hinders their understanding the affordances of a new system, but once their perspective is shifted, the teachers may be able to freely apply their interpersonal classroom skills and facilitate meaningful social learning in the homework. We recognize one major limitation of this study is the small sample size, mostly made up of teachers with significant classroom experience. As such the findings have limited capacity for generalization. While this work uncovered teachers' views based on their emotional and pragmatic needs, future work will include formal testing within the context of real classrooms, and research on how students and families perceive such socially interactive homework.

We believe the findings of this study can help Learning Scientists engage in designing interventions and changes to teaching practices, where adopting change is often of paramount importance. Because a teacher's pedagogical expertise may prevent them from immediate recognition of the affordances of a new approach, it may be important to find the right catalyst to help change existing mental models, potentially enabling the teacher to bring new, expanded insights directly drawn from that same expertise. We believe this work makes important contributions to existing theory and will help guide future work in this area.

Expanding Preservice Teachers' Conceptions of Science Teaching and Learning

Allison Metcalf, Florida State University, atm14e@fsu.edu
Lama Jaber, Florida State University, ljaber@fsu.edu
Shannon Davidson, University of Alabama, sgdavidson1@ua.edu

Abstract: To support students' sense of belonging in science classrooms, K-12 teachers should recognize and appreciate learners' diverse experiential, cultural, and linguistic repertoires as valuable resources for sensemaking in science. This approach to teaching necessarily entails expanding what has been traditionally considered as ontologically and epistemologically valid and valued in disciplinary learning spaces so that students' diverse ways of thinking, talking, and feeling are honored and built upon, rather than dismissed. This study explores the emergence of such expansiveness in the context of STEM preservice teacher education. Using preservice teachers (PSTs)' written reflections and in-class discussions, we identified different ways in which such expansiveness manifested in PSTs' discourse. We end with some implications for supporting teachers' expanding conceptions of science teaching and learning.

Introduction

Learners have varied and rich life experiences, cultural practices, and linguistic repertoires that serve as valuable resources for their sensemaking in science (Rosebery et al., 2010). In the United States, however, these resources often do not align with the Western disciplinary practices and discourses that are privileged and romanticized in traditional instructional goals (Bang et al., 2012). Such instructional goals are informed by a "selectively appropriated… unnecessarily narrow" framing of science that depicts the discipline as culturally neutral, value-free, and objective (Bang et al., 2012, p. 314). These zero-point epistemologies shape what is ontologically and epistemologically acceptable in science classrooms, often devaluing learners' own experiences and ways of knowing (Warren et al., 2001). This is especially true for learners from marginalized cultural, linguistic, and racial groups, as this narrow framing (re)produces deficit narratives about such students (Nasir et al., 2006; Rosebery et al., 2010).

It is crucial, then, to *expand* teachers' conceptions of science teaching and learning in ways that push the traditional boundaries of "what counts" as intellectually generative for scientific sensemaking and "who counts" as capable of meaningful engagement in science (Rosebery et al., 2016). Such expansive considerations necessarily entail orienting to all students as sensible and brilliant (Robertson & Atkins-Elliot, 2017), recognizing students' diverse ways of knowing and being—their onto-epistemic heterogeneity—as valuable for their science learning (Kayumova & Dou, 2022), and understanding the sociopolitical realities of schooling (Madkins & McKinney de Royston, 2019). Here, we examine how preservice science teachers' (PSTs) begin to develop such *expansive conceptions of science teaching and learning* in an early teacher education course. Toward this end, our exploration in this work is guided by the following: *(1) what are the ways in which PSTs developed more expansive conceptions about science learning? and (2) how do these expansive perspectives influence PSTs' evolving ideas about science teaching?*

Conceptual framework: Expansiveness

By expansiveness, we refer to teachers' broadened conceptions of science teaching and learning along three components: having asset-based orientations to learners, recognizing the value of onto-epistemic heterogeneity, and developing political clarity.

In traditional framings of science teaching and learning, students' own sensemaking resources are often ignored or viewed as deficient, which negatively impacts students' investment in their own learning and the opportunities they have to use these resources (Kayumova & Harper, 2020; Suárez & Otero, 2014). When seeking to expand teachers' conceptions of science teaching and learning, it is essential to cultivate their **asset-based orientations.** By asset-based orientations, we refer to the way that teachers orient to the strengths and merits of students' ideas, experiences, and forms of participation. Such orientations are grounded in the assertions that students are capable of engaging meaningfully in science, and that their own intellectual resources support their sensemaking (Celedón-Pattichis et al., 2018). Asset-based orientations frame students' engagement in the classroom such that teachers orient to the brilliance of students, rather than ascribe to deficit views (Mejia et al., 2018).

Another central component for expansive conceptions of science teaching and learning is recognizing **onto-epistemic heterogeneity**, or "differences in perceived ways of being, thinking, doing, and interpreting," as *valuable* for scientific sensemaking (Kayumova & Dou, 2022, p. 1099). Going a step further than asset-based orientations, valuing onto-epistemic heterogeneity refers to expanded considerations of “what counts” as intellectually generative for students’ scientific sensemaking (Rosebery et al., 2016). Such expansive considerations include, for example, valuing “practices of argumentation and embodied imagining, the generative power of everyday experience, and the role of informal language in meaning making” (Warren et al., 2001, p. 532). This does not entail an ‘anything goes’ view of science instruction nor a rejection of dominant views of science, but rather a “conscious form of heterogeneity of learning and engagement” (Bang & Marin, 2015, p. 542) that centers the varied cultures, languages, and experiences of students as valuable for knowing and being in science.

Expansive conceptions of science teaching and learning also entail a recognition that Western, narrow ideations of science are rooted in colonial historicity, and continue to define “settled” expectations about who counts as a valid constructor of knowledge (Bang et al, 2012; Mignolo, 2010; Warren et al., 2020). This contributes to the systematic cultural exclusion of students who exist outside of these racialized, classed, and gendered norms (Kayumova & Dou, 2022; Ladson-Billings, 2007). It is therefore essential to support the development of teachers’ critical awareness of such power and historicity, the deficit narratives they (re)produce, and structural and systemic inequities that shape students’ opportunities to learn science. Madkins and McKinney de Royston (2019) refer to this “deep understanding of how schools and society operate to reproduce inequalities and are structured to differentially privilege certain experiences and forms of knowledge over others” as **political clarity** (p. 1325).

Methods

This study is part of a larger project aimed at cultivating PSTs’ capacities for understanding, valuing, and responding to students and their ideas in ways that affirm their humanity and dignity. Each of the PSTs in this study are double majoring in a STEM field of their choice and in education, with the goal of becoming a secondary STEM teacher. In the semester from which the data are drawn, nine PSTs participated in the study.

The goals of the course at the center of this study are to develop PSTs’ knowledge and curiosity about learners’ ways of thinking and feeling, promote PSTs’ critical awareness of their own prejudice and biases, and support PSTs to recognize learners’ brilliance and honor their full humanity in designing and enacting instruction. PSTs engage in several course activities in service of these goals: (1) reading research and practitioner articles about student thinking and diverse ways of knowing; (2) engaging as learners in science and mathematics activities that require them to think deeply about concepts; (3) analyzing videos and transcripts of students engaging in mathematical or scientific inquiry; and (4) closely interacting with learners through a capstone “Learning to Listen” project, which requires PSTs to engage a group of learners in an open-ended science or mathematics question. Throughout these activities, PSTs are asked to critically reflect on their own experiences as leaners as well as on K-12 students’ ideas and experiences. Using multiple data sources, including PSTs’ written assignments and in-class discussions, we examined evidence of PSTs’ expansive conceptions and explored how they manifested in their evolving ideas about science teaching.

We first cataloged each of the PSTs weekly discussion board posts where they reflected on course readings and analyzed videos of student thinking. Using a grounded theory approach (Charmaz, 2006), we then took several iterative passes reading the PSTs’ discussion board posts and tracking instances of expansiveness. Examples of such instances included moments when PSTs discussed the merit in a student’s idea and their sensemaking resources or reflected on larger societal narratives that shape classroom experiences. The first and second authors met weekly to discuss such instances and share their analytical noticings around them. Through this work and our ongoing discussions, we identified themes to describe the ways in which expansiveness surfaced in PSTs’ engagement with the course materials, and how this expansiveness manifested in their ideas about science teaching.

Findings

Due to space limitations, here we illustrate our findings using data from only one discussion where PSTs reflected on an essay from Warren and Rosebery (2008), “Using Everyday Experiences to Teach Science.” The themes discussed below, however, apply more broadly across posts and reflections. In this essay, the authors feature vignettes of students using their everyday experiences as resources for sensemaking about water cycle and gravity.

Research question 1: Expansive conceptions of science learning

Our first research question concerns the ways in which PSTs developed more expansive perspectives around science learning. In their analysis and reflection on the piece from Warren and Rosebery (2008), we saw clear evidence of PSTs' expanding conceptions of science learning in how they oriented to students' everyday experiences and their valuing of heterogeneous ways of sensemaking. For example, PST Molly wrote:

> "The students seemed to be very good at applying what they were trying to understand to things that they had experienced in real life… even though their wording was not what I would have expected… it makes sense that students from different backgrounds would have different criteria on what makes water unusable. I just was not thinking about it and it surprised me."

Here, even though the students' language surprised her, Molly recognized the value of students' varied experiences as resources for their sensemaking about a complex scientific phenomenon. Through this comment, Molly acknowledged that her expectations ("their wording was not what I would have expected") and her sense of surprise were stemming from her failing to consider how students' experiences and backgrounds may engender heterogenous ways of sensemaking and expression.

PST's expansive conceptions also manifested in how they problematized deficit discourses. Reflecting on the reading, another PST, Serena, tuned in to "negative assumptions" sometimes held by teachers about the capabilities of students who speak languages other than English, which she refers to as "outlandish and antiquated." Such assumptions, Serena noted, can impact the learning experiences of culturally and linguistically diverse students by making "it seem as though the gap between what these students can learn and what they already know is so large that it might be futile to even try." Relatedly, another PST, Kendall, noted that these deficit narratives are reproduced by "a system where curricula and rules are centered around being White and the White experience." In this system, she writes, marginalized students must either "conform to the Whiteness of the schooling system… [which] is a very large burden to carry" or be "alienated."

Research question 2: Expansive conceptions of science teaching

With respect to conceptions of science teaching, we saw evidence of expansiveness in the ways PSTs described the importance of opening up and holding space for students' ideas as well as in their critical reflections on their own biases and practices. For example, in connecting Warren and Rosebery's (2008) essay to her future teaching, PST Adeline asserted that "Students can't possibly be blank slates, and I wouldn't want them to be," because students' everyday ideas are "resources for learning." Adeline acknowledged that even though it would be "challenging to imagine" how she might work to make disciplinary connections to students' everyday ideas, this is a goal she aspires towards in her future practice. In another reflection, Adeline noted:

> "Students bring knowledge to the classroom that forms their understanding…and teachers need to listen to students, understand their thinking, and then adapt their teaching to best fit their students' needs so they can better understand the whole concept… we need to learn to listen and not assert our own ideas, assumptions, or expectations on our students."

In this reflection, Adeline recognized that an important aspect of teaching is learning how to "listen to students" to "understand their thinking" instead of evaluating and judging learners based on one's "own ideas, assumptions, or expectations." This stance of decentering from one's own perspective to tune into students' is a productive beginning towards a more expansive framing of teaching, a framing that centers and holds space for students' own ways of knowing. PSTs also commented on the importance of attending to and confronting their own assumptions and biases that might stand in the way of enacting such instruction. For example, in thinking about her future teaching practice, Kendall reflected on how such introspective work and critical reflection is an essential "first step":

> "Our first step is to recognize that we can be biased. If we are able to examine our own behavior and biases, then we can also critique and adjust them. It would be beneficial to… ask myself 'who did I talk to the most in class?' or 'what students were most engaged? And did I work to engage some students more than others?'"

Discussion

In science education, there is a call to trouble narrow assumptions that (re)produce deficit narratives and injustices (Kayumova & Dou, 2022). This presents a unique challenge for science educators because dominant portrayals of science depict narrow framings of the discipline that bound what counts as ontologically and epistemologically valid, and marginalize students with divergent ways of thinking, knowing, and participating in science (Bang et al., 2012). As we seek to expand PSTs' understanding and appreciation of students' meaning-making repertoires beyond what has been traditionally valued, it is essential that we understand how PSTs begin to form more expansive considerations for “what counts” as intellectually generative for science learning and “who counts” as capable of learning science. In our study, we found that such expansive considerations manifested in PSTs’ developing insights about the brilliance and capabilities of students, their valuing of diverse perspectives and intellectual resources, and their recognition of the harm that deficit narratives cause to minoritized learners.

Additionally, we found that these expansive conceptions of science teaching manifested in PSTs' ideas about teaching science. As PSTs discussed and reflected on the practice of teaching, they tuned in to the importance of making space for students and their diverse ideas, responding to students’ contributions and forms of engagement in affirming and humanizing ways, and critically reflecting on their own biases and assumptions. These teaching considerations are a crucial first step toward enacting teaching practices that honor students’ humanity and agency in epistemically just ways. When teachers support students in bringing their whole selves to their science learning and value students’ cultural, linguistic, and experiential repertoires as valuable for sensemaking in science, they send messages to students that they are capable, agentive, and brilliant (Robertson & Atkins-Elliot, 2017).

It is important to note here that, while we share here a picture of productive beginnings towards more expansive conceptions of science learning and teaching, we are not suggesting that these orientations are in any way a “finished product” or that these PSTs—or any teacher, for that matter—would “hold” and enact such conceptions at all times and in all contexts. Conceptions may indeed be contextually constructed and may change over time. In future research, therefore, it will be important to explore how these expansive conceptions may stabilize over longer periods of time, and how they might manifest, and perhaps shift, in interactions with students in the complex work of teaching. Relatedly, there is a need for continued research on the design of educative experiences and support structures that uphold both preservice and in-service teachers in the work of problematizing and desettling dominant discourses around science, science learning, and science teaching, towards cultivating more expansive and humanizing science learning environments.

STEM Education for Sustainability: Finding Grounds for a Constructive Dialogue in Indigenous Contexts.

Martín Bascopé Julio, Centro UC de Desarrollo Local (CEDEL UC), Pontificia Universidad Católica de Chile,
mbascope@uc.cl

Abstract: This paper argues that Science, Technology, Engineering, and Mathematics (STEM) education can overcome an instrumentalist perspective on these challenges and provide spaces for transdisciplinary dialogue to affront the loss of meaning when facing complex and divergent problems that cannot be solved logically or that rely on ethical assumptions. The present work corresponds to a section of a doctoral dissertation that provides an inductive and holistic perspective for early science education (from age 4 to 10), based on local challenges to affront sustainability dilemmas. The paper provides a five-domain framework to plan and develop STEM projects that promotes a dialogue with local and indigenous knowledge.

Context and aims of the paper

The physicist and mathematician G.N.M Tyrell proposed the terms "convergent" and "divergent" to distinguish between problems that can be solved logically from those that are not. The positivist perspective, the reductionism, and hyper-specialization of science, sometimes fail to provide a practical solution, especially when facing complex challenges such as climate change or socio-ecological dilemmas. What can science education do about it? How can the schools become part of the solution? What happens in intercultural and indigenous contexts where diverse worldviews collide during the educational experience?

Sustainability and complex socio-ecological problems (e.g., climate change, land-use conflicts, responsible consumption, production) are usually divergent problems that cannot be easily solved instrumentally or logically. All the frameworks referring to the so-called challenges of the XXI century are aware of this complexity and the necessity to adapt the educational systems to understand that the instrumental or standardized scope in science education is neither sufficient nor an adequate path to follow. The present paper makes an effort to land the global challenges of sustainability in kindergartens and schools. It emphasizes the importance of an inductive, integrated, and place-based scientific approach to give tools for constructive dialogue and the development of new localized knowledge in indigenous contexts, providing small solutions for sustainability challenges. In this way, it presents evidence on how to conduct learning experiences to develop basic argumentative and practical skills to attend to local sustainability issues and provide the possibility of a fruitful dialogue in indigenous and intercultural contexts.

Besides the necessity to re-think the scientific scope to affront the complex problems of the XXI century, there is also the need to reach all students with scientific education, particularly those who have been historically marginalized for their cultural distance to science. Scientific structure, logic, and scientific narratives are sometimes far away from real-world situations and could be considered external or imposed in regions with a colonial history. The idea of initiating a genuine dialogue and open discussion on the ethical and epistemological foundations of science is necessary to promote change and give tools to the new generations to affront a complex future scenario.

This paper elaborates how integrated and context-relevant scientific education opportunities can raise students' motivation and develop agency towards sustainable futures. It also observed how STEM education opens to local knowledge in indigenous contexts and helps understand how children, teachers, and the community can benefit from these initiatives. As a result of the research process, this paper will provide a conceptual framework to guide further research in the area, providing ideas for further research to measure skills, motivation, and contextual aspects to consolidate what nowadays is an emergent field of research.

The idea of rethinking scientific education at an early stage implies not only proposing new methods to learn scientific content but also being aware of the importance of the ethical foundations of the scientific perspective, how permeable sciences are to the diversity of contexts, and assuming the ethical foundations behind the positivist scope. The scientific evidence about the limits of the earth, and the prediction about climate all over the globe, urges the necessity of building diverse and contextualized ethical foundations along with solid scientific skills and integrated educational opportunities.

This does not mean by any chance the idea of replacing the specialized for a holistic scope in science. It would be naïve to neglect the remarkable progress of scientific knowledge through the reductionist lens. However, understanding that the new challenges for science cannot be entirely solved by reducing complexity (since we are facing many divergent problems) opens a path for transdisciplinary dialogues and collective constructions with practitioners in diverse contexts.

At the school level, the idea of approaching divergent problems through active STEM methodologies and the development of inductive thinking to creatively affront real-world problems will be discussed in this paper. This framework contributes to the relatively new discussion on education for sustainability and STEM education, providing a theoretical basis for the implementation of coherent and inclusive STEM educational opportunities based on the latest articles, reviews, international frameworks, and the empirical work conducted after eight years of implementing a STEM education program in the south of Chile. I will elaborate on the importance of including the school's context to provide culturally relevant learning experiences, focusing on indigenous contexts, presenting a five-domain frame to promote a dialogue between scientific and indigenous knowledge.

Constructive dialogue with Mapuche knowledge

Mapuche means people (che) of the land (Mapu). Like those of many Amerindian and eastern civilizations, their worldviews and traditional practices are essentially ecological, recognizing humans, plants, bodies of water, and other beings as co-inhabitants. (Rozzi, 2013). Opening the scholar culture and the STEM education research in specific, making it permeable to these diverse worldviews under a broad understanding of what STEM education means, can make a big difference in the challenge of sustainability and environmental degradation.

When talking about Mapuche learning and worldviews, it is vital to avoid falling into stereotypes and essentialist views about their traditions and ways of living. Nevertheless, there are some previous efforts to establish a constructive dialogue between scientific education and Mapuche learning traditions. Torres et al. (2011) stress the importance of a sociocultural perspective on learning, which puts on the center the idea of learning by doing to incorporate culturally relevant knowledge. Knowledge about nature and society are embedded in social memory and transmitted from generation to generation, and new pedagogical approaches can be an opportunity to incorporate new sources to establish a fruitful respectful dialogue.

Studies focused on Mapuche ways of learning have observed interactions between learners and teachers, finding that the teacher figure does not exist. Instead, there is an image of wise people who share knowledge through interaction in outdoor spaces and everyday life situations rather than by formal means (Quilaqueo et al., 2010; Quintriqueo & Torres, 2012). Parents and adults are knowledge managers in children's environment and model how to put knowledge into practice, either through play or in the daily chores inherent in community and home life (King & Schielmann, 2004; Llanquinao, 2009). In this adult-child relationship, the autonomy of children in resolving the situations they face is privileged, and few instructions or orders are observed (Ibáñez-Salgado, 2015).

School dynamics can dramatically break local epistemologies, approaches to learning, and the relationship with adults, setting new structures under the umbrella of "good behavior". As a result, the school contents can lose their experiential character, often becoming distant, odd, and foreign to the students. Teachers have a central role in the classroom, giving orders and shaping the practices and ways of learning in the classroom. However, this situation can be remedied and redirected by the school by using educational approaches that integrate students' prior knowledge and learning dynamics in their cultural systems. (Bascopé & Gutiérrez, 2019; Bascopé & Reiss, 2021). Here STEM4S projects with the previously defined characteristics can establish a path to promote culturally relevant learning and create the spaces for a dialogic and constructive learning experience for the students to confront complex challenges in their daily lives, both during their school experience and in their future.

In this direction, we developed a five-dimensional framework to build STEM4S projects (Bascopé & Caniguan, 2016). After proving its usability during the ethnographic work in 2019, a summary of this five-domain framework was published (Bascopé & Reiss, 2021). To build this five-domain framework, we conducted comprehensive fieldwork with a group of five schools and their external communities in 2014 and 2015, covering different territories of the Araucanía region in Chile. Using a qualitative methodology based on in-depth interviews with teachers, traditional educators, families, and indigenous community leaders, we aimed to find suitable sources and topics of local knowledge that might be included in a scientific inquiry-based learning curriculum (Bascopé & Caniguan, 2016). The five domains were produced after a systematization and coding process and compared to the Chilean national curriculum to examine curricular objective coverage at the primary level, revealing many objectives per dimension across the primary curriculum. The following is an overview of how these domains apply to STEM4S projects, based on the experience of 2019:

Health and the human body

This domain connects with several UN sustainability goals, being a fruitful space for connecting global with local challenges. Traditional medicine and knowledge about medicinal herbs are used daily in Mapuche communities, with profound knowledge connected to the native forests and traditional green gardening practices. Therefore, recognizing these traditional sources of knowledge to establish a dialogue with the curricular objectives is a fruitful field to start STEM4S projects. This domain's contents can be developed both inside and outside of the classroom, and they can be supplemented with specific knowledge of native flora and its peculiarities. The chemical processes behind the preparation of the medicines, the importance of the relationship between species for socio-ecological systems' conservation, and the historical struggles associated with the perpetuation of this ancient knowledge are just some examples of the fruitfulness of this domain

Traditional foods and culinary processes

Cooking recipes and food preparations represent another area for profound dialogue between scientific and indigenous knowledge. Processes of dehydration, fermentation, and decomposition of food are linked with different flavors, textures, and techniques that allow food preservation. The knowledge present in the kitchen is intrinsically connected with family traditions and everyday routines. It is a trendy topic for the schools' external community, especially to generate an intergenerational dialogue with a significant presence of grandparents. The elders can share their history and the reasons behind the recipes and dishes that have started to be forgotten due to the scarcity of the ingredients or the replacement of familiar traditions and rituals. Sustainable food consumption and production are at stake, along with health and alimentary sovereignty topics that can be explored and discussed in this domain. It provides a solid ground for creating STEM4S projects giving diverse routes for exploration, all of those with the potential of gaining interest and producing impacts in the community.

Crafts and tools manufacture

Tool manufacture, goldsmithing, and other crafts are connected with local traditions and the ongoing work and expertise of parents in the school community. For example, the dyeing of wool with vegetable species is a traditional practice, and it connects the importance of the local environmental conditions with ancestral sources of know-how that have been losing their strength as working opportunities for the new generations. Same with all the locally relevant manufacturing techniques that use local resources. This is another fruitful field for starting STEM4S projects. It connects local environmental challenges with local and scientific knowledge and provides an opportunity to revitalize ancestral techniques renewing their value and providing opportunities and start new endeavors based on a solid research path conducted by the school in collaboration with the local community.

Ecosystems and agriculture

This could be the more straightforward domain for the implementation of STEM4S projects. It is not about the blind incorporation of traditional agricultural practices but rather about exploring local practices with all the accumulated knowledge on agroecology and sustainable management. Local traditions can be connected with modern agroecological perspectives, allowing learning about traditional practices and combining them with other sources to improve land use and diminish the impacts that traditional practices might have on the ecosystems. The traditional conservation focus of environmental education, which has been criticized in the literature as a "not good enough scope", can be combined with a modern technological solution and complemented with perspectives from the community to provide new ideas for local development. The identification and naming of flora and fauna and local legends about different species and their relationships are all part of previous generations' narratives and can be a significant source of constructive conversation and meaningful answers to local concerns. The soil types found in their territories, for example, will be crucial in deciding the agriculture and varieties of planting to be established, as well as enabling for activities such as pottery, vegetable fiber work, and others, depending on the species found in their territories. This topic also gives space for discussing the importance of biodiversity or understanding the complexity of the ecosystemic balances.

Worldviews and spatial-temporal notions

There are specific ways of measuring and interpreting time to guide domestic work, ceremonies, and other locally-relevant activities. Learning about ancestral calendars and symbolic representations of time are also fundamental aspects to connect and understand the local environment and social characteristics around the educational facilities. These structures are designed to track how much time one spends doing or should spend doing specific activities. Knowing some natural cycles, for example, can help determine the best times of day to do particular agricultural or other traditional activities. In addition, local knowledge about space, the stars, and other signs, that may be related to weather and other social and environmental phenomena is a highly appreciated local knowledge that can inspire motivating STEM4S projects. Furthermore, local worldviews, myths, tales, and oral traditions also reveal the value system of the previous generations, giving sight to the ethical and aesthetic perspectives grounded in the schools' contexts that can contribute to the debate about sustainability. Value-based discussion can help to create a climate of open dialogue and understanding of the moral dilemmas present in the complex sustainability problems that schools face in their surroundings.

Although the five domains presented here seek to connect local knowledge in indigenous contexts with STEM knowledge and skills, it is worth noting that local knowledge should not be trivialized or reduced to scientific thought codes. The inclusion of these topics, on the other hand, creates a place for discourse on historical and cultural issues, which, despite not directly agreeing with the scientific perspective, allows official learning opportunities to be placed in dialogue with other worldviews.

This analytic exercise does not intend universality in terms of covering all possible connections with local knowledge in Mapuche contexts. It is just a way to open the debate about the significant number of possible connections that can be proposed with an integrated and transdisciplinary scope, to open the schools to their territories, complexity, and main problems. It also opens the door to educational practitioners to find routes to transform educational opportunities, generating a real connection of the curriculum with their contexts and creating a space to build small solutions and make contributions to solve actual local and global challenges.

It is important to remark that this is not by any chance an attempt for a comprehensive understanding of the Mapuche perspective. Any attempt will end with a reductionist vision of the great diversity present in the Mapuche community. Instead, this analytical exercise tries to overcome the common essentialisms and provides opportunities to create constructive dialogues to affront real socioecological challenges. The Mapuche context is just an example that can be extrapolated to other indigenous and non-indigenous territories, like schools with high immigration populations willing to work in connection with their communities.

"Shake the Slinky More": Exploring the Medley of Meaning in Middle School Science Students' Language

Jared Arnell, Utah State University, jared.arnell@usu.edu
Hillary Swanson, Utah State University, hillary.swanson@usu.edu
LuEttaMae Lawrence, Utah State University, lu.lawrence@usu.edu

Abstract: Learners routinely struggle to adapt to the rigorous nature of scientific language. Discrepancies between scientific terms and their casual counterparts can create challenges for science communication and instruction. We observed the language used by a classroom of middle school science students as they learned about mechanical waves. We documented instances in which the same language was used to convey different meanings. Specifically, students used "speed" to refer to both velocities and frequencies and used scientific terms like "force," "energy," and "power" interchangeably. The teacher was dedicated to helping students make sense of the meanings behind the words they were using, however, time constraints made it difficult for her to address all the terms. Developing tools and interventions to identify language challenges and providing educators with the skills and resources needed to implement those tools are important tasks for the Learning Sciences.

Introduction

The language of science can be difficult to master. Casual, everyday words can transform into rigid, definitional vocabulary in the physics classroom, sometimes with radically different meanings and connotations (Williams 1999). Experienced physicists have years of practice exercising precision in scientific language. Novices must develop their language practices while simultaneously incorporating novel terminology into their lexicon. Often, physics educators and textbooks will use physics terms without considering the disparity between their technical definition and students' informal definitions. Students then formulate conceptual connections based on how they understand the terms in use, leading to alternative conceptions that can increase the challenge of learning normative science conceptions (Touger, 1991). Student difficulties with language can persist beyond introductory courses; Itza-Ortiz et al. (2003) found that a majority of nonscience majors surveyed in a traditional physics course struggled to articulate the difference between the everyday and formal definitions of words like force, momentum, and impulse. Going further, intermediate physics students who have completed the introductory courses and moved on to more advanced classes still misplace terms and use imprecise language (Arnell et al., 2022).

Refining students' use and understanding of scientific language is paramount to supporting their learning. Linguists have long examined the profound influence language has on cognition (Lakoff & Johnson, 1980). Every aspect of language, from definitions to grammar, shapes the way our minds conceptualize the subjects of our communication (Evans & Green, 2006). Such influences are especially important in science communication, where conceptual models can be encoded by the grammatic and semantic components of language, even when the speaker is unaware of the subtext (Brookes & Etkina, 2007; Talmy, 1988). This work positions the natural language of novices as a window into student understanding; our goal in this paper is to attend to the words used by young learners during sense-making activities and decipher their meaning.

Theoretical framework

The development of the featured instruction and the subsequent analysis of its data were guided by a cognitive perspective called knowledge in pieces (KiP; diSessa, 1993), which views knowledge as a complex network of atomized elements and resources that guide sense-making when activated. Novices tend to both under- and overextend resources due to inexperience, misleading cues, or context. For novices to cultivate expertise, they must gradually reorganize and repurpose knowledge elements and their contextual applications. This view of refinement over replacement makes KiP a constructivist, anti-deficit framework (Smith et al., 1994) and sets KiP in contrast to "misconceptions" perspectives, which label prior knowledge as an obstacle to learning (McCloskey, 1983). Where these perspectives would frame the purpose of instruction as identifying and confronting students' incorrect ideas (Maclin et al., 1997), KiP advocates encouraging students to articulate and reflect on their own thinking (Hammer et al., 2012).

KiP is well suited to analyze the language of naïve learners. In his foundational monograph, diSessa (1993) postulated that primitive knowledge resources would be situated in "areas of strong descriptive (representational) capability" (p. 122), predicting a close relationship between student intuitions and the language they use to describe their reasoning. Later KiP work would refine the methodological considerations for applying the theory to language analyses (diSessa et al., 2015). Redish and Kuo (2015) discuss in depth how KiP and the wider cognitive linguistics field have many congruent tenets, such as conceptualization through bodily experience, flexible application of ancillary knowledge, and context-driven synthesis of meaning. As a language-centric example of KiP, Parnafes (2007) compared the way physics students speak when reasoning about a swinging pendulum or a vibrating spring. Parnafes found students used terms like “fast” and “quick” to refer to both the velocity of the pendulum and the frequency of the spring, despite these characteristics being conceptually distinct. The ambiguity seemed unproblematic from the student’s perspective but presented a challenge for their learning, as the blended concept interfered with their ability to attend to relevant system features. The application of KiP theories to these episodes elucidated both the origin and consequence of students’ language decisions.

Methodology

The data discussed in this paper come from the classroom of one teacher, whom we call Mrs. K, who teaches in a rural middle school in the Intermountain West region of the US. Mrs. K’s classroom had 31 eighth-grade students who worked both alone and in small groups. We partnered with Mrs. K as part of a larger design-based research project to co-design instructional units that engaged students in scientific theory-building practices. This study comes from one unit that scaffolded students’ construction of sound wave models. The sound wave unit covered two weeks and included a wide variety of demonstrations, activities, and visual aids. We draw our observations from one activity, in which the students were split into small groups and given a slinky, which they used to physically model waves. The students were given a worksheet which prompted them to state their predictions, record their observations, and articulate their reasoning while engaging in a theory-building process. We selected two open-ended questions from the worksheet for analysis: the first (Q1) asked the students how they might make a wave with higher frequency, while the second (Q2) asked how they might make a wave with higher amplitude.

Data analysis was done in accordance with knowledge analysis (KA; diSessa et al., 2015), a methodological approach which often accompanies KiP research. KA uses an iterative process of coding which allows patterns to emerge organically from the data. The students’ answers to each question were initially categorized by the language used in each response. These categories were then analyzed to understand how the students were using various scientific terms to represent their underlying reasoning. Video recordings of Mrs. K leading a classroom discussion at the end of the sound wave unit were also collected. These transcripts were reviewed to analyze Mrs. K’s reaction to the students’ language use.

Findings and discussion

Shaking the slinky

The focal activity asked students to stretch a slinky along a table and shake it to create mechanical waves. Q1 and Q2 asked the students to consider how they might alter the frequency and amplitude of the waves, respectively. The most common responses are shown in Table 1, along with a characteristic example.

Table 1

Frequency and Examples of Common Response Categories from Q1 and Q2

	n (Q1)	Q1 examples	n (Q2)	Q2 examples
Speed	7	“Move the spring way faster”	6	“Move hands faster”
Movement	0	*N/A*	8	“Shake the slinky more”
Effort	3	“Use more force and energy”	5	“More force moving the slinky”
Trade-off	4	“Go smaller”	1	“Make waves that are kind of slow”
Precise	2	“More pulses”	5	“Move the spring farther out”

Statements that incorporated the concept of *speed* were the most common response to Q1 (how to raise frequency) and featured prominently in Q2 (how to raise amplitude) as well. This is noteworthy because the physical motions to achieve higher frequencies and amplitudes are distinct: higher frequencies are made by making the slinky perform more wave cycles in a given time, while higher amplitudes are made by moving the slinky farther from equilibrium with each wave. At first, it may seem surprising that students would describe two experientially unique movements with nearly identical language. However, as was experienced by the students, both movements do result in the lateral movement *speed* of the slinky (or the hand holding the slinky) increasing. The tendency for students to use generic *speed* responses for both circumstances is in line with the findings of KiP. Novices have not yet developed the overarching or global connections of experts, resulting in a narrow focus on whatever concepts are deemed most relevant to the immediate problem. This contextual limitation was exemplified by three students who provided *speed* responses to both Q1 and Q2, despite the activities being only minutes apart. From the vantage point of the students, it was irrelevant that their *speed* statements could have also applied elsewhere; the salience and relevance of *speed* within the immediate context was enough to justify its use in describing the phenomenon.

The *speed* answer can be correct in either case, but only conditionally: increasing *speed* would increase frequency only if the amplitude remained constant, and it would similarly increase the amplitude only if the frequency remained constant. None of the students who provided *speed* answers gave these conditions; instead, they categorically provided short, simple answers like “go faster,” “do it faster,” and “move it faster” in both Q1 and Q2. These minimalistic responses were likely perceived by the students as being wholly sufficient. After all, they could see the increased *speed* of the slinky directly causing a change in the properties of the wave. With such an easily observable causal mechanism, further clarification would seem unnecessary. The lack of specificity in the students’ *speed* responses means that these answers have multiple interpretations, only some of which may be correct for a given question. For an instructor attempting to assess the accuracy of their students’ conceptions, such responses could indicate success but could also hide crucial misunderstandings.

Another common response was to use more *effort* when shaking the slinky. This response had the most variation, with statements ranging from the casual “move it harder” to the more scientific “use a greater force and energy” and “more force and power.” These responses seem to be a more embodied version of the *speed* responses, focusing instead on the *effort* needed to grant the additional *speed* rather than the resulting *speed* itself. Once again, these answers are technically correct, but lack necessary precision. Increasing the *effort* used to shake the slinky could increase the *speed*, frequency, and amplitude in any number of combinations depending on the way the *effort* is expended. However, these numerous possibilities for the applications of *effort* were likely not present when the students were reasoning through their responses. Instead, they were merely reporting on the bodily sensation they felt when trying to impact the frequency and amplitude of their wave, and they used familiar language to describe the experience. Notably, the students’ *effort* responses appear to use the terms force, energy, and power somewhat interchangeably. This looseness with vocabulary also reflects the casual relationship the students have to the language used in their responses; they have likely heard force, energy, and power used similarly to describe *effort* in everyday conversations and are applying that informal definition here.

Overall, the students did not appear to struggle with conceptualizing the wave characteristics or how to modify them. In fact, the students showcased a variety of productive resources to explain their experiences; they were merely using accessible or casual language to describe their observations. This informality was seen as the students used identical *speed* language to describe multiple phenomena while also using a variety of *effort-related* language to describe a singular embodied experience. As a result, most responses (34 out of a total 40) were statements that may indicate correct reasoning but lack the precision necessary to interpret meaningfully. Only one student gave an answer that could only be interpreted as incorrect (saying “go shorter” for Q2).

Making sense of students’ language

At the close of the sound wave unit, Mrs. K invited each group of students to reflect on their experiences and summarize the most salient lessons they had come to understand through the activity. Mrs. K asked each group to share one lesson or observation in a class-wide discussion. She added each group’s on the board at the front of the classroom. Mrs. K noticed that several groups’ suggestions had similar imprecise wording. Four groups provided statements which described the relationship between volume and the size of a sound wave, though their language was inconsistent and unclear. Among their responses were “the closer the person is, the sound is bigger” and “the louder the volume, the greater the sound wave.” Mrs. K sought to bring the students’ attention to their use of language, saying “We have people saying things like ‘faster, greater, louder,’ and I’m not sure we’re all talking about the same thing… what does ‘greater the sound waves’ mean and look like?” Students attempted to clarify, suggesting that it meant “there are more waves moving through” and “the waves look bigger.” For each suggestion, Mrs. K offered methods for how the students could verify if these suggestions were valid, such as counting the number of waves in a period of time. If more time had been available, it may have been possible for Mrs. K to review more student responses, recognize these patterns, and address the problem areas. However, as is seen often in secondary education, she needed to move on to keep pace with the curriculum.

Conclusion

Helping novices develop precise language is of utmost importance to science education. Young learners need more experience to comfortably wield scientific jargon in the manner of experts, and so resort to using comfortable or familiar language. In doing so, they may inadvertently sow seeds of misunderstanding by entangling scientific words with their often-dissimilar lay counterparts. To compound the matter, novices should not be expected to be aware of such discrepancies, which means they will go unaddressed unless attention is actively directed to them by guiding experts. Catching these incongruities early and course-correcting is crucial to ensure students' knowledge systems develop in the direction of normative science.

We observed numerous examples of middle school science students using vague or ambiguous language when studying wave mechanics. They regularly gave answers which contained productive elements but lacked the context or clarity to ensure an accurate interpretation. The most prominent example was the students' application of the concept of *speed*, as students simultaneously applied the vague notion of *speed* to refer to conceptually distinct phenomena. The students also routinely used "force," "energy," and "power" interchangeably. When attempting to address the inconsistencies of her students' language, Mrs. K began to help her students disentangle the multiple meanings they were giving their words, however, she did not have sufficient time to allot to the discussion and was forced to move on, leaving a number of language issues unattended.

Misalignments between students' understanding and articulation can create challenges for later conceptual learning. The refinement of student language is an important facet to consider when designing interventions, curriculum, or learning tools. The utilization of KiP frameworks can help researchers identify the many diverse meanings underlying language used by students and locate productive resources for building scientifically precise and appropriate vocabulary.

Exploring Algorithm Building Through Designing and Making Kinetic Sculpture

Joey Huang, Lora Cawelti, Kylie Peppler
joey.h@uci.edu, lcawelti@uci.edu, kpeppler@uci.edu
University of California, Irvine

Abstract: Algorithm building, creating a step-by-step procedure to carry out a solution, is a challenging concept for youth to learn and practice. Kinetic sculpture is a novel context for examining how students may learn algorithms through designing and making. As part of a larger study, we collected and analyzed a total of 18 student pre- and post-tests on computational thinking, physical computing, and arts. To examine how students build algorithms in the process of designing and making a kinetic sculpture, we analyze two vignettes from two small groups in a STEAM-based workshop. Findings show that while designing and building kinetic sculpture, students learned computational thinking and applied algorithms by incorporating inputs, outputs, and variables during the process. This study offers a springboard to investigate how students create and apply algorithms in designing and making kinetic sculpture and provides empirical evidence on how students learn algorithms in a STEAM learning context.

Introduction

Computational thinking (CT) includes conditional logic, debugging, distributed processing, and algorithm building (Wing, 2006). In computer science, algorithms are step-by-step responses to problem-solving and used to generate solutions as well as serve as heuristics to design processes to solve complex problems. Additionally, algorithms are identified as a required concept to learn in K-12 computer science (CS) education (CSTA, 2020). Applying algorithms allows learners to create a suitable output for a given input (Denning, 2009). Furthermore, algorithms are primarily explored within CS courses in K-12 schooling (Ciccone, 2021), which creates missed opportunities for developing students' algorithm building in other disciplines or multidisciplinary contexts. In this paper, we define an algorithm as the practice of creating a step-by-step sequence of procedures for carrying out a solution or process.

Studies have examined how students learn CT and algorithm building in robotics and STEM (Ioannou & Makridou, 2018). However, recent studies have shown how students can learn CT more effectively in STEAM-based learning environments than traditional programming activities due to participation of design-based activities (Wang et al., 2022). Kinetic sculpture is a promising application for learning complex concepts in arts, STEM, and computing for college students (Yilmaz, 2014). Sculptures take three-dimensional space, requiring both visual and structural balance. Kinetic sculpture may be designed and programmed to interact with nature, using wind or water to exert force, or it may incorporate technologies like simple crank motors or preprogrammed servo motors and LEDs. As such, interacting with a kinetic sculpture supports the learning of complex CT concepts, such as parallelization (Chowdhury, 2015). However, it was unclear how students learn CT, particularly algorithms, through the process of making and designing a kinetic sculpture. Therefore, we argue that it is compelling to investigate how students learn and build algorithms through designing and making a kinetic sculpture in a STEAM-based learning environment. In this study, we ask: 1. To what extent do students learn CT in making a kinetic sculpture? 2. How do students apply and build an algorithm in the process of designing and making a kinetic sculpture?

Workshop design

Grounded in a constructionist approach to learning through hands-on designs (Papert & Harel, 1991), we understand learning of CT to be both an individual and social process mediated by the design and sharing of external artifacts (Kafai & Proctor, 2022. Additionally, this study is guided by Wing's foundational work defining algorithm building to identify targeted key practices of algorithm building in action in a classroom setting. Kinetic sculpture was chosen because of its promising application for applying complex concepts in arts, STEM, and computing. In our lessons, fifth- and sixth-grade students designed sculptural movement using inputs like sensors, buttons, and potentiometers, and preprogrammed outputs like servo motors and LEDs. Over the course of a 4-day workshop, students started by learning and programming inputs and outputs of their kinetic sculpture with varied variables. Later in the workshop, we gave students freedom to create any abstract or representational design they wished. Creating kinetic sculptures required students to think across multiple domains and apply CT and algorithms to building an original design that moves.

We designed the lessons in this study with consideration of both media arts standards (NCAS) and engineering design standards (NGSS) as well as California computer science standards in two core concepts: 1) Decompose problems and subproblems into parts to facilitate the design, implementation, and review of programs; and 2) Seek and incorporate feedback from team members and users to refine a solution that meets user needs. According to the standards these two concepts centered on algorithms which students create and build step-by-step procedures to solve a problem or carry out a solution. In this paper, we focus on the ways students apply algorithm building by using the components and concepts like inputs (e.g., potentiometer), outputs (e.g., servo motor), and variables (e.g., speed, time) as well as design materials during the process of designing and making a kinetic sculpture. Over the course of the workshops, objectives were sequenced around learning arts concepts through kinetic sculpture and physical computing with the Grove Beginner Kit for Arduino and a block-based Arduino coding platform, Grove Blockly, designed by the research team. Students worked collaboratively to design and create kinetic sculptures by using computational and electrical (e.g., Grove Blockly, servo motors), structural (e.g., cardboard, foamboard), and aesthetic materials (e.g., feathers, colored felt). Students apply and create algorithms, step-by-step procedures (sequencing), in order to solve the problem they identified in iterative design processes. Table 1 shows the workshop sequence and duration.

Table 1
Lesson Sequence and Duration

Day 1	Day 2	Day 3	Day 4
Pre-Test Administered 30 minutes	Group A: Physical computing and coding lesson (identify the inputs and outputs, program LED and servo motor with push buttons and potentiometer) 1 hour, 15 minutes	Group A: Art and design lesson 1 hour, 15 minutes	Combined making: All students making kinetic sculptures (coding, connecting, building); Post-Test Administered 2 hours, 20 minutes
	Group B: Art and design lesson (identify elements and features of kinetic sculpture, plan and design using servo motor or sensor with LED) 1 hour, 15 minutes	Group B: Physical computing and coding lesson 1 hour, 15 minutes	

Methods

This study was conducted in spring 2022 at a charter school in Orange County, California in a combined 5th-6th grade classroom. A total of 25 students participated in the study (and a near equal split of students that identified as girls and boys in the classroom). Based on the results of pre-survey from students, 9 students were White, 6 were mixed race, 2 were Latinx, 2 were Asian, and 6 were other. Most students (over 70%) had no prior experience with physical computing but reported prior arts experiences (e.g., painting, crafting) before the workshop. We used 360° cameras placed next to students in small groups and collected a total of 15 hours and 44 minutes of video across four focus groups (3 dyads, 1 triad). The lesson sequence occurred over four days (see Table 1).

A total of 25 students participated in the workshop and seven were removed from the analysis due to absent consent and incomplete pre- or post-test. To answer the research question, we analyzed 18 students' (M =7, F =11) pre- and post-test to examine the learning of STEAM concepts, focusing on physical computing, CT, and arts on the topic of kinetic sculpture. Particularly, this paper will focus on the results of physical computing and CT to examine students' learning gains on algorithm building. The pre-test included demographic questionnaires and questions regarding prior knowledge on physical computing and arts for researchers to better understand students' backgrounds. We applied paired sample t-tests to examine if there were learning gains from pre- to post-test. Building on the results from pre- and post-test, we then included two vignettes to unpack the ways in which students applied and built step-by-step algorithms with outputs and variables from the processes of design and making. The vignettes included one dyad and one triad group. In this paper, we chose to focus on these groups because, as we reviewed the collective video data, we noticed the unique ways they negotiated sequential design choices for their sculpture including sophisticated decisions around sequencing and problem solving. The video selected is from the final day of instruction where students were finalizing their designs and building their sculptures with minimal teacher-led direction.

Findings

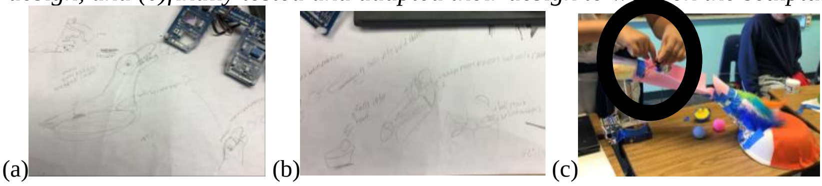
In this study, we explored how students build, develop, and modify algorithms during a co-design process including the use of inputs, outputs, and variables. First, the paired sample t-test results showed that students improved significantly from pre- ($M = 3.83$, $SD = 3.92$) to post- ($M = 17.11$, $SD = 5.32$) test $t(17) = 10.19$, $p < .001$. Particularly, students showed improvement on the questions of CT and physical computing from pre- to post-test. The results indicated that students had better understanding on electrical components and concepts (e.g., servo motor, input, output), computational (e.g., loops, conditional logic) and arts concepts (e.g., shape, form, texture) from pre- to post-test. Ten out of 19 questions focused on CT and physical computing also indicated students' learning on algorithm building, including – describe an output of an algorithm, create step-by-step procedure with inputs, outputs, and variables, and identify inputs and outputs from a step-by-step procedure. The results of the paired sample t-test inform the qualitative analysis to further examine how students apply algorithms with inputs, outputs, and variables during the designing and making processes.

Applying algorithms in design

To understand how students incorporated inputs, outputs, and variables in building an algorithm, we include two vignettes as examples to show how these elements were used in the process of design and making a kinetic sculpture. First, the dyad group with Dolores and Amber (pseudonyms), considered revised their sculpture design for balance and functionality, considering how they could use the motor (output) to "feed" ping pong balls to a bird sculpture, filling its stomach. Vignette 1 shows how the group decided to use the servo motor (output) in their design and then used planning and testing to solve a problem in making the sculpture.

Figure 1

(a)The group modified design drawing of the kinetic sculpture for balance and movement, (b)planned a step-by-step motion of ping pong balls by applying an algorithm with motor design, and (c)finally tested and adapted their design to work on the sculpture



Vignette 1

Line	Transcript
1 2 3 4	**Dolores**: It was originally just going to be the head but then it wouldn't balance great, so then we decided to do the body of it too (see Figure 1 left). When you put ping pong balls up to the motor it goes like right there (indicates the top of the cup shoot; see Figure 1 center, drawings numbered 1 and 2) and then the ball gets, it's like right there, and then when you turn it, it goes in (see Figure 1 center, drawing numbered 3).
5	……..
6 7 8	**Dolores:** (picks up a structure made with a wooden base, 6 inch dowel, paper cup attached on its side, bottom cut out) This is where these (the balls) are gonna come out (moves a ping pong ball to the cup opening). We're going to have a motor and it's going to go through (see Figure 1 right).

Dolores explained to the researcher that they planned to feed balls into the bird's mouth using a separate tower structure with the servo motor releasing the balls as it moved (Line 1-4). However, during the making process, they realized that there was a balance problem with their sculpture, and they decided to give the bird a wider stomach as the base. From there, they designed a step-by-step motion plan as building an algorithm (Figure 1 center; numbered 1, 2, and 3 in the drawing) to illustrate how the servo motor will move and spin, so ping pong balls will fall into the bowl and then tested and adapted their design as they built (Line 6-8). This vignette indicated how the group incorporated a servo motor (output) in their design by applying a sequence algorithm based on the motion of the servo motor in an iterative design process.

Building algorithms in making

In Vignette 2, the group discussed what design materials (e.g., paper bowls, cups) to include for the sculpture and how they incorporated the output components (LED light and servo motor) into the design.

From Line 1-6, Naia identified a problem (weak base) of their sculpture, and Simon provided his opinions regarding the size and weight (variables) of the sculpture design. Linda asked a question about the materials they used which led to the conversations regarding where the servo motor can be placed in the sculpture. Line 9-18 shows how the group made a step-by-step design decision by incorporating the servo motor, LED light, and variables like the size of the materials. Using the servo motor to drive the design of sculpture, the group created a sequence of decision-making in the process of making.

Figure 2

(a)The group discussed the components of their spinning sculpture, (b)The final look of the sculpture

Vignette 2

Line	Transcript
1	Naia: I don't think this is strong enough for the base.
2	Simon: It's not like we're making something big and heavy though, the servo motor is really tiny.
3	Linda: Yeah, we just need it to be big enough to support the (picks up the paper bowl and indicates the sides) (see Figure 2 left).
4	Are we using this for the whole thing?
5	Simon: Yeah, that's what I was thinking.
6	Naia: Um yeah. So this (picks up the paper bowl) would be on top of this (puts it over the small pie tin)?
7	Linda: And then this would spin. [Linda demonstrates the spinning motion]
8	Naia: But then how would that work?
9	Linda: Let's take everything out [Linda dumps balls and pipe cleaners from the bowl] and we could try going like this but then I
10	think that's (a single small pie tin) too small. Oh wait, but then we could go like this, put them all together [Linda places three
11	pie tins in a triangle formation for the base] and then this one would go like [Linda places the paper bowl on top].
12	Naia: Yeah, all of these three can be together.
13	Linda: Yeah but then how do we get the servo motor through there.
14	Naia: We could have the motor going though these (indicates the center of the base) like this.
15	Linda: Yeah I guess that would work.
16	Naia: [picks up the bowl] Or instead of having it spin we could make it with lights.
17	Linda: Simon doesn't want lights.
18	Naia: Really? I think it would look really cool. Okay, Let's start by hot gluing these (indicates the three pie tins) together first.

Discussion

This study aims to explore how students create and apply algorithms in the process of designing and building a kinetic sculpture. At first glance, algorithms seem to be a linear, one-way direction in building a step-by-step instruction toward a problem solution. However, the layer of algorithms can be complex regarding the elements and variables that are used as part of the algorithms. Particularly, the process of design and making are iterative and it is critical for students to review and modify the proposed algorithms to ensure they achieve the desired outcomes. This study not only offers a springboard to understand how students incorporated inputs, outputs and variables in building the algorithm through design and making, but also includes empirical evidence on learning CT and algorithms in a STEAM-based workshop.

Abstract: As both data science and computer science (CS) grow increasingly ubiquitous as a part of professional practice and daily life, efforts are needed to design and implement equity-driven CS curricula that can leverage the affordances of online platforms as valuable and engaging data sources. To this end, this work reports on the systematic design of a culturally relevant curriculum for pre-college students that uses the social media platform Twitter as a source of user-driven big data on real-world contemporary topics. Developed and refined through co-design with teacher and youth stakeholders, the design of the "Coding Like a Data Miner" curriculum consists of four iterative modules that apply an inquiry-based learning approach with different levels of support to guide students through the examination of topics of their choosing using computer and data science techniques. The paper concludes with implications of this work for future CS research and education initiatives.

Introduction

Data and Computer Science (CS) are widespread, and their increasing ubiquity has revolutionized modern society in myriad fields (NSF, 2022). In this landscape, online platforms that make large-scale user datasets available (e.g. Twitter) are a valuable resource for learners to use data science techniques to examine diverse opinions and perspectives on socially and culturally relevant topics (Carpenter & Krutka, 2014). One example of the impact of data science literacy on social media occurred during the COVID-19 pandemic, when computationally savvy content creators significantly impact public awareness (Wu, 2018). This underscores the need for design principles that support data science education consistent with prevailing national calls for CS4ALL (Adams, 2020) at earlier stages of the data science CS education pipeline: pre-college learners who represent the next generation of public consumers. Fulfilling this need not only supports pipeline innovation, but would also create a cohesive and federated infrastructure for the job industries and public awareness, which are quintessential to developing a 21st-century computationally literate and data-capable workforce (NSF, 2022).

Efforts to address this need have flourished in higher education, typically through math and computer science departments (Adams, 2020; Berinato, 2019). Fewer efforts have gained traction in high school (Harris et al., 2017), an age group that shows promise for productive CS engagement (Lee et al., 2021; Hendrickson et al., 2021). Others have cited problems in literature and coursework among pre-college groups, where learners use pre-generated datasets instead of datasets they create themselves that have potential to be more socially and culturally rich (Lee et al., 2021). While exemplary applications exist in research through the use of digitally and culturally-mediated STEAM projects such as e-textiles (Tofel-Grehl et al., 2017), and authentic, socially relevant data science curricula for female high school students (Grover et al., 2022; Alvarez et al., 2022), applications are still needed that connect to students' personal values, culture, and sociopolitical contexts. Such an approach would support equity-driven, constructionist educational praxis by providing opportunities for learners to connect with data science and acquire CS technical skills (Kafai et al., 2020; Fields et al., 2021).

This short paper reports on the systematic design of a culturally relevant computer science data mining and data science curriculum for pre-college students that responds to participation challenges associated with underrepresented groups. This in-progress research and design project was conducted by an interdisciplinary team with expertise in computer science, data science, and learning sciences as part of a CS demonstration and project learning implementation entitled "Coding like a Data Miner" that addresses these issues by providing learners with opportunities to access and leverage big data drawn from social media platforms (e.g., Twitter) to explore real-world contemporary issues. Two groups of teachers and youth co-designers who serve or identify as members of underrepresented groups engaged in two rounds of co-design with the research team to create and refine the culturally relevant data mining and analytics curriculum with the goal of answering the research and design question: What critical learning and instructional resources are needed to productively sustain a CS curricular intervention that emphasizes culturally relevant data mining and analytics?

Coding Like a Data Miner curriculum

The Coding Like a Data Miner curriculum leverages Twitter's application programming interface (API) to teach learners how to gather, process, analyze and then communicate insights learned from big data sets. Learners choose a topic or question, then edit and run Python code to mine tweets from the Twitter application processing interface (API) using chosen search parameters (e.g., hashtags, date) that can address the question. Students then process, analyze, and visualize results from their datasets with the support of slides, worksheets, tutorial videos, and the execution of further Python code using Google Colaboratory (Colab). The project concludes with a final showcase of project outcomes through a variety of potential activities (e.g., news report, website, etc.). All curricular materials are designed to flexibly adapt to the needs and contexts of future participating educators and schools, such as optional introductory slides on data science for students new to CS. Artifacts will be tailored by educators for each class, but may include records of learners' execution of python code on Colab, outputs from code (e.g., analyses, visualizations), written worksheet responses, and students' final showcases (e.g., slides).

Culturally relevant and responsive design

Design of the "Coding Like a Data Miner" curriculum was informed by culturally relevant (Ladson-Billings, 2008) and responsive (Gay, 2018) pedagogies as asset-based perspectives that constructively center diverse learners and the social and cultural assets they bring to STEM (Johnson & Elliott, 2020). From these perspectives, learning experiences start with relevant topics for students and affirm lived, social, cultural, and linguistic experiences (Mensah, 2021). These pedagogies were applied through three primary design features.

First, design emphasized student access to datasets from the social media platform Twitter. In line with Papert's description of accessible learning platforms (Resnick & Silverman, 2005), Twitter provides access to data sources that are innately familiar to existing generations of social media natives (low floors), but also expansive in terms of topics and opinions represented, enabling users to participate along trajectories couched in their personal and ranging interests (wide walls). Twitter users who create potential future datasets are also particularly diverse (Uddin et al., 2014), allowing learners to explore topics from a variety of perspectives.

Second, curriculum development was structured around student understanding and use of Twitter's Application Programming Interface (API): a software intermediary that can allow learners to systematically access and download large-scale datasets of tweets on their personalized needs and interests with search parameters they can tailor and curate (e.g. specific topics, types of hashtags, etc.) (high ceilings). Ultimately, these design decisions were intended to create a sandbox-like environment that empowers learners to go beyond their typical roles as consumers of information, and instead to actively serve as producers of that knowledge on their own terms. Accessing API datasets also requires students to learn and use programming languages, providing an embedded opportunity for the development of practical computer science skills.

The third feature of culturally relevant and responsive design in the project involved the adoption of a participatory approach to curriculum design that invited educator and youth stakeholders to actively share feedback, design ideas, and sample curricular artifacts during iterative co-design sessions. The co-design approach proved valuable as a way to center participants alongside researchers in critical action and reflection on the content of the future curriculum (Bang., & Vossoughi, 2016). Feedback from student co-designers impacted design in terms of content (e.g., pop culture dataset examples for guided data collection activities), difficulty level (e.g., providing different levels of programming complexity), and pedagogical scaffolds (e.g., more in-depth explanations in worksheet activities). Teacher co-designers offered step-by-step guides for curricular implementation and suggested the development of professional development sessions for future educators as part of the application of the curriculum (see www.cs.utep.edu/DataMiner/ for developments).

Modeling authentic data science practices

The initial goal of curriculum design was to position students as data scientists engaging authentically with data science skills, knowledge, identities and values in ways that are self-directed, collaborative, and multi-modal. This aligns with calls for data science-based computing education that leverages humanistic approaches (Lee et al., 2021) to connect CS processes to real-world issues and contexts. Through co-design with youth and educators, a series of typical steps taken as part of data science praxis were identified and modeled through guided activities centered around Twitter data that could be aligned with student and teacher needs and interests (See Figure 1). The first step was characterized as (1) Data Gathering, which includes identifying the appropriate tools (e.g. Application Processing Interfaces), choosing Twitter hashtags or keywords related to a topic of interest, and using those hashtags to mine a sample of data from Twitter. The second step was labeled (2) Data Pre-processing, and involved cleaning, checking, and preparation of sampled Twitter data to prepare for analysis. Next, the curriculum supported student engagement with (3) Data Analysis techniques including assessments of data variability, data variance, and identification of outliers. Data Analysis was designed with flexibility in terms of the complexity level of statistical analyses introduced to adapt to the learning context. Finally, students using the curriculum could engage in (4) Data Visualization using tools to create different models of patterns (e.g. pie chart, word cloud) in their chosen datasets. Curricular design guides students through these four steps repeatedly with different degrees of scaffolding to support the exploration of questions and data they find personally relevant and meaningful from a humanistic perspective.

Figure 1

Design examples from co-designed curriculum for each step of the data science process

1. Context or Interests

   #tiktok, #covid19, #tacotote, #whitesandsnationalpark, #pridemonth, #fitness

2. Socio political Issues

   #schoolsafety, #election2024, #blm, #gunsafety, #roeversuswade

3. Cultural issues

    wc = WordCloud(
        width = 1600 ,
        height = 800).generate(" ".join(dataframe['Text']))
        # change 'Text' to 'Language'
    plt.imshow(wc)
```

Inquiry-based constructionist approach

As students repeatedly engage with the four steps of data science practice, the arc of activities in the curriculum was grouped in to four modules with a learning progression designed to shift from guided introduction and scaffolded inquiry of topics to increasingly open engagement, where learners have greater freedom to choose and carry out pursuits (See Figure 2). The aim of this design model was to provide foundational information and skill development so that students with emerging understanding of data science and CS practices might have access to needed supports, all while gradually shifting students to practices of greater autonomy in data collection, pre–processing, data analysis, and data visualization decisions. Building on the success of existing research on constructionist approaches in CS education (Fields, et al., 2021), four inquiry-based modules also leveraged constructionist design to emphasize real-world, project-based activities intended to empower learners to use their emerging awareness of CS practices to further develop their knowledge and skills.

Conclusions and implications

The goal of this in-progress research and design project is to provide a roadmap of the systematic development of a culturally relevant curriculum for pre-college students that iteratively guides students through CS processes using Twitter data and an inquiry-based, constructionist approach to model authentic data science practices. Detail on the design and development of the curriculum is intended to serve as a potential model for future practice on (1) how to extend learner engagement with data beyond consuming and navigating information to producing their own interpretations and meanings, and (2) how to connects CS activities to culturally and personally relevant real-world issues and contexts from a humanistic perspective. Research and development is ongoing; future work will involve piloting the curriculum with underrepresented high school student groups in the South Central United States to explore what learning experiences and outcomes result when implementing a CS education program that emphasizes culturally relevant data mining and analytics.

Abstract: Comics are a familiar art form that has been underexplored as a tool for data-driven storytelling in K12 classrooms. Making data comics provide an opportunity for students to contextualize data within a visual style and narrative structure. This paper focuses on the second-year implementation of an interdisciplinary curriculum in seventh grade classrooms with one art and one math teacher. Students compared sample data from a national survey conducted by Pew Research Center, a nonpartisan US-based think tank, and data taken from their own survey on friendship perceptions and experiences. Students created comics based on those data using Pixton, a digital comic-making tool. Our study asks: *How do students' use narratives to demonstrate different kinds of data reasoning?* Thematic analysis of 47 data comics revealed the ways students constructed narratives, showcasing how the comic-making process cultivated students' reasoning around data and their informal inference-making skills.

Introduction

As data becomes increasingly central in youth's social lives, there is a pressing need to connect data reasoning to their lived experiences. However, the way youth learn about data is often disconnected from its context leading to a simplification in how data is created, situated, and perceived. In recent years, approaches to statistics education have focused on developing students' informal inferential reasoning, or reasoning about claims that generalize beyond the data and represent limitations through the language of uncertainty. Generalizing beyond the data requires an understanding of the data context (Pfannkuch, 2011; Wolff et al., 2016), including characteristics of the environment and people represented or affected by data, as well as how the data were generated—i.e. the study design and how variables were defined and measured (Pfannkuch, 2011).

Narratives can facilitate communicating about and with data through supporting elaborations and integration of context as students reason around data (Knaflic, 2019; Lund, 2022). Comics, in particular, act as syncretic texts by providing a visual and narrative structure (Bach et al., 2017) that supports learners in exploring personal connections to data (D'Ignazio & Bhargava, 2016) and leveraging students' lived experiences, cultural perspectives, and local ecologies (Gutiérrez et al., 2020). In this current study, we present findings from the second year of co-designing a seventh-grade arts-integrated data literacy unit. The unit engaged students in making comics that examine personally-collected data about friendships and Pew Research data on teens and technology. Students practiced data analysis skills such as graph reading and proportional reasoning, while creating digital comics to communicate stories about and with the data. The primary research question guiding this study was: *When creating their own comics, how do students' use narratives to demonstrate different kinds of data reasoning?*

Methods

Participants in this study included 84 seventh graders from three classes in a public middle school in a large urban area in the Northeastern United States. The team of four researchers and two middle school teachers, one who taught math and another who taught art, met over several months to design and plan the data comic unit that teachers then implemented in their classrooms in Spring 2022. This unit was the second iteration of a data comic unit that was initially implemented in Spring 2021 (Year 1) with the same art and math teachers (Vacca et al., 2022). Based on feedback from the math teacher, we aimed to incorporate more targeted scaffolds for mathematical reasoning, which she felt was largely missing from students' data comics in Year 1. We amended the curriculum to include opportunities to reason about proportions and make predictions when comparing two samples. To scaffold this process, the co-design team developed worksheets that guided students through the calculations of sample proportions prior to creating their final data comics. The data included students' responses to a 32-item survey about their friendships that was adapted from a national study conducted by Pew Research

Center on teens' views on friendships, technology, and social media use (Lenhart, 2015). Students analyzed and interpreted graphs from the national survey and compared these to findings from their grade and classroom data.

Our data set included 47 student-generated data comics; incomplete data comics were excluded from the analysis. In order to answer the question of *how do students use narratives to support different kinds of data reasoning*, we first identified the types of data reasoning represented in students' comics. Drawing from the literature on the central concepts and practices for data literacy and informal inference-making, we coded for instances of describing data, situating an instance of the data, comparing, predicting, making meaning (connecting to the real world), reasoning why, and questioning the validity of data (Franklin et al., 2020). Additionally, we used narrative coding, which applies literary devices and conventions to qualitative, story-based texts such as comics (Saldaña, 2021). In the narrative codebook, these categories emerged: non-narratives, data inquiry (meta-narrative), vignette, exposition, and narrative arcs which are described in Table 1.

Table 1
Codebook for how narratives from students' data comics were categorized

Narrative Codes	Description
Non-Narrative	May include data but does not have any storytelling elements related to the data
Data Inquiry or Meta-Narrative	Where character is involved in the data investigation or inquiry process (e.g., ask questions about the data; discusses how data was collected)
Vignette	Includes a short sketch to demonstrate context and instances of data, which can work as standalone frames; however, vignettes do not tell complete data stories on their own.
Exposition	Contains storytelling elements other than vignettes (e.g., context/setting, character backstories, plot, etc.) but does not have a complete story arc.
Narrative Arc	Has a story arc that contextualizes the data within a problem and resolution (e.g., plot involving the data)

Findings

Students reason with data through lived experiences and real-world contexts

Students demonstrated different kinds of data reasoning in their comics. About 87% of the comics were identified as *describing data* in which they described, explained, or reported descriptive statistics, including percentages and measures of center, by having characters speak directly to the audience or with other characters. In Panels 4, 5, and 7, the main character explains the pie charts embedded in the panels, which were based on data from the survey question: "In a typical week, how often do you get together with friends online?" (see Figure 1). Approximately 79% of the data comics went beyond this description of data by illustrating specific data-contexts—i.e. placing characters in real-world situations to make sense of the data—this type of data reasoning was coded as *situating an instance of the data*. In Figure 1, Panel 1 sets the scene and context of the data. The narrator explains how being "a busy student" competes with time spent with their friends introducing the audience to a specific context and identifying online apps on which they communicate with their friends. In some cases, students went beyond the data and began to make inferences. They *made meaning* by sorting through implications and consequences of the data (15% of the data comics), provided *reasons why* the data looked the way it did (51% of the data comics), and questioned the soundness and *validity of the data* (13% of the data comics) by asking about its source, reliability, or whether the data was an accurate representation of how kids their age feel about friendships. In the comic in Figure 1, the narrator provides a reason why they believe there were differences between the two samples as evidenced in the caption at top: "Difference in the population sampled". Lastly, as exhibited in Panel 5, the narrator begins to question the validity of the data as they discuss the degree of its accuracy: "These statistics would be more accurate due to the larger sample size".

Students used different types of narratives to support their data reasoning

In Figure 1, each frame represented in Panels 2 and 3 included *vignettes* that showed how the character spends time with their friends by doing homework together on Zoom (Panel 2) or keeping themselves accountable online so that they can meet in person after their homework is done (Panel 3).

Figure 1

This comic excerpt highlights data reasoning skills through vignettes and data inquiry

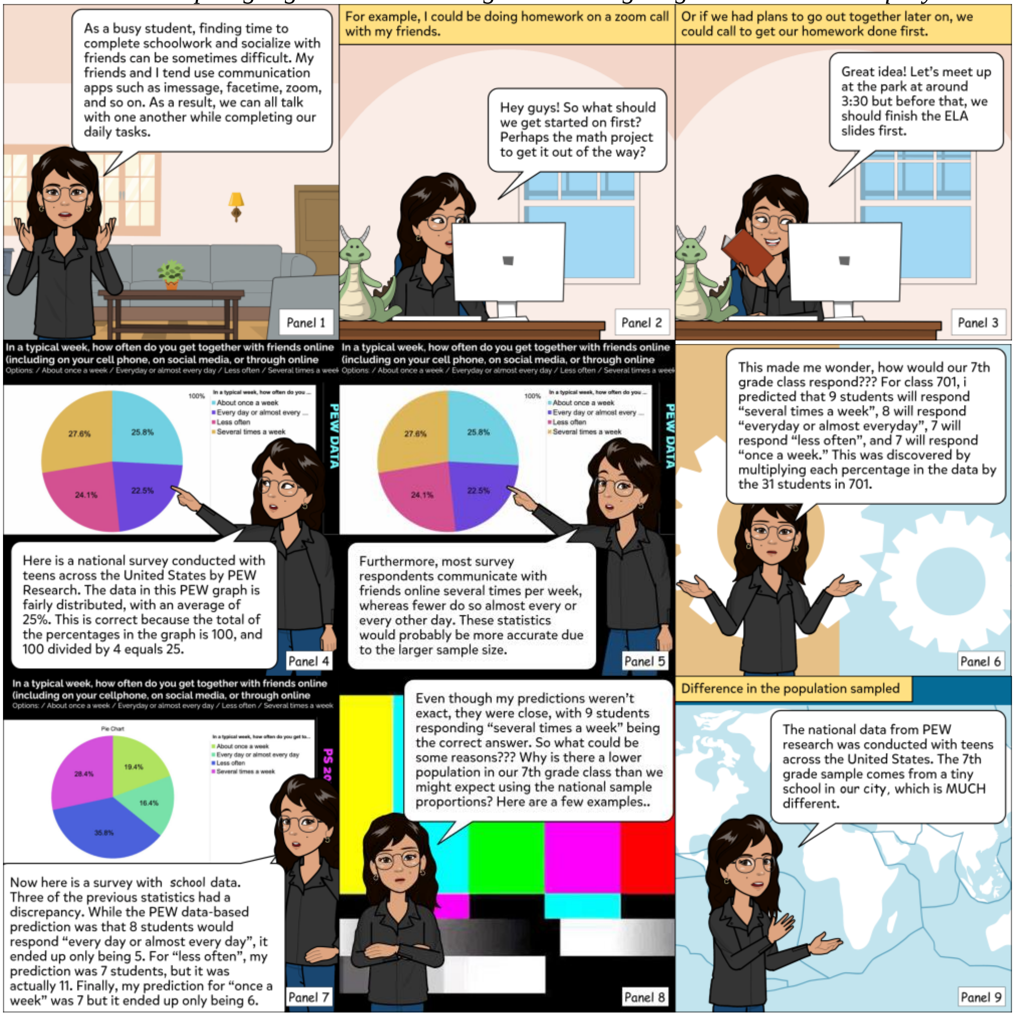

Table 2

Heatmap comparing frequencies of data reasoning by narrative type

Narratives **Data Reasoning**	Non-Narrative	Data Inquiry (*Meta-Narrative*)	Vignette	Exposition	Narrative Arc	**Total**
Describing	9	17	18	2	7	**53**
Situating Data	4	16	17	2	10	**49**
Makes Meaning	1	4	5	0	1	**11**
Reasoning Why	3	12	12	1	5	**33**
Data Validity	0	3	6	0	0	**9**
Total	**17**	**52**	**58**	**5**	**23**	**207**

The comic in Figure 1 was also identified as a *data inquiry* (see Table 1 for narrative codebook description), since the narrator discusses the survey and questions how the data were collected (Panels 7-8). Across the 47 data comics, students engaged in different kinds of data reasoning by integrating different storytelling elements as evidenced in Table 2. For comics coded as *data inquiries* or *meta-narratives*, there were

17 instances of *describing data*, 16 counts of *situating an instance of the data*, 4 instances of *making meaning* beyond the data, 12 counts of *reasoning why*, and 3 instances in the data comics where characters began to question the *validity of the data* (Table 2). In particular, *vignettes*, which were the most prevalent of the storytelling elements used by students, provided more opportunities for students to elaborate on their conceptual understanding of the data. Finding a *narrative arc,* where students create a story that contextualizes the data within a plot, was not as common. One explanation for this might be that comics written with a *narrative arc* require a level of abstraction from the data–moving beyond the given data–where students at the early stages of statistical thinking will eventually reach. The findings suggest that, more often, when creating their own data comics, students in our study reasoned with data through *vignettes* and *data inquiries*, positioning themselves directly in the data exploration process (e.g., making explicit the process of data collection and survey administration), and in some cases, characters became data detectives.

Conclusion

Narrative construction, specifically the use of comic creation, affords students opportunities to contextualize data using their own lived experiences in ways that support informal inference making. While some students used the comics to explain their data reasoning, other students used the comics to construct narratives that connected the mechanics and procedures of making predictions to broader contexts of variability within data and relationships between variables which is the basis for more advanced statistical thinking. Future work may focus more explicitly on how scaffolds can guide students to move from data explanations to richer narratives that further contextualize data and wrestle with issues of variability, related data relationships, and validity using their lived experiences and funds of knowledge. It seems apparent that this, like any artistic and interdisciplinary process, needs to be iterative, and perhaps serves as a jumping off point for further discussion, where explanations, elaborations, and discussions become the heart of students' conceptual and contextual understanding of data and leverages their lived experiences.

The Expansive Framing of Engagement Survey: Instrument Validation Insights From Confirmatory Factor Analysis

Tripp Harris, Daniel T. Hickey
triharr@iu.edu, dthickey@indiana.edu
Indiana University

Abstract: *Expansive framing* is a situative instructional approach hypothesized to promote learning transfer. The Expansive Framing of Engagement survey measures students' perceptions of their engagement to explore the relationships between expansively framed instruction, learner engagement, and learning outcomes. Building on a prior exploratory factor analysis (EFA), confirmatory factor analysis (CFA) was used to validate the theoretical alignment of the survey's hypothesized factor structure. The initial analysis yielded evidence of strong internal consistency for all six scales (alphas ranging from 0.77-0.87) and suggested collapsing two of the hypothesized six factors into a single factor. Following the initial findings, the results of the CFA for the five-factor model structure yielded an acceptable model fit with *CFI*=0.929, *TLI*=0.909, and *RMSEA*=0.091. A second CFA was conducted with six-factor model specification and yielded slightly better model fit with *CFI=0.939, TLI-0.917,* and *RMSEA=0.087*. These findings support our expectations of theoretical alignment with the expansive framing principles.

Introduction

Online learning has influenced the higher education landscape for decades (e.g., Castro & Tumibay, 2021; Wallace, 2003). Opportunities to take online courses expanded rapidly during the COVID-19 pandemic, and the discussion of corresponding issues and challenges have expanded accordingly (e.g., Dhawan, 2020). But the point that Kozan and Richardson argued in 2014 remains: Extended research is needed around *specific* theories of learning in online contexts to maximize the quality of online learning opportunities. In this light, the situative framework for expansive framing (Engle et al., 2012) may offer a useful lens through which to study online course design and the experiences of students taking fully online courses. Expansive framing insists that students should problematize course content from their own perspectives and experiences.

We designed the Expansive Framing of Engagement (EFE) survey to gather evidence of expansive framing in online courses. This work presents an alternative to the well-known *Community of Inquiry* framework and survey (CoI; Arbaugh et al., 2008). The CoI framework and survey concern the three *presences* (*social, cognitive,* and *teaching*) that Garrison et al. (2000) used to define a socio-constructivist framework for online education. The hypothesized factor structure of the CoI survey has been strongly validated (e.g., Swan et al., 2009; Kozan & Richardson, 2014). Numerous studies have used the survey to study the three presences in online courses and to document their (almost always positive) correlations with learner satisfaction and *perceived* learning outcomes (e.g., Stenbom, 2018).

Despite validation and widespread use of the CoI survey, there is no evidence showing that increased perceptions of presence from the CoI survey are related to *actual* learning outcomes (see Rourke & Kanuka, 2009; Maddrell et al., 2017). An underlying assumption of our research is that perceptions of expansive framing may be more strongly associated with actual learning outcomes than those of the CoI framework. The EFE survey promises to support future studies to test the hypothesis that expansive framing is more strongly associated with learning outcomes than *expert framing* (i.e., when course content is framed from the perspectives of instructors and other established sources of authority; Itow, 2020).

Further validation and refinement of the EFE survey is necessary if it is to be used to study engagement and learning outcomes in online course contexts. Following Kozan & Richardson's (2014) approach to validating and refining the CoI Survey, this study follows up the exploratory factor analysis (EFA) reported in Hickey et al. (2021) by carrying out confirmatory factor analysis (CFA). These responses were gathered when a proposed EFE survey was included as experimental items in an administration of the National Survey of Student Engagement (NSSE). Future administration of the refined survey will explore the relationships between expansive framing and other constructs of interest, including constructs measured by other scales included in the NSSE survey.

Expansive framing

Expansive framing emerged from situative views of learning and transfer (e.g., Greeno, 1998) and Engle's (2006) examination of how *framing* of learning impacts transfer. Engle (2006) studied aspects of engagement that supported transfer through the lens of *intercontextuality* (e.g., Floriana, 1993), which is attained when learners form numerous connections between their prior experiences, the learning environment, and future transfer contexts. As elaborated in Engle et al. (2012), instructors can foster intercontextuality by pushing students to find personalized connections with people, places, topics, and times outside of a given course context and by positioning learners as authors of disciplinary knowledge at these intersections, rather than as passive consumers of that knowledge. Engle et al. (2012) contrasted expansive framing with *bounded* framing, where instructional frames are tied to a given learning setting at a given time, which may constrain future transfer. Engle et al. (2011) experimentally showed that learners in expansively framed tutoring sessions demonstrated dramatically stronger transfer than learners in bounded tutoring sessions that positioned learners as "spokespersons" for disciplinary resources. Hickey et al. (2021) argued that by focusing on three forms of *presence* rather than learners' connections with contexts beyond the course, the CoI framework is relatively bounded and less likely to support learning that transfers readily.

Engle and colleagues (2012) offer five testable explanations of why expansive framing should support transfer: (1) Learners expect that they will use what they are learning in future settings, which leads them to adopt more effective and more active learning strategies; (2) Learners view what they have previously learned as relevant as they engage in potential transfer opportunities, which helps them recognize those opportunities; (3) Learners view previously learned knowledge as consequential for current learning. This leads them to *transfer-in* relevant prior knowledge during initial learning; (4) Authoring content in the learning environment leaves learners with more confidence using (i.e., authoring) that knowledge in the transfer environment; (5) Authoring content repeatedly in the learning environment generalizes to future experiences, leaving learners more confident authoring new knowledge in new contexts (including actively generating and adapting new knowledge).

Systematic reviews (Harris et al., 2023; Freedman et al., 2023) confirmed that the expansive framing principles have been used in dozens of peer-reviewed studies. But other than Engle et al. (2011), there is little evidence supporting these compelling theoretical explanations of expansive framing and no other experimental or quasi-experimental evidence from studies comparing expansive framing with other engagement strategies in face-to-face *or* online settings. The EFE survey aims to lay the groundwork for such studies.

Expansive framing survey instrument

The EFE survey builds on the original survey of expansive framing that Engle et al. (2011) created for their tutoring experiment in a face-to-face high school biology classroom. The 16-item EFE survey was created to represent six scales associated with expansive framing (*time:past*, *time:future*, *other places*, *other topics*, *roles:authoring*, and *roles:accountability*; the 16-item limit was imposed by NSSE policies for experimental items). These scales were designed to capture the degree to which students experience each of Engle and colleagues' (2011, 2012) design principles for fostering expansive framing (i.e., the extent to which students perceive opportunities to make connections between course content and people, places, topics, and times outside the bounds of their coursework, position themselves as authors of disciplinary content, and hold themselves and their peers accountable for defending their interpretations of disciplinary ideas).

Method

This data was collected from student responses to the experimental items of the EFE survey included in NSSE in 2019. Among the included respondents, 6,452 fully online college students completed the 16 experimental EFE survey items on the survey. Of these, those who completed all items (6,200 participants) were included in Hickey et al.'s (2021) initial EFA and were retained for the CFA.

We extended the EFA in Hickey et al. (2021, conducted using odd-numbered respondents) which suggested collapsing two of the scales (*time:future* and *other places*) into a single factor. We split the response set and conducted a CFA with five factors on the even-numbered responses to validate the hypothesized factor structure and its alignment to the elements of expansive framing. Since the initial EFA suggested that six factors could *potentially* be present in the response set, we ran an additional CFA on the even-numbered responses with a hypothesized six-factor model specification that separated *time:future* and *other places* into two distinct factors.

Results

The CFA for the five-factor model yielded acceptable fit (x^2=2511.21, df=94, p<.01). The results for comparative fit index (CFI) and Tucker-Lewis index (TLI) were both greater than 0.90, and the Root Mean Square Error of Approximation (RMSEA) was less than 0.10. This suggested adequate fit for the model with *time:future* and *other places* collapsed into a single factor (*CFI*=0.929; *TLI*=0.909; *RMSEA*=0.091; Levesque et al., 2004).

The CFA conducted with six-factor model specification also suggested adequate model fit (x^2=2181.933, df=89, p<0.01). Notably, the results for this six-factor specification indicate slightly better model fit according to both the comparative fit and Tucker-Lewis indices, as well as the RMSEA (*CFI*=0.939; *TLI*=0.917; *RMSEA*=0.087), compared to the five-factor model. We hypothesize that NSSE's 16-item constraint hindered the model fit by requiring us to eliminate items from certain scales—resulting in some scales with three items and others with two. Further, these findings indicate that a six-factor model with *time:future* and *other places* separated into two different factors provides a slightly better model fit (as opposed to collapsing the two into one factor as in the five-factor model specification above).

These findings align with our theoretical expectations that *time:future* and *other places* should represent two separate factors. It is certainly plausible that learners could make connections between course content and other places, in which they encounter those other places in future times (and in which case the two factors would collapse into one). But we contend that learners are more likely to make connections to other places that are not specifically bound to *future* times. Rather, we assume that they are more likely to make connections to other places that they have encountered during the past, present, *and* future, and even to places with which they have no specific timeframe association (e.g., other places they have never encountered nor envision themselves encountering in the future). This assumption is grounded in Engle et al.'s (2012) view of intercontextuality where learners participating in expansively framed course settings recognize connections between disciplinary content and their own social contexts without bounded framing imposed by their instructors.

The confirmatory validation offered by these results—taken together with our earlier results showing evidence of correlations between the survey scales and perceived learning gains—will contribute to the refinement of the EFE instrument. Further refinement will help researchers explore students' perceptions of framing of course interactions and activities and the relationships between framing and outcomes, especially when this survey is administered alongside interviews with students enrolled in fully online, hybrid, and face-to-face courses.

Conclusion and next steps

Given that the 16-item constraint imposed by NSSE required that two of the EFE survey scales have only two items, we find these results encouraging. Interpretive analysis of the items in the two scales that failed to diverge in the initial EFA results suggests that these items could be reworded to make them more distinctive for respondents (specifying, for example, that learners' envisioned connections to *other places* are not inherently embedded within *future times*). With the rewording and the addition of one more item to each of the two-item scales, we will administer the expanded 18-item survey to students enrolled in online courses. In the longer term, we plan to administer the revised survey to students in online and face-to-face courses, and to explore the relationships between perceptions of expansive framing and various indicators of learning transfer, achievement outcomes, and other NSSE scales associated with academic engagement.

Given the continuing expansion of online course options in higher education, the burgeoning market for fully online degree programs at both the undergraduate and graduate levels, and the widespread challenges presented by emergency remote teaching and learning at the beginning of the COVID-19 pandemic, it is more important than ever to invest in research and development of online learning innovations and to explore students' perceptions of online course features that may promote transfer and other desired outcomes. Given the massive (and sometimes, seemingly, exclusive) reliance on the CoI survey, we belief that the EFE survey has the potential to support theoretical diversity and advancement in studying online learning. Results from future broader use of the EFE survey in targeted online contexts will also contribute to future research seeking to support the implementation of expansive framing in remote learning settings.

Ecological vs. Construct Validity of Persistence in Game-Based Assessment

Jennifer Scianna, Luis Felipe Martinez-Gomez, YJ Kim
jscianna@wisc.edu, lfmartinez@wisc.edu, yj.kim@wisc.edu
University of Wisconsin - Madison

Abstract: Persistence is a well-defined construct that has been researched in various contexts; technology-enhanced learning environments, such as games, have been successful at providing evidence for construct validity of feature-based measurements of persistence. However, questions arise when considering whether these construct valid interpretations align with teacher expectations and understandings that would be considered ecologically valid. By investigating a subset of co-design sessions that teachers participated in to develop analytics and visualizations for persistence in a game-based assessment called Shadowspect, this paper explores the tensions between the two types of validity.

Introduction

Game-based assessment (GBA) has the capacity to simultaneously generate instruction and assess learning in a performance-based and process-oriented way situated in simulations of authentic contexts (DiCerbo, Shute, & Kim, 2017). GBA has shown to be successful at supporting and measuring various academic domains (Klopfer & Thompson, 2020) as well as non-cognitive skills, such as persistence (Kim et al., 2022) and creativity (Chuang et al., 2015; Kao et al., 2017). While GBA has shown to be effective at measuring "soft skills" or "21st Century skills" (Shaffer & Gee, 2012), these skills are deemphasized in school-based education compared to standardized testing (Shute & Becker, 2010) leading to relatively little focus on working with teachers to both incorporate these skills into instructional time and assess students to foster their growth. Thus, questions arise as to how teachers might use such assessments in their classrooms.

These questions led to our interest in understanding the utility of a game-based assessment of persistence, Shadowspect, in classrooms. Shadowspect was intended for mathematics classrooms to assess spatial reasoning skills, one of the foundational skills that has high predictive power for later involvement (and ultimately success) in STEM fields (Uttal & Cohen, 2012). However, the game also was designed to incorporate elements which would lend it construct validity for assessing persistence. Construct validity is well-documented for persistence (Ventura & Shute, 2013), but in working with teachers to co-design a learning analytics dashboard for Shadowspect, we recognized that there was potential for misalignment with the ecological validity of teacher's needs. This work serves as an example of how learning science scholars may begin to reconcile these discrepancies and continue pushing our work to align to the contextual realities of the classroom.

Operationalizing persistence

Construct validity regards to what extent the assessment measures what it intends to measure (Trochim & Donnelly, 2001). Repeated measurement and validation of persistence in technology-enhanced learning environments provide evidence for construct validity in future implementations. Yang et al. (2018) included features related to challenges learners face: number of reattempts to unsolved problems, proportion of difficult problems attempted, and time spent on resources after failure. Ventura and Shute (2013) investigated construct validity of persistence in a puzzle game using time spent on unsolved problems over all player events over the five sessions. Similarly, DiCerbo et al. (2014) measured persistence in a game using four features per quest: time spent on quest events, number of quest events completed, maximum time spent on an individual quest event successfully completed, and time spent on the last event prior to quitting. The algorithmic metric measuring persistence in Shadowspect draws on these earlier examples to ensure construct validity.

By investigating applications of assessment tools in natural real-life settings, one can investigate to what extent these measures are ecologically valid (e.g. Krolak-Schwerdt et al., 2018). It is well-documented how teachers' use of validated assessment tools in practice can vary across contexts, and this discrepancy is likely to amplify when and how the construct is being defined and operationalized. This tension between what the research team could build, a persistence measurement algorithm based on the validated features and definitions in the literature, and what teachers see as useful and actionable in their own contexts leads us to the following research question: How do ecologically valid teacher perspectives on measuring persistence in a mathematics educational game compare to the metrics and algorithm designed with construct validity in mind?

Method

Educational game context

Shadowspect is a 3D geometric puzzle game that was intentionally designed to assess spatial reasoning skills, persistence and common core geometry standards using the evidence-centered design framework (Kim et al., 2016; Mislevy et al., 2003). The primary mechanic of Shadowspect includes players arranging various 3D geometric primitives to match perspectives along three axes. As players move the shapes around, they are constantly comparing their current perspective with that of the shadowed "goal" (Figure 1).

As players move through the game, the levels build on additional constraints by either removing shape types (i.e., having to complete the puzzles without cubes) or limiting the number of figures players can use (i.e. only being allowed to use 4 shapes total). These added constraints push students to construct more creative solutions as they must reassess the utility of certain shapes. A cone, for example, may serve the same purpose that a cylinder and prism did previously. Levels become intentionally challenging; scaling difficulty beyond the threshold of student capacity has the affordance of allowing students to demonstrate persistence.

Figure 1

Shadowspect players move figures around a platform to match snapshot perspectives.

The silhouettes hint that some objects will need to be rotated 45 degrees.

There is no way to move the camera to view this assembly as a vertical cross.

You can add 0 more objects

Measuring persistence in Shadowspect

Gameplay in Shadowspect is captured via an event logging system. Events were categorized into three sources: game, task, and player. Game events include the logistical events of beginning and ending gameplay as well as assignment of user information. Task events include puzzle specific events: screen changes (moving from a menu into a puzzle), starting and ending a puzzle, and restarting a puzzle. Player actions are most diverse capturing every move that a player may take.

These events were then aggregated through multiple iterations to identify metrics that both aligned with prior research and helped to describe differences in student gameplay. Because students were participating in play alongside teacher participation in dashboard co-design, their gameplay could be compared to one another, thus percentile aggregates of several features were calculated based on all students' gameplay. For example, instead of using the raw number of events from level X in models, the student's play would be compared to how many moves each student made in level X to yield a percentile. This also allowed for the combination of metrics into similar weights for use in the persistence assessment algorithm (See equation below).

Analyzing and understanding teacher perspectives

Eight teachers participated in a co-design process of building learning analytics and dashboard for Shadowspect over the course of 12 months, in 2021. All 10 co-design sessions were conducted via Zoom due to Covid-19. All meetings were recorded and transcribed for analysis, and activities and artifacts were digitally preserved.

The research team conducted a thematic analysis of teacher verbal and artifact contributions to understand teacher's perspectives on Persistence. Transcripts were filtered for all conversations that were relevant to persistence, and each reference was identified as belonging to a current theme or creating a new one. Once all of the transcript references and design artifacts were reviewed, we began to whittle the themes to the most salient thoughts teachers were voicing especially attending to features which connected with the algorithmic measurement of persistence. In our analysis, we provide a summary of the teacher's perspectives as a description of ecological validity for persistence and offer a comparison between the ways they envision persistence operating in practice and how Shadowspect's persistence algorithm provides insights.

Analysis

In this analysis, we begin by outlining the features of the persistence algorithm used by Shadowspect to assess students before contrasting the teacher's description of persistence as they would utilize it in their classrooms.

Construct valid assessment of persistence algorithm

Persistence is measured in Shadowspect at the granularity of a given level attempt. The student-based, per-level features incorporated into the metric include the level's difficulty, student's active time, number of actions, and number of times students checked their solution. Additionally, puzzle difficulty, which was determined a priori by the design team, is included in the final, weighted average which aggregates performance across puzzles:

$$\boldsymbol{Persistence} = \frac{difficulty_i \quad \frac{percentile\ active\ time + percentile\ \#\ of\ events + percentile\ \#\ solution\ checks}{3}}{\sum_{i=1}^{n} difficulty_i}$$

Percentiles are used for active time, number of events, and number of solution checks because they standardize the relationship between the three metrics. They are also specific to the population of students who participated in the sample; the percentiles are between players on a given level, not between one player on many levels. Shadowspect's persistence algorithm aligns with prior work in the way it selects features from player data.

Teacher perspectives on difficulty

Difficulty was one of several metrics used in the persistence algorithm that were revoiced by teachers during the co-design workshop. They noted that there is a zone before students quit where difficulty might showcase a student who is being persistent in conjunction with other metrics: "Like, some of these levels, like 14, you know, this looks like great persistence to me. Like, you know, they spend a good seven and a half minutes working hard on this level, and then succeed on it and move on."

However, not all teachers thought of difficulty as a puzzle characteristic as the Shadowspect team had. Instead, teachers were interested in honoring the way difficulty is perceived by the student. Low difficulty was important for explaining low persistence scores in context, if "they had zero failures, [...] they're not gonna get a strong persistence score." Difficulty needed to be thought of relevant to the student's perception.

Activity through time, moves, and solutions

Time was able to give definition to how teachers made sense of multiple aspects of student behavior. One teacher asked, "So, is that a way that we could try to break down what persistence looks like? Time spent on a puzzle, time spent before trying something new, whatever. Versus, here are the actions that I'm actually using to try to show my persistence." Other teachers wanted more specificity for what time represented. One method of representing time was to only consider times when the student was active because, "total time isn't necessarily a good indicator of, of production." The teachers valued production as a basis for persistence.

Moves serve as a proxy for production in the algorithm, but teachers noted that the sheer number of moves might not be enough to classify a student as being persistent: "I don't think somebody could tell me that a kid made 15 moves, and I would know from 15 moves whether those were an indicator of persistence or not. Like, what 15 moves was it? Was it 15 moves of them just spinning the same shape 45 degrees? 'Cause then, that's not persistence, that's just time-wasting." This became an important distinction for teachers. They wanted to be able to interpret the meaning behind aggregates, to uncover the nuance that differentiated productivity and wasting time. Persistence seemed less important if it meant "sitting there working on the same puzzle, bashing your head against the wall." Unproductive persistence was associated with struggling for extended periods of time, and teachers wanted to ensure that students were still making progress in the game, "'cause it's one thing to not demonstrate persistence, but to also never solve anything." Solution checks seemed like one way to tell if students were moving ahead, although in implementation the metric muddies the water between students who are successfully completing (low numbers of solution checks) and those who are struggling or time wasting. Ultimately, teachers reached similar conclusions to the developers suggesting that is may be beneficial to "weight the persistence score also by whether or not it was completed successfully."

Discussion

In this paper, we review the similarities and discrepancies between an algorithmic assessment of student persistence which was designed with construct validity in mind and teacher perspectives regarding the utility of persistence as a metric in the classroom. Overall, the teachers valued similar aspects of student gameplay to the algorithm: amount of action, time spent working on the puzzle, and attempts. However, we also identified several ways in which these perspectives were misaligned. Namely, the level of personalization demonstrated by the features feeding into the algorithm was not at the level that teachers believed would be useful. It also seems that teachers needed to be able to see the components of the algorithm to make sense of the outcome.

Tensions appear between data science practices and the practitioners that their products are intended to serve. The metrics practitioners ask for are not always feasible for implementation even if they would generate a better model for practical use. For example, attempting to derive the difficulty of each puzzle for each player may be possible, but it would not be efficient for creating a metric that teachers could act on in the moment. Similarly, adding specificity about type of move or distribution of moves might have improved the persistence model, but it would have involved a more nuanced metric, specific to a given level.

This study presents a key limitation in that we have not yet presented a means to operationalize the teacher's thinking to find a middle ground between construct and ecological validity. It seems that a critical component of the process includes testing cases of each iteration to determine if a given algorithmic model is close enough to meeting the ecological validity of classroom implementation while not losing its connection to construct validity. A more comprehensive study of algorithmic use in practice or through case vignettes (Krolak-Schwerdt et al., 2018) may be helpful in identifying alignment issues beyond our isolated examination.

The work of educational assessment has often used construct validity as the gold standard for design, but this has led to minimal adoption in classroom due to the disconnect with what teachers need in practice. As learning scientists, we must not lose sight of the forest for the trees. Broadening the scope of our understanding of how our work manifests in context with stakeholders can help identify and bring forward questions on how construct and ecological validity work in tandem and in conflict in our respective areas.

Data in the Wild: An Exploration Into Hobbies as Contexts for Data Literacies

Samuel T. Arnold, University of Illinois at Chicago, sarnol4@uic.edu

Abstract: This research investigates the data practices of two hobbyists who have learned to recognize and take action with data in self-directed and goal-oriented ways. Drawing from research on data literacy and informal learning, a conceptualization of hobbies is used to attend to the contexts and voices of non-professionals who routinely engage in sophisticated data practices in activities that occupy large parts of adult life and, yet, are largely absent in discussions of data literacy. We draw from two interviews in which Astrid, a video gamer who enjoys playing Massively Multiplayer Online Role-Playing Games (MMORPG), and Tony, a musician who enjoys playing his guitar for others, describe how they have learned to recognize and use data for the enjoyment of participating in their respective hobbies.

Introduction

Data literacy represents a growing area of interest among researchers and educators, especially as discussions around growing fields, such as data science education, continue across professional spaces. Entangled in these discussions exists a tension in how data should be positioned in schools (D'Ignazio & Bhargava, 2020). While some researchers have focused on the technical skills involved in data literacy, others have called researchers to critically attend to the personal (Pangrazio & Selwyn, 2019), theory-laden (Hardy et al., 2020), and situated (Jiang et al., 2022) nature of data. In part, the presence of data generation and data use in virtually every aspect of society has demanded an examination of how people come to understand and use data as they produce it across contexts. The subject of this demand includes not only how experts, such as scientists and engineers, analyze and interpret data, but how non-experts and non-professionals actively and routinely integrate and use data in their everyday lives; this includes how they make sense of current events (Calabrese Barton et al., 2021), worldwide pandemics (Radinsky & Tabak, 2022), or life-threatening conditions (Lee & Dubovi, 2020). While some research has begun to examine and speculate around the situated nature of data literacy, many voices and contexts remain absent in these discussions. These include the data literacies that are lost to the mundane (Pink, et al., 2017) and everyday routines (Kennedy, 2018) that are obscured in plain sight. This study adds to this burgeoning area of research by exploring how two hobbyists learned to use data in self-directed and goal-oriented ways.

What are hobbies?

To describe both hobbies and the learning that occurs within them, we draw from two theoretical lenses. First, hobbies are defined from an informal learning perspective (Rogoff et al., 2016) as activities that are non-didactic and both personally meaningful and interesting to the learner. Engagement in a hobby is driven by the hobbyist's care for the activity (Azevedo, 2013) rather than by occupational or academic demands. Second, hobbies are historically established activities that perpetually develop within and across larger communities. This conceptualization of hobbies emphasizes participation as self-directed while also attending to the larger social structure of the activity. We hope to give voice to the contexts and practitioners who have developed and deployed ways of producing and using data in activities far from those found in occupations or schools. Thus, this study examines *how and why hobbyists produce and use data in relation to their hobbies*.

Methods

Context and study design

This study reports the findings from two semi-structured interviews that were conducted with participants who identified themselves as using data in their hobbies. Recruitment occurred in two ways. First, recruitment posts on general and specific hobbyist forums were made in collaboration with forum moderators, and second, snowball sampling was included as a recruitment method for additional participants. Each interview lasted approximately 60-minutes and followed a semi-structured interview design in which questions for data use and hobby participation were developed in advance of the interviews alongside potential follow-up questions.

The intent of this study is not to generalize results to larger populations but to explore and compare the reasons and conditions hobbyists attribute to their data practices and to make explicit the history of their experiences with data. A case study design is used because it affords the comparison of similarities and differences within and across cases (Moss & Haertel, 2017).

Participants

The two cases presented in this paper are of two hobbyists, with the pseudonyms Astrid and Tony, who identified data as being useful in their practice. The first hobbyist, Astrid, is a 32-year-old logistics operator who has an extended history playing Massively Multiplayer Online Role Playing Games (MMORPG) as his hobby of choice. MMORPGs are video games in which players control online avatars in a virtual world. These characters generally have swappable clothing, armor, skills, and weapons. This case focuses on how Astrid learned to use damage-per-second (DPS) as a quantitative metric to help them defeat challenging foes in a popular MMORPG. Astrid learned to manipulate various factors involved in the production of DPS in order to optimize the number they produced. Astrid discusses how the use of quantitative and qualitative forms of data can be effectively used to evaluate their own performance and the performance of others.

The second hobbyist, Tony, is a 29-year-old retail manager whose hobby is playing guitar for the enjoyment of both himself and others. Tony began playing at the age of 11 and has had extensive training from teachers. Although he is no longer enrolled in formal lessons, Tony continues to challenge himself with music he enjoys. He also performs for local audiences and with other musicians. In terms of data, this study focuses on how Tony uses beats-per-minute (BPM) and video recordings as quantitative and qualitative metrics to assess progress. These forms of data have continued to help him through challenges in learning new, enjoyable music.

Analytic method

The analysis for this study uses a qualitative coding approach to generate codes, categories, and ultimately descriptions of each case. This process was iterative and involved discussions with other members of the research team. The interviews were first transcribed and read through as a process of familiarization. Initial ideas were developed through memos, and a subsequent round of In vivo coding was conducted to retain the voices of each participant. This process allowed us to identify how participants were describing and using data in relation to their hobbies. We then traced each type of data and associated practices through each interview, which was necessary as each participant mentioned different data practices and different forms of data.

Findings

The analysis of both interviews produced three central findings related to data use. These findings are presented with excerpts from both hobbyists in order to make explicit the similarities and differences between how and why both hobbyists use data.

Data practices are shaped by communities

Astrid and Tony attributed their initial data use to individuals they met as they pursued hobby specific goals. To Astrid, who plays an MMORPG as a hobby, using data came from interacting with senior players who were engaged in difficult, yet desirable, content. They recounted, “I was specifically wanting to play some harder and more difficult content. So I would say it started off with mimicry, you know, doing what other people did and then doing it so often that it got to the point where I started recognizing the data.” To Astrid, data use started as a social practice for evaluating performance, typically in the form of DPS, that was taught to them by experienced players. They continued, “it became less of a community thing and more of a now I know how to do this…. [I] start looking for what exactly I wanted out of the game and uh, what data to use to kind of get me there.” Although data were initially byproducts of Astrid’s interactions with others, data evolved into an integral part of their practice.

Tony learned to measure BPM at an early age when learning to play guitar. He attributes this practice to his guitar teacher, saying, “[My] guitar teacher taught me to register a certain BPM and a limit for myself. And then pushing that limit and recording the BPM to make a comparison.” Learning to recognize BPM as a source of data has helped Tony in learning to play his guitar. In fact, while he has not had formal guitar lessons in years, he has continued to integrate BPM into his practice, saying, “So now-a-days if I have a metronome going, that’s a way to kinda analyze where my starting point [is] and how fast I can progress as far as BPM.” Like Astrid, Tony’s use of data started as a lesson from an experienced player and quickly became interwoven in his practice. In the cases of Astrid and Tony, the lessons of recognizing and using data developed from interactions with other practitioners, and these interactions had a lasting effect in shaping their participation.

Data are a source of feedback

In examining how both hobbyists used data, similarities and differences were discovered that situate data in the uniqueness of each hobby. For example, Astrid described the process of testing methods for maximizing performance as an important practice of data use, saying, “A lot of video games produce numbers…. When I’m coming up with the DPS build, trying to test things is how to maximize my output [DPS].” To Astrid, the process of testing a “DPS build” refers to revealing how a specific combination of items and skills equipped by their character are reflected in the character’s total DPS. Put differently, Astrid actively manipulates various inputs in their character’s performance to produce DPS. This process involves pressing different skills at different times or using different gear modifiers. Astrid stated, “I see if changing which skills to use in what order might change the numbers.” This led Astrid down a path of testing how to accomplish their goal: “I go in and actually test the DPS and that produces another data, which is I did that much DPS at that point.” The act of figuring out how to maximize their DPS involved the production of a new dataset. In many ways, the goal of playing harder content became a goal of optimizing performance, and data were the central and necessary components to how Astrid played the game.

Tony described the way he integrated BPM into his practice, saying, “I will play for five minutes on whatever BPM is comfortable, and then jump it up by five bpm. This difference isn’t really noticeable to the ears, but it’s very noticeable to the hands.” Tony described using this method of practice for every song he is interested in learning to play. During this process, Tony described the potential for encountering trouble while learning to play particular styles of guitar. Consequently, he would record himself with video data to further interrogate the issue: “If I’m really struggling then I can go to the video recording to kind of get a visual on what I’m doing. It is much different when seeing yourself from a completely different angle.” While difficult to capture in any one quote, Tony noted that the use of video data was only necessary if he had identified an issue using BPM, such as a plateau in his performance. Looking across cases, Astrid and Tony had independently developed a system of data use that involved multiple forms of data. Both hobbyists were using data as a source of feedback in developing their skills.

Data are felt phenomena

An important distinction so far between Astrid and Tony relates to how they experience the production of data. Throughout the interview, Astrid went into great detail concerning how they felt in relation to the data they were producing, saying, “There are definitely times where I have been way more angry about a video game than I should have been just from viewing data of me underperforming. You know, it’s frustrating.” Astrid continued by describing how these emotions became so intense they had to stop using data for a short period of time, “I just stopped paying attention to the data. I had to do that for a few weeks. I had to cool myself off for that.” Apart the unpleasant emotions Astrid experienced, there were instances of pleasant emotions around their general data practice, “It can also be very satisfying when you do hit the numbers.” From Astrid’s description, the interpretation of data appears more than a cold, mechanical process; it seemed to amplify and create emotional experiences that were partly different from the actual hobby Astrid was experiencing.

To Tony, emotions were equally present in how he described his data practices, saying “It feels really good when you can nail something at the correct tempo or build to it very quickly and see how far you’ve progressed.” Writing down the BPM gave Tony a way of seeing himself progress over time. Conversely, experiencing stagnation leads to feelings of disappointment and frustration, saying “being frustrated on the other end. it is very frustrating and kind of drive me back to other styles [of playing].”

Discussion and conclusion

This study examined how two hobbyists learned to produce and use data for their respective hobbies, and three findings were discussed. First, Astrid’s journey with senior players and Tony’s music lessons highlight the importance of communities in fostering data literacies in hobbies. For both hobbyists, the integration of data was a byproduct of engagement with others, which fundamentally shifted how both Astrid and Tony. These cases provide a reminder of the profound effect data literacies have in shaping people’s future activities. We can see in Astrid’s description that this integration fundamentally shifted how they experienced other MMORPGs: Optimizing performance became a way of approaching other games. Similarly, Tony continued to record and measure BPM despite not participating in formal lessons for many years.

A function of data in informal contexts is to provide feedback on how hobbyists make progress toward their goals. Astrid modified their character gear and skill rotation to optimize DPS, and Tony evaluated progression and technique using BPM and video footage. The production of performance data brought about a process of problem identification that led to the creation of new forms of data. Tony and Astrid used the forms of data they created to troubleshoot issues related to their performance and to develop their skills in self-directed ways.

Furthermore, Astrid and Tony cared deeply about their performance and this passion had implications in how they used data. Both hobbyists expressed frustration as well as satisfaction from using data, and in both cases, there were changes to how data were being used: Astrid needed to stop using data entirely for weeks because of their frustration while Tony was driven back to familiar styles of guitar playing by frustration with the lack of progress.

The cases of Astrid and Tony provide only a limited perspective into how data literacies can involve social, technical, and personal experiences. However, more research is needed in understanding the influence data use has in directing future participation and in shaping future experiences. Similarly, more research is needed in exploring how we might support hobbyists and learners alike in managing the emotional and personal impact of data.

Signals of Teachers' Readiness for Change in Next Generation Science Professional Development

Bonni Jones, Utah State University, bonni.jones@usu.edu
Hillary Swanson, Utah State University, hillary.swanson@usu.edu
Ha Nguyen, Utah State University, ha.nguyen@usu.edu

Abstract: Change in the domain of education is complex. Research has begun to uncover factors that influence the success of proposed initiatives. This paper examines factors influencing science teachers as they wrestle with implementing innovative teaching practices. We present a theoretical framework that unpacks a construct we call *signals of readiness for change (readiness signals).* We define readiness signals as elements of teachers' talk that signal a teacher's sentiment toward a proposed initiative. Signals often reflect tensions that must be resolved for initiatives like the Next Generation Science Standards to succeed and endure. These tensions exist in teacher beliefs, confidence in their ability to implement innovative practices, and motivation to invest in change. The investigation of readiness signals adds insights into struggles surrounding the adoption of change in education.

Introduction

The Next Generation Science Standards (NGSS) urge educators to radically transform the way they teach science. To help teachers shift their classroom practices to align with the NGSS vision, researchers and educators have introduced teachers to the new standards through professional development (PD). Despite the learning this PD supports, many teachers struggle to implement innovative NGSS-aligned curriculum in their science classrooms. The tensions teachers experience between traditional science teaching practices and NGSS standards are significant (Shelton, 2021). A shift to NGSS practices requires change at multiple levels and across multiple dimensions (Holt & Vardeman, 2013). Teachers communicate their feelings on the change being asked of them through a myriad of signals. We call these signals: *signals of readiness for change*, or simply, *readiness signals*. This paper examines the readiness signals teachers communicated during a PD focused on creating NGSS-aligned lessons featuring computational modeling activities. We present a theoretical framework that identifies the tensions teachers experienced during the PD. The framework can be used to identify readiness signals, which can be examined to understand teachers' change aptitude, or their inclination and ability to change. Comparing counts of positive and negative readiness signals can provide a measurement for change aptitude. We use Epistemic Network Analysis (ENA) to understand how positive and negative readiness signals co-occur, as a measure for change aptitude.

Understanding the tensions

Teachers work in complex epistemic frames, or ways of knowing in a community of practice (Shaffer and Ruis, 2017). In these frames, the rules that shape their actions and the norms they use to interpret classroom interactions can be established at legislative, district, administrative and personal levels. Common educational epistemic frames have practices that include preparing lessons, delivering lectures, and proctoring assessments. Current research suggests that experiences where students explore phenomena and define their own problems provide richer learning. When teachers attempt to implement innovative research-aligned approaches, the new approach can create tensions for teachers as the rules and norms can require significant shifts in time allocation, teacher, and student roles, and evaluation. Phillips et al. (2021) used Epistemic Network Analysis to show complexity in the teacher decision-making process by illuminating co-connections between tensions. We suggest that readiness signals can capture the tensions that arise when teachers are pressed to adjust rules or norms in their epistemic frames. The overarching goal of this work is to use *readiness signals* to help education leaders identify tensions that need to be addressed before innovations such as the NGSS can be successfully implemented. The specific research questions to be addressed in this paper are:

- What readiness signals do teachers communicate with respect to proposed innovations, when engaging in professional development around NGSS?
- Do our partner teachers' *change aptitudes* shift after participating in PD?

A framework for assessing aptitude for change

Our work began in the summer of 2020 working with three middle school science teachers in a 4-week synchronous online professional development (PD). The purpose of the PD was for teachers to create and implement novel science curriculum where students construct their own computational models of phenomena. Throughout the training, various remarks from the teachers regarding their thoughts and feelings implementing the novel curricula caught our attention and raised questions about their readiness, or aptitude, for the change we were asking of them. Words connected to their ability, beliefs, and motivation showed up repeatedly in the teachers' utterances. These themes were expressed at the following levels: personal, students, other teachers, the school, and the education system requirements. Some of the facets emerging in our data were mentioned in the change readiness literature (Rafferty et all, 2013). Yet the current change frameworks, mostly focusing on corporate change, failed to represent all the elements found in our science education data. Thus, we integrated frameworks (Bandura, 2001; Grenny et al., 2013) to produce a framework featuring the elements we saw in our data.

Bandura's (2001) framework provided an initial characterization for the emerging readiness signals in our data. Self-efficacy, belief, ability, and motivation appeared to be critical factors for teachers' willingness to innovate. While Bandura's perspective shows the multidimensional influences surrounding agency, the research of Grenny et al. (2013) clarified that ability and motivation must be present at personal, social, and structural levels for individuals to adopt change. Our framework provides a guide for taking a deeper look into the complex system of abilities, beliefs, and motivations associated with the adoption of innovative practices in science education (Jones & Swanson, 2022). The vertical levels in our framework are personal, school (students, staff, administration), and education system. The horizontal dimensions are abilities, beliefs, and motivations. This guide is meant to support reflection and discussion that uncover tensions in how the dimensions intersect, which can then be considered and addressed.

Methods

Participants

The inspiration for this work came from the teachers' talk during a 4-week summer PD with daily meetings conducted by two of the authors. The participants, Katie, Mary, and Rebecca (pseudonyms) were science teachers working at middle schools in a Western United States city with 25, 7 and 17 years of experience, respectively. Katie and Rebecca taught at the same school. For the summer PD, they attended daily online meetings, created lesson plans, and worked with software developers to co-design computational models on a topic included in one of their lessons. Participants explored how they might integrate NGSS practices such as developing and using models, asking questions, conducting investigations, and constructing explanations.

Data sources

As part of the PD, we held daily morning meetings via Zoom to build team connections and to get a daily read on how everyone was doing. The conversations and activities provided an opportunity for teachers to communicate their feelings on the innovations they were being asked to implement. Video recordings of these meetings were transcribed using Otter.ai. Transcripts from Week 1 and Week 4 discussions were analyzed to understand teachers' readiness signals at the start and end of the PD. The themes of Weeks 1 and 4 were different. Week 1 focused on introductions, relationship building and exploration of new teaching goals, classroom interaction norms, and instructional activities. Week 4 focused on curriculum development, feedback, revision, reflection and integrating these new goals, norms, and activities into their classrooms.

Procedures

This study takes a deep dive into the details of the teachers' talk during the PD. It explores their reactions to the new ideas, pedagogies and practices associated with creating and implementing computational modeling lessons. The analytical procedures occurred in four steps.

Step 1. Codebook creation and code refinement

We began with a previous iteration of our framework (Jones & Swanson, 2020). To test and refine the framework, we used it to code readiness signals in the PD data. Utterances were determined by a change in speaker and each one was evaluated for instances of the nine specific readiness signals. The revised codebook is presented below (Table 1). The codebook operationalizes the theoretical framework by specifying the kinds of language associated with each of the nine signals.

Table 1
Readiness signals codebook

This table is meant to be used when the subject of a conversation is proposed innovations or change, and the teacher has communicated a reaction to it.	
Personal change signals—Check to see if the statements use personalized words like I, my, we, us, or ours.	
BP	**Belief**, Does the person convey interest, hope, belief, doubt, or disbelief about doing something?
AP	**Ability**, Does the person provide some indication that they are able or not able to do something?
MP	**Motivation**, Does the person provide some indication that they are overwhelmed, hesitant, or stressed?
School change signals—Check to see if the statements discuss students or school personnel. *School* includes students, staff, and administration.	
BS	**Belief**, Does the person indicate that students or school personnel convey disinterest, disbelief, or doubt about doing something?
AS	**Ability**, Does the person indicate that students or school personnel are able or not able to do something?
MS	**Motivation**, Does the person indicate students' or school personnel's willingness to do something?
Education system change signals—Check to see if the statements discuss something like standards, expectations, time, or requirements. The education *system* includes state legislators, district leaders and principal.	
BE	**Belief**, Does the person indicate that the system supports or makes it difficult to do something?
AE	**Ability**, Does the person indicate that the system is able to accommodate to these changes?
ME	**Motivation**, Does the person indicate that the system will adapt to allow them to do something?
Positive or negative - Are the statements communicating a predominantly positive or negative sentiment?	

Step 2. Establish inter-rater agreement and code data

To check for bias in the coding, we trained a person not associated with the research using 3.3% of the data. Codebook revisions, coding practice, comparison and discussion were conducted to reach the desired interrater reliability with a Cohen's kappa of 0.65. The first author coded the remaining data using the revised codebook. Each turn of talk was evaluated according to the nine questions and whether the readiness signals had positive or negative sentiments.

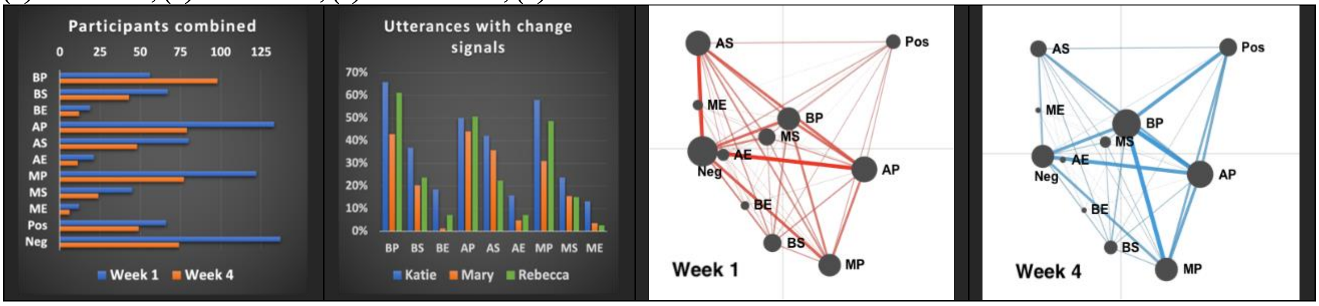
Step 3. Understand shifts in readiness signals

We used Epistemic Network Analysis (ENA) to quantify the readiness signals in teachers' language and illuminate their co-connections for each week. ENA uniquely provides the ability to visualize multiple readiness signals communicated by the teachers, the occurrence frequency (line thickness), and number of connections being made (network density) (Shaffer & Ruis, 2017). By visualizing a teacher's network of readiness signals at different points in time, ENA provides a way to detect subtle shifts in change aptitude.

Findings

What readiness signals do teachers communicate with respect to proposed innovations, when engaging in professional development around NGSS? To answer these questions, we counted all instances of readiness signals demonstrated by each teacher for Weeks 1 and 4. We counted positive and negative remarks for each week to see if teacher's aptitude for change shifted from the first to the fourth week of PD. From the combined participants chart (Figure 1), we can see that eight readiness signals dropped in number, but personal belief (BP) increased. We can see that even though the number of negative change signals dropped greatly, negative signals still outnumber positive signals by about 30%. In Figure 2, which shows utterances featuring readiness signals, we can see that all three personal signals -- belief (BP), ability (AP), motivation (MP), and ability school (AS) -- appeared in a higher percentage of the spoken utterances than the other change signals in both weeks.

Figure 1
(a) Combined, (b) Utterances, (c) ENA Week 1, (d) ENA Week 4



Do teachers' change aptitudes shift after participating in the PD? Comparing Figures 3 and 4 shows some shifts in positive connections. The network density from the positive node in Week 4 has decreased yet the strength of the connections co-occurring with all three personal signals (BP, AP, and MP) has increased. An aptitude shift is happening but not across all signals. The negative node maintains dense connections in Week 4, yet some of the links have decreased in frequency. These co-occurrences tell us that teachers continue to evaluate and communicate the challenges they face in adopting these new teaching practices. Readiness for change in the areas of personal belief, ability and motivation have a stronger presence in the conversations.

Limitations

The limitations of this work recommend areas of focus for future work. First, there might exist interpretation bias with a small number of coders. Future studies could follow up with participants, discuss the readiness signals, and address misinterpretations. Second, since the sample size is small, we did not check statistical significance in the analyses and could not validate patterns in readiness signal shifts.

Discussion and conclusion

We have taken an in-depth look at the discussions that occurred during the first and last weeks of a month-long NGSS-based PD that urged three educators to radically transform the way they teach science. We illustrate the feasibility of using our theoretical framework to explore potential tensions in teachers' adoption of curricular innovations. The readiness signals framework helped us see the complexity of teachers' thinking and decision making when introduced to innovative educational approaches. These readiness signals can indicate teachers' feelings towards proposed innovations. The data show an increase in positive readiness signals from the first to final week of a PD. Still, a significant number of negative signals suggest lingering concerns regarding the incorporation of these new norms and practices into their classrooms.

This work provides a framework for assisting those involved in educational innovation. The framework directs attention to readiness signals that communicate teachers' hesitance with adopting change. We have shown that our signals of readiness for change framework is a useful tool for uncovering the kinds of things teachers are considering when faced with the request to innovate in their classrooms. Our investigation of readiness signals can assist innovation leaders in better seeing their group's own readiness for change. Our data reveal that teachers are concerned about changing roles (i.e., teacher to facilitator), gaining new skills, leading learning experiences without seeing exemplars, and facing unknown outcomes that may not work. Teachers experience confusion around the meanings of different standards and their priorities. They struggle to choose what to spend time on and how much time to give each topic. It is our hope that discussions across all dimensions in this framework can help us move science education forward in new and productive ways.

How Kinetically-Held Gestures Support Collaborative Problem Solving in Physics

Virginia J. Flood, University at Buffalo, SUNY, vflood@buffalo.edu
Benedikt W. Harrer, University at Buffalo, SUNY, bwharrer@buffalo.edu

Abstract: Embodied forms of communication like gesture are essential for problem solving, but we know little about how they are used in group interactions. Drawing on ethnomethodology and conversation analysis (EMCA), we examine how undergraduate physics students use the *temporality* of gesture to orchestrate productive interactions: Using *kinetically-held* (frozen in place) *gestures,* students (1) recruit attention, (2) mobilize responses, (3) weather interruptions, and (4) facilitate extended consideration of elaborated and clarified ideas.

Introduction & theoretical approach

Collaborative problem solving in STEM engages students in productive disciplinary practices and knowledge building (e.g., Engle & Conant, 2002; Roschelle, 1992), but learning outcomes of groups are contingent on the quality of their interactional processes (Barron, 2003; Roschelle, 1992). The learning sciences have documented many interactional resources students use to coordinate interactions during collaborative STEM problem solving, including strategies for releasing tension (Sohr et al., 2018), managing uncertainty (Conlin & Scherr, 2018), and navigating off-task behavior (Langer-Osuna et al., 2020). While we know much about productive forms of *talk* that are conducive to generative collaboration, less is known about how gesture helps orchestrate productive group interactions. In this study, we examine how undergraduate students use the *temporality* of gesture to coordinate collaborative physics problem solving. In particular, we show how students use *kinetically-held gestures* (Kendon, 2004) – suspended representational gestures – to support productive group interactions.

Detailed, mechanistic examinations of interaction are crucial to understand sources of variability in collaboration and how outcomes emerge (Barron, 2003; Koschmann & Zemel, 2009; Roschelle, 1992). Roschelle (1992) illustrated how students must carefully monitor and repair shared understandings in group work: collaborators must not move on from proposals until they have sufficient evidence of shared understanding. Barron (2003) discovered another key interactional characteristic: based on how *responsive* students were to each other's verbally shared proposals, equally competent groups performed dramatically differently on problem solving tasks. Unsuccessful groups ignored, interrupted, and rejected (correct and incorrect) proposals before they were elaborated or clarified. We ask, how might representational gestures shape these interactional processes?

Representational gestures, which illustrate objects and processes (Kendon, 2004), are especially useful for collaborative STEM work because students use their hands and bodies to work out, model, and make sense of scientific and mathematical phenomena together (e.g., Alibali & Nathan, 2012; Roth & Lawless, 2002; Scherr, 2008; Singer et al., 2008; Walkington et al., 2019). An understudied affordance of representational gestures is their temporality. Participants can control how a gesture evolves *over time*. Representational gestures have distinct phases: (a) a *preparation* where the hands leave a resting position, (b) one or more *strokes* that carry semantic information, and (c) a *retraction* where the hands resume rest. A *gesture hold* occurs when, after a stroke is completed, the hands *do not* return to a rest position but remain frozen for a period of time (Kendon, 2004). Holds both illustrate content and project information about participation or turn-taking. They are used to mark turns-in-progress that speakers intend to resume after speech disfluency (e.g., a pause to find the right words), interruptions, or because a speaker struggles to gain attention (Park-Doob, 2010; Sikveland & Ogden, 2012). Holds can also be used to mobilize responses from participants, e.g., by demonstrating the speaker's expectation that a listener should supply an answer to a pending question (Kendon, 2004).

Study context, methods, and findings

We examined 11 groups of 3-4 students completing 4 problems from the Collaborative Learning through Active Sense-Making in Physics curriculum (Potter et al., 2014) in an undergraduate physics class (25 hours of video). We identified 100 instances of group members' use of representational gestures where representational gestures were held for more that 1.0 second. All groups used holds. We selected a single interactional sequence to present representative examples of *each* of the different interactional functions of kinetically-held gestures in group work we observed in our collection. Our EMCA-inspired microanalysis traces the temporality of representational gestures, including their preparations, strokes, holds, and retractions to reveal how holds are coordinated with other semiotic resources to organize interaction. Our transcripts adapt (1) Jefferson's conventions for talk*;* (2) Mondada's conventions for gaze, facial expression, and body movement: -- *extended duration,* --> *action continues;* and (3) Kendon's conventions to annotate gesture preparation, strokes, holds, and retractions:

preparation phases ~~~, *strokes* ^^^, *held gestures* ***, and *retractions* -.-.; *beginning and end of phases* are denoted with |. Symbol sequences illustrate the timing of gesture phases, aligned with co-occurring speech syllables and other semiotic activity. Each gray box shows a set of vertically aligned co-occurring semiotic resources, and speech tracks are aligned horizontally to show sequential turns. Gesture is marked in blue, speech in black, and other activity in gray.

Kit, Leo, Ian, and Jen are working on a problem that requires them to model a toy car launcher with a spring inside that gets compressed by the same distance each time a car is loaded. This distance indicates the amount of energy stored in the spring. When the car is launched, the spring decompresses. The energy in the spring is converted to kinetic energy of the car, which is released with a certain initial velocity. Students are asked if *all* cars will have the same launch speed. Kit turns to the group with a proposal: The initial distance should be *greater* than zero, and the *final* distance should be zero because the spring is initially compressed and must return to its relaxed state as the car is being accelerated. Kit's proposal is consistent with the convention that the energy in a spring is zero when it is not compressed or stretched.

Barron (2003) observed that unsuccessful groups often have issues with *recruiting* each other's *attention* to joint problem spaces (Roschelle, 1992). Making sure a proposal will be adequately considered and understood means ensuring that it is not ignored. Kit turns from the board to his group, making a bid to share a proposal. He begins with "So-" (E1.03) and pauses (E1.04) while moving his right arm out toward the group (r**Prep**, E1.01). Leo, Ian, and Jen are all gazing at their notebooks (E1.02). Without looking up, Ian asks a question about the spring (E1.05). Kit restarts his turn (E1.06) and makes a shrinking pinch shape with his right thumb and index finger (r**Stroke**, E1.01), evoking the image of a spring contracting. He then starts to hold this pinch shape (r**Hold 1**, E1.01; **E1.a**). As the group maintains gaze on their notebooks, Kit starts a third attempted turn in E1.09 and also cuts it off but continues holding his pinch gesture (E1.07). He points to the board with his left hand (l**Hold 1**, E1.11; **E1.b**). With both arms outstretched (r**Hold 1**, E1.10; l**Hold 1**, E1.11), he starts a fourth time, now making a complete proposal: "The initial should be greater than zero" (E1.13). Ian raises his head to look up at Kit (E1.12). With Ian's attention secured and still holding his gesture (E1.14-16), Kit elaborates his proposal, providing additional evidence: "It's not at equilibrium" (E1.17). By deploying several cut-off phrases and false starts, accompanied by a visible gesture held out towards the group, Kit succeeds in not having his proposal be ignored. Speech restarts are an effective tactic for recruiting visual attention as a speaker when trying to take a turn (Goodwin, 2018). However, Kit also deploys a *gesture hold* to *recruit attention:* Continuing to hold his hand outstretched (E1.01-14), he displays he has something to share that requires their attention.

Even when shared attention has been achieved, groups may not acknowledge a proposal (Barron, 2003). An important interactional strategy is to *mobilize a response* (Stivers & Rossano, 2010) when proposals have been shared. After successfully gaining Ian's attention (E1.16 in Figure 1), Kit releases his first gesture hold in Figure 2 and produces a new representational gesture that he holds (**Hold 2**, E2.18; **E2.a**) as he provides additional support for his assertion that the spring is not at equilibrium (E1.17): He says, "you see it's bent right here" (E2.20), bringing both index fingers together vertically and evoking an image of a compressed spring (**Hold 2**, E2.18; **E2.a**). He holds this gesture (E2.18,24) as he gazes at Ian. Ian, still looking at Kit, replies, "Yeah" (E2.22). Kit directs attention to the gesture ("you see," E2.20) and, by not immediately releasing the hold, demonstrates he expects a response: Hold and talk solicit an *assessment* of his assertion made in speech and illustrated in gesture. Making sure they agree that the spring is compressed is useful to re-calibrate their shared understanding of the situation. Kit's utterance and hold *mobilize a response* from Ian who accepts the premise (E2.22). This is key for gathering consensus and moving forward, even though they still disagree about the significance of the premise.

```

Barron (2003) also observed frequent interruptions in unsuccessful groups, where proposals were cut off and abandoned. Kit uses a third hold to *weather an interruption*: After securing acceptance from Ian, he begins a second part to his proposal in E2.27, saying "and then wh-", as he sweeps his vertical index fingers apart, evoking the image of the spring expanding (**Stroke**, E2.24). Leo, who has been gazing at his notebook, looks up (E2.26) and interrupts with a counterproposal (E2.28,33). Kit *verbally* abandons his turn (E2.27) but keeps his hands suspended in the air (**Hold 3**, E2.24,30; **E2.b**). This displays to the group that he considers his turn incomplete and projects that he will resume it. Notably, Leo also produces representational gestures (E2.25,31) and a gesture hold (**Hold 4**, E2.31; **E2.b**) as he interrupts. He repeats Kit's pinch-shaped "compressed spring" gesture (**Stroke**, E2.25), and he also moves apart his vertical index fingers to repeat Kit's "expanding spring" gesture (**Stroke**, E2.31). Both Leo and Kit hold the same two-handed vertical index finger gesture at the same time (**Hold 3**, E2.30; **Hold 4**, E2.31). Leo holds his gesture past the boundary of his spoken turn, mobilizing an assessment from the group. He successfully solicits a strong agreement from Ian (E2.34). After obtaining acceptance of the counterproposal from Ian, Leo releases his hold (**Retract**, E2.31). All the while, Kit has maintained *his* hold (**Hold 3**, E2.24,30) to *weather the interruption*: Although Leo interrupts with his counterproposal, Kit's maintenance of his turn with the gesture hold in Figure 2 provides a new opportunity for more discussion in Figure 3.

Figure 3

Using gesture holds to allow for elaboration, clarification, and extended consideration

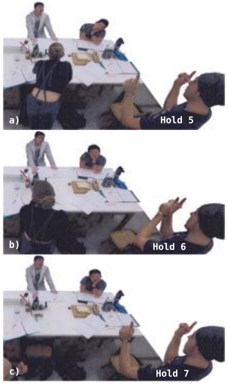
54                                                              (0.1)
```



The ultimate consequence of nonengagement with proposals is not having time or space to adequately consider them before prematurely rejecting them and moving on (Barron, 2003). Kit produces another series of holds as he *elaborates* and *clarifies* his proposal, providing new information to the group. The holds both support Kit to make the overall proposal more detailed and explicit, and they make space for the *group's extended consideration* to think about and assess each new piece of information. Kit is still holding his gesture from Figure 2 and has not been able to fully lay out his proposal. He restarts, repeating "and then" (E3.38), and reperforms the "expanding spring" gesture (**Stroke**, E3.37). As he continues talking, he maintains his hands frozen in this position (**Hold 5**, E3.37; **E3.a**) while providing two new important details about the uncompressed state of the spring: When released, the spring "goes back to zero" (E3.38), and *this* is returning "to its equilibrium" (E3.40). Holding the gesture throughout his explanation, Kit *elaborates* his proposal by illustrating the *final position* of the free end of the spring after it is released and has returned to its relaxed state, asserting the *value* of this final position, and establishing that this final, relaxed, position (and *not* the compressed position) should be considered *equilibrium*. In response, Leo leans backwards and furrows his brow (E3.41,42), in a silent but visible display of "doing thinking" (Goodwin, 2018). While still holding the gesture and providing a space for the *extended consideration* of these additional details, Kit elaborates further, claiming he is supported by the lab manual (E3.44). Leo provides a "hmm" (E3.46), displaying his continuing consideration of the proposal. Kit treats Leo's response as an absence of acceptance and understanding, and continues his explanation, using it as an occasion to *clarify*. He speaks with marked emphasis and repeats his gestures, using two holds to illustrate that "This is not zero" (E3.48; **Hold 6**, E3.47; **E3.b**) and "this is zero" (E3.50; **Hold 7**, E3.49; **E3.c**). In these turns, Kit takes the time to make each part of the proposal even more explicit. His holds are now what McNeill (1992) calls *catchments:* repeated images that help bring continuity and coherence through complex explanations. As Kit holds the last gesture (**Hold 7**, E3.49), Leo provides another display of his ongoing consideration ("Huh," E3.52), and then upgrades his acknowledgment of Kit's proposal to an acceptance and claim of understanding ("Okay," E3.52).

Concluding remarks

Our analysis demonstrates how *kinetically-held* gestures can play a role in ensuring proposals are taken up and explored by groups. Holds can provide an interactional antidote against pitfalls that Barron (2003) observed: Kinetically-held gestures can (1) recruit attention to proposals and ideas, (2) mobilize responses to proposals, (3) weather interruptions so proposals can be resumed, and (4) allow for extended consideration of proposals. Our investigation adds to previous studies in STEM education that illustrate how representational gestures are essential tools for learning when students try to make sense of complex phenomena together (e.g., Alibali & Nathan, 2012; Singer et al., 2008; Walkington et al., 2019). We explored the *temporality* of representational gestures and were able to identify and characterize new ways representational gestures contribute to problem solving by organizing and coordinating participation and turn-taking. Our study contributes to broader definitions of competence in collaborative work in STEM: By focusing on uncovering the fine details of the interactional practices students use to build, repair, and maintain a sense of shared meanings in interactions, we were able to recognize more of the assets students bring to STEM work and problem solving.

Navigating Emergent Divisions in a Coalition for an Antiracist School

Nicole Louie, Leema Berland, Amanda Coviello, Mariana Pacheco

Abstract: Disagreement often leads to polarization and division in activist groups. Here, we examine relationships between learning and conflict in a coalition working toward building an antiracist school community, which included staff and parents at one elementary school and their university partners (including three authors of this study). We analyze a key conflict in the group regarding whether our efforts should focus exclusively on Black students and families or take a more racially and ethnically inclusive approach. We then explore how members of our coalition positioned one another throughout these discussions. We find that participants positioned themselves and one another dichotomously, as either right or wrong, not only conceptually but also morally. This disrupted learning opportunities and eroded trust within the coalition—yet as we show, it was reasonable given multiple layers of context. We conclude by offering implications for design to support transformative learning in groups working toward antiracist change.

Purpose

Even as they advocate for a more just and inclusive society, socially progressive and radical groups may engage in divisive and exclusionary internal politics. This phenomenon has been rampant among justice-oriented groups in recent years (Grim, 2022). In this paper, we explore dynamics within a coalition that aimed to build an antiracist learning community at one elementary school. With our analysis, we seek to contribute to understandings of the kinds of ideas that divide members of school-based antiracist coalitions in the current moment, how members position others whose ideas they perceive as conflicting with their own, and the implications of these dynamics for learning within these coalitions.

Prior research

Intra-organizational conflict has been a rich area of study in research on social movements. Scholars have examined factors that contribute to such conflict, stages in the development of factions, and the consequences of factionalism (Kretschmer, 2013). Generally, however, this literature has not examined relationships between conflict and learning. In contrast, many studies within the learning sciences have, converging on the conclusion that learning is hindered by a competitive ethos but enhanced by a collaborative approach to disagreement (e.g., Barron, 2003; Chiu, 2008). But these latter studies focus on conceptual disagreements in classrooms, in which participants are likely less invested in the outcome than participants in activist groups are.

The present study attempts to bring these disparate literatures together to investigate how division may emerge within groups whose members share a commitment to social justice—a commitment that other studies of collaborative learning suggest should produce a “safe haven” (e.g., Picower, 2011)—and the implications for learning. In doing so, we also attempt to coordinate attention to broad social context and moment-to-moment interaction. We thus build on growing efforts in the learning sciences to link what we know about learning and design with studies of activism and social change (e.g., Pham & Philip, 2021).

Theoretical perspective

Building on Kendi (2019), we take antiracism to be a set of actions that counter ideas, practices, and structures that perpetuate hierarchies based on race and intersecting systems of oppression, and actively work toward equality. Making sense of precisely what this means in any given moment requires ongoing negotiation because the contours of racism and antiracism are specific to time and place, shaped by both local and extralocal contexts. Further, White supremacist ideologies are extremely powerful in shaping our unconscious assumptions about what is good, what is natural, and what makes sense (Louie, 2018; Philip, 2011). Thus, rather than assume that antiracism is a static state, we argue that antiracism requires ongoing, intentional, and communal negotiation and critical reflexivity—rigorously and continually examining the ways that we participate in and reproduce racism and intersecting systems of oppression, despite our conscious intentions.

Heterogeneity is a vital resource for this negotiation of meaning (Bang & Vossoughi, 2016). Racism impacts and is hence perceptible to different people in different ways, all of which must be understood in order to enable collective antiracist transformations. While embracing heterogeneity requires that we seek to understand ideas that are offered in good faith, it does not mean embracing every idea as if it were sound, humanizing, or just. Nor does it necessarily mean leveraging diverse views to reach a tidy conclusion. Rather, it can mean holding competing ideas in tension and grappling with them as a means of generating new knowledge. This contrasts with the dichotomous thinking that often arises from conflict (Wood & Petriglieri, 2005), which frames two differing positions as mutually exclusive; privileges one position as inherently better than the other; and eliminates possibilities for coexistence or other positions beyond the binary (Prokhovnik, 2001).

Methods

This study centers on a coalition of university researchers (the first, second, and fourth authors and three others) and faculty, staff, and parents at Eastwood Elementary.[1] In 2019, 90% of the Eastwood staff was white, 25% of students were Latino/a/x, 25% were Black, 18% were multiracial, 17% were white, and 8% were Asian (primarily Hmong). The school had a stated equity vision, but racism and racist acts persisted throughout the school, targeting multilingual students, Asian American students, and Black educators. At the request of the school, the university researchers partnered with the school to work towards building an antiracist school community. We met for a year and a half, including bi-monthly meetings with the school-based leadership team, and 6- and 5-day summer retreats for learning in 2019 and 2020 (on Zoom in 2020 due to Covid-19).

For the present analysis, we focus on two episodes from the 2020 summer retreat, one from a debrief meeting with the school leadership after Retreat Day 1 and one involving the whole coalition on Day 2. Both discussions took up the topic of whether the coalition should focus on Black students and families exclusively or take a more inclusive approach to antiracism. These conversations were rife with conflict and thus afforded a window onto the group's divisions. The debrief meeting included the Eastwood principal Amy (a White woman), assistant principal Keith (a Black man), and the teacher who initiated our partnership, Malik (a Black man). Five university faculty members were present: Carl (a Black man), Leema (a White woman), Mariana (a Chicana woman), Nicole (a Chinese American woman, and Kat (a White woman), as well as graduate student Laura (a White woman). We did not record this meeting but took extensive field notes. The meeting of the whole coalition on Day 2 involved 21 Eastwood teachers and staff and four mothers from the Eastwood community—one Black, one Hmong, one Latina, and one White. One particularly vocal participant in the episode we analyze was David, a White social worker. We recorded this Zoom session.

We analyzed the episodes to characterize (a) what speakers seemed to be advocating (b) and how we positioned ourselves and one another. We examined our own participation in the coalition in the same way as our partners', seeking to simultaneously reveal what made our actions reasonable and how these actions may have been problematic. Focusing on individual utterances helped us (somewhat) to distance ourselves from our own opinions, recollections, and experiences. Additionally, Amanda—who was not part of the Eastwood antiracist coalition—joined us for data analysis and writing and provided an additional check against our biases. After analyzing each episode individually and in pairs, all four authors compared and discussed our analyses. Our different characterizations were complementary and mutually supportive, bolstering our sense of the validity of our interpretations. Preliminary findings are based on our consensus account.

Preliminary findings

Three themes emerged from our preliminary analysis: (1) concern that some members were approaching antiracism in ways that allowed antiblackness and poor outcomes for Black students to persist, (2) concern that some members were espousing ideas and practices that dehumanized people of color, and (3) concern that some members were not willing, or able, to take concrete steps to confront racism in any form. Due to space limitations, we focus on selected aspects of the first and second themes.

Allowing antiblackness to persist

A concern voiced by some members of the coalition was that others' approach to antiracism was insufficient to address deep-seated antiblackness. For example, in the Day 1 debrief, the school principal, Amy, expressed her dissatisfaction with how the full meeting had gone, saying, 'I don't want to veer from talking about Black students in particular. … They are the most affected.' Similarly, on Day 2, David said, "Our Black boys and Black girls at [Eastwood] are the ones most frequently not accessing things in the classroom, are kicked out of the classroom, are getting referrals." Amy and Malik also argued that Eastwood teachers 'don't know how to teach Black students' (Amy) and 'seem to be inadequately trained' to work with Black students (Malik). Given limited time, Amy, Malik, David, and Keith argued that focusing on the area of greatest need was strategic. They contended that 'aiming too wide' (i.e., taking a more inclusive approach to antiracism) would allow teachers to 'shuffle around and not dig into the work they need to do' (Keith), more specifically to 'not engage with their thinking regarding Black students because this requires particularly hard discussions' (Amy).

Amy, Malik, and David's concerns were sensible given local, national, and global mobilization in the spring of 2020 demanding racial equity for Black people. Just weeks before the retreat, George Floyd was murdered by the antiblackness endemic to the United States (as argued by kihana ross (2020) in a *New York Times* op-ed that the coalition read). Moreover, a few years earlier, a report had shown that Eastwood's county produced some of the largest Black/White achievement gaps in the nation, and throughout the coalition's duration, various pro-Black initiatives were ongoing in Eastwood's district and highly salient for school staff.

Dividing and excluding

Several coalition members voiced concerns about focusing strictly on Black students, to the exclusion of Eastwood's Latina/o/x, Hmong, and multiracial students and families. For example, Carl compared ignoring 'Hmong, Latinos, … everyone who are of color' to 'go[ing] into a school that is on fire and bring[ing] only the Black kids out.' Nicole said she could not 'be part of an antiracist coalition that erases Hmong and Latinx students,' and Mariana stated she would 'resign and not be part of this group' if the coalition was going to engage in the explicit 'exclusion of Latino students.' Similarly, on Retreat Day 2, Nicole stated that "it is literally impossible to have a caring, inclusive, antiracist community that is caring, inclusive, and antiracist for only some people."

The concerns expressed by Carl, Nicole, and Mariana were responsive to the multilingual, multicultural, and multiracial demographic context in which they were situated. National discourses had long focused on a Black/White binary, erasing the contributions of Latinas/os/xs and Asian Americans as well as the racism their communities faced. This was mirrored by Eastwood's district, where there were no parallels to pro-Black initiatives for Latina/o/x or Hmong students, despite comparable levels of academic achievement (as measured by standardized tests), and in the case of Latina/o/x students, an equal or larger population at many schools (including Eastwood. Further, in visits to Eastwood, university partners documented that Latina/o/x and Asian American students were ignored in classrooms even as their most basic learning needs went unmet. Moreover, a Hmong mother had shared on Retreat Day 1 that she did not feel "welcome" at Eastwood, saying, "I have to sacrifice my culture to teach my kids to make it in this school." Additionally, for Mariana and Nicole, their own racial identities (as Chicana and Asian American, respectively) made the erasure and exclusion of Latina/o/x and Asian American students and families from the coalition deeply personal.

Positioning those with conflicting ideas

Participants positioned those whose ideas they perceived as threatening their own in a variety of ways, which we group here under two major themes: positioning each other as morally compromised or worse, and positioning each other as aligned. Under the first theme, our preliminary analyses indicate that participants positioned each other as dishonest, ignorant, hypocritical, complacent, and racist. For example, Nicole's and Mariana's statements about leaving the coalition suggested an unbridgeable chasm between themselves and the advocates of a strict and exclusive focus on Black students. Moreover, in objecting to how this focus 'erases Hmong and Latinx students' (Nicole) and arguing that 'if we're being honest and authentic,' the coalition should be re-named for its exclusive focus on Black students and 'not antiracist' (Mariana), they positioned advocates of this position as both racist and dishonest. Keith rejoined that the conversation had 'turned to All Lives Matter,' positioning Nicole and Mariana as both ignorant of 'our teachers' at Eastwood and as racist, grouping them with a movement opposed to Black Lives Matter. This positioning of one another as morally wrong is consistent with dichotomous thinking and inconsistent with valuing heterogeneity and critical reflexivity.

Almost every participant also made efforts to close distances between themselves and others, positioning everyone on the same side. Some of these efforts attended to others' feelings more than to the content of what they said (e.g., 'I hear you'). Other efforts cast contrasting views as complementary, not competing. During the Day 1 debrief, several university participants (Carl, Leema, Nicole, and Laura) attempted to leverage a focus on classroom practice to bridge gaps. Similarly, on Day 2, Leema summarized the different positions thus: "The actions need to be creating space for all cultures. … But what I hear David saying is that … we cannot accomplish that without doing some hard internal work about our internalized antiblackness." She then stated, "I don't see it as an either or. I see it as doing what Amber [another teacher] is asking for and also doing internal work simultaneously." However, none of these attempts were taken up in a way that advanced a shared understanding of antiracism or of the coalition's mission. One possible explanation is that participants could have been so caught up in the emotional experience of having their values threatened and 'attacked' (to use Keith's word) that conciliatory moves did not register very deeply. Or, efforts to resolve tensions may have been conceptually unsatisfactory to participants, insufficiently engaging with the details of their positions and the possibility that some tensions could not or should not be resolved.

Regardless of why the attempts to close gaps and construct alignment within the coalition were not taken up, their presence shows that the participants recognized the importance of trust, vulnerability, and positive relationships in the coalition. However, it seems that we perceive a conflict between tending to those relationships and other deeply held concerns and convictions—concerns and convictions that were informed not only by what happened in the immediate setting of the coalition but also by other contexts and our specific positions and identities in relation to those contexts.

Discussion and conclusion

It is clear that we missed opportunities to learn from one another throughout this retreat, particularly if we take learning to arise from "the coordination and dynamic coexistence of multiple ways of seeing and knowing" (Bang & Vossoughi, 2016, p. 184). Instead of coordinating, participants reiterated or further justified their positions without building on, inquiring into, or otherwise directly engaging the logic, evidence, or feelings beneath contrasting views. Further, no attempts to engage in critical reflexivity are evident. Working to coordinate our divergent perspectives and experiences could have resulted in a richer, more nuanced understanding of race, racism, and antiracism at Eastwood than any single person or faction could have developed alone. Failing to coordinate them produced flatter understandings, eroded trust, and foreclosed opportunities to develop a shared understanding.

It is easy to say that collaborative learning toward antiracism requires people to treat each other with trust and respect. But our case shows that this can be much harder to accomplish than studies of "safe havens" suggest. Indeed, trust and respect can break down because the same deeply felt commitments that bring participants to the table can lead them to perceive others' competing commitments as morally repugnant. This leaves participants with little room for mutual, shared learning. Better understanding the conditions under which this occurs is necessary to help antiracist learning communities to design for heterogeneity, curiosity, and critical reflexivity, and support groups to leverage contrasting ideas to generate better understandings of each other, themselves, and antiracism, as well as better plans for antiracist action.

Endnotes

(1) The three other members of the coalition from the university were Carl Grant, Kathleen Nichols, and Laura Roeker. "Eastwood" is a pseudonym, as are names for non-university participants throughout the paper.

Who is Disabled? The Social Construction of Disabled Bodies in Embodied Activity

Morgan Vickery, Indiana University, moravick@iu.edu

Abstract: This exploratory review dissects the social and cultural construction of bodily ideals and 'disabled bodies' in embodied learning spaces by drawing on an interdisciplinary corpus of literature. First, this paper attends to the limitations of current embodied learning scholarship and explores notions of the many sociocultural and institutional pressures that shape youth's bodies in the habitus of both modern-day schooling with attention to how learning environments 'disable' and 'enable' students whose bodies fit the hegemonic bodily ideal.

Introduction

Within the embodied learning literature, the human body is positioned as a resource for engaging in negotiating and constructing meanings within the social and physical world (Nathan, 2021). Equity-oriented scholars have further proposed embodiment as in-motion, focusing on the dynamic relationships that bodies have with places, movements, and times (Warren et al., 2020). Yet, by nature, embodied activities constrain what forms of embodiment are 'counted' in design and carry a set of implicit assumptions around learners' ability and willingness to physically and visibly perform in a particular context (Mathayas et al., 2022). For the 'ideal' learner, the body is considered yet another tool that can be leveraged in instructional design to pursue learning objectives. But by neglecting to consider the needs of learners who do not fit into the model of this 'ideal' body in embodied activity design, we pressure learners to either conform to some developmental norm (Annamma & Booker, 2020), tolerate the denial of learning pathways and resources (Nasir et al., 2020), or 'push them as they are' through an environment custom-built and optimized with another user in mind (Uttamchandani, 2020). This functionally dehumanizes, coerces, and denies dignity to learners.

Learners engage in external processes of *becoming* (Nasir, 2002), self-formation, and discovery as they navigate the various possibilities for bodies (Wolputte, 2004). Thus, the nature of bodies is inherently multiplicitous, fluid, and indeterminate while remaining subject to the same cultural and social processes. While this review will not be comprehensive in its discussion of how each of these domains has historically conceptualized body normativity, I offer a narrative that holistically considers bodies as a product at the intersection of multiple social and cultural axes. I adopt a critical approach to *intersectionality* that attends to how individuals experience and are confronted by multiple co-occurring systemic and institutional oppressions. By identifying these vectors of oppression, we can name and understand the multiple interwoven marginalizations that people experience (Annamma & Booker, 2020; Gillborn, 2015) as learners engage in learning processes.

Defining the 'ideal' body

Learners are constantly subject to a set of socially-constructed bodily ideals that dictate how and whether their bodies are worthy of attention, practice, and social capital (Fitzgerald, 2005). These ideals furthermore feed into a system that stratifies youth based on culturally constructed ideological and material systems for determining one's 'goodness' and 'smartness.' Particularly in the United States, these conceptions of youth as inherently 'good' or 'bad' are discursively and institutionally intertwined with aspects of race, class, and gender; 'good' bodies are those which conform, assimilate, and subjugate themselves to those who represent the 'ideal' white, able-bodied, male standard. (Broderick & Leonardo, 2016)

Annamma and Booker (2020) discuss the normative standard of being as the determining force through which one attains access to power; access increases as one becomes more closely perceived as the norm. Expressions of difference from the norm become the grounds through which institutions and social structures work to shame and correct individuals' appearances and behaviors for the sake of developmental likeness (Annamma & Booker, 2020). Interpersonally, these expressions of difference fail to activate the same level of social capital within peer groups (Fitzgerald, 2005) and are perceived, treated, and punished as acts of noncompliance by authority figures/instructors (Goodwin, 2020).

Communities have long designed systems of social organization around the definition of the "other" defined as and by opposition to those in power. "Othering" functions to delegitimize, demonize and eventually erase non-dominant ways of being to maintain and enable social, cultural, and institutional dominance over those 'others' (Lee et al., 2020). Within the United States context, this "othering" is rooted in the practices and logic of settler-colonialism through which western white settlers establish a society founded on the commodification, dehumanization, and domination of non-white bodies. It is these histories and the establishment of racist, cis-heteropatriarchal, and ableist systems designed to ensure the stratification and erasure of bodies classified as existing too far from the white, masculine, able bodily idea through the denial of access to opportunities, resources, and power. These systemic denials of power and resources function to deny people that which makes them human, then reinforce and sustain beliefs and narratives which stigmatize, and stereotype social groups ultimately determining the criteria of who is and is not considered ‘human’ (Lee et al., 2020; Nasir et al., 2020, Rogers et al., 2020).

Physical education spaces as sites of dehumanization

Bodies and minds perceived as disabled have historically been perceived as a threat to society instigating the use of social and institutional efforts of erasure (Stiker, 2019; Lester, personal communication, April 22, 2022). Educational settings in particular affirm a normative presence in the facilitation of activities that require that bodies perform and be assessed according to how their body demonstrates mesomorphic, masculine, and motor-competent traits. While this includes learners with known physical, cognitive, and/or social disabilities, stigma built around bodily ability is also inexplicably tied to issues of gender, race, sexuality, and body size.

The assignment and possession of social capital and its relationship to the understanding of bodies as particularly salient within the disability studies literature pertaining to physical education and athletics contexts. In these spaces, attention, and value are given to technique-based athletic performance within a strict range of abilities and skills (Nyberg et al., 2020). This phenomenon is further exacerbated when physical education spaces take on a competitive, aggressive, and masculine atmosphere further deterring participation for those who do not perform ‘appropriate masculinity’ (Wellard, 2006). These pressures and values associated with athletic participation can additionally be fueled by community attitudes toward and perceptions of athletics: elite and high-socioeconomic often consider athletic achievement and participation as integral to the schools' image, reputation, and in-school identity (Wright & Burrows, 2006). Consequently, youth experience multidimensional pressures for their bodies to adequately perform at risk of being perceived as lacking effort, worth ethic, or some inherent capacity to ‘do’ physical activity (Wright & Burrows, 2006).

Thus, we create a system where social, embodied, and cultural capital is prescribed on the basis of achievement in activities designed to ensure that only a limited proportion of the population can excel (Penney et al., 2018). This inequitable distribution of social capital within physical education spaces leads to the deterrence of, avoidance by, and outright exclusion of youth from such activities (Allender et al., 2006; Fitzgerald, 2005; Penney et al., 2018; Wright & Burrows, 2006). This dilemma has prompted researchers to combat the stigmatization of these bodies and minds through the reconceptualization and re-mediation of educational activities and spaces requiring physicality (Fitzgerald, 2005; Maher & Fitzgerald, 2020; Nyberg et al., 2020; Penney et al., 2018; Pocock & Miyahara, 2018; Qi & Ha, 2012). Such work provides insight into what oppressive and disabling characteristics of physical education may be present in embodied learning environments and how we might adapt our activity designs to be more inclusive of learners who have been deemed ‘disabled.

Conclusion

Fitzgerald (2005) reminds us that the normative ideals that (re)enforce these barriers for students are deep-seated in the habitus of modern-day schooling and thus cannot be resolved exclusively with such instructional “superficial remedies.” Yet, if we are to engage in ethical and dignity-affirming educational practice (Booker et al., 2014; Curnow et al., 2019), we must also acknowledge how our bodies carry a multitude of presentations, histories, and experiences that are under repression and control (Vossoughi et al., 2020) and are imbued with historical, axiological, and epistemological orientations of the world (Marin & Bang, 2018).

I posit that embodiment scholarship must come to (1) recognize unwelcome, coerced, or dehumanizing actions in situ, (2) understand the consequences of these interactions for learners’ psychological and physiological well beings, and (3) design to proactively subdue dignity-denying processes by enabling learners to exercise their bodily autonomy. If we as educators are to ‘do no harm,’ it is vital that we consider the invisible oppressions embedded in our activity designs and the consequences of disregarding the lived experiences youth’s bodies carry such that no body falls through the cracks.

“Growing as a Person”: Authoring Identity Across Formal CS Education and Everyday Computing Contexts

Jacob Wolf, Harvard University, jwolf@g.harvard.edu
Jenny Han, Stanford University, jennyhan@cs.stanford.edu
Chris Proctor, University at Buffalo (SUNY), chrisp@buffalo.edu
Emma Brown, Independent Schools Foundation, eqbrown@isf.edu.hk
Jonathan Pang, Teachers College, jonathan@fablearn.net
Paulo Blikstein, Teachers College, paulob@tc.columbia.edu

Abstract: To understand how learners develop identities in computer science (CS), we must investigate learners’ experiences with computing throughout their lives. Drawing from a theory of learning as participation in communities of practice, we analyze interviews with high school students at the end of their time in a 2-year, constructionist CS course to better understand how these students’ CS education affected their experiences with computing in their everyday lives. We identify moments where students begin to “re-see” technology which offer insight into how students author their computational identities. However, our analysis reveals that re-seeing does not inevitably align with a positive trajectory of participation in CS. Instead, we discuss how the nuances of students’ “re-seeing” experiences combine with various social factors to influence students’ computational identity authorship.

Introduction

As computer science (CS) education expands in K12 education around the world, there is a growing opportunity– and a growing urgency–to design for CS learning experiences which positively influence learners, their communities, and the world. Traditional measures of content learning will not be enough to ensure that CS learning experiences have a positive influence; we cannot simply ask, “Are students learning CS?” Instead, we must focus on what learners need in order to participate in a world where computation plays an increasingly significant role. In addition to supporting participation in computing, CS education must prepare learners to decide *whether* and *how* to participate in our increasingly computationally-mediated world (Vakil, 2020; Ryoo et al., 2020). As a practice which helps learners recognize, make sense of, and solve computational problems, Wing’s (2006) Computational Thinking (CT) has become the most common way to describe how CS might help learners solve real-world problems. While early work largely understood CT as an individual cognitive phenomenon, more recent frameworks also recognize CT as a social practice embedded within systems of power (Kafai et al. 2020). In these framings, learning is understood in terms of participation in communities of CS practice. Identity is a central construct which models the processes by which learners show up and act in a community of practice. If CS education is to prepare youth to participate in and help shape our computational futures, we need a better understanding of how learning environments support learners in developing computational identities (Penuel and O’Connor, 2018; Kafai 2016; Tissenbaum et al. 2019; Dindler, et al., 2020). Because learners’ computational identities extend throughout their lives, we must investigate this construct across formal CS education and everyday computing contexts. Such an investigation can help us understand the roles that formal CS education can play in learners’ broader lives and help us provide resources to learners as they negotiate their computational identities. In this paper, we present a phenomenographic analysis of beginner high school CS students’ experiences negotiating their computational identities. In analyzing these experiences, we highlight the ways students feel their CS education contributes to this experience, supporting or constraining them in their use of technology. In doing so, we contribute to an understanding of computational identity that spans both formal CS education and everyday computing contexts.

Background

Our definition of computational identity begins with the understanding that learning happens through participation in communities of practice (Wenger, 1999). In order to characterize learning as a process of social participation, this framework outlines four components of learning: (1) doing, (2) belonging (3) experiencing, and (4) becoming. In this framework, the process of becoming is interconnected with the processes of doing, belonging, and experiencing. We are constantly developing identities (both our own and others') through our actions, which are in turn dependent on our positions and experiences within the community. How we position ourselves relative to others in a community of practice allows us to author our identities (Holland et al., 1998). At the same time, identity authorship is also restricted by the ways other members of a community of practice recognize (or don’t recognize) our participation. This development of identity through practice is rarely linear, instead consisting of many fluctuating moments where learners feel stronger or weaker identities relative to a field. Applying this framework to the work of a CS course helps us to see that course as situated within many different community contexts including the classroom, learners' home environments, and even digital spaces like StackOverflow. Identity development in CS has been charted as learners experience success and failure (Dahn and DiLiema, 2020), join or get excluded from communities of practice (Shaw et al., 2021; Margolis et al., 2008), and face stereotypes about who can be successful in the field (Love et al., 2021). This development is not always ultimately positive. Learners' participation in computing communities of practice can create distance in their computational identities, either because they feel incapable or uninterested in participating (Kang et al. 2019) or because the computing communities of practice are exclusionary (Nasir and Vakil, 2017).

Learners' experiences in communities of CS practice, both positive or negative, contribute to their trajectories of participation in the field of CS (Drier 1999). These trajectories of participation take into account learners' positions in communities of practice as well as the ways they navigate between different communities of practice. As learners have experiences in these communities, they develop expectations (of the discipline and of themselves) that determine what they see as possible and appropriate forms of participation in computing communities of practice. Rather than being deterministic, trajectories of participation should be seen as the resources and constraints that influence learners' perspective on what are possible forms of participation in their communities of practice. To investigate the process of identity authorship through participation, we are particularly interested in moments where learners feel their perspectives are shifting–moments where learners are "re-seeing" their computational worlds and their place in them (Silver, 2014). To paint a full picture, we must understand this re-seeing in formal computing settings and across multiple everyday uses of computational tools and ideas (Shaw and Kafai, 2020). With this in mind, we are interested in the following questions:

1. How do the ways learners use or feel about technology change as they learn CS?
2. Is there a relationship between these changes and how learners author their computational identities?

Methods

This study was conducted at a private bilingual K-12 school in Hong Kong, where twenty-eight ninth graders participated in a two-year curriculum. In this cohort, thirteen consented to participate in this research (14-16 years; three girls, ten boys). The central goal of the course is to "create a rich, diverse community of people making things with code, through which they can develop personal relationships with powerful ideas" (Proctor et al. 2020). The course was composed of six units (e.g. computational art, data science, web development, etc.); for each unit, students completed an open-ended project that applied skills and concepts from that unit.

At the end of the program in May 2021, three researchers who were also teachers conducted a semi-structured exit interview with each student. We asked students to reflect on formative moments with technology throughout their lives as well as changes in their relationship with various technologies (such as the internet and their computers) over the course of the two years. With these interviews, we extend Wilkerson et al.'s (2020) methodology for locating computational thinking in everyday spaces of learning to identify "locally constructed definitions" for identity in CS (p. 269). To analyze the data for this paper, three of the authors conducted a thematic analysis and identified students' reflections about the computational world and their place in it. One author then re-coded the interviews to identify all instances of "re-seeing" the computational world, drawing from students' own language to create the category. In this paper, we seek to capture the experience of our students as individuals rather than summarize across the class. We contribute these select perspectives to the literature on identity in CS education while laying the foundation for future work to explore broader categories of perspectives in our class and other populations. Students' names have been changed for anonymity.

Findings

Re-seeing the computational world

Though they had a wealth of experience with technologies from gaming PCs to learning management systems prior to the course, students frequently reported a change in their interactions with technologies during their exit interviews. Reflecting on watching a music video on a Virtual Reality platform, one student, Tina, said:

> "It made me think more about what I was using and what I was doing. And like the interaction between person and digital device, that kind of relationship. . . Like, "oh," if I click on this button, there's a whole bunch of code behind the color of this button and the depth to make it look like a button. And this button links with some other page. And it's like a whole process of coding and effort for me to just click on a button to get to a new page."

In total, we found that in ten of the thirteen student interviews we analyzed (77%), students discussed an experience where they used technology differently or felt differently about technology compared to their experiences before the course. Many, like Tina quoted above, described a realization of the many layers through which their interactions with technology flowed, unveiling servers behind web pages and file systems behind graphical user interfaces.

Re-seeing and computational identity authorship

Along with their shifting perspectives, some students described enacting this perspective as part of their computational identity authorship. During the data science unit, one student, Noa, chose to find her own datasets to answer a question about her experiences as a competitive athlete in a water-based sport. This experience was a critical moment in Noa's trajectory as a computer scientist. After completing the project, she went on to do a variety of data analysis projects that were connected to her interests in the ocean and in sustainability. In her final interview, she connected all of these experiences back to the data science project, saying, "the data science [project] actually helped [her] develop as a person," and "doing data [science] led [her] on to give [her] the opportunity to do [a conference publication] and many other projects developed after that." Reflecting on these experiences and how she developed over the two years of the course, Noa said:

> "I think a lot of it was character development, me growing as a person and as I mature, I feel I'm being more aware of the people around me, and the events happening around me... I'm actually doing more service. I want to do more for the world."

Though many students, like Noa, shared ways that their re-seeing experiences were connected to positive trajectories of participation in CS, students also shared examples of the ways their experiences affected their trajectories in negative ways, making them feel less confident and less excited to continue learning CS. For example, Tina noted that she respected people in CS "because it's very difficult" and described how in the first year of the course she began thinking that she "might not be built for computer science." This feeling extended through her final project of the class in the web applications unit. Looking around at the other projects, Tina felt like other students were progressing more quickly than her and her partner. For Tina, CS is "an interesting topic, but [she is] not necessarily enthusiastic about it compared to other people." In contrast with Noa's experiences, Tina's comments highlight the ways that she feels separated from others practicing CS.

Discussion and future work

Our findings highlight the cognitive shifts that occur when our students "re-see technology" in their everyday interactions. However, considering how changing perspectives affect students' identity, we interpret the act of "re-seeing" as a series of social negotiations that ultimately affect trajectories of participation in CS. Indeed, students' perspectives of technology were always changing within their communities of practice; they were "re-seeing" as they were doing, becoming, experiencing, and belonging (Wenger, 1999).

For students like Noa, their changing perspective on CS promoted a positive trajectory of participation in CS. However, this was not always the case. Even while developing a new perspective in CS, some learners' experiences were connected to a negative trajectory of participation. Tina's experiences offer a particularly interesting case study. Like many other students, Tina described the ways her CS education helped her see new features of technology. However, for Tina, this complexity still represented something she felt she would never understand. Tina's comments about feeling like "she wasn't built for CS" based on her perceptions of the field and on her experiences in the class align with research showing how stereotypes that students and educators hold about CS can limit learners' participation in the field (Love et al., 2021). At the same time, Tina's comments that CS is "an interesting topic, but [she is] not necessarily enthusiastic about it" do not seem flippant. Throughout her interview, Tina described ways that she imagined her CS education could serve her in the future and even sent a follow-up email to her interviewer clarifying that she felt her CS education had positively "changed [her] thinking about learning." This leads to another reading of Tina's experience: that given what she knows about CS and about herself, Tina decides to limit her engagement with the field. Though her formal CS education has not (yet) culminated in a positive trajectory of participation in CS, Tina is still negotiating her computational identity by refusing further engagement with CS education. While these two readings of Tina's negative trajectory are different, we believe that both are necessary to make sense of Tina's computational identity. We are critical of the ways the course community of practice contributed to Tina's sense of exclusion, *and* we recognize the agency Tina exhibits in refusing to participate further.

While Noa's and Tina's examples represent different trajectories of participation in CS, they both describe kinds of computational identities assumed by students, the experience of these identities in students' lives, and the CS education resources that influenced students to take on these identities. However, these examples represent just two of many in our data. In future research, we plan to use these insights as a foundation for further exploring how students' experiences with computing shift as they learn CS and for determining how specific experiences with CS education influence students' computational identity authorship. As technology increasingly intersects with problems in our world, this research is essential for designing CS education that prepares learners to participate in the world with the intention and ability to use computing as a force for good.

Comparing Teacher Educator and Novice Teachers' Frames in Making Sense of Feedback During Rehearsals

Marta Kobiela, McGill University, marta.kobiela@mcgill.ca
Zhikun Zhang, Beijing Normal University, zhikun.zhang@mail.bnu.edu.cn
Enista Sharonne Chiniah, McGill University, enista.chiniah@mail.mcgill.ca

Abstract: In this study, we compared the frames that a teacher educator (TE) and preservice novice teachers (NTs) within a math teaching course used to interpret feedback that the TE provided during rehearsals. We conducted video-elicited interviews with the TE and two NTs in which they watched excerpts of TE feedback from a rehearsal video to understand: a) how the TE and the NTs described the problems of practice (PoP) that the TE feedback focused on and b) the frames the TE and the NTs used to interpret those PoP. We present two major differences in the types of frames that participants drew upon to describe the PoP. Our results highlight the importance of considering the frames that NTs may bring to rehearsals.

Introduction

Researchers have long sought to understand how to better support teachers to bridge theory and practice (Ball & Cohen, 1999). Several teacher education programs have implemented opportunities for pre-service teachers (NTs) to connect theoretical understandings from their courses to the enactment of teaching practice through rehearsals of teaching (e.g., Lampert et al., 2013). In a rehearsal, an NT practices teaching a lesson to their peers, who act as students, with a teacher educator (TE) serving as a coach. A key aspect of rehearsals is that the NT or the TE can interject (pause the teaching) to provide feedback related to problems of practice (PoP) that arise (Lampert et al. 2013). Feedback provided during rehearsal interjections may be evaluative (i.e., judging an action), and/or directive (i.e., suggesting a next step) and can take different forms (e.g., questions, comments) (Lampert et al., 2013). Such feedback can provide *potential* opportunities to learn pedagogical content knowledge (Ghousseini, 2017) and adaptive expertise (Ghousseini et al., 2015). Yet, the way that feedback is interpreted may depend on NTs' *frames* – that is, the lens they use to make sense of an event (Goffman, 1976). Frames have been shown to shape how in-service teachers interpret PoP (Vedder-Weiss et al., 2018). However, research is lacking about the frames that pre-service teachers use to interpret PoP, particularly within rehearsal feedback. Accordingly, we asked: 1) How do NTs and the TE describe the PoP that prompted the rehearsal feedback? 2) What frames do the TE and NTs use when they interpret those PoP? Our aim is to understand if and how NTs' frames may alter their interpretation of a TE's feedback. This is important, as feedback may be less effective when teachers fail to understand it (Sanyal, 2017).

Theoretical perspectives

We drew on two theoretical perspectives. First, we drew on Greeno's (2011) *situative perspective of learning*, which suggests that understanding and learning are social in nature, situated within contexts, and constructed through interactions. This means that NT and TE interpretations of feedback are shaped by their interactions with tools and people within the rehearsal. Rehearsals are often designed around two tools: (a) NTs teach an instructional activity with a routine structure that can be adapted to different content and ages (Lampert et al., 2013). (b) NTs may also be asked to focus their learning on a set of core teaching principles (e.g., children are sensemakers) and practices (e.g., eliciting student thinking) (Lampert et al., 2013) that provide a common framework for analysis of PoP (Ghousseini et al., 2015). Second, we drew on Goffman's (1974) notion of frames. Frames "provide interpretive contexts that support participants in a given situation to understand what kind of task they are engaged in, what kinds of knowledge are relevant or valuable, and what sort of behavior they and others are expected or entitled to engage in" (Louie et al., 2021, p. 97). Frames are rooted in people's experiences and beliefs (Alvidrez et al., 2022). The action of using a frame to make sense of a situation is called *framing* (Goffman, 1974). When frames are applied to interpret a problem, it is referred to as problem framing (Bannister, 2015). Problem framing can allow teachers to unpack and reflect on pedagogical practices and interactions (Vedder-Weiss et al., 2018). Therefore, NTs and TEs may collectively learn as they engage in problem framing during rehearsal interjections. Teachers may use different frames when problem framing, including epistemological and positional frames. Epistemological frames are about how knowledge is perceived to be created (Alvidrez et al., 2022). Positional frames are about the role of the participants in an activity. When engaging in positional framing, participants interpret their own and others' positions and the relationship between them (e.g., students-as-capable of tackling errors and students-as-incapable of addressing errors) (Alvidrez et al., 2022). When used to interpret a problem, epistemological and positional framing can take two different forms: *Diagnostic framing* is about how people identify a problem and its cause, while *prognostic framing* is about what people propose as solutions to a diagnosed problem (Bannister, 2015). Feedback provided during rehearsal interjections may be interpreted using either diagnostic or prognostic frames or both.

Methods

This study took place in a mandatory elementary math teaching methods course offered in the second year of a teacher education program in Eastern Canada. The course aimed to support NTs to learn about knowledge and practices for teaching number and arithmetic. Most NTs had limited in-class teaching experience. As part of the course, each NT participated in one rehearsal in a group of 2-3. NTs selected one instructional activity (quick images or strings) and were provided a lesson plan to use. To prepare for the rehearsals, NTs were introduced to a set of core principles (e.g., children are sensemakers) and practices (e.g., pressing on student thinking) (Lampert et al., 2013). Participants included three TEs (each teaching a separate section) and NTs enrolled in the course. We use gender-neutral pronouns (they/them) to refer to participants. For this paper, we selected one of the TEs (TE-1) and two NTs enrolled in TE-1's class (NT-1 and NT-2). We selected TE-1 as a case because they were experienced with providing feedback during rehearsal interjections. We selected NT-1 and NT-2 as cases because we had observed that their responses differed and might allow us to see a greater range of frames.

We conducted 60-minute semi-structured interviews with TEs and NTs in which they watched video-recordings of rehearsal interjections. For this initial analysis, we focused on the first interview (out of 2-3) conducted with participants. Participants viewed the same rehearsal video, selected based on three criteria: a) there had to be at least three interjections, b) interactions were typical (e.g., in terms of participation), and c) there was consent from all who participated in the rehearsal to have the video used in the interview. NTs did not necessarily watch their own rehearsal as their presence in class was sufficient to interpret and reflect on their TE's feedback, and we were interested in what NTs might learn from all rehearsals, regardless of their role. TE-1 was asked two sets of questions. One set was asked after viewing 30-seconds of the video before an interjection in the rehearsal: 1) You are about to pause. Why did you pause here in the rehearsal? 2) What did you notice that caused you to pause? The other set was asked after viewing the interjection: 1) What did you want the NTs in your class to understand there? 2) Why do you want the NTs to understand that? 3) How do you think your comments/questions help support NTs' learning? NTs watched the 30-seconds prior to the interjection and the interjection that followed and then were asked: 1) Explain in your own words what you think [TE-1] was saying or trying to say. 2) What do you think that [TE-1] wanted you and the other future teachers to understand? 3) Why do you think that [TE-1] wanted you and the other future teachers to understand that?

To understand the ways that participants framed PoP during rehearsals, we conducted a frame analysis (Goffman, 1974), drawing upon methods of discourse analysis to understand how participants conveyed significance, positions in activity, connections between actions and ideas, and perceived values and norms (Gee, 1999). First, all interview videos were transcribed and then parsed into episodes. Episodes started when the interviewer started to play the rehearsal video and ended when the interviewee finished answering the questions for that clip. We numbered the episodes in each interview to correspond with the same interjection in the rehearsal. This resulted in a total of 10 episodes. We then analyzed the transcripts iteratively using a set of analytic questions based on literature and refined through our discussions of the data. To identify PoP, we asked: How does the participant describe what the TE said and why the TE paused during the rehearsal? To identify frames, we asked: How does the participant justify the solution of the PoP and/or why the PoP is problematic? Through this process, we identified several categories of frames to further analyze the data. Examples include: a) formal course principles and practices of teaching (when participants used the exact terms in the course core principles and practices), b) informal course principles and practices of teaching (description of the core principles and practices using other language), c) perspectives on learning (general ideas about how students learn), and d) positional (how students are positioned as learners and teachers as educators). Finally, we compared episodes to identify commonalities and differences in how participants framed problems.

Findings

We describe two major distinctions in the types of frames that participants used to make sense of the PoP in the rehearsal. These frames impacted how problems were described. To illustrate our findings, we will draw upon Episode 5 from the participants' interviews because they used different frames to interpret PoP. In this episode, the participants watched two consecutive video clips from a quick images rehearsal taught by another NT in the class (not NT-1 or NT-2), who we refer to as the rehearsing-NT (R-NT). Quick images is an activity in which students are quickly shown images of dots and asked to determine how many dots there are. In the rehearsal, the R-NT presented the quick image in two ten frames (grids composed of 10 rectangles). In Episode 5, the R-NT had asked a student to share their strategy for finding the number of dots in the quick image. The student explained that they had imagined moving the dots from the left card to the right card to fill in the empty cells. The R-NT then revoiced the student strategy and asked whether any other students had another strategy to share. TE-1 paused the rehearsal and asked, “How do you know [the answer is] ten?” The interjection then ended.

Formal vs. informal frames

Unlike the NTs, the TE more frequently drew upon the formal course principles and practices to frame PoP. For example, in Episode 5, TE-1 explained the pause by drawing upon three different course practices: “I want [R-NT] to understand that [they] missed the opportunity to press to reach [their] goal. [They] just assume[d]. I said, ‘How [does] it makes ten?’ Because [the student] said, ‘I put those four [dots] and I put them.’ Okay, but how do you know it’s ten?...There's no pressing on students’ thinking. [They] just revoice[d].” Here, TE-1 used three formal course principles and practice as frames to make sense of the PoP: pressing on students’ thinking, teaching toward an instructional goal, and revoicing students’ thinking. The practice of revoicing students’ thinking provided a diagnostic frame to make sense of what the R-NT had been doing that TE-1 saw as problematic. The other two practices provided a prognostic frame for understanding what the R-NT could have done instead.

In contrast, NT-2 sometimes drew upon core principles and practices but often used different language to describe those principles and practices. For example, when watching the same rehearsal moment, NT-2 said, “[TE-1] was asking [student]...where you get that ten from since [R-NT] did not make that clear...So [R-NT] didn't ask [student] to explain [their] answer. So just make sure that us as future teachers continue to engage students and to represent their thinking and explain their thinking.” When asked what they meant by representing, NT-2 explained, “So as [student] did on the board, [they] showed [their] work, representing, and then explaining it afterwards which is important to make sure that all the other students in the class to understand [their] way of thinking, how [they] solved that problem.” Here, NT-2 also drew upon a similar prognostic frame to what TE-1 described as “pressing” but used different language: “explain their thinking.” However, NT-2 drew upon another formal course frame, representing students’ thinking, yet used it in a different way from how it was defined in the course: as the student representing on the board (instead of the teacher representing). This frame focused NT-2’s attention on the student’s action of writing on the board instead of the teachers’ action of revoicing and targeting an instructional goal (that TE-1 had focused on), and thus led to slightly different framings of the problem.

Student vs. teacher positional frames

All three participants drew upon positional frames in many episodes but did so in different ways. TE-1 often simultaneously drew upon a mix of positional frames that positioned students as capable and teachers as facilitators of students’ learning and often connected these positional frames to the math of the lesson. In contrast, NT-2 tended to only draw upon positional frames that suggested students were capable of learning on their own. NT-2’s positional frames were often coupled with frames about perspectives of learning. For example, in Episode 5, when NT-2 was asked to explain why it was important to have students explain their thinking, they responded: “To make sure that your students are gaining from other students’ knowledge. ...if the student doesn't explain how they thought of it, all the other students in the classroom will not gain from how the original student thought of it, and the teacher will not gauge how much the student like compr- like understands it.” Here, NT-2 drew upon a frame that learning is social (a perspective on learning). In addition, by viewing students’ explanations as important for each others’ learning, NT-2 also used a positional frame that placed students as capable.

NT-1 tended to use positional frames about teachers’ authority roles in the classroom. In doing so, they sometimes positioned students as less capable. For example, after watching the same video clip in Episode 5, NT-1 described what the TE said as, “[TE-1] said [they] understood that- if we filled the whole cell [of the ten frame], that's a full cell, but [TE-1] said [they] didn't understand how it made 10.” NT-1 then explained, “[TE-1 wants future teachers to understand that] you're not going to have everyone following because it's information we said, it's been a long time since [the teacher said it]. If we have a complete cell [in the ten frame], it gives 10 boxes and so we should have written it next to it.” When asked why this was important, NT-1 explained that primary school students “are not going to have the same abilities as us, so we must not take for granted they are following everything we do and that they will have the same ability to remember things.” In this excerpt, NT-1 drew upon two positional frames: (a) the teacher’s role is to clarify ideas for the students and (b) adults are different in their abilities to remember and understand. The NTs’ differing positional frames may have partly been due to their perceptions of the TE’s role in the rehearsal. NT-1 revealed that they understood the TE to be acting as an elementary student asking a question to the teacher. Because of this perception, NT-1 framed the problem as a *student* issue: that students may not be following what is happening because the information was said a while ago. In contrast, NT-2 understood the TE to be modeling a question for the rehearsing NT to ask, thus framing the problem as a *teacher* issue: that the teacher did not ask students to explain their thinking.

Discussion

In this paper, we have illustrated how different frames from NTs and the TE can shape how they interpret PoP in the rehearsal. Our findings highlight the affordances and limitations of learning through rehearsals of teaching. Both NTs were able to provide interpretations for all episodes, suggesting that they engaged with the feedback to some level. On the other hand, their understandings of the feedback often differed from what the TE intended. Our results also show that NTs constructed pedagogical concepts – connections between lived concepts (e.g., particular examples of questions teachers can ask) and formal concepts (general principles or theories about teaching and/or learning) (Horn et al., 2017). In many episodes, participants similarly described what TE-1 said and the actions that occurred in the rehearsal that prompted the interjection (the lived concepts). However, even with this alignment, they still often generalized the problem into a formal concept differently depending on the frames they used. This was evident in Episode 5: Both TE-1 and NT-2 described how the R-NT had failed to ask the student to explain his thinking, yet TE-1 generalized the problem as an issue related to targeting the instructional goal of the lesson. Although subtle, such connections may alter how NTs reason about and respond to future pedagogical situations. Our results also show how the complexities of the rehearsal context shifted which frames NTs drew upon. In particular, in Episode 5, their interpretation of the role of the TE changed how they drew upon and prioritized frames about teachers and teaching or frames about students. Thus, our results suggest that TEs and NTs need to have greater awareness of the frames that they bring to their collective inquiry of PoP.

Abstract: This paper examines data collected from in-depth interviews with 20 participants of the Young Scholars Program (YSP), a STEM enrichment initiative for middle and high school students in the U.S. that was funded by the National Science Foundation from 1988 to 1996. Using social cognitive career theory (SCCT) as the guiding framework, the analysis considers how the students' motivation, self-efficacy and sense of identity may have been influenced by the YSP experience and how these constructs may have been connected to the development of their careers. Applying epistemic network analysis (ENA) to the data, it was found that greater levels of STEM motivation, identity and opportunities were central to the career development of individuals who ultimately remained in STEM-related professions.

Introduction

Various STEM enrichment programs in K-12 settings have been implemented over the years to increase student knowledge, skills and interest in STEM topics and subjects. A key aim of such programs, particularly those funded through public resources, has been to support and encourage the entry of individuals into STEM-related academic disciplines and ultimately into the STEM workforce. However, whether a young participant eventually decides to pursue and sustain a career in a STEM-related field has been difficult to evaluate. The long-term retrospective study of the Young Scholars Program (YSP) is an effort to address this challenge. The YSP was a federally-funded STEM enrichment initiative that was carried out across the U.S. between 1988 and 1996. Designed for middle and high school students, the YSP sought to: (1) enhance participants' knowledge of and exposure to STEM fields; (2) foster interest in STEM education and research; (3) increase awareness of academic for STEM careers; (4) gain familiarity with universities and research institutions; and (5) enhance confidence in making career-related decisions (National Science Foundation, 1993). With more than twenty-five years having elapsed since the end of the program, the current age of YSP participants range from late 30s to early 50s. Through surveys and interviews of the YSP participants, the retrospective study seeks to examine the impact that the YSP may have had in the subsequent academic and professional trajectories of the young students.

In this context, this paper examines data collected from in-depth interviews with 20 YSP participants. Guided by social cognitive career theory (SCCT), this paper considers how the students' motivation, self-efficacy and sense of identity may have been influenced by the YSP experience as well as how these constructs may have been connected to the development of their careers. Building on Bandura's (1986) social cognitive theory, SCCT focuses on the role of self-efficacy and outcome expectation in mediating interests and goals that lead to choice behavior (Lent et al., 1994). It provides a framework for understanding the relationship and interactions among constructs affect career-related decision-making processes (Lent, Brown, & Hackett, 1994). SCCT also accounts for environmental factors and individual learning experiences in addition to personal attributes, such predispositions and demographic information (Lent et al., 2000). Through the notion of an iterative and dynamic feedback loop, SCCT recognizes the effect that previous career-related actions can have in subsequent decisions (Lent et al., 1994). While not an explicit component of SCCT, the importance of identity formation in career development has been emphasized, particularly in adolescents. In the process of identity formation, adolescents seek to gain a deeper understanding of their own beliefs, values and emotions as well as a sense of their interests and abilities (Gushue et al., 2006). A key component of this process is career exploration, whereby students begin to develop their own vocational or career identity (Macht Jantzer et al., 2009).

Methods

This paper analyzes data collected from semi-structured interviews of 20 YSP participants. Convenience sampling was utilized, as comprehensive lists of participant names and contact information were not retained for many of the YSP projects. The professional fields of YSP participants included in this analysis were split evenly between roles that are STEM-related and those that were not (see Table 1). Both groups of interviewees consisted of individuals from diverse demographic backgrounds.

Table 1

Summary of participants by professional field, gender and race/ethnicity

	Current Professional Field	
	STEM Field	**Non-STEM Field**
Gender		
- Female	5	8
- Male	5	1
- Non-binary	0	1
Race/Ethnicity		
- American Indian/Native American	0	1
- Asian	1	1
- Black/African American	2	2
- Hispanic/Latinx	1	1
- Pacific Islander	1	0
- White/Caucasian	5	3
- Other/Not specified	0	2
Total	**10**	**10**
Sample Professional Roles	Research Scientist / Administrator, Science Teacher, Professor (STEM), Aerospace Engineer, Computer Network Engineer	Artist/Writer, Designer, Judge, Professor (Non-STEM), Business Executive, Higher Education Administrator

Interviews were carried out using an online video conferencing platform. The first part of the interview focused on the experiences of participants during their involvement in the YSP while the subsequent portion concentrated on the development of their academic and professional careers and the influence of YSP in this process. The recorded interviews were transcribed and segmented by sentence. The data was coded independently by two raters using a codebook comprising a total of 13 codes organized around four categories: (a) topic/field; (b) self-reflective constructs; (c) description of YSP experience; and (d) career-related factors (see Table 2). Codes in categories a and b were applied to both sections of the interview data; codes in categories c and d were each applied to interview sections one and two, respectively. For each dataset, two coders reached agreement on the final coding through a process of social moderation (Herrenkohl & Cornelius, 2013).

Epistemic network analysis (ENA) was then used to model the connections between the codes present in the interview data. ENA is a tool in quantitative ethnography, applies statistical and visualization techniques to identify patterns in discourse (Shaffer, 2017). Specifically, connections among codes are modeled in ENA by quantifying their co-occurrences in the recent temporal context (Siebert-Evenstone et al., 2017). The unit of analysis was defined as a participant and a conversation was specified to be the set of lines contained within a section of an interview. A moving window of size 4 was used to model the co-occurrences of codes between a given line and three preceding lines in the same conversation. For each section of the data, subtracted ENA networks were created to compare the patterns of discourse in the reflections of YSP participants currently in STEM-related professional fields and those working in other sectors.

Table 2

Codebook of constructs included in the analysis

Category	Code	Description
Topic/Field	STEM	Direct reference to a STEM-related discipline, field, area or topic
	Non-STEM	Direct reference to a discipline, field, area or topic that is not STEM-related
Self-reflective constructs	Motivation	Gaining interest, desire or intent to pursue further action toward a goal; setting goals/expectations (to propel forward) or a having a sense of direction for the future
	Self-efficacy	Confidence, pride or sense of accomplishment in themselves; belief in one's own ability to complete a task, achieve a goal or succeed; expectation of positive change in their abilities
	Identity	Reference to sense of self, sense of independence or a sense of belonging; reference to permanent or long-term characteristic, ability or state the participant attributed to self
Description of YSP experience	Knowledge Acquisition	Gaining of knowledge or skills by the speaker; description of learning processes in which the speaker took part
	New Experiences	Reference to a new or eye-opening experience for the speaker; description of experiences that enabled the speaker to broaden their perspective

	Peer Interaction	Interactions, exchanges or relationships with peers in social and academic contexts; references to the development of interpersonal/social skills with other participants
	Engagement	Reference to active participation and involvement in an task, project or activity
	Positive Affect	Experience described through explicit expressions of joy, fun, excitement, positive regard
	Negative Affect	Experience described through explicit expressions of stress, sadness, anxiety, regret
Career-related factors	Career Opportunities	Reference to opportunities offered to the speaker for academic and professional development or advancement
	Career Challenges	Reference to academic, professional and personal challenges confronted by the speaker (challenges can refer to obstacles, loss of opportunities, failures, etc. that hinder advancement or development in a particular field, area or career path)

Results

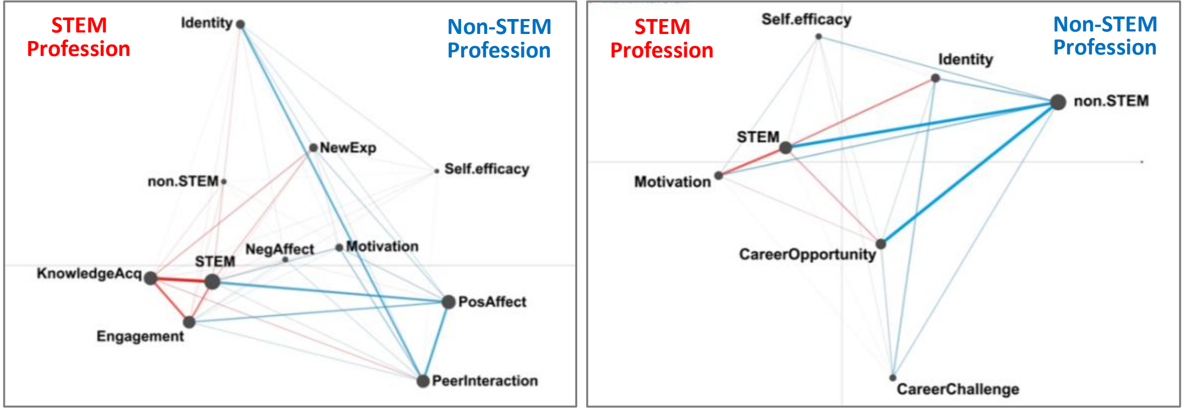
Reflections of YSP experiences

The first analysis explored the differences in the reflections of participants about their YSP experiences (see Figure 1a). For participants who are currently STEM professional fields, their discourse patterns exhibited relatively stronger connections among STEM, Knowledge Acquisition and Engagement. This suggests that the active involvement in the learning of STEM content during the YSP left a strong imprint in their minds. As one participant in this group noted: "…prior to the program, I had just a basic, most basic, rudimentary understanding of what science, engineering and math meant in the real world and this very much concretized my ideas, expanded my ideas" (Participant 13).

On the other hand, stronger associations between Positive Affect and both Peer Interaction and STEM as well as between Peer Interaction and Identity can be observed for participants in non-STEM professional fields. This points to the emphasis given to the sense of enjoyment and belonging that these students felt while being with each other and working on STEM-related activities. This connection was articulated in the following manner by a participant in this group: "Yeah, for me, it was just a sense of belonging and that what might have made a person cool or popular or approachable at school didn't really need to cross over into that particular space because we all knew that we were nerds like that. That was kind of like, you know, the baseline. So it's like, we [are] good…we don't have to compete" (Participant 2).

Figure 1

Subtracted ENA models for the discourse patterns of YSP participants in STEM and non-STEM professional fields: (a) reflections of YSP experiences; (b) reflections on career development and YSP influence



(a) (b)

Reflections on career development and YSP influence

Examining the differences in the reflections about career develop and the impact of the YSP, participants working in STEM-related fields displayed relatively stronger connections between STEM and the constructs of Motivation, Identity and Career Opportunity (see Figure 1b). This is indicative of the mutually reinforcing nature of gaining interest, finding opportunities and enhancing one's sense of belonging within the STEM domain. The linkages between STEM topics, identity, motivation and self-efficacy were captured in the comments by a participant in this group: "I think that having YSP and along with some of the other STEM programs that I participated in, I think all contributed to my love... I mean, number one, my love of science, but number two, that I could do it" (Participant 16).

For individuals who ultimately pursued other professional fields, the reflections placed greater emphasis on the connections between NON-STEM and CAREER OPPORTUNITY as well as between NON-STEM and STEM. The first association is likely to be indicative of the opportunities garnered from other fields that may have eventually led them to their current profession. At times, it was being in the right place at the right time. Reflecting on the shift that he had been asked to make at his company, one participant in this group reflected: "They didn't have somebody to head up product management and brand management and market management. So they asked me to kind of create and manage and develop a team for all of that globally. So I'm now over the product management and brand teams…" (Participant 11). Second, scientific thinking and reasoning continues to benefit participants despite their transition from STEM-related fields. Another participant described how she was able to apply scientific approaches to her first job: "I started that job a week after I graduated college, but there was something about again being thrown into, like this is how STEM is in the real world that I think just helped me be like…well, just take it one step at a time. You know, like, have a hypothesis" (Participant 6).

Discussion

This analysis focused on the interlinkages among motivation, self-efficacy and sense of identity contained in the reflections of YSP participants. Examination of key differences in the reflections of participants currently in STEM-related versus other professions revealed some interesting findings. First, participants working in STEM fields placed greater emphasis on the depth of STEM learning during the YSP, which was followed by higher levels of STEM motivation, STEM identity and STEM opportunities in the development of their careers. This may be reflective of the iterative feedback loop described in SCCT (Lent et al., 1994), whereby their YSP participation may have served as the first career-related action toward a STEM profession. Second, participants in non-STEM fields highlighted the role of peer interactions in enhancing their sense of identity and enjoyment with STEM topics during the YSP. Although they were drawn to other sectors by various opportunities, they nevertheless maintained a connection to the scientific approaches they had learned. Building on this preliminary analysis, further work should seek to investigate the how the three social cognitive constructs relate to career development at the individual level.

Learning Scientists' Perceptions of Their Impact on Teacher Education Programs

Abstract: Informing teacher education programs and impacting teaching practices has long been a stated goal of learning sciences research. As a first step in understanding the reality of this impact, we conducted a survey of individuals who identify as learning scientists from 39 different higher education institutions distributed internationally. Survey questions asked these learning scientists to describe both current engagement with teacher education programs at their institution and aspirations for future engagement. Results indicate that learning scientists see their current overall impact on teacher education as low-to-moderate, but they also perceive a high potential for stronger impact in the future. Barriers to successful engagement and specific ideas for how to build bridges with teacher education programs are detailed.

Introduction

From its origins, the learning sciences has coupled an investigation into the processes of learning with attempts to shape those processes in real world educational contexts such as classrooms. In the inaugural issue of the *Journal of the Learning Sciences* (JLS), editor Janet Kolodner states that the objective of the journal is "to foster new ways of thinking about learning and teaching that will allow the cognitive sciences to have an impact on the practice of education" (Kolodner, 1991, p. 1). Over the last three decades, JLS has become a top tier educational research journal, and the community of learning scientists continues to grow. However, the field's "impact on the practice of education" is difficult to assess. While there have been several papers and volumes that have described how research findings from the learning sciences can be used to inform the practice of teaching (e.g., Jurow et al., 2012; van Aalst et al. 2017), there is no simple metric with which to evaluate the extent to which these ideas are being taken up in schools. One place that may offer a partial picture of this impact is the interface between learning scientists and teacher education programs at higher education institutions that have both.

To conduct this investigation, we administered a survey to learning scientists and asked them several questions about their involvement with teacher education at their institutions. We took a similar approach as the "What Do Learning Scientists Do?" study (Yoon & Hmelo-Silver, 2017) which also surveyed learning scientists, though the unit of analysis in this study was institutions that had both learning sciences researchers and teacher education programs. We sought to collect survey responses from one learning scientist at as many institutions worldwide that we could reach, and we report on our initial findings from this survey below. We readily acknowledge that to get a more complete picture of the impact the field is having on teaching would require much more extensive engagement with pre-service and in-service teachers who are in teacher education programs, and perhaps also with students and to observe classrooms where these teachers are putting their training into action. However, we believe that a reasonable place to start this inquiry is to examine what activities learning scientists are currently involved in with their teacher education programs and what ideas they have for future involvement.

Survey

The impetus of this survey came from members of the International Society of the Learning Sciences (ISLS) Education Committee. The authors of this paper are a subgroup of the committee that was charged with developing and administering a survey that would inform future engagement efforts with teacher education programs.

Study recruitment and respondents

The aim of our survey was to get the broadest sense possible for how learning scientists are engaging with teacher education programs at institutions with a learning sciences presence. Because some institutions may have multiple learning scientists who interact in some way with teacher education and may share similar perceptions and experiences, our goal was to get a response from one person at each institution. Our purposive sampling method began by sending an email to the contact person identified for each institution in the Network of Academic Programs in the Learning Sciences (NAPLeS). This list, which is hosted by the ISLS website, currently includes 39 institutions with a learning sciences program. We identified additional institutions with learning scientists through contact recommendations from the ISLS Education Committee, the ISLS leadership team and Board of

Directors, and survey respondents. In total we sent survey invitations to individuals identified as learning scientists at 66 universities. We received responses from individuals at 39 different universities, resulting in an institutional response rate of 59%. Of the 39 survey responses we received, 25 were from US or Canadian institutions, 8 from Europe or the UK, 5 from Asia or Australia, and 1 from South America.

Survey framing

The survey was administered using Qualtrics and participants accessed the survey using a weblink that was sent to identified learning scientists at each institution. After completing a consent form, participants were taken to an introductory screen that explained the intent of the survey and why they were being invited to participate. Part of this framing text states: "*We have asked you to take this survey because you have been identified as a learning sciences researcher who has significant interaction with, or significant knowledge about, the teacher education programs at your institution.*" To ensure clarity, we defined teacher education programs as "*the instruction, mentoring, and training that aims to prepare individuals to teach in formal education contexts."* Although survey respondents self-identified as learning scientists, we still felt it important to establish a shared definition that participants could refer to when giving their responses, and so we stated the definition of the learning sciences given by ISLS: "*the interdisciplinary empirical investigation of learning as it exists in real-world settings and to how learning may be facilitated both with and without technology.*"

Structure and items

There were 28 total items on the survey comprising a mix of short answer, closed-list selections, and open-ended responses. It took most participants between 15 and 30 minutes to complete the survey. The first six items asked basic institution and contact information (respondent's name, title, email, institution name, department or unit name, and a brief 1-2 sentence description of any unique characteristics or emphases of the learning sciences program at their institution). The overall approach for our substantive questions was to inquire about both the *current state* of the interface between learning sciences and teacher education programs at their institution, as well as what they see as the *potential* for interaction in the future. For example, the first question from the body of the survey was "*On a scale of 1-7, with 1 being very low and 7 being very high, how much does learning sciences research influence teacher education programs at your institution* ***currently****?*" This question was immediately followed by the question "*How much potential do you believe there is for learning sciences research to influence teacher education programs at your institution* ***in the future****?*" The body of the survey was grouped into 4 primary topic areas: 1) **General** questions about the relationship between learning sciences and teacher education programs, 2) **People**, 3) **Courses**, and 4) **Outreach and Informal Activities**. For each of these topic areas there were questions that asked the respondent to rate the current and future impact/engagement of the learning sciences with teacher education programs (e.g., "*How much do you believe the* ***teacher education courses*** *at your institution draw upon the learning sciences?*"). These questions were followed by a closed list question that allowed participants to select the specific areas or activities where the engagement was manifest.

Each topic also included 1-2 open-ended questions seeking institution specific details about the engagement activities. For example, the survey asked the respondent to list the names of courses "*that explicitly incorporate learning sciences theories and empirical research*." The survey also asked for respondents' ideas for how learning scientists could engage teacher education programs in the future. Under the topic of Outreach and Informal Activities, for example, the survey asks: *Briefly list some of the ideas you have for how learning sciences theories and empirical research could be applied to* ***outreach and informal learning*** *opportunities for teachers at your institution (but do not currently).* The survey was also asked about perceived challenges to having a successful impact on teacher education programs.

Survey findings

Because we explicitly sought the perceptions of learning scientists, two of the 39 respondents were removed from the sample because they rated themselves a 3 or lower, out of 7, on the "identifies as a learning scientist" item.

Quantitative results

Table 1 shows the average rating to five survey questions that asked participants to respond on a 1 to 7 scale, with 1 being very low and 7 being very high. Except for the two respondents removed from the dataset, the individuals who completed this survey generally reported a strong identification with the learning sciences (mean of 6.1, *SD*=1.1). This suggests that we were overall successful in directing this survey to individuals who saw themselves as learning scientists.

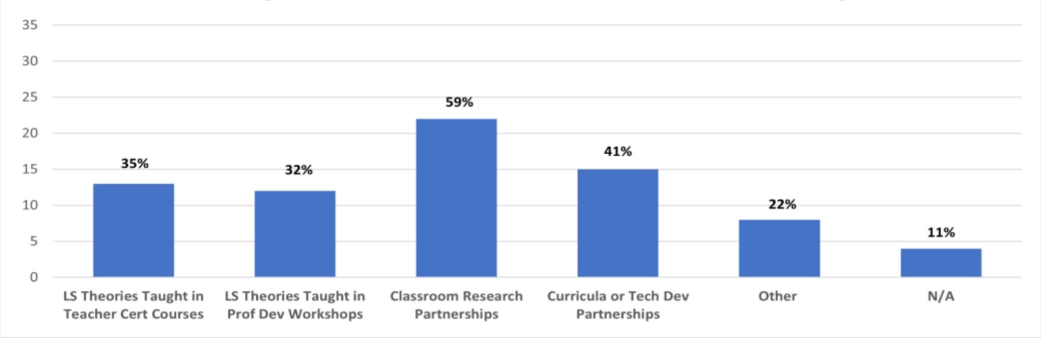
Table 1
Average survey responses on scale of 1 to 7.

Survey Item	Average Rating	SD
How much do you identify as being a Learning Scientist?	6.1	1.1
How much does Learning Sciences research influence Teacher Education programs at your institution *currently*?	3.2	1.4
How much potential do you believe there is for Learning Sciences research to influence Teacher Education programs at your institution *in the future*?	5.2	1.4
How much do you believe the Teacher Education courses at your institution draw upon the Learning Sciences?	3.1	1.4
How much do you believe the outreach and informal learning opportunities for teachers at your institution are influenced by the Learning Sciences?	3.4	1.7

On average, survey respondents rated the impact of learning sciences research on teacher education programs at their institution as 3.2 (*SD*=1.4). This suggests that learning scientists see their impact on teacher education as low-to-moderate. However, when asked about the *potential impact*, respondents gave an average rating of 5.2 (*SD*=1.4), a full 2-point average difference compared to the current impact. Perceptions of impact from learning sciences research on courses in the teacher education program (3.1, *SD*=1.4) and on informal learning opportunities for teachers in teacher education programs (3.4, *SD*=1.7) were also in the low-to-moderate range.

When asked about specific activities where learning sciences research intersected teacher education programs at their institution, many respondents reported that multiple different activities were occurring (Figure 1). For example, over half of the 37 respondents (22) indicated that teachers in the program were being exposed to the learning sciences through classroom research partnerships, and 41% of respondents (15) reported teacher involvement in curriculum or technology development projects influenced by the learning sciences. About a third of respondents (13) indicated that learning sciences theories were explicitly taught in teacher certification courses. Only 11% of the survey participants (4) indicated that none of the listed activities involving learning sciences research were occurring. Eight of the respondents selected “Other” and listed some additional activities such as “*Learning Sciences researchers run workshops that student teachers are invited to*.”

Figure 1
Number of responses (and percentage of 37 total respondents) for each answer to the question: “What are some of the ways Learning Sciences research influences Teacher Education programs at your institution currently?”



Qualitative results

The authors adopted an emergent coding approach (Charmaz, 2008) to analyze the open-response questions on the survey. We each individually read the responses, made notes about the emerging categories, and then we engaged in synthesis conversations about the important themes that came from the surveys.

Several respondents described a ***perceived lack of awareness of the learning sciences*** at their institutions, both within specific departments and across disciplines that may ordinarily be considered linked to the learning sciences. For example, when asked to describe the barriers to engaging with teacher education programs, one person stated, "*A barrier might be that other faculty that are involved in Teacher Education at my university do not have a clear picture of what the 'Learning Sciences' actually is.*" This perception that academics outside of the learning sciences are not familiar with the field seemed to contribute to the overall low-to-moderate impact assessment that respondents conveyed.

While some survey respondents cited ideological differences or definitional issues with integrating learning sciences into teacher education programs, it was more common for them to refer to **structural and pragmatic challenges**. In most institutions learning scientists are situated in different departments than teacher education programs, meaning that any attempts to collaborate or exert influence was susceptible to typical issues of academic siloing and associated resistance to cross-disciplinary work.

The learning scientists who took this survey generally acknowledged that their field was seen as **more focused on long term research goals**, such as contribution to theory, and **less on the application of that theory to practice in the classroom**. While many felt that learning sciences theory and findings have much to offer to teacher education and teachers, there has not been enough translational work and application to provide an immediate value-add. As one respondent put it "*most LS research does not speak to the reality of teaching or student learning in an accessible way*."

Finally, respondents felt that **publication pressures and metrics associated with promotion** were barriers to engaging more formally with teacher education programs. Multiple respondents referred to a "*perceived lower prestige of teacher education*" as a possible reason why more learning scientists do not choose to engage. A couple of people noted that there seemed to be a lack of bidirectionality in the work that learning scientists carry out in the field of teacher education; there is a sense that the learning sciences only informs teacher education and not the other way around.

Strategies to build bridges and concluding remarks

The most frequent suggestion was for there to be co-development of funded research projects with teachers as research partners or co-investigators, rather than cultivating a perception of teacher education programs as "testbeds" for learning scientists to conduct their research. In addition to increasing the amount of research done with teachers as part of teacher education programs, it was also suggested to adjust the focus of research to make it more relevant and timelier to teachers. For example, a number of respondents suggested more emphasis on equity considerations in research with teachers, where these considerations are front and center to their practice. It was widely stated that co-planning teacher education programs would provide the best opportunity to address challenges perceived by the learning scientists who took this survey. It was believed that meaningful partnerships would provide a pathway for a more nuanced integration of learning sciences theory into the curriculum that might then translate into teaching practice.

A reasonable next step would be to extend this inquiry into a survey or interview with select teacher educators and teacher education students who are participants in the programs captured in this survey. Asking these individuals about their perceptions of the learning sciences–either by name or by relevant theories and ideas–could be one component to understanding how effective learning scientists are in engaging with these programs.

What Influences Epistemic Actions on Social Media?

Eleni A. Kyza, Christiana Varda

Media Cognition and Learning Research Group, Department of Communication and Internet Studies, Cyprus University of Technology

Abstract: Social media have permeated people's lives and have become spaces where people retrieve and engage with information. Social media offer opportunities for epistemic engagement with information, which may be demonstrated by people's goal-oriented epistemic actions during information evaluation. This study examined whether epistemic actions are influenced by individual or contextual characteristics. Adults (n=242) were presented with a Twitter post focused on the impact of meat consumption on climate change, using different rhetorical appeals and were asked to decide on the actions they would take on the post. Findings indicate that while the type of rhetorical appeal did not directly influence epistemic actions, personal characteristics – demographics, epistemic beliefs– did. Implications for learning and future research directions are discussed.

Introduction and theoretical framework

In 2022, 4.59 billion people were reported to use social media platforms, worldwide, and the number is projected to reach six billion by 2027 (Statista Search Department, 2022). Yet, social media as spaces for informal learning is still an under-explored area (Greenhow & Lewin, 2016). The use of social media for learning has been mostly investigated in higher education settings, with the goal of making classes more engaging and participatory (Evans, 2014). In a review of K-12 teachers' use of social media for teaching or for professional development between 2004-2017, yielded only five studies reporting on learning and, of these, only one study discussed student learning (Greenhow, Galvin, Brandon & Askari, 2020). While researchers have argued that social media can help bridge formal and informal learning, others argue that social media practices do not portray advanced forms of learning (Greenhow & Lewin, 2016). The present study is motivated by the overwhelming presence of social media in our everyday activities and the scant attention that this engagement has received so far in learning sciences research. Coupled with reports about the pitfalls of using social media and the risks of being exposed to and influenced by misinformation, we aimed to understand which personal or contextual characteristics might mediate laypeople's epistemic engagement with a social media post. We take a situated view of epistemic engagement, contextualized in the actions laypersons take on posts encountered on social media; epistemic actions indicate information exploration and aim to enhance understanding or further knowledge.

Epistemic engagement on social media may be influenced by the affordances and constraints of the social media platform and by the message characteristics. In this study we examined epistemic engagement on the same simulated social media platform but varied the message design by using three Aristotelian rhetorical appeals for creating persuasive messages (Cope & Sandys, 2010): logos, ethos and pathos. *Logos* refers to the rational aspect of discourse, and specifically to fact-oriented argumentation; *Ethos* refers to qualities that may convey credibility or reliability; and *Pathos* refers to emotional appeals during communication that may lead to the experience of emotions. Appeals to reason (logos) may include claims, warrants, evidence and conclusions; appeals to credibility (ethos) may include references to one's professional expertise or experience and appeals to emotion (pathos) may include emotionally charged language or outline a positive or negative scenario. Aristotle argued that communication is persuasive when all three rhetorical appeals are employed by the speaker. However, on social media, where persuasive information may be short in length by design, there is a restriction on the number of appeals that a speaker can rely on. Hills (2019) coded Twitter posts around politicized issues and found that only 5 out of 300 posts relied on all three appeals; the majority of posts relied on appeals to credibility (ethos). In an analysis of misinformation strategies used in over 26,000 misinformation posts on social media, Chen et al. (2021) found that the rhetorical strategy mostly employed was appeal to negatively-valenced emotions.

Personal characteristics may also influence one's epistemic actions on social media. Cano (2005) reported differences between secondary school girls' and boys' epistemological beliefs, suggesting that it might be worthwhile to explore the impact of gender on the participants' epistemic actions. Finally, capacity for self-directed actions, goal setting and beliefs are formed over one's life and may differ depending on lived experience. Therefore, in this study we explored whether the participants' epistemic actions differed due to demographic characteristics, such as age and stage of life.

Research questions

Based on prior work and the review of the literature, we, therefore, asked the following research questions:

a) Can a short (about 280 characters) post on a controversial issue on social media elicit epistemic actions? b) Does the design of the message of the post have an effect on the participants' epistemic actions? c) Did epistemological beliefs and climate change attitudes influence intent to take action in response to a post? And d) What is the relationship between beliefs, intentions, trust and epistemic actions?

Methods

Intervention and participants

We collected data from 242 adults (male:126; female:115; prefer not to say:1) using a representative sample through an online panel in Cyprus. Participants were randomly assigned to one of four rhetorical appeal stimulus conditions (Ethos: 59, Logos: 61, Pathos: 61, Combination: 62) and were matched on age, gender, education, field of education and vegetarian status across all conditions. Participants in each condition were asked to indicate the extent to which they trusted the post using a Likert scale of 1-10 and explain why. They were then asked to what extent they would take any of the following seven actions: (a) like, (b) share the post with others, (c) add a comment, (d) search for additional information, (e) save the post for future examination, (f) follow the profile of the user to receive updates on new posts, and (g) search for other posts by the same user. Finally, participants were asked to indicate if the post persuaded them to reduce meat consumption and whether they would take any other actions. The intervention used four variations of a Twitter-like post on the controversial issue of the climate impact of red meat consumption. Each condition used a different rhetorical appeal: Ethos (C1), Logos (C2), Passion (C3), and a combination of all Ethos, Logos, and Passion (C4). *Ethos* named a scientist, an academic institution and a journal, *Logos* used argumentation to illustrate a logical argument, *Pathos* used emotional language and second-person pronouns for personal appeal, and *Combination*, combined elements of all three.

Data collection and analysis

The participants' science epistemology beliefs and climate change beliefs and intentions were collected at the end of the intervention through two validated surveys: the Scientific Epistemological Beliefs Instrument -SEBI- (Lin & Tsai, 2017) and the Climate Change Attitude Survey -CCAS- (Christensen & Knezek, 2015). Demographic data on age, gender, educational background, use of social media and vegetarian status were also collected. The quantitative data were analysed using SPSS 26.0 and Mplus 7.3. To examine the differences among versions of stimuli, we conducted a MANCOVA analysis, having stimulus condition (C1, C2, C3, C4), age, gender (male, female, prefer not to say), and vegetarian status (yes, no) as independent variables. The level of trust and the various actions (a-g) the participants could take were set as the dependent variables, while the factors of the SEBI and CCAS questionnaires were set as covariates. After this analysis, a path model using Mplus was performed, to test the relationships between beliefs, level of trust, and willingness to take various actions. Correlations between the continuous variables in the study were also run, along with linear regression analyses to examine whether actions could be significantly predicted by epistemological beliefs and climate change beliefs.

Findings

Did the social media post elicit epistemic actions?

Participants viewed the post on a screen and were then asked to indicate if they would take an action in response to the post they viewed using a Likert scale of 1-10. Regardless the rhetorical appeal condition, most participants indicated higher tendencies for intention to act for the same two actions: a) search for additional information, and b) review the author's profile to examine other posts they have shared. Therefore, we can assert that, even if the post is short, social media can also provide space for activating epistemic engagement.

Did the design of the post have an effect on the participants' epistemic actions?

The Aristotelian rhetorical appeals (ethos, logos, pathos) are still used as strategies to create persuasive texts. In our analyses we examined whether any of these appeals, or their combination, could have a differential effect on how persuasive the post was and on one's intent for epistemic engagement. A MANCOVA examined the unique and interaction effects of the independent variables (stimulus condition, age, gender, vegetarian status) on the dependent variables (level of trust in provided information, various actions), when controlling for their beliefs and intentions about climate change and their science epistemological beliefs. It was found that the stimulus condition did not have an independent effect on the dependent variables, when controlling for the beliefs and intentions about climate change and the participants' science epistemological beliefs, with Λ=.82, F=1.27, p= .16, $\eta_p^2 = .07$. Age, gender, and vegetarian status all had significant unique effects on the dependent variables, with Λ=.74, F=1.87, p= .004, $\eta_p^2 = .09$, Λ=.83, F=1.78, p= .022, $\eta_p^2 = .09$ and Λ=.87, F=2.58, p= .006, $\eta_p^2 = .13$, respectively.

Further exploration showed that males (M= 6.30) who were in the *ethos condition* had higher levels of trust compared to females (M=4.66; p= .003) but had lower levels of trust compared to females when they were in the other three conditions and especially when they were in the *logos condition*. Similarly, males from the ethos condition were less likely to perform any actions on the post compared to females (M=1.94, M=1.96, whereas in all other conditions females were less likely to perform any actions on the post compared to males (logos: M= 1.52, M=1.80, pathos: M=1.76, M=1.90, combination: M=1.83, M= 1.95).

Relationship between beliefs and epistemic actions

Beliefs about climate change and intentions about climate change did not have independent effects on the level of trust or on the willingness to take actions about the presented information, with Λ=.94, F=1.24, p= .27, $\eta_p^2 = .07$ and Λ=.95, F=1.04, p= .42, $\eta_p^2 = .05$, respectively. Between-subject effects showed that beliefs about climate change had a significant effect on the level of trust (F=6.34, p= .013) and on sharing the post (F=4.10, p= .044), whereas intentions towards climate change had a significant effect on commenting on a post (F=4.85, p=.029). Multiplicity and uncertainty of knowledge had a significant unique effect on the dependent variables, with Λ=.89, F=2.14, p= .02, $\eta_p^2 = .11$, but the other two factors — development and justification of knowledge and purpose of knowing and knowledge — did not, with Λ=.99, F=0.27, p= .99, $\eta_p^2 = .02$ and Λ=.94, F=1.06, p= .40, $\eta_p^2 = .06$, respectively. Linear regression analyses of whether *actions* could be significantly predicted by epistemological beliefs and climate change beliefs, regardless of the stimulus condition showed that the model was significant with F(1, 240)= 14.62, p< .001 and could predict 6% of the variance of trust. Believing that climate is changing predicted increased trust in the posts. The regression model for *liking the post* was significant with F(1,240)= 11.11, p= .001 and could predict 4% of the variance of liking the post. The only independent variable that could significantly predict this action was Multiplicity and uncertainty of knowledge, with b= -.21, t= -3.33, p= .001. That is, believing that knowledge is retrieved from multiple sources and is uncertain predicted less likes of a post. The regression model for sharing a post was significant with F(1, 240)= 18.33, p< .001 and could predict 8% of the total variance of this action. The variables that could predict *sharing a post* was Multiplicity and uncertainty of knowledge, with b= -.27, t= -4.28, p<.001 and beliefs about climate change, with b= .13, t= 2.04, p= .04. That is, believing that knowledge is retrieved by multiple sources and is uncertain predicted less shares of the post and believing that climate is changing predicted more shares of the post. The only independent variable that could significantly predict this action was purpose of knowing and knowledge, with b= .13, t= 1.99, p= .047. That is, believing that there is a purpose in knowing and in knowledge predicted more checks of the profile who did the post. The regression model for reducing meat consumption was significant with F(1,240)= 24.80, p< .001 and could predict 12% of the variance of meat reduction. Reducing meat consumption was predicted by Multiplicity and uncertainty of knowledge, with b= -.31, t= -4.98, p< .001 and beliefs about climate change, with b= .17, t= 2.77, p= .006. That is, believing that knowledge is retrieved by multiple sources and is uncertain predicted lower reduction in meat consumption and believing that climate is changing predicted higher reductions.

Effect of age and gender on trust and intent to act

Younger participants were less likely to comment on the post (M= 2.86, p< .001) or share the post (M= 3.14, p= .017) compared to older participants (M= 5.33 and M= 4.60, respectively). Also, older participants (50-64: M=5.33, p= .003 and 65+: M= 5.69, p< .001) were more likely to report that they would reduce their meat consumption after reading the posts, compared to the younger participants (18-29: M= 3.57).

Relationships between beliefs, intentions, level of trust and epistemic actions

The interactions between the continuous variables of the study were also examined using a path model in Mplus to identify any causal relations. The variables inserted were level of trust, actions on the post, beliefs about climate change, intentions towards climate change, Multiplicity and uncertainty of knowledge, development and justification of knowledge, purpose of knowing and knowledge. The path model showed that believing that the climate is changing predicted higher levels of trust of the participants on the posts. Then, higher levels of trust predicted more willingness of the participants to act on the post with various actions. However, actions that needed more effort (i.e., commenting on the post, following account, reducing meat consumption) were also predicted by lower levels of Multiplicity and uncertainty of knowledge. Believing that scientific knowledge is constructed by self-acquired knowledge from multiple sources and that knowledge is certain resulted in participants reporting that it was more likely to comment on the post, follow account or reduce meat consumption.

Discussion

This study investigated adult laypeople's responses to a controversial statement on a social media post, seeking to understand the epistemic actions the participants wished to take, but also which factors might influence their epistemic engagement. As laypeople's epistemic engagement on social media is an under-examined area of study (Greenhow & Lewin, 2016) we asked the question of whether such encounters with short social media posts have the capacity to elicit or activate epistemic actions. We then asked which individual or contextual characteristics might be influencing epistemic engagement and explored relationships between them. The first finding is that social media posts can activate one's curiosity and interest to search for additional information on a controversial issue as indicated by their intention to take knowledge-driven actions. This is promising, as it shows that laypeople can activate resources to approach even a short social media post from a critical point of view. Nonetheless, we do not know if they would do so without the prompting of this experimental setup. A second main finding was that even though a short post on social media can elicit epistemic actions, analyses show that there was no straight-forward relation that explained what influenced which action. Rather, epistemic engagement appears to resemble a complex system "composed of a number of constituent components" (Mercer, 2011, p. 435). In this study, we examined whether the persuasive characteristics of a social media post might influence participants' epistemic actions. We also explored the possibility that other factors, such as demographics and beliefs might be influencing one's intent to epistemically engage with the information on social media. Results suggest mediation effects, as also suggested by the path analysis model and the regression analyses. Findings reinforce that people notice different aspects of a message and this has implications for educational and instructional practices. Adopting a virtue responsibilism approach, which "characterises intellectual virtues as acquired or learned cognitive character traits such as curiosity, intellectual autonomy and open-mindedness" (Heersmink, 2018, p.2), we would like to argue that differences, and interactions, such as the one identified in this study can alert the teacher or designer of learning scenaria that they need to support learners' understanding of persuasion strategies used in the design of social media posts. Our study was short in duration and was limited to the participants' sharing of their intended actions. Epistemic engagement is more than intentions though. This study has identified several open questions that we believe should be explored in future studies through more in-depth qualitative work.

What Can Students Learn From Their Own Data? Data Literacy With Student-Facing Learning Analytics

Nora Patricia Hernández López, Xiao Hu
noraphl@connect.hku.hk, xiaoxhu@hku.hk
The University of Hong Kong

Abstract: With the increasing need to make sense of the ever-growing quantity of data originated from digital interactions, data literacy skills become a basic requirement to navigate everyday tasks. In the field of education, data has gained wide attention, especially with the introduction of analytics from teaching and learning data. Current trends of research on data literacy in learning sciences focus on educators' needs of specific training and knowledge about how to make data-driven decisions that benefit students' progress. Despite little research at the intersection of developing learning analytics (LA) for students and developing their data literacy skills, we argue that student-facing learning analytics (SFLA) can be leveraged for strengthening students' data knowledge and skills. Based on an integrative review of existing literature, we briefly discuss several important considerations that will benefit future implementations at the intersection of SFLA and data literacy.

Introduction

The growing availability of data and, more importantly the need to make sense of them, in technology-mediated societies has caused the rise of data literacy (DL) as one the key skills for the 21st century. D'Ignazio (2017) refers to DL as the knowledge about "how to collect, find, analyse, and communicate with data" (p. 6) and adds to its benefits the emancipatory power that comes with a critical inquiry supported by data. DL gains relevance in the knowledge society, as social, economic, and civic participations rely more on data-mediated interactions. Therefore, critical perspective on how data systems interact with the world, and the role humans play in how data is collected, analysed, and used, is crucial given the ubiquity of artificial intelligence (AI) in everyday situations (Markham, 2020).

The increase in data availability has permeated various fields, with teaching and learning being no exception (Lang et al., 2022). Particularly, this concerns the field of Learning Analytics (LA), which relies on data collection, analysis, and interpretation for understanding learning (Lang et al., 2022) and informing teaching and learning practices (Hernández-de Menéndez et al. 2022). Research recognises two main skills demanded for the success of the LA-enabled classroom, namely 1) data literacy, for being able to interpret data; and 2) connecting data to pedagogic knowledge, for being able to adapt teaching and learning practices based on information provided by the data (Papamitsiou et al., 2021).

While some LA-tools are designed for teachers, student-facing learning analytics (SFLA) are directed exclusively for students. SFLA track behaviours of students in online learning environments and report such data as feedback back to the students (Galaige et al., 2022). SFLA has the premise to promote student agency and involvement, and thus, students' autonomy in their own learning (Bodily & Verbert, 2017; Hu et al., 2022). SFLA is expected to empower learners to take responsibility for their own learning, improving learning experiences and outcomes (Galaige et al., 2022; Lang et al., 2022) by offering authentic learning experiences.

Despite the need of DL for LA is often mentioned as a prerequisite for successful LA implementations (Papamitsiou et al, 2021, Wolff et al. 2016), students' data understanding and practices are often forgotten in research (Xing & Wang, 2021). In studies with SFLA, students are expected to benefit from monitoring their own learning behaviours progress with LA tools. However, this has been found to be overwhelming for most students (van Leeuwen et al., 2022). Given that current research relies on the assumption that students are capable of understanding the information that is presented to them in SFLA, it also becomes crucial to address DL skills in the same context. Therefore, we are interested in unveiling whether and how students can acquire data skills by interacting with LA tools that are directed for them.

In this study, we aim to provide preliminary answers to how recent research has studied the relationship between students' DL and SFLA, and illuminate if this interaction can provide an authentic learning environment that may naturally benefit students' DL. We conducted an integrative literature review (Torraco, 2016) to synthesise representative perspectives of emerging discussions and practices at the intersection of these topics. In the rest of this paper, we first introduce the methods used to investigate the literature, and then present the synthesis of the literature review results followed by a discussion of the findings.

Method

We conducted an integrative review of the literature (Torraco, 2016) to investigate the relationship between data literacy (DL) and student-facing learning analytics (SFLA) in current research. An integrative approach for reviewing the literature is suited for emerging topics that have not been yet reviewed comprehensibly and helps establish a preliminary conceptualisation of the topic of interest (Torraco, 2016). For defining the search strategy, we started from the premise that SFLA can be adopted for leveraging DL skills among students, and defined search queries that include specific keywords such as "learning analytics", "data literacy," and "student-facing learning analytics." We searched for potentially relevant articles using three major databases: Web of Science, Scopus, and the Association for Computing Machine Digital Library (ACM-DL). The queries matched title, abstract, and keywords in all databases, and we did not impose restrictions for language or publication year.

After deleting duplicates, the total number of records identified by the search is *N*=85, including records published between 2012 and 2022. By far, the most popular venue for publications about these topics is the International Conference on Learning Analytics and Knowledge (LAK), and other venues include conferences and journals related to human-computer interaction and educational technology. The results contained *N*=6 conference proceedings and workshops, *N*=10 review articles, *N*=1 article in Spanish, and *N*=1 not in the field of LA (addressing DL in the field clinical neuroscience research) which were excluded from the review. After this elimination, *N*=67 papers were considered for further evaluation. Relevance of each article was assessed based on their inclusion of DL within the context of LA/SFLA, or vice versa. We include all empirical and theoretical studies that are published in English, and that discuss explicitly the relationship between DL and LA or SFLA; and articles that do not include students in these discussions were excluded. All articles were screened based on title and abstract. First, we filtered out articles that exclusively focus on technical development or advancements of LA tools or guidelines, or that do not focus on students as the primary beneficiary group of DL or LA (*N*=41 excluded). Nonetheless, some of these articles were also read to find other ways in which DL and LA research has been conducted so far; for example, among teachers. Then, we aimed to identify within the remaining articles (*N*=26) those that either address the relationship between DL and LA/SFLA, or studies that evaluate how DL and LA/SFLA impact students' outcomes.

We identified the emerging themes from the literature based on iterative reading of the pool of articles. Because the purpose of the review is to provide integrative synthesis of the existing literature and explore perspectives that might have not been fully explored, we first identified the main concepts developed in each of the articles, and then synthetise the emerging ideas in themes that encompass related concepts (Torraco, 2016). We grouped ideas in two themes that are presented in the following section.

Preliminary results

From the reviewed literature, we identified *N*=26 articles that include DL and LA/SFLA within the same discussion, and *N*=11 of them focus specifically on students. From these studies, we identify two major themes: 1) Reiterating the need for data literacy: Studies that identify the need for DL for adequate design, implementation, and widespread adoption of LA/SFLA, or that aim to assess the factors that play a significant role in this process; and 2) Gaming the system: Studies that have implemented practices to develop data skills with SFLA use.

The need for data literacy

Researchers are not oblivious of the critical need for DL to grow the development and adoption of LA systems across different educational levels and stakeholders. *N*=16 of the articles reviewed include explicit remarks on the lack of DL skills and why it is important to increase their presence for effective LA implementations. Only *N*=4 of them addressed this need specifically for students. Yet, none of them elaborate on strategies to promote DL among students in the setting of LA-mediated learning. All the studies discuss the topic in the higher education context. Some studies (*N*=2) find statistically significant support for DL as a critical mediator of the acceptance, usage, and perceived usefulness of LA systems. Xing and Wang (2021) found that university students' data literacy significantly influences the perceived data autonomy, digital identity, and reflectiveness, and students' data practices are culturally mediated. Similarly, teachers' pedagogic competence for teaching technology-related topics is strongly related to students' data literacy as identified by Lin et al. (2022).

On the other hand, frameworks and guidelines emerging from practical implementations or a series of interviews or workshops to identify needs and usability of SFLA designs, often remark that the complexity of information presented to the students requires contextualisation and pedagogical support to interpret the analytics (Chen et al. 2018). Wise (2014) identifies that effective design of SFLA tools should not only consider that students are provided with the relevant information about their learning but that they can interpret such information leading to satisfactory performance. Interpretation of information conveyed through SFLA might be scaffolded with the acquisition of DL skills.

Wasson and colleagues (2016) are more specific on their requirements for data literacy and use for learning. They recognise the need for assessing various configurations of SFLA tools and their impact on data generation, and thus, the competences required for interpreting the results. Reflections arising from their findings on data literacy use for teaching serve to pose questions about what kind of data is representative of students' learning, how to present this information to students, and what students need to know about LA, self-reflection, planning, or self-directed learning to make sense of the information and being able to learn with it. Conclusions from their research emphasise the need for a framework that addresses these concerns while advocating for ethics, privacy, and protection of data.

To game or not to game the system?

One of the most common fears that researchers and teachers might face when introducing SFLA to learners is that they gain sufficient knowledge about how the system works and will try to obtain the desired performance without *really* learning nor achieving learning outcomes. In this review, we identified practices (N=2) that resemble the intuition behind trying to *game the system*, but that actually benefit understanding of how data is collected, processed, analysed, and presented, and offer students an opportunity for learning through critique. Shibani et al. (2022) promote critical engagement with automated feedback in a writing analytics tool. Essays written by students are analysed automatically by the system, and then students must answer whether they agree on the output and argue why. With this critical posture, students should annotate the feedback and adjust their writing if they consider it necessary. While this approach is effective for promoting awareness that data systems could be wrong, there is no explicit scaffolding for students to make sense of the information received, and the learning is focused on their writing skills.

Kitto et al. (2018) take this intuition one step further. They propose "Active Learning^2 (squared; AL^2)," a framework to motivate DL through ill-performing machine learning (ML) models. In their implementation, students learning task is to post comments on a discussion forum, from which their performance is classified and presented back to the students. Later, students learn how text classification works and what their behaviour profile looks like; then, they are required to challenge the classifications that they think are wrong. In this way, the learning is two-fold (AL^2): This re-labelling is used by the system to improve algorithmic performance, while students are exposed to an open reflection of how ML models work, and more importantly, how they can produce a wrong output.

We identify two driving factors in the interventions described: 1) pedagogic design that allows students to interact with SFLA and not simply blindly rely on the output, and 2) the possibility of imperfect ML models driving the results. In this scenario, DL is an enabler and a side learning outcome that empowers learners to be critically aware and escape the repetition of patterns often encouraged by some designs of LA systems. As if they were trying to *game the* system, students are required to learn how the system produces its outputs and try to beat it, but they must reflect on whether the output could be incorrect, why, and how to make it better. This pedagogic approach with SFLA does not attempt to group or rank students but takes advantage of the imperfections of the system to actively engage them in a critique process that also benefits disciplinary learning outcomes. The critical posture adopted by students incites to liberate learning from algorithmic bias and alight data usage and transparency issues that usually accompany data-based systems (D'Ignazio, 2017).

Finishing remarks

The study of data literacy (DL) and learning analytics (LA) has shown their importance for improving learning and, more importantly, their interdependence. Current literature has noted the close relationship between DL and LA but is dominated by one way of the relationship: DL is essential for the development and implementation of LA. Nonetheless, how LA supports the improvement of DL among its users has not been widely discussed yet. In this review we aimed at identifying current discussions and practices around the use of student-facing LA (SFLA) for improving DL among students.

This review revealed the fact that the research at the intersection of these two topics is scarce, yet the potential of SFLA as precursor for DL has started to be studied and offers attractive paths for new research. We identified innovative and promising practices that serve this purpose, yet none of the studies attempted to measure the effect of LA/SFLA usage over DL. Empirical interventions aimed at this objective should benefit our understanding of how students learn about data in an authentic learning environment. Learning supported in this premise should include designs with sound theoretical and pedagogical backgrounds that encourage students' reflections on their analytics and cultivate critical practices around data, including ethical considerations that comprise the whole process.

Abstract: Mobilizing the power of arts in and through inquiries within the field of learning sciences can forge a new space for learning. Our paper highlights how arts-based methods inaugurate spaces for critical transdisciplinary understanding of soil with refugee children who participated in our multimodal land-based learning program. Refugee children's artwork and dialogic interactions were examined in social and scientific contexts through the conceptual framework of arts integration and critical pedagogy to elucidate relationality through land-based learning experiences. Careful planning and composition of soil portraiture offered insight into soil as a living entity and medium which fostered co-creation and unearthing of sociopolitical awareness surrounding body consciousness and (de)colonial relations with the land.

Backgrounds: Toward critical conceptualization of arts and transdisciplinarity

Evoking the power of arts in and through inquiries within the field of learning sciences can open a new space and opportunity for learning. As Lee (2001) powerfully demonstrated, engaging Black youth in historically salient, rich literature by Black authors can open spaces for their intellectual reasoning to shine. Gutiérrez (2008) showed how migrant youth poetically and poignantly tell their lived histories, *testimonio*, inspired by artistic scholarly texts such as Paulo Freire's (1970) *Pedagogy of the Oppressed*. More recently, arts in the learning sciences have been brought to attention of the field, as Halverson and Sawyer (2022) maintain that arts in the learning sciences research have received relatively little attention, or arts have been reduced to tools to learn more hegemonic disciplines such as Science, Technology, Engineering, and Mathematics (STEM). Our paper highlights how integration of arts created otherwise impossible learning opportunities through the intentional pedagogical design of the Soil Camp (Takeuchi et al., 2021). In this paper, we pay attention to the power of arts to show and deepen racially and linguistically minoritized refugee learners' understanding of disciplinary concepts in STEM, which is entangled with their understanding of "life" (their lives and other lives in intertwined manners). Recognizing that the Western education paradigm has perpetuated oppressive, colonial ways of knowing (Battiste, 2013; Poitras Pratt et al., 2018), the theoretical framework of this research positions arts-based pedagogy as a form of resistance with transformative potential. Decolonial Indigenous frameworks (Battiste, 2013) together with anti-colonial land-based approaches to art education with refugee youth (Bae-Dimitriadis, 2020) inform the research design and interpretations of findings.

These critical ways of seeing arts can challenge underlying disciplinary norms and colonial formation of disciplines, especially in the disciplines of STEM that has historical entanglement of explicit and implicit militaristic and colonial agenda (Philip et al., 2018; Takeuchi & Marin, 2022). As Strong et al. (2016) have demonstrated in their enactment of critical transdisciplinary pedagogy, youth can mobilize the power of arts to invite snapshots of their lives (that is often neglected in school contexts) and their community expertise into STEM disciplines. Arts in embodied forms for youth (e.g., choreography and dance movement developed among Black communities) could be seen as funds of knowledge for learning physics, which has been historically treated as a school discipline removed from youth's lives (Solomon et al., 2022).

Our ways of seeing learning is fundamentally sociocultural and historical. Sociocultural theories of learning helped us to design the learning ecology that could break disciplinary silos between home, community, and school (Gutiérrez, 2008; Lee, 2001). Sociocultural theory of learning sees arts as a medium to bring "horizontal forms of learning, the movement" (Gutiérrez, 2008, p. 150) into disciplinary learning. Our analysis will shine a light on children's sense-making of *the soil as living*, seen through the process of artworks generated by children.

Methodology

Our approach was grounded in social design research methodology (Gutiérrez & Jurow, 2016) that centers historicity, diversity, equity, and ecological resilience as design principles and aims to co-design just practices and futures in partnership with a range of communities. Soil Camp pedagogical design was led and facilitated by preservice teachers, educators, researchers, and various community partners with 85 refugee children and youth (Takeuchi et al., 2021). Child participants hail from Syria, Northern Iraq, Kurdistan, New Guinea, Pakistan, South Sudan, Ethiopia, and Eritrea, having resettled in Canada within the last five years. Eighteen teachers and teacher candidates (who are mainly racialized multilinguals) joined as facilitators of Soil Camp. The participants engaged in numerous environmental justice workshops and were invited to learn more deeply about land stewardship from Indigenous perspectives through the relationships with Indigenous Elders and Knowledge Keepers who storied the land by bringing forward animacy and spirit through circular epistemology (Poitras Pratt et al., 2018, p.5) that centers the importance of multidimensional understandings of our interconnectivity with plants, animals, and the soil. The focus activity of "soil painting" discussed in this paper was nested within these ethos, as a sensory-imbued activity that involves painting with soil pigments and painting about the soil. The pigments were created by mixing a variety of fine soil sediments with an acrylic medium and a few drops of water. The soil samples were crushed with a mortar and pestle or sifted with handmade and professional soil sieves by the children. There was immense variability in the texture, tones, and overall quality of the soil pigments created by the children.

Data and analysis

A team of researchers collected video data, interviews, fieldnotes over two years since 2021. Drawing from the participatory design research framework (Bang & Vossoughi, 2016), our research team invited the participants to engage with us in the documentation of learning and help us highlight telling moments and observations. For this paper, we closely analyzed video data amounting to 157.69 minutes collected during the soil painting activity facilitated by Anita who has disciplinary backgrounds in arts and art histories, and the artworks created by the children and youth. On-site interviews with the participants were conducted to elicit the participants' backgrounds, their sensory experiences on the land (what they see, feel, smell, and hear), and their developing sense of soil and understanding of the land. Individual artworks were then selected based on iterative analysis of video and transcripts, reflecting the pertinent influence of Marin & Bang's (2015) framework of nature-culture relations. The research team analyzed 53 soil paintings made by the children and youth, through the lens of Lawrence-Lightfoot's (2005) notion of portraiture as a method of inquiry to document, analyze, identify, and narrate recurring patterns and themes. In our analysis, we saw arts as a critical tool that provided an opportunity for children to engage in sense-making while glimpsing into their emerging understanding and worldview (Hickey-Moody, 2021). Instead of focusing on pre-set STEM concepts, our analysis focused on the ideas constructed and communicated through children's artworks and conversations, on their terms. The research question that guided our analysis was: how did children deepen their corporeal relationality with and through soil during the transdisciplinary arts integrated experience of creating soil portraiture?

Findings

The children's paintings were a direct reflection of land-based learning interactions and their lived experiences on the land. Through their paintings, the children were able to present macro and micro visions of soil and ecosystems. Paintings of the landscape contained depictions of the visible and familiar elements above the ground such as the sun, soil, plants, trees, grass, flowers, and mushrooms. Below the soil surface, children depicted their interpretation of invisible components such as bacteria and other microbes based on their abstract and emerging understanding. We saw expanded visions of soil in how children chose to depict earth's matter on watercolour paper: macro, micro, introspective, and relationally focused compositions. The invisible complexity of soil ignited the reflexive imagination of our participants and ushered in a network of connections encircling themes of cognizant socio-emotional understanding, cycles in ecosystems (that include human as a part of the ecosystem), and body politics (with a particular focus on human reproduction and soil fertility). For example, one of the children remarked that the microscopic view of soil "looks like the inside of someone's body." Similarly, another child, Aly (children's names are pseudonyms) drew parallels between soil ecosystems and the female reproductive system. As shown in Figure 1, her artwork was composed with a light wash of soil paint and a sketch of roots in the soil which she also exemplified as fallopian tubes, veins, and blood. This network also resembles mycelium (fungal threads) found underground that was showcased in Driver's (2021) interactive video that the participants watched. Aly spent the majority of time sketching this network of intersecting lines with careful precision while engaging in a conversation with other children at the table (see Table 1). Exposure of the children's shared understanding and interpretive reflections during the artistic process transformed the space into a site where children could engage in critical dialogue to make sense of their world and the world in which soil invisibly cooperates and exists.

As the children were sketching and painting, the facilitator walked around the table to support and assist them. Meanwhile, the children engaged in conversations while simultaneously working on their art. One such conversation as shown in Table 1, unfolded in the absence of the facilitator as Aly was sketching. A lighthearted conversation that began as making fun of each other led to a moment of critical sense-making as some of the girl-identified children began to unpack their understanding of women's abortion rights (utterance 6 to 9 in Table 1). While the children were somewhat familiar with the sociopolitical issue through media and lived experiences, they did not take a specific stance or engage in a debate, instead, Lily (utterance 8) and Rita (utterance 9) presented two sides of the argument. This dialogic interaction unraveled naturally and was prompted within several interrelated contexts for ideologies in learning (Philip et al., 2018). Participants shared analogies of the fertile landscape soil exhibits with the female reproductive system and noted similarities and comparisons between root systems and the network of blood and veins that run through human bodies. The last week of Soil Camp occurred in early July 2022 directly after the U.S. Supreme Court's June 2022 Ruling to overturn Roe v. Wade — the decision that had guaranteed a constitutional right to abortion for nearly 50 years. This highlights an intersectional inquiry process that takes place on the land as a response to changing climates, whether they are ecological or sociopolitical.

Figure 1
Aly's Painting Analogy between Soil Fertility and the Female Reproductive System.

Table 1

	Time Stamp	Speaker	Utterances
1	#00:02:45-2#	Aly	When mom made you, she said, oh gosh, I'm not ever having any more kids ↑
2	#00:02:55-3#	Sherry	When mom made you, she said, ah not another one
3	#00:02:59-3#	Aly	Then why did she keep going on?
4	#00:03:03-8#	Sherry	She had no choice
5	#00:03:05-0#	Habiba	Wait! But how'd you know, she's older than you!
6	#00:03:09-6#	Lily	I'm confused about the abortion thing, is it in Canada too?
7	#00:03:14-2#	Lily	You know how there's women's rights for abortion or something?
8	#00:03:23-1#	Lily	I don't think it should be a thing, you're killing babies
9	#00:03:33-2#	Rita	Yeah, it's tight, it's not your choice. Before the [embryo develops, you can actually kill it. Before it turns into an actual human. So, it doesn't matter

Discussion

Through an arts-integrated approach, soil painting provided an opportunity for transformative and liberating learning to occur by establishing a safe space for semiotic expression, embodied communication, and affirmation of identity. By touching, feeling, smelling, observing, and interacting with soil as a whole environment containing millions of living organisms, participants activated interpersonal cognizance by questioning the role soil plays in our own ecosystems and how it contributes to abundance in life. As demonstrated in our findings, a deep sense of belonging to a community can be in essence established by fostering artistic agency with epistemological exploration achievable through artistic engagement and can lead to emancipation and critical awareness (Freire, 1970). A seed for ideological expansion (Philip et al., 2018) was planted in and through these learnings mediated by the participants' intertwined sense-making of the soil and human body. The explicit deepening of collective knowledge at Soil Camp is reflected in our presented case in findings as a direct result of the artmaking *process*, demonstrating how children obtain obscure information about the life of soil and parallel ideologies surrounding human reproduction and soil fertility. The children's desire to understand the current and complex sociopolitical milieu illustrates art as a method of communication for heterogeneous understanding of life in and around the soil. Critical transdisciplinary relationality emerged through dialogue on soil paintings and acts of artmaking, where children and youth explored themes of identity, community, belonging, social values, and human rights. The examination of entangled lived experiences through soil painting offers rich perspectives of curiosity, inquiry, and bodily autonomy through critical awareness curated by means of material agency on the land where children actively created and composed extensive life cycles to creatively question, challenge, and disrupt mainstream narratives by breaking the silos between STEM concepts and realities of refugee children (Strong et al., 2016; Takeuchi & Marin, 2022). By expressing feelings visually using lines, shapes, forms, tones, colours, and textures of soil paint, the children emerged as soil advocates or those who value, appreciate, and protect the soil for future generations to heal present day iterations of colonialism.

Harnessing Student-Generated Questions as a Learning Strategy

Mrinalini Sharma, University of Toronto, mrinalini.sharma@mail.utoronto.ca
Yutian Ma, McMaster University, may60@mcmaster.ca
Faria Sana, Athabasca University, fsana@athabascau.ca

Abstract: The use of student-generated questions (SGQ) is a relatively novel educational strategy that can result in learning gains across diverse student populations and educational settings. This paper examines the effectiveness of three conditions (generation, retrieval, and re-reading) against two categories of question (factual and applied) through a between-subjects study design. After completing one of the three learning conditions: student-generated questions (generation or SGQ) with simultaneous access to content, practiced free recall of the learnt content (retrieval), and re-reading of the study material (re-reading), content learning was evaluated through a final test. Results demonstrate the learning potential of generation and hint at an association between question type and condition, suggesting that SGQ is an effective strategy to boost student learning, with potentially stronger results in specific contexts.

Purpose

Many educators and researchers continue to investigate new modes of active learning to engage learners more deeply than traditional lecture methods. A variety of approaches have been reported that highlight the benefits of adopting a learner-centered approach (Brindley et al., 2009; Conrad & Openo, 2018; Kearns, 2012). One method that has gained recent traction within e-learning literature is that of student-generated questions (SGQ) (Belanich et al., 2003; Ebersbach et al., 2020; Mishra & Iyer, 2015; Shakurnia et al., 2018; Su & Chen, 2018; Yu & Liu, 2009; Yu & Wu, 2012). SGQ is a method that begins a shift to more student-centered learning by enabling students to generate their own questions based on to-be-tested content. Ample empirical literature has shown that student-generated questions (SGQ) can increase learning gains for diverse student populations, across a variety of platforms and learning domains (Belanich et al., 2003; Ebersbach et al., 2020; Mishra & Iyer, 2015; Shakurnia et al., 2018; Su & Chen, 2018; Yu & Liu, 2009; Yu & Wu, 2012). However, evaluating SGQ against other robust and common learning strategies, such as retrieval and re-reading practices, requires further experimentation. The underlying cognitive mechanisms which differentiate these techniques also require further insight. In addition to differentiating the potential cognitive understanding between different active learning mechanisms, the present experiment contrasts the effectiveness of SGQ to other learning strategies and question styles in order to better understand its educational potential.

Literature review

A range of research explores the perception and effectiveness of SGQ within educational contexts. Research by Su & Chen (2018) indicated that SGQ positively facilitated learner motivation, attitude, and engagement within flipped classrooms. Shakurnia et al. (2018) found that students within a medical education environment benefitted from using SGQ, though the technique was unpopular and unfamiliar. Yu & Wu (2012) implemented survey research methodology within an undergraduate course to uncover cognitive mechanisms behind SGQ and perceived value for learners; ultimately, their data analysis established that students who adopted SGQ engaged in deeper learning.

Cognitive accounts of SGQ have been offered, suggesting that SGG is a rendition of the "generation effect" (Slamecka & Graf, 1978), defined as enhanced learning due to the generation of novel content. Generation is an active form of learning that likely allows for deeper level processing, with the offset of increasing cognitive load. Despite this theoretical derivation in the 1970s, literature on this effect provides contrasting results. Arguably, this stems from an erroneous utilization and understanding of the word generation. Research by Slamecka & Graf (1978) and Karpicke & Zaromb (2010) incorporates generation through various word-pair associations. While this technique was standard methodology due to the high level of control it allowed researchers, Karpicke & Zaromb (2010) criticized word-pairs and aptly re-named them "incidental recall". Modified generation methodologies have since been explored and tested (Berthold et al., 2007; Schwamborn et al., 2010). Though they offer less control and more in-depth data analysis, many free generation techniques (like SGQ) have exhibited stronger learning effects than incidental recall activities (Berthold et al., 2007; Karpicke & Zaromb, 2010; Schwamborn et al., 2010; Slamecka & Graf, 1978).

Other established student learning strategies include retrieval and re-studying approaches. Retrieval practice is a well-known cognitive effect, heavily supported within educational literature (Carrier and Pashler, 1992; Roediger & Butler, 2011; Karpicke, Lehman, & Aue, 2014). Unlike the popular (and considerably less effective) method of re-reading content to study, retrieval practice is an active form of learning that involves variations of free recall. Despite the robust effects of retrieval practice, students are not keen to adopt this practice within their study routines. Theoretically, retrieval is proposed to have two key mechanisms: context and retrieval strength (Carpenter, 2009; Karpicke & Blunt, 2011; McDaniel & Fisher, 1991). Context refers to the ability of environmental cues to elicit memories during retrieval practice (McDaniel & Fisher, 1991). On the other hand, retrieval strength refers to the potency of the association between any cue and a memory (Karpicke & Blunt, 2011). During retrieval practice, one or both of these mechanisms may be contributing to learning.

Materials & methods

145 first-year Introductory Psychology students completed this online study in person, within a laboratory setting, under the supervision of a trained facilitator. There were approximately 47 students in each of the 3 conditions: generation (SGQ), retrieval and re-read (control). An online survey tool known as LimeSurvey was utilized to conduct this experiment. A four-paragraph reading passage about mirror neurons was utilized as the target learning content. The passage was specifically simplified for experimentation, though traditionally it is studied in upper- year Neuroscience courses. Thus, it was reasoned that most students would be unfamiliar with this content because *Introductory Psychology* is a prerequisite to these upper year courses.

All participant completed the following phases of the study: a timed reading phase, followed by a timed, condition-based study phase, two brief distractor tasks, and a final testing phase. A pilot study with less than 20 participants was conducted in order to determine the length of time sufficient for a full reading of the passage, the time required to generate MCQ questions, and to rectify any digital shortcomings. Each participant completed the reading phase for 10 minutes, read the corresponding condition-dependent instruction page, and completed the randomly assigned condition-based study phase. In the re-read condition study phase, there was renewed access to the passage for another 16 minutes. In contrast, the retrieval condition consisted of a free recall period for 8 minutes, allowing participants to transcribe as much of their learnt content onto a blank online page accordingly. This was followed by access to the full passage for another 8 minutes, to restudy and remedy any previous retrieval errors. Participants in the generation condition were provided consecutive access to one of four paragraphs in the passage for 4 minutes each, for a total of 16 minutes. Within this 4-minute timeframe, participants were provided a sample of a good MCQ and then asked to generate one MCQ with one correct answer and three distractors based on the content of the available paragraph. Final testing phase consisted of 24 MCQ, a randomized mix of 12 factual MCQ and 12 applied MCQ. Factual MCQ were derived verbatim from the reading passage into question format, a standard testing strategy used within most undergraduate education. The 12 factual MCQ comprised of 3 MCQ from each of the four paragraphs to ensure evenly distributed testing of the passage. In contrast, applied MCQ comprised of detailed explanations of novel situations to assess deeper understanding as opposed to rote memorization.

The retrieval and generation conditions were consciously designed to prevent overlapping between possible mechanisms responsible for learning. The retrieval condition allowed students to practice free recall without access to the passage, but with a subsequent chance to correct any errors. In comparison, the generation condition solely examined whether the creation of novel content with parallel access to the passage, bypassing conflicts with possible retrieval mechanisms, had any effect on a final assessment of learning.

Results & conclusions

We conducted a general linear model analysis to examine the effects of the independent variables of question type (factual and applied) and condition (re-read, retrieval, and generation) against the dependent variable, final test performance. The between-subjects effects highlighted a significant main effect of condition on final test performance, $F(2, 142) = 20.998$, $p < .001$ with a moderate effect size of $\eta^2 = .228$. The within-subjects contrasts of question type on final test scores suggests a weaker connection between the two, $F(1, 142) = 3.607$, $p = .060$, $\eta^2 = .025$. Moreover, a significant yet small linear effect of the interaction between both independent variables was observed, $F(2, 142) = 3.998$, $p = .020$, $\eta^2 = .053$. This indicates the potential interaction of condition on question type for final test scores.

Subsequent pairwise comparisons revealed significant mean differences between all conditions: generation and retrieval conditions, $t(142) = .113$, $p < .001$, generation and re-read conditions, $t(142) = .242$, $p < .001$, and retrieval and re-read conditions, $t(142) = .126$, $p < .001$, respectively. Pairwise comparisons of factual MCQ scores against condition highlighted the non-significant mean difference of test performance between generation and retrieval conditions, $t(142) = .033$, $p < .372$. All other pairwise comparisons of factual test performance validated the study by displaying significant outperformance of the control condition: generation and re-read conditions, $t(142) = .158$, $p < .001$, and retrieval and re-read conditions, $t(142) = .124$, $p < .001$, respectively. Pairwise comparisons for applied question scores demonstrated significant mean differences against all conditions: generation and retrieval conditions, t(142) = .073, p < .021, generation and re-read conditions, t(142) = .200, p < .001, and retrieval and re-read conditions, t(142) = .128, p < .001, respectively. Overall, results are supportive of the hypothesis that SGQ (generation) is as effective a learning strategy when compared to the robust effects of retrieval practice. Interestingly, results also suggest a greater learning potential for applied contexts when implementing SGQ.

Scientific significance of the study

The present study may inform the analysis and further study of active cognitive learning mechanisms. Differences between factual and applied question performance for generation and retrieval conditions suggest similar mechanisms for factual recall and potentially different underlying mechanisms for applied scenarios. With equivalent performance for factual questions in the generation and retrieval conditions, both study strategies may utilise the cognitive mechanisms of increased retrieval strength and context. Greater retrieval strength would allow for stronger associations during learning for memory and cues whereas increased context would heighten the number of cues available for later recall (Carpenter, 2009; Karpicke & Blunt, 2011; McDaniel & Fisher, 1991). Either of these techniques would sufficiently enhance learning for factual questions. However, application questions test broader understanding which is semantically distinct from learnt content. In this instance neither retrieval mechanism would boost learning. In contrast, generation through the creation of SGQ may go beyond cognitive mechanisms of strength and context by promoting integration of learnings with prior knowledge. Nevertheless, the cognitive mechanisms of retrieval strength and context discussed above may still be present within generation. For instance, they may be enhancing neural activation and pathways like retrieval practice while still increasing novel connections to prior knowledge and improving overall retention of material. This principle of integration may be crucial for performance on applied questions which bypass rote memorization to evaluate student understanding through novel scenarios. Moreover, transfer-appropriate processing theory may also have a role in this study. Since the present experiment utilised only MCQ, there could be an increase in memory as a result of the similarity between the processes used to generate new material and the ones used when answering an application MCQ. More extensive research is required to determine the robustness of the generation effect and the learning potential of SGQ for application-based questions.

Our results and supporting comprehensive literature on SGQ suggest that SGQ can be effectively harnessed as another form of active learning in post-secondary education. While studies have validated the strength of SGQ within academic, online and flipped classroom learning contexts, this technique was often studied in isolation, as opposed to direct comparisons with other study techniques (Shakurnia et al., 2018; Su, & Chen, 2018; Yu, & Liu, 2009). However, Ebersbach et al. (2020) provide further insight into the potential of SGQ. Using developmental psychology as content, they tested the long-term recall effects of generation against the testing effect and restudy (control) conditions for factual and applied (transfer) questions. Results of their linear regression model revealed non-significant effects between generation and retrieval but positive significant effects when compared to the control condition for overall final test performance. Subsequent Bayesian analyses revealed smaller positive effects for factual and applied question scores for generation and testing conditions. Comparing our results to those of Ebersbach et al. (2020) hints at a slight increase in the generalizability of SGQ from MCQ to open-ended questions, and from neuroscience to developmental psychology content. The differences between both sets of results demonstrate the need for future studies to address potential cognitive differences of retrieval between the testing effect and free recall, and the similarities or differences when compared to generative learning strategies.

Despite its benefits, educational experts and students may be hesitant to embrace a generative approach to learning. One way to potentially encourage this practice could be in the integration of SGQ with new technologies and software. Many studies have tested this idea, providing strong results for the efficacies of such strategies within e-learning programs (Belanich et al., 2005; Yu & Lai, 2015; Kay et al., 2020). Furthermore, studies have also been conducted on the benefits of including certain features of these programs. For instance, Yu & Wu (2020) found that student feedback along with SGQ provided a noticeable benefit to student learning. Other potential features may include access to model questions and the ability to remain anonymous when generating questions. These features may be the key to encouraging students to use SGQ as a study method; Yu (2014) found that as more features were added, students' perception of the usefulness of SGQ software correspondingly improved. Moreover, implementation of SGQ within digital education platforms may serve to improve student engagement and retention of core content within applied contexts. Ultimately, SGQ has the potential to be an important active learning strategy, with the potential for implementation in various educational settings (online or in- person), and the ability to refocus attention on student-centric learning.

Strategies for Supporting Epistemic Discourse About Ideals

Na’ama Y. Av-Shalom, Rutgers University, naama.avshalom@gse.rutgers.edu

Abstract: Scientists construct, evaluate, and revise epistemic products collaboratively through epistemic discourse. Similarly, students need opportunities to engage in epistemic discourse towards collaboratively establishing epistemic norms and using them when engaging with epistemic products, such as models. Teachers have an important role in guiding this discourse. However, less is known about what strategies teachers can use towards that end. The data in this study are from one teacher’s implementation of a model-based inquiry curriculum in her middle school science class. I use the Apt-AIR framework to identify and explore several strategies that one teacher used to support her students’ discourse around epistemic criteria throughout the class discussion and while discussing particular criteria. The strategies identified in this research can support curriculum design and point to future directions.

Introduction

Science is a social practice. Scientists construct, evaluate, and revise epistemic products such as scientific models collaboratively. These collaborative processes happen through *epistemic discourse*—the varied discussions that communities—like science or classroom communities—have as they develop norms (Longino, 2002). Among these norms are *epistemic ideals*—or criteria—which scientists use to guide their engagement with epistemic products, such as models (Longino, 2002). Some epistemic ideals may include that a scientific model is good if it *aligns with the body of evidence*, or if it is *parsimonious*. These ideals are the shared criteria that scientists use as they evaluate, revise, or discard epistemic products, and ultimately ratify ideas into knowledge. Given their centrality in science practice and their inclusion into recent educational standards (e.g., NGSS Lead States, 2013), it is important to support students in understanding and developing facility using epistemic ideals.

Teachers have an important role in guiding students’ understanding and engagement with epistemic matters (e.g., Ke & Schwarz, 2021), including ideals. Several studies have looked at how teachers can support epistemic discourse about different scientific practices such as evidence construction (Manz & Renga, 2017) and argumentation (McNeill & Pimentel, 2009). Recent research has also shown that, with support, middle school students are able to use criteria when evaluating models and explanations (e.g., Ryu & Sandoval, 2012). However, less is known about the teacher strategies that can be used to support students in engaging in increasingly sophisticated epistemic discourse about epistemic criteria. In this paper I present a case taken from a larger study of a class discussion about evaluating scientific models to investigate *what instructional strategies does a teacher use to support student in engaging in more competent epistemic discourse around epistemic criteria?*

Theoretical framework

To characterize whether a teacher is guiding students towards greater competence in engaging in epistemic discourse I draw on the Apt-AIR framework (Barzilai & Chinn, 2018). The authors identify *apt epistemic performance* as an important educational goal. To unpack this goal, it is helpful to first look at the starting point of the framework, the AIR model of epistemic cognition (Chinn et al., 2011). This model lays out three components of epistemic cognition, a) epistemic Aims, which are the goals that someone has with respect to epistemic matters, such as *evaluating the quality of a scientific model* or *understanding an idea*, b) epistemic Ideals, the criteria used to determine whether epistemic aims have been met, as discussed above, and c) Reliable epistemic processes, the processes used to achieve epistemic aims, such a *synthesizing all the evidence* when evaluating a model. From these components, *apt epistemic performance* is successfully achieving one’s epistemic aims through competence—that is, through using reliable epistemic processes and epistemic ideals.

The Apt-AIR model outlines five aspects that characterize competent engagement with the three AIR components: a) *Cognitive engagement in epistemic performance*—engagement in cognitive processes that reliably achieve epistemic aims in accordance with epistemic ideals. In the case of teachers, this can often include directing students to engage in cognitive processes. e.g., When evaluating scientific models, the teacher could comment on qualities of a good model or explain features of the models. b) *Regulating and understanding epistemic performance*—having metacognitive knowledge about epistemic aims, ideals, and processes and using epistemic metacognitive skills to guide their usage. e.g., A teacher could help students monitor their understanding of ideals for evaluating models. This paper will be focusing on these two aspects. The latter three are c) *Adapting epistemic performance*—an ability to achieve epistemic aims in an adaptively across diverse situations, d) *Caring about and enjoying epistemic performance*—the dispositions to achieve valuable epistemic aims, and e) *Participating* *in epistemic performance with others*—achieving epistemic aims in varied *social* configurations. Using the Apt-AIR model it is possible to identify whether the ideals constructed and endorsed by science classroom communities are appropriate to the varied situations that the class encounters. In this study, I will be using Apt-AIR to characterize the strategies that the teacher used to support students' engagement with epistemic ideals.

Methods

Context, participants, and data

The data come from one teacher's implementation of a life-science, model-based inquiry curriculum over several months in one of her seventh grade classes (students: 12-13 years old), as part of the Promoting Reasoning And Conceptual Change In Science (PRACCIS) project. The teacher, Ms. Pisano (all names are pseudonymous), taught at a suburban school in the United States and maintained a high fidelity to the PRACCIS curriculum.

The focal discussion occurred while the class was engaging in a unit about cell membranes. The students were exploring the guiding question, "How do lead particles get into our cells?" The focal discussion occurred early in the unit, before students had seen most of the evidence. Earlier in the unit the students had received five models about the topic that were constructed by undergraduates and were chosen to highlight different possible strengths and weaknesses of models. Students individually evaluated and ranked the models and then discussed their rankings in small groups. The teacher then led a class discussion about the students' evaluations (focal discussion). To support their modeling practice, students had previously developed a class list of criteria for good models. Their list was publicly displayed in the classroom and referred to during discussions. One purpose of the focal discussion was to use students' evaluations to refine this criteria list. It thus provides an opportunity to investigate how the teacher supported students in engaging in more apt discourse about criteria.

Analysis

To get a broad look at the discussion, I first coded whether any ideals were being discussed in each utterance, and which. This included explicit mentions of the ideal, as well as descriptions of it or direct responses to other people's discussions of the ideal, such as agreement about a definition, or an elaboration. I also coded whether the teacher or a student had first brought up the ideal within a series of contiguous utterances about it (see Fig. 1).

Based on the findings, I identified four focal ideals. I then coded the instances of discussion of these focal ideals using a scheme that I developed based on the Apt-AIR framework (Barzilai & Chinn, 2018). I identified whether and how each of the five aspects in the framework was used. To further specify the continuum between cognitive and metacognitive engagement and the degree of metacognitive engagement, I drew from Av-Shalom et al.'s (2019) categories of metacognitive discourse. Two of these categories are outlined in Table 1. The analyses revealed several strategies for supporting students' discourse about ideals, which I discuss below.

Table 1
Degree of cognitive to metacognitive discourse within two categories

Expression of thought	**Applying understanding to particular topics**
Cognitive: statement has no expressions of thought	**None**
Borderline: statement includes qualifiers that could also just be elements of speech (e.g., "I think X"; "maybe it's Y")	**Applying**: speaker specifies that a particular ideal is relevant (e.g., "This model *is detailed*")
Monitoring-self (Mon-self): statement includes explicit expressions of what someone is thinking (e.g., "First I/our group thought X, but then I changed my/we changed our mind")	**Tailoring**: speaker explains why an ideal is relevant (e.g., "This model *is detailed because X*")
Monitoring-others (Mon-others): statement includes speculation about what other people *may* be thinking (e.g., "I think she might be confused"; "It seems like she thinks X")	**Refining**: speaker discusses a qualifier or boundary of the ideal (e.g., "so how about *we only need relevant or necessary details*" [refining ideal: "details"])

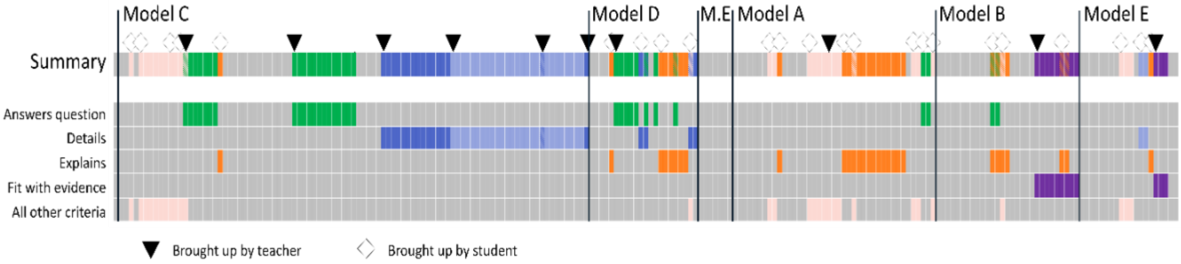
Findings and discussion

As the class discussed the five models, the students and teacher brought up many ideals (Fig. 1, summary line). However, Ms. Pisano guided the discourse towards only one or two focal ideals at a time. Only when students began to use the focal ideal(s) appropriately did she shift the focus to another ideal. At the beginning, Ms. Pisano raised and highlighted two ideals, that models are good if they *answer the question* (Fig. 1, green) and if they *are detailed* (Fig. 1, blue). Later in the discussion, the students began bringing up those ideals spontaneously and appropriately, demonstrating a growing understanding of and proficiency using them. These two ideals became less prominent in the discourse as Ms. Pisano shifted the focus towards a third ideal, that the model is good because it *explains well*. Unlike the first two ideals, "explains" was raised by the students, not the teacher. It first arose early in the discussion, but Ms. Pisano steered the students to other ideals. However, after the second time students raised it Ms. Pisano picked up on the ideal and supported students in discussing it further. Once students had discussed and refined "explains," Ms. Pisano repeated the process with a fourth ideal, fit with evidence.

Below I will discuss two contiguous excerpts that highlight two of the strategies that Ms. Pisano used to guide her students' discourse about ideals. Throughout the excerpts, we can also see a shift in the discourse from metacognitive to cognitive and back. The first excerpt begins with a metacognitive expression of thought (monitoring-others: "What question would you think they're answering?") and shifts to a cognitive articulation of the students' own goal. Later, it shifts again, this time to another category—not as an expression of thought (bolded in excerpts), but towards students applying their understanding to the model (underlined). In the second excerpt we see the discourse move from applying the ideal, to tailoring and then refining it, before shifting back to applying. This continual shifting happened throughout the discussions of the other ideals in the episode as well, and points to a more general strategy that Ms. Pisano may have been using across contexts.

Figure 1

Ideals brought up in utterances in a class discussion



Strategy: Introducing a metacognitive process: "backwards checking"

Early in the discussion, the students raised various critiques about Model C, saying that it was not descriptive, it "doesn't make sense," and that the pictures were "weird." Ms. Pisano acknowledged the students' contributions, but steered the discussion to a new ideal by asking them, "If you just saw this model, what question would you think they're answering? If you had no idea what question they answered … if you just read it, what would you think?" After a brief digression about whether Model C was really the worst of the five, Ms. Pisano circled back and explicitly re-introduced her query as a process for identifying whether the ideal had been met (line 1). Ms. Pisano them modeled how to use the process (lines 2-6) and guided a student to compare the questions (line 7).

1	Ms. P	**What question do you think this person's answering?** I think that's a good way to see if the model's on topic, is to look at the model and say, 'okay, if I had to guess what question they were answering this is what I would guess.'	**Mon-others** Tailoring
2	Mika	How does the lead get into-- how does the lead need to get into the cell?	
3	Ms. P	Okay, so how does it get maybe *to* the cell?	
4	Mika	Mhmm	
5	Ms. P	And **what's our question?**	**Cognitive**
6	Mika	How does the lead get *into* the cell?	
7	Ms. P	Okay, so does this, does this answer the question?	Applying

This is an example of a metacognitive process that Ms. Pisano would later in the year name "backwards checking" and which she and the students would continue to use. This is a sophisticated strategy for helping students understand and regulate their epistemic performance: answering the question might be a familiar ideal to students but they may struggle to identify whether it has been met. This strategy seemed to have helped students better understand the ideal, and they began raising it spontaneously when discussing subsequent models.

Engaging in metacognitive process: Refining ideals

Several times, Ms. Pisano supported students to refine the ideals they were using. Following the prior excerpt, the students were still divided about whether Model C answered the question (Line 8). Ms. Pisano responded to a student's explanation of how the model *did* answer the question (line 10) by refining the ideal (lines 11-13). She then s the students to engage with the newly refined ideal (line 13). Ms. Pisano went on to support students to refine other ideals as well, and these refined ideals became part of the students' revised class list of criteria for good models. In preliminary work from other episodes, this is a strategy that Ms. Pisano seems to have used often, even in discussions that were not explicitly aimed at identifying or engaging with criteria.

7	Ms. P	Okay, so does this, does this answer the question?	Applying
8	Various	No, yes	
9	Ms. P	Okay, Anna	
10	Anna	In one of them it says, like, the lead breaks down the membrane so it can enter into the cell.	Tailoring
11	Ms. P	Okay, so part of it does answer. Does the *whole* thing answer the question?	Refining
12	Various	--Students shake their heads no--	
13	Ms. P	Okay, so **I think something that we need to think about is**, does the entire model answer the question? [1] What parts maybe could you get rid of or change in this model to make it more on topic? [2]	**Mon-self** Refining [1] Applying [2]

Conclusion and future directions

This paper begins to identify different approaches that teachers can use to support students to engage in high quality epistemic discourse about ideals. The methods also show a demonstration of how two of the aspects of the Apt-AIR framework, cognitive engagement in epistemic performance and regulating and understanding epistemic performance, can be considered two sides of a spectrum, and can benefit from further specification. The analysis of these two aspects highlighted another interesting pattern—a continuous shift between degrees of cognitive and metacognitive engagement. In a larger study I am exploring how and when this occurs in other episodes of classroom discourse, and how this shifting may support students' understanding of and engagement with epistemic ideals, as well as with epistemic aims and processes. This research can give us insight about what strategies are possible as well as why, or towards what end, Ms. Pisano used the strategies that she did and what affordances and results they had within the discussion. This can provide a model for how teachers can engage in epistemic discourse towards supporting students in deepening their understanding of and engagement with epistemic ideals.

Infrastructuring Pathways to Technology Learning for Older Adults in a Public Library

Sari Widman, University of Colorado Boulder, sari.widman@colorado.edu

Abstract: While gaps in older adults' technology use and learning are significant, they are often overlooked. This paper centers older adults' technology learning in public library contexts, with a focus on how interconnected infrastructures can serve to support their learning. Through an exemplary case study spanning several public library programs targeted at older adults, I ask: How did interconnected infrastructures support or fail to support pathways to technology learning for older adults in a public library setting? Through this study, I hope to contribute to knowledge that can support design and infrastructuring for meaningful technology learning for older adults in public library contexts.

Introduction

There continues to be a significant gap in technology use and proficiency for adults over the age of 65, despite technology being increasingly consequential for core life activities such as communication, accessing medical resources, and managing finances (Anderson et al., 2019). This leaves older adults at increased risk of isolation, as the COVID-19 pandemic has highlighted how much we rely on technology for social connection (Xie et al., 2020). Technology resources and learning opportunities through public libraries and library makerspaces are one promising avenue for addressing these gaps and vulnerabilities (American Library Association, 2007; Koh et al., 2018).

It is important to understand how older adults find and access these technology learning opportunities, and what motivates and deepens their engagement. While lifelong learning is upheld as a core value in the Learning Sciences, the study of how older adults access and participate in learning communities is rarely centered. Adult learning in public libraries has also been under-researched (Lee & Phillips, 2019). In this exemplary case study I hope to build on that knowledge by asking: How did interconnected infrastructures support or fail to support pathways to technology learning for older adults in a public library setting?

Theoretical framing

Infrastructures are the (often taken for granted) underlying structures that shape and inform activity in a particular place or system. In the context of learning environments they are important for understanding how educational innovations can be sustained, what constraints educators are working within, how learners can or can't access opportunities, and how learning is scaffolded (Ma & Hall, 2018; Penuel, 2019; Smirnov et al., 2018). Infrastructures are locally situated and relational, taking on meaning as interconnected pieces that both shape and are shaped by organizational and group practices within particular social and historical contexts (Penuel, 2019; Ruhleder & Star, 1996; Star, 1999). They are "big, layered, and complex", and embedded "inside of other structures and social arrangements" (Star, 1999, p.381).

In this study, I look at how infrastructures interact to influence older adults' technology learning pathways. For the purposes of this study I consider a learning pathway to consist of the process of a learner: (1) being brokered (i.e. connected with a learning opportunity or resource) (Ching et al., 2016) into a learning environment, (2) accessing the learning environment, and (3) having a learning experience there.

Methods and context

The study took place in a public library system in an affluent, predominantly white suburban neighborhood in the Mountain West region of the U.S. The site of this case study was chosen because the library's makerspace was very successful at engaging older adults, and the library and county at large had a robust infrastructure for engaging older adults in technology resources and arts and craft programs. The library hosted programming engaging older adults across several sites, including outreach at senior living facilities. I focused my analysis on the two sites that had the most robust programming: the library's makerspace (located in a separate building from the library), and the county's community center. The makerspace held all-ages drop-in hours several times a week, bi-monthly intergenerational project-based workshops on the weekends, and seniors-only hours Thursday mornings. At the community center, library staff hosted bi-weekly drop-in tech help and senior iPad classes, and monthly afternoon craft workshops. While the craft workshops and tech-help were not exclusively for seniors, the majority of participants were older adults.

Data collection spanned 3 months as part of a larger exploratory study on adult and intergenerational Science, Technology, Engineering, Arts, and Math learning programs in public libraries. Data included in this analysis consisted of observational fieldnotes of programs (*71 hours of observation for intergenerational programs, 17 hours for older adult programs*) and staff meetings (*11 hours*), notes from conversations with staff and program participants, and interviews with 5 staff members and two older adult makerspace volunteers.

In my analysis, I first did a round of descriptive coding across data sources to identify moments of older adult (adults confirmed or appearing to be over age 60) technology learning and talk of older adult technology learning and programs. This was followed by several iterative rounds of inductive and deductive coding (Miles et al., 2018). Deductive codes identified social, material, and procedural infrastructures. Inductive codes, drawn from data collection memos with further emergent coding during analysis, focused on moments of brokering and connection, and expressed identities, interests, and motivations. I also created relational maps of participants, the programs they participated in or moved between, and how they were introduced to them.

Findings

Significant infrastructures appeared at the organizational level and programs level, with *social*, *material*, and *procedural infrastructures* stretching across these. In this section, I describe how these infrastructures appeared to work together to support brokering, accessibility, and learning for older adults, and when breakdowns in these infrastructures occured. Because of the complex and relational nature of infrastructures, I will present them as such in my findings, rather than attempting to disentangle them into discrete infrastructural categories.

Infrastructure and brokering into and between programs

The community center where the library held drop-in technology help and iPad classes was an ideal location for outreach because of a combination of *social*, *material*, and *procedural infrastructures*. It already had a lot of programming for older adults and housed the offices of senior services staff. The county's social and cultural services existed under one umbrella, making it easier for library staff to coordinate library events at the community center. Based on my observations, older adults were often connected to the iPad workshops and tech-help through one of two *social infrastructures*: (1) through staff at a library circulation desks when they approached them to ask a tech related question, or (2) through senior services staff during participation in other activities at the community center. I regularly saw the same participants at multiple programs held at the community center, and based on conversations during tech programs, they seemed to be connected with a number of different programs and social groups based at the community center.

Friends and family members often introduced each other to the makerspace. Adult children sometimes brokered their parents into the space, and friends would invite each other to workshops or to come see the makerspace. The project-based workshops the makerspace hosted were another common way older adults were introduced to the makerspace. Regular sewing workshops were well attended by older adult women, and I commonly observed them return to the space; first to finish projects they started during the workshops, and later to work on new projects. Some primarily stuck to sewing. Others became interested in using different tools in the space (*material infrastructure*) that they saw others using (*social infrastructure*), like the vinyl cutter, or "egg bot", a robot that could be programmed to draw patterns onto eggs.

Library staff, a *social infrastructure* at the library, had an opportunity to broker connections to the makerspace for older adults who attended tech programs and craft workshops at the community center. This would have enabled participants who engaged in technology or craft learning to deepen their engagement with creative technology. However, I didn't observe library staff doing this. As a participant observer, there were several instances where I took on that role, successfully brokering older adults between these programs and the makerspace. In these instances I became a temporary element of the *social infrastructure*. On several occasions when staff observed me doing this, they expressed an interest in connecting people between the programs.

This disconnect flowed in the other direction as well. In an interview with an administrator who was instrumental to setting up the makerspace, she said that some adults would come in without a baseline of technology knowledge that would enable them to meaningfully engage with the tools in the space. This made it difficult for them to move from traditional crafting to using technology to create projects. When I asked her if they referred those people to drop-in technology help or technology basics classes facilitated by library staff at other locations, she said they didn't, but they should. I also didn't observe much brokering happening at craft workshops facilitated by library staff at senior living homes. Residents had varying degrees of independence in their living arrangements, and didn't always have access to transportation. A makerspace staffer planned to begin attending some of these outreach programs to make some of the makerspace's resources available off-site. However, this did not happen during the time of data collection.

The disconnect between programs seemed to result from elements of the *procedural*, *material*, and *social* infrastructure at the organizational level. Makerspace staff and other library staff organizing programs targeted to older adults had different supervisors, were located in separate buildings, and weren't able to meet frequently because of the timing of their respective work and program hours. During staff meetings, there was frequent discussion of how staff in different programming positions felt disconnected from what their colleagues were doing and wished there was more time or support built-in for collaboration or communication.

Infrastructure, accessibility, and participation

Older adults reported that consistent hands-on one-on-one support from library and makerspace staff (*social infrastructure*) was consequential for engagement with technology learning in both skill's based technology workshops and drop-in technology help, and makerspace open hours. As one participant said to a library staffer while receiving one-on-one assistance during tech help, "I love that I have people I can ask questions to and not feel stupid." During this same conversation the participant expressed getting comfort from knowing that support resource was available to them on an ongoing basis.

Weekly open hours for older-adults were important to many seniors who regularly participated at the makerspace. This was initiated by a makerspace staffer after open hours switched to afternoons and early evenings, and older-adults were vocal about missing morning hours. Some exclusively came to the morning hours, when it was quiet and they had more energy. In conversation with each other, attendees at older-adult open hours expressed their enjoyment of working on projects and being social with others of the same age.

All ages open hours were also important to older adults' participation in the makerspace. I frequently observed grandparents or other older family members or caregivers collaborating on projects with children. They often engaged with technology like the vinyl cutter and laser cutter to support youth in their projects, and some branched out to work on their own projects as well. In one example of this, a grandfather who had come in with his daughter and grandchildren was overheard on the phone excitedly telling someone about the "cool tools" they had at the makerspace. He later came back several times to use the laser cutter.

Volunteers, who were largely retirees, played an important role in facilitating both drop-in tech hours and makerspace programming. Volunteer opportunities were an important infrastructure for brokering some older adults into the makerspace and encouraging sustained participation. The majority of these volunteers were retired teachers or identified as educators in some way. While a handful of the older adults I spoke to and observed over the course of the study reported being retired technology professionals, or coming in with prior technology knowledge, most reported originally learning technology tools they used in the makerspace from younger makerspace staff. As they developed more proficiency with the technology in the space, they were able to teach and assist each other, as well as younger participants, moving the group collectively from primarily cross-generational learning to increasingly more intragenerational learning. This was true of both older adult volunteers and many of the most active makerspace participants.

While I saw volunteers who had more expertise in crafting deepen their knowledge of technology tools and softwares over time, there were also missed opportunities to deepen their expertise. In one instance during an e-textiles workshop, two of the regular volunteers helped people with craft-based things, like threading needles, poking LEDs through fabric, and transferring circuit patterns onto fabric. After the workshop they mentioned to makerspace staff that they felt like they couldn't help troubleshoot the circuits because they had not had the opportunity to make the project themselves before the workshop.

In closing interviews with makerspace staff, they reported that they had been getting increasingly busy, and anticipated having less and less capacity for one-on-one troubleshooting and teaching. This may have implications for the comfort of older adults newly participating in the makerspace in the future, and makes the tech learning of their peers who have been regular participants and volunteers even more consequential.

Discussion

By making infrastructures more visible, we can learn how to deliberately design for infrastructuring pathways for older adult technology learning in public libraries, as well as other community and informal contexts (Penuel, 2019; Ruhleder & Star, 1996; Smirnov et al., 2018). Social infrastructures within the library were supportive to older adult's technology learning pathways, as were their existing relationships and social networks. Infrastructuring can be done to support older adult's participation by leveraging the different types of social networks and relationships they have. Based on the study's findings, it may be important to infrastructure a mix of intergenerational and same-age affinity space for older adults to further participation and deepen their learning. For example, some older adults wanted to exclusively participate in quiet making time during morning hours. For others, bringing children to the makerspace and supporting them in their projects was their entry point to engaging with new technology tools. Supporting volunteering opportunities was also an important way to help older adults deepen their technology knowledge while engaging their desire to support others in their learning. As noted above, it also may be an important means of infrastructuring support for new learners who need hands-on assistance if makerspace staff are no longer able to provide that level of support on their own.

The lack of networking infrastructure between programs or departments was a pervasive issue, making it challenging to broker opportunities between internal programs, let alone outside of them. Staff were unaware of or struggled to remember and execute strategies for connecting with older adults at programs facilitated at other locations, in part due to the lack of infrastructure for communication between staff members who were physically located in different buildings. For example, one library staffer asked a regular makerspace participant to distribute flyers to her craft group, but hadn't thought to give flyers to her colleague who facilitated technology workshops for seniors at the community center. This points to a need for prioritizing time for staff collaboration across departments and locations.

A major limitation of this study is the primarily white and middle class participants. While the makerspace was very successful at engaging older adults, those older adults, like other age groups at the makerspace, were predominantly white. This study can not speak to the design of infrastructuring learning pathways that facilitate equitable and culturally relevant or sustaining participation for older adults with diverse racial and ethnic identities, or linguistic practices. Older adults will have different material and cultural needs dependent on their held identities, lived experience, and material realities. Further research should prioritize building knowledge that supports the needs of older adult learners with historically marginalized identities, or from under-resourced communities. Infrastructural issues identified in this study will likely be even more challenging for the many public libraries who are significantly less resourced than the one in this study. Further research is needed to understand the scope of infrastructure related challenges in these settings, as they will present differently in relationship to the resourcing and capacity of the organization, staff, and, patrons.

Abstract: This symposium features four presentations that illustrate variations in the opportunities and challenges encountered in RPP work focused on educational improvement targeting teachers' learning to engage students in inquiry-based disciplinary learning. A coherent theme across these presentations is the variation and specificity within as well as across each of the projects. Nevertheless, across the projects, three principles/processes of RPP work stand out as critical to building productive communities of practice: (1) negotiation and re-negotiation of shared goals, (2) breaking through traditional roles and power dynamics to enable truly collaborative relationships among partnership participants; and (3) adaptation of partnership processes and indicators of progress to suit the specific contextualized circumstances of each partnership (Penuel, et al., 2020).

Introduction

Learning sciences research aimed at facilitating professional learning has increasingly trended toward research-practice partnerships (RPPs) that embrace the multi-leveled complex systems in which teaching and learning are embedded (Bronfenbrenner, 1994; Cobb et al., 2003; Coburn et al. 2021; Cohen et al., 1993). Classrooms are dynamic systems requiring that teachers be equipped to engage in principled adaptation of instructional practices (Penuel et al., 2022). Engaging in instruction as principled adaptation necessitates that teachers understand the underlying principles, important ideas, and authentic practices of the disciplines they teach; how to best support students' engagement with these; and the diversity of resources that students bring to learning situations. At the same time, classrooms are embedded in institutional, district, state, and national contexts that impact teachers' learning and what happens in classrooms (Goldman et al., 2022). Accordingly, instructional improvement work requires collaborations among the multiple stakeholders in educational systems and those based in learning and education sciences communities (Penuel, et al., 2020). Building such collaborations presents both opportunities and challenges for developing and sustaining RPPs.

The presentations in this symposium illustrate variations in the opportunities and challenges encountered in RPP work focused on educational improvement targeting teachers' learning to engage students in inquiry-based disciplinary learning. The theme across them is the contextual specificity of RPP work. The uniqueness of each RPP increases the criticality of attending to three principles/processes of RPP work if it is to result in building productive communities of practice: (1) negotiation and re-negotiation of shared goals; (2) breaking through traditional roles and power dynamics to enable truly collaborative relationships among partnership participants; and (3) adaptation of partnership processes and indicators of progress to suit the specific contextualized circumstances of each partnership (Penuel, et al.. 2020).

Specifically, Kavanagh et al. examine processes involved in enabling researchers and practitioners to cross the boundaries of their traditional roles and relationships to enable deeper understanding of the nuances of in-the-moment instructional decision making that enables adaptive teaching. Gibbons et al. illustrate how a detailed understanding of between-school differences in institutional contexts and teachers' prior experiences working with researchers was critical to establishing adaptive partnerships. Feng et al. investigate the impact of high school disciplinary department cultures and values on the negotiation of shared goals and evolution of partnership work, highlighting the importance of attending to the multiple institutional levels that impact teachers' learning and instructional practices. Castro Superfine and Superfine highlight the implications for measuring the impact of RPP work given differences among districts in the problems of practice that they prioritize.

Partnering in the black box: Breaking the Fourth Wall to take RPPs into instruction

Sarah S. Kavanagh, Hala Ghousseini, Elham Kazemi, & Elizabeth Dutro

Teacher-researcher collaborations involve the coming together of two communities that, while overlapping, are distinct in the roles individuals play, their day-to-day work, and organizational expectations and cultures. In such collaborations, scholars of research-practice partnerships (RPPs) argue it is productive to attend to how researchers and practitioners engage with each other in relation to these distinctions by conceptualizing collaboration within RPPs as occurring at boundaries of sociocultural difference (Akkerman & Baker, 2011; Penuel et al. 2015). Collaboration at the boundary can be a source of learning where individuals work to make sense of differences, understand their own and others' perspectives more clearly, and develop new practices that merge or transcend existing practices (Akkerman & Bakker, 2011; Engeström et al., 1995; Wenger, 1998). Such work holds potential for learning and design of innovations that take into account the complexity of educational change in classroom and school contexts. Existing studies examine how collaboration at the boundary between researchers and teachers supports the design of tasks, lessons, and assessments that deepen classroom teaching and learning (e.g., Penuel, et al., 2007). While designs that have been generated through RPPs can support teachers' enactment of instruction, existing research provides limited understanding of how researchers and teachers might collectively negotiate the moment-to-moment improvisational decisions teachers make during instruction.

In our most recent work (Ghousseini et al., 2022; Kavanagh et al., 2022), we have considered the potential for learning at one boundary that often exists between researchers and practitioners as they collaborate on instructional practice: the boundary between performing teaching and observing teaching. In this recent work, we argue that typically, even if researchers and teachers are closely collaborating before and after instruction, during instructional time when students are present, teachers perform and researchers observe. This boundary between performers and observers is what scholars in theater and film studies refer to as a fourth wall. The "fourth wall" is the invisible line that divides the stage (where the actors perform) from the house (where the audience observes). Our work has examined the potential mechanisms for learning (Akkerman & Bakker, 2011) that occur when researcher/practitioner teams acknowledge, interact with, cross, or break the fourth wall to collaborate with one another during instruction. In this presentation, we examine the *coordination* work (Akkerman & Bakker, 2011) that researcher/practitioner teams engaged in to make ongoing joint-work at the boundary of the instructional fourth wall possible. Specifically, our investigation is guided by the following question: What coordination efforts enabled researcher/practitioner teams to acknowledge, interact with, cross, or break the fourth wall that typically exists between performers-of-teaching and observers-of-teaching?

Theoretical background

In some Western theatrical traditions, artists choose to break the fourth wall for didactic purposes (Brecht, 1898–1956) to allow the performer to alternate between being in character and stepping out of character to bring the audience inside the complexity of a dramatic action. This form of boundary crossing opens possibilities for both performers and observers: the performer can engage in a dialectical relationship with their role and with the audience and the observers can get a more nuanced sense of the performance and have more agency in the unfolding of the drama. In their review of studies of boundary crossing across disciplines, Akkerman & Bakker (2011) identified four potential learning mechanisms that can occur in situations of boundary crossing: identification, coordination, reflection, and transformation. The mechanism of identification involves practices and norms of each community coming to light, requiring definition and articulation. Reflection involves both perspective taking and making as actors come "to realize and explicate differences between practices and thus to learn something new about their own and others' practices" (Akkerman & Bakker, 2011, p.145). The mechanism of transformation comes into play when cultural differences lead to joint-work and the emergence of in-between practices through the negotiation of shared problems. While our previous work has looked across these learning mechanisms, in this analysis, we focus specifically on the mechanism of coordination, which involves developing the means and procedures that diverse practitioners can use to engage in joint work at the boundary. Akkerman and Bakker (2011) identify four processes that researcher/practitioner teams use to coordinate boundary-crossing work: building communicative connections (through shared boundary objects), translating across communities (e.g., research results into applications), enhancing boundary permeability (so that actions and interactions run smoothly), and routinization (finding procedures by means of which coordination is becoming part of automatized or operational practice). We draw on these four processes as conceptual tools for understanding the various coordination efforts that researcher/practitioner teams used as they prepared to work together at the boundary of the fourth wall.

Context and methods

We focus our analysis on four researcher/practitioner teams working together in four K-8 schools with rich cultural, racial, and linguistic diversity. Over the course of two years, these four teams engaged in professional learning experiences that involved an established, ongoing routine for joint-work at the boundary of the instructional fourth wall through a professional development (PD) structure called Learning Labs (LL). In each LL, teachers engage in cycles (McDonald, et al., 2013) of professional inquiry focused on leading disciplinary discussions in mathematics and literacy. In LLs, teachers and teacher educators come together to co-plan lessons that they enact all together in one of the teachers' classrooms, at times 'passing the chalk' and at times pausing to discuss students' ideas and instructional next steps. In our previous work (Kavanagh et al., 2022), we have analyzed these pauses, which we colloquially called "Teacher Time Out" or TTO (Gibbons et al., 2017). In a TTO, researchers and teachers interact at the boundary of the fourth wall and work to collaboratively enact classroom instruction with students. They may jump into a performer role to ask students a question, pause instruction while teaching to ask for ideas about where to go next, or pause the flow of instruction to discuss and puzzle through the design of responsive instruction in the moment. In this work, we move away from analyzing TTOs directly and turn the clock back to understand how researcher/practitioner teams built their capacity to engage in this type of boundary-crossing work together during instruction.

We analyzed the first six labs at each site (a total of 24 labs) to provide a common data set across the varied sites. Because we were interested in how researcher/practitioner teams *prepared* to engage in boundary crossing during instruction, we focused on the preparation portion of labs during which teachers and researchers prepared to go into classrooms to teach together. To analyze the preparation portion of these 24 labs, we used Akkerman & Bakker's (2011) coordination processes as our primary codes to better understand what researcher/practitioner teams did to prepare to engage in boundary crossing at the fourth wall of instruction. For each of the 24 labs, we identified the work that teams did to (1) build communicative connections between diverse participants, (2) engage in translation across researcher and practitioner communities, (3) enhance the permeability of the fourth wall, and (4) develop routines for boundary crossing during instruction.

Results

Our analysis revealed examples of how researcher/practitioner teams engaged four different coordination processes that allowed them to acknowledge, cross, and break the fourth wall during instruction.

Building communicative connections: Other work on coordination at the boundary within RPPs has focused on how research/practitioner teams have used boundary objects that are shared by multiple parties to allow for the exchange of information across communities of practice (Christiansen & Varnes, 2007; Landa, 2008). Unsurprisingly the four researcher/practitioner teams in our study also used boundary objects to build communicative connections across participants during instruction. The most important of these was the lesson plan. At each site, participants built the lesson plan together and at many sites they printed enough copies for every participant prior to entering classrooms together and on the plans took pains to note how they would be working together. These plans became touchstones for participants in moments when they worked together at the instructional fourth wall.

Engaging in translation: Additional important coordination work involved identifying where researchers and practitioners held different understandings and working to engage in collective sensemaking across divergent understandings. For example, at one site, teachers and researchers spent significant time investigating their conceptualizations of the concept of "comprehension," a concept that was central to their work in classrooms, but that held different meanings for practitioners than it did for researchers. This proactive translation work then allowed researchers and practitioners to communicate at the instructional fourth wall in ways that would not have been available to them before.

Enhancing the permeability of the Fourth Wall: Prior to entering classrooms together, researcher/practitioner teams did considerable work to acknowledge the instructional fourth wall and to make plans for how they might engage with it when they visited classrooms together. Some teams decided on questions that they would address together at the boundary of the fourth wall and other teams role-played what it might sound like to cooperate across the fourth wall during instruction. This preparatory work made it possible to come together during instruction to consider knotty questions about children's thinking and content complexities.

Developing routines: As in other work on coordination at the boundaries within researcher/practitioner team (Lutters & Akkerman, 2007), we found that developing routines for boundary crossing was instrumental in preparing researcher/practitioner teams for collaboration at the fourth wall. The development of Teacher Time Out (TTO) as a routine, one that had a standard structure, but was still malleable in-the-moment, offered participants a pathway into collaboration during instruction. In early labs, before participants had a vision of this routine, collaboration was much more difficult.

Conclusion

Our previous work (Ghousseini et al., 2022; Kavanagh et al., 2022) suggested that there are things to be learned in RPPs that are best learned in "the rush of minute-to-minute practice" and that cannot be learned elsewhere, but preparing to cross boundaries during instruction is complex work. The findings of this analysis offer important insights into how researcher/practitioner teams can build their capacity to collaborate together during instruction. Acknowledging, crossing, and breaking the instructional fourth wall for the purpose of teacher learning is not only counter cultural, but also risky in a variety of ways. Without careful coordination work in researcher/practitioner teams, the potential of this kind of work is not likely to be met. This research begins to offer illustrative examples of how researcher/practitioner teams have prepared to do this kind of instructional boundary crossing. We hope that these examples might illuminate pathways forward for even deeper work at the boundary of the instructional fourth wall.

Examining institutional settings for teacher learning

Lynsey Gibbons, Anne Garrison Wilhelm, & Latrice Marianno

We are scholars who are committed to working alongside teachers and principals to conduct research that is guided by the priorities of both groups. In our current research-practice partnership work with elementary schools, we aim to support teachers to orchestrate productive classroom talk that positions students as capable sense-makers and supports deep disciplinary learning (Michaels & O'Connor 2015) as well as support school leaders to attend to teachers' development. The goal of our current partnerships is to work alongside educators to organize structures within their schools that support regular engagement in collective professional inquiry (Little, 2002), investigating issues related to supporting children's learning through deepening their classroom discussion practices.

When developing a partnership aimed at supporting teacher development, it is important to understand teachers' interpretations and understandings of their work, while simultaneously treating those interpretations and understandings as situated in and at least partially constituted by the institutional settings in which they work (Cobb et al., 2003). Individual's actions are shaped by but also produce, reinforce, and change the structural conditions in which individuals interact (Feldman & Orlikowski, 2011). We have proposed a theoretically-grounded approach for getting to know partner educators and the contexts in which their work is situated (Gibbons et al., 2022): (1) the broader backdrop – including local, state, national policies, and current events – within which each of the partner schools is situated; (2) existing supports and structures (as designed and enacted) that educators experience routinely; (3) teachers and school leaders' current expectations and the extent to which there is coherence between and among supports and expectations; and (4) the everyday practices of educators as they carry out their work. In this paper, we describe a comparative case study involving two elementary schools as we began partnering with them. We sought to understand what we learned about the educators and the settings in which they worked that informed the design of research and professional learning that was responsive to their current lived experiences and needs.

Context, data collection and analysis

This study is part of a larger project focused on understanding how elementary school teachers learn to facilitate classroom discussions. We partnered with two elementary schools in two neighboring districts to support teachers and school leaders to engage in a set of job-embedded, collective inquiry experiences using the Learning Labs (LL) structure (Kazemi et al., 2018). For this study, we leveraged data from interactions with teachers (14 at School A, and 9 at School B) and school leaders (2 at School A, and 2 at School B) that took place before the LLs commenced. Individual interviews with teachers (lasting 45-60 minutes) included questions regarding their' perceptions of classroom discussions, existing structures for collaboration, past professional learning supports, and expectations from leaders. Individual interviews with school leaders focused on their goals for learning and teaching, conceptions of teacher learning, instructional leadership, and district expectations. Researchers also attended 1-2 weekly grade-level team meetings to learn about teachers' interests and challenges. With information gathered from the educators, the team met to plan LLs and identify goals for teacher learning based on our understanding of teachers' needs. We continued to learn about the teachers and school leaders as we engaged in the LLs. Each LL was video-recorded and teachers completed exit tickets about their experience.

To understand the educators and institutional settings in our partnership schools, we analyzed the interviews, LL videos, and exit tickets using codes built around the categories that allowed us to attend to both educators' institutional setting and everyday actions: (1) the broader contexts, (2) existing supports and structures, (3) teachers and school leaders' current expectations, and (4) the everyday practices of educators as they carried out their daily work. In our coding, we were open to other emergent themes (Saldaña, 2016). Coding was conducted by teams of two; subsequently, we met to engage in consensus conversations.

Findings

We examined the two schools constituting this comparative case study to explain how the institutional settings were more or less conducive to supporting teachers' development in order to inform our work as partners when designing and researching teachers' professional learning. In this presentation, we highlight the findings most salient to uncovering aspects of the institutional setting that supported or hindered teacher professional learning.

Partnerships with both schools happened amidst the Covid-19 pandemic, a situational factor that had many implications, including curricula, availability of substitutes to free teachers for collaboration, and teachers and school leaders' wellbeing and health. Differences existed between the schools with regards to the alignment between the instructional program and leader expectations. In School A teachers were expected to continue to use an online mathematics curriculum that was carried over from when learning was offered online in the 2020-21 school year, which was tied to their evaluation. Additionally, how much time teachers were to spend on which instructional activities was prescribed by the district. The online curriculum and instructional block did not supply opportunities for teachers to engage in classroom discussions with students. In contrast, in School B, the mathematics curriculum had embedded opportunities for classroom discussions, as well as a district expectation that teachers would use a "ten minute" instructional routine that included discussion everyday. For both schools, embedded in each curriculum was an assumption about what the work of teaching is and the extent to which teachers are to be responsive to students' current understandings. These assumptions had implications for how we considered beginning our work to support classroom discussions.

Histories of professional learning, as well as orientations toward the improvement of instructional practice differed between the two schools. Teachers at School A had been offered little professional learning opportunities that focused on classroom discussion or that positioned students as sensemakers. Previously School A had been involved in a university-based research experience that emphasized fidelity to the curriculum in teaching. There was variation among teachers' perceptions of autonomy in their classrooms: Some felt they had more freedom to make instructional changes than others who felt like they had to adhere to the district's specified instructional block and curriculum. Thus, in establishing our relationship with them, we had to support some School A teachers in understanding that our partnership with them involved experimenting and exploring new instructional practices to see how students responded, as well as innovating past instructional practices. In School B, there was a richer history of engaging in collective inquiry and experimentation with practice as a means to improve instruction. This history served as a strong foundation for the professional learning collaboration.

Conclusions

We found that attending to aspects of the institutional setting (such as curriculum materials, histories with professional learning, teacher evaluation systems) as well as the degree to which teachers feel a sense of autonomy to make decisions about their teaching had implications for the extent to which they were willing to learn about and experiment with new instructional practices related to facilitating classroom discussions. Future analyses will examine how what we found in each school context informed decisions we made as researchers and professional learning designers to be responsive to their needs.

Challenges and opportunities within RPPs: A tale of two departments in one district

Mee Na Feng, Susan R. Goldman, Mon-Lin Monica Ko, & Allison H. Hall

This paper presents a case study involving two departments embedded in one high school district in the midwestern United States. The research team and the district collaborated to establish a research practice partnership (RPP; Coburn & Penuel, 2016) focused on enhancing classroom discussion to further disciplinary learning in (1) science, and (2) literary reasoning. The interests of the research team were on teacher learning processes as these were manifest through collaborative efforts of the partnership to deepen students' disciplinary practices and reasoning. Especially with inquiry-oriented instruction, teachers need to flexibly apply their knowledge in the dynamic context of the classroom while not compromising on underlying principles and practices central to the discipline in which inquiry occurs (Bereiter, 2014; Brown & Campione, 1994; Darling-Hammond & Bransford, 2005; Zech et al., 2000). At the same time, teachers operate within complex ecosystems: classrooms are embedded in departments, departments in schools within districts located in communities within larger geographical regions, states, and countries (e.g., Bronfenbrenner, 1994; Cohen et al, 1993). All levels of the system impact and are impacted by other levels in the system. Thus, teacher learning is contextualized and situated within particular local and national contexts that impact opportunities for their learning as well as whether their learning is realized in practice in their classrooms.

In the case of high schools, department organization and culture play a significant role in shaping teacher practices, learning, and collaboration (Fullan, 1994; McLaughlin & Talbert, 1993/2006; Siskin, 1991). This suggests that department-level support is important for enacting RPP work. This paper explores how a partnership with a high school played out in the Science and English departments, each with its own values and culture manifest in curriculum decisions and degree of teacher autonomy with respect to instructional choices. The research study investigates (1) the processes by which the partnership evolved – how they were similar and different between the two departments, and (2) what the implications were for teacher learning processes and trajectories with respect to deepening students' disciplinary practice and engagement.

Methods

The district partner for this work was identified via initial contact with the Curriculum Director of this small suburban high school district near a large midwestern city. The Curriculum Director was familiar with the prior work of the research team wherein inquiry-oriented instruction in literary reading, science, and history and teacher professional learning opportunities had been successfully developed and implemented (Goldman, et al., 2019; Goldman, 2018). The Curriculum Director indicated that an RPP focused on promoting classroom discussion was a good fit with the district's direction.

Data sources include transcripts of meetings among the research team and the district partners (curriculum director, department chairs, instructional coaches), field notes and transcripts of researcher-teacher design collaboration meetings, as well as analytic memos written over the 3 - year period from July 2019 – July 2022. Independently, the researchers engaged in repeated readings of these data sources to develop descriptive accounts of (1) the district-level partnership work around shared goals and (2) research-teacher design collaboration trajectories within each discipline. Researchers met to develop consensus accounts, reviewing relevant data sources in the case of disparities in the accounts (Saldaña, 2016).

Findings

Shared goals were established at an early face-to-face meeting in which each department chair agreed that the research focus on teachers' learning to engage students in disciplinary practices through discussion and other means was consistent with the culture and values of their respective departments. At this meeting, the curriculum director endorsed these goals as consistent with the four conditions of learning that had been adopted by the district: (1) independent reading of complex disciplinary resources; (2) composition of original thought; (3) construction of evidence-based arguments and explanations; and (4) discussion used to problem pose, process, reflect, and solve disciplinary problems. These conditions of learning were intended to achieve three broad district aims: (1) create confident problem solvers through relevant and authentic texts, (2) provide post-secondary pathways for students, and (3) work toward equity and justice.

The working plan coming out of that meeting was researcher-teacher collaborations with two science and two English teacher volunteers, for purposes of exploring the supports teachers in each discipline/department needed to foster deepening disciplinary thinking and reasoning practices. The dyads started from their current practices (materials, tasks, and instructional strategies) and worked collaboratively to enhance these to support students in the disciplinary work. Subsequently and based on those small-scale partnerships, the RPP intended to to expand in each department, with the assistance of the district instructional coaches.

The work in science was focused on instruction aligned with Next Generation Science Standards (NGSS) as a vehicle for remodeling the science curriculum per the district remodeling initiative. A member of the research team proceeded to collaboratively work with two biological sciences teachers on an NGSS-aligned unit that they would implement. As that work proceeded, the department head raised questions with the teachers and then with the research team and curriculum director regarding how the unit that was being designed would fit into the course and content sequence within the department (e.g., Honors Biology -> AP Biology). This revealed an inherent tension between the agreed upon partnership goals and the culture, values, and curriculum in place in the science department. The value placed on content and content sequencing relative to that placed on the three-dimensional

NGSS approach was particularly evident in the science department's response to the pandemic: The teachers collaborated to produce one online set of materials (lectures, texts, activities) for each course in the department and abandoned any effort to encourage student interaction and talk. Ultimately the lack of alignment with the RPP goals led to abandoning the NGSS design work and further science department participation in the RPP.

Unlike the science department, the English department provided more latitude for individual teachers with respect to unit design. Rather than specific books or content that had to be covered so that students were "ready" for the next course, the emphasis was on deepening the use and recognition of literary practices (rhetorical devices, figurative language, themes) with increasingly complex texts. The choice of specific texts and practices was left to individual or grade level groups of teachers to decide. Thus, in the design work, the researcher and two teachers in literature focused on choosing texts and designing tasks that opened up opportunities for interpretive discussions that followed conventions of literary reasoning practices. The value placed on student interaction that fostered literary thinking was evident in how the English department responded to the pandemic. Teachers continued to attempt to foster student discussion and engagement with each other through online collaborative tools, experimenting with a variety of different applications purchased by the district and available to all departments. For example, students interacted through text chats and posts to flipgrid, jamboards, and other communication software. Post-pandemic enthusiasm in the English department and among the district instructional coaches was high for expanding the partnership through researcher-coach collaborative work on professional learning opportunities for additional English teachers and to additional disciplines.

Discussion

The analyses of the RPP meetings elucidate the opportunities and challenges that arose in the work within the two departments and the resultant disparate outcomes. That the partnership work was abandoned in the Science department whereas a productive and ongoing relationship evolved with the English department illustrates that all levels of the multiple contexts in which teachers are embedded play critical roles in determining the trajectory of partnership work. Although both departments were operating within the same district mandates regarding objectives and conditions of learning, the course sequence and content structure of the science department was in tension with the process the partnership attempted to enact to achieve the shared goal around disciplinary discussion as a vehicle for deepening disciplinary learning. In contrast, the affordances within the English department provided space for the researcher-teacher collaborative work to develop in ways that led to a commitment of the district to expand the partnership to include the instructional coaches and additional English teachers. This RPP work highlights the criticality of context at multiple levels (research team, district, department) in working to develop shared goals. Consistent with prior work examining instructional improvement in high schools (e.g., McLaughlin & Talbert, 1993; Siskin, 1991), RPP infrastructuring work at the department level surfaced as critical to the success of partnerships as a context for teacher learning.

Measuring the impact of research-practice partnerships: Lessons from the CASPIR math project

Alison Castro Superfine & Benjamin Superfine

Research-practice partnerships (RPPs) are an efficacious and increasingly common approach for educational improvement (Coburn et al., 2021). While there are various forms of RPP approaches, they generally engage researchers and practitioners in long-term, joint work that involves a diversity of expertise around local problems of practice and promote evidence-based inquiry into how such problems might be addressed through the identification and application of relevant evidence (Penuel et al., 2011). As such, RPPs can also be a productive approach for developing the capacities of RPP participants and the organizations in which they are situated if they are strategically and deliberately designed with this goal in mind (Fishman et al., 2013; Kali et al., 2018). However, RPPs do not simply work as intended "out of the box," as sometimes envisioned by researchers. They develop over time and across various stages and require different types of individual and organizational learning as they progress through such stages. Preliminary or initial developmental stages, in particular, have a significant impact on the life of partnerships (e.g., Law & Liang, 2019). Moreover, RPPs generally addressing the same challenge (e.g., mathematics teaching and learning in an elementary school district) may focus on different local problems of practice, given their unique contexts. As such, the focus of improvement work in even similarly oriented and designed RPPs can differ across time and place, creating challenges for both the improvement work of RPPs and research on RPPs. Indeed, despite their growth and visibility in education, there remains a significant gap in our understanding of how to measure the impact of RPPs over time. Current research on RPP effectiveness focuses primarily on the presence or absence of certain principles and features (e.g., Henrick et al., 2017), and not on tracing developmental changes across time and setting.

In this paper, drawing on data from several, multi-year RPPs with elementary school districts, we discuss two challenges associated with studying the impact of RPPs: (1) measuring qualitative changes in RPP participants' understandings of the joint work over time, and (2) measuring and comparing "progress" on different problems of practice across different settings. As part of the Collaborating Around Structures, Processes and Instructional Routines in Math (CASPIR Math) Project, university researchers and professional developers formed RPPs with four school districts. The goals of CASPIR are to co-develop and co-implement a multi-component professional development intervention designed to improve teachers', teacher leaders', and administrators' understanding of effective math teaching and learning, and to enhance the organizational capacities of schools and districts to support such instructional improvements in math. CASPIR employs a design-based implementation research (DBIR) process involving collaboration between researchers, professional developers, and district and school personnel. As such, improvement in math teaching and learning is to be directly responsive to local problems of practice specific to the school districts and identified by RPP participants in each district. In the cases of both districts, district math leadership teams (DMLTs), in collaboration with the university team, constitute the organizational unit responsible for identifying the problems of practice and where the project's efforts at developing structures and processes for ongoing RPP work were focused.

Theoretical background

CASPIR is grounded in a DBIR approach to improving math teaching and learning. DBIR is an expansion of design research to develop and test innovations and supports for improving teaching and learning. There are four key features of a DBIR approach: (1) focusing on user-centric problems of practice, (2) iterative, collaborative design, (3) developing a theory of improvement through systematic inquiry, and (4) developing capacity for sustaining change in systems (Penuel et al., 2011). Such an approach recognizes that "achieving successful change in complex work systems means recognizing that one cannot predict ahead of time all of the details that need to be worked through nor the negative consequences that might ensue" (Bryk et al., 2015, p. 7). Moreover, RPPs, such as the partnership between districts and the university team in the Project, are directly aimed at learning to do such work not simply from an individual perspective but also an organizational one. Indeed, the development of organizational capacities, such as routines and processes, shared insights and understandings, and information processing abilities, are foundational elements for building organizations that can effectively engage in DBIR (Basten & Haamann, 2018). Accordingly, a DBIR approach to RPPs requires that participants adapt their work to the specific problems at hand and the ways in which they change over time, simultaneously attending to organizational processes, structures, and routines that are aimed at promoting improvement.

Challenges of measuring RPP impact

Although the Project focuses on math instructional improvement in elementary school districts, the problems of practice identified by each of the four RPPs were different. For example, given its local challenges, one RPP broadly identified the selection and implementation of cognitively demanding math tasks as an area of improvement, while another RPP focused more narrowly on the teaching and learning of number sense. Particularly in the early stages of RPP development, it is highly unlikely that any improvement work would impact a range of student and teacher outcomes. The initial RPP work focused on instituting the processes, structures, and routines for the DMLTs so that the participants could identify problems and develop strategies to address them. Once the RPPs began to develop and implement strategies (e.g., professional development for teachers around cognitively demanding math tasks), improvement would likely be measurable only in the areas in which the strategies were implemented. Because improvement strategies and focal areas were not the same across RPPs, comparing the progress of RPPs became a significant challenge. To unpack this challenge, we drew on a range of data sources, including teacher knowledge assessments, classroom observations, and student achievement data. Nevertheless, we encountered difficulties comparing the impact of the RPPS across the different settings.

The Project also highlighted a challenge in measuring RPP impact on participants' understanding of the joint work over time. For example, in each RPP, members of the DMLTs met monthly across two years and engaged in inquiry cycles centered on a unique problem of practice. The DMLTs are comprised of teachers, school and district administrators, working alongside each other in ways that disrupted the usual power dynamics between teachers and administrators (DeVoto et al., forthcoming). For the teacher participants, in particular, engaging in continuous improvement work at the district level is work for which they are not professionally prepared. Consequently, the nature of the joint work and participants' understandings emerged and changed over time in ways the research team found challenging to anticipate. As the beginning phases of the joint work focused on building routines and processes within the DMLTs, the qualitative analyses focused on the establishment of such routines and processes, and participants' initial understandings of the joint work. Over time, it became challenging to re-conceptualize the initial qualitative codes in ways that were both grounded in the data and sensitive to future development. This was particularly challenging because the research team could not perfectly anticipate future development of the RPPs, nor did the extant research on RPP effectiveness offer applicable guidance. To unpack this challenge, this paper draws on a range of data sources, including individual interviews, surveys, DMLT meeting transcripts, field notes and DMLT meeting artifacts. We show the challenge of using such data sources to measure the impact of the RPPs on participants' understanding of the joint work over time.

Abstract: This symposium presents an exploration of how three different out-of-school-time (OST) or informal learning contexts shape both the nature of learning opportunities and also potential future learning trajectories for the youth engaged in these OST activities. A goal of the symposium is to highlight both divergence and congruence across OST settings, highlighting the spectrum of learning opportunities and perspectives on learning across different contexts. Discussants will critique the work against the larger universe of OST/informal learning study in the Learning Sciences and invite the community to engage with this work towards developing common ways to describe learning in OST contexts.

Symposium overview

Learning happens everywhere. Though much scholarship on learning focuses on formal or school-based settings, the Learning Sciences has long championed work on learning in out-of-school time or informal settings as well (e.g., Crowley et al., 2014; Halverson & Peppler, 2018; Lyons, 2018). This symposium explores learning in three different and divergent out-of-school time (OST) providers in order to highlight how purpose and context lead to different types of learning, and in turn how those differences can shape future learning opportunities. Such an exploration is important for several reasons. First, though there has been much excellent work focused on the design of OST activities, there has been less attention paid to documenting OST learning (Tai et al., 2021). Such documentation can be useful not only for learner use in future aspirations, but also for OST providers in making a case for their impact and for securing ongoing funding. Second, a better understanding of the learning within OST contexts and how that learning is valued by youth and families allows providers to tune their offerings to better serve their intended audiences. And finally, understanding and documenting learning in OST settings can help elevate its role in accessing future learning opportunities.

In this symposium, we aim to both clarify and problematize different aspects of OST learning. The symposium presentations strive to highlight tensions inherent in this work, including how to include a focus on assessment in informal learning without inadvertently “formalizing” it, how to create systems that sustain learning and development, and how to balance sometimes conflicting stakeholder values. Another way to consider this is to ask who “owns” learning, school or individuals/communities (Fishman & Herrenkohl, 2022)? Attempts to formalize learning tend to cast it in a school-based frame, whereas valuable learning often does not fit into formal frameworks or structures.

The three OST contexts represented in this symposium are all partners in the Mastery in Out-of-School-Time Learning, or MOST project, a study exploring the potential for documenting OST learning for future use in college admissions, job seeking, or simply further OST learning. The OST providers were purposefully selected for their differences. One is a university-sponsored college preparatory program designed to enrich learning for high school students in a particular region and prepare them for success in higher education. Another is a middle-grades coding program designed to enhance learner self-concept around computing. The third is a community-based program for mixed income, refugee and immigrant youth. To study learning opportunities in each of these OST contexts, researchers conducted interviews and focus groups with youth and families engaged in the activities, and with the providers of the OST activities. The interviews and focus groups were transcribed and coded qualitatively to identify learning opportunities and other themes related to values, engagement, and similar topics. As part of this same project, researchers are also conducting qualitative interviews with college admissions personnel, with the ultimate aim of developing a transcript-like representation of learning that could play a role in the college admissions process. This symposium will not present findings from the college admissions perspective, though individual presentations will reference this work.

The symposium will open with presentations about the types of learning opportunities observed in each OST context, with cross-cutting discussion highlighting differences and how these differences are related to how we might report on learning in ways that are both valued by learners and which might be recognized by others seeking to evaluate readiness for future learning or work. After the three presentations, featured discussants representing a range of expertise in the study of OST learning will present commentary and critique, and then the conversation will be opened to all. This symposium is a space for interrogating a spectrum of informal learning contexts to consider how activities that differ along that spectrum are framed and understood by different groups, including potential consumers of information about youth OST learning. Our hope is that this symposium advances the field’s thinking about how to frame and study learning in OST settings.

Wolverine pathways: OST learning as preparation for college success

Lo Lee, Denise Jones, CaVar Reid, Steve Cederquist, Xingjian Gu, Barry Fishman, & Leslie Rupert Herrenkohl

Wolverine Pathways (WP) is a supplementary pre-collegiate program that provides free college preparatory enrichment and advanced academic programming for 7th through 12th grade students in Detroit, Ypsilanti, Southfield, and Grand Rapids, Michigan. WP works to confront the barriers that limit the college and career aspirations of highly motivated students from under-resourced communities in Michigan, believing that every student deserves the opportunity to pursue a wide range of professional and academic pathways. Since its inception in 2016, Wolverine Pathways has served over 1,100 students in southeastern Michigan, has awarded over 200 full-tuition scholarships for the University of Michigan, and boasts an overall 90% matriculation rate to competitive four-year institutions for its scholars. The student body of WP is racially, ethnically, and socio-economically diverse, with over 80% being Black/African American and Latinx/Hispanic, and nearly 50% requiring free or reduced lunch. Additionally, over 30% of WP alumni are first-generation college students.

Youth involved in WP experience rigorous advanced coursework, success coaching, and individualized tutoring that sets them up for early college success. They explore career opportunities through internships, career days, and informational interviews with WP corporate partners, such as an automotive company and an IT organization. Participants have opportunities to explore the UM campus and take a summer course from UM faculty. They also gain a network of mentors, professionals, and peers who offer support and guidance on their academic journey.

Through the first round of conversations, we interviewed 24 youths and 10 WP alumni (current undergraduates). All interviews were audio recorded upon agreement and transcribed for later analysis. Following the qualitative content analysis technique (Hsieh & Shannon, 2005) and social moderation process (Frederiksen et al., 1998; Herrenkohl & Cornelius, 2013), we open-coded each document and created codes inductively. Each data source, including verbatim transcripts and interpretable content logs, was coded at least twice using qualitative data analysis software, Dedoose. When one document was finished with coding by two coders, the first and second coders would meet to discuss discrepancies in code applications and excerpts, reach a consensus, or agree to disagree. We also created memos throughout data analysis to record thoughts that may serve to inspire insight in later analysis.

Based on our data, we report four preliminary themes that illustrate how youth engaged in OST STEM learning. First, overall, youth found their participation in WP helpful in seeking college admission, exploring career interests, and gaining real-world experiences. One interesting point shown in the interviews is that although youth may not be willing to join the program at the very beginning when their parents asked them, they still regularly returned to WP because they would like to see and hang out with their friends there. Some youth were also aware of the benefits brought by WP regarding college preparation. For example, Melanie, a senior in high school who has participated in WP since the sixth grade, explained why she chose to stay in WP for years:

> Many of my friends dropped out of Wolverine Pathways around seventh or eighth grade, in one or two years. But I stuck around because I genuinely saw the potential in it. [...] I was fortunate enough not to have sports or anything to do. Plus, even people who didn't have sports just really weren’t committed. I was committed because I honestly valued it enough to keep sticking to

> going because I liked it too. I got to be around my friends, and it was college readiness and all of the opportunities and benefits that come along with it. That's why I stuck around. (Melanie)

Second, other than being aware of the future, youth in WP also displayed a keen awareness of the world around them. This is especially true when youth expressed how they were able to connect OST learning to their everyday life and attach meaning to the learning experience. Relatedly, they touched on the value of sharing when they stated how they got chances to showcase their learning outcomes in a wide variety of settings and with different people. For instance, Tanya, a high school student, elaborated on how she seized opportunities to share what she learned both in formal schooling and outside of classes:

> I'm a big supporter of connecting different assets in my life together. In school, if I learned something from Wolverine Pathways, and it applies to what I'm learning in class, I'll definitely raise my hand and talk about it, like the math stuff we learned. I'll even spout out random facts to my friends sometimes. [...] In Wolverine Pathways, we used to have an academic showcase at the end of every session where all of the scholars would come together and do a little group-project, final-project-type thing and present what they learned in the course for the entire session. I remember when I did in the pharmacology lab [...] at the end of the session, we came back with this giant poster board with all the stuff we learned and all the processes we did [...] The final presentation was a really great way for us to look back and see how much we actually learned. (Tanya)

The third theme we identified revolves around transferable skills that youth developed after joining WP courses. In particular, many youth brought up information and financial literacy and interpreted them as essential skills when asked about what they learned and found helpful in WP. By attending relevant classes in WP, youth developed practical knowledge on how to evaluate the credibility of information sources and realized they could begin managing their finances before college. This point and the mentioned two skills reflect the role of transferability in OST learning by which youth could apply what they acquired to various contexts beyond schooling. Tiffany and Lydia, both high school students who took part in WP for years, highlighted the breadth of WP programming and how it helped them grow:

> I feel the things I get in Wolverine Pathways I wasn't getting in my regular academic regime - like the classes they were offering. I got financial literacy when I was in 6th grade. You don't even get econ until you are a freshman in high school. (Tiffany)

> Wolverine Pathways really holds you accountable for your whole journey, like a big picture of where you want to be and what your values are. Like, they want you to go to them and get into U of M, but they're also like, "what do you want to do in life?" And like, "how do you get there?" And other soft skills like networking, researching topics online or fact-checking the news. So it really is a well-rounded resource base for you to discover ways to be a good person and be a competent student going into college. (Lydia)

The last theme we recognized, which can be considered an extension of our first theme on the significance of peers for youth, is the value youth placed on in-person learning in an OST setting. To youth participating in WP, their continual physical interaction with peers is a crucial factor leading to their profound engagement in OST learning. Accordingly, the lack of bodily interaction resulting from COVID, mainly causing the change from physical to remote learning, was regarded as unfavorable to a lot of youth. Melanie gave a great illustration of how she treated WP as a big family:

> Before the pandemic, it was a very family-oriented vibe because we saw each other in person every day. It was very much giving family in Wolverine Pathways because we had songs; we sang, like we had the good morning song, we had different songs. So I feel relationships, friends, and new friends I made were very valuable at Wolverine Pathways. (Melanie)

Furthermore, the disadvantage of remote learning is also mentioned by some parents who highly suggested WP add more physical events to increase face-to-face interaction between students. For instance, Wayne, a father whose two daughters are both parts of WP, noted that it would be "neat" if WP could "somehow facilitate a monthly potluck dinner in one of the dorms or something for the WP kids" that attended U of M.

Wayne explained that this was especially true for those who went through WP virtually due to COVID because in-person gatherings would benefit youth to have some camaraderie and support during their first year of college.

Based on the preliminary themes above, we identified an emerging tension in documenting OST STEM learning. As shown by youth, what they learned through participating in WP is often unquantifiable. For instance, Melanie illustrated why she decided to be part of WP for many years, whereas she saw some of her friends dropping out. Here, we are able to recognize her perseverance and awareness of the benefit of OST learning as a way to prepare her for the future. In the case of Tanya, she expressed how she was capable of building connections between what she learned and, if applicable, knowing when to demonstrate her learning to people. We find this showcasing skill crucial in youth’s learning experiences in WP, though it may be difficult to appropriately capture in the current documentation system for college admission. Apart from Melanie and Tanya, the information and financial literacy skills described by Tiffany, which are also commonly shared by other youth, are critical abilities to be applied in everyday life. Nonetheless, since such non-academic skills are usually hard to assess using numerical data or a quantitative approach (Stasz, 2001), it can be a potential challenge to overcome in the documentation. In other words, how may we foreground the processual aspect of OST learning by treating it as multidimensional rather than one-dimensional to demonstrate its qualitative and interpretable value?

“The spaces and places she’s in”: Digital divas and the work of families forging a youth STEM identity

Nichole Pinkard, Yolanda Majors, & Alex Samuelson

Evanston, Illinois, a community with about 35% of its public-school students qualifying for free or reduced-price lunch and almost 60% of its public school students identified as students of color (Illinois State Board of Education, 2020a, 2020b), has long been perceived as one of the wealthiest school districts in the nation. However, over the last several years, Evanston has garnered national attention for its large racial and socioeconomic achievement gaps (Rich et al., 2016) and its attempts to alleviate the systemic inequities that generate them (Belkin & Hawkins, 2020). While often discussed concerning the past, the impact of historical fiscal and policy decisions continues to mediate the daily lives of Black Evanston families, particularly those living in the historically Black 5th Ward, who have borne the brunt of the infrastructural changes used to integrate Evanston's schools without integrating its neighborhoods. Consequently, 5th Ward families have had to exert more effort than other Evanstonians to access everyday learning activities from their home addresses, such as walking to school, going to the library, getting to and from sports or music practice after school, and talking about school with neighbors.

5th Ward families, in particular youth, have persistently been underrepresented in STEM programs and STEM-related careers partly because of educational and cultural norms and lenses that have led to *de facto* exclusion based on race, ethnicity, and class. For 5th Ward youth, such exclusion has led to limited access to Evanston’s “participatory culture” (Jenkins, et.al., 2009), where membership cultivates one’s willingness to engage in collaborative, STEM-related work, knowledge of how to manage information, self-direction of one’s learning, meaningful interaction with valuable tools, and the building of collective intelligence (ref. DYN). Long-term STEM-culture participation requires parents to discover their community’s STEM opportunity landscape and motivate their youth to participate in programming where they are most likely the minority (especially as kids get older). Often this results in ‘joining’ a program and entrusting their children’s STEM learning journey to that organization.

This presentation considers *how and why 5th Ward families (decision makers) understand and choose to participate in one Evanston STEM OST space, Digital Divas, as a learning opportunity for their children, specifically their middle-school-aged daughters*. Digital Divas is an OST program located in Evanston that engages middle school girls, especially those from non-dominant communities, in design-based engineering and computer science activities driven by a narrative story. The program supports girls to develop STEM identities by participating in face-to-face and online spaces to design, create, and re-imagine everyday artifacts (jewelry, hair accessories, music) and activities (dancing and talking to friends) using collaboration techniques critique, circuitry, coding, and fabrication. Since 2013, over 300 girls have participated in core Digital Youth Divas in Chicago. Middle school girls involved in Digital Divas have demonstrated increased domain-specific content knowledge and development of initial interest in STEM.

We draw on data from three focus group interviews: one group of 6 Digital Divas, one group of 6 Parents, and one group of 3 program facilitators. In addition to insights into the STEM-based problem-solving capacities of Divas’, our analysis spotlights several themes corresponding to the role of families in developing STEM-related identities, values, understandings, and engagement. One of these is “youth exposure vs. “youth opportunity.” We characterize OST “exposure” to STEM as having fixed boundaries of time and space, where youth can experience a baseline introduction to general STEM skill sets, such as coding and 3D building and printing. Findings from family interviews indicate that while much of Evanston's OST STEM programming does a "phenomenal job" of exposing their child to activities grounded in STEM, such exposure is insufficient:

> "There's a big component of the whole child. It's like, how can we include some other skills… You know? How do we bring in the leadership? How do we include life skills? And then how do we also get out of the exposure and go more into the opportunity"

Across each focus group, a tension emerged: "how do we turn exposure" of STEM skill development "into real opportunity" pathways that further specific development of skills.

Drawing on Jenkins and colleagues' (2009) idea of participatory culture, we characterize OST "opportunities" as participatory engagement across time, place and space where youth expand their knowledge as they move across spatial borders and boundaries, engage and expand upon pre-existing knowledge around something shared and valued, decode it in some way and make new meanings around it. Opportunity spaces, therefore, are youth-serving OSTs that provide practitioners, youth, and families with STEAM (science, technology, engineering, arts, and math) related engagement opportunities that are geographically available, socially equitable, youth access, and at the right learning level (Pinkard et al. 2020).

A second theme to have emerged was parents' emphasis on Divas' gendered identity development as a critical determinant of their child's involvement in programming opportunities throughout Evanston:

> It's not easy to be a Black girl… It's the idea of identity and figuring out who she is in the space that she's in and being comfortable in all the different spaces that she's in.

For parents of Divas, positive identity, interests, and social skill development were greatly desired core outcomes of their child's engagement in STEM inquiry, engineering processes and other associative learning opportunities presented through their involvement:

> What's most important is developing their love for science and different STEM identities in spaces where they can be who they are.
>
> They are learning the scientific method, definitely learning this engineering design process, but they also learn how to create, how to bring their identity into the things that they do.

Fundamental to all points along a STEM opportunity pathway is the human capacity for curiosity –the desire to engage, to develop and extend knowledge and do what is meaningful beyond life's challenges, what is immediately accessible, evident, or within current practice. We argue that this desire for learning through participation in identity-affirming activities motivates Divas' families to prioritize programming that reaffirms black girl identity even over STEM programming, especially if the programming is in non-familiar spaces. resources in exploring what one can learn by seeing, thinking, and doing. Due to the historical disinvestment in the 5th Ward as described in the opening, Divas families, whose aspirations of a more equitable future for their daughters are predicated on reimagining the locations, allocation, and use of the resources they steward to create a more equitable learning ecosystem. We imagine that this more equitable learning ecosystem would be unapologetically tuned to facilitate the ability of Black families to seamlessly navigate and engage in Evanston's full spectrum of learning resources to support the intellectual, physical, social, and emotional growth and development of Black youth, toward their fullest potential.

STUDIO: Designing OST STEM opportunities across stakeholder desires

Jiyoung Lee, Katie Headrick Taylor, & Leslie Herrenkohl

"Culturally relevant learning" often describes the design ethic of OST STEM contexts (Moore et al., 2022). However, without essentializing participants' cultures, ignoring intersectionality as an individual reality (e.g., Cabado et al., 2013; Gutiérrez & Rogoff, 2003), and considering the cultural heterogeneity of urban neighborhoods (and the young people that live there, Iloh, 2018), designing for cultural relevance can generate tensions between co-designers, stakeholders, and participants of different ages and perceived roles (e.g., Worker & Ching, 2016). In an OST neighborhood-based STEM program called STUDIO, young participants from Immigrant and/or refugee families (from across the globe), and their caregivers, described different, sometimes contradictory values and purposes for OST STEM programming. Young people valued joyful modes of STEM engagement too often obsolete in schools; several caregivers viewed *joyful STEM* as ancillary to programming that supports in-school achievement. These differing priorities from young people and their caregivers, as well as from funders and evaluators, create a tenuous design space for OST STEM educators.

STUDIO program context

STUDIO is a research-practice partnership between the University of Washington (UW) and a family-serving organization situated within a HOPE VI housing development in a Pacific Northwest city. Youth in STUDIO are all youth of color from diverse cultural and ethnic backgrounds. Most youth are from South East Asian (13%), and East African (42%) countries of origin and identify as belonging to immigrant and/or refugee families. African American youth living in the area also participate in STUDIO. Our partnership includes organization staff, and university faculty, graduate, and undergraduate students working together to design, research, and facilitate project-based STEM curricula. Youth attend STUDIO sessions twice a week at organization facilities but also use the facility with families for other purposes (e.g. game night, community events) (Please see Herrenkohl et al., 2019 for more program details). Findings for this session come from a total of 15 interviews (4 undergraduate mentors, 5 facilitators, 4 youth, 2 parents), transcripts of which we open-coded. Coders at UW and UM met regularly to discuss common and site-distinctive codes across WP and STUDIO.

The purpose of STUDIO

Interviews revealed that adult caregivers and youth have differing desires and purposes for OST STEM programming; organization staff who especially bear the largest burden of recruiting youth participants (with adult caregiver consent), do their work within and across these differences. Adult caregivers often viewed STUDIO as a supplemental program to school, and valued it as a place where their children can get STEM homework help, or experiences that would position them to succeed in schools and future jobs. Youth valued STUDIO because it provided different social and STEM learning opportunities from school. Hiroshi, one of the longest serving staff members in STUDIO with deep ties with residents in the community, clearly identified tension:

> Parents want youth to participate in opportunities in whatever way that the parents believe will provide them an advantage in applications or scholarships, careers or for schools of secondary education for their youth. For youth, it is often around more soft skills, social navigation or life skills. And, it is often around exploring new opportunities that they normally would not be able to explore in school… Being able to provide those opportunities is definitely a balance, because we want to honor the parents' goals and values as well, but also really want to see the youth for what they are and their own goals for success as well.

A parent of a STUDIO participant expressed this priority (identified by Hiroshi above) in her own words, saying, "STEM is the future; children are going to use STEM [knowledge] in the future, and it will help them to have better education, and a better future." Hiroshi also shared that parents often approached him with requests to provide more homework help, and tutoring sessions within STUDIO time so that the youth can get support in subjects like math and science in school.

On the other hand, when youth were asked to share what they got out of STUDIO, most youth talked about learning within a community where they felt safe to develop their social skills, and "do cool things" with great company. Hiroshi extrapolated that youth want to learn about "life skills and soft skills" because they are anxious about going to college as first generation prospective students. As children of new immigrants in the United States, youth often wondered whether college was the right fit for them, and craved opportunities to explore other interests related to STEM but often separated or obsolete in schools (e.g., computer science, arts-based engineering). STUDIO was one of the places youth experienced as providing opportunities to express their creativity. Youth reported that they "got to go outside the boundaries, and [do] fun things that they wouldn't typically do in school," and were also able to "grow as a community with friends and mentors who encouraged " their ideas and, "always welcomed them." Hiroshi described an example of how an activity in STUDIO might differ from school:

> While there may be opportunities in schools to do cooking as an elective class or as a club, sometimes there's not enough capacity for those classes or clubs or it's around recipes that the youth are not interested in. Youth have more voice, and choice in what they can or want to explore in our program than they may be able to at school.

An example of culturally intersectional STEM programming in STUDIO

In this exchange, Hiroshi is referring to STUDIO's online cooking program called World through Food (designed primarily by Jiyoung Lee). This program models for young people that STEM learning (and teaching) can foster and center aspects of care for one's self and the community. Centering care in STEM programming was especially important during the early and highly uncertain months of the COVID-19 pandemic (Taylor, Lee, Riesland & Ikeru, in preparation). In World through Food, youth cooked food from world cultures and trends that they were interested in (like Dalgona coffee, a trendy drink in Instagram in 2020), and also learned how to make ethnic dishes that represented the participants' diverse cultures (e.g. red beans and rice, Somali style pasta). Making and experimenting with Dalgona coffee on Zoom not only allowed youth to explore the chemistry behind sugar crystals supporting the structure of coffee foam, but also opened-up opportunities for interpersonal encouragement and support as they marveled at each other's creations. Teaching each other about dishes from their families' respective countries of origin provided young people an opportunity to express themselves and appreciate the stories of others. STUDIO activities intentionally highlight the layered and powered dimensions of STEM learning that include affect, aesthetics, and uncertainty. Students recognize these aspects as being absent in their in-school STEM learning.

Conclusions

Co-designers of STUDIO cannot ignore the importance of adult caregivers' desires for OST STEM programming for their children. Additionally, connecting to in-school STEM achievement (including how content is taught and tested) also drives funders' concerns and assessments of the "efficacy" of the organization. However, we see that young people bring a different orientation to OST STEM programming. This orientation values learning in a community that is culturally intersectional and pursuant of current topics, questions, and trends with friends and adult facilitators; these STEM inquiries center cultural knowledge and heterogeneity. We see a failure to acknowledge youth desires in OST STEM programming as detrimental to participation (as in, young people will stop showing-up), but also as a missed opportunity to model STEM practices as un-settled (Vakil & Ayers, 2019), uncertain (Anthony-Stevens & Matsaw, 2020), and joyful. We hope the next step is to see evaluations for OST STEM programs (Stephenson Reaves et al., 2022) that "perpetuate and foster–to sustain–linguistic, literate, and cultural pluralism" (Paris & Alim, 2014, p. 88) and intersectionality.

Abstract: Challenging assimilationist science requires examining relationalities—the ways we are bound to each other, our personal histories and interactions, and the broader sociopolitical histories of learning contexts. We take up the need for understanding powered relations in this innovative extended-time and hybrid engagement symposium with opportunities for engagement before, during, and after ISLS23. We recognize all learning as political and examine powered relations and relational possibilities across four settings: drawing on Black methodology to disrupt how researchers and educators come to understand Black girls' learning in a summer camp, two pre-service teacher programs to explore "becoming" and challenging dominant logics, and how an in-service teachers' shifts towards humanizing and empowering kindergarten learners. Together we explore how participants' and researchers' understandings of relations in how we "see" science teaching and learning and ways to theorize and design for spaces that open multiple relational possibilities in science learning and teaching.

Session overview

In the past few decades, the Learning Sciences community has increasingly considered power, purpose, and positionality in teaching, learning, and research (e.g., Esmonde & Booker 2017). In particular, a growing body of work points to how normative K-12 science learning experiences require assimilation into unevenly powered relations between students, teachers, more-than-humans, and science disciplinary knowledge and practice, foreclosing opportunities to consider more just and heterogenous relations between learners and science (Barrett et al., 2017; Rosebery et al., 2010; Warren et al., 2001; Warren et al., 2020). In these assimilationist approaches, science learning has been designed to apprentice children into one way of doing science, established by the standards and not always reflective of professional scientific practice, learners' competence, nor their cultural repertoires (e.g., Hudicourt-Barnes, 2003; Keifert & Stevens, 2019; Levine et al., 2020). Rather than intercultural processes (Warren & Rosebery, 2011), assimilationist science learning imposes forms of alienation; "untenable epistemological positions that work against engagement in meaningful learning of scientific ideas, practices, and phenomena," actively harming learners from nondominant communities (Bang et al., 2012, p. 304).

Challenging this assimilationist approach requires us to reflect on our relationalities—the ways we are bound to each other, our personal histories and interactions, and to the broader sociopolitical histories of learning contexts. Developing alternatives to assimilationist approaches to science motivates us to re-think the relationships between teachers and students, between researcher and researched, between scientists and laypeople, between dominant communities and marginalized ones, and between humans and more-than-humans. Yet, this re-thinking must also involve recognizing the powered histories of these relationships. Recognizing, for instance, that historically, young White women were recruited as teachers to enculturate Native and immigrant populations (d'Amico Pawlewicz, 2020p; we capitalize White per APA 7). Western Modern Science constructed scientific knowledge as property of colonial (White male) scientists that led to the exclusion of the plurality of Black Diasporic and Indigenous peoples' humanity and knowledge systems (Palmié, 2002). That dominant portrayals of science maintain their dominance by continuing to narrate scientists as separate from nature, as omniscient observers and manipulators of the natural world (Castro-Gómez, 2021). Working towards more just and caring relations in science teaching and learning involves reflecting on our conceptual, epistemological, and ontological goals. It also involves interrogating our values, reflecting on our axiological goals to consider "the moral and ethical underpinnings that guide learning and participation in scientific and engineering practices" (Krist & Suárez, 2018, p. 424; see also Philip et al., 2017).

We take up the need for understanding powered relations in this innovative extended-time, hybrid engagement symposium. We explore the design and interactional space held by foregrounding axiological goals as we conceptualize relational possibilities between learners, teachers, more-than-humans, and cultural repertoires of knowledge and practice, including Western and other scientific practices. Considering caring relations (Krist & Suárez, 2018) in this work, we hope to engage members of the Learning Sciences and Science Education community in theorizing & designing for relational possibilities in science teaching and learning. We first draw on prior work to conceptualize the idea of power relations and relational possibilities. We then present questions we will examine together, followed by an overview of the extended temporal wings of this session, starting before the ISLS annual meeting, including a synchronous recorded session during the meeting, and concluding the week after the meeting.

Conceptualizing powered relations and relational possibilities

We are particularly interested in understanding how learners, educators, and science knowledge and practice are positioned in relation to one another. Specifically, our efforts are towards theorizing and designing in ways that explicitly acknowledge the power dynamics in these multiple relationships. Rather than develop new theory in this symposium, we draw on existing conceptualizations of power, relationships, roles, responsibilities, privileges, and relationalities in STEM teaching and learning to examine possibilities that emerge(d) in particular STEM designs. Forwarding a power explicit lens to understand relationships, we enter a speculative space to examine and imagine relational arrangements and possibilities that do not yet exist within dominant power structures.

Collectively we recognize all learning as political (e.g., Freire, 1970). We assert educators and teachers can both be learners, all relationships are powered, power must be interrogated, and the authority and agency for learning must be (re)distributed across participants. We recognize that science learning is fundamentally a relational activity (Calabrese Barton & Tan, 2018), contextualized and embedded in histories of the discipline, particularly science as White property—science as objective, neutral, separate from, based in Eurocentric thought and practice, and owned by White men (e.g., Bang et al., 2012; Mensah & Jackson, 2018).

To understand the particulars of each study and the multiple dimensions of relationality, we draw on multiple perspectives to understand powered relations and relational possibilities. Specifically, while all teacher-student (or adult-child, adult-youth) relations are inherently powered, these relations are multiply impacted by individuals' identities and relations with oppressive systems. Identities may include members in Black, Indigenous, Asian, LatinX, disabled, LGBTQIA+, multilingual, immigrant, and other communities that experience historical and continuing oppression in the U.S. Thus, powered relations between standards-teachers-students, old-timers-newcomers, researcher-researched, scientists-laypeople, dominant communities and marginalized ones, and humans and more-than-humans must be understood within the histories of oppression relevant in their context (i.e., in our case, U.S. informal and formal learning). Thus, to explore ways of disrupting oppressive relationalities in science education, we draw on interdisciplinary Black methodologies (McKittrick, 2020), becoming and diffraction (Barad, 2007, 2014), redressing multiple harms (race- class- gender-based) experienced by pre-service teachers of color (Mensah & Jackson, 2018), and humanizing approaches to teacher education (Kang, 2022; Louie et al., 2021).

Our work in the theorization and design of each learning context requires a powered analysis of "both interconnectedness and difference through how we subjectively construct ourselves and the other" (Calabrese Barton & Tan, 2018, p. 766). As we do this work, we hold space for participants to draw upon existing relations often excluded from traditional STEM learning environments (e.g., teacher as learner, imaginative embodiment) and for potential new emergent relations. This work is critical as it centers meaningful and humanizing STEM learning in ways that acknowledge that "my humanity, my integrity, and my dignity are rooted in my willingness to safeguard your humanity, secure your integrity, and protect your dignity" (Olivares & Tucker-Raymond, 2020).

Session summary and shared questions

Across multiple contexts, our presentations explore powered relations between teachers, learners, science, and culture, as well as how hegemonic relations can be disrupted. The first paper deploys Black methodology to disrupt how we, as researchers and science educators, come to understand Black girls' learning in the context of a summer camp exploration of light through photography and in the context of connections to Beyoncé's music and visuals. This paper questions how normative understandings of "seeing" background political labors and powered relationship dynamics that honor Black girls' brilliance. The second and third papers explore powered relations in the context of pre-service teacher learning, exploring pre-service teachers' relations to science and their own teaching. One paper considers pre-service teachers' "becoming" through noticing focused on videos of their own teaching, and the other explores how pre-service teachers challenge dominant logics to acknowledge relationality in their own scientific journeys. The last paper explores how in-service teachers' relationships to students and science shift in the context of a multi-year professional development to contribute to more inclusive kindergarten science teaching.

In the four presentations and the two discussants' comments, we examine the following questions about powered relationships and their role in science teaching and learning across contexts.

1. How do participants' and researchers' understanding of relations shape how we "see" science teaching and learning?
2. What are the different ways in which we theorize and design for spaces that open multiple relational possibilities in science learning and teaching, particularly in light of dominant relations that often repeat?

Innovative hybrid symposium design

We are excited to submit this symposium in the innovative hybrid category. Our goals are to extend engagement beyond the immediate synchronous session to include broader temporal wings (before/after the annual meeting) and multiple modalities of engagement.

Table 1
Temporal wings and multiple modalities of engagement for the hybrid symposium

	Pre-Conference	During Conference Session	Post-Conference
Discussion Forum	Proceedings include focal studies + discussants Prompts prepared + posted	Discussion forum topics/questions summarized and shared by chair	New prompts based on synchronous session
Video	Short clips visible to ISLS members to intro the four focal studies	Live Zoom Session In-Room chat monitoring + mic use Full hybrid format engagement across in-person and virtual attendees supported	Link to recorded Zoom session available for 1-week post-conference

The primary hybrid recorded session will include a 5-minute introduction by co-chairs, 10 minutes for each focal study, 5 minutes for each discussant, and 25 minutes for collective discussion. Please note, the pre-conference is one week before the opening session and post-conference is one week after the closing session. We have done this to attend to concerns about the safety of making recordings of scholars and their data of learners in action, particularly scholars and learners from nondominant communities, visible over long periods of time and to unknown audiences. We feel that the one-week extended temporal arms give opportunity for the more intentional engagement of the conference with the possibilities of hybrid and asynchronous engagement.

We also wish to point out that the proceedings submission will include brief discussant remarks including recognition of themes and articulation of preliminary questions that push forward our conversation (see next). As a result, the pre-conference proceedings and initial discussion forum prompts will include input from the four focal papers as well as discussants to invite the broader ISLS community into conversation.

Weaving together intersectional identities and positionalities to center justice, equity, diversity, and inclusion

Déana Scipio (discussant)

As I enter into conversation with these scholars and practitioners I am struck by the foundational commitments to relationality across contexts. I am eager to enter into conversations about how relationality foregrounds intersectional identities and creates opportunities for teachers, students, and researchers to explore the relations between their intersectional identities and positionalities within science teaching and learning contexts in order to center justice, equity, diversity, and inclusion. Thinking about intersectionality (Crenshaw, 1991) and positionality can allow us to hold multiple relations while honoring the complexity that students, teachers, and researchers are bringing to science teaching and learning contexts. Humans are negotiating their position with respect to joy, community, relationships, power, privilege, and oppression. I look forward to continued discussions with the scholars in this session that will draw out these commitments and connections across this innovative hybrid session.

How centering relationality in learning leads to just and humanizing education

Phil Bell (discussant)

The images of science learning and science teacher learning lifted up in this session sequence significantly advance our understanding of how ***centering relationality in learning environments*** promotes more just and humanizing education. The approaches explore how to center multiple ways of knowing from across academic and community life (Warren et al., 2020), how to support learning and becoming around the diversities of learners' subjectivities and multiplicities in a relational universe, and how to instructionally attend to the significant relations held by learners in humanizing ways. I look forward to learning more about: (a) specific learning and interactional processes from these situations, (b) the life-wide interactions experienced by learners (e.g., how preservice teachers made sense of the supported relational worldview in relation to others in their program), (c) how the centering of multiple, coordinated epistemologies becomes a desired platform for the learners amidst a powered landscape that is frequently hostile and resistant to such efforts (e.g., how learners learn how to fight the epistemic and ontological harms and insecurities that may resurface in other contexts), and (d) how might we as a field learn to support these vital, insurgent campaigns for a 'science otherwise' (Stengers) centered on multiple ways of knowing in active resistance to the hegemonic, multi-scalar structures of science education?

Slaying and seeing: Light and optics with black girls

Natalie De Lucca & Vanderbilt University

Viewing Blackness, whether within a K-12 physical science classroom or a learning sciences research space, is a deeply political process.

This study emerges from my experiences as a Black woman co-designing and instructing a four-week science course in a summer camp (n=35) predominantly attended by Black girls (n=33). Throughout the class, I prompted students to explore phenomena of light and color towards developing an aesthetic sense of "meaningful" digital photos. Notions of "meaningful" were student-developed: inflected with their lived experiences and evolved as a collaborative photographic practice where students learned to adjust the manual settings of digital single-lens reflex (DSLR) cameras. From a collection of field notes, class session video and audio recordings, and course products, I weave together a narrative case that stitches Beyoncé's (2016) music video and song, Formation, together with a trajectory of a single group of girls' photographic experimentation for two weeks. I present this case to raise questions about how we—as learning scientists, science educators, and researchers—approach "seeing" as an empirical practice.

Here, I deploy an interdisciplinary Black methodology: bringing together multifarious texts "not to capture something or someone, but to question the analytical work of capturing" (McKittrick, 2020, p. 4). Bringing different texts together — relationally — engenders a wonder and curiosity which treats Blackness as a living and active knowledge-making endeavor. The wonder that arises from convening interdisciplinary Black texts is responsive to (yet outside of) violent logics whose claim to absolute knowledge apprehends and delegitimizes Black intellectual labors (McKittrick, 2022). This attunement rejects the extraction of meaning from Black girls as objects of study. Instead, wondering involves posing questions as rigorous scholarly activities that build more livable and intellectually affirming learning spaces for Black girls. For AbdouMaliq Simone (2019), this is a strongly ethical stance toward Blackness: a "care that comes from having endured nearly everything" (p. 58).

Reading across two texts (a single group of Black girls' experimental trajectories and Beyoncé's music video and song Formation), I produce a narrative case which wonders about how we come to "see" Black girls within science educational literature and how we come to "see" Black girls' knowledge production. The narrative case stems from a pivotal moment where members of this group seemed to cohere around the production of a meaningful genre of photos. I reproduce part of this episode below:

Cycling through the photos taken as the girls adjust their ISO settings and positions relative to the ring light, we see an ecology of meanings developing as they experiment with their visual expression. Jaelyn photographs Janine and suddenly shrieks: "Oh my god, that's BOOTIFUL ... SLAY!" Jaelyn shrieks "YASSSS" as she looks at the five-second previews of an image just taken on the camera screen. In the tens of pictures just taken, as both Janine and Jaelyn shift their choreography in response to their shared endeavor, it becomes clear that this is not just a win for Jaelyn or just Jaelyn and Janine. The entire group shifts their orientations and settings in light of this discovery, their experimentation - purposive changes in camera settings, spatial organization, light, and intimacy - to give texture to a shared affective terrain of visuality. In this terrain, sociohistorical grammars of object/capture are not legible; instead, the ways the girls hype each other up, negotiate what settings to change, and share intermediate results signals sensibilities towards forms of self-making and world-making (Monday, June 27th)

Jaelyn's proud cry of "SLAY!" is etched in my memory; it signals a creative genealogy of Blackness outside of the audio-visual record. The term "slay" as an affirmation of stunning self-presentation in attitudes, posture, clothing, and accessories dates back to Black queer Ballroom communities in the 1970s-80s (Livingston, 1990), with particular genres shaped by hyper-local Black queer music cultures and histories (Tan & Smith, 2014). So, while Beyoncé is often credited with popularizing the term with the lyrics in Formation, foregrounding this genealogy centers on the creative, political labor of Black queer and gender-expansive communities for self-definition within intimate spaces of creativity. In Formation, Beyoncé's use of slay is not only to characterize herself, "Sometimes I go off (I go off), I go hard (I go hard)/ Get what's mine (take what's mine), I'm a star (I'm a star)/ Cause I slay (slay)..." her chorus calls in Black femmes to also use this term in a call and response fashion: "We gon' slay (slay), gon' slay (okay), we slay (okay), I slay (okay)." Jaelyn, Janine, and their peers' verbal and visual arrangements call and respond to each other, signaling shared ways of Black living and being beyond the audio-visual record.

A Black interdisciplinary methodology allows us to complicate the underlying assumptions behind empirical questions of "seeing," drawing into relief non-linear ecologies of Black cultural and political practice that actively produce racial and gender formations of Black girlhood. When assumptions of "seeing" — within K-12 physical settings and common video-analysis methods used to understand the process of learning — often depend on describing what is in linear observable time-space, we miss ways of understanding our relationship to the "viewed." Here, we see empirical questions of "seeing" involve withdrawing one's active engagement and solidarity when "viewer" of Black life and precarity (Campt, 2021). When translated into other spheres, bringing these texts into analytic proximity prompts questions about how we come to know Black girls (as subjects of learning research) and Black girls' knowledge (as social-cultural-political activities).

Diffracting noticing to become differently: Re-imagining relationalities

Sophia Jeong

Drawing on posthuman theories, in particular, Barad's (2007, 2014) work on becoming and diffraction, this conceptual paper investigates the productive interplay of diffracting noticing as a novel concept for elementary preservice teachers of science to become differently and re-imagine relationalities in their science teaching and learning. As accounts of wicked problems cause sufferings and loss caused by discrimination, oppression, marginalization, and violence across geo-political contexts (Crowley & Head, 2017), science educators are urged to consider concepts that assume the subject as irreducible, multiple, and continually re-assembled through social, discursive, material relational entanglements with other entities (both human and more-than-humans).

The purpose of this conceptual paper is to provide empirical illustrations and groundings of the concept, diffracting noticing that can be used to nurture elementary preservice teachers' diverse array of becomings in the context of a science methods course. Diffracting noticing theorized in this paper is a relational-ontology-oriented experimentation: it is a concept that can be used to rupture ontological concerns about stable entities that often take a stronghold in our worlds. This paper uses posthuman theories to re-conceptualize our stable "beings" as effects of work produced from the entanglements of the actors of an assemblage - thus, as vibrant becomings.

First, the author re-conceptualizes the notion of preservice teachers' learning as becomings (Barad, 2007, 2014). As opposed to static beings, becoming is based on the notion of dynamicity, multiplicities and differences. Second, Barad's radical concept of diffraction entails "re-turning" as in turning" it on its head over and over again, "iteratively intra-acting, re-diffracting, diffracting anew" (Barad, 2014, p. 168) as a way to re-turn what we would do with the different way of becoming. In addition, the author also applies Haraway's (2016)'s concept of response-ability that invokes ethical sensitivity and the ability to respond accordingly and that offers insights into fostering collective knowing and doing, and considering one's becoming with others and rendering them capable. In the context of this study, diffracting noticing demands one's attention to relational encounters: 1) articulation of the differences that were produced when preservice teachers juxtapose and "see" themselves in relation to others, and 2) the effects or a discursive-material mark on entities that were left by these differences. Diffracting noticing engages preservice teachers to reflect on their experiences in relation to others by re-turning and re-diffracting on what they "see," thereby iteratively shedding new insights about their experiences as well as producing new temporalities, patterns, understandings etc. (Barad, 2014). Diffracting noticing is both a process and an effect of the work produced from the actors who are entangled in that process.

The author's position as the science methods instructor of the course was to provide conditions for fostering preservice science teachers' becomings, or people-yet-to-come (Tillmanns & Salomão Filho, 2020, p. 1), and providing opportunities to enact their conceptualization of equity and inclusion in the way that mattered to them. This science methods course used Science & Engineering Practices (NGSS Lead States, 2013) as entry points to anchor and frame science teaching practices through an equity lens. Alongside the practices, the author shared her own tenets of Duty of Care that articulated ways to foster respect for the preservice teachers, their peers, and their future K-12 students. This paper used and analyzed artifacts of preservice teachers' learning that included videotapes of themselves teaching a science lesson incorporating Science & Engineering Practices. Preservice teachers engaged in course activities to view, discuss and provide feedback. Using feedback, preservice teachers planned or modified their lesson planning.

Preservice teachers' discussion of what they noticed provided an opportunity for them to juxtapose, challenge, and contest their teaching practices as a collective relational experience. They were entangled with one another along with the artifacts of their teaching in these modes of encounters: 1) Articulating, 2) Reflecting+Diffracting, 3) Analyzing, and 4) Re-articulating. During these encounters, preservice teachers reflected on where they were in the "middle" (Deleuze & Guatarri, 1987) of their becomings in relation to others' becoming as they began to see and make sense of equitable and inclusive teaching. In so doing, they were able to "see" differences that were produced in terms of their teaching practices and ideas, and the differences became an artifact that could be used to re-turn to, turn it over to diffract and look at them through a new lens (Articulating and Reflecting+Diffracting). Once these differences were produced, the juxtapositions created productive tensions (Analyzing). The productive tensions with which preservice teachers tried to wrestle seemed to leave a mark on the preservice teachers in the form of re-articulating what they could or would do differently in their future teaching (Re-articulating) and what began to show up as effects.

Differences and juxtapositions about how they made sense of and chose to enact equitable science teaching left a mark by way of preservice teachers becoming accountable or response-able for the knowledge that was collectively co-constructed about equity and equitable science teaching and learning. Briefly, the author argued that preservice teachers were part of an assemblage that is organized and re-organized, and is composed of and entangled with heterogeneous actors or entities (Deleuze & Guattari, 1987). Assemblages produce effects of work that actors do as they organize, re-organize their relations. In this vein, preservice teachers who could "see" themselves and their teaching practices in relation to others were becoming differently. In becoming differently as they were sense-making equitable and inclusive teaching practices in the manner that mattered to them, what began to vibrantly matter (Bennett, 2010) in their becomings was ethics and duty of care showing up in their teaching practices. Preservice teachers were also becoming more response-able and rendering themselves and others capable to become more equitable science teachers.

In summary, diffracting noticing as a concept is not just an experimentation: it is meant to be used, distilled, and applied in order to offer re-imaginings and find infinite possibilities for a different way of becoming. In so doing, science educators can work alongside preservice teachers and other entities to provide a different way of becoming (i.e., knowing and learning) for our preservice teachers and their future K-12 students, thereby creating conditions for more equitable and inclusive learning environments. This notion of becoming differently through diffracting noticing contributes to a re-imagination of the traditional notion of teacher change and agency. Allowing teachers' diverse array of subjectivities and multiplicities of enactment of teaching practices (Kayumova & Buxton, 2021) is a first step in rupturing the notion of power as we know it, and fostering similar opportunities and possibilities for K-12 students' multiple ways of knowing and learning.

Redressing harm: Relationalities in preservice secondary teachers' science prep

Jessica Watkins & Natalie De Lucca

Preservice science teachers (PSTs)—particularly PSTs of color—often endure racialized, classed, and gendered harm in their scientific preparation (Mensah & Jackson, 2018). In this paper we are interested in how PSTs grapple with *relationalities* in science to navigate and redress this harm and to imagine more equitable futures for their students. We foreground relationality to acknowledge that the ways we make sense of ourselves, the broader cultural narratives about our communities, and our social structures are not formed in isolation, but rather through our engagement with others' identities, with other cultural narratives and structures (Hoagland, 2007; Shah, 2017). For instance, historically, Anglo-European scientists did not emerge as a community independently or autonomously, but by demonizing and exterminating of pagan and Jewish women healers during the Roman Catholic Inquisition (Hoagland, 2007, p. 98). Critical race scholars have emphasized relationality in the construction of whiteness: White people obtain privileges through the objectification and exclusion of Black people (Harris, 1995). Leonardo and Broderick (2011) extend this perspective on relationality to smartness, arguing that the ways schooling constructs some students as "smart" (thereby deserving of resources and opportunities) simultaneously constructs other students as "not smart" (thereby less deserving of these resources).

While these relationalities are fundamental to the construction of our world, dominant logics of oppression center on denying relational perspectives (Hoagland, 2007). For instance, Western Modernity is narrated as the culmination of a natural progression of thought, rejecting the ways it developed through colonial and imperial interactions (Castro-Gómez, 2021). These logics therefore position dominant cultures as autonomous, independent and ignore the agency and voice of the oppressed. While these logics pervade dominant discourses, we argue that a relational perspective is imperative for PSTs to make sense of themselves, their students, and the disciplines they plan to teach. Here we analyze how two PSTs grapple with relationalities coming from different worlds, yet both troubled by how to make sense of their family histories, academic presents, and futures as science educators.

This study is conducted within a larger project to redesign a content-focused science teacher education course to create opportunities for PSTs to engage in expansive scientific sensemaking themselves, in which multiple ways of knowing and engaging are valued and integrated. In the course, students engage in two extended units in which they pursue coherent and causal understandings of phenomena. The first unit focuses on light and color, framed by the question "Are all the colors in the rainbow?". The second unit pairs formal experiments with Wisconsin FastPlants with field work in their local neighborhoods to explore the expression of purple/red color in plant leaves and stems. In each unit, students kept an online science journal with their wonderings, observations, reflections, procedures, photographs, and personal notes. Inspired by Kimmerer's (2013) reflection: "Isn't this the purpose of education, to learn the nature of your own gifts and how to use them for good in the world?" (p. 239), students are asked to create a final project that reflected their "gifts" in science, how these could be disruptive and do good in the world. We present case studies of two PSTs to explore how they challenge dominant logics that deny the relationalities that shaped their experiences.

Case 1. Carla grew up in rural Georgia, as a White woman with Cherokee ancestry and the first person in her family to attend college. She pursued a PhD in chemistry before switching to teaching as her intended career. Carla spoke about a rupture in who she is across contexts: At home with her family, her ways of knowing, communicating, and relating to the natural world stood in conflict with how she experienced academic science. In the university, she changed her Southern accent to not be perceived as ignorant or dumb, and separated from her family's knowledge about the natural world in her chemistry pursuits.

While Carla experienced a chasm between her home and academic science, we consider how these parts of herself are relational, constructed as counterpoints to each other. Carla's status as a scientist—the recognition of her and other scientists' intellectual abilities to understand the natural world—comes about due to the subjugation of the ways of knowing and communicating in her family and rural community. Dominant logics of oppression deny this relationality (Hoagland, 2007), positioning scientists as separate, independent entities, while laypeople are recipients of their knowledge, dependent on their discoveries. These logics limited who she could be in science, keeping her from bringing these parts of herself together. For Carla, the field work conducted in the class became a site for the seemingly disparate parts of herself to meet, a place to marry her understandings developed as a PhD student in chemistry with her family stories and farming practices. "I was able to make connections [between]… my field work in class and then my knowledge from my family… Trying to make sure I honor both parts of knowledge."

Case 2. Ally was a sophomore Japanese American student majoring in chemistry and secondary education. Her case highlights the ways Japanese Americans have had to navigate the dominant relationality of serving as "model minorities." Within dominant logics of oppression, Japanese Americans had to transform from "problem minority" to "model minority" to be rendered worthy to be citizens. To realize this transformation, Japanese American internees were forced to pledge loyalty to the country that imprisoned them, suppress their cultural identities, and maintain silence about their oppression; these practices contributed to intergenerational, cultural trauma (Nagata, Kim, Nguyen, 2015). In STEM fields, this trauma re-emerges in the model minority myth that "Asians are good at math," which serves to deny Asian Americans full personhood and again positions them against other minority groups (Shah, 2017). Indeed, Ally grappled with the ways that she is minoritized, but as an Asian American not under-represented in science, leading her to question how she belongs.

In her final presentation, Ally positioned crafting as a practice that pierced these dominant logics. Throughout the course, Ally's journals were populated with images showing her joy and facility with materials: she used her feet to project filtered flashlights on the wall, developed new color filters with nail polish and eyeshadow, used string to develop a grid system to keep track of her plants. For her final project, Ally drew on these material experiences to narrate herself in new ways in science, connecting to her family's history with crafting. She linked her cultural practices to her family's experiences in Japanese internment camps. Ally described that "Crafts were used as a form of expression for internees," elaborating that these practices helped Japanese Americans cope with the emotions of enacting as "model" citizens while being incarcerated and tap into their cultural histories. By incorporating and celebrating these cultural practices as part of her scientific work, Ally re-negotiated the relationalities of the model minority myth, positioning science as entangled with culture, politics, art, and emotion.

Both Ally and Carla experienced harm in their scientific preparation as teachers, in which they had to forgo parts of themselves in science to feel as though they belonged. Our analysis highlights the relational dimensions of this harm, unpacking the relationalities not just between broader narratives or structures, but within their personal stories. Importantly, their stories do not end with harm, but with the reparative work they did to resist dominant logics and acknowledge the social, historical, and political relationalities of their experiences. As teacher educators conceptualize expansive and humanizing teacher education (Carter Andrews, et al., 2019), these cases shed light on the need to create opportunities for PSTs to grapple with relationalities as part of their becoming in science and as future educators.

Teacher-student relationships and inclusive kindergarten science teaching

Ashlyn Pierson, Adam Bell, Bethany Daniel, D. Teo Keifert, Sarah Lee, Andrea Henrie, & Heather Johnson

Teacher education has historically focused on the role of teachers and teaching practices (e.g., core practices; Philip et al., 2019). This focus backgrounds students, their knowledge, practices, and interactions, which is particularly harmful for learners from non-dominant communities (Bang et al., 2012; Warren et al., 2020). Additionally, those in power can interpret national to state standards in harmful ways, positioning young learners (e.g., Kindergartners) as not capable of the practices and interactions central to science inquiry (e.g., Keifert & Stevens, 2019). Along with normative expectations about children, families, and cultural repertoires, these powered dimensions shape how teachers design for learning.

Recently, researchers have called for humanizing approaches to teacher education to attend to students as full human beings with many resources (e.g., Kang, 2022; Keifert & Stevens, 2019). This focus can help teachers see *relations* (between teachers, students, standards, and practices) in ways that challenge previous assumptions about students and about science (e.g., ideologies rooted in whiteness; Mensah & Jackson, 2018). We ask: How do teachers' shifting relations–with young students and science–influence learning designs? We analyze data from 2 years of professional development (PD). In the 1st year (2019-20), PD focused on phenomenon-first science instruction and representations, foregrounding the teacher's role in the elementary classroom. In the 2nd year (2021-22), PD focused on multiple ways of knowing in science and on the many resources that students bring to classroom learning (Warren et al., 2020). We analyze data (video, artifacts) from a kindergarten teaching team's planning and implementation of the same two units after the 1st and 2nd PD years, demonstrating how this shift in teachers' perspectives resulted in more inclusive learning designs.

We draw on the FAIR noticing framework (Louie et al., 2021) and Olivares and Tucker-Raymond's framework for *critical relationality* (2020) to understand how ideological framing influences teachers' relationships with their students and the disciplines they teach. These frameworks are premised on humanizing pedagogies that require teachers to welcome relationships that students have in their lives. We consider how PD helped teachers shift the focus of their teaching to center on relationships students have out-of-school and with classroom peers, in addition to student-teacher and phenomena relationships, all of which are foundational for student-driven learning.

We analyze episodes that make visible shifts in teachers' perceptions of students' *relationships* with others and the relevance of relationships to science learning. We focused on the kindergarten team because we could follow the same unit over multiple years. We created content logs and rough transcripts (Erickson & Schultz, 1997) as a basis for turn-by-turn analyses. We analyzed transcripts of classroom observations and triangulated them with video of PD sessions and interviews with participating teachers. We used Discourse Analysis (Gee, 2014) to closely analyze the ways teachers attended to students, science, and relationships (Louie et al., 2021).

Our findings consider two units the kindergarten teaching team designed which responded to shifts in our PD wherein students' inquiry (e.g., feeling, exploring, questioning) and life experiences (e.g., family structures) were central to the science lessons. First, we present data from a unit called "What animal am I?" designed to address the state standard "make observations to show that young plants and animals resemble their parents." Building on the initial PD of phenomena-based instruction, the teachers focused on selecting a phenomenon familiar to students: baby and parent squirrels in a park near the school because "squirrels abound and kiddos see them every day." This foregrounded an in-school shared experience between students and the nearby park. To describe the phenomenon, students were asked to "compare and contrast a *mother* and her baby, then write about ways the baby is similar to its mother." During the second summer PD, teachers were asked to consider how they could make space (Haverly et al., 2020). One way this was demonstrated was through our use of a Summary Chart. In addition to a space for noting claims and evidence, we added a column for students to make connections to their family, friends, language, experiences as home, culture, etc. One teacher explained a shift to the language of *parent* and baby: "in my classroom, I have students who are adopted [and] students who don't have a mom…Even though they're adopted by someone who has a different skin, they have features that are the same as humans, and that helps us understand that this is still a parent and a baby." This inclusive framing came as teachers attended to students' out-of-school relationships as relevant to science.

Second, we present data from a unit about materials. The unit shifted from teaching students a classification system (e.g., "draw the stick part, that's the wood part") to allowing students to develop their own personally meaningful categories (e.g., sound alike; has a hole in it) and engage with one another as sensemakers. Positioning students as sensemakers led teachers to shift from a traditional Initiate-Respond-Evaluate pattern (Cazden, 1988) in the initial implementation (e.g., "Oh, I'm asking [student]...hold onto that connection, we'll talk about it") towards cultivating Kindergartners' capacity to share their thinking with their peers (e.g., "Orange Tiger, do you agree with that?" and "Blue Cheetah, I like your thinking but you need to share it with your group."). With students positioned as sensemakers, teachers centered students' considerable repertoires of practice in classroom conversation. Ultimately, attention to relationships created a more inclusive classroom environment that honored students' interactions in the shared development of knowledge, recognized young learners' competence as inquirers and sensemakers, and honored multiple ways of understanding the standard.

Abstract: This international collection of papers examines the many ways teachers exercise agency in light of the challenging realities they and their students face to create caring, engaging and transformative learning environments. The teachers in these studies exercise agency in various ways — as individuals, collectives, and fluid inter-professional and personal collaborations — to construct their professional identities and contribute to social change in their schools and society. Across these papers, we also find empirical evidence about the reflexive relationship between individual agency and social structures in shaping each other.

Symposium summary

Currently, students' lives are touched by economic inequality, racism, environmental crisis, and the ongoing global pandemic. Thoughtful teachers seek ways to reshape their practice in ways that respond to these realities. To support teachers' meaningful learning, professional education needs to account for teachers' agency, particularly as they confront the heightened ambiguity of the present moment. Instead of the commonplace approach of "delivering" professional learning for teachers to apply in their classrooms (Zeichner, 2010), recent scholarship recognizes teachers as sensemakers who are active agents in interpreting what they learn and in shaping learning environments considering their students' needs and public good. Nonetheless, the nature of teacher agency and, relatedly, how teachers' agency can be supported in professional learning and work environments is not well understood. In this symposium, we bring together studies that highlight many ways that teachers exercise agency in their practice, which has implications for professional learning.

This collection of papers takes a sociocultural view on learning and agency. In particular, we are interested in how teachers consciously make decisions and act to deal with problems of practice; to transform and expand their practice; to influence policies and procedures within their departments or schools; and to support their own learning by employing the social, material, and conceptual resources (Edwards, 2010; Engeström et al., 2020; Eteläpelto et al., 2013; Vygotsky, 1997). Importantly, in this sociocultural conceptualization, agency is not understood as a fixed quality, disposition or capability which resides in the individual mind (Biesta & Tedder, 2007; Haapassaari et al., 2016). It is socially constructed, achieved according to the constraints and resources of the social environment, and manifests in social practice (Lipponen & Kumpulainen, 2011).

In Papers 1 and 2, we see teachers improvise during and after the transition to remote learning during the COVID-19 pandemic. Paper 1 describes teachers' strategic maneuvering to prioritize their students' wellbeing during remote learning. In Paper 2, we witness how a teacher and her students collectively exercise transformative agency to overcome the stressful conditions of transition after remote pandemic learning by reconfiguring the demands of the learning environment. Papers 3, 4, and 5 document teachers' agentic responses to longstanding issues in and beyond schooling: lack of administrator support (Paper 3); structural racism in curricular pathways (Paper 4); and environmental crisis (Paper 5). These papers press our imaginations about what it might mean to support teachers' agency in their professional learning and work environments. To conclude, we offer Paper 6, a conceptual paper that highlights the complementary role of different levels—individual, collective, and relational— at which agency is exercised and resources are created.

The studies in this symposium attend to teachers' active role in solving problems, improving their practices and supporting their students' learning and well-being, in the heightened uncertainties they contend with in the broader school and world contexts. These studies show how teachers' environments constrain and enable teachers' agency, with implications for the design of professional learning and the organization of teachers' work. From the conceptual lens provided by Paper 6, we conclude that while most of these studies focus on teachers as individuals, we see evidence of the potential for teachers' collective agency and relational agency as they work with others to solve the complex problems they face. The 90-minute symposium will be organized as a structured poster session. Each author will give a 5-minute overview of their papers (30 minutes), followed by 40 minutes for participants to visit the different posters. For the last 20 minutes, we will facilitate a group discussion.

Paper 1: Achieving agency within the authoring spaces of pandemic teaching

Katherine Schneeberger McGugan

Objectives

The COVID-19 pandemic drastically altered the contexts of U.S. schooling and students' needs, thereby changing what teachers had to respond to. This study examines how teachers made sense of and navigated these complex contexts. I take a socially constructed view of teacher agency as a function of their participation in figured worlds to explore the ways in which teachers' institutional commitments may have shifted.

Theoretical framework

I turn to Calabrese Barton and Tan (2010), who theorize agency through the lens of Holland and colleagues' (2001) conception of figured worlds: the particular set of meanings, practices, and actors that are recognized and assigned significance. The presumed stability of the figured worlds of school practices (Edwards, 2017) was ruptured by the COVID-19 pandemic, making room for teachers to reorganize themselves into a new figured world of online teaching. In this sense, all teachers were novices to the figured world of teaching during a pandemic, drawing an analytic lens toward their authoring space, the boundaries of which are determined by how teachers "choose to accept, engage, resist, or ignore appropriate dispositions tagged to their identities" (Calabrese Barton & Tan, 2010, p. 193). The ways in which teachers take up or reconstruct the identities ascribed to them by the moment and the context is both driven by and drives the possibilities for asserting agency within the new figured world of pandemic teaching.

Data sources and methods

To capture both the moment and participants' experiences as they changed over time in unanticipated ways, I designed an interview method I refer to as Reflexive Longitudinal Lifeworld Interviewing (RLLI). My sensemaking as a researcher evolved alongside my participants, as different phases as the pandemic unfolded, resulting in a need for the researchers to engage in in-process data analysis (Emerson et al., 2011). The findings of these ongoing analyses were then used in the development of subsequent interview protocols.

This study extends a four-year ethnographic study of experienced secondary mathematics teachers' learning. Data for this study includes five interview transcripts from eight participating teachers and content analysis of relevant district announcements and national media coverage of education (Altheide & Schneider, 2012). Analysis revealed that teachers continually prioritized students' wellbeing across three main authoring spaces — *structuring time, content*, and *grading* — as they reorganized their identities in their figured worlds.

Results

Teachers in this study achieved agency by *structuring their class time* in ways that attended to students' wellbeing as a result of negotiating their pedagogical responsibilities (Horn & Garner, 2022) to prioritize their ethical commitment to care. For example, Amber spoke of her responsibility to prioritizing students' social and emotional health during the pandemic, describing the variety of ways she uses this time to create a supportive space for her students' personal needs. Jason described having informal, non-mathematical conversations at the beginning of his classes, explaining that "It's more important that we're making that connection than that we get through the content" (*Interview 3*). Amber and Jason both achieved agency in the way they structured their time with students, prioritizing support and personal connections over mathematical instructional time.

Many teachers described loosening their stronghold on the teaching of mathematical *content* in ways that they hadn't before. Linda prioritized personal connections over her pre-pandemic commitment to mathematics. Kasey expressed a similar sentiment: "Students are not going to look back and be like, 'Whoa, I wish I had learned this.' I think what's important is that students feel like we care about them and that we're there for them" (*Interview 3*). Teachers ultimately achieved agency by valuing supporting students' wellbeing over teaching mathematical content.

Teachers also achieved agency in the *grading* space by attending to their ethical commitments over the institutional demands of assigning grades. As Brad described in Interview 2, "It's just going to be grading obviously at your discretion, being mindful about kids' situations.” Jasmine also explained her commitment to kindness, saying “I decided to give credit in terms of extra credit, so that it doesn't harm their grade at all, and anything that they do, I will take it because I want to be kind right now” (*Interview 1*). When teachers thought about grades in their figured worlds of pandemic teaching, they negotiated the balance between institutional traditions of grades and their ethical commitments to care to better serve their students’ personal needs.

Significance

Situated in a time where norms and institutional structures were temporarily suspended, this study explores the ways teachers negotiated and acted on their commitments to serve a community of students that was particularly vulnerable during COVID-19. Its findings speak directly to established policies by furthering our understanding of how institutional conditions shape instructional practice.

Paper 2: Teacher “response-ability” as sociopolitical allyship: Seeding rightful presence in middle school STEM

Angela Calabrese Barton & Edna Tan

Objectives

This study focuses on three teachers’ “response-ability” in one middle school during the return to in-person schooling after remote learning during the COVID-19 pandemic. We investigate how teachers witnessed the oppressions minoritized youth experience through the political and structural continuities that shape science classrooms during a multi-pandemic, and the practices they enacted to transform these conditions.

Theoretical frameworks

In our study, we use the Rightful Presence framework to investigate teachers’ transformative agency. The Rightful Presence framework attends to historical and contemporary inequities in teaching and learning, calling attention to the necessity of allied political struggles educators and youth collectively engage in to re-author rights. Transformative agency is both collective and relational and involves intentional analyses of power and action in relation to systems of privilege/oppression (Bajaj, 2018). Transformative agency sheds light on teachers’ practices for fostering rightful presence. Learning to notice/disrupt/transform systemic oppressions through critique, action, and reflection involves “response-ability” — “to witness beyond recognition” and “to enable response-ability from others” (Villenas et al., 2019, p. 156).

Data sources and methods

Teachers taught a STEM unit — “how can I make my classroom more sustainable?” — in a school serving predominantly Black and Latinx youth. Students used engineering design practices, disciplinary core ideas and a sustainable communities framework to build authentic projects to support their classroom communities.

Using critical participatory ethnography, the following data were generated: Class video recordings, student/teacher interviews, fieldnotes, and artifact collection. Data were analyzed in the grounded theory tradition (Strauss, & Corbin, 1998).

Findings

We present an illustrative vignette followed by our main claims. Ms B’s students returned to “in-person” after 15 months of remote school. Due to “learning loss” and safety concerns, the school day was restructured: Students stayed in the same classrooms and small groups. Specials were eliminated, and science instructional time was reduced. Students described school as stressful and boring:

> There is a lot of pressure on kids. Me personally, it’s like, *you need to do this! You need to do your work!* They [teachers] don't give us much freedom from that. . . Before [COVID] it was like, we have more fun, getting more breaks. But then when it [in-person school] started, it's like, we couldn't, because COVID. (Ana, 6th grade student)

Ms. B launched the return to in-person with the engineering unit to support students in building a caring classroom community. One morning, when she announced STEM class was over and it was lunchtime, students ignored her and kept working. Instead of reprimanding them, Ms. B. paused, asking how they could keep working and still eat. Students developed plans to take turns gathering lunches, allowing them to eat and work. Contrary to the prevailing somber mood, the 6th-grade hallway filled with the sounds of students’ excitement.

Ms. B then pushed afternoon math to another day, creating more time. She asked students what they needed and how she might support them. The ensuing conversation centered students' desires to be in school differently, while elevating their insights and imagination. Consider the Zen group's project, a "light-up Zen poster" (rainforest mural with lit-up animals) meant to transport the viewer to "not school" with the animals bringing "joy and relief". The group needed help to identify a place where kids could "take a break without a mask." Another group worked on the LEH game, consisting of light-up sliders and a timer to be built on the gym wall, supporting students' "movements breaks." This group needed help getting their light-up sliders to work, and in, seeking support from other teachers for activities that took place outside the required day-long pods.

Ms. B engaged in pedagogical "response-ability" — or to witness beyond recognition — as acts of transformative agency. For Ms B, this response-ability took two forms. First, she *engaged in-the-moment strategic pausing, halting forward trajectories of certain assumptions,* such as when Ms. B paused clean-up to support students in planning their work/lunch sessions, or when she paused the mathematics curriculum. This pausing pushed back against normative stances on what it meant to support student learning and what kind of learning mattered. Second, *Ms. B engaged her students in the material and discursive reclaiming of space and time*. The engineering artifacts themselves paused student stress induced by stringent COVID school protocols, the desired effects of the projects — the laughter, movement, and de-stressing — filled the space created by such pauses, re-creating what schooling and STEM could be and feel like.

Significance

Ms. B and her students collaboratively engaged with existing school structures to transform them by leveraging the youths' wisdom. Strategic pausing created opportunities for transformative agency to emerge through the allied political struggle among teachers and students that transformed the norms of 6th-grade STEM that inserted youth joy into strict COVID protocols. For rightful presence to orient STEM experiences in just ways, it requires educators to be critically aware of how the routine practices of STEM, manifest in the discourses, practices and relationships enacted therein, can (re)produce injustice.

Paper 3: "I'm trying to rebuild a relationship with him": Teachers reconstructing instructional practice amidst conflicting pedagogical responsibilities

Ilana Horn, Yeliz Günal Aggül, Jessica L. Smith, Christine E. Hood, Brette Garner, Katherine Schneeberger McGugan, & Karen Underwood

Objectives

When teachers commit to responsive instruction, they constantly reshape their practice through an interplay between their *agency* and their *pedagogical responsibilities*. But what happens when teachers' commitments are at odds with institutional demands? How do they reconstruct their practice within that complex space? We explore this through a case of a teacher who found herself in such a situation.

Theoretical framework

To investigate teachers' reshaping of instructional practice amidst conflicting demands, we draw on two constructs: teacher agency and pedagogical responsibility. While teacher agency has been conceptualized numerous ways, we focus on *relational agency,* the agency that arises in collaboration with other practitioners and supports expansive interpretations of problems of practice (Edwards, 2017). Additionally, *pedagogical responsibility* describes what teachers view as non-negotiable in their reconstructions of practice—their obligations to ethical principles or situational constraints (Horn, 2019).

Data sources and methods

To understand teachers' reconstructed practice in contradictory situations, we examine the case of Veronica Kennedy, a high school math teacher in a large urban school district in the Western U.S. Through a research-practice partnership, we developed a video-formative feedback (VFF) process to support the teachers' learning about groupwork monitoring practices (Ehrenfeld & Horn, 2020). As part of this process, we filmed one of Veronica's lessons using a five-camera set-up: one whole-class view; one teacher point-of-view camera; and three 360° recordings of student groups. Using the whole-class video and a floor plan of the classroom, we also transcribed Veronica's movement (Shapiro & Garner, 2021). Our team reviewed the videos and movement transcript to understand Veronica's monitoring practices. Then, a debrief session was conducted during which two researchers facilitated a discussion about the lesson with Veronica and her colleague, sharing video clips and discussing her monitoring practices.

To understand Veronica’s reconstruction of her practice in the face of contradictions, we used an ethnomethodological lens, where analysts pursue participants’ meanings (Heritage, 2013). This consisted of two phases: (1) analyzing lesson videos, and (2) analyzing video of the debrief. In Phase 1, we examined Veronica's monitoring practices, looking for patterns and anomalies, such as the notable difference we shared with her. Phase 2 involved analyzing Veronica’s account of her moves/actions in the class.

Results

While preparing the debrief, we noted that Veronica visited one group more often than others. Specifically, she uniquely asked them leading questions, offered step-by-step instructions, and checked to ensure the group was on-task. This unique instance of monitoring was Luca’s group. In contrast, Veronica asked other groups open-ended questions and supported their inquiry. Veronica also checked on other groups half as many times as Luca’s. When we explained that this pattern piqued our curiosity, Veronica leaned back in her chair, saying, “Let’s do it. You want to know the context on Luca?” When we agreed, she spent over seven minutes recounting a critical event (Emerson et al., 2011) involving Luca.

Luca had come to her classroom during a different period, asking to retrieve something he had left behind. When Veronica let him enter, he started a fight with another student. Veronica described this fight as “so freaking traumatic, outrageous, throwing punches, throwing bodies.” When Veronica asked that Luca be assigned to another teacher, administrators insisted that he remain with her, thus excluding her from decision-making and reducing her relational agency. This made Veronica feel powerless in the aftermath of the situation.

Despite compromising her relational agency at the institutional level, Veronica maintained agency within her classroom. Retaining Luca in her class presented her with conflicting pedagogical responsibilities: maintaining her commitment to a welcoming and inclusive classroom and keeping Luca in class. Veronica reconstructed her practice in this narrow space by emphasizing gentleness over challenging Luca’s mathematical thinking. As she explained, “I'm really purposeful, trying to rebuild a relationship with him. Even though…[*trails off*].” An observer without knowledge of this relational context might presume that Veronica simply had low expectations for Luca and his group. However, her interactions resulted from her diminished relational agency, as she did not know how to push Luca mathematically (for fear of him exploding) or request support from her administration (who had shown themselves unsympathetic). These changes to her relational agency and pedagogical responsibilities shaped her practice.

Significance

Teaching is socially embedded, ambiguous, and contested (Horn & Garner, 2022), yet research often treats it as a technical activity. Because of its indeterminacy, teacher agency becomes a critical component of instructional practice, particularly their relational agency within a school. When Veronica’s relational agency was limited, she resorted to forms of practice that were otherwise unusual in her instruction. This study highlights the extent to which teaching practice, and therefore teacher learning, is shaped by sociocultural contexts.

Paper 4: “He should have been giving me a gold f-ing ribbon”: Mathematics teachers’ learning of creative insubordination

Samantha A. Marshall

Objectives

For teachers, creating more equitable learning opportunities for students can be a daunting task. Teachers may feel overwhelmed by the weight of an unjust system (Gutiérrez, 2016), and working against the status quo may come with serious risks to reputation and status. Yet some teachers disregard policies to create more just learning opportunities for their students — what Crowson & Morris (1985) call *creative insubordination.* This study investigates two urban mathematics teachers’ learning of creative insubordination to open liberatory mathematical pathways for their students.

Theoretical framework

To understand teacher learning of creative insubordination, I take a sociocultural perspective, foregrounding context and agency in the learning process (Calabrese Barton & Tan, 2010; Lewis et al., 2007). To conceptualize agency, I draw on Burkitt’s (2016) theory of *relational agency*. In line with sociocultural and ecological views of agency that look beyond the individual (Biesta & Tedder, 2007; Cong-Lem, 2021), this view considers the context as paramount for the achievement of agency. However, rather than viewing agency as simply enabled or constrained by relationships or contexts (Emirbayer & Mische, 1998), this perspective considers relationships as "constituting the very structure and form of agency itself" (Burkitt, 2016, p. 336). Indeed, "one's action is rarely one's own and rarely for one's own sake only … it is always already co-authored" (Phạm, 2013, p. 37). Agency, then, is neither held nor achieved by individuals, but unfolds in and from relations.

Data sources and methods

This investigation draws from a 4-year study of teacher learning (Horn & Garner, 2022), focusing on Lee and Doha, mathematics teachers at Falconer Middle School in a large urban district in the Western United States. Data consist of ethnographic fieldnotes, videos and transcripts from interviews, classroom observations, and PD activities. As primary data, I conducted a series of interviews with the focal teachers, who had restructured their classes to accelerate students who wanted to learn more than grade-level content. Analysis was guided by grounded theory and constant comparative methods (Boeije, 2002; Harry et al., 2005) seeking to understand sources of and sociocultural influences on teachers' learning to open mathematical pathways for students.

Results

Analysis reveals that teachers' learning was spurred by students' self-advocacy, guided by teachers' sense of pedagogical responsibility toward students (Horn & Garner, 2022), and mediated by both oppositional and supportive professional relationships. The teachers described how students' desires catalyzed their learning of creative insubordination; one 7th-grade student asked how he could take algebra as an 8th-grader, which initially seemed impossible to the teachers. However, together they began figuring out how to open this pathway. They helped this student enroll in community college classes, buying his books and successfully advocating for an exception to the 13-year-old minimum age. Through this process, this student (and later, others) achieved readiness for calculus by 9th grade, and gained admission to highly competitive high schools.

Lee and Doha then convinced their principal to allow Lee to teach multiple courses in the same block — with several simultaneous rosters assigned to him — so students could get credit for algebra or geometry in 8th grade. He managed this through strong collaboration with Doha and differentiated curricula, adding this to the community college support as another means of opening mathematical pathways. The teachers' sense of pedagogical responsibility was key — they saw this work as leading to greater equity for their low-income, immigrant students who are typically not afforded such opportunities.

Lee and Doha's creative insubordination also required navigating opposing views, including from respected colleagues. Lee explained that a district employee once told them to "shut it down" because all programs were required to be approved and available district-wide. However, the teachers knew that this would undermine the work; their ability to keep these pathways open at all hinged on their relationships and reputation with the community college. Lee added, "I felt like he should have been coming to me and giving me a gold fucking ribbon but that's not what happened." Lee gambled, "I bet he's never going to check in with me to see if I did all this," but added that they would have found a creative way around it even if the district had followed up. This analysis reveals that in contrast to individual views of agency, teachers' agentic learning to open liberatory mathematical pathways for students was fundamentally co-authored (Phạm, 2013).

Significance

The field knows little about both how teachers learn to subvert oppressive systems (Chen & Marshall, 2018) and the "micro level negotiations" that shape teachers' learning and achievement of agency (Edwards, 2005, p. 180). Theoretically, this case of teachers' learning of creative insubordination highlights the relational constitution of agency and learning (Phạm, 2013). Here, agency unfolded within contradictory social relations (Burkitt, 2016) and was shaped by teachers' relationally-informed sense of pedagogical responsibility (Chen et al., 2021; Horn & Garner, 2022). These findings contribute to our understanding of how teachers learn.

Paper 5: Transformative teacher agency for sustainable futures: Manifestations, conditions and resources

Antti Rajala

Objectives

Schools and teachers can arguably play a role in humanity's learning out of unsustainable, fossil-fuel-dependent human activities, which have already made irreversible changes on the planet's climate and environment (Värri, 2018; Taylor & Pachini, 2015; Rajala et al., in press-a). This paper examines teachers' agency as critical educators committed to supporting their students in taking a critical view of their society and taking environmental action towards more sustainable futures (Freire, 1998; Wals, 2019; Rajala et al., in press-b). Drawing on teacher interviews and observational fieldnotes, this study focuses on teacher's accounts of their environmental action projects in three Finnish Upper Secondary schools. The study asks: How does transformative teacher agency for environmentally sustainable futures manifest in Finnish Upper Secondary School teachers' work, if at all? What conditions and resources support or inhibit transformative teacher agency?

Theoretical framework

Prior research indicates that teacher agency is an important aspect of teacher professionalism, entailing teachers' negotiation of educational visions and meanings that give a long-term purpose to their work (Rajala & Kumpulainen, 2017; Toom et al., 2015). Teacher agency is related to organizational commitment, work satisfaction, and professional learning (Horn & Kane, 2015; Eteläpelto et al., 2015).

To account for teacher agency that addresses the environmental crisis, this study takes a sociocultural and transformative approach (Rajala et al., 2016; Gutiérrez & Calabrese Barton, 2015). Accordingly, human learning and agency are co-constructed by people, understood to be agentive actors of social practices, their own lives, identities, experiences, and common history (Stetsenko, 2017). Thus, agency refers to contributing to collaborative transformative practices, implicating a "sought-after future," and a commitment to realizing it.

Data sources and methods

Data were collected during the 2020-2022 academic years in three upper secondary schools in Southern Finland (two rural, one metropolitan). In the schools, teachers organized environmental education projects to engage students in climate actions. The data were collected for the duration of the school projects, informed by an ethnographic research approach (Hammersley & Atkinson, 2007). The primary data for this study are the interviews of four teachers and fieldnotes. Each teacher was interviewed multiple times throughout the project.

The interview data and observational fieldnotes were analyzed using an inductive qualitative analysis approach (Strauss & Corbin, 1997) based on open coding of excerpts that formed thematically coherent, continuous units of analysis. Guided by the two research questions, coding focused on manifestations of teacher agency as well as the resources and conditions that appeared to support or hamper teacher agency. The two data sets were compared to triangulate the data. Thematic analysis was used to identify patterns and synthesize the insights emerging from the open coding (Saldaña, 2011).

Results

The findings illuminate a rich variety of manifestations of teachers' transformative agency as they facilitated environmental actions of and with their students. The scope of environmental actions varied across school, municipality, and national levels. Examples of environmental actions included: promotion of vegetarian food in the school cafeteria (school level), experimenting with innovative forms of food production (school level), teaching younger students about the environmental crisis (municipal level), and winning an initiative in the city council (municipal level). The degree of radicality of the manifestations of the teachers' agency varied. Dominantly, the environmental actions were about individuals' actions for a sustainable environment. Many of them strived to create infrastructures for such individual actions. However, our analysis also illuminates rare, radical forms of teachers' transformative agency that involved questioning corporate power or fossil capitalism.

These findings also illuminate the conditions and resources that supported and inhibited specific forms of teacher agency. Supportive conditions and resources included teachers' personal networks and lives outside of work (e.g., local political activities, participation in social movements), support of colleagues and school leadership, and cooperation of students. Correspondingly, a lack of these conditions and resources created obstacles for teacher agency and over time made it harder for the teachers to pursue their commitments. Notably, the political climate and dominant values of the local setting appeared to be a central mediator of teacher agency.

Significance

This study highlights the importance of transformative forms of teacher agency as a mediator of educational responses to the environmental crisis. Profound changes are necessary at every level of society, as humanity is crossing planetary boundaries for biodiversity and climate change (Steffen et al., 2015). The findings of this study advance a nuanced understanding of transformative and even radical forms of teacher agency (e.g., Stetsenko, 2019), as well as the conditions and resources that mediate and sustain them in educational settings. These under-researched forms of agency are necessary for teachers whose professional commitments extend beyond the implementation of curriculum to world-building for sustainable futures with their students.

Paper 6: Capturing multiple levels of agency in teachers' workplace learning

Yeliz Günal Aggül & Ilana Horn

Researchers who study teacher agency from a sociocultural perspective largely agree about the reflexive relationship between individual agency and social structures (Biesta & Tedder, 2007; Edwards, 2017; Haapasaari et al., 2016). Yet they differ in conceptualizing it as an individual, collective, or relational phenomenon. We argue that these three levels should be examined separately and seen as complementary so that we can capture different aspects of teacher agency. To frame this conceptual discussion, we organize this paper around these questions: *How is teacher agency conceptualized, and what kinds of resources are at stake at each level? What are the implications for designing teacher learning environments?*

Individual level: Recognizing the influence of identities on teachers' agency

Some empirical studies focus on individuals acting in relation to their environments (Biesta & Tedder, 2007; Eteläpelto et al., 2013, 2015). In this perspective, teacher agency is shaped by teachers' professional identities, i.e., pedagogical ideals, knowledge, and competencies; work-related histories; future goals and motivations; and present engagements, all of which constitute resources for teachers as professionals to exercise agency in making decisions about their practices and improving their work (Biesta & Tedder, 2007; Eteläpelto et al., 2015; Priestley et al., 2012). At the same time, empirical findings reveal the significance of structural factors (e.g., support from school principals, school counselors, or colleagues; or a clear and robust professional discourse of teaching) in influencing individual teachers to continue exercising agency (Biesta et al., 2015; Eteläpelto et al., 2015). We maintain that a collective form of agency that goes beyond the individual level is needed to transform the constraining structures and create the conditions where individual teachers can sustain their agency. As Happasaari et al. (2016) highlight, "although initiated by individuals, agentive actions gain their meaning, their consequences, and their continuity in the interplay between individuals and their collective" (p. 235).

Collective level: Recognizing the community's role in making agency sustainable

The sociocultural teacher learning literature points to the importance of the resources created and owned by teacher communities in influencing teachers' understandings and changes in their classroom practices (Horn, 2005, 2010; Horn & Kane, 2015). Researchers who conceptualize agency as a collective phenomenon do not explicitly reject individuals' agency, but their analytical focus is on how collective agency emerges. They are interested in how communities create shared epistemic artifacts (e.g., Damşa et al., 2010) or transform their collective activity by engaging with the collectively unraveled problems of practice by envisioning new possibilities, employing resources to address them, and taking actions to design new patterns of activity (Haapasaari et al., 2016).

Conceptualizations of collective agency mostly focus on how groups create or transform *established practices and work cultures*. Teachers, on the other hand, need to engage in fluid forms of relations with other professionals to deal with the everchanging situations of their practice (Edwards, 2010). Drawing on Edwards' (2005) notion of *relational agency*, we move our focus from the collective level to the relational level to "understand how people are able to come together, however fleetingly, to interpret a problem and to respond to it" (p. 172).

Relational level: Dealing with the complexities of teaching via fluid forms of relations

Relational agency refers to the individual's capacity to act flexibly to address unpredictable aspects of their practice by engaging with different professionals working on the same problems of practice, taking others' perspectives, and making their own perspective visible to others in approaching it (Edwards, 2005, 2010). Relational agency differs from individual agency since the relational plane is where teachers and other professionals act agentically with resources that emerge only in interaction. Accordingly, Edwards (2010) suggests shifting attention from "discrete activity systems and how they change" to "emerging inter-professional practices and their capacity for knowledge generation" (p. 140-41). However, under "heavily boundaried systems" of schooling, teachers find limited opportunities to interact with others to respond to the challenging problems in their practices in a tailored way (Edwards, 2017). For instance, as Paper 3 in this symposium suggests, the lack of relationality in Veronica's school constrains her development of responsive practice to an unpredictable situation in her classroom.

Conclusion

We provided a conceptual lens to capture teacher agency at the individual, collective, and relational levels. We conclude that teachers' different professional identities are resources that influence their agency, and that teacher collectives and fluid forms of inter-professional engagement are key to achieving sustainable forms of agency and finding solutions to education's complex problems.

Abstract: This symposium advances walking methodologies, and the kinds of learning and research relations that emerge through walking, as a significant process for “road making” toward more equitable futures in the Learning Sciences. The papers gathered here highlight diverse forms of walking together: from cultural anthropological research (Lee & Ingold, 2006) to walking with and alongside community activists (Curnow, Davis, & Asher, 2018; Takeuchi & Aquino Ishihara, 2021), to walking as learning and coming to know with and from the land (Marin & Bang, 2018), to reimagining place from transnational perspectives (Adams, 2013), and wayfaring as figuring both science and identities (Rahm, Gonsalves, & Lachaîne, 2022). Through dialogue within and across papers, we emphasize the ways in which walking methodologies make visible materiality and relations with the more-than-human world (Marin, 2020), as well as effects and experiences of inequity, with attention to co-constructing caring and equitable relations through shared walking.

Overall focus of the symposium

Background

The field of the Learning Sciences is in the midst of developing broader understandings of central concepts—including transdisciplinarity, design, cognition, technology (Shanahan, Kim, Takeuchi, Koh, Preciado-Babb, & Sengupta, 2022) (1). Situated on the land that is now called as “Canada,” we have been acknowledging the ongoing figuring and refiguring of the field of the Learning Sciences as a pivotal process enabling the field to learn and grow from historically silenced perspectives while moving toward an equity- and social justice-oriented ethos (Takeuchi, Vadeboncoeur, Krishnamoorthy, Hladik, Rahm, Kim, & Clark, 2022). Given the location where the International Society of the Learning Sciences conference will take place, we cannot ignore the histories of settler colonialism (Bang, 2020) and racial inequity that manifests in and through the phenomenon of learning. Where the conference is to be held, Quebec, is also the place where Joyce Echaquan, an Indigenous woman, was verbally abused and died while awaiting care in a hospital. It is in Quebec that six Muslim men were fatally shot in a mosque due to Islamophobia. Our symposium is grounded in our commitment to reconsider and reimagine our learning research and scholarship in ways that take into account and respond to these events seriously.

As one way to advance our commitment, we attend to the seemingly mundane act of walking. Walking together is “a social practice and method for knowledge building” (Marin, 2020, p. 9), as well as a practice of joint road-making, of making our way as we go (Horton & Freire, 1990, p. 6). Walking methodologies include diverse forms of walking together—from those incorporated into cultural anthropological research (Lee & Ingold, 2006) to walking with and alongside community activists (Curnow, Davis, & Asher, 2018; Takeuchi & Aquino Ishihara, 2021) to walking as learning and coming to know with and from the land (Marin & Bang, 2018), reimagining a place from transnational perspectives (Adams, 2013), and wayfaring as figuring both science and identities (Rahm, Gonsalves, & Lachaîne, 2022). There are likely other ways to walk with and alongside community members, to learn from and with them about racialized, gendered, and cisheteronormative practices through walking, and to begin to re-make the worlds we live in through generative interactions that create new ways of attending and seeing with, of becoming together, and of making change. Our research holds space to move beyond walking as a tool, or a means to an end, to advance possibilities for walking as a way of re-centering "bodies-in-motion as well as lands/waters" (Marin, 2020, p. 4) in learning theory, practice, and research. We also see a possibility of learning as being "embodied" and "emplaced" (Takeuchi & Aquino Ishihara, 2021), as a practice of walking toward justice in a material world that is "always already" a living ecosystem. As Lee and Ingold (2006) described, "walking itself can consequently become a practice of understanding, so that the record of the walk, and of the experience it affords, is just as important—and just as valid a source of field material—as the record of the 'discourse' that might have accompanied it" (p. 83). Our purpose in this symposium is to describe and inquire into our own research into learning, which incorporates different forms of walking methodologies located in various places within "Canada," in order to highlight both lessons learned and next steps as we continue to work toward advancing racial equity.

This kind of research requires attending and seeing with each other, in significant ways. Ingold's (2014) notion of attending is based upon the idea of entering into the unknown in our encounters with others. For example, it is worthwhile to attend to what is unfolding, including affects and ordinary encounters (Blaise, Hamm & Iorio, 2017; Taylor, 2020; Taylor, Blaise, & Giugni, 2013), matter and materials (Osgood & Andersen, 2019; Rautio, 2013, 2014), and more-than-human relations (Marin & Bang, 2018; Marin, 2020; Nxumalo & Pacini-Ketchabaw, 2017; Taylor & Pacini-Ketchabaw, 2017). One intention of our work is to decenter the person, or perhaps better said, to attend to what research on persons has previously made invisible, including material worlds and ecosystems and the material effects of racialization, as well as how these components affect or contribute to inequitable conditions for racialized people. Evoking Horton and Kraftl's (2006) invitation to attend to "what else" matters in research, we include bodies, places and spaces, affects, trees, sidewalks, material objects and other "minor actors" (Taylor, 2020) to better understand how what matters makes new horizons visible.

Attending more closely to what matters, and the matter(s) with which we are engaged, enables learning from and with participants and community members, and it also requires becoming affected by our experiences walking together with and alongside. Drawing an analogy to MacLure's (2016) work with children, we note that perhaps participants and researchers "are caught up in events that move at different speeds and are sometimes imperceptible to one another" (p. 180). From the perspective of the researcher, the activity may be ordered and regimented given typical research requirements, while the pace in which the life of the participant unfolds may be interrupted by research. These differences may remain "below the threshold of visibility set by the categorizing gaze that already 'knows' what is and is not significant" (p. 8). Concepts like attunement (Blackman, 2012; Stewart, 2011; Vossoughi, Jackson, Chen, Roldan, & Escudé, 2020), correspondence (Ingold, 2017), and passionate immersion (Tsing, 2010) in the lives of participants, "among other things," may enable researchers and participants to walk together during fieldwork in ways that advance understanding and contribute to social and ecological justice.

Innovative ways of attending, seeing, and becoming—both in research methodologies and when working toward changing larger ecosystems—require changes to research relationships, roles and responsibilities, what counts as learning, and how what is learned is utilized, by whom, and under what conditions. Walking methodologies expose the taken-for-granted in traditional research relationships by changing the balance of power between participants and inquiring into various kinds of power, their limits and limitations. Both highly visible actors in research and "minor actors" contribute in significant ways to the creation of "meaningful places" inside educational institutions (Panina-Beard & Vadeboncoeur, 2022), as well as "place attachment" (Scannell & Gifford, 2010). A logic-of-inquiry that advances research as attending, witnessing, walking, and storying with and alongside participants impacted by inequity offers opportunities to make visible the effects and experiences of racial inequities at a time in Canadian and world history when moving toward reconciliation and racial equity is urgently needed.

Symposium format

As a collective of scholars, and part of the leadership team for the Network of the Learning Sciences in Canada (https://www.canadianlearningsciences.ca), we believe in Open Access and equitable knowledge exchanges that can be achieved through a hybrid format. We are aligned with the vision set out by the International Society of the Learning Sciences, while also amplifying voices and context-specific, place-based scholarship from the geopolitical margins. While we embrace transnational scholarship reflecting the histories of immigration and refuge in Canadian society, and we use "Canada" in our Network to reflect our organizing efforts to foster equity-oriented scholarship of the learning sciences to include non-American contexts, we also acknowledge the colonial histories that the national marker, "Canada," carries. We know that the place we share was first called Turtle Island and as a collective, we commit to reflect on Canada's colonial past, learn from emerging truths, and act toward reconciliation with, and the resurgence of Indigenous communities.

To be aligned with our vision, we aim for this symposium to be a space for inter-university and inter-generational dialogues. We invited faculty members, postdoctoral scholars, and students as well as our community partners (where it is appropriate). In addition to the place-bounded symposium to take place in Montreal, we will create a virtual meeting room where the participants can join our symposium virtually. We will also invite the participants to continue dialogues with an asynchronous, online discussion board. The Network has been experimenting with alternative formats, learning from conferences, and creating our own Invited Learning Symposia throughout the year. During the COVID-19 pandemic, we have learned many things, including the value of holding online conferences. With an online option, we may be able to meet some of our shared goals; for example, we can reduce barriers for participation and our collective environmental "footprint." For this reason, while we honor the participants who wish for in-person interactions achieved through face-to-face conference, we will also mobilize our collective knowledge for virtual conferences to run an effective hybrid session.

The total length of this symposium will be for 75 minutes. Our symposium will start with a five-minute summary from co-chairs to frame the session (Vadeboncoeur, Takeuchi, Rahm). Then, four papers will be presented for 12 minutes each. The Discussant (Marin) will be invited to thread ideas across the papers for ten minutes, highlighting generative differences as well. A virtual discussion board (Padlet) will be used to facilitate online discussion throughout the symposium. During this time, our symposium will be made available virtually for the ISLS participants who decided to participate remotely. We will conclude with a reflection and discussion with the audience, which will happen both in the conference room in Montreal and in the virtual room. Co-chairs will divide the task of moderating discussion both in-person and online.

Paper 1: We make the road by walking: Toward abolitionist research methodologies

Joe Curnow & Abolitionist Futures Collective

Over the last years we have seen a groundswell of abolitionist organizing around the world, calling for anti-racist interventions to defund, disarm, and abolish police and prisons. Abolitionism is a social movement and political ideal that not only calls for the abolition of the carceral state (Gottschalk, 2015), including prisons, police, child welfare, and other racialized and colonial systems of surveillance and punishment, but, more affirmatively, for building a world in which community-led, life sustaining services prevent the harms that these violent systems claim to respond to, but often exacerbate (Davis, 2011; Gilmore, 2007). The abolition of policing and prisons is often critiqued as an unrealistic or utopian dream. To imagine a world without police and prisons requires a radical shift; such imagination is a collaborative learning accomplishment that enables abolitionists to engage in their practice. How then do we shift what is considered possible, and what people imagine justice could look like? This research asks how abolitionist organizers learn to facilitate for expanding abolitionist imaginaries and future-making.

This work takes place in Winnipeg, a city in central Canada, 60 km from the geographic centre of the continent. While much is made about Winnipeg being at the heart of Canada, the fact that Winnipeg is widely referred to as the most racist city in Canada reveals some greater truth about what lays at the heart of Canadian society. Winnipeg's racism, in part, stems from its long history of Indigenous dispossession and settler colonial violence (Toews, 2018). In the last decades, this has manifested through dramatic increases in policing, imprisonment, and child welfare apprehensions (Dobchuk-Land, 2017). More recently, we have seen a proliferation of policing in everything from public libraries to grocery stores, justified through thinly veiled racialized language around the threat that Indigenous people pose. These shifts have not gone uncontested—a coalition of organizers from different communities have come together to fight for a vision of Winnipeg wherein mutual aid and investment in communities might create antiracist and anticolonial paths to community safety that do not rely on the harmful practices of policing, prisons, and family separation. As elsewhere, this coalition has struggled against mainstream attitudes that seemingly cannot imagine a city without police, or where safety means anything other than the securitization, surveillance, and foreclosure of public space.

This presentation builds from work in the learning sciences which attends to the political and ethical dimensions of learning (Politics of Learning Writing Collective, 2017; Vea, 2019), as well as learning in social movements (Takeuchi & Aquino Ishihara, 2021; Tivaringe & Kirshner, 2021; Uttamchandani, 2021). Over the last decade, this work has laid critical foundations within sociocultural studies of learning that emphasize the impossibility of neutrality (McKinney de Royston & Sengupta-Irving, 2019; Philip & Sengupta, 2021), the necessity of political struggle (Curnow & Jurow, 2021), and the importance of using the learning sciences toward more equitable futures (Booker et al., 2014; Politics of Learning Writing Collective, 2017).

This paper considers what an abolitionist methodology would look like, feel like, and prefigure. First, we describe our collective and the principles which underpin our collaboration. Second, we argue that work toward abolition requires a commitment to "slow justice" (Neville & Martin, 2022), which we exemplify through a participatory action research design that has centred relationship building, meal-sharing, skill-building, and mutual aid. We argue that walking is a key piece of our relationship building strategy during COVID-19, in that shared walks have created space for one on ones, strategic planning, and interpersonal check-ins in the face of otherwise isolating conditions. Some of these meetings are in our neighbourhoods, while many are at the rallies, protests, critical masses, and community meetings our comrades have organized. Walking, in this sense, is also a collective action, a solidarity-building exercise, and an intergenerational opportunity to build relationships and power simultaneously.

For the learning sciences, attention to an abolitionist methodology brings a politicized perspective and walking methodology to work on participatory design and reorients us toward world-building as an expression of political and ethical investments in the field. This extends the emerging work on walking methodologies (Marin & Bang, 2018) and learning on the move, and draws out the connections between these methodologies (Taylor, 2020) and the radical world building they can prefigure.

Paper 2: Walking together to heal: Anti-colonial relationality in learning with the land

Miwa A. Takeuchi, Kori Czuy, Anita Chowdhury, Mahati Kopparla, & Sophia Thraya

Walking can simultaneously be methodology, pedagogy, and learning that weave in multiple intergenerational stories and knowings of the land (Hermes, Engman, Meixi, & McKenzie, 2022; Marin & Bang, 2018). This sensitivity to walking is rooted in Indigenous epistemology that centers whole body knowing grounded in "relationality—relationships with humans, more-than-humans, lands/waters, and mobility" (Marin, 2020, p. 281). For communities impacted by forced displacement and detachment from their homelands, resurgence of this relationality is a form of resistance to the destruction of the land and intergenerational knowledge (Betasamosake Simpson, 2014). For us, the act of walking *together* on the land, with people who sought refuge in "Canada" from war is a political collective action (Curnow & Jurow, 2021) that moves us toward healing. We view healing not as an individual act, but rather a political act achieved through "designing resilient ecologies" (Gutiérrez, 2016, p. 187). In this paper, we present the portraits of transdisciplinary learning that emerge through our collective action of walking together, toward healing from intersectional systems of oppression (Combahee River Collective, 1974) that affect both our participants and us as researchers. Our collective action to challenge intersectional systems of oppression is entangled with healing of the land who was damaged by the displacement of Indigenous communities who passed down intergenerational knowledge to live with the land and whose ecology was destroyed due to factory and road building in urban development.

We draw from participatory social design research methodology (Gutiérrez & Jurow, 2016), which centers historicity, diversity, equity, and ecological resilience as design principles, and aims to co-design just practices and futures in partnership with a range of communities. Our collaborative design aimed to re-center embodied and emplaced knowing for refugee children who come from traditional agricultural backgrounds, and whose intergenerational knowledge is often dismissed and disregarded in dominant school settings. By centering this community knowledge of soil, ecosystems, and socio-environmental justice, our design aims to leverage the valuable insights and expertise that refugee and immigrant communities offer. The designed program, called "Soil Camp" (https://www.soilcamp.ca), was held on a 30-acre community urban farm, that served as a space for refugee and immigrant communities to engage in local and sustainable agriculture with visions for decolonization and reconciliation with Indigenous communities (cf. Call 93 of the *Truth and Reconciliation Commissions of Canada: Calls to Action*).

Since the year of 2020, 85 refugee children have joined our program. 18 teachers and teacher candidates, mainly racialized multilinguals, joined us as facilitators. We as a team of researchers collected the following datasets: 1) video data, including Handycam video cameras and Go Pro cameras (worn also by teacher facilitators and children), 2) "life notes" (Dillard, 2000, p. 661) taken voluntarily by us and the facilitators, and 3) art works, makings, and journals made by children.

In our presentation, we draw on both the Go Pro camera video footage of us walking *together*, and our life notes to provide a glimpse into the transdisciplinary learning that occurred as we pursued our collective hopes for healing. Our analysis was conducted collaboratively, guided by our life notes which embody "the meaning and reflections that consciously attend to a whole life as it is embedded in sociocultural contexts and communities of affinity" (Dillard, 2000, p. 664). Through this work, we present instances of our shared learning, such as when we developed shared understanding of number line and scale in the context of colonial histories of the land, which paralleled the refugee children's experiences of colonization and displacement. We also depict our shared learning when the Western notion of pesticide and medicine was questioned during a walk that was shared between a Blackfoot facilitator, refugee children, and ourselves.

These portraits of learning collectively challenge apolitical views of walking, as our collective action of walking is fundamentally aimed at challenging the socio-environmental injustices that have long constrained the emergence and exchange of embodied and emplaced knowings connected to the land. Through our shared experience of walking together, we hope to mobilize land-based transdisciplinary learning toward socio-environmental healing.

Paper 3: Youth co-created photographic journeys that speak to more-than-human relations with nature, mobilities, and future oriented entanglements in the making

Jrène Rahm

In this paper, I explore human-material-nature relations by tuning into two visual co-created data sets that emerged from joint work with youth in science clubs that I ran over time in collaboration with a community organization in the first case (ArtsScience from 2010-2013), and a high school in the second case (ScienceClub from 2015-2017). I assume that more-than-human relations are central to and constitute learning and development (Marin, 2020). By attending to nature-culture relations, I aim to "recover how relations and systems of meaning making between the natural world and cultural worlds" (p. 37) are articulated and lived by groups of urban youth who participated in the club activities. I ask, 1) what relations and storylines do the photographs taken by the youth speak to and center? and 2) how do they shift our gaze and understanding toward heterogeneity, multiplicity, and profusion as radically generative for educational research (Taylor, 2016)? I center entanglements of learning and becoming while also attending to the "multiplicity of identity, the mobility of meaning, and the contestability of knowledge" (p. 7). I am guided by Massey's (2005) definition of space as "stories-so-far" and as essentially unfinished, yet telling of "interconnections between the past, present, and future" (Marin, 2020, p. 38). These ideas position place-based youth-initiated photography projects as stories still in the making, marked by interrelations and coexisting heterogeneity, and continuously reconfigured in light of new imaginaries and possible futures. Stories that speak to mobility, yet also place-making, and embodied perspectives of learning and becoming in and through re-awakened relations with nature and "worlding."

The visual data sets I rely on in this paper were endorsed as an imaginary of being methodologically in the mesh (Ingold, 2011), engaging with the here and then, while also attending to the emergent (Taylor, 2016). The positioning of myself within the complex meshwork of the two data sets made visible the hidden while it permitted me to become attuned to more-than-human-relations and to be affected by the experiences I draw from and that emerged from walking with youth over time. In the first case, we physically walked with youth back and forth from their community to a summer camp in robotics and video game development led by an Engineering School. In the second case, we jointly walked to and within a summer gardening programing organized by the local Botanical Garden where youth were assisting educators of summer camps. Analysis was pursued by attending to the storylines captured by the photos and reflected upon in fieldnotes and journals that centered youth voice. Analysis was possible through reflexivity, remembering, and reawakening our joint walkings.

The first case engages with science and human-nature relations that youth captured on their way to camp and in their maker activities. Photographic journeys seemed to speak to the remaking of relations with more-than-humans, whereas the maker projects seemed to undermine the kinds of material-body entanglements the former supported. This case also offers a glimpse of how affect and sensations drive the taking and sharing of visuals of surroundings. It is a form of multispecies mapping that mediates the rebuilding of relationships with place, space, history and land and questions Eurocentric visions of science and becoming in science. The second case speaks to youths' rebuilding of relations with nature and place, entangled with materials they previously never noticed or engaged with in the manner the camp suggested. Youth became immersed in nature as they walked the botanical garden with the campers and through engagement in creative eco-art projects and working the soil, taking care of youth gardens and crops, and essentially by contributing to the common good —the well-being of self, nature and others within that community—all of which they captured through photography.

I conclude with implications including that visuals and walking methodologies are key tools to center bodies in motion, interrelations between bodies and nature, and socio-material configurations. They also offer rich insights into future oriented entanglements in the making.

Paper 4: Walking alongside/towards desire: Re-thinking and theorizing through a desire-based lens

Sarah El Halwany, Rachael Edino, Sophia Marlow, Nadia Qureshi, Kristen Schaffer, Kristal Turner, & Jennifer D. Adams

Often, there is a tendency in research practices to focus on supposed needs and problems faced by racialized students in postsecondary education in an effort to mitigate experiences of marginalization and discrimination. Tuck (2009) argues that this kind of research unintentionally runs the risk of pathologizing communities, reinforcing a one-dimensional view of people. Tuck distinguishes between damage-centered research and desire-based research and calls for moving research towards crafting theories of change rather than damage (Nxumalo & Tuck, 2022). Inspired by Eve Tuck's proposition, Leitão (2020) draws a parallel between needs-based research used by social designers and damage-centered research to argue how they both reproduce a model of life, whereby "what is 'desirable' is supposedly known from the start and/or externally defined" (Leitão, 2020, p. 2). Moreover, what's desirable continues to be approached through "band-aid solutions." This forecloses the creation of new possibilities and ways of world-making—where multiple centres can flourish, i.e., Pluriverse—while being driven by the desires of the communities with whom we engage.

As researchers in the Creativity, Equity and STEM lab we have been longing to be in different relationships with data. The #BlackLivesMatter movement raised awareness in Canada about racial inequities in society and specifically, education. As such, our team was mobilized to learn about the experiences of racialized students in postsecondary STEM in order to enact change. We became attuned to notions of desire while reading Eve Tuck's work alongside other authors whose scholarship re-center desire as a productive and agentic force (Tuck, 2010) that is often neglected and/or relegated to the erotic/private (i.e., McKittrick, 2020; Zembylas, 2007).

In our presentation, we seek to reclaim desire, as an embodied force that moves us (metaphorically speaking) to craft new desirable worlds with our participants. We attempt to act on those desires by caring with our participants, rather than caring for them (Tronto, 1993). Caring for, in this context, sets the participants in a relation of indebtedness, claiming that they need our empathy and our externally defined solutions. On the other hand, *caring with* our participants compels us to center their own desires, in ways that can transform the world by claiming their dignity and humanness. In this way, we see desire as a *movement* that needs our special attention and care to design for a "pluriverse world" (Leitão, 2020). Often social design (e.g., research and pedagogical design) is limited to problem-solving, similar to a running race, directed by its finish line (Leitão, 2020; Nxumalo & Tuck, 2022). Instead, we view designing with desire as a point of departure for the researcher, where the research path is necessarily open and unpredictable, with the collective yearnings of the different stakeholders and the complex tensions that will necessarily arise along the way (Leitão, 2020).

We discuss how we are re-interpreting some of the data using a desire-based lens, positing creative and aesthetic analyses that attend to desire as an assemblage (Barlott & Turpin, 2022), gathering affirming ways of living and being. Those affirming ways of being entangle the quotidian with the structural. We join others who call for "befriending our desires" as a methodological commitment for "walking the talk" of allowing us to envision, new alternative, oppositional acts (hooks, 2014) of designing for equitable, just, and empowering STEM educational environments.

Endnotes

(1) Author Note: We are intentionally resisting the APA 7th style that requires us to erase co-authors in in-text citations. This practice not only hinders communicating the sense of collaboration and co-authoring, but also makes invisible/erases the presence of co-authors in text, even when they contribute substantively. We are also concerned that the author order could be, in some cases, a manifestation of hierarchies and power negotiations and, instead, would like to recognize the collective contributions of all authors. Therefore, we are citing all the co-authors in in-text citations.

Abstract: To center critical youth research methodologies of praxis and care in post-pandemic times, we bring together youth and researchers from four different partnership projects. Through dialogue circles with and between youth, we desettle taken-for-granted perspectives on research in the Learning Sciences. We ask: 1) How does engagement in co-creation and partnership projects offer all partners opportunities to reimagine research in education, a re-envisioning of it as humanizing and grounded in respectful relations ? ; 2) What does it look and feel like at the beginning, when relations are established, and later, as they are maintained through joint work and critical reflections about learning, teaching, and becoming? ; and 3) How does such joint-work support new future imaginaries for humanizing learning opportunities and meaningful joint research? A co-creation project will be pursued simultaneously, mediated by a local artist and further enriched by the discussant, leaving traces of the exchanges and shared with the larger community.

Symposium overview

The goal of this innovative symposium is to challenge taken-for-granted perspectives in research by centering youth voices, dreams, and future imaginings in the Learning Sciences. We come to this challenge as educators, learning scientists, anthropologists of education and artists, representing multiple disciplinary and social locations. Together we aim to unpack dominant research methodologies by engaging with youth and young adults from long-term partnerships with community organizations and joint social design studies in unique places across the globe. These partnerships and relationships are deeply grounded in respectful relations with one another, in ways that informed our understanding of learning *together*. As noted by Nasir et al. (2021), not only our understanding of learning calls for an interdisciplinary approach, but the research methods we draw on also need to come from across disciplines. In their words, it is “critical that this future research takes seriously the goal of creating experiences of learning that are liberatory, and which traverse current boundaries and limitations imposed by deficit assumptions and attendant research frames and methods" (Nasir et al., 2021, p.562).

Conceptual framework: Learning and unlearning together

By purposefully changing the presenter format in this symposium, we aim to respond to such calls and desettle taken-for-granted perspectives, and center conversations with and between youth across the globe to highlight imaginaries of just and empowered futurescapes with youth. However, we acknowledge that such work is not easy, and requires a dialogue of care, paying attention to "who we are in conversation with" when imagining and pursuing humanizing, decolonial and transformative joint research projects and community partnerships (Ali & McCarty, 2020). As noted by Takeuchi and colleagues (2023), "refiguring and transforming these histories in the present requires many forms of inquiry, including inquiries into our scholarship as well" (p. 255). It is the latter that is at the center of this session.

We contend that the bringing together of youth organizations and youth for a dialogue across differences and shared strengths is a beginning in the right direction towards "weaving an otherwise." We understand learning and unlearning as "learning together" and imagine creative qualitative methodologies as powerful tools to grapple with and in light of it to then better "align research with our heart, values, visions and hopes" (Tachine & Nicolazzo, 2022, p. 2), which we understand as the crux of joint and ongoing meaning-making in the Learning Sciences. The pandemic made rather clear that times are changing, that none of us can ignore any longer the manner our lives and stories are entangled with the sociopolitical fabric and realities of injustices around us. That reality pushed many of us to more deeply engage with research methodologies, our positionings, and our axiologies, and in doing so reimagine research designs where "human connections are central to, rather than stripped from it" (Tachine & Nicolazzo, 2022, p. 6). As we engage in rethinking and unpacking our dominant methodologies, we will also engage in re-envisioning them from political ontologies of pluriverse whose basis is rooted in care and mutual connection that have been discounted in conventional research (Authors, 2022). Engaging in such methodologies help us envision research as an enactment of knowing-in-being that emerges in the event of doing research itself" (Taylor, 2016, p. 18), as we bring together youth from different community organizations. We aim to re-imagine an otherwise together. Building on the notion of critical response-ability, the idea is that we need spaces where everyone's voices and responses could be heard, validated, and taken as points of action. In doing so, we aim to imagine the "looks" of future partnerships that bring forth values of care, mutual well-being, respect, trust, and relationality. We understand that simply supporting youth is not enough. Instead, we have to put into action re-humanizing policies, practices, and measures that celebrate the full humanity of youth. These practice essentially become about "the cultivation of collective knowing, desiring, being and making-with so that we render each other capable" (Murris & Bozalek, 2019, p. 11).

Format

We propose an innovative symposia format, including a hybrid session during the ISLS annual meeting (in-person dialogue mixed with participants joining in through ZOOM), centering deep engagement with reflexivity, responsibility, and relationships by engaging youth from four community programs and ongoing joint research in a conversation. While interested in a dialogue among youth from across the globe, we begin such a dialogue in this session by bringing youth together from the meeting location with others who will join in from other locations.

To build trusting relations among the participating groups and youth, two dialogue sessions will be organized prior to the meeting during which we will get to know each other and exchange ideas about what themes should drive the session (two one-hour ZOOM sessions in April and May 2023 in anticipation of the meeting). The three dialogue circles we currently imagine for the actual symposia are organized around the following broad questions which will be further refined by the overall team during our online meetings prior to the symposium: 1) How does engagement in co-creation and partnership projects offer all partners opportunities to reimagine research in education, a re-envisioning of it as humanizing and grounded in respectful relations (Argenal, 2022)? ; 2) What does it look and feel like at the beginning, when relations are established, and later, as they are maintained through joint work and critical reflections about learning, teaching, and becoming?; and 3) How does such joint-work support new future imaginaries for humanizing learning opportunities and meaningful joint research? These questions will also be taken up in a co-creation project mediated by a local artist that will happen at the same time as we dialogue together. The artist will summarize ideas the youth raise, while all youth participants physically present will be encouraged to add a personal touch to the mural during or immediately following the actual presentation. The discussant's comments will also be taken up in the mural. Following the session, the art project will be exhibited on the ICLS website and on the meeting grounds.

The conference symposium session will have the following agenda: A brief introduction (3 minutes), followed by three dialogue circles focusing on the questions raised above (15 minutes each/45 minutes). Note that the dialogue circles will be deliberately constructed and facilitated to have participation from in-person *and* remote participants. The first dialogue circle of 15 minutes will imply a brief presentation of the youth program by youth as well. The discussant will then highlight some ideas the mural and youth focused on (12 minutes), followed by an invitation of the larger audience to comment and contribute to the co-creation of the mural and dialogue (last 15 minutes of session).

Description of each project

Each project description below offers a glimpse of the youth voice driven partnership project that the participating teams have been engaged in. Each team also responds to one of the three questions and themes the symposium raises in its description. As suggested by the title, while we aim to center critical youth research methodologies of praxis and care in post-pandemic times, we also have to do so through the creation of communities like the one we aim to create in this session, that are deeply grounded in respectful relations and true dialogue. Only this way are truly empowering and new imaginaries possible. The joint project with an artist and comments by the discussant will ensure that youths' voices are heard, and their brilliance centered. Our invited discussant also brings much experience to such work and will be a further key actor in supporting the creation and maintenance of a safe environment where youth feel free to speak up and where their ideas will be captured in and through artistic expressions. Through engagement with questions intended to decolonise research methods and conference practices, we aim to name together both the transformative potential yet also challenges and limitations of critical youth research methodologies in praxis, as well as arts-based methods (Seppälä, Sarantou, & Miettinen, 2021). And as the descriptions of pertinent themes by each of the participating team and partnership make evident below, pluralism, mulivocality, and dialogue in research unify the different partners, resulting in important critiques yet also new imaginaries of possibilities. Research is about power, yet through deep self-reflection and unlearning, practices can be jointly remade, as this session aims to make evident.

Youth curation in the museum: The Viviendo Aquí Project

Kristina Stamatis, Jose Rogelio Manriquez Hernandez, Tupak Barrios Palacios Luna, & Atzin Rene Luna

Context & setting

The Museum (Muse) is a small local history museum located in the foothills of a small U.S. mountain-west city. The Muse Teen Corps program takes place during the school year. At the start of each season, museum personnel recruit youth from schools around the city and engage them in different aspects of exhibit planning. Youth typically collaborate with museum personnel to learn about the museum and its collection and to participate in different projects based on the Muse's curation efforts. During the 2020 – 2021 school year, in the middle of the COVID-19 pandemic, Muse staff collaborated with two local university researchers to develop and examine programming toward youth curation of museum exhibits. This collaboration grew into the *Viviendo Aquí* project, a museum exhibit designed by Latinx youth in which an undergraduate student and three lead members of the Teen Corps designed and curated an exhibit that drew contributions from 39 Latinx teens across the city. The exhibit was designed around the question: How do Latinx teens represent their lives and their cultures in our city? The teens, all of whom self-identified as Latinx, participated in twelve weeks of programming, designing their exhibit through activities that took place weekly. The exhibit was displayed in the spring of 2021 and drew more than 1,500 visitors.

Methods and analysis

This project was informed by theories of youth participatory action research (Fine, 2008) and community-based design research (Bang & Vossoughi, 2016). In this project, a team of researchers and participants gathered to engage in iterative cycles of design (Condliffe et al., 2020) to create a museum exhibit that would restory the museum toward participants' experiences (Stornaiuolo & Thomas, 2018). Participants include Jose, a Chicano male undergraduate research assistant, Tupak, a Mexican male student who was in tenth grade at the time of the project, and Atzin, a Mexican female student who was in ninth grade at the time of the project. This was Jose's first research project with the Teen Corps, and he acted as both a participant and researcher on the project, leading the design activities and supporting the analysis. He continues to collaborate on the research that resulted from the exhibit. Tupak and Atzin are siblings who immigrated to the United States from Mexico with their brother and mother. They each have been involved with the Muse since 2016 when they immigrated to the city. "Our mom wanted to make sure we were involved with the community," Atzin explained when she reflected on their participation with the Teen Corps. As the participants with the most experience in museum exhibit development, Atzin and Tupak acted as the lead designers, helping to create activities with which their peers would engage. Atzin and Tupak continue to be engaged in the Teen Corps.

Findings & implications

Our preliminary reflections aligned with the questions posed for this session and focused on the notion of projects that reimagine who is centered in research and how that research is interpreted toward more humanizing ends. When asked how our collaboration in the *Viviendo Aquí* project supported them to imagine new possibilities for the museum, Jose reminded us that the exhibit they created was not just about the youth and their stories, but about their families and those who had come before them. For example, when asked about a story that described his life in our city, Tupak spoke about his mom. “We think about social justice because my mom. In Mexico, my mom and I would go to the nearby town and help Indigenous women. They helped us too. Social justice is important to me because of my family.” Atzin agreed, explaining, “Our mom helps us understand that connecting to family means also connecting to our values and to social justice.” When asked to explain what social justice meant to them, Atzin explained, “It’s something that brings us together…fighting for rights, it’s part of our culture and our family ties.” When we consider the ways that joint-work might support new future imaginaries for humanizing learning opportunities, these young people remind us that collaboration and joint-research must not only attend to the needs of partners in the interactions we share, but also to the ways that cultures and traditions have shaped these interactions across generations and political geographies.

Rethinking notions of care and dignity in the context of STEM: Through the voices of junior youth researchers

Shakhnoza Kayumova, Akira Harper, Esmeralda Bereavalez, Feyza Achilova, & Gianna Richards

The context and setting

The youth experiences and voices draw from a longitudinal research program titled, *STEAM Your Way to College*, aimed at understanding the intersection between language-based racialization and science identity development among multilingual youth from nondominant communities. Youth participated in a 2-week all-day summer program engaging in STEM projects tackling sustainability issues in the community. The overall goal of the program was to understand what it means to dismantle deficit-based discourses rooted in raciolinguistic ideologies by positioning multilingual youth in asset-based terms and subsequently equipping youth with research-based tools to re-position themselves as cognitively advantaged. Within the program, we drew on theories of pluriverse and positioning theories to co-design asset-based learning spaces in which the students, teachers, and researchers were positioned as co-authors, co-researchers, and co-creators of knowledge (Kayumova & Dou, 2022; Kayumova & Tippins, 2021).

Methods/analysis

The three girls started in the program 4-5 years ago respectively. They have been positioned as co-researchers, mentors, and junior researchers over the years. In this study, we will provide cases of creatively power research inquiries that youth engaged in around issues of care and humanization in the context of STEM education. Youth researchers took up creative methods of “shared experience” through songwriting, journalistic interviews, sharing favorite music, and drawing to engage in dialogues about their raciolinguistic experiences and meanings of care and humanization as the basis for transforming dominant STEM spaces and expanding what it means to be a STEM person.

Findings & implications

Our results with the youth over time speak to the manner joint-work can support new future imaginaries for humanizing learning opportunities and meaningful joint research. Our research shows that multilingual youth who experienced raciolinguistic ideologies coped with them through the support of their family, friends, and community – a theme this team will speak to. As one of the youth described their dignity-denying experiences in schools and wider society due to their language difference, “[w]e don't have the full rights and [we] don't speak English, as [our] first language and because of that, they find that offensive to them like ‘That's disrespectful, go away.’ For them, to be a true American, we have to know English and if you don't know English, you're not American.” Their social imaginations and hopes for the future were driving forces in their resilience toward racialized experiences. Despite their experiences of marginalization, the youth collectively held on to ideas of care and collective well-being. “I would like to do seminars for kids that are like me now, when I'm in the future… So, I can create a good environment where they can be who they are no matter what and tell them to fight for their dreams, don't give up, and to embrace who they are, no matter if they have accents, no matter if they don't speak English fluently, but they will always be smart and capable of doing great things, no matter what people say." However, the youth were not willing to open up and eagerly share their experiences with adults and teachers. They did not share their perspective as readily as it is suggested in the research. It was when the youth took on the roles and positions of junior researchers and created spaces of inquiry through "shared experiences" the youth and adults began to open up. The youth created songs and videos about what it means to be a caring person in STEM, and they used community wealth posters to illustrate diverse ways of showcasing caring relations. In light of this special session, the work of this team makes evident that not only data and research findings are important but how the research is done. As we will share based on our experiences in this partnership, creative approaches to inquiry and research developed with, and alongside youth, can help develop more response-able relations with youth, accounting for interconnectedness, dignity, and caring relations that stand in contrast to dominant unidirectional, hierarchical, and neutral ones.

Affective solidarity in design-based research

Christian Ehret, Emily Mannard, Karl André St. Victor, & Christian Degenais Rogers

Context

The Côte-des-Neiges (CdN) borough of Montréal is amongst the most culturally diverse in Canada, with over half of its population comprised of immigrants from beyond North America. This paper reports findings from a youth-led project embedded within a multi-year, community-based design research project (cite) at Chalet Kent (CK), a CdN community center. CK serves youth ages 11-17, many of whom are racialized, and who represent the borough's broad diversity of languages and cultures. The larger project has been ongoing for five years, straddling the 2020 global pandemic, and has focused on developing opportunities for CdN youth to learn industry-relevant practices in videogaming, including in esports, game design, and livestreaming. The subproject's goal was to explore how CdN youths' diverse histories of 'low'-tech physical activities, movement cultures (e.g., basketball; freestyle break dance) and related affective practices (e.g., team building; affective intensities produced and shared through dance) were assets for learning 'high'-tech practices, specifically livestreaming and esports. Analysis foregrounds how youth themselves understand their diverse experiences and feelings of learning in 'low'-tech movement cultures as integral to 'high'-tech learning. Through the concept of 'vibes,' they further describe how these experiences and feelings contributed to the research collective's stance toward antiracist, asset-based solidarity-driven codesign.

Feeling the vibes as affective solidarity in design-based research

Through this subproject, the research collective (center youth workers, university researchers, and youth-researchers together) developed concepts of affective dissonance and affective solidarity, established in feminist theory (Hemmings, 2012) and critical educational theory (Zembylas, 2022), as essential tools both for developing concepts crucial to understanding youths' learning, and for putting into action antiracist and re-humanizing practices that honor youths' full humanity. Hemmings (2012) describes affective dissonance as the difference "between an embodied sense of self" and the self that youth "are expected to be in social terms" (p. 149). Through this project, we worked to foster affective solidarity as a means of transforming this dissonance into asset-based modes of learning, knowing, and being together throughout the esports program and across the youth center.

This critical approach emerged from tensions around competitiveness in the esports team that concerned the collective when an affective atmosphere made the esports space feel less welcoming for newcomer participants or onlookers. Rather than discipline the boisterousness, as racialized and youth often experience disproportionately (Diamond & Lewis, 2019), the collective discussed how paying attention to the 'vibe' in esports activity might help players maintain an inclusive atmosphere. Youth participants linked the process of attuning the vibes in esports learning to the vibes produced through the movement culture-oriented hip hop fitness program integrated through the subproject. In the session, two youth will describe the process of transforming affective dissonance into affective solidary through 'feeling the vibes' across movement cultures and esports as part of the collective's research design process. The two youth (15 and 17) from CdN's Filipino community have participated in the program for one and three years respectively. These youths' analysis will develop, and has developed, the concept of 'vibes', which social theorists have defined as the affective register of an experience (e.g., Adjirakor, 2021), as an affective, social design tool for learning scientists.

Implications

A wide body of research has described how youth draw on their everyday social practices for learning and creating with digital media within and beyond schools (Nasir, et al., 2021). However, how youth draw on their specific histories and cultures of moving and feeling for learning is not well understood. Analysis illustrates how youths' histories of feeling the vibes in movement cultures became an asset not only for design but also for collective learning. The design process of moving from affective dissonance to affective solidary in feeling the vibes contributes a uniquely affect-attuned, anti-racist, and asset-based design tool for solidary-driven design work in the learning sciences (e.g., Ishimaru & Bang, 2022). Such affect-attuned tools are necessary for designing more culturally sustaining learning opportunities alongside youth, whose embodied and felt ways of knowing are too often overlooked, especially when those ways of knowing emerge from communities and cultures that themselves are already marginalized. This team will bring such a focus to our joint conversation.

Centering critical youth research methodologies of praxis and care in post-pandemic times: From respectful relations and dialogue towards new imaginaries

Emily Diane Sprowls & Allison Gonsalves

Context & setting

The STEAM Team is a partnership between a public elementary school in Montreal and McGill University designed to facilitate collaborative learning and relationship building among youth, university students, and researchers. Sixteen fifth and sixth graders participate in a weekly after school club to do STEAM (Science, Tech, Engineering, Art, Math) activities with undergraduate student volunteers from the Faculties of Science and Education. The STEAM Team provides a space outside the traditional constraints of a classroom where youth participate as co-learners and co-teachers alongside university students and researchers as they co-investigate and co-create science projects together. The program works to facilitate just relations through knowledge co-creation and shared epistemic authority (Stroupe & Carlone, 2022), while also navigating institutional desires to recruit future science teachers, to enhance teacher education, and to showcase the school's underutilized science facilities. This expansion of science learning beyond traditional teacher-student models has required all actors to renegotiate epistemic positions of learners and "experts," and to refigure their perspectives on science and science learning. This research is motivated by the opportunity and responsibility to disrupt and expand "traditional" science learning and practices, rather than merely expanding access to narrowly defined science knowledge and settings (Ma et al., 2020; Schenkel et al., 2019).

Methods/analysis

The youth are sixth graders that signed up for "Science – Fun – Community" when the club launched in Fall 2022. With a goal of ensuring the activities in the club were "youth-led" (Rahm et al., 2016) we conducted several activities to elicit ideas from the youth about the directions they wished to take for the duration of the term. Youth engaged in discussion circles and sticky note voting to yield several themes around which the facilitators began recruiting university volunteers to facilitate different STEAM challenges. The youth are responsible for bringing to the program their curiosity about science along with their enthusiasm for hands-on creating and their eagerness to connect with university students. To ensure that the goals of the program are met, youth and university students engage in weekly sharing circles and cogenerative dialogues (Tobin, 2006), where they contribute their reflections about their learning and their relationships with other members of the STEAM Team.

Findings & implications

Upon joining the STEAM Team, youth were bursting with ideas for "doing science" activities in collaboration with their peers and vocalized their desires to create and build projects together. Dialogue circles at the beginning of each session prompted youth to verbalize goals of "everybody getting along," even while others shared their struggles with collaboration. In offering multiple opportunities for youth to partner with university volunteers and with each other, their eager engagement in hands-on co-creation opened up spaces for building relationships and acknowledging each other's contributions. Youth from this team, together with the researchers will speak up on some of these issues through their participation in this session.

Abstract: The goals of this symposium are to explore Making as a pathway to meaningful engagement with STEM disciplines and meaningful disciplinary engagement within a STEM discipline, how Making can enrich and transform scientific practices, and the tensions involved. Making experiences will be examined from perspectives such as equity and justice, personal relevance and affect, the role of materiality in scientific practice, disciplinary engagement, educational reform, and the role of teachers. These issues will be explored in different informal and formal US and international settings, and in terms of the diverse identities of the participating adults, teachers, children, youth, high school and undergraduate student Makers. Together, these rich and diverse perspectives and contexts will provide an in-depth and broad discussion of Making and its promise for STEM education.

Symposium overview

Making is an emerging contemporary "do it yourself" trend that capitalizes on the growing accessibility of digital fabrication tools and open-source hardware and software. Makers "play with technology" (Dougherty, 2012); they engage in creating new devices and tinkering. In the last two decades, numerous maker-spaces have opened (e.g. FabLabs) that provide the space and tools for makers to create and share their ideas and designs (Blikstein & Krannich, 2013).

The Making movement holds great promise for STEM education (Bevan, 2017a) through its democratization of knowledge in engineering and science (Blikstein, 2013), its alternative pathways to STEM (Martin & Dixson, 2016), venues for STEM learning that offer equitable opportunities to engage underrepresented youth (Calabrese Barton, Tan, & Greenberg, 2017) and opportunities to experience, express and explore meaningful relations with others and develop a sense of personal value (Vossoughi, Jackson, Chen, Roldan, & Escudé, 2020). Concurrently however, standards, predefined curricula, uneven distribution of resources, and school cultures present many challenges to the incorporation of Making into the classroom (Halverson & Sheridan, 2014). Moreover, meaningful engagement in Making does not necessarily entail profound disciplinary engagement in science or mathematics (Kapon, Schvartzer, & Peer, 2021), and very few studies examined detailed learning processes in which disciplinary practice emerged from Making.

The goals of this symposium are to explore axiological dimensions of Making in the context of deepening meaningful engagement with computing and STEM disciplines (papers 1 & 2) and epistemological dimensions of meaningful disciplinary engagement within a STEM discipline (papers 3, 4, 5). Collectively, the papers illustrate how Making can both enrich and transform scientific practice in educational contexts, while also highlighting the tensions involved, and how these tensions were resolved in each context. The first presentation discusses how moral and affective dimensions of experience can be foregrounded in the context of working with simulations of complex scientific and socio-scientific phenomena in informal spaces. The second presentation is situated in an afterschool STEM Making community and examines how and why a group of Black youth extensively iterated on a "name plate" project, how this expanded iterative process disrupted normative power hierarchies and the emergent tensions. The third presentation discusses a science reform project at district-level in a Brazilian city, and examines the work of a group of collaborating science teachers who employed a Making environment to create and personalize instructional resources (science kits) for their students. The fourth presentation examines how students' disciplinary authentic engagement in physics was facilitated and emerged from Making that was incorporated into the formal instruction of physics in high school. The fifth presentation examines the connections between making, materiality, and disciplinary learning to explore how making deepens and extends students' engagement in a computational physics course at the undergraduate level.

Significance and contribution

Together, the presentations address the goals of the symposium from multiple perspectives: equity and justice, personal relevance and affect, the role of materiality in scientific practice, disciplinary engagement, educational reform, and the role of teachers. They explore these issues in various contexts and settings in terms of informal and formal education, in the US and internationally, and the diverse identities of the participating Makers - adults, teachers, children, youth, high school and undergraduate students. In doing so, the presentations collectively uncover different axiological and epistemological dimensions of the affordances and challenges in transforming Making experiences into meaningful disciplinary learning. The rich and diverse perspectives and contexts reflect different perceptions of 'meaningfulness' that problematize and provide in-depth and broad overview of Making as pathway to both meaningful disciplinary engagement in and/or with STEM disciplines.

Format

The symposium will begin with a brief introduction to the session (2 min), followed by a presentation of five papers (10 min each). The discussant, Flávio Azevedo, will examine themes and juxtapositions across the papers, flash out and raise question about the implications of the collective work (10 minutes), and open the floor for a discussion with the audiences (13 minutes).

Paper 1: Re-making code through moral and historical re-orientations in public spaces

Pratim Sengupta, Marie-Claire Shanahan, Apoorve Chokshi, & Basak Helvaci Ozacar

Introduction & theoretical background

This paper investigates the interplay between moral, affective and epistemological dimensions of making (Vossoughi et al., 2020), in the context of a public computing environment (Authors, A). Our work arises from the concern that technocentric (Papert, 1987), neoliberal (Takeuchi et al., 2020; Irani, 2019) and colonial ideologies (Philip & Sengupta, 2021; Vakil, 2018) that have largely shaped computing and maker education have resulted in an overemphasis on symbolic and technical productions over the heterogeneous and historically embedded human experience of learning (Sengupta et al., 2021; Ames, 2019; Rosebery et al., 2010). Rather than positioning making in terms of technocentric framings of convivial uses of microcontrollers and code (e.g., Halverson & Sheridan, 2014), we foreground the affective, moral and historical dimensions of experience in such spaces (e.g., Vossoughi et al., 2020; Espinoza et al., 2021). Using such an approach, we illustrate how participants re-orient canonical computational simulations of flocking (Reynolds, 1987) and ethnocentrism (Hammond & Axelrod, 2006) toward socially and historically marginalized voices.

Research question

How can moral and affective dimensions of experience be foregrounded in spaces that involve coding and computation?

Study design & method

Observations were conducted in X (name redacted), a public computing environment (Authors, A) located in an indoor public walkway at a large public research university in Canada. X consists of three 80" touchscreens, each powered by a desktop. These screens display open source simulations of complex systems. Visitors can use the screens to interact with these simulations, where the aggregate level patterns (e.g., flocks) emerge from simple, rule based interactions (e.g., alignment, cohesion and separation) between many individual agents (e.g, boids). We present two illustrative cases in which visitors interacted with a simulation of flocking (Case 1) and ethnocentrism (Case 2). Our observations were video recorded and transcribed for analysis. We conducted grounded theoretical analysis using constant comparative method (Charmaz, 2006), identifying how participants re-oriented specific code segments, algorithms and other representational elements of the simulation (e.g., labels of specific variables, parameters of the simulation and visualizations).

Analysis

In Case 1, a female adult with two elementary age children interacted with the Flocking simulation over approximately 30 minutes. The children first modified the flocking algorithm using very high values for the numerical parameters, resulting in the flock taking the form of a pulsating, overcrowded, circular cluster of boids. As the participants interpreted the visualization, they created new linguistic references (e.g., “bonking”; “Boid prison”), and re-contextualized the emergent visual pattern through a discussion on overcrowding in prisons led by the adult with them. In Case 2, a White graduate student interacted with the ethnocentrism simulation over approximately an hour, facilitated by an immigrant graduate student of color. Through discussion they verbalized how the underlying algorithm positioned immigrants (in the simulation) in deficit terms. They worked to alter the parameters of the code to ensure that immigrants were not forced to assimilate in the predominantly White society of the simulation.

Conclusion and discussion

The cases illustrate acts of re-orientation through moral (Case 1 and 2) and historical (Case 2) recontextualizations of disciplined (Mignolo, 2007) formations (algorithms and visualizations). The products of making here are more than computational artifacts. Participants are re-making disciplinary assumptions and models from axiological perspectives.

Paper 2: “This IS me, complex, messy and unfinished”: Community epistemologies and wisdom in iterative black youth STEM-rich making

Angela Calabrese Barton, Day Greenberg, Edna Tan, & Melissa Perez

Purpose

In communities, youth make with a critical awareness of the world as it is and a desire to author a world that could be. Using participatory critical/relational ethnography, we documented how/why a group of 12 Black youth iterated over *four months* on a “name plate” project intended to last *three weeks*, guided by these questions:

- How, when and for whom did youth iterate on the name plate project? How did these iterations support youths’ opportunities to draw upon community epistemologies in conjunction with STEM knowledge?
- How does an expanded iterative process disrupt normative power hierarchies in *community-engaged, STEM-rich* making? What are the emergent tensions in the process?

Perspective

Iteration, defined as successive rounds of design towards optimization within the prototyping process, is an important epistemologically-grounded maker practice (Martin, 2018). However, little attention has been paid to the intentional incorporation of community epistemologies towards new forms of legitimate STEM-rich maker knowledge/practice through iteration.

We use both terms – *community-engaged* and *STEM-rich* – to set up a necessary tension and existing connections historically elided in STEM/making, towards justice-centered efforts in maker education. We foreground how maker knowledge/practice is localized and distributed within community (hooks, 2003), where the necessary know-how to make involve Black youths’ existing knowledge and wisdom (Evans-Winters, 2019). We emphasize the importance of access to STEM knowledge and practices in supporting making, and in the functionality of made artifacts, while noting this is *fraught* given the colonial and racialized history of STEM (McGee, 2021).

Methods

This work takes place in the Green Club program for middle school youth, a community-based makerspace serving a predominantly Black and low-income population. Data generation involved giving critical witness to youths’ making through include maker artifacts, conversation groups, interviews, and video of maker sessions. Analysis involved multiple stages and levels of coding based on procedures for open-coding and method of constant comparison.

Findings

In the first three weeks of the GC program, youth designed and built “name plates” using woodworking tools and materials. Afterward, several expressed interest in expanding the project, indicating they “weren’t done representing me.” Educators and youth spent the next three months co-planning novel ways to iterate on their nameplates, adding new layers (Figure 1):

- Lighting (building electrical circuits).
- Motion (complex circuitry incorporating motors to power youth-designed extensions),
- Sound (programmable speakers/coding)
- Sustainability (replacing batteries with renewable energy, e.g., solar panels).

Figure 1

One youth’s intermedia board: (Top left) woodworking; (Top right) adding lights (soldering circuit); (bottom left) after adding a sound system; and (bottom right) illustrating how the motor powers the moving hearts.

As youth explained, we renamed these “layered named plates” as “intermedia boards” because “this board is to tell about me” … “this IS me. Complex, amazing...really messy, and not finished.” The boards proudly hang in the makerspace.

We illustrate three findings.

1. Youth leveraged a range of experiences, desires, identities and ideas for how they re-presented themselves;
2. Layers of iteration became liminal spaces of expanding STEM-rich maker knowledge while projecting how these ways of knowing are historicized, as youth re-imagined projects in their likeness and desires.
3. Iterations expand how community knowledge/practice becomes more legitimized in STEM-rich making, re-shaping whose knowledge has capital.

Implications for supporting justice-seeking cultures of STEM-rich making are offered.

Paper 3: Reframing the use of makerspaces resources for disciplinary integration in the Global South

Cassia Fernandez, Tatiana Hochgreb, & Paulo Blikstein

Theoretical perspectives

Engagement with science and engineering practices is an essential learning dimension in contemporary science standards (e.g. ACARA, 2016; British Columbia Ministry of Education, 2017; National Research Council, 2012). Makerspaces' tools and resources could enable more meaningful and practice-based ways of learning science and engineering (Quinn & Bell, 2013; Martin, 2014; Bevan, 2017). However, in traditional makerspace implementation models, resources are meant for students to create their own personal projects. While attractive and feasible for after-school programs, or in affluent schools or countries, in more typical school settings worldwide, teachers need to scaffold instruction attainable to a limited lesson time and many students. Moreover, most research in this field has been derived from US-based experiences, and perspectives from the Global South could contribute to a more diverse range of strategies to integrate makerspaces into disciplinary contexts.

Objectives

In our study, we describe how teachers have been transforming models of makerspace use, using its resources for science teaching in public schools in a medium-size Brazilian city, and discuss alternative ways of makerspaces' implementation based on local specificities.

Context & methods

Our data is drawn from an ongoing five-year science reform project at the district level (Anonymous, 2020, 2022) that includes: (1) the redesign of municipal science standards, (2) long-term participatory professional development for teachers, (3) implementation of makerspaces, and (4) hiring a dedicated lab teacher to the makerspace, who co-designs curricular units with other teachers. Since 2017, as part of this project, we have worked with a group of teachers to co-design science curricular units through four cycles of design-enactment-reflection (Anonymous, 2020). Our data includes field notes, documented teacher interactions, interviews, and lesson plans. We analyzed how makerspaces' resources were integrated into the lesson plans using emergent themes to categorize them.

Findings

Our findings indicate that in this educational context, with little time for science classes (around 100 minutes/week) and 30-35 students, teachers soon realized that the US-inspired model of implementation would not work, and instead, after many cycles of redesign with our team, reframed makerspaces resources to produce inquiry-based, constructionist toolkits for students to use as part of their newly designed learning activities. The data revealed three types of goals for these toolkits: (1) create analogies and representations of scientific phenomena; (2) engage with specific scientific ideas; and (3) explore phenomena through testing ideas.

Contribution

Our findings illustrate new ways devised by teachers to integrate makerspaces into instruction for meaningful disciplinary engagement. The toolkits created allowed them to expand their pedagogical possibilities in creating new learning activities, enabling students to engage with more advanced scientific practices (such as using models and carrying out investigations) and with "big ideas." In this context, digital fabrication tools helped produce innovative constructionist materials, which made it possible to implement student- and inquiry-centered, equity-focused activities made available for all students during the regular instructional time--achieving more ambitious learning goals defined by the teachers, as opposed to only resourcing to regular textbook activities or class-wide demonstrations of experiments.

Paper 4: Facilitating the emergence of authentic disciplinary engagement from a meaningful engagement in making

Tal Peer & Shulamit Kapon

Objectives

The integration of Making into the formal instruction of STEM disciplines is not straightforward. Maker projects prioritize creativity and personal relevance, whereas learning mathematics and science is constrained and often driven by predefined curricula and standards (Bevan, 2017b; Sheridan et al., 2014). This paper explores how disciplinary authentic engagement in physics emerges from a personally meaningful engagement in Making, and the role of instructors in fostering and facilitating this emergence.

Analytic lens

We define students' sense of personal relevance (Kapon, Laherto, & Levrini, 2018) during an interaction as high engagement; i.e., when students: (1) actively "choose to engage in the activity, given a choice"; (2) "persist in the activity, given a choice"; (3) "invest personal resources, such as effort, in the absence of coercion or outside incentives"; and (4) demonstrate "affective responses toward the activity" (Azevedo, 2006). We operationalize students' authentic disciplinary engagement in physics as enactments of practices and behaviors that reflect "thinking like a physicist" (Kozminski et al., 2014).

Method

The educational context of the work was a Physics-Maker-Based Challenge (PMBC). The students had to design and construct a launcher to launch a marble that could reproducibly move through a series of increasingly smaller rings placed on a vertical wall (projectile motion), and land in a cup, test its performance, and present and defend their design. The activity took place in a school Maker-space environment during lessons devoted to inquiry in physics (18 academic hours). The participants were 10th grade students (N=18) enrolled in advanced-level physics. Two physics teachers facilitated the activity. Students were encouraged to express their creativity.

We present a case study of a pair of students, drawn from an ethnographic study that documented the intervention. The data include video recordings of group work, follow-up interviews with the students, the artifacts the students generated and used during the inquiry (e.g., spreadsheets), and a research journal. The analysis examines students' discourse to identify instances of students' high engagement and authentic disciplinary practice, as well as their interactions with the facilitating teachers.

Results and conclusion

We present two episodes from the design phase of the launcher. In the first, the students discuss three optional launchers based on different mechanisms which emerged from their independent brainstorming, and try to intuitively figure out how to control the velocity of the launched marble in each. The analysis highlights various aspects of high engagement such as deep affective involvement, and the investment of time and effort without external incentive. In the second episode the students have already worked on the design of one of the launchers, which they imagined as having an explosion mechanism. Because they had trouble translating their idea into a concrete design, they asked for assistance. The analysis illustrates how the teacher's conversational moves navigated and fostered the students' meaningful engagement in disciplinary practice.

Contribution

The findings illustrate how Making can be incorporated into the formal study of physics, its affordances for meaningful disciplinary practice, and the pivotal role of instructors in fostering the emergence of disciplinary engagement.

Paper 5: Expanding meaningful disciplinary learning with computational making

Brian E. Gravel, Ezra Gouvea, & Timothy Atherton

Objectives

We describe a pedagogical approach called computational making. Our paper contributes to research building connections between making, materiality, and disciplinary learning (Bevan, 2017; Blikstein, 2014; Kapon et al., 2020; Manz, 2015). Computation is fundamental to physics disciplinary practice (Humphreys, 2004) and the learning and development of students and professionals (Clark & Sengupta, 2013). We critically re-examine perspectives on doing science—which has been narrowly constructed in physics pedagogy (Weiman & Perkins, 2005). We explore how making deepens and extends students' engagement in a computational physics course (Phillips et al., under review).

Theoretical perspectives

The practice of going back and forth between seeing phenomena in the world to modeling those phenomena computationally (Chandrasekharan & Nersessian, 2017) is challenging for students (Gravel & Wilkerson, 2017), requiring them to select representations (e.g., mathematical expressions) that correspond to the entities of the physical phenomena (Greeno, 1983). We build on computational making (Gravel et al., 2022; Rhode et al., 2015) as a pedagogical approach that foregrounds learner attention to materiality and efforts to describe the "rules" of constructed artifacts. We draw on design as material conversations (Schön, 1992), computing with objects (Knight & Stiny, 2015), and disciplinary engagement (Engle & Conant, 2002), asking students to make objects (Figure 1) they then model computationally. We ask: How does computational making change the accessibility of students' resources to model and make sense of the physical world?

Methods and data

We present data from a design-research project (Brown, 1992) investigating students' changing relationships to tools, materials, and each other. In an undergraduate computational physics course, students were prompted to "make an oscillator" with simple craft materials and to model their creation computationally. We used interaction analysis (Jordan & Henderson, 1995) to identify characteristics of computational making and describe these using three cases.

Findings

We identified three areas where students' relationships with modeling and materials were entwined:

- *Ontological (re)negotiation*. M and C grappled with the bizarre behaviors of their two-magnet oscillator. By trying to represent the poles in these circular magnets, they discovered the magnets did not behave as they expected; they renegotiated their assumptions about the nature of the material, and created a rich computational model.
- *Range of agency in composition*. J and E noticed discrepancies between their empirical results and their computational model—leading them to recompose their model to account for previously unnoticed twisting of the nylon string. Their available agency to iteratively (re)compose both the computational model and their artifact contributed to nuanced understandings of material properties and modeling choices.
- *Iterative accommodation of materials*. The Ramp Group iteratively explored a curved surface anchored at four points. The iterative conversation with their idiosyncratic materials pushed them toward creative ways to process their data in order to build a better computational model.

Figure 2
(Top left) J & E explore the string in their oscillator; (Top Right) C explores the two magnets as M examines magnetic field diagrams; (Bottom) The ramp group explores how objects roll on different configurations of the ramp.

Significance

We illuminate a unique pedagogical pathway. Centering materiality contributes new ways of understanding how students listen and respond to the physical world as they build representations in different ways. The implications open opportunities for future pedagogical innovations and further study of the relationships between computational making and disciplinary practice.

Abstract: Understanding how youth make sense of machine learning and how learning about machine learning can be supported in and out of school is more relevant than ever before as young people interact with machine learning powered applications everyday—while connecting with friends, listening to music, playing games, or attending school. In this symposium, we present different perspectives on understanding how learners make sense of machine learning in their everyday lives, how sensemaking of machine learning can be supported in and out of school through the construction of applications, and how youth critically evaluate machine learning powered systems. We discuss how sensemaking of machine learning applications involves the development and integration of conceptual, creative, and critical understandings that are increasingly important to prepare youth to participate in the world.

Symposium overview

Recent calls to promote artificial intelligence (AI) literacy in K-12 education highlight the importance of engaging young learners with big ideas, preparing them for careers in computing and to be critical consumers and designers of technology (Touretzky et al., 2019; DiPaola et al., 2022; Wang et al., 2021). Within AI literacy, fostering an understanding of machine learning (ML), which involves the use of data rather than code to shape the behavior of computer programs, is crucial (Long & Magerko, 2020; Zimmermann-Niefield et al., 2019). Machine learning is a new paradigm in computing education (Shapiro & Tissenbaum, 2019) that learners must engage with to become computationally literate and be empowered to participate in computing (Kafai & Proctor, 2022).

Despite the fact that machine learning is often black boxed in consumer applications, research shows that children construct naive explanations to make sense of how these work (Druga et al., 2017; Williams et al., 2019). At the same time, designing machine learning applications requires thinking like a scientist and building hypotheses, using data sets to train and test models to make predictions (Shapiro et al., 2018; Langley, 1988). Both using and building ML-powered applications demand making sense of how models work and how data shape their behaviors. Yet little attention has been given to how youth integrate conceptual, critical, and creative understandings in making sense of ML-powered applications. Sensemaking involves explaining observed phenomena using theory and evidence (Newman et al., 1993; Crowder, 1996) to "figure something out" by dynamically building and revising explanations using both formal and everyday knowledge (Odden & Russ, 2018). Whereas sensemaking has traditionally centered on conceptual understanding, learners also engage in explanation building when considering ethics to critically understand how systems work. At the same time, making applications engages learners in creative understanding, by having to make decisions on how to create personally relevant projects they build and revise explanations. In this symposium we bring together research on young people's novice sensemaking of ML, that is how they come up with and revise their explanations of how machine learning works as well as how their sensemaking can be supported through the analysis and construction of ML-powered creative applications in and out of school. Participants discuss the following questions:

(a) How do youth build on their everyday experiences with technology to make sense of ML?
(b) How can youth sensemaking of ML be supported through the design of ML-powered applications?
(c) How do youth critically evaluate and understand ML-powered systems?

The invited works provide examples of how conceptual, creative, and critical understandings of ML and AI can be integrated. Presenters apply Learning Sciences perspectives on embodied cognition, critical literacies, modeling and design-based research to the analysis of ML sensemaking with studies conducted in computing and non-STEM contexts, out of school and in K-12 classrooms: Castro and colleagues investigate youth's understanding and embodied learning of ML and in a computing and dance intervention; DiPaola and colleagues examine how embedding ethics into three project-based curricula supported students to develop understandings of ML applications as sociotechnical systems; Lee and Soep study meaning making processes when youth create projects about and with AI/ML technologies through a critical perspective; Long and Magerko research how embodied interaction through dance can support learning about ML in informal spaces; Morales-Navarro and Kafai investigate how youth make sense of ML when encountering failure cases as users and creators of applications; Solyst and Ogan study girl's funds of knowledge and knowledge gaps around AI/ML and fairness; Tatar and colleagues adopt a situated learning perspective to analyze students' data modeling experiences and their impact on shaping students' understanding of AI/ ML.

The symposium is organized in three sections: (1) the chairs will introduce the topic and then each presenter will give an one-minute teaser about their work (~10 min); (2) the first half of the presenters will have 20 minutes to share their work using posters placed around the room, followed by the second half of presenters (20 minutes)—this arrangement will give the audience and presenters time to see each other's posters; (3) our discussant Sepehr Vakil, an expert in justice-centered computing with experience in community-centered AI education, will synthesize and reflect on findings (10 minutes) followed by a Q&A with audience and presenters (~15 min).

1. Shuttling between contextualized creative computing and learners' understanding of machine learning algorithms in the real-world

Francisco Castro, William Payne, & Kayla DesPortes

Integrating movement practices from dance into computing and machine learning (ML) education can lead to culturally sustaining experiences where learners draw upon cultural ways of knowing as they explore identity across individual, social, and political dimensions (Castro et al., 2022; DesPortes et al., 2022; Payne et al., 2021). Novel dance-computing technologies and curricula, like danceON, must not only leverage cultural assets but set out to sustain communities (Paris & Alim, 2014). In our work, we explore how BIPOC youth shuttle between embodied knowledge and reasoning of ML concepts and how their personal and sociopolitical understanding of ML reaches beyond the learning environment.

Wild and Pfannkuch (1999) articulate the importance of learners shuttling between their disciplinary and real-world knowledge in statistical thinking. Researchers have found this can support purposeful and meaningful exploration of concepts (Ben-Zvi & Aridor-Berger, 2016). We draw on their framing of shuttling as we examine how learners build their mental models of computing systems through creating dance-computing artifacts, then leverage this understanding to explore personal experiences and implications of computing systems in society.

We examined a section of a 15-week internship with 6 high school learners from STEM From Dance (stemfromdance.org), a community organization that engages young women of color in STEM and dance. Within these sessions, learners trained classifiers to identify two poses with Google's Teachable Machine while also working with danceON, a creative coding environment that enables learners to code animations over dance videos (Payne et al., 2021). In tandem, they read articles about misuse and biases within ML systems. We reviewed two sessions that were recorded and transcribed verbatim and identified instances where learners discussed general ML concepts (who uses and develops systems), ML processes (training, testing, etc.), and ML behaviors (pose detection); this enabled us to identify when learners (1) reasoned about ML concepts with their body and (2) shuttled between their embodied experience of ML, their personal experiences of ML, and understanding of ML in society.

Learners regularly encountered limitations of pose detection as they witnessed animations and body points drawn incorrectly. They hypothesized possible causes such as occlusion, movement speed, and clothing, and incorporated strategies for improving accuracy through movement. Through making classifiers with

Teachable Machine, learners identified gaps in the training data and discussed how more iterations of data collection may improve accuracy. Finally, in discussions, learners connected their conceptions and understanding of pose detection with personal experiences with other ML systems, such as limited performance of home assistants within a family of non-native English speakers and reasoned about the impact of biased ML systems for others. Our work highlights the affordances of creative dance computing spaces as avenues toward the embodied learning of ML. By engaging in activities and discussions of ML within the embodied, cultural, and collaborative nature of dance, we found concrete instances of shuttling between their understanding built through dance and their understanding of the real-world context—i.e., the impact of human-driven design decisions on the implementation of ML, and their personal experiences with AI systems. Through continued exploration of co-designed scaffolds, we can further develop the ways in which asset-based experience in cultural practices like dance can facilitate sociopolitical examination of ML, which is a key component of supporting culturally sustaining pedagogy.

2. Use, understand, create: Embedding ethics in machine learning curricula for middle school youth

Daniella DiPaola, Randi Williams, Safinah Ali, & Cynthia Breazeal

Machine Learning (ML) is a powerful computational tool that can greatly benefit, but also potentially harm users, especially those from systematically marginalized communities (Buolamwini & Gebru 2018, Noble 2018, O'Neil 2016). The tension between benefits and harms should be presented in an age-appropriate way to all students learning about ML. However, recent work shows that computer science educators typically withhold or exclude ethical issues in their courses, to the detriment of their students (Fiesler, Garrett, & Beard, 2020).

This work discusses the design principle "embedded ethics" and how educators can incorporate ethical thinking activities into project-based ML curricula. "Embedded ethics" involves teaching ethics alongside technical concepts helps students develop a fuller understanding of the technology, including the long-term implications of systems they create (Saltz et al., 2019, Skirpan et al. 2018, DiPaola, Payne, & Breazeal 2020). This work aligns with the Use-Understand-Create framework for digital literacy and shows how ethical thinking can be a part of every stage of students' learning progression (MediaSmarts, 2021).

This paper presents three project-based curricula on emerging ML topics – generative adversarial networks, affective perception, and supervised machine learning (Williams et al., 2022). Each curriculum includes the use of real-world ML demos, conceptual discussion, and open-ended creation to teach students about ethical thinking. In an introductory activity in Creative AI, students learn to anticipate potential beneficial and harmful uses of various generative AI tools. In Dancing With AI, students employ their technical understanding to predict the impact of ML classifiers trained with flawed datasets. In How to Train Your Robot, students consider different stakeholders' values in their final project designs. In the summer of 2020, we trained 11 middle school teachers, primarily from Title 1 schools, to co-teach one of the three curricula to 78 middle-school students from 8 states across the USA. A mixed methods approach was used to evaluate their mastery of ethical thinking in different activities. This encompassed statistical methods to evaluate AI concept surveys pre-post, thematic coding to evaluate classwork, and rubrics to evaluate final projects. These measures were developed by the authors for the purposes of this project.

Before the workshops, the surveys showed that most students had an agreeable disposition toward AI, associating it with positive words like "exciting" and positive impacts like "making jobs easier." Students' classwork demonstrated an increased ability to imagine potential societal repercussions of AI systems and apply ethical decision making to their final projects. In students' final project creations, students were able to transfer their knowledge of ethical implications of AI systems to areas of personal interest. Overall, the authors observed that embedding ethics into curricula led to students developing a nuanced understanding of ML applications as sociotechnical systems.

This paper describes three approaches taken to teach students about ethical thinking throughout all stages of their learning trajectory. In previous work, researchers found that tools for ethical analysis enabled students to critique and then redesign AI systems that they were familiar with (DiPaola, Payne, & Breazeal 2020). The three empirical studies examined in this work showed students going one step further and implementing reimagined AI systems through their own projects. For example, one student in the Dancing with AI curriculum, inspired by the effects of COVID-19 on their community, created a project to classify different types of masks based on their effectiveness.

3. Learning with and about ethical artificial intelligence through youth-made media

Clifford Lee & Elisabeth Soep

This study seeks to understand how young people underrepresented in STEM make meaning of the role of AI in their lives and society and how their relationship to the technology evolves when they create their own AI-based tools and media. This research analyzes the curriculum and pedagogy behind three ethics-centered AI learning activities housed within an after-school multimedia production organization. Critical Computational Expression (CCE) is a conceptual and pedagogical framework that integrates the three distinct traditions of: critical pedagogy, computational thinking, and creative expression (Lee & Soep, 2022). Interactive youth developers are attuned to the aesthetics, design, and creative representations of their products while being conscious of the sociopolitical messages and computational sophistication of their interactive stories (Lee & Soep, 2016).

Our ethnographic study centered participant observation, through audio recordings of moment-to moment interactions in class, end-of-session focus group interviews, and analyses of youth-generated artifacts within the learning environment over the course of two and a half years. Our research team used a grounded theory approach to code, reduce, and analyze the data to generate themes according to our Critical Computational Expression framework. This paper addresses the following research questions:

1. What can we learn about young people's understanding of AI when they produce media with and about it?
2. What are the design features of an ethics-centered pedagogy that promotes STEM engagement via AI?

In the three activities examined in this study, young people: repurposed their phones' text autocomplete features to produce poetry; countered Spotify's system for rating pop songs' danceability by designing an interactive experience of their own; and developed a drawing tool inviting users to scribble over photographs of faces to determine what degree of disguise was required to dodge facial recognition software. In total, sixteen producers, aged fifteen to twenty-four, who are predominantly youth of color and those contending with economic and other barriers to full participation in STEM fields, engaged in this study.

Our findings suggest that students can feel disempowered by their increasingly intelligent technologies. Through ongoing observation and analysis, we see students deepen curiosity about and understanding of AI that allows them to exercise agency and conceptualize creative projects using their new knowledge to manipulate and hack AI-dependent algorithms. Additionally, our results show that participating in ethics-centered learning activities and developing AI-powered tools do not create a permanent evolution of youth's understanding of their agency as it's related to AI in their lives; instead, these modes of involvement offer meaningful glimpses into how the problematic dimensions of AI systems are pervasive, yet not undefeatable in terms of young people's positioning with respect to technology and their role in the culture it produces.

By drawing on digital tools and practices that youth are familiar with as consumers, young people develop sufficient technical know-how, creative engagement, and critical curiosity about the implications of these systems to demystify how everyday tools work, then start envisioning ways to spark new action and conversation. Understanding the mechanisms that shape human interactions with AI to conform with the patterns embedded in its functioning afforded students the opportunity to discover ways to disrupt these systems with creativity, originality, and new ways of thinking.

4. Using embodied interaction and creative making to foster machine learning sensemaking in informal learning contexts

Duri Long & Brian Magerko

Our research explores how embodied interaction and creative making can engage family groups in discussions surrounding machine learning in informal learning contexts like homes and museums. We design activities to support creative, embodied learning experiences and study participants' learning talk and interest development surrounding these activities.

We conceptualize embodied interaction as physical interaction with and/or control of the activity. Creative making refers to the production of personally relevant artifacts, especially those that persist beyond the activity. We hypothesize that the emphasis of these constructs on the self can help learners reconceptualize AI and ML as relevant areas of interest for people "like me" (Papastergiou et al., 2008; Magerko et al., 2016; Guzdial et al., 2013; Buechley et al., 2008). In addition, we hypothesize based on prior work (e.g., Antle et al., 2013; Horn et al., 2009; Sulmont 2019) that embodied interaction can make abstract concepts–like AI–concrete for learners.

We have engaged in design research to develop two activities that support learning about ML. The first, *Creature Features*, engages learners in building a training dataset for a feature-based ML bird classification algorithm using a tangible interface. Learners can explore issues like dataset bias and representation using cards and tokens and can iteratively revise their datasets after viewing the algorithm's results. The second activity, *LuminAI*, engages learners in improvising dance with an AI partner. After dancing with the AI, learners can explore an interactive, 3D visual representation of the way the dancer uses unsupervised ML to group gestures in memory. We recruited 14 family groups (38 participants; 21 age 6-17 and 17 age 18+) to interact with the prototypes in their homes. Family members were given an age-appropriate survey following their interaction. We asked both Likert-scale and free-response questions to assess interest development, content knowledge gain, and whether the activities elicited creative interactions. We also had family members record audio of their interactions with the activities. We coded the transcribed dialogue to identify instances of *learning talk*—i.e., conversation that was relevant to the learning goals of the activity (Roberts & Lyons, 2017). The quantitative results from the survey data supplemented with the qualitative analysis of the audio transcripts provided insight into which exhibits led to learning talk, interest development in AI, content knowledge gain, and creative engagement.

The tangible interface and iterative cycle of testing and revision in *Creature Features* supported in-depth discussion of features and their impact on the algorithm. The activity was most successful with families with kids aged 10+, and more scaffolding may be needed to help learners connect the activity with "real-world" technologies and issues. Although *LuminAI* focused on teaching AI through a creative activity, the ephemeral nature of dance means learners did not generate a lasting artifact. This may have limited the impact of *LuminAI* on interest development. Although learners scored well on the content knowledge questions related to unsupervised ML in *LuminAI*, learners expressed that they were intimidated by the interface. This suggests that interactive visual interfaces–even when building on embodied metaphors in a creative domain–may necessitate additional scaffolding for novice audiences. Our results indicate that tangible interaction can be an effective design feature for promoting sensemaking about ML. Future research is needed to examine whether creative making can be an effective design feature for promoting learning about ML. Our work contributes to understanding how to design casual AI learning experiences for novices that can integrate into everyday life.

5. Youth's sensemaking through failure cases in machine learning powered applications

Luis Morales-Navarro & Yasmin B. Kafai

Youth encounter machine learning (ML) applications every day and while several studies have investigated their understanding of how machine learning works (Druga et al., 2017; Williams et al., 2019) most of it has centered around success, that is when ML applications work as expected. We present results from an exploratory study in which we investigate how youth make sense of ML when encountering failure cases as users and creators of physical computing applications. By investigating how youth make sense of failure cases we aim to analyze youth's conceptual understanding as well as their consideration of the limitations and implications of ML technologies.

Whereas conversations about ML, society and ethics are often disconnected from technical issues (Fiesler, 2020; Petrozzino, 2021), the consequences and implications of ML applications are closely intertwined with functionality failures (Raji et al., 2022). To investigate youth's sensemaking of ML and its implications, that is how they build and revise explanations using both formal and everyday knowledge (Odden & Russ, 2018), we build on previous work on youth's interaction with failure artifacts. Failure artifacts are applications that have deliberate failures, bugs or mistakes and can elicit learners' understanding of how computing applications work (Fields et al., 2021). At the same time, encountering failure when creating projects can support sensemaking as students resolve failure cases, avoid recurring failure, prepare for novel failures, and calibrate their confidence (DeLiema et al., 2022).

We conducted a ML+eTextiles workshop at a science center in the Northeastern United States with 12 (15-16 years old) youths of Color during the Spring and Summer 2022. In the Spring, youths were presented with consumer applications with failure cases and eTextiles ML-powered failure artifacts. Using stickies and big paper methods (Yip et al., 2013, Woodward, 2018), we asked them to brainstorm how these applications worked and if they encountered any failures how they could fix them. Following, during the summer, youths learned to create ML-powered eTextiles and designed their own personally relevant projects. As they worked on their projects we had several sessions during which they reflected on failure cases they encountered. We analyzed workshop artifacts and recordings using iterative thematic analysis (Braun and Clarke, 2012).

Prior to any instruction on ML, half of the youth voiced ideas of how ML applications used data to generate predictions. They also brought up issues of bias and its ethical implications when discussing failure cases in consumer technologies and reflected on their personal experiences using some of these technologies. As they built models for their eTextile projects, they encountered failure cases particularly with regards to diversity of training data and overfitting. These failure cases generated discussions on the importance of testing and iterative design of data sets, considering who and how the projects would be used, and anticipating how the projects would affect people. This poster provides evidence of youth's understanding of ML as users and producers when encountering failure cases. Using failure cases and failure artifacts in instruction and reflection on failure in their own creations may be particularly helpful to foster youth's understanding of how technical failure and social implications and limitations may be intertwined.

6. Talking about fairness in artificial intelligence and machine learning with girls

Jaemarie Solyst & Amy Ogan

Children are the future users and creators of AI. However, girls and particularly girls of color are often excluded in the design of technology while simultaneously being greatly impacted by issues of fairness in AI. Educational opportunities about AI and ethics designed for girls, their interests, and their funds of knowledge, are essential. Through a series of workshops, we aimed to understand those funds of knowledge as well as their sense making, including knowledge gaps around AI and fairness, focusing on the critical age prior to high school.

In our workshops, we based our learning materials on culturally responsive computing (CRC). Positioning learners as technosocial change agents, poised to advocate for justice in technology, CRC leverages: Asset-building by adding onto what learners know, Reflection by prompting learners to critically analyze and decompose existing power structures, and Connectedness by strengthening and taking into account relationships that the learners have within the learning environment and their broader communities (Scott et al., 2015).

We ran a series of six workshops online and in-person with middle school girls (11-14) and an additional in-person workshop with fifth and sixth graders (ages 9-12). Workshop material was based on CRC with a main focus on AI. We introduced the basics (e.g., what is an algorithm, what is AI, and how training data is involved in machine learning). We then instigated discussions around various AI technologies and how they could be fairer, as well as design activities where learners made sense of and thought of their own AI-powered inventions. We conducted thematic analysis on transcripts, chat logs, and artifacts.

Our findings showed that girls' ideas around fairness followed models of equality/inequality and nice/kind vs. rude/mean, i.e., many learners defined fairness as everyone getting the same resources, as well as having kind interactions (e.g., a nice robot), while unfairness was defined as the opposite. Some learners brought up more complex ideas like equity, or technology accommodating user differences. We saw that in older groups (e.g., seventh and eighth graders), learners had existing understandings of bias and could apply it to technology being unfair. Younger girls and those with lower prior knowledge in computing needed more scaffolding to critically discuss and question technology. Middle school learners were able to see unfairness in existing examples of AI (e.g., bias in Google search image results). Lastly, applying fairness to more technical aspects of AI, such as how training data can impact ethical ML, was a more challenging topic that needed more time and explanation for learners who did not have a lot of prior STEM exposure.

This suggests that fairness should be a main focus of AI and ethics, supporting exposure to more complex ideas about fairness (e.g., equality vs. equity) before considering fairness applied to more technical topics, such as training data. It also indicates that this is a critical set of ages at which conceptions of fairness are beginning to emerge and shift; perhaps necessitating different educational interventions, where for younger children, fairness and ethics may be a specific topic. Older children (e.g., 12-14) were more able and eager to discuss power and privilege, but younger children may need considerably more scaffolding for these topics in a curriculum.

7. The impact of a technology-enhanced unit on high school students' understanding of artificial intelligence & machine learning

Cansu Tatar, Shiyan Jiang, Jie Chao, & Carolyn P. Rosé

Despite the substantial interest in K-12 AI curriculum development, there is a lack of intervention-based research, in particular regarding the effects of AI curriculum on K-12 students' understanding of AI and machine learning (Chiu et al., 2021; Estevez et al., 2019). This study explores high school students' understanding of AI & ML before and after a technology-enhanced curriculum intervention. We adopt a situated learning perspective as our theoretical framework to understand students' data modeling experiences and their impact on shaping students' understanding of AI & ML. Modeling has been an effective learning strategy for knowledge construction that describes a process of developing representations of phenomena being experienced in order to engender conceptual change (Jonassen, 2011).

A Journalism teacher participated in our professional development workshop for four weeks and implemented our technology-enhanced AI curriculum in her Journalism classroom for three weeks. This class included twenty-eight students: three 10th graders, nine 11th graders, and sixteen 12th graders. Students used StoryQ to build machine learning models with text data. Students did not receive any formal training in AI before this curriculum intervention. Before and after the curriculum intervention, students completed a knowledge assessment. This assessment was designed by following the scenario-based representation model (Sun et al., 2003) and validated by machine learning experts and teachers. Students' responses were analyzed by following open-coding strategies (Strauss & Corbin, 1994), focusing on their understanding of AI & ML and reasoning about everyday AI technology.

Our analyses revealed that before the curriculum intervention, students mostly viewed AI as robots that help people perform certain tasks. This could be due to the media portrayal of AI as robots, which is one of the most common themes in movies and popular culture. After the curriculum intervention, students defined AI as a technology that mimics human intelligence. We also asked students to share their understanding of ML. In the pre-assessment, most students indicated that they were not familiar with the term. Their responses included random guesses like learning through machines. After the intervention, their conceptions shifted from random guesses to more detailed explanations including feature selection and recognizing the importance of training data for model development. Additionally, we found that students mostly viewed Siri as a pre-programmed technology before curriculum implementation. In the post-assessment, most students used AI concepts to explain the working mechanism of Siri. During the curriculum intervention, students experienced feature selection when building ML models. This hands-on experience in building ML models might help them reason about how virtual assistants (e.g., Siri or Alexa) work. This study demonstrated that a technology-enhanced AI curriculum offering opportunities for building ML models helped high school students gain a more in-depth understanding of AI & ML and its applications. A fertile area for future studies is exploring patterns of model development in different kinds of ML modeling tasks and investigating how to best support students' diverse ways of building models.

Abstract: The influence and reach of maker education continues to grow, bringing new possibilities for hands-on, student-centered, design-oriented, and/or transformational learning to more people in more spaces. Maker education has also more recently attended to issues of justice, equity, and culture. What does the future of maker education hold? What materials and practices will these spaces offer next? What support do teachers need to enact pedagogically sound and culturally relevant learning? How will developing technologies respond to teachers' and learners' needs for accessibility and sustainability? How will maker-based learning be documented and assessed? To answer these and other questions, we propose convening a panel on the Future of Maker Education to both solicit panelists' ideas on the future of maker education and foster audience discussion around these issues.

Symposium overview

Despite being inspired by several other previous educational ideas and reforms, Maker education as a mainstream movement gained prominence only about ten years ago. However, this rapid rise and expansion into schools has raised crucial questions around its educative purposes (making towards what ends?), cultural processes (the 'how' and 'for whom' of making), and conditions that support expansive making (the design and practice of maker education, and educator learning) (Vossoughi et al., 2016; Barajas-López & Bang, 2018). These questions will continue to drive research on making and learning, and their answers are transforming our understanding of both making, learning, and the relationship between the two. How might educational making transform schooling, and how might research on educational making transform the learning sciences? We propose this panel to convene researchers and thinkers towards answering these questions for future of maker education.

We anticipate that the next decade of work on maker education will pursue multiple paths to disrupt the dominance of traditional STEM schooling goals, outcomes, and identities in order to better serve more learners. One such approach is the study and inclusion of cultural making practices that "powerfully engage youth with the political, human, and social challenges of subverting and transforming one's reality through powerful tools and representations" (Blikstein, 2020, p. 125). In particular, recognition of arts practices as assets that young people bring to learning can offer one way to turn to desire-based scholarship and pedagogy and create equitable education systems. Other researchers advocate for pedagogical designs and practices that nurture justice-oriented forms of worldmaking with students, educators, and communities (Simpson, 2009) and highlight the relationships between making and forms of political education that intentionally weave together critical social analysis, the imagination of possible futures, and the creation of lived-in elsewheres in the here-and-now (Vossoughi, 2014). Yet another approach focuses on recasting the relationships among materials and people to increase inclusion and equity in historically inequitable domains (e.g., Keune et al., 2019). For example, materialized action proposes a new way of integrating (rather than excluding) worldly concreteness into the mathematics classroom, promising a new kind of relatability that may shift participation structures.

In this session, we will discuss how these and other approaches will shape both the research and practice of maker education going forward. We have invited researchers whose work has been foundational in the field to share their thoughts on the future of maker education. We organize the symposium in *four sections*:

1. The chair introduces the topic and gives each presenter 5 minutes to share their thoughts (30 min)

2. Panelists will respond to each others' presentations and to questions from the chair (20 min), including:
   a. How do you see maker education efforts addressing the criticisms of cultural-insensitivity, hegemony, or exclusivity?
   b. From both an environmental and curriculum standpoint, how do you anticipate maker education rising to meet the challenges of sustainability?
   c. As currently new maker technologies become more accessible and novel constructive possibilities arise, which tools or practices most excite you for their potential?
3. Our discussant synthesizes and reflects on the shared ideas (10 min)
4. We will close with a Q&A session for the audience and panelists (15 min).

Innovative features

ISLS introduced for the first time the possibility of "innovative" symposia formats. We intend to take advantage of this possibility by generating more in depth materials that could be accessed before and after the event. Our symposium will have two innovative, "long tail," hybrid features:

(1) Video interviews between the symposium authors: If the proposal is accepted, from March to May we will organize about 6 "interview sessions" in which the authors will interview each other via Zoom for about 10 minutes. Authors will have a chance to articulate their critique and their imagination of possible futures for maker education with more time and in collaboration with a colleague.

(2) Testimonies of teachers and students on their experiences and ideas for maker education: Respecting research ethics and parental consent, we will select participants in each of our research sites and projects, and ask teachers and students volunteers to record about 10 short video/audio testimonies on meaningful, problematic, or promising practices within their classrooms or communities.

All the videos will be posted on the symposium webpage and on YouTube. Around April 2023, we will ask the ISLS organizing committee to include the link to our website in their regular conference communication, so that attendees can watch them before the conference, comment, and ask questions. These will help inform the final presentations and discussion at the conference. After the symposium, ISLS members would continue to have access to the pre-conference materials and the actual video of the symposium.

The following six briefs summarize the participating panelists' work and potential contributions toward the discussion on the future of maker education.

Arts practices as assets as the future of maker education

Erica Halverson

The rise of the STEM movement has provided a fruitful context to re-insert the arts into conversations about what counts as education through the introduction of STEAM, especially if we aim for a "mutually instrumental" relationship between the arts and STEM (Mejias et al., 2021). When we focus on the pedagogical advantages of arts practices, the STEAM framework rejects the concept of "artsy" or "mathsy" people and instead, "places them in a context that is purpose driven, offering an opportunity for creative and flexible thinking that maps onto their key outcomes" (Bevan et al., 2019). Maker education has the potential to build some of the mutuality with the arts that STEAM aims for. However, maker educators face the same challenges that STEAM proponents do – the urge to instrumentalize making in service of accountability measures, such as science content recall or workforce development, without attention to the epistemic practices that STEM and the arts share.

A clear solution is to embrace the asset-based approach of culturally sustaining pedagogies into STEM/Maker education (Ryoo & Calabrese Barton, 2018). *Cultural making* is an approach to asset-based pedagogy that aims for a balance between respecting the local culture and context and the introduction of new elements that teachers or designers bring to the learning setting. Cultural making focuses on, "powerfully engaging youth with the political, human, and social challenges of subverting and transforming one's reality through powerful tools and representations" (Blikstein, 2020, p. 125). Cultural making is visible in art-science projects like the Embodied Physics Learning Lab where choreography is a mechanism to both understand and represent the principles of physics through the medium of modern dance (Solomon et al., 2022). Similarly, the fiber arts can be used to teach math and computing through working with your hands to construct representations of mathematical concepts while valuing the cultural contributions of traditionally feminine art forms (Peppler et al., 2020).

In our work. we use Critical Qualitative Inquiry (CQI) as a methodological approach that seeks to both challenge dominant research approaches, to interrupt discriminatory practices, and to work towards social justice aims (Paris & Winn, 2014; Tunstall et al., 2022). Specifically, we are inspired by Critical Indigenous Research Methodology (CIRM), as scholars who are engaged in CIRM call out the "damage-centered research" that dominates the education space and shift to "desire-based scholarship" in order to avoid pathologizing young people (Tuck, 2009 as cited in Brayboy et al., 2012).

We draw our predictions for the future of maker education from two large studies we recently conducted – one that focused on a maker-mentorship program with rural teens (Nixon, Halverson & Stoiber, 2021) and a second exploring arts practices in community youth arts organizations in historically marginalized communities (Halverson, Martin, et al., forthcoming). In both studies, we gathered longitudinal, qualitative data collaboratively with participants and allowed their interests and expertise to shape the conversations we had and the artifacts they generated. Three key themes are prevalent across these two studies:

1. The arts are not in service of STEM. Leveraging youth assets results in a reframing of what is valuable knowledge and expertise in makerspaces.
2. Drawing on youth's assets highlights how cultural and technical knowing are mutually valuable.
3. Arts-practices-as-assets is broad ranging and includes longstanding, multigenerational practices and rapidly changing youth culture. Valuing this range and living in its complexities is crucial.

The next generation of maker education aims to disrupt the dominance of traditional STEM schooling goals, outcomes, and identities. Cultural making – specifically the use of arts practices as assets that young people bring to learning – can offer us a way to turn to desire-based scholarship and pedagogy and to create equitable systems on our own terms.

The future of making as a return to our roots

Kylie Peppler, Nickolina Yankova, Anna Keune, & Sophia Bender

With close links to mathematics and computing (e.g., Essinger, 2004; Taimina, 2009), historical fiber crafts present an opportune context for maker-centered constructionist learning experiences, focused on challenging domain ideas, such as unitizing within proportional reasoning. Proportional reasoning (PR), or the multiplicative part-to-whole relationship of rational quantities (de la Torre et al., 2013), has persistently challenged learners (Lobato & Thanheiser, 2002). We focus on micro-developmental learning processes within fiber crafts to examine hands-on and transformational learning for youth as they engage in personally meaningful design (Peppler, Keune & Thompson, 2020). We advance the notion of materialized action, the natural inquiry process that results through emergent patterns between learners and the materialized traces of their actions.

We ground our work in constructionism (Harel & Papert, 1991), where learning occurs best when learners design shareable physical (or digital) "objects to think with" that are at once material objects and internalized mental structures. We further draw on relational materialist views (e.g., Hultman & Lenz-Taguchi, 2010) that challenge hierarchies between people and materials, calling for lowering and even flattening such hierarchies.

Situated in an out-of-school workshop developed by crafting professionals and mathematics educators, this study takes a qualitative approach that combines design and intervention. We co-designed workshop activities to support engagement with PR through three fiber crafting traditions (i.e., knitting, crochet, and pleating). Using artifact analysis (Thompson, 2020) and modal analysis (Abrahamson, 2009), we focus on three youth as case studies to capture, analyze, and theorize how the coming-together of materials prompts hands-on and transformational learning. We first engaged with all three crafts to make sample projects toward proof-of-concept. We then drew on video data from the craft workshop and over 200 photographs of learner projects to understand how fiber crafting traditions cultivated mathematical understanding of PR.

We theorize three nested layers of units within fiber crafting. In contrast to preformed units as the basis for ratios and PR, fiber crafts afford tinkerability with units and personalization of produced artifacts. Through choice of materials and individual level of tension, the crafter forms an initial *stitch unit*. Multiplying stitch units produces *pattern units*, larger building blocks, which are reproduced to form the even larger *project units*. Unitizing within fiber crafts reflects materialized actions at play, which we observed in youths' crafting practices. Youth formed relationships with the domain concepts of unitizing and PR through iterative engagement with the materials as they crafted in preferred ways.

Studying relationships among materials and people within maker education can shift not only theoretical understanding of learning in context but can also impact educational practice toward more inclusive and equitable approaches within domains that are still marked by inequitable participation (e.g., Keune & Peppler, 2019). Materialized action proposes a new way of learning about units and PR as well as how to integrate (rather than exclude) worldly concreteness into mathematical practice, promising a new kind of relatability that may shift participation structures in maker settings. We predict that the future of maker education will continue and expand on these practices within and beyond mathematics, opening new possibilities for theory and practice by reconceptualizing traditional dynamics between Maker and material.

The relational, embodied and pedagogical futures of making as transformative educational practice

Shirin Vossoughi

The rise of making has raised important questions around educative purposes (*making towards what ends?*), cultural processes (*the 'how' and 'for whom' of making*), and the conditions that support expansive making (*the design and practice of maker education and educator learning*) (Vossoughi et al., 2016; Barajas-López & Bang, 2018). I will share what my colleagues and I have learned about the relational, embodied, and pedagogical conditions that support making as transformative educational practice, the relationships between *making* and *worldmaking*, and some of the edges of thought that can support the future of making design and research.

I draw on critical (Freire, 1972), socio-cultural (Nasir, et. al., 2021; Vygotsky 1978) and embodied (Goodwin, 2013) theories to elucidate the pedagogical forms, axiological principles (Bang, et. al., 2016), and intentional practices of embodied relationality (Vossoughi et al., 2020) that we have found to be generative within making settings, particularly those nourishing the educational dignity and dreaming of minoritized children and youth (Espinoza, et. al., 2020). I also consider how the empirical study of making settings has contributed to our understandings of human learning and educational justice, and their emergence within moment-to-moment interaction.

Critical, ethnographic, participatory and interactional methodologies (Bang & Vossoughi, 2016; Erickson, 2012; McDermott & Raley, 2011; Paris & Winn, 2013) guide our efforts to carefully attune to the pedagogies and shifts in thinking, making and relationships with learning that emerged within two settings: the Tinkering Afterschool Program (Bay Area) and the STEAM summer experience (Chicago/Evanston). Our inquiries address the specific pedagogical forms that support expansive making and relationality, the relationships between making and opportunities for young people to engage in critical social analysis and dreaming, and the conditions that support robust educator learning.

Data sources include extensive co-authored field notes of teaching and learning interactions in both settings over the span of 3-4 years each; audio-video recordings of making interactions as well as in-depth circle-time dialogues with children and youth; interviews with students, caregivers and educators; images of artifacts in process; audio recordings of routine educator debriefs; and audio recordings of partnership meetings and co-design sessions.

Major themes that have emerged from our long-term research in these settings include:

1. The need to move beyond the binary of adult vs. child-centered education and to consider intergenerational learning, joint-activity and pedagogical artistry as key modes of justice-oriented education (Vossoughi et al., 2021);
2. The significance of moment-to-moment embodied interaction to the experience of educational dignity and expansive relationality (Vossoughi et al., 2020); and
3. The relationships between making and forms of political education that intentionally weave together critical social analysis, the imagination of possible futures and the creation of lived-in elsewheres in the here-and-now (Vossoughi, 2014; 2021).

Brief examples of each will be shared to elucidate these themes.

Looking to the next 10 years of maker education, I consider the conceptions of pedagogical design and practice that are necessary for learning environments organized around making to nurture justice-oriented forms of worldmaking with students, educators and communities (Espinoza, 2009; Kelley, 2003; Simpson, 2009).

A celebration of locally-defined making conceptualizations, technologies, and practices

Marcelo Worsley

For the past ten years, many discussions about making have been dominated by a core set of digital fabrication technologies (e.g., laser cutters, 3-D printers) and a related agenda around advancing STEM education (Blikstein, 2013; Martin, 2015; Vossoughi, Hooper, and Escudé, 2016). Not surprisingly, some of the making opportunities that emerged over the past decade have been among STEM organizations eager to recast their work as new and exciting. At the same time, the field has also seen innovative organizations move outside of the normative frames and technologies of making and embraced local community values (Bodon, Kumar, and Worsley, 2022, Lee and Worsley, 2019; Shaw, Fields, and Kafai, 2019; Worsley and Bar-El, 2020). The next ten years should see more diversified forms of making and a related set of new making technologies.

This work builds on prior work around identity development (Nasir, 2002) and interest-based learning environments (Ito, 2013). Youth identity development interacts with learning and goals in ways that may show up particularly well in making experiences where youth are provided opportunities to bring their identities and interests into the learning space. Moreover, aspects of this work reflect ideas about intentionally centering minoritized identities and interests within the context of making.

Ethnography (Atkinson and Hammersely, 1998) is the primary methodology used to ground this research. The author worked as a researcher, educator, and teacher educator throughout the past 6 years in a variety of in-school and out-of-school making experiences. In aggregate, the author interacted with and observed work with more than twenty making-related organizations. Observations, student work, and field notes from interactions with students and teachers are the primary basis for this presentation.

I identify four trends that I believe will shape the next ten years of maker education. First, teachers and students have gravitated towards making activities that bridge making and student interests related to sports (Worsley, 2022), music (Bar-El and Worsley, 2019; Horn et al., 2022), fashion (Shaw et al., 2019) and games (Kafai & Burke, 2015; Maloney et. al., 2010). In many cases, participants tap into a different set of making tools (Das et al., 2020) or find novel ways to use existing technologies (Bar-El et. al., 2018). Hence, in addition to intersecting making with new disciplines, making will likely see the introduction of new (and old) tools. Second, organizations are developing bridges between making and non-western cultural practices. This observation has particularly been made in organizations in Thailand and Hawaii where students connect a commitment to protect the environment with the practices of making. Third, organizations that work with youth with disabilities are defining making in ways that resonate with their community. This involves re-evaluating the tools that are used in making and questioning normative definitions of concepts like creativity (Worsley and Bar-El, 2020). Fourth, making is becoming embedded into day-to-day learning experiences. As more pre-service teachers engage with making as part of their training, we can anticipate that they will more easily adopt making as part of their practice.

The next ten years will hopefully see making shift and adapt to a broader set of disciplines, concepts, cultures, and communities. In so doing, more of the work currently taking place along the fringes of the community might become more central.

The future of making: A robust focus on maker educator preparation

Lee Martin & Ciara Thomas Murphy

The past ten years have dramatically expanded our understanding of maker education, its potential benefits for learning and identity development, and the ways in which learning environments can be made more equitable for all learners, especially those, like women and people of color, often excluded and marginalized in such spaces. While more research is needed on all these fronts, we already know a tremendous amount about how to create good quality, equitable maker learning environments, and we have several stellar examples of such learning environments documented in the literature.

We believe the next decade of maker education research should robustly study how people learn to become maker educators. Educational reforms too often doom themselves through inattention to teachers and how they learn (Tyack & Cuban, 1995). We must build from the small but significant body of work on maker educator preparation (e.g., Harlow et al., 2018) to develop models and practices that elucidate how people prepare to work as maker educators in ways that support richly meaningful, equity-oriented making.

We discuss insights from our studies of maker educators to outline two possible areas for inquiry. We draw from studies of teacher noticing (e.g., Jacobs et al., 2010) to consider how educators can begin to see students, materials, and learning environments in new ways. We also draw upon the idea of parallel process (Sarnat, 2019) to examine how educators relate their own experiences as makers to their role as facilitators.

Data for this presentation include interviews and written reflections. We conducted interviews with two groups of maker educators: one group reflecting on their efforts to facilitate remote making during COVID (Martin & Thomas Murphy, 2022) and another group learning about and reflecting on making and tinkering by engaging with such activities themselves (Thomas Murphy & Martin, 2022). We also draw on written reflections from undergraduates learning to work as mentors in maker education settings. We engage in thematic analysis of the whole body of interview and written reflection data (Braun & Clarke, 2006).

We identify two interrelated themes that we believe offer a fruitful addition to a research agenda on the future of maker education. First, educators' own experiences with making and tinkering provide important opportunities for them to learn to notice pedagogically relevant and meaningful features of making activities (Mason, 2002). For example, educators learn to see sticking points and avenues for resolution in a new light through their own making. Second, educators must work to transcend their own experiences as makers to see their students' experiences wholly and distinctly (hooks, 1994). Here, we see connections to play (creating non-judgmental space for personal expression) and relationship building (developing empathy and seeing others more fully). Moving beyond one's own experience is a critical move for equity-oriented pedagogies as educators work to recognize and highlight students' assets.

A focus on educator preparation will allow the field to translate findings from the past decade into better maker education experiences for young people in the next decade. This presentation contributes to an agenda for that work.

The future of making: Resolving maker education's category error

Paulo Blikstein, Yipu Zheng, Leah Rosembaum, & Richard Davis

Though certainly not unique to this field, we propose that maker education has reached a crossroads where the multiplicity of meanings ascribed to its name, and the multiple competing historical trajectories that explain its origin, have begun to distract research and development efforts. We suggest reconsidering a taxonomy of making, crafting, and fabrication practices to more clearly delineate the modes of activity, spheres of operation, and possibilities for creativity and learning.

Taking a historical view, and analyzing the literature and non-academic documents, we investigate the history of maker education and its predecessors, to examine some critiques currently leveled against maker education. Before Make Magazine and Maker Faire imparted the Make brand on fabrication activities within educational spaces, kids were doing creative, technology-enabled projects well-aligned with constructionist principles under names like "crafts," "robotics," "tinkering," "engineering," or "digital fabrication" (e.g., Eisenberg (2002); Jeanne Bamberger's (2014) "Laboratory for Making Things" from the 1980s). Research and development on such practices worked to serve diverse and nondominant learners (Milner, 2009; Sipitakiat, 2005).

With the increasing prominence of the MAKE organization in the educational mainstream came MAKE's (now infamous) claim of ubiquity: "every kid is a maker" and, consequently, almost everything is "making." This popularization invited criticism. Buechley (2013) specifically addressed the lack of diversity and representation within MAKE Magazine's publications. Entrepreneurship was part of it, as well as a discourse of national competitiveness, pointed out by Vossoughi et. al (2016). Both researchers emphasized that communities had been "making things" for centuries, and that the "Make" brand was misappropriating the term and recasting it as something invented in Silicon Valley. Many of those critiques were directed at the branded version of the movement; but many of the previous, non-mainstream versions of "making" were doing very different types of work (e.g., Milner, 2009). That nuance was lost in translation, and the critique was generalized, glossing over the very significant differences between mainstream Making and other experiences. "Maker education" needs urgent semantic attention.

We need a new taxonomy of making practices, from industrial production to artisan-scale, that captures its multitude of goals: expression, competition, ritual, learning, subsistence. An adult crafting practical items for their home or community carries vastly different implications for equity, empowerment, and learning than do kids tinkering with robotics or an Indigenous artisan creating a ceremonial item. Referring to all these practices as "making" blurs their distinctions and dulls the generalizability of research claims about them. It also invites critiques that focus on the semantics of the term instead of looking at the empowering and agentic possibilities for learners.

In the last ten years, it has become somewhat passe to extoll the virtues of maker education–and in many cases, for good reason. But project-based, student-centered learning remains leagues better than what traditional classrooms offer. Today we have not one, but many version of "maker education," from the corporate, cookbook-style, and Silicon-Valley-themed workshops, to rich and complex community driven, emancipatory educational projects. In this presentation, we will bring a rich historical and conceptual documentation on the history and theories behind maker education, towards creating a conceptual taxonomy of making practices and pedagogies that can help clarify the research claims and focus of each of its versions, so that their future educational possibilities - and problems - might be better understood.

Abstract: This symposium brings together researchers and practitioners from four regions in three countries who localized, adapted, implemented, and evaluated a 24-lesson kindergarten curriculum called Coding as Another Language (CAL). CAL uses ScratchJr and unplugged activities, to promote computer science learning and computational thinking development. Given the growing need for evidence-based curricula that allow the integration of computer science and computational thinking into early childhood, this symposium brings together educational researchers and practitioners who worked with CAL in kindergarten classrooms to share their experiences. This symposium presents comparative experiences, across languages and continents, which involved adaptation of curricular materials and assessment instruments, language localization, training research partners, conducting professional development for teachers, mixed-methods data collection with children and teachers, and analysis of results. Lessons learned about working in cross-cultural settings, integrating computer science in the early childhood classroom, and different conceptions of literacy, across different countries will be shared.

Description

This symposium brings together researchers and practitioners in four locations: two regions of the United States (one on the East Coast and one on the West Coast), Argentina, and Israel. The researchers and practitioners worked to localize, adapt, implement, and evaluate a 24-lesson kindergarten curriculum called Coding as Another Language (CAL). CAL uses the ScratchJr free programming language, along with unplugged activities, to promote the learning of computer science and the development of computational thinking.

The pedagogical foundation of CAL involves the understanding of coding as a literacy, that is, putting powerful ideas of computer science in conversation with those taught in language arts. Since kindergarten is a schooling period in which children are starting to be exposed to symbolic systems of representation, CAL introduces the teaching of an artificial language (i.e., programming blocks of ScratchJr) at the same time as instruction about the children's natural languages (in this case, English, Spanish and Hebrew).

The Coding as Another Language (CAL) approach (Bers, 2019, Bers et al., 2022) views the learning of computer science as a new literacy for the 21st century that supports young learners in developing new ways of thinking and expressing themselves. The CAL approach is not about teaching children how to code so they become software developers. It is about children developing character strengths, problem-solving strategies, and collaborative attitudes, along with technical skills and computational thinking (CT), to become future global citizens who can think and act in new ways. Based on this pedagogical approach, the DevTech team, directed by Marina Bers, has developed the K-2 CAL curriculum units using the free ScratchJr introductory programming language.

CAL was designed using principles of three theoretical frameworks: Curriculum Research Framework (CRF), which proposes different phases of work in the creation of research-based curriculum (Clements, 2007); Constructionism, which presents a computationally-rich project-based methodology based on identifying powerful ideas from a learning domain (Papert, 1980); and Positive Technological Development, which intentionally integrates socio-emotional and ethical dimensions into curricular experiences (Bers et al., 2012). The CAL curriculum introduces powerful ideas from computer science, in conversation with literacy, in playful, structured, and developmentally appropriate ways. The curriculum consists of 24 lessons, designed for a total of 18 hours. Through unplugged games, storytelling, movement, singing, and coding, students learn computer science and develop problem solving and computational thinking in the context of creating their own projects using the ScratchJr coding app. In addition, to strengthen the literacy connection, students explore two books, a non-fiction book exploring a historical figure in STEM and a fiction book with a narrative story and a social-emotional component, to write creative, fun programs on ScratchJr. In the kindergarten curriculum, the two books are *A Computer Called Katherine* and *Knuffle Bunny*, which are both available in Spanish as *Una computadora llamada Katherine* and *El conejito knuffle*. Alternative books were selected for the Hebrew curriculum, as is described in Paper 3.

CAL has been used over the last few years by thousands of children and hundreds of teachers all over the world and has been translated and localized from English into Spanish and Hebrew. Given the growing need for evidence-based curricula that allow the integration of computer science and computational thinking into early childhood, this symposium brings together educational researchers and practitioners from three different countries who worked with CAL in kindergarten classrooms to share their experiences.

This symposium presents comparative experiences, across languages and continents, which involved adaptation of curricular materials and assessment instruments, language localization, training research partners, conducting professional development for teachers, mixed-methods data collection with children and teachers, and analysis of results. Lessons learned about working in cross-cultural settings, integrating computer science in the early childhood classroom, and different conceptions of literacy, across different countries will be shared.

Each of the papers in the symposium addresses four interrelated issues:

1. Researcher-practitioner collaboration to implement CAL and study the impacts of CAL in kindergarten programs.
2. Localization of CAL to achieve feasibility of implementation and evaluation.
3. Learning outcomes in terms of coding, CT, and literacy for students participating in CAL.
4. Teachers' experiences regarding the construct of "coding as a literacy."

As new curricula and experiences are developed, implemented, and evaluated, it is important to understand the factors that make this feasible, sustainable, and scalable internationally. Furthermore, while coding is a universal language, when integrated into classrooms across the world that have different educational practices regarding the teaching of alphabetical and computational literacy, lessons can be learned about culturally responsive instruction.

This symposium will help move the field forward by contributing to the emerging understanding of how to integrate coding and CT in diverse early childhood settings and exploring implications for both research and practice across the world.

The papers in this symposium address each of these issues by presenting the experiences in four different locations: 1) On the East Coast of the United States in a large urban district in Massachusetts and several districts in Rhode Island; 2) On the West Coast of the United States in a large district in California; 3) In Argentina in two large districts in Mendoza and Corrientes; and 4) In Israel in a small school in Haifa.

Symposium structure

The session chair will introduce the symposium theme and goals, as well as the CAL curriculum and ScratchJr programming language and the methodological approach used in the comparative study (15 minutes). Then, four papers, each describing one of the studies: US, East Coast, US: West Coast, Argentina and Israel will be presented in the order listed in the proposal (10 minutes each). After this, the chair will comment on general trends and discuss converging themes and implications (10 minutes). The session will conclude with a moderated discussion between the presenters, coordinated by the chair) and open Q&A with the audience, focusing on implications for research and practice (10 minutes).

Methodology

All papers presented in this symposium involved the following components:

- Conducting professional development(PD) about the ScratchJr coding app, and the CAL curriculum and pedagogy.
- Providing ongoing support to teachers implementing the CAL in kindergarten classrooms
- Examining impact on teacher's attitudes and knowledge and students' computational thinking and coding skills
- Understanding teacher and student experiences regarding coding and literacy

- Trained research assistants administered student computational thinking (Tech Check) and coding (CSA) assessments over Zoom before and after the CAL curriculum was implemented.
- Teacher surveys, lesson logs, focus groups, and end-of-year interviews were used.

Paper 1: Coding as Another Language on the East Coast of the United States

Parastu Dubash, Zhanxia Yang, Tess Levinson, & Marina Bers

On the East Coast of the United States, we conducted a randomized control trial of the Coding as Another Language (CAL) ScratchJr curriculum in kindergarten, first, and second grade classrooms in two New England states. The curriculum was initially designed for this setting, so it was not adapted to be localized for this implementation. This paper will primarily focus on the kindergarten implementation.

Schools were randomly assigned to either the "treatment" condition or a "control" condition. For the treatment condition, the CAL curriculum was introduced in 18 total kindergarten classrooms from three public school districts in one state (Site 1) and five schools from a large urban public school district in a different state (Site 2). These nine schools were randomly assigned to implement the CAL curriculum. Twenty-seven teachers from these nine "treatment" schools received a 4-hour, virtual professional development. The professional development covered ScratchJr, a block-based programming language that enables young children (ages 5 and up) to create their own interactive stories and games, the CAL pedagogy, the CAL curriculum, and the research study protocol. Participating teachers then taught the CAL curriculum, completed surveys and lesson logs, and participated in focus groups.

Nine additional schools participated as "control" schools in this randomized control trial. In these schools, teachers completed "business as usual," meaning they taught their traditional existing curriculum without including the CAL-ScratchJr curriculum or making modification. Therefore, these teachers did not receive ScratchJr and CAL curriculum training and did not implement the curriculum. In these control schools, 10 Kindergarten classrooms with 166 students participated in the same one-on-one virtual coding games assessments with a trained research assistant where student coding skills and computational thinking (CT) were assessed at two points in time, similar to the times the students in the treatment group were assessed.

Two-hundred forty-seven kindergarten students (158 from Site 1 and 116 from Site 2) were assessed on coding knowledge and computational thinking (CT) using the Coding Stages assessment (CSA) and TechCheck assessment before and after completing the curriculum (Ruiter and Bers, 2021, Relkin et al., 2020). Students who received the CAL curriculum had a mean pre-curriculum coding score of 1.87 (SD= 1.23) and a post-curriculum coding score of 7.75 (SD= 3.23). The intervention group showed significantly higher growth of coding performance ($\beta = 4.14$, Hedge's $g = 0.39$) than the control group, who grew from a mean coding score of 2.31 (SD=1.47) to 3.99 (SD= 2.05).

The intervention group also grew on the assessment of computational thinking, with a pre-curriculum TechCheck score of 7.042 (SD= 2.32) and a post-curriculum TechCheck score of 8.53 (SD= 2.43). However, this increase in students' computational thinking scores across time was not significantly different from the control group, who had a pre-curriculum TechCheck score of 7.11 (SD=2.42) and a post-curriculum TechCheck score of 7.96 (SD= 2.36).

Teachers' self-reported efficacy (confidence that they could teach various aspects of the coding curriculum to their students) from both Site 1 and 2 increased significantly after the PD training ($t(42) = 7.48$, $p < 0.001$), $t(31) = 6.97$, $p < 0.001$). Self-efficacy was reported on Likert scale from 1 to 5 and grew from a mean of 2.8 (SD = 1.14) to 3.98 (SD = 0.73). These results include all K-2 teachers who participated in the PD training, not just kindergarten classroom teachers, as the PD and study included both classroom teachers and enrichment and support teachers who taught the curriculum in multiple grades.

Additionally, qualitative data from these teachers who taught and supported kindergarten classrooms provide opportunities to explore many differences in these samples including collaboration, support, and teacher role. While some teachers are the sole participating teacher at their school, others have participating colleagues to collaborate with. Also at Site 1, designated Tech Leaders at each school provide ongoing support to teachers. In addition, classroom teachers may have flexibility regarding when and how often to implement, while enrichment teachers may have limited scheduled times. These conditions along with teacher reports of support and curricular modifications are examined as well as their impact on outcome measures.

Teachers shared that their students, "asked to do it [the CAL curriculum and ScratchJr] every day. If we couldn't do it, they were disappointed." One teacher mentioned, "watching the kids get up to help other kids naturally and organically without being told someone needs help… that's a highlight when you see kids taking over the responsibility in the room themselves."

Yet another teacher emphasized, "Post-Covid, it was just what we needed. It was interaction, it was dynamic, give and take." She also added, "And I had five students where English was not their second language, and loved watching how they all did with this."

In terms of integrating the CAL curriculum into their existing curriculum, one teacher mentioned, "We were learning about different ecosystems... and they [ScratchJr app] happen to have the jungle and the ocean, and so kids were able to explore with those backgrounds and add the animals that belong there."

When asked if they would recommend the CAL curriculum to other teachers, one teacher said, "I've recommended it a million times. We are actually going to be training all of the K-2 teachers in our district; that's going to be my role…They know I've been talking about perseverance, and grit, and applied skills, and those soft skills… cooperative learning, collaboration, and so they know… that this is going to be a really exciting time for them.

Our findings suggest that the CAL curriculum was both a successful program for improving coding knowledge on the East Coast of the United States and was enjoyable to classroom and support teachers. This second feature is promising for future use of the program, as an enjoyable program is more likely to be implemented in the future and remain part of the school's program. As mentioned above, the curriculum was not adapted to be localized for this implementation. However, that does not mean that the curriculum may not have been adapted for local cultural contexts, as individual teachers may have localized the curriculum to meet the cultural contexts of their classroom. In future research, we will examine individual classroom differences in teachers' experiences and implementation practices of the curriculum, as well as student responses to the curriculum.

Paper 2: Coding as Another Language on the West Coast of the United States

Sharin Jacob & Mark Warschauer,

As evidence-based curricula scale, it is crucial to account for local contexts to co-design instructional materials that are appropriate for diverse and often marginalized communities. This paper investigates teacher implementation of the Coding as Another Language (CAL) curriculum for California's culturally and linguistically diverse learners.

Our study draws from the Jacob & Warschauer (2018) model of computational literacy, grounded in sociocultural theory, including the work of Barton and Hamilton (1998); DiSessa (2000); and Gee (2000). The Jacob & Warschauer (2018) model takes an asset-based approach to understanding how teachers can leverage students' literacy skills to develop their computational thinking skills and vice versa. This paper builds on this work to consider the cultural and linguistic factors contributing to the development of computational literacies for diverse learners. As a result, this new culturally responsive model explores how teachers can mobilize the rich traditions and cultural practices present in marginalized communities.

This Design-based Implementation Research (DBIR) pilot study followed three teachers as they implemented the CAL curriculum in their culturally and linguistically diverse classrooms. The participating district in California has among the highest percentages in the US of Latinx students (93%), low-income learners (89.7%), and students designated as English learners (62.7% in the elementary grades). Therefore, we focused on culturally responsive instructional adaptations and strategies teachers used to develop computational literacies for Latinx and multilingual students.

Data sources included field notes on co-design meetings with teachers who engaged in reflection cycles, in which we collected their feedback and reflections to improve the intervention. The field notes focused on instructional strategies and their relationship to student engagement, coding activities, and language use. Co-design teachers were also formally interviewed at the end of the year to better understand their instructional goals and practices and to collect feedback for improving the curriculum and PD.

Teachers suggested several adaptations to the curriculum that would better meet the needs of their Latinx and multilingual students, including 1) integrating culturally responsive materials, such as storybooks depicting Latinx computer scientists, into the curriculum; 2) providing additional language support; 3) balancing guided instruction with exploration; and 4) increasing multimodal and digital resources. We will use these and other findings to revise the curriculum to meet the needs of the district's diverse learners.

Considering that Latinx and multilingual students have unequal access to technology and CS learning (Irwin, 2021), it behooves researchers to focus more attention on culturally responsive CS interventions that promote equitable participation for these students. Implementing culturally responsive instruction that accommodates local contexts of diverse communities leads to increased teacher uptake of evidence-based curricular interventions such as CAL and better supports both scaling efforts and overall sustainability.

Paper 3: Coding as Another Language in Haifa, Israel

Avia Ben-Ari, Rinat Rosenberg-Kima, & Marina Bers

In this case study, we implemented the CAL-ScratchJr-K curriculum in a Hebrew-speaking kindergarten classroom in Northern Israel. The implementation included a professional development (PD) training for teachers and curricular implementation over the course of seven months. We were interested in teachers' self-efficacy and objective ability to implement coding in their classes while using the CAL-ScratchJr-K curriculum. Furthermore, we were interested in accounting for the adaptations needed to implement the CAL-ScratchJr-K curriculum as a program developed in alignment with American pedagogical standards and culture, which are very different from the ones in Israel.

Kindergartens in Israel are part of the preschool education system as opposed to the American elementary school system. As such, kindergarten programs in Israel differ greatly from their American equivalents in terms of literacy instruction, which officially starts in the first grade. Thus, the children we worked with were not yet exposed to formal reading and writing. Nevertheless, informally, students were immersed in a culture in which the Hebrew language is written from right-to-left, as opposed to left-to-right. The ScratchJr coding language is assembled left-to-right, which might create a mismatch in directionality between coding and natural language in Israeli children. We were interested in whether this would interfere with children's development of coding skills.

The CAL-ScratchJr Kindergarten curriculum was implemented in a Hebrew-speaking kindergarten classroom for a period of seven months. Two teachers and 26 children (14 boys, age mean=6, sd=0.33) participated in this project. All student and teacher-facing materials were translated to Hebrew, and necessary cultural adaptations were implemented. For example, instead of using the book *Hidden Figures*, teachers taught the book of *My First Hero: Marie Currie* to better integrate the coding curriculum with their broader science unit.

Teachers' coding stages assessments (CSA) and their self-efficacy surveys were collected before and after PD completion. Teachers also completed a mid-curriculum survey. Furthermore, teachers reported all adjustments made to the curriculum. Students' pre-CSA (coding) and TechCheck (computational thinking) assessments were collected at the beginning of the curriculum and again at the end. In addition, 26 ScratchJr projects created by each child were scored using the ScratchJr project rubric. Teachers' summative in-depth semi-instructed interviews were also conducted at the end of the curriculum.

Children's average CSA stage was *Pre-Coding* at baseline, with an average TechCheck score of 7.56 (SD=1.7). At post, children's average CSA stage was *Emergent*, with an average TechCheck score of 8.23 (SD=1.86). Both teachers scored higher on their CSA stage following the PD training, moving from the *Emergent* stage to the stages of *Fluency* and *New Knowledge*. Likewise, their self-efficacy to teach basic coding principles improved following PD completion. In terms of cultural adaptations to the curriculum, age-related cognitive abilities and cultural considerations urged the omission of all charts and tables as well as of most nursery songs, and required further scaffolding in literacy activities. Interestingly, teachers reported that the platform's inherent English aspects did not hinder learning.

Results suggest that the CAL-ScratchJr-K curriculum may support teachers' perceived self-efficacy and objective ability to implement coding in their classes, contributing not only to the teaching of coding at early ages but also to the empowerment of early childhood teachers and children *within* the educational system. This conclusion is depicted in the following account, given by the primary teacher who taught ScratchJr in her classroom: "I've always thought that computers were a 'boys' thing' [and] I used to have a serious computer phobia (…), and today I do everything on my own! Suddenly, I've come to realize that I am a programmer, a technician, that I *solve* problems! I really went through an empowering process. I felt valuable. My [coding] knowledge gave me strength." Furthermore, despite pedagogical and linguistic differences, the translation of the curriculum and its cultural adjustments do not seem to require the adaptation of the ScratchJr coding platform itself.

Paper 4: Coding as Another Language in Argentina

Tess Levinson, Pamela Gonzalez, Hernan Gonzalez, Carolina Gimenez, & Marina Bers

According to data provided by the World Bank, the rate of learning poverty, an indicator that combines the concepts of schooling and learning at the end of primary education, based on reading literacy and school enrollment indicators generated in the reporting process of Sustainable Development Goal 4- showed in the 2018 Development Report, that in low and middle-income countries more than half of children cannot read and understand simple text at the age of 10 years (World Bank, 2017). On average, learning poverty in Argentina is 53.9%.

This project was designed to address learning poverty in two provinces in Argentina, Mendoza and Corrientes, by focusing on the development of new literacies (coding and computational thinking) in conversation with traditional alphabetical literacy. Additionally, the pilot project was designed to learn lessons that could later be replicated to other provinces in the country and in Latin America. The CAL-Argentina study in kindergarten reached 39 teachers across the provinces of Corrientes and Mendoza. Assessment and data collection was done both virtually and in-person depending on Wi-Fi-dependency and other resources available at each site. All instruments, training, consents, and study materials were translated and localized into Spanish. Spanish versions of the curriculum books were identified at this time. In the classroom while teaching, teachers made further decisions regarding localization, including adapting songs, games, and lesson activities to fit their classroom and curriculum. These decisions were documented in teachers' lesson logs and further recorded during focus groups and will be analyzed in future papers.

Like in the United States, schools were randomly assigned to a treatment condition (receiving the CAL curriculum) or a control curriculum (with instruction as normal). Seventeen schools, with 62 teachers and 529 students participated in the study, with 284 students receiving the CAL intervention and 245 students in the control condition. Both student and teacher data were collected to parallel data collected in the CAL-ScratchJr studies in the United States. Student data included the Coding Stages Assessment of coding knowledge and the TechCheck assessment of computational thinking collected before and after the curriculum and ScratchJr projects collected at three time points during the curriculum. Teacher data included the CSA and TechCheck assessments before and after training, surveys at four timepoints, and focus groups before, during, and after curricular implementation. 223 kindergarten students participated in the study.

In the kindergarten sample, the mean coding stage for a child at baseline was in the Pre-Coding stage with a CSA score of 3.32 (SD = 2.55). There was a significant interaction effect of condition and timepoint on coding knowledge, $F(1, 435) = 100.25, p < 0.0001$. Students who received the curricula scored higher on the post-curriculum coding stages assessment (M = 9.90, SD = 4.07) than students in the control condition (M = 4.70, SD = 1.97).

Overall, kindergarten children had a mean TechCheck score of 7.37 (SD = 2.14) at baseline, with a mean score of 8.40 (SD = 2.66) for children in the control group and a mean score of 7.79 (SD= 2.47) for children in the treatment group. This difference was statistically significant. Unlike in the United States contexts described above, there was a statistically significant interaction of condition and timepoint on computational thinking, with the treatment group (M = 10.42, SD = 2.23) surpassing the control group (M = 9.56, SD = 1.73) on post-curriculum TechCheck scores, $F(1, 435) = 11.69$, $p < 0.001$.

These results, and the differences between the Argentinian and United States findings, suggest that in adapting an early childhood curriculum across international settings, collaborators should consider that expected developmental trajectory across the school curricula differ across different countries. Curricula and resources for kindergarten programs, both generally and specifically for technology, vary across countries. Additionally, when discussing kindergarten programming, we should consider that language and literacy programs for kindergarten students differ across languages and countries. The available resources may also affect the implementation of the CAL curriculum, as different schools may have different environmental features such as movable tables, flexible seating, or available crafting materials. Further research should examine how these factors play a role in the effectiveness of the CAL program implementation across countries. We should also consider variations in the existing computational thinking and computer science curricula experienced by the children in control conditions in various countries, as what is considered developmentally normative for the control group may in fact be a feature of a country's existing curriculum. Moving forward, this variation in development should be accounted for as we continue to develop coding language and computational literacy curricula and programs for children in early childhood in a variety of national, cultural, and linguistic contexts.

Abstract: In the US in recent years, public engagement in public schools has become highly politicized, reflecting the polarized discourses circulating in media and inflamed by national figures. “Official” spaces for public input exist alongside multiple less officially policy-relevant spaces where youth and adults learn and negotiate the function/ing of public education. This symposium examines how diverse school-adjacent spheres of public life function as pedagogical spaces - spaces where the discourses and technologies of schooling are learned through the cognizant and non-cognizant design and organization of discourse and activity. The cases considered span from youth-centered spaces such as the school bus and a middle school debate team to a case examining the intersection of how news and social media is negotiated at a public committee meeting and closing with two contrasting examples of school district-sponsored public forums addressing issues such as overcrowding and budget.

Symposium overview

As persistent issues of inequality in educational spaces rise to the forefront of national conversations in the US, we are reminded that education and schooling is everyone’s business. Even those who are not presently children, parents, teachers, or school administrators have at some point experienced school, learning through experience what school is, shaping ideas about what it should or could be, and licensing public commentary on education from people in all walks of life. Notably, the school building is not the only place where we learn what school is, what it can be, or how to participate in public discourse shaping policy in response to these questions. In this symposium we consider how people learn in and through school-adjacent spaces both what school is or can be and how to participate in public discourse about school.

In the US, public engagement in public schools (schools supported by public funds) has become a highly politicized space, reflecting the polarized and often vitriolic discourses circulating in media and inflamed by national figures. “Official” spaces for public input, such as through the election of public school boards, open school board meetings, and district-sponsored public forums exist alongside multiple less officially policy-relevant spaces where youth and adults learn and negotiate the function/ing of public education, drawing on long histories and reflecting possibilities for our children’s futures.

Public school boards, one type of semi-public forum for shaping public education, is one space where an official governing body has substantial power as it “(a) defines reality, (b) orders behavior, and (sometimes) (c) allocates resources accordingly” (Levinson et al., 2009, p. 770). Public participation and commentary on policy making is one place we can look to to see how the status quo is maintained or challenged. On the one hand, public spaces like school boards can be places of possibility where citizens have the opportunity to affect policy making decisions, as described by Collins (2021): “This opportunity for efficacy [in affecting policy decisions] is particularly available at the local level, where schools boards and city councils govern within reach of the citizenry” (p. 790). However, school board meetings in particular are often an authoritative and ritualistic (e.g., Robert’s rules of order) space where local politics and civic life collide in less-than-transformative ways. Learning to engage with the body politic of school boards, and likewise learning to participate in formal debate, requires learning genres of public comments, of argumentation, rebuttal, and the power of non-authorized policy actors (i.e., students, teachers, community members; Collins, 2021; Jenkins, 2022; Levinson et al., 2009; Tracy & Durfy, 2007).

Other types of spaces organize public engagement with education in different ways, opening alternative affordances for learning and numerous ways that actors can be positioned. For instance, public engagement in participatory grassroots organizing efforts—building on affinity spaces as well as affordances of connected social media spaces—shows potential for citizenship that can organize into powerful vehicles for demanding critical and consequential change (Ito et al., 2015). This does not mean that informal or grassroots organizers are inherently equitable, as social power differentials can lead to the privileging of certain narratives and inequitable results—particularly narratives driven by white supremacy (Ewing, 2018; Joffe-Walt et al., 2020).

Youth participation in public narratives on education abound, but are seldom recognized as legitimate civic participation and may even be positioned as disrespectful or insubordinate (Kelly, 2020). Interactions in places such as social media or after-school clubs and activities provide insight into youth perspectives and the ways they both learn and teach the ways of talking, thinking, and participating in shaping the future of education and school. We are interested in how youth spaces such as the debate team or even school buses may be important political spheres for learning about schooling.

Conceptual framework: School-adjacent spaces as pedagogical

We examine how diverse school-adjacent spheres of public life function as *pedagogical* spaces - spaces where the discourses and technologies of schooling and public participation in public schooling are learned through the cognizant and non-cognizant design and organization of discourse and activity in those spaces. In other words, “space is treated as a product of social practice, not simply a frame for it” (Nespor, 2000, p.25). We bring together diverse cases in order to consider how different spaces beyond the school building may shape how the public learns what public school is or can be. We see this work as extending emerging work in the learning sciences that explores learning as political by examining learning in and as a feature of power in the political spheres of public life (Booker et al, 2014; Esmonde & Booker, 2016; The Politics Writing Collective, 2017). Moreover, we suggest that understanding these spaces as pedagogical may provide critical insight into how our imaginations are shaped regarding what is possible in schools and add to work that “elucidate[s] the way that policy typically serves to reproduce existing structures of domination and inequality” (Levinson et al., 2009, p. 769) as well as looking at ways these policies can be disrupted.

Format

The cases considered span from youth-centered spaces such as the school bus and a middle school debate team to a case examining the intersection of how news and social media is negotiated at a public committee meeting and closing with two contrasting examples of school district-sponsored public forums addressing issues such as overcrowding and budget. The symposium format intentionally brings together diverse cases in order to consider official and unofficial policy-relevant spaces, voices from youth and adults, and examples of both the perpetuation, disruption, and re-storying of existing narratives surrounding purposes and possibilities of public schooling. After each case, virtual and in-person participants will have time to discuss and compare the pedagogies of each case.

The symposium itself will be briefly introduced by the Co-chairs, Karis Jones and Emma Gargroetzi. Each of the five cases will be presented. Following these presentations, Discussant Tanner Vea, with expansive expertise studying power, politics, and learning, particularly in social change efforts and design, will provide commentary on the necessity and potential of understanding school-adjacent spaces as pedagogically consequential for education and public school. A significant portion of the time will be held for discussion and conversation with attendees. We invite participants to consider with us: Where and how does learning across these five cases suggest reproduction or transformation in the face of material and discursive systems that shape schooling? How might unveiling these possibilities and constraints support new forms of learning and engagement with public education?

Significance

In a moment where high-stakes decisions about banning books, silencing history, restricting bathrooms access, and arming teachers with automatic weapons threaten the lives and livelihood of both children and adults in schools, the stakes of the political life of schools continue to grow. Yet, these decisions are largely made outside of schools themselves. This symposium contributes needed attention to the question of where and how people learn what can and should be expected from schools, and what it means to participate in conversations about these very topics. In framing and examining the activity of these school-adjacent spaces as pedagogical, we offer a lens that may be productive for uncovering insights about the design and organization of these spaces as products of social practice (Nespor, 2000). In unveiling the socially produced nature of these spaces, we leave them open for disruption, and can perhaps more freely imagine them being produced anew, with more just and joyful possibilities for the future.

Re-storied journeys: The school bus and the narrative of public education

Antero Garcia

This paper explores the role of the school bus as a form of public discourse about education and the ways youth voices are largely silenced in their daily commutes as passengers to and from sites of formal education. Everyday, millions of students across the US rely on public school buses to get to and from school. These gigantic vehicles-brightly painted, hissing with hydraulic brake systems, and puttering away slightly below the speed limit improbably operate out of the vision of school policy and social discussion. These vehicles impact nearly every school in the US and yet seem to be invisible when it comes to discussions of schooling and structure. The fact that the school bus does not come up as a central policy discussion (except for when a global pandemic causes it to stop operation) is a reminder of how central the school bus is to the day-to-day operation of schooling.

Despite not changing in design for nearly a century, the school bus's function as an intervention on the educational outcomes of students in the US makes it the most substantial form of educational technology in this country (Garcia, in press). As a cognitive technology, the school bus disrupts education in two ways. First, its role in shifting school demographics post Brown v. Education is so profound that the verb "busing" is synonymous with addressing desegregation mandates. Second, as a hulking piece of machinery, the bus is a form of (albeit) archaic technology that acts on the lives of young people every day. Both of these disruptions are so persistent and long lasting that it's arguable that they are even disruptions at this point rather than a part of the status quo.

Spending a year of ethnographic participant-observation (Geertz, 1973) alongside young people on a school bus and engaging in historical research on the development of the school bus and the policies that structure it, this paper explores how public engagement with the school bus reinforces an understanding of the bus as implicit and necessary in the operation of public schooling. Every moment of on-bus bullying, of traffic-control through the use of a blinking set of lights, and of picking up and dropping off of kids at local stops is a reminder that these buses act as a part of the seamless infrastructure of American schooling (Edwards, 2021). Further, as a temporary space that reorients and transforms the behaviors and possibilities of its users, the archaic bus is also a reflection of contemporary representation of the role of platforms on education and policy (e.g. Gillespie, 2010; Srnicek, 2017).

Finally, drawing on the work of Thomas and Stornaiuolo (2016), the narrative of the school bus is not fixed; we can "restory" it. While the narrative of the school bus conveys it as a sometimes uncomfortable but necessary component of how students interact with and participate in schooling in the US However, through shifting the gaze of schooling from a structural analysis of school systems to a humanistic perspective of young people's learning opportunities, this paper argues that school buses might be sites for resistance, imagination, and realigning public discourse.

Reconstructing debate as public pedagogy: Advocating for speculative civic futures

Nicole Mirra

Purpose

This paper illuminates the organization of learning within a middle school debate team that sought to transform the activity of debate from an academic exercise to a critical enactment of public pedagogy aimed at envisioning new possibilities for civic life. Specifically, it examines how youth who identified as recently arrived immigrants remixed a policy debate topic asking them to consider "both sides" of immigration restrictions. By rejecting artificial premises of "pro" and "con" argumentation, sharing personal family histories, and inviting judges, opponents, and community members to consider a borderless civic future, the team fostered a transformative public learning environment encouraging heteroglossic dialogue (Bakhtin, 1981; Vossoughi, 2014) to temporarily create a speculative public sphere (Mirra & Garcia, 2022).

Theoretical framework

The paper draws upon frameworks of cultural historical activity theory (Cole & Engeström, 1993), critical pedagogy (Freire, 1970), and borderlands theory (Anzaldúa, 1987/2012) along with critical race approaches to debate (Reid-Brinkley, 2012) and shares interpretive ethnographic analysis of several key interactions among the debate team participants to reveal how the activity system of the afforded opportunities to re-mediate binaries that often stymie efforts at critical civic dreaming and movement building in hybrid formal/informal learning spaces (Zavala, 2016) – binaries including citizen/immigrant, school/community, and objectivity/bias.

Methodology

The Debate Liberation League (DLL) - the name that the debaters chose for their team - included ten middle school students and three adult mentors. Grounded in social design-based methodology (Gutiérrez & Jurow, 2016), data collected over the course of one school year included field notes from 15 debate practices (2 h each), as well as audio recordings of selected discussions and practice rounds (5 h). Interviews were conducted with the three adult mentors (30-60 min each) and two focus groups were conducted with the students (60 min each). Artifacts included student reflections/notes, debate case materials, poetry, and analytic memos co-written by the students and researcher.

Findings and implications

Student debaters altered the structure and function of traditional policy debate structures in order to claim their right to public space and re-define the terms of persuasion from a policy win to an ontological affirmation of their humanity. They utilized performative literacies to re-envision debate not as a battle for a zero-sum win, but as a way to discursively construct a more equitable civic sphere that valued (immigrant) marginalized voices. This paper focuses on moments of public pedagogy that speak to possibilities of dialogue across difference as well as the ways that the grammar of schooling and normative structures of US civic life continuously interrupt and complicate these moments. For instance, during debate rounds, the DLL made translated copies of all of their personal narratives and calls to advocacy around borderless society so that opposing team members and judges would be able to understand everything students were saying and to encourage them to participate in a border crossing linguistic experience. An adult mentor also provided live translation services when the team began qualifying for national tournaments as both a means of ensuring accessibility for all during a round and of stressing the importance of bilingualism as a method of opening debate to a wider range of expressive possibilities.

“We cannot sacrifice one child for another”: Articulations toward public theories of learning

Jasmine Y. Ma, Christopher Ostrowdun, Lauren Volgelstein, & Ali R. Blake

While a substantial goal of the learning sciences is the construction of theories around learning, alternative theories simultaneously develop in other domains. In this paper, we investigate theories of learning constructed in public spheres of discourse around education. We begin to characterize these *public theories of learning* and offer one way they get shaped, through *articulations* (Hall, 1986), or linkages, of news and social media content that mediate the boundary between activity internal to schooling and public spheres. There are multiple interacting lines of communication between school and the public at play simultaneously (e.g., news, social media, parent councils), and these are not neutral, but subject to interpretation as fragments from across lines are articulated by the public. In other words, instead of concerning ourselves with meanings inherent in these communications, we analyze meanings produced through connections between fragments through public discourse. Interrogating these articulations helps us understand “how ideological elements come, under certain conditions, to cohere together within a discourse” (p. 53). In our case, we explore how they serve to make connections between the contentious space of what happens in schools and public discourses about schooling. These articulation practices are one way that news and social media are organized as pedagogical spaces, shaping the public’s perspectives about what *does* happen in schools and what *could* happen in schools (Hall, 1989).

We explore public discourse around a New York City (NYC) public middle school, M.S. 100, where, in the fall of 2021, students were involved in a series of verbal and physical fights (as were students at several schools at the time; Green, 2021). We focus here on incidents that occurred at M.S. 100 and how they were addressed by the parents of the children involved, school staff, members of the local school board, known as the Community Education Council (CEC), and others in the public sphere without direct involvement in the incidents. Disagreements and physical altercations between students are not uncommon, though detailed knowledge of their occurrence rarely leaves the school’s sphere (e.g., the students involved, parents, school administration), in part to protect the privacy of children. The incidents at M.S. 100, however, circulated beyond the school’s sphere and became highly publicized in mainstream news and social media.

While there is no singular “public,” the term is salient to the CEC, which is charged with solicitation of public input and is required to hold regular meetings open to the public, with time allocated for public speaker sessions, where anyone can sign up to speak on a topic for two minutes. The CEC's use of "public" refers to anyone not a member of the Council itself. Additionally, we recognize that public discourses may address what could be named a "common concern," but in fact are not common at all due to systemic societal inequities (Fraser, 1990). For example, "common concerns" of violence reported at a local middle school: a concern for the safety of a primarily white portion of the student body; a concern for effective use of taxpayer money in public schools; or a concern for healing and restorative justice of a community hit hard by the pandemic lockdown and remote schooling. The public sphere is multiple, with its discourses populated by counterpublics "where members of subordinated social groups invent and circulate counterdiscourses, which in turn permit them to formulate oppositional interpretations of their identities, interests, and needs" (p. 67). Using a critical perspective, we take up the multiplicity of common concerns at a public NYC CEC meeting to better understand how news and social media were articulated to construct public theories of learning.

Methods

Data included a publicly-available recording of one 5.5-hour CEC meeting which occured in February 2022, as well as news and media items featuring M.S. 100 between September 2021 and February 2022. We investigated how news and social media were variously deployed and resisted in the service of public understandings of–and arguments around–fights and subsequent events at M.S. 100, a large racially and economically diverse public middle school. Rather than attempting to identify what "really" happened, our analysis focused on how articulations were constructed and used by various people and groups, depending on their position and priorities. Then, we surfaced public theories of learning embedded within these articulations; we treated arguments about how learning happens and what factors influence it as public theories of learning, looking for arguments that were constructed and deployed regularly (in demonstrably relevant ways) within the meeting we analyzed. We used methods of interaction analysis that privilege the meaning-making of participants (Jordan & Henderson, 1995). We examined turns at talk that showed how people contributed to shaping the lines of communication and articulations of information, and how they were linked to spheres of discourse (Hall, 1986). Articulations are "thus the form of the connection that can make a unity of two different elements, under certain conditions." (Hall, 1986, p. 53). For our analysis, we position the CEC as straddling the spheres of the school and the public, and the CEC meeting as a space where members of the spheres engage in shaping and using lines of communication.

Findings

Below, we summarize two articulations of news stories centering interviews of Isabella, the parent of a student involved in incidents at M.S. 100, and zoom in on how one of them gives shape to a public theory of learning commonly deployed by conservative members of the CEC. In news stories published by conservative US news outlets Fox News and the New York Post, and in a speaking turn at the CEC meeting, Isabella provided descriptions of the "verbal and physical abuse" their son had experienced, arguing that the school's approach of "restorative justice is not working [and] kids need to learn accountability for their behavior." She also publicized two Snapchat groups as evidence of the severity of the incidents called "Yo, we on drugs" and "M.S. 100 Fights" where students shared video clips of the incidents.

One articulation from within the sphere of the school by Naomi, a Parent Teacher Association co-president at M.S. 100, critiqued both the information within and the existence of the line of communication itself. Naomi remarked on "concerns around the misrepresentation, misinformation, and misunderstandings" about what information was conveyed. She also critiqued Isabella's and others' publicizing this information as an "organized campaign of negativity" and a "major distraction" that "has traumatized, demoralized, and…confused the children." In Naomi's articulation, the "negative light" in which Isabella and others who publicized M.S. 100 "reeks of fear and racism." She contrasts this with depicting M.S. 100 as "a school that represented every child" in the district, and that believes "children make mistakes. Children are not disposable." These linkages between fear and racism and the negative misrepresentation and misinformation about M.S. 100 are further held together by the counter-representation of every child being cared for and not disposed of at the school.

In contrast, Councilmember Leung, of the CEC, supported the use of news outlets as a mechanism to make the happenings of schooling public and accountable to public spheres. Leung argued, the Department of Education (DoE) had a history "where incidents happened, [and] it's been covered up," and that the "free press…[has a] responsibility…to report on things." Leung urged "all families to report it to the police and make noise." Leung's articulation of school safety, DoE cover-ups, reporting to free press and police to protect children leveraged Isabella's representations of *some* children at M.S. 100 as violent and disruptive, ratifying her public representation of M.S. 100. Additionally, Leung produced a linkage between the free press and the police holding the DoE accountable against a backdrop of debate over whether school safety is the concern of social workers or the police, as well as discourses of carcerality (Wang, 2018) in schools. We argue that these elements articulated together in this way reproduced, as Naomi argued, a racial ideology (Bonilla-Silva, 2018), the articulation and ideology mutually elaborating one another.

Leung continued, pitting "violent children" against "the 29 other students in that classroom," arguing that "we cannot sacrifice one child for another," that "children will not learn" if there is fear in the classroom, and "they will have social emotional problems on top of that." At the same time he acknowledged "this child…need[s] support, but…we cannot wait, put them back in the classroom." Leung's rationale for police intervention brought into relief a theory of learning that centered the fear, social emotional state, and learning of "the other 29" while denying those for the child he characterized as "violent" and "disruptive" (as opposed to, for example, considering the violent incident as situated and a characteristic of the context rather than an individual). This is an example of a public theory of learning–pitting hypothetical, individual, undesirable children against "our" children who for a variety of reasons, deserve safe, rigorous, or otherwise well-resourced learning environments–that emerged repeatedly in speakers' articulations of news and social media that ferried information from within schools into the public sphere.

Significance

Leung's call to report information to the free press is not what it seems. The news and social media do not simply communicate neutral pieces of information, but instead provide a space for articulated interpretations that uphold particular ideologies. These articulated interpretations are not held together as natural fact but made to cohere (Hall, 1986) by people, and give shape to public theories of learning. Our paper provided an example of how fragments from the same event (Isabella's report to the news and the CEC) were made to cohere in two different articulations, with different ramifications for how the public understood what was happening at M.S. 100. As well, the associated public theories of learning are necessarily situated and sociopolitical. The analysis is important for expanding our understandings of how members of the public sphere make sense of what is happening in schools and participate in collective action.

The production of a crisis at Wilhelm Elementary: Collective construction of a discourse through parents' public comments

Carlos Nicolas Gómez Marchant, Alexandra R. Aguilar, & Emma C. Gargroetzi

We demonstrate our modeling of the "webs of mutually constituting statements that represent and position people and social phenomena in particular ways" (Shah & Leonardo, 2016, p. 51) from a community's two opposing sides on the attendance rezoning of Wilhelm Elementary. Our objective is to demonstrate the collisions and coalescences over time of each side's shared discourses. We see the construction of a collective model through civic and political engagement as a form of learning the racialized discourses of a political space to be more influential in determining district policy and regulations. Castro et al. (2022) emphasizes the need to focus on the racialized discourses existing within the constructed models of rezoning schools within these political spaces.

Theoretical framework

A critical race spatial perspective follows the tenets of critical race theory (see Delgado & Stefencic, 2016; Solórzano & Yosso, 2002) and expands them to incorporate a spatial dimension inspired by Soja's (2010) and Du Bois' (1904/1994; see Morrison et al., 2018; Solórzano & Veléz, 2016). These tenets guided our exploration of whiteness in the political discourse revolving around the two opposing sides in the rezoning of Wilhelm. A critical race spatial perspective provided the tools necessary to follow Leonardo's (2004) call to reveal the discourses of whiteness. In this study, we view the parents' continuous interactions with racialized discourses as learning how to participate in differing political spheres of influence.

Method

Creator ISD is a large independent school system located in central Texas. The district administration organized five opportunities for public comments to be made by community members about changing the attendance zone of Wilhelm Elementary. A total of 81 public comments were given by 45 individuals. The five meetings were recorded by Creator ISD and made publicly available online per the Texas Open Meetings Act. Public comments were transcribed by the research group for analysis. We implemented a grounded theory approach for our discourse analysis of the public comments (Malagon et al., 2009; Solórzano & Yosso, 2002). We began by coding for actors (e.g., students, renters, homeowners) and issues (e.g., overcrowding, infrastructure). Through a process of code comparison within and across code groups and the five school board meetings, analytic memoing, and research team conversation we articulated a theory describing how three layers of discourse collided and coalesced to produce an outcome of school rezoning that re-segregated a district along racial and socioeconomic lines. Specifically, we identified these three layers of discourse as: 1) Production of a crisis; 2) The modeling of the crisis; 3) Leveraging the model for political gain.

Preliminary results

Those advocating for the shift of Wilhelm's attendance zone instigated the production of a crisis. Consequently, the first layer of discourse focused on the production of the overcrowding student crisis that necessitated urgent intervention by the school board. The crisis discourse emphasized costs to children's learning and well-being. This forced those opposed to the changes to Wilhelm's attendance zone to respond to the constructed crisis. The second layer of discourse entailed modeling the crisis as a mathematical model of equality (Tate et al., 1993) that included and excluded certain variables as ir/relevant and in/appropriate. Thereby shifting the framing of the crisis from one of overcrowding to one of student population balance across school sites. The final layer of discourse involved parents leveraging the objective and neutral myth of mathematics to gain political influence. These layers of discourse are evidence of the parents' learning of political engagement within the confines of school boards. These findings help in deconstructing political discourses and emphasize the role mathematics plays in civic engagement.

Schools can't do more with less: Reframing budget narratives in the Jersey City public schools

Karis Jones, Jyl Josephson, & Nooreen Fatima

Context

Often cited as the most diverse city in the U.S., Jersey City is a rapidly gentrifying area with a divide between the city residents and the youth enrolled in the public schools, as the Jersey City Public Schools serve a larger percentage of Black and Brown youth (and a lower percentage of White or Asian youth) compared to the city's overall population. In 2008, New Jersey adopted a new funding formula intended to provide guidelines for how much revenue local districts should contribute as well as the level of state funding required to provide for the educational needs of students in each district.. By 2018, the legislature passed S2, a revision of the School Funding Reform Act of 2008 SFRA, with a seven year time frame to reduce state adjustment aid to districts that, according to the formula, were "overaided"--receiving more in state adjustment aid than the state formula indicated they should receive. This was bad news for Jersey City. The state adjustment was scheduled for a seven year process of defunding, with an increasing percentage taken from Jersey City each year. Given how the formula was written, the actual dollar amount of state aid withdrawn would be determined each budget year, adding more uncertainty to the process. The "local fair share" for Jersey City was hundreds of millions of dollars more than the existing school tax levy. This meant that the school tax would need to be increased significantly and quickly. Without significant annual increases in the local levy, it would be impossible to run the school district. This paper will examine how this issue of school budget was framed and contested in the discourse surrounding a Jersey City school board budget vote in March 2021.

Theoretical framework

With respect to school funding, one current ideological battle in the public square is the conceptualization of school as a commodity vs. a public good. Kumashiro (2020) explains that viewing schooling as a commodity leads to problematic consequences with respect to social-economic status, as poorer communities pay greater percentages of their income while still seeing less per-pupil spending. Kumashiro urges that such issues must be seen through an intersectional lens (Crenshaw, 1991), particularly as histories of racism and classism contributed to the structural inequalities built into property tax systems. Thus, we take up a critical framework on equitable public funding in a way that surfaces the intersectionality between race as well as other identities such as SES, disability, and immigrant status.

Data & methods

The researcher team intentionally brings together various positionalities across the Jersey City educational landscape: Dr. Jyl Josephson, resident since 2004 and parent of a child attending the local schools as well as a leader in the Education Team in the grassroots activist group Jersey City Together; Dr. Karis Jones, resident since 2015 and relative newcomer to the JCT Education Team, and Nooreen Fatima, joining as an analyst with experience in local public organizing contexts. See Table 1 for the breakdown of research questions, data sources, and analysis techniques.

The team collaboratively applied critical discourse analysis tools to critically examine these sources for ideological conflicts around the budget crisis. Following Ewing (2018), we take up tools of muted racism--"when people make statements that are subtly racist not because of what is said, but because of what is not said" (p. 178)--to show how stakeholders are constructed in public discourse in racialized ways. This framework from Davis (2007) includes three tools surfacing racism in discourse even when it is not directly mentioned: deflection, indexicality, and omission. Deflection is the technique of minimizing and dismissing racism as the cause of social problems clearly connected with race. Attending to indexicality allows the researcher to examine how people use coded words to make statements about race without explicitly saying it. Finally, omission is the way that data showing racial disparities is discussed without mentioning racism as the cause. We take up all these tools through an intersectional lens, looking for ways that the intersectionality between SES as well as other identities such as race, disability, and immigrant status were defected, indexed, or omitted.

Table 1
Methods Table

Research Question	Data Sources	Analysis Technique
RQ1: How are the stakeholders and competing narratives around the JCBOE school budget constructed and leveraged in public discourse in intersectional racialized ways?	-Jersey City and Jersey City Public School Demographics -Newspaper articles relating to JCBOE Budget from 2020-2021	Critical discourse analysis using tools of muted racism (Davis, 2007) and intersectionality (Crenshaw, 1991; Kumoshiro, 2020)
RQ2: What are some of the discursive moves used by the public to engage/combat discourses of inequity?	-Transcript of March 2021 Special Budget Hearing -Field Notes of JCT Meetings collected from 2020 - 2021	

Findings & significance

Addressing RQ1, we saw several ways that racism and other intersectional identities were deflected, indexed, or omitted with respect to marginalized youth in the district but explained more thoroughly with respect to adult stakeholders. In local reporting about issues of equity in the district, the marginalized status of youth were indexed through categorizations such as English language learners, students with special needs and students who qualify as free and reduced lunch (often used as a proxy for low socio-economic status). However, in the article no work was done to contextualize for the readers how these categories related to educational barriers, even though each of these categories have complex ties to race (Flores & Rosa, 2015; Abrham et al., 2011). On the other hand, in reporting discussions about the tax base, the concerns of taxpayers were described in detail, with journalists reporting on complex sociopolitical forces at play in the city including rising rent costs due to gentrification--a phenomenon explicitly at the intersection of race and SES. Oddly enough, the equity concerns relating to low-SES city residents who had not even called in to the budget meeting were animated in detail while the forces oppressing the 16,000 students qualifying for free and reduced lunch were left for the readers to parse out for themselves.

To answer RQ2, we saw that to respond to narratives of deflection that elevate low-SES taxpayer struggles above the needs of youth, parents explicitly named the structural inequities experienced by children in the city. Instead of othering certain groups of students by merely indexing marginalized categories, parent activists used collective possessive pronouns (e.g. "our kids," "our schools") to emphasize how the collective student population was being harmed by underfunding. Parents responded to issues of omission by calling in with specific examples of ways that the underfunding led to inequities, describing how they had seen their children's schools struggling with overcrowding, overworked teachers and staff, and lack of resources and support services. Though they point to the experiences of particular marginalized groups ("I have been hearing a lot, lately, some of the woes of the parents with children with special needs and how they have to fight to get the services that their kids deserve"), they also pointed to the collective benefits of these services ("All kids could benefit from [smaller class size, one-to-one support, gyms, occupational therapy]").

To combat tools of omission, we saw parents explicitly naming the connection between deprioritization and students' intersectional identities: "Our schools only have 27% of the property tax pie when the state average is 53%. Why do public officials think our children deserve so much less? Is it because a majority of them are English-language learners, come from under-resourced neighborhoods, are Black, Indigenous, and other people of color, and have special needs?" In this comment, the parent activist explicitly named how intersectional forces of marginalization keep resources away from the youth in Jersey City, in explicit contrast to other wealthier and whiter cities across New Jersey. Through the use of such tools which worked to "unmute" racism hidden or omitted in stories about taxpayers, activist parents worked to shift the narrative, leading to the passing of a fully funded local budget in 2021.

Abstract: This symposium brings together eleven projects across three continents to examine notions of disruption in educational research. Historically, notions of disruption have pointed to the ways research leverages innovation and transformative practice. However, amid global pandemic and intersecting unrest, the authors in this session recognize the need for deeper conversation across contexts to understand the ways that educational research in the learning sciences can leverage disruption toward transformational learning. To respond to this year's call for building and sustaining knowledge in community, we seek to foster conversation about the ways that designed for and encountered disruptions act as opportunities for critical reflection and new kinds of engagement in educational research. Together, we examine various notions of disruption as they exist in our disparate work. We seek to provoke meaningful conversations about the ways educational research can embody the contemporary realities of learning with and toward disruption.

Overview and significance

Notions of disruption have been used in educational research to recognize innovation, shift oppressive systems, and engage in transformation of business-as-usual across organizations. Historically, educators and scholars seeking to design and study expansive and liberatory learning environments have characterized their work as a disruption of entrenched systems (e.g., Kafai et al., 2014; Ma, 2016; Nasir & Vakil, 2017; Stetsenko, 2017). However, the global turmoil of recent years — the COVID-19 pandemic, as well as the continuing escalations of the climate crises, white supremacy, and authoritarianism — have sparked ongoing conversations positioning disruptions as forces external to educational settings that must be overcome lest they lead to "learning loss" (e.g., UNICEF, 2021). Recognizing the dichotomy between what we conceptualize as *designed for* and *encountered disruptions*, the scholars in this symposium consider how we might foster dialogue across projects to see both forms of disruption as opportunities for critical reflection and engagement in educational research. Specifically, we look across 11 projects that took place on three continents and within a variety of educational contexts to examine the ways that notions of disruption in education can be not only theorized but also operationalized to change hegemonic expectations of educational systems toward expansive ways of knowing, doing, and creating.

Responding to the ISLS call for innovative symposia to respond to changing times while building community, we use this hybrid structured poster session to question the ways that both designed and encountered disruptions to educational structures can offer opportunities to co-construct new ways of knowing across intimate networks, learning communities, and institutions. We follow colleagues such as Lopatovska et al., (2022) to consider the ways that young people and their educators are not only resilient but powerful agents of change in the face of challenging circumstances. In this proposed session, scholars draw from sociocultural and constructivist theories of learning, as well as notions of criticality, embodiment, temporality, and design to reconsider the ways that our work can build knowledge and community collectively *because of*, rather than despite, the continuing disruptions in our individual lives and global society. We also examine the ways that different groups of learners, particularly those with historically marginalized identities, have been positioned as disruptive and have experienced disruptions to learning in differing and often violent ways (e.g., Patel, 2015; Tuck, 2009). This session will provide theoretical, methodological, and practical tools that can inform learning sciences research concerned with promoting change in educational opportunities toward more liberatory, participatory, and just futures.

Although the posters feature a variety of methods, all share perspectives that data can and should be representative of the multiple and complex ways that learners and educators navigate the world (Bridges, 2020). This complexity is part of the analysis that examines *designed for* and *encountered disruptions* across projects. While each project investigates notions of disruption, they span different timelines before, during, and after the pandemic. These multiple timeframes also mean that the authors take up a spectrum of perspectives ranging across constructivist, critical, and post-structural epistemologies. Despite these differences, each of the projects suggests new ways of theorizing or operationalizing disruption toward equitable and transformational ends for learners.

Poster abstracts are listed below alphabetically by first author and referred to here by number in this sequence. Some of the posters, including 3, 4, 6, and 11, examine disruption as an outside-of-project force that asked partners to reimagine what it means to collaborate in the face of environmental changes, including COVID-19 and the climate crisis. Others, including 1, 2, 5, 7, 9, and 10 take up socio-cultural/critical perspectives to question what it means to design learning experiences and environments toward the disruption of traditional systems of power. Many of the posters speak to the tensions in between these perspectives, addressing the ways that both kinds of disruption intersect and reshape educational research. While a few of the authors engage more traditional methods and perspectives around technology and design, all question the ways that young people have been positioned to learn (or not) within traditions of education. Finally, poster 8 pushes critically against other perspectives in the session, questioning the ways that notions of disruption are often embedded in theories of whiteness. These authors offer creative counterpoint, enriching the potential for conversation by posing questions of institutional resistance that requires learning to be theorized as a fugitive act (Patel, 2015) if it is to serve those historically marginalized and barred from educational spaces.

To effectively bring these pieces into conversation, we engage in a 75-minute innovative structured poster session that will include hybrid and multimodal components alongside traditional posters to allow for participation from across continents. The session will open with a brief introduction, followed by highlights of each poster. There will be two rounds of free-form time during which the audience can engage with the different posters; in each round, only half of the poster-presenters will be at their posters, to allow presenters to engage with each other. The session will conclude with two discussants, both with extensive research in the learning sciences related to the ideas in the session. Drs. Sherice Clarke and Joseph Polman will offer both provocations and contextualization of the works in the context of the field. There will be ample opportunity for audience active participation during free form segments, and following the commentaries. We see this session as an opportunity to facilitate necessary conversations responding to the conference theme about how to engage in learning research toward community, while attending to technology, relationality, and the ever-present need to disrupt whiteness toward more expansive ways of knowing and being.

Poster 1: Biliteracy practices by indigenous language teachers

Zaynab Gates

In Latin America, home to 42 million Indigenous peoples speaking more than 500 languages (Sichra, 2009), bilingual education is key to protecting Indigenous children's right to learn in their mother tongue. Teaching in Indigenous languages requires, in turn, the preparation of Indigenous teachers who can develop effective oral and written bilingualism in their students. Centering the voice of Indigenous language teachers and drawing from the continua of biliteracy framework (Hornberger, 2004), this study at two teaching institutions in Northern Argentina examined the challenges and strategies Indigenous language (Qom or Wichí) teachers employed to disrupt hegemonic notions of language acquisition that have historically stolen language from Indigenous youth and instead become Indigenous language promoters.

This paper responds to the session call to examine notions of *designed disruption* by theorizing Indigenous methods of storytelling as a means of language preservation that can halt the white supremacy and settler colonialism (Tuck, 2009). The authors will use the poster to explore the ways that Indigenous storytelling can act as a tool to disrupt the loss of culture and transform educational experiences for Indigenous youth. Using Indigenous storytelling interviews (Iseke, 2013) and collaborative analysis of data with Indigenous researchers, this study contributes to understanding motivation, strategies, and concepts used by Indigenous language teachers to persevere in their educational trajectory and to design learning experiences as Qom or Wichi language teachers.

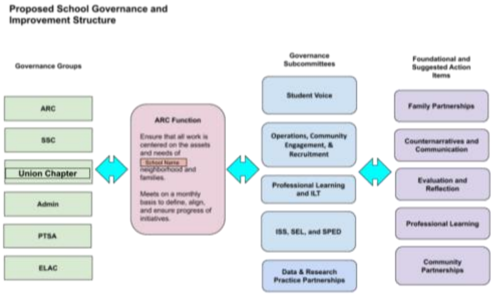
Poster 2: School governance policy for racial justice: Disruption as impetus for policy infrastructuring

Ung-Sang Lee & Marcus Van

This poster presents a case study of efforts to refine the infrastructures (Dantec & Disalvo, 2013; Penuel, 2019) for a research-practice partnership (RPP) between a university and a partnership secondary school serving historically minoritized students to center racial justice. Such infrastructuring led to the formation of new school governance policies that reconfigured the roles of students, teachers, family members, and researchers. This work was situated in a school-university partnership that housed multiple RPPs in their formative stages. The *external disruption* to schooling from the COVID-19 pandemic, as well as broad anti-racist organizing, created opportunities to engage in RPP infrastructuring work framed by three priorities identified by partners: 1) to center anti-racism in the school-university partnership, 2) to align the somewhat disparate RPPs around shared goals and processes, and 3) to deepen the participation of students and their guardians in RPP efforts. In response, over a six-month period, 30 students, guardians, teachers, school administrators, and researchers met weekly in efforts to redesign the school-university partnership infrastructures. The school's Anti-Racist Committee (ARC), successfully reformed governance structures so that ARC members had representation on the School Council. Further, ARC was able to guide all RPPs that took place in the school (Figure 1). ARC members viewed this localized policymaking as a model for broader systemic change and sought to scale the governance policy even beyond the school district.

The case illustrates the ways efforts to disrupt policy contexts in the face of unexpected disturbances, such as the COVID-19 pandemic, can support educational change that privileges minoritized school stakeholders and the assets they bring to bear. Such forms of participation serve as fertile ground to disrupt traditional notions of educational policy making. As such, universities and policy makers are encouraged to consider how policy making intersects with RPPs and how such intersections may advance justice-focused educational change.

Figure 1
ARC School Governance Proposal



Poster 3: Remote classroom research toward equity during the COVID-19 pandemic

Tomohiro Nagashima, Gautam Yadav, & Vincent Aleven

School classrooms are a critical part of learning sciences and technology research that aims to understand and support learning in an *authentic* learning environment. However, during the COVID-19 pandemic, K-12 schools in the U.S. were forced to make a transition to "emergency remote learning" (Khlaif et al., 2021), where students and teachers were required to continue their teaching and learning remotely, at least to some extent (e.g., hybrid teaching). While this drastic change in schools led to issues that made teaching and learning challenging, especially amongst students and families in under-resourced communities, it also offered new opportunities to make sense of the realities that students, their families, and teachers were coping with during their teaching and learning activities. To align with this session's examination of *external disruption* that catalyzed educational change, we ask: What can the the COVID-19 pandemic teach learning scientists as they continue to collaborate with school partners in times of crisis?

We propose that remote classroom studies can help advance the learning while proactively promoting equity in educational technology research during such a crisis. Although remote classroom research on learning technology (i.e., observation through a video conferencing platform while students are using the technology) can be challenging, it has potential to offer new opportunities for learning and participating in research in remote and under-resourced communities that may not have been accessible for partnerships before the COVID-19 pandemic.

During the COVID-19 pandemic, we conducted nine classroom studies remotely in five states in the U.S. These studies created opportunities for partnerships with educators in rural and remote areas that had been unavailable before the pandemic and offered a window into students' learning by allowing for study of unmoderated home learning. Analysis of teacher interviews from these experiences led to the development of a framework for conducting remote classroom research on learning technology (Nagashima et al., 2021), which can be used to help researchers address equity and logistical issues when planning and conducting classroom research on educational technology remotely. In the proposed poster session, we will discuss the possibility for this framework to act as a *designed disruption* of more traditional notions of classroom research and the ways that remote engagement in learning research might offer more equitable perspectives on the learning communities in rural and remote areas.

Poster 4: COVID-19 opportunity for transformation within research-practice partnerships

Robbin Riedy, Kristina Stamatis, Caitlin Farrell, Paula Arce-Trigatti, Alison Fox-Resnick, & William R. Penuel

Research-Practice Partnerships (RPPs) have potential to "support the mutual learning of partners to change practice while continuously adapting to turbulent environments of schools" (Penuel, et al., 2021). However, as the COVID-19 pandemic and its intersections with political unrest and police violence created one of the most turbulent environments schools in the U.S. have ever faced, many RPPs found themselves struggling to continue pursuing collaborative goals (Ishimaru et al., 2022). In this poster, we explore data from 24 RPPs to understand the ways that members characterized their work together amid these global *encountered disruptions*. We ask: What are the characteristics of RPPs that leveraged the COVID-19 pandemic toward transformation?

This work acts as a secondary analysis of interview and survey data from 24 RPPs in which 112 members provided self-evaluations of their partnerships across five dimensions of effectiveness and equity (Farrell et al., 2022). We frame this analysis with theories of active waiting (e.g., Lee et al., 2020), which refer to the planning and action that can take place during periods of turbulence and offer a way to theorize the characteristics that supported some RPPs in leveraging *encountered disruptions* toward more transformative goals (Tanksley & Estrada, 2022). Our data illustrate in RPPs that aimed to improve traditional measures of school success; many partners said their work was delayed during the pandemic. In some cases, the pandemic reinforced a sense of futility. As one partner said, "COVID has shown that a lot of things in our society are broken." However, in RPPs that had focused their work on disrupting traditional power relationships in education, many partners said the urgency of the pandemic energized their work. In these RPPs partners spoke of developing more empathy for their colleagues while revisioning the ways their work could transform education. This kind of active waiting meant partners acted toward change, even as their intended work was disrupted due to COVID-19.

Given initial analysis, we conjecture that RPPs' stances towards how they achieve their objectives — through either working within traditional measures of educational success or attempting to disrupt the system all together to create new models of educational equity–influenced how they approached the period of active waiting during the pandemic. This paper contributes to the objectives of this symposium by exploring the ways that RPPs were able to navigate their work and relationships in the midst of *encountered disturbances* and addresses the conference theme by examining the ways RPPs can leverage disturbance and change toward transformational community learning.

Poster 5: Memes in memory institutions: Youth interests and literacies as encountered disruption in design-based cultural heritage work

Emily Oswald, Line Esborg, Palmyre Pierroux

Cultural heritage institutions face changing expectations about engaging with and representing diverse constituencies, including young people. While many museums and archives have developed projects and programs that involve collaboration with new audiences, these activities can reproduce the very power dynamics they seek to disrupt or introduce disruptions that institutions are poorly equipped to engage with productively. How can museums develop new practices to become more just, democratic and participatory institutions?

Building on a previous study (Oswald, Esborg & Pierroux 2022) of youth, memes and memory institutions, this poster explores an encountered disruption in New Voices in the Archive, a youth engagement program at the Norwegian Folklore Archive. Aiming to expand the representation of young people in the archive's collections and their participation in institutional practices, the program was developed through a university-initiated, design-based collaboration (McKenney & Reeves 2019) involving educational and cultural heritage researchers and young people (ages 16-19) from Oslo, Norway. The study involved three interventions over the course of approximately one year. During the implementation of the second intervention, researchers identified young peoples' knowledge of internet memes (Shifman 2013) as a potential focus area for the third intervention.

To explore how the New Voices program resulted in the emergence of novel and participatory knowledge practices at the Norwegian Folklore Archive, we propose that young peoples' interest in and knowledge of internet memes can be conceptualized as an encountered disruption within a design-based research process. We describe how researchers responded to initial references to memes during in-person meetings and the ways in which the task of selecting and contextualizing memes supported the young people's agency by demonstrating their literacy with memes as a genre of digital media. We argue that New Voices, a program designed to disrupt the archive's established approaches to collecting folklore, was successful in large part because the ways researchers' and young peoples' engaged with this encountered disruption.

Poster 6: Frames of the planet: Climate justice in the science classroom

Sushil S

The latest report by the Intergovernmental Panel on Climate Change (IPCC) projects some damage to human systems and ecosystems in the near future if we fail to limit the global temperature level increase to 1.5 degrees Celsius above pre-industrial levels (Pörtner & Roberts, 2022). At the same time, around 84% percent of the children in the ages of 12-14 years across the world are enrolled in schools, with younger children enrolled at even higher rates (UIS, 2019). However, particularly in early grades, while there is some evidence of strong scientific teaching, the "overall picture of understandings of scientific inquiry is not what is hoped for after completing 6 years of elementary education in any country" (Lederman et al., 2019, p. 486). Worldwide, there is a prevalence of compulsory school attendance laws that suggest that schools must take an active role in attending to and planning for *encountered disruptions* such as climate change. Recognizing the precarious situation of young people in the world due to the impending impacts of climate change, this study examines how teachers draw from their own knowledge and potentially reach beyond pedagogy and content to shape students' frames of the planet.

In this study, I take up Goffman's (1974) notion of frames as the multiple ways that individuals construct, organize, and differentiate meanings of their lived experiences. I examine the ways that teachers drew upon their own knowledge of science and its application in their own lives and cultural backgrounds to understand how they shape student framings of climate change. Data collection took place through qualitative inquiry into a high school earth science teacher's pedagogical practice. The data for this study, collected over two units across 8 weeks, include conceptual interviews, classroom discussion transcripts, and field notes to examine how the science teacher's frames traveled through their planning, teaching, and reflection as they taught two different units. Additionally, the data also include student conceptual interviews at the beginning and end of each unit to examine connections between how the students' frames shifted through each unit with and against the frame deployed by the teacher. This study adds to the literature of how frames are deployed by teachers and learned by the students in the classroom. Findings from this study can inform further research and action on how researchers and teachers might redesign and disrupt unsuccessful or limited processes of constructing scientific knowledge in the classroom to make way for knowledge that engenders actions towards climate justice worldwide. Reframing scientific inquiry toward more action is a necessary step in research and classroom design if we are to use collective action to address and disrupt the disaster that climate change and global warming currently promise.

Poster 7: Re-imagining learner identification with discursive protocols in times of change

Stephen Sommer

This ongoing research project explores notions of *designed disruption* within the process of unlearning, reimagining, and cultivating belonging as high school students (re)discover how they identify as learners through multiple iterations of structured community presentations of learning (POLs). This study took place at an independent, tuition free school for "students who were not otherwise finding success" in traditional learning contexts (school website). As a move to disrupt students' experiences with traditional schools, three times each year across their multi-year tenure, students organize a POL of their own human development. These POLs act as interactive portfolios in which students present examples of both their academic and personal growth. Students then use a discursive protocol based upon exhibitions of learning (Sizer, 1992) to engage in structured discussions with peers, teachers, and community members. These conversations take place in multiple rounds over two or three days. Throughout this discursive process of presentation and then in the subsequent fielding questions from community members, students come to recognize sites and experiences of growth beyond the confines of the classroom (Tracy & Robles, 2009).

In this study, I examine the process through which learners develop identifications (e.g., Polman, 2011) and how that process is supported and enabled through the designed structure of the POLs, the investment and sense of belonging in a committed community of learners, and multiple opportunities to engage in this performative ritual (e.g., Bucholtz & Hall, 2005). This multi-year ethnographic study draws data from video recorded POLs, interviews with students, faculty and school designers, as well as an analysis of student generated artifacts including visual aids, letters to community panelists, personal reflective essays, and guided prompts such as "I used to be…but now I am." My findings indicate that throughout the process of engaging in POLs, students recognize and articulate an expansive view of learning that is attentive to their full self well beyond a narrow assessment of gaining or retaining academic content. Additionally, findings suggest that the POL experience empowers young people to recognize sites of their own learning and increase agency in exploring and articulating their evolving identities. This paper has potential to support understandings of designed disruption by bringing youth voice to bear on the ways traditional learning design requires disruption to support the development of learner identifications.

Poster 8: Plática as circle and crossroad: Fugitive counterstories of chị em author: Fugitive chị em apapachando

Trang Tran, Marlene Palomar, Adria Padilla-Chavez, Ashieda McKoy, Brenda Aguirre Ortega, Fabiola Palomar, Trang B. Tran

Patel (2016) reminds us that learning is, at its core, a fundamentally fugitive act. In this paper, we push back against the notions of disturbance included in this session. Identifying as first-generation femmes of color, our endeavor to seek doctoral degrees in the field of education has faced enduring opposition. These include institutional resistances to change and difference; curricula and pedagogies that reinforce white supremacy, oppression, and trauma; and personal interactions that left us with feelings of tokenism, isolation, invisibility, and invalidation (Harris, 2016; Hubain et al., 2016; Patel, 2015). In addition, systemic pushback has created disruption against heterogenous ways of knowing and has historically forced learners towards a dominant, assimilative culture. In this reality, our group strategically fled from institutional hostility to seek a counter space. Fugitive wellness is an act of self-preservation and political warfare (Lorde, 1988, p.130). Our *fugitive wellness* has been grounded at the crossroads of healing, *hermanidad*, and quenching desires for dignity. In an alternative space we have created, imagined, embodied, and nurtured an environment for safety where we allowed ourselves to be vulnerable; this is where we laid a foundation for critical dialogues and collective sense-making of our own experiences, intellective survival, and our futures in the academy. We seek to develop *fugitive practices* (Patel, 2019) to defy and disrupt individualistic, competitive, and linear trajectories of achievement—ones that are perpetually reproduced in our academic institution. Our practices redefine learning through a lens of solidarity where learners are attentive to each other's emotional and spiritual health. As a group, we become a beacon of hope for one another.

We disrupt this session through collective and creative autoethnographic work. In this symposium, we will use artistic portrayals of selves as data to reflect on our group's engagement with different modalities during meaning-making, storytelling, and writing. As we frequently find each other in counter space to process, affirm, and devise strategies for wellness, we explain how such fugitive practices took place in various mediums of human communication, including poetry, imagery, sound, sensory, emotion, and movement. Such multimodalities have been important for how our group makes available physical, mental, and emotional support for each other as we sustain this sacred fugitive counterspace. Such processes of joy and strength have sustained our collectivity and offered nutrition–like *apapachos (hugs)*--for our souls.

Poster 9: "It was nice to know that they felt the same things we did": Disrupting generational hierarchy and mental health stigma in a youth program through adult facilitator vulnerability

Sari Widman

To address the mental health crisis that has increasingly gained attention following the COVID-19 pandemic, educators must move beyond traditional notions of social-emotional learning (SEL) and invest in collective intergenerational work that is designed to disrupt oppressive systems that contribute to mental-unwellness (Jagers et al., 2021; Rosen et al., 2021). Prefigurative practices of relationship-building, that put into practice caring relations to disrupt hierarchies, are core to justice-oriented learning and collective social movements (Uttamchandani, 2021). Here, I look at the role of "check-ins" as a prefigurative relationship-building practice in a youth leadership program.

The program engaged BIPOC youth who identified as facing a variety of mental health challenges, as being neurodivergent, or as having queer identities. Interviews were conducted with 7 of 11 youth participants in June 2022 following the first months of the 1.5-year program. There were six adult facilitators (including the author), who regularly attended sessions and provided support. The program was designed to create social change by engaging youth in collective art making around issues of mental health to disrupt cycles of intergenerational trauma and strengthen networks of community care. Check-ins were conducted at the beginning of each weekly program session to give youth and adults the opportunity to share about their lives and emotional states. Based on analysis of interviews with youth to understand their perceptions of adult facilitators' participation, I found facilitators' vulnerability during check-ins helped to disrupt generational hierarchy, stigma, and traditional narratives around mental health.

While youth consistently talked about the importance of check-ins for feeling less alone in their experiences and creating a safe environment, the process of opening up was gradual. One youth, who described opening up during check-ins as shifting from their least favorite to favorite part of the program, said that facilitators modeling openness and vulnerability helped her feel comfortable doing the same, "It's okay to you know, not be okay. It's okay to open up." Youth also described adult sharing and "being themselves" as creating a sense of safety in the space that built connections between their experiences as teenagers and those of the adults. This sense of relatability and connection shifted ideas of differences between how adults and teens might experience mental health challenges. As one youth put it, "It was nice to know that they felt the same things we did, even though they were adults, you know, like the generational gaps didn't really change anything." Youth also expressed that adults sharing was "eye opening." One described hearing that teen mental health struggles were "just a phase" and so thought adults "don't have any issues." Disrupting this idea of mental health struggles allowed youth to revision their own experiences. This poster unearths the potential for *designed disruption* of the hierarchical and linear narrative of youth as struggling and adults as authoritative figures.

Poster 10: Disruption of gender representation in computational toys and kits for young children from a design perspective

Junnan Yu

While the importance of introducing computational thinking (CT) to young children has been widely acknowledged, inequities persist as CT is accessible differently along gendered lines. Despite these inequities, early childhood is fertile ground for cultivating young people's interest in computing and has even been found to hold potential in mitigating gendered stereotypes around coding and robots (Bers, 2017; Clements & Gullo, 1984; Papert, 1980). Computational toys and apps, also called coding kits, are the major media for children ages seven and under to engage in coding and CT (Yu & Roque, 2019). Although many coding kits are available, much remains unknown regarding their impacts on young children, especially how they may welcome participation from children of different genders.

In this study, I seek to understand how designers might use *designed disruption* as a means of reimagining expressions of gender equity in computational toys and coding kits. This perspective is critical because children start to conceptualize gender at approximately 18-months (Martin & Ruble, 2004; Rubegni et al., 2019; Weisgram et al., 2014) and may have already formed the stereotype that boys are better at programming than girls as early as six years of age (Martin et al., 2016). Further, children's gender conceptualization can impact their engagement with toys–for example, avoiding toys that do not fit with their formed gender identity (Carter & Levy, 1988; Weisgram et al., 2014)–which can perpetuate inequities in access to CT. Creating gender-inclusive coding kits are especially important to disrupt gender stereotypes about computing and welcome participation from children of different genders, particularly given that computing is already a field heavily dominated by males (Hill et al., 2010). However, no studies have examined gendered design features in coding kits and so few guidelines exist for designing gender-inclusive coding kits and broader learning technologies for young children.

This poster will examine gender representations in coding kits for young children and present a framework for *designed disruption* of traditional computational kits and toys. Specifically, I will (1) present a developing framework to evaluate and disrupt gender-related design features in toys for young children and employ the framework to analyze how existing coding kits represent genders; (2) discuss the ways young children (target users of coding kits) and their parents (gatekeepers of coding kits) assess the gender orientations of some representative coding kits. This poster contributes to the symposium by raising notions of gender in discussions of disruption and presenting a potential framework that can be used as design guidelines when designing for disruption in computational settings.

Poster 11: The effects of educational technology games on students' conceptual understanding of algebra in the context of COVID-19 pandemic

Jenny Yun-Chen Chan, Avery H. Closser, Vy Ngo, Hannah Smith, Allison S. Liu, & Erin R. Ottmar

Prior work has shown that middle schoolers struggle with algebra (Kieran, 2006), but educational technologies, such as DragonBox12+ (Liu et al., 2015) and From Here to There! (Decker-Woodrow, in press) have potential to disrupt this struggle by engaging students in game-based (Connolly et al., 2012) and embodied learning (Abrahamson et al., 2020) to support students' algebraic performance. Uses of technology became even more important during the *encountered disruption* of the COVID-19 pandemic when students were often receiving inconsistent instruction in mathematics. However, it remains unclear *which* aspects of algebraic knowledge are impacted most by these technologies. Leveraging data collected during the 2020-2021 academic year, we aim to advance understandings of whether these technologies improve students' *conceptual knowledge*, *procedural knowledge*, and/or *procedural flexibility* in algebra during these kinds of *designed disruptions* of traditional educational instruction.

Using an experimental design study with pre- and post-tests, we found that seventh graders significantly improved and maintained learning gains on conceptual knowledge throughout the technology-based interventions (Pretest: M=46%; Posttest: M=53%). However, they did not improve on procedural knowledge (Pretest: M=55%; Posttest: M=51%) or procedural flexibility (Pretest: M=52%; Posttest: M=44%). This pattern of results was consistent for students across interventions, suggesting that while these technologies may support conceptual understandings in algebra, further work is needed to explore how technologies might support student learning of algebraic procedures.

These findings have implications for research on the educational impacts of the COVID-19 pandemic and ways to support algebraic learning through technologies beyond educational disruptions. Specifically, DragonBox12+ and From Here to There! can engage students in algebraic learning and improve conceptual understanding. These gains are worth noting given the drops in math performance among U.S. students during the pandemic (NAEP, 2022). Both may help students engage with mathematical content and foster their positive attitudes towards math especially during educational disruptions. Supplementing middle school algebra curricula with game-based technologies may provide additional opportunities for students to deepen their conceptual knowledge. This poster contributes to the symposium by raising issues of impact within designed disruptions of traditional teaching, particularly when intersected with other *encountered disruptions* that may necessitate the use of technologies for learning.
