Abstract: Computation has become an essential part of today's personal, educational, civic, and career living, which necessitates preparation of a generation of future citizens who are knowledgeable of computational thinking (CT) concepts and are able to apply CT skills in daily life and work. Because of CT's use across fields, it is important that we take an interdisciplinary approach and ground the teaching and learning of CT in authentic and meaningful contexts with learners. This symposium explores different approaches of integrating CT into topics in formal settings. The six empirical studies of this symposium present designs of authentic environments that aim to infuse CT into plant science, literacy, ecosystems, general biology, and chemistry. These studies also report the findings of teacher and student learning from the implementations. Collectively these studies provide unique insights towards design recommendations, challenges, pedagogies, and opportunities in the rapidly developing STEM+C field.

Symposium overview

In today's high-tech and ever-changing world, computation is and will continue to be used in almost all walks of life (Vogel et al., 2017). It is increasingly clear that our students must learn to think computationally and resolve complex and ill-defined problems using computational tools for future thriving (Ventura, Lai, & DiCerbo, 2017). To meet this urgent need, public policy makers and educators have called for the incorporation of computing into K-12 education. For example, broader educational initiatives such as the CSforALL movement have emerged. Code.org has developed a suite of activities to expand access to computing opportunities in school (e.g., the Hour of Code program). The CSTA has created a framework for K-12 CS education and subsequent national standards. Despite these efforts, there remain substantial barriers to implementing computing education during K-12 in-school-time activities, often intersecting with positionalities of race and ethnicity, gender, socioeconomic class, and/or additional markers (Blikstein, 2018; Rodriguez & Lehman, 2017).

One barrier may be related to the fact that the field of computing education remains relatively new and there exist controversies surrounding the definition of computational thinking (CT). For example, Wing (2006) posed a seminal (re-)definition of computational thinking (CT) that "involves solving problems, designing systems, and understanding human behavior, by drawing on the concepts fundamental to computer science" (p. 33). Weintrop and colleagues (2016), in collaboration with practitioners, developed a taxonomy that defined CT specifically in math and science classrooms, including details about practices of modeling and simulation. More recently, Kafai and Proctor (2021), drawing upon their experiences in crafting, computer science, and language arts, have positioned computational thinking in three framings under an umbrella of *computational literacies* (*cognitive*, *situated*, and *critical* framings). They urge a reframing of CT from "a general-purpose skill" towards a tool for various individual/cognitive, collective/community/identity, or cultural/societal/liberatory purposes (p. 147). Amidst these various framings, researchers have agreed that CT is a foundational skill for a variety of STEM and non-STEM professionals (Malyn-Smith & Lee, 2012).

To accelerate the take-up of CT in K-12 classrooms, one emerging theme and endeavor is to employ interdisciplinary approaches to integrating computing into other disciplines. The traditional method of teaching computing through computer science coursework, while successful for many students, often is difficult to staff, disengaging to learners who are from groups underrepresented in STEM/computing education, and reinforces the stereotyped views of professionals working in CT related fields (Rodriguez & Lehman, 2017). An interdisciplinary approach can expose students to authentic contexts of using CT to solve real and meaningful problems across content areas. It can help students draw connections between application areas of interest and CS and broaden the participation of students, to whom such integrated learning environments can appeal (National Academies of Sciences, Engineering, and Medicine, 2021). Despite the efforts to promote interdisciplinary learning in CT (e.g., Lee et al., 2020), there remains a knowledge gap of how to develop authentic interdisciplinary learning experiences for students and teachers in K-12 settings.

Our contributors are from different disciplines and backgrounds (e.g., learning sciences, literacy education, science education, and human-computer interaction) and explore interdisciplinary STEM+C education in classrooms from different perspectives. Specifically, this symposium consists of (1) three presentations around promoting CT through computer modeling: Lee and Perret investigate a high school chemistry curriculum featuring computational modeling and decoding practice; Chao et al. present the design of a modeling environment using domain-specific modeling languages to support high school students in assessing the risk of natural hazards; Wagh et al. examine an interdisciplinary curriculum that bridges 6th grade Math and Earth Science through interactions with computer models of scientific phenomena; (2) two presentations around promoting CT through scientific experimentation and problem solving: Zhang et al. illustrate the unique affordances of using physical computing to foster middle school students' interest in CT and plant science; Jackson draws on perspectives of social identities and participant structures to investigate teacher learning in fostering student interest during four iterations of a smart greenhouse project; and (3) a presentation on promoting CT through digital storytelling: Proctor explores assessment of both English/Language Arts and CT through digital storytelling, employing rhetorical analysis to show how sixth-graders used computational affordances to expand notions of character identity and reader agency. Together, these papers exemplify different approaches to overcome the barriers of bringing CT into K-12 classrooms and shed light on strategies for promoting CT's nature of interdisciplinarity from the angles of learning environment design, pedagogy, and assessment. This symposium will contribute significantly to the field's understanding of infusing computational education into existing school coursework, in order to help achieve and sustain the adoption of equitable computing education for all K-12 learners.

We will structure the symposium following these steps: co-chairs introducing the contributors (2 minutes), contributors briefly presenting their research in a sequence (8 minutes per presentation and 1 minute transition, total: 54 minutes), discussant briefly discussing the themes emerged from the presentations and future directions (7 minutes), contributors engaging in a Q&A with attendees facilitated by the co-chairs (10 minutes), and co-chairs summarizing the discussed topics (2 minutes).

Interrogating and assessing computer models to deepen students' understanding of scientific processes

Irene Lee & Beatriz Perret

Numerous attempts have been used to integrate computer science (CS) and computational thinking (CT) into science classrooms through computer modeling and simulation practices (Grover et al., 2020). A common approach involves engaging students in constructing computer models of scientific phenomena via programming in a computer language. While this "programming first" approach has shown promise, its adoption has been hindered by teachers' limited preparation in CS, time constraints, and lack of understanding of how to integrate CS into their classrooms (Israel et al., 2022). Thus, Education Development Center's "Computational Sciences Pathway Option for Massachusetts High School Students" project ("Science+C") was funded by the National Science Foundation's STEM+C program to investigate a different approach. Rather than constructing computer models, the project's Chemistry+C curriculum engages high school students in using, decoding, and modifying *existing* computer models of scientific phenomena as the means to deepen their understanding of scientific processes while exposing them to computer science. This approach is "authentic" in two ways: it provides students with agency to investigate and solve problems, and it mimics the work of modern scientists who need to interrogate models to assess their validity and adapt computer models for their own uses rather than creating them from scratch.

The Chemistry+C curriculum was implemented during the 2021-2022 academic year by four Massachusetts high school chemistry teachers who participated in the year-long Science+C professional development program. In the curriculum and PD, a new practice called “decoding” was operationalized as a thinking process necessary when analyzing a computer model made by someone else. In particular, in a science context, decoding involves comparing a coded mechanism in a model to the scientific process it represents in the real world. When the coded mechanism closely matches what the student knows about the real-world scientific process being modeled, the model is deemed “valid” whereas when a mismatch is identified, the student is encouraged to modify the model to increase its validity. Our research aims to investigate whether and to what extent students who experience the integrated Chemistry+C curriculum featuring decoding show changes in knowledge and skills in both computational thinking and science learning. Summative assessments of student learning (pre-post surveys) were used to measure students’ ability to map between coded mechanisms and the scientific processes they represent, students’ understanding of CS constructs integral to CT for modeling and simulation, and science concepts. This paper describes the design of the Chemistry+C units and findings from our exploratory study of student learning through the intervention. We close with insights on design, challenges, pedagogies, and opportunities for future decoding curricula that may be of interest to designers, researchers, and practitioners who wish to engage students in computational thinking within science contexts.

Designing a domain-specific modeling language for secondary students to explore multivariate probabilistic simulations of scientific phenomena

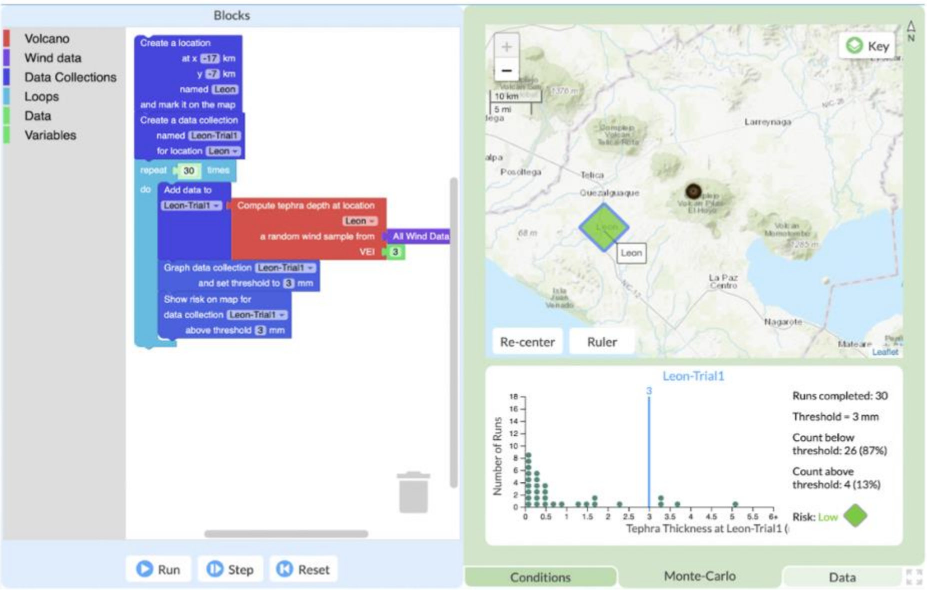
Jie Chao, Amy Pallant, Hee-Sun Lee, Christopher Lore, & Charles Connor

Computational modeling has become an essential practice in various fields of science. Scientists use programming languages to construct computational models of natural phenomena and run simulations to test theories and evaluate solutions (Shiflet & Shiflet, 2014). Recently, this practice has received much attention as an approach to integrating computational thinking (CT) into science classrooms (Wang et al., 2021). Computational modeling has been adapted as a form of learning activity that engages students in using, modifying, constructing, and evaluating computational models in programming environments (e.g., Aksit & Wiebe, 2020). As most students in science classes are not formally trained in programming, teachers are reluctant to devote too much class time to learning programming languages. Often, teachers themselves are not familiar enough with programming to support students in complex programming activities. Due to these constraints, block-based programming languages have become popular for their novice-friendly interface, syntax error prevention, and instant visual feedback (López & Hernández, 2015). However, generic block-based programming languages still require students to learn many lower-level language primitives as well as the syntax for composing with these primitives. To address this issue, researchers have been developing domain-specific modeling languages, which include alternative language primitives, often called custom blocks, for students to grasp more intuitively and interact more directly with the models of the target phenomena (Hasan & Biswas, 2017; Anderson & Wendel, 2020; Hutchins et al., 2020).

How can domain-specific modeling languages be designed to support high school students in learning multivariate probabilistic simulations? This study investigated this question in the context of the Monte Carlo simulation application for assessing the risk of being impacted by volcanic ash fallout. Some volcanic eruptions produce tephra, i.e., rock fragments and particles of various sizes. The tephra can disperse over a large region and affect people’s health, damage crops, block transportation, and even collapse buildings. Its dispersion is mainly influenced by the explosivity of the eruption, wind speed, and wind direction. Geoscientists have developed tephra dispersion differential equations and computer algorithms to predict the tephra fallout at a specific location based on these three parameters as well as others. However, numerous eruption scenarios exist because each parameter has a wide range of possible values. For example, wind speed and wind direction change every day. This makes forecasting a challenge because the weather condition at the time of a volcanic eruption event cannot be known. Yet it is possible to forecast the likelihood that the depth of tephra is beyond a dangerous level at a specific location. To assess this risk, the tephra dispersion computational model needs to be run many times, each time with a set of parameter values (wind speed and wind direction) randomly sampled from the probability distribution of a historical wind data set for that given location (wind measurements taken several times a day for years). When the outcomes of all the runs are aggregated, the risk can be assessed.

We designed a computational modeling environment with domain-specific custom blocks called GeoCoder, shown in Figure 1. It includes a collection of custom blocks to address the critical aspects of investigating tephra dispersion after a volcanic eruption, a set of dynamic visual tephra outputs in real-world geography, and the probabilistic sampling mechanism in a Monte Carlo simulation. For instance, there is a custom block for the tephra dispersion model. It takes three inputs: a location, volcanic explosivity, and a set of wind speed and wind direction randomly sampled from historical data. The block generates a predicted tephra fallout thickness displayed on a graph. The idea of running the model many times and aggregating all the outputs is often difficult for students to grasp. To make the idea concrete, we designed a data-collecting block to collect individual outputs from the tephra dispersion model and dynamic graphing blocks to visualize the individual outputs and the aggregated results. This set of custom blocks can be configured and wrapped in a loop block to implement the Monte Carlo simulation. When students step through the code, the output from each iteration is added to the graph, and as more iterations are completed, the aggregated results emerge.

Figure 1
GeoCoder, a domain-specific modeling language for multivariate probabilistic simulations (i.e., Monte Carlo simulation) in geohazard risk assessment



```
Create a location
    at x -17 km
    y -7 km
    named Leon
and mark it on the map
Create a data collection
    named Leon-Trial1
    for location Leon
repeat 30 times
do  Add data to
    Leon-Trial1   Compute tephra depth at location
                      Leon
                      a random wind sample from  All Wind Data
                      VEI 3
    Graph data collection Leon-Trial1
        and set threshold to 3 mm
    Show risk on map for
    data collection Leon-Trial1
        above threshold 3 mm
```

Runs completed: 30
Threshold = 3 mm
Count below threshold: 26 (87%)
Count above threshold: 4 (13%)
Risk: Low

We developed a two-week curriculum module using GeoCoder to introduce computational approaches for geohazard risk assessment to secondary students. We piloted the module with 84 ninth-grade students taught by four teachers in a suburban public high school in the southwestern US. All four teachers implemented the module remotely due to COVID-19 restrictions. Our findings suggest that students showed varied understandings related to random sampling from multiple parameters and the visual outputs from the Monte Carlo simulation in GeoCoder. At least half of students understood that the variability in model input parameters as well as the random sampling method itself would generate variability in individual outputs, resulting in different distributions of tephra depths among aggregate outputs. Other students' suboptimal understandings might result from the lack of opportunity to see that the same Monte Carlo simulation code could produce different aggregate outputs and think accordingly. These students may benefit from guided interactions with the sample code and close examination of outputs with specific characteristics that promote conceptual learning.

In this presentation, we will describe the design of GeoCoder, discuss student learning patterns from their written and block code artifacts, and propose several principles for designing domain-specific modeling language for secondary students to learn and use multivariate probabilistic simulations.

Physical computing learning experience for middle school science classrooms

Helen Zhang, Mike Barnett, Sheikh Ahmad Shah, & Jaai Phatak

The past two decades have witnessed the rapid growth of computer science (CS) or computational thinking (CT) education at the K-12 level across the United States. Despite its expansion, CS/CT education for students who have been traditionally underrepresented in STEM education remains a challenge. Recent research shows that most current approaches to implementing computational science in educational settings have focused on programming and mathematical computing via decontextualized coding skills training (Fowler & Vegas, 2021; Margolis et al., 2011). Such decontextualized approaches are highly likely to continue to disengage the majority of students from underrepresented populations, who have already felt that computer science is boring and distant from their life (Garcia et al., 2020). Thus, a new report by the National Academies of Sciences, Engineering, and Medicine (2021) called for teaching computational science through authentic experiences to cultivate youth's interest in learning about computation and understanding the role it plays in their future endeavors.

This paper contributes to the call by presenting the design and implementation of a physical computing learning experience among middle school students. Physical computing involves combining software and hardware to build interactive physical systems that sense and respond to the real world (Hodges et al., 2020). A physical computing system includes sensors to sense its environment, a microcontroller to process information, and devices such as actuators or displays to perform actions accordingly (Psycharis, 2020). This "sense–think–act" cycle connects the physical world with the digital/virtual world. When working on physical computing projects, learners engage in building tangible computational artifacts that allow them to explore connections between real world phenomena and computer programs. The interweaving of building and programming makes coding more meaningful and concrete to students, engaging those who might be turned off by decontextualized approaches of teaching CS/CT. A few research studies have found that physical computing can be much more positive than a more traditional screen-based experience because it more readily supports open-ended ideation, rather than causing frustration through syntax restrictions (Przybylla & Romeike, 2015). Students appreciate building real devices and report that physical computing stimulates their creativity (Devine et al., 2018; Sentance et al., 2017) and fosters collaborative learning as it enables students to work together in a visible way (Horn, 2018; Marshall, 2007).

In this paper we report the design of the smart greenhouse project, during which students learn to use and code a tabletop greenhouse (a physical computing system) to control and manipulate the environmental conditions to grow plants. Learners utilize a BBC micro:bit microcontroller to collect data from a variety of sensors including air and water temperature, light, and humidity, then display the data on a small screen and stream the data using a WiFi chip. They use actuators (relays) to control components of the greenhouse such as the lights and air flow (e.g., turning on the grow light when the light level is low and turning on the fan when the temperature is high). To support learners in wiring the sensors to the micro:bit, we use a shield that allows them to simply plug in the sensors rather than using a breadboard or soldering. The sensors are coded through Microsoft's MakeCode block-based interface, and each sensor is enabled through the micro:bit extension library, allowing students to focus on how to code the sensors to collect their data rather than spending time getting the sensors to work. Figure 2 shows an image of the greenhouse and example code. The curriculum includes four modules: Module 1 focuses on assembling the greenhouse, how to code micro:bit using MakeCode, and fundamental concepts of plant science; Module 2 focuses on how to connect the sensors to the micro:bit and how to program to display temperature, humidity, and light levels data from the sensors on the OLED display; Module 3 centers around automation, i.e., students learn how to program so that the greenhouse acts (e.g., turning on and off the fans and the lights) based on the data from the sensors; and Module 4 focuses on using the WiFi chip to stream data to ThingSpeak for students to monitor and visualize the environmental conditions in their greenhouses in real time. In total students spent 12 days on this project (55 minutes per day).

  pause (ms) 3000
```

We implemented the smart greenhouse project in two middle schools (*N*=175 students and families completed assent and consent forms, respectively) with diverse student populations: 46.9% male, 42.9% female, 9.1% non-binary/blank/prefer not to say; 3% African-American, 23% Latino/x, 45% White, 4% East Asian, and 25% Mixed-race/others. The data collected included a pre/post-survey assessing students' interest in coding (12 items, α=.92), career futures (i.e., views of the value of coding in future jobs; 4 items, α=.80), competency belief (i.e., beliefs about their own competency of coding; 6 items, α=.86), anxiety (4 items, α=.71), and STEM identity (8 items, α=.94) using 5-point Likert-style questions. We also collected classroom observation notes of student reactions when learning with the smart greenhouse curriculum, as well as post-interviews with a group of students (*N*=30) selected for maximum variation (Creswell, 2013) with respect to race and ethnicity, gender, and performance in science class. The interviews addressed students' conceptual understanding of the code and their views of using coding in science. A paired t-test of means for student responses to the pre- and post-survey found statistically significant increases at the α=.05 level for students' competency belief (Pre Mean=3.21, SD=.71, Post Mean=3.43, SD=.84; *t*(141)=3.14, *p*<.01) and STEM identity (Pre Mean=2.79, SD=.88, Post Mean=2.96, SD=.97; *t*(141)=2.14, *p*<.05). The classroom observations showed that almost all students actively participated in the project. They worked in pairs: typically, one student led construction (e.g., assembling the greenhouse frame, connecting wires) and the other focused more on coding. Students tended to work together on troubleshooting. Exit interviews further confirmed these social dynamics. Almost all interviewees commented that they could start from building the greenhouse or from germinating seeds if they were not comfortable with coding. Students also commented that the smart greenhouse helped them visualize how programming can be used to control and automate plant growth conditions. Overall, our results suggested that physical computing, and especially this project with its many access points, is promising for engaging students of diverse backgrounds, supporting them in recognizing their capability for coding and in developing their STEM identity.

"A reason to do the coding": Teacher growth in fostering student interest across four years of an automated greenhouse project

David W. Jackson

To ensure equitable access to and participation in K-12 computation, scholars are working to embed computation in required courses for science, technology, engineering, and mathematics (STEM; Cateté et al., 2018; Lee et al., 2020; Vogel et al., 2017). While progress has been made, studies tend to focus on cognitive outcomes in monodisciplinary settings; more work is needed around affective outcomes in interdisciplinary or pluridisciplinary settings, especially for the sensitive period of young adolescence (Cateté et al., 2018; Jackson et al., 2022). Previous studies have focused on deep analysis of student *engagement* in a *single* iteration (e.g., Jackson et al., 2022); the current study considers student *interest* across *four* iterations. This study addresses the research questions, (1) In what ways did four iterations of an automated greenhouse project support student interest, within and across disciplines of computation, engineering, science, and technology?; (2) How were learning activities related to student interest?; and (3) How were knowledge and attitudes of both students and teachers related to student interest?

The research team of the Innovation in Urban Science Education lab (IUSE lab) at Boston College partnered with an urban-ring public school district in the Northeast US that we call "Mills City Public Schools". For four out of five years from 2018-2022, our research-practice partnership took a *social psychology* approach to design-based research (Bell, 2004), with professional development, co-design, and co-implementation of an eighth-grade automated tabletop greenhouse project, which we call the "smart greenhouse project". On average about 200 students per year participated in the project, and were diverse in terms of race and ethnicity, gender, culture and language, and socioeconomic status (e.g., about 45% students of color; 49% female, 49% male, and 2% identifying as non-binary; 50% speaking multiple languages at home; 35% classified as economically disadvantaged). The current phenomenological qualitative case study (Creswell, 2013) looks at lived experiences of both students and teachers. Data sources included representative sampling (Creswell, 2013) of mid- and post-interviews from the two teachers who most consistently participated at each of two middle schools, namely "Mr. Meloney" (2018, 2019, and 2022) and "Ms. Kade" (2021 and 2022). Our first round of coding was deductive per the four phases of interest from Hidi and Renninger (2006), the four major disciplines in the project (science, technology, engineering, and computing), and the 18 design considerations of its social infrastructure (Bielaczyc, 2006), alongside inductive coding. The second round of coding looked for trends and connections within and amongst the first-round codes, or *pattern* and *axial* coding, respectively (Saldaña, 2009).

The research team's analyses resulted in five themes across the four iterations of design-based research for the smart greenhouse project, of which we present three due to space constraints. Firstly, we found evidence of development of interest (Hidi & Renninger, 2006) that was flexible due to the pluridisciplinary nature of the project. For example, teachers emphasized technology such as LED light strips that stimulated triggered situational interest; teachers incorporated biology such as plant growth and environmental conditions, which supported maintained situational interest; teachers scaffolded experiences with computation, especially extra "challenge" activities or open-ended explorations, to foster emerging individual interest; and teachers sought to prime students for well-developed individual interest through recommendations of future clubs, camps, and classes. Secondly, we noticed teachers evolving in their adaptations of *the planned learning activities*, as well as the *social identities* and *participant structures* (Bielaczyc, 2006) of both themselves and the students. For instance, teachers grew in their repertoires for scaffolding of activities depending on students' prior and current experiences. In other words, over time teachers improved in their adjustments for students who initially had more coding proficiency *and* for students who mostly developed their proficiency during the project. Thirdly, we saw troubleshooting as a practice that could stimulate *or* stifle development of interest, depending on identities and participation of students and teachers. In general, students who had greater internal confidence and external encouragement tended to persist through troubleshooting their code, while the inverse also tended to be true. However, there were some exceptions to those trends, which teachers endorsed as a counterbalance to what they observed in their monodisciplinary science units (e.g., students who previously succeeded solving well-defined problems got needed practice in addressing ill-defined problems).

Our study confirms and extends much of the extant scholarly literature on embedding computation in required STEM courses. Honoring the tradition of research at the high-school level, our work highlights educational design considerations (Bielaczyc, 2006) that are most salient for the sensitive period of middle-school (Cateté et al., 2018). Rooted in cognitively intensive activities, and combining them with more affective concepts like social identities and more behavioral concepts like participant structures, we extend understandings toward more holistic conceptions of learning. In sum, our work has implications for the support of developing student interest in computing through required classes, using pluridisciplinary approaches to give each student and all students, in the words of Mr. Meloney, "a reason to do the coding".

Integrating math and science through CT in a 6th grade curriculum

Aditi Wagh, Emma Anderson, & Irene Lee

The development of reasoning about scientific processes relies heavily upon representational resources from mathematics (Weinberg, 2017). Mathematics underpins the computational modeling of scientific processes (Wilkerson & Fenwick, 2017). In other words, translating a target phenomenon of a scientific process into computational representations involves sense making of components/elements/concepts related to mathematics, science and computational thinking. The Making Sense of Models (MSM) project designed and tested an interdisciplinary curriculum that bridges Math and Earth Science through interactions with computer models of scientific phenomena. Our goal is to examine how attending explicitly to the links between math and science when negotiating the relationship between phenomena and their target computer models can impact student learning of math, science and computational thinking. The unit, "It's Getting Hot in Here", invited students to draw on their everyday lived experiences of hot summers in the Southwestern region of the United States; to conduct a physical experiment to measure the temperature of differently colored surfaces exposed to sunlight; to explore and manipulate the code embedding the cause and effect mechanism of an object's behavior upon collision with a surface within a math context; then to apply their understanding of that mechanism when reading and analyzing coded procedures in a scientific model of reflectance and absorption in solar heat gain. These experiences connect concepts in math and science to students' lives and environmental concerns.

In this paper, we report on the design of this unit and implementation of the unit in two 6th grade classrooms in the southwestern US. Our study examines whether and how this interdisciplinary approach contributes to students' understanding of science, math, and computational thinking as discrete yet connected subjects, as well as their ability to find and fix errors in coded representations of scientific processes. Data collected include pre- and post-surveys, classroom observations, and student interviews. We found that when fixing errors in a computer model, students run the model to produce a simulation, notice discrepancies, then interpret the math and science in the code, and reason about how to fix it. Encountering and fixing errors in models provides students opportunities to apply their understanding of the focal phenomenon and the mathematical and scientific bases of mechanisms that generate the phenomenon. The findings from this study contribute to research on how CT may support students' reasoning about scientific processes.

Assessment in interdisciplinary CS/ELA: Rhetorical analysis of student-produced computational texts

Chris Proctor

The US has made substantial progress over the past decade toward the goal of universal K-12 computing education, including state policy, curriculum standards, teacher preparation, and teacher professional development (Yadav et al., 2021). Following this progress, there is increasing interest in K-12 interdisciplinary computing, for principled reasons (e.g., literacy across the curriculum) as well as practical reasons (e.g., the difficulty of adding computer science coursework to full school schedules and the lack of qualified teachers). Unfortunately, many proposals for interdisciplinary computing pay more attention to epistemologies and learning goals in computing (computational thinking, CT) than to those of other disciplines. One common pattern – mapping problems from a non-computing domain into privileged computational representations – is exemplified in Wing's (2006) vision of a future in which other subjects are improved by turning them into computer science: "Computational thinking will have become ingrained in everyone's lives…when trees are drawn upside down" (p. 34).

In this paper, I specifically consider interdisciplinary computing in the context of English/Language Arts (ELA). Assessment practices drive pedagogy (Eisenhart, Finkel, & Marion, 1996), so I develop an approach to assessing student-produced computational artifacts that supports the assessment of CT while being grounded in epistemologies central to ELA. A literacy-based approach to computing would value the skills and knowledge required for effective programming, debugging, and reasoning about computational problems, but as prerequisites to participation in a computationally-mediated society, rather than as ends in themselves (Kafai & Proctor, 2021). If we want to support and assess students' CT development from a literacy perspective, where the terms of quality are themselves normative and community-defined, we need a way of understanding students' work in terms of the audience for which they were produced. This approach is likely to yield approaches to interdisciplinary computing which are more palatable to ELA educators, while also developing a more productive account of interdisciplinary epistemic practices drawing on CT and literary criticism.

This study presents several case studies analyzing student meaning-making in the context of interactive storytelling (Proctor & Garcia, 2020) using a programming language which offers affordances of both literary prose and code. These case studies were selected from a ten-week unit using interactive storytelling in a sixth-grade computer science classroom of a small city in the US midwest. I use a method of rhetorical analysis developed by Proctor and Blikstein (2019), which extends reader-response literary theory (Rosenblatt, 1968) to computational artifacts. Stories are qualitatively coded along four dimensions: (1) how they take up literary and computational affordances (e.g., characterization, point of view, manipulating state, manipulating of the story's graph structure); (2) rhetorical modes of meaning-making (e.g., suspense, granting or withholding agency, directing the reader's empathy); (3) figured meanings (e.g., school, the city, violence, gender); and (4) criticality (e.g., identity authorship, voice, worlding). Tracing the co-occurrence of codes across these four dimensions illustrates how the hybrid text-code medium supports emergent forms of social meaning-making, ultimately creating new opportunities for participants to discuss and reinterpret important experiences from in and out of school. For example, authors used emoji and SMS speech bubbles to model identities and discourse dynamics from text message communication; they combined first-person narration with nonlinear story structures to destabilize the idea of a unified sense of self; and they structured the user interface to strategically grant and withhold agency from the player to explore ideas of guilt, shame, and regret.

These case studies illustrate some of the ways in which CT learning and digital rhetoric can be mutually-supportive and point toward open-ended pedagogies of computational literacy in which we interpret the meanings of student-produced computational artifacts, rather than scouring them for expected representations of CT learning. The case studies ground a broader analysis of the 578 stories written by 49 study participants during the study, which will document the diffusion of practices through the classroom community as well as the emergence of genres and audiences that make room for new identities and voices.

Reimagining the Future of Teaching and Learning Using Black Feminist-Womanist Storytelling Methodologies

Mia S. Shaw (chair), University of Pennsylvania, mshaw12@upenn.edu
Naomi Thompson, University at Buffalo, naomitho@buffalo.edu
Ti’Era Worsley, The University of North Carolina at Greensboro, tdworsle@uncg.edu
Aireale J. Rodgers, University of Wisconsin-Madison, arodgers4@wisc.edu
Stephanie Toliver (discussant), University of Colorado, Boulder, stephanie.toliver@colorado.edu

Abstract: In this symposium, four Black women learning scientists use Black feminist-womanist storytelling as an approach for restorying the future of education. Through sharing past and present learning and teaching experiences, each researcher will interrogate dominant narratives that often marginalize Black girls and women throughout their learning trajectories. Resisting these narratives, they will draw from missing or silenced perspectives to reimagine more liberatory futures for learners at the intersection of multiple systems of oppression. Through analyzing and theorizing their stories, the discussant (another Black woman education researcher) will review overarching themes across each story to demonstrate how centering the knowledge, experiences, and practices of Black women and girls offers unique epistemologies and methodologies for transforming education.

> *“Remember to imagine and craft the worlds you cannot live without, just as you dismantle the ones you cannot live within.” - Ruha Benjamin.*

Session summary

In this symposium, four Black women learning scientists use Black feminist-womanist storytelling as an approach for restorying the future of teaching and learning. Baker-Bell (2017) defined Black feminist-womanist storytelling as a methodology that blends autoethnography, Black women’s language and literacy practices, Black feminist and womanist theories, and storytelling to “create an approach that provides Black women with a method for collecting our stories, writing our stories, analyzing our stories, and theorizing our stories at the same time as healing from them” (p. 531). As opposed to foregrounding educational designs or empirical study, this symposium centers Black women’s collective storytelling as a method for not only addressing educational injustices, but also draws on their unique knowledge and histories of resistance to reimagine possible liberatory and dignifying futures.

Objectives of the session

The objectives of this symposium are to address the role narratives and everyday storytelling play in upholding oppressive power structures in educational spaces. As articulated by De Fina and Georgakopoulou (2012), narratives can act as “sites for the imposition of forms of domination by powerful individuals and institutions” and are “used to negotiate new roles and norms by members of society” (p. xii). Within learning environments in particular, learners employ narratives—which include sociohistorical and social constructs such as race, gender, and class (Nasir & Shah, 2011; Leyva, 2016)—to better make sense of themselves and others (Gresalfi & Hand, 2019). This symposium aims to leverage an intersectional praxis, Black feminist-womanist storytelling, to address the presence and impact of narratives in the experiences of learners, specifically Black girls and women. Through engaging in restorying practices (Stornaiuolo & Thomas, 2018), this symposium will demonstrate how collective storytelling rooted in Black feminist/womanist theories can become a site not for the imposition of domination, but for healing and transformation.

Significance of the session

While there has been recent enthusiasm within the learning sciences community for speculative approaches to education that critique intertwining systems of oppression, there also exists the need for innovative methodologies for creating speculative yet equitable learning environments within the field. Such methodologies would provide researchers with tools for not only examining our pasts and presents but also tools for imagining possible futures, particularly in the context of teaching and learning. As a qualitative method, autoethnography through Black feminist-womanist storytelling allows us as researchers to use our personal experiences to “describe and critique cultural beliefs, practices, and experiences” while also using deep reflexivity to “name and interrogate intersections between self and society, the particular, the general, the personal, and the political” (Adams, Holman

Jones, & Ellis, 2014, pp. 1-2). In this session, we combine autoethnography with the speculative literacy practice of restorying.

With deep roots in narrative scholarship (i.e., Clandinin & Connelly, 2000; Clandinin, 2006), restorying describes the ways marginalized communities reread and rewrite the world (Thomas & Stornaiuolo, 2016). Recent configurations offer youth of Color a conscious process for analyzing present and past realities to reimagine more just futures (Shaw & Kafai, 2020). Rooted in critical race theory, restorying offers a framework for collecting the stories of marginalized people through counternarratives, or narratives that present alternatives to dominant perspectives (Cooks & Dixson, 2013). Such a process involves educators and youth presenting the realities of their everyday worlds, situating those realities within historical practice and current discourses, and telling stories from missing or silenced perspectives to imagine alternate futures (Stornaiuolo & Thomas, 2018). Interrogating and reimagining dominant narratives about education—which can act as grand stories or myths that connect to broader societal ideologies, imaginaries, and stereotypes (e.g., Gresalfi & Hand, 2019)—not only reveals whose knowledge, experiences, and interests are most centered but also whose perspectives are most often less visible.

Evans-Winter and Esposito (2010) stated, “Girls of African descent are at the bottom of the social totem pole in society; thus, there is an urgent need for a theoretical framework that serves to expose, confront and eradicate race, class and gender oppression in our families, communities and schools” (p. 22). Black feminist and womanist epistemologies illuminate how the intersections of race, gender, sexuality, and class inform one another and assume that they cannot be analyzed as disparate phenomena (Baker-Bell, 2017; Collins, 1997). These ways of knowing recognize Black women as knowers and producers of knowledge and practices that are distinct from other groups based on their social position of being Black women. It is the group consciousness that comes from Black women’s historical position at the nexus of raced, gendered, and classed liminality that provides deep insight about the workings of structural power, privilege, and oppression (Collins, 1997). We are learning scientists who work towards creating expansive learning communities where Black women and girls can thrive. Therefore, we push back on dominant, White, cis-het-patriarchal perspectives that too often constitute conventional knowledge about educational practice. We leverage Black feminist and womanist epistemologies because “the existence of a self-defined Black women’s standpoint using Black feminist epistemology calls into question the content of what currently passes as truth and simultaneously challenges the process of arriving at that truth” (Collins, 2002, p. 221).

Weaved throughout the narratives of Black women writers like Octavia Butler, Toni Morrison, and Zora Neale Hurston exist a demand for the “seeing and knowing of Black girls and women’s lives in varied and heterogenous ways while at the same time calling for a collective vision and aspiration for their humanity” (Muhammad & Haddix, 2016, p. 303). We see significance in integrating Black women’s everyday knowledge, experiences, and histories as a theoretical contribution for addressing intersectional forms of oppression in education and the study of human learning. Not only does storytelling reflect one of Black women and girl’s most powerful language and literacy practices, but it also functions as a vehicle for Black women and girls to transmit our unique knowledge of the world in hopes that our narratives can promote societal change, as well as self- and communal healing (Baker-Bell, 2017; Richardson, 2003). This symposium offers restorying through Black feminist/womanist epistemologies as a framework for engaging researchers in critical race methodology—which offers researchers a space and the tools to challenge multiple systems of oppression by grounding research in the experiences of and knowledge of people of Color (Solórzano & Yosso, 2022.

Structure of the session

After a brief introduction by the chair to the theme and focus of the symposium, participants will be polled on whether they recognize the five dominant narratives from each presenter, which are displayed on the screen one at a time. Participants are then given ten minutes to reflect on and share a dominant, taken-for-granted narrative that creates a tension in the work that they do via another poll. Afterwards, each presenter will give a seven-minute story in which they share about their educational pasts and presents as Black women and girls and how they connect these experiences to their current work in reimagining the future of teaching and learning. Weaving in her own insights and experiences about teaching and learning as a Black woman, our discussant will review overarching themes and address the following research questions: (1) How might collecting, analyzing, and telling our educational stories provide Black women learning scientists the space for reimagining alternative futures for education and healing? (2) In efforts towards a more just future, what can the learning sciences research community learn from centering the knowledge, experiences, and practices of Black women? We will then open the symposium to Q&A with the audience.

Being soft and vulnerable makes you weak

Mia S. Shaw

For as long as I can remember, my family has described me as “soft” and “sensitive.” While I knew soft was a desired attribute when describing moisturized skin or mashed potatoes, growing up I perceived it as a character flaw when it came to succeeding in the real world. Having grown up in racist towns in the South and New England, my parents educated me about the insidious forms of racism I was experiencing throughout my private, religious schooling and taught me to remain strong in the face of challenges—lest I would be taken advantage of. When I was a child and teenager, I believed that strength came in the form of proving others wrong (in this case, it was my racist teachers and peers) about my abilities and hiding when I needed help. So even when I struggled emotionally throughout high school and college, I learned to redirect my pain into my academics and my work, wearing the badge of a “strong, Black woman,” one who was not “soft” and did not need anyone’s help.

Unlike visibly harmful stereotypes like the jezebel or mammy, the trope of the strong Black woman recharacterizes us as superhuman and immune to pain or suffering (Wyatt, 2008; Collins, 2000). In my case, I developed a habit throughout undergrad and my first years teaching of putting on a brave, level-headed face and not reaching out for help, despite my unawareness that I was struggling with anxiety and depression. My Black, Christian upbringing did not encourage therapy or sharing one’s issues and vulnerabilities with others outside of family, but when I observed my students struggling with similar issues, my approach as an educator shifted to one that emphasized care. Further, I became motivated to design learning environments that allowed Black and Brown youth to bring their full selves to the learning process, as well as reframe teaching and learning as a site for community and belonging. Growing up, education was a competitive endeavor, and to succeed financially in fields like medicine, I needed to learn how to be the best and the best “never lets others see them sweat.” However, I now see education as what bell hooks (1994) calls “the practice of freedom” and designing the worlds and relationships we want with each other—ones that allowed us to be whole and allowed us to be soft.

Anger isn’t ‘appropriate’ for classroom learning

Aireale J. Rodgers

> *“To my sisters of Color who like me still tremble their rage under harness, who sometimes question the expression of our rage as useless and disruptive…I want to speak about anger, my anger, and what I have learned from my travels through its dominions”* (Lorde, 1984, para 15).

From a young age, I was always confused about whether and how to express my emotions. My mother always kept her feelings concealed, like cards close to her chest. As I reflected on how I was socialized to act in schooling settings—both by educators and my most beloved family—I realized how large a role emotion management has played. In fact, it has been a deeply formative part of the hidden curriculum. As Black women and girls navigate formal schooling, we are often made keenly aware of the dangers of falling into the ‘angry Black woman’ stereotype. I learned that my emotions didn’t matter as much as others’ comfort. Surely, as a fat Black woman, any anger I felt had no place in the classroom and compromised my standing with my colleagues.

But the anger never went away. Instead, it has intensified over time. The more I was exposed to the inequities and violence embedded in educational policy and practice, the angrier I have become. I have tried to swallow the anger. I have tried to translate it into niceties. I have tried to make my anger palatable and deliver it with a smile. Ultimately, I treated my anger as anything other than what it was. I betrayed my anger, and it became grief.

Everything changed for me when I read Audre Lorde’s (1984) *The Uses of Anger: Women Responding to Racism.* I began to understand that my anger was not a liability. When I embrace my anger intentionally and meaningfully, it can be a powerful catalyst for transformative change in the world. My anger reminds me that I am neither despondent nor numb, and it calls me to act in ways that squash injustice and create something different. In this way, I have learned that anger can be pedagogical—an intellectual resource available to us. For example, I often ask students “how do you *feel* about what we are learning together? What is your anger teaching you?” Scholars in the learning sciences have recently pointed to the importance of emotions (e.g., Curnow & Vea, 2020; Vea, 2020), specifically anger and rage (e.g., Curnow et al., 2020), in learning. I work towards the cultivation of learning spaces where Black women and girls can bring their full selves—including their anger—to their learning and value it as a resource.

Separate yourself from your Blackness to be successful in academics and in life

Naomi Thompson

I didn’t have a Black teacher until college (see Madkins, 2011, for a discussion of the history of the Black teacher shortage). That didn’t mean I didn’t think Black people could be smart—I thought my mom and dad were smart. My dad’s job in telecommunications was so obscure and technical that my sisters and I just decided he was actually a spy and made up stories about his job to keep us off the scent. Sometimes we still think that. I knew my maternal grandmother had been a teacher in Jamaica. She lived with us while I was growing up, and she used to take me on walks around the neighborhood and quiz me on my multiplication tables. I imagine her spirit frowning (and laughing) every time I use a calculator to double-check 7 x 8. I still believe my mom is both the smartest and prettiest woman on the planet, I will not be taking questions about that at this time. So I knew Black people could be smart, could be teachers, could be engineers.

But even at home, that truth came with caveats. To this day, my mom tells stories about the Jamaican patois she sometimes spoke with friends but could never use at home lest she face the wrath of her own mother. They were proper Jamaicans who spoke proper English, nothing else was acceptable (Green, 2006). Similarly, I didn’t grow up speaking patois, or AAVE, or any dialect other than midwestern (white?) English. The very few other Black students at my school clocked that immediately. They teased me, asking why I talked like a white person? Surely at least one of my parents was white? No? Then why were we so different? I had no answer. I told my parents I was being teased at school. They told the school counselor I was being bullied. I also didn’t have a Black friend until college.

Of course, I know now that there are infinite ways to be Black, and that those students and I were both acting within a white supremacist system that wanted to constrain us, to make us smaller, to keep us apart (e.g., Shaw-Taylor & Tuch, 2007). But I didn’t have the language for that then. I continued to succeed in school, with no Black classmates in my honors or AP classes, no Black teachers, and no examples of what it might mean to hold my Blackness close, to let it take up space, to make me bigger. I made it through, but I have a lot to (re/un)learn. Today, I am lucky enough to bask in the presence of Black women and femme scholars, in my professional network and in my new home. I’m still figuring out how to let my Blackness take up more space in my research, but I’ve started by looking for examples and clinging to them. I have so many Black teacher.

“Maybe you’re not cut out for engineering”

Ti’Era Worsley

Learning opportunities are informed by one’s connections to specific places. How we come to know places is by the experiences that we associate with them; however, experiences are not static and can be (re)edited individually (Ma & Munter, 2014). Those experiences determine connections developed and can be informed by space/time spent in a place, types of learning that occur, or physical/mental boundaries. As I reflect on my own upbringing and experiences as an undergraduate in mechanical engineering, I wonder what the possibilities could have been if I had educators who created learning opportunities for me to engage in STEM in varied ways. As an informal STEM educator to predominantly Black youth within a Boys and Girls Club, I often reflect on how and who I want to be for youth. My pedagogical practices are in direct correlation to what I needed for myself during my upbringing. While I cannot revisit my childhood, I make it my goal to create spaces where youth have the supports they need.

When I was an undergraduate I was so excited, especially as a first-generation college student, to make myself and my family proud. However, within my second year, I struggled with a physics course. I was too resilient to give up so I searched for opportunities to overcome my struggle with passing the physics course. I spoke with the undergraduate advisor to see what resources were available and without a second glance, she said “If you can’t hack physics then you can’t hack engineering, so look into something else.” In that moment I felt that my career was being taken from me before I even started. *What was I supposed to do?* was the only thought that ran through my head. My mom encouraged me to look at other majors and said “you only fail if you give up.” After speaking with the coordinator of advising for the engineering department, I found a major that fit my interests and immediately switched. When I think back to this interaction, I realized that I was not as affected by switching my major. What stuck with me was how the conversation with the mechanical engineering undergraduate advisor left me feeling so dehumanized and belittled.

Because of this, I make it my priority to reauthor spaces for the Black youth I currently work with. I work to create space and community for them and myself. Almost as a form of self-healing, alongside these youth, I too, am provided learning opportunities to continue my own exploration of STEM. As a Black woman who loves to tinker, teach STEM in non-traditional ways, and discover my own rightful presence in STEM and STEM education, I work hard to ensure that the youth I work with and myself feel humanized when engaging in STEM. Instead of taking a deficit approach to determine who is able to engage and be a part of STEM, I disrupt the power dynamic to support youth in seeing themselves as doers of STEM

Abstract: This symposium widens the lens on "what counts" as civic engagement to include social movements, acts of dissent, and counter-narratives that center the voices and rights of BIPOC youth and elders, people without homes, and immigrants. The authors all share a commitment to learning that moves beyond the walls of a classroom, from immigrants members of decision-making bodies across the state of Oregon; to the streets and sidewalks of Seattle neighborhoods, to libraries and community walks in the Southeastern US; to the online political engagement of BIPOC undergraduate students during the 2021-2022 school year; and finally to an out of school design-build program for Black and Brown high-school-age girls of color. By bringing together these myriad learning environments in one symposium, we emphasize how civic learning trajectories are best supported by a diversity of settings which mutually reinforce individuals' and collective agencies, interests, and civic opportunities.

Focus of the symposium

Normative notions of "civics" in the United States assume all people have legitimate and equal rights to participation in public discourse (Mirra & Garcia, 2017) and place-making (Taylor et al., 2018). However, who (and what) counts as having rights has been constructed within the historical context of a nation developed on the enslavement of Black people, the land dispossession and attempted genocide of Indigenous Peoples, and the global militarization of predominantly Asian and Latin American countries (e.g., Mojab & Carpenter, 2011). Our symposium widens the lens on "what counts" as civic engagement to include social movements, acts of dissent, and counter-narratives that center the voices and rights of BIPOC youth and elders, people without homes, and immigrants. This parallax on civic engagement necessarily holds White folks and systems of White supremacy accountable for committing and upholding inequities and injustices across public spaces of learning (e.g., classrooms, parks, libraries, neighborhoods, online forums); what learning "interventions" do White people require to become better citizens? We believe seeing this version of civics and civic engagement anew could catalyze material redistributions of resources (a.k.a. wealth) to communities of historical disenfranchisement.

Education plays a crucial role in this new vision of civic engagement and development (Dabach et al., 2018)—particularly if education is understood expansively, as "a social process and function (that) has no definite meaning until we define the kind of society we have in mind" (Dewey, 2004 p. 93). Our imaginaries of society – heterogeneous (e.g., Rosebery et al., 2010), more equitable (studies cited in this symposium), and caring (Uttamchandani, 2021) – shape learning contexts that focus on civic engagement and responsibility. This learning, we argue, includes a diversity of practices that are life-long, life-wide, and life-deep (Banks et al., 2007).

Understanding trajectories of civic engagement through resistance efforts within the Learning Sciences can be traced to reimagining Chicago public schools for Black students (Lee, 1992); reimagining migrant intellectual citizenship in the University (Gutiérrez et al., 2009); organizing grassroot political campaigns with multiracial young people (Kirshner, 2008); BIPOC youth engaging city planners in reimagining transportation routes (Taylor & Hall, 2013); and creating solidarities in the march for science (Bang et al., 2018). These acts of civic organizing worked at the edges of school contexts or through community-led efforts to support greater justice for BIPOC youth and communities. Building on this work in the Learning Sciences, Jurow and Shea (2015) developed an argument for the field to expand notions of learning by studying social movements where community members were organizing for greater justice within their neighborhood. These efforts support a movement within the field to see sites of civic resistance or social movements "as productive sites where people work together to critique, re-imagine, strategize, and re-make how we can engage with one another now and in the future" (Curnow & Jurow, 2021, p. 14). Learning and civic engagement recast through social movement organizing allow the field to theorize learning with the efforts of immigrants engaged in participatory budgeting (Meléndez, 2021), youth activism both in South Africa (Tivaringe & Kirshner, 2021) and in US LGBTQ+ youth groups (Uttamchandani, 2021), as well as with migrant women intervening for human rights in Japan (Takeuchi & Ishihara, 2021). In these examples, the range of ages, the central organizers for learning, and the contexts for where learning takes place all offer the potential to reimagine civic learning to be based on heterogeneity, equity, and care. This symposium furthers these efforts by attending to a wider scope of practices that "count" as civic engagement and developing our collective imagination for how resistance and counter-narratives offer new possibilities for understanding civic learning.

Our session interrogates processes that privilege and reproduce certain kinds of civic engagement, while foregrounding techniques to unsettle the status quo (including processes to define "civic engagement"), opening new possibilities to develop a more just society. The authors all share a commitment to learning that moves beyond the walls of a classroom, from immigrant members of decision-making bodies' across the state of Oregon; to the streets and sidewalks of Seattle neighborhoods, to libraries and community walks in the Southeastern US; to the online political engagement of BIPOC undergraduate students during the 2021-2022 school year; and finally to an out of school design-build program for Black and Brown high-school-age girls of color. By bringing together these myriad learning environments in one symposium, we emphasize how civic learning trajectories are best supported by a diversity of settings which mutually reinforce individuals' and collective agencies, interests, and civic opportunities (Ito et al., 2015). Through this dialogue we invite learning scientists to ask how existing or developing learning environments support or constrain intersectional civic identities across generations and settings, and to develop design principles which could help forge supportive civic learning trajectories, particularly with historically marginalized people to disrupt White hegemony. In this way, we hope learning scientists can participate in these trajectories so we, as a society, can live up to our ideals of justice and equity.

Themes explored by the collective work

Trajectories that best support civic engagement in its multi-dimensional complexity

The global *reflexive turn of citizenship* began in the 1970s and 1980s, as communities that had previously been excluded from civic forms of participation started demanding recognition in response to social, political, and economic turmoil (Ellison, 1997, p. 698). "This resulted in expanded citizenship, civic identity, and public participation in civil society, and participants previously barred from making claims to democratic activity began to voice their needs as rights" (Meléndez, 2021, p.3). In the United States, this reflexive turn of citizenship has been taken up in the literature on cultural citizenship, becoming associated with "the process of claiming space and rights" (Flores, 2003, p. 89). This formulation has been especially meaningful in developing the identities of communities that have traditionally been excluded—either legally or socially—from state-sponsored forms of citizenship (Appadurai, 2001; Dabach, 2015; Ellison, 1997). Therefore, by centering underrepresented groups in public-sphere activities, such as the ones highlighted in this symposium's papers, the conversation around important issues expands, creating the potential for more informal and local modes of civic engagement to happen and take their rightful place in the civic engagement landscape.

Political and civic imaginaries to reconceptualize society and develop practices and identities of civic engagement

Imaginaries are ways to see the past, present, and future, connecting individual or collective historical experiences with new insights that transcend previously understood structural restrictions with expansive possibilities for new ways of action and being (Gutiérrez & Calabrese Barton, 2015). Through imaginaries, participants become "*historical actors* who can become designers of their own futures" (Gutiérrez & Jurow, 2016, p. 3). The participants in the various papers in this symposium move towards imagining or social dreaming (Freire, 1972) as a step towards *conscientizacion*, (1973). The process of "acquiring critical consciousness and becoming political subjects" (Flores, 2003, p. 93) mediates the "political imaginary," of under-represented communities and individuals in the public sphere (Meléndez, 2021). As Meléndez has argued, these are specific types of *citizen imaginaries*, where individuals move into a position of critically questioning what is possible in relation to structural and institutional limitations. This symposium highlights the role of heterogeneous, equitable, and caring imaginaries; for if democratic ideals are to be actualized or embodied, civic spaces—whether created for, by, or with—people from underrepresented communities, these spaces must be intentionally designed and actualized for said communities to sustain agency over their participation.

Consequential learning: Developing an identity in practice while serving on decision-making bodies across the state of Oregon

José W Meléndez

The use of public decision-making bodies to inform policymakers is common governance practice in the U.S. (Bryson et al., 2013). Whether required by law or as a strategy for both gathering information and securing public buy-in around decisions that impact communities directly (Ibid), these bodies should be representative of the demographic makeup of their communities. Yet, civic engagement by and of immigrants is a contested topic in the public sphere since it challenges normative definitions of citizenship. It raises the fundamental question on what voice immigrants should have in decisions that impact their communities, given that the diversification of who participates holds the potential to alter systems of governance that up to now have been designed to preserve the benefits of White supremacy to more privileged communities. Studying the public involvement of immigrants in decision-making bodies that advise and/or govern across levels of government is a gap in the literature on civic engagement and learning. This paper applies socio-cultural-historical theories of learning (Engeström, & Sannino, 2021; Vygotsky, 2012) to government practices that are idealized in democratic theory.

In this paper, I present findings related to a multi-phased, cross-sectional study entitled, "Oregon's Decision-Making Bodies: Diverse and Equitable Representation" (Meléndez, et. al., 2021). Using a discourse analysis approach, we analyzed 46 interviews of immigrant members on Oregon's decision-making bodies that were conducted between the fall of 2019 and March of 2020. Framing immigrants' board service as a third type of civic engagement, the study created an inventory of members across the 503 bodies at the city, county, and state levels in our study and determined how many self-identified as first-generation or second-generation immigrants. The interview analysis focused on how immigrant participants reflected on what they learned thought participation and what roles they began to take on or were inhibited from doing so while serving on these bodies. I highlight findings related to the development of an identity in practice (Lave, 2012), that supplement and sometimes contradict the findings related to learning of professional development skills and how government works. I argue that through our analysis, I found evidence of what Vygotsky referred to as the *microcosm of consciousness* (Collins, 2011), or an awareness of how one's behaviors are in relation to the environment one is acting in and how they are generatively interrelated. In so doing, I discovered that for participants developing an identity in practice, it was geared towards achieving or changing what they understood the policy purposes (the object of activity) for their respected body was. We discovered that for many participants the object of activity was grounded in concerns over representation and how they could be a representative of and for their community—both within the inner practice of their respective bodies and beyond—that centered on achieving tangible policy changes for their communities.

Analytically, I found that claims related to representation were connected to participants' reported learning and its impact on their participation. Three distinct types of learning were identified: professional development; government; and dispositions. For professional development, participants reported learning how to collaborate, manage processes and differences, and "see the big picture. Across types of bodies, those who discussed learning about local government indicated learning about how resources were distributed and that learning the lifespan of policy development from conception to implementation was instrumental to making sense of their role on the boards. When analyzing how board service changed participants' dispositions, three outcomes emerged: building self-esteem; increasing agency; and enhancing self-efficacy. One participant on the state's Commission on Hispanic Affairs reflected: "As I mentioned in the beginning…we need to be in those spaces. We can't shy away from that—it's happened too many times before. At a minimum … by doing that we enter the record. And we are stating the case."

I argue that in the current political climate, when immigrant enters the public sphere, it is a revolutionary act that confronts normative expectations of who is meant to engage and how. As such, for immigrants sitting on these bodies, their participation helped connect local/cultural civic acts to more explicit political ones along the continuum of civic engagement trajectories by providing the opportunity to develop an identity in practice. Learning how to identify as a commissioner, or a board member, requires citizen imaginaries (Meléndez, 2021), especially for immigrant members in such a racially homogenous state as Oregon, which is so by design given the state's White supremacy history (Tichenor, 2021). Subsequently, the ability to imagine and identify with one's public service role may be a key variable to explaining how sitting on decision-making bodies is in fact a prerequisite experience that many elected officials share (Meléndez et al., 2021). Yet, this "middle type" of civic engagement has received little scholarly attention, particularly in the literature on immigrants. As a form of consequential learning across scales of time and activity systems (Hall & Jurow, 2015), our interview participants wrestled with key concepts of governance, such as representation. What it means to enact representation, both as a practice while serving on decision-making bodies and for their respective communities is a complex question needing further research.

Yet, this study's findings on consequential learning for immigrants serving on these bodies are generative, since each of these decision-making bodies constitute but one activity system within a network of activity systems (Engeström, & Sannino, 2021) that form the backbone of governance in the U.S. Therefore, engagement in any one of these systems holds the potential for immigrant participants to learn about government and the topical content focus of each body (e.g., transportation, budget, education, etc.). Just as critical, they also learn what social identities are validated in practice (Lave, 2012), that can be expanded beyond White rational modes of participation (Meléndez & Hoff, 2022; Renirie & Meléndez, 2022). The findings reported in this paper support the link between participants' identity development and their ability to express those identities meaningfully in deliberative democratic spaces.

Neighborhood visions coalesce in a collaborative filmmaking project

Ari Hock

Civic learning is often conceived as the development of a particular kind of engaged citizen (Hope, 2022). This logic tends to reinforce normative developmental trajectories which locate the impetus of and responsibility for sociopolitical transformation within the individual. In contrast, Gert Biesta suggests a conception of public pedagogy, in which "becoming public *is* the creation of (a) public sphere," (Biesta, 2012, p. 693). This processual, collective understanding is particularly important when considering civic learning related to the interconnected socio-ecological challenges that many cities are facing: rising housing prices, physical and cultural displacement, and environmental racism.

To overcome these complex challenges, learning scientists are looking beyond civic learning as a discipline and seeking to understand the ways in which civic learning is supported, constrained, and accomplished in practice. To that end, some researchers have used ethnographic methods to theorize participatory budgeting meetings as sites for learning (Meléndez, 2021); and have engaged in design research to connect young residents' spatial epistemologies with grid epistemologies employed in planning meetings (Taylor, 2020). Both examples demonstrate how learning scientists can work with community members to design civic infrastructure which fosters better dialogue across stakeholder groups.

The present study, *Visions of Wallingford*, builds on these efforts through a critical place inquiry (Tuck & McKenzie, 2014) in a predominantly White Seattle neighborhood. Wallingford has been a lightning rod for recent debates, with competing interests around historic preservation, affordable housing, and "livability." Community members share a common concern about the rising costs of housing but competing discourses around neighborhood change have manifested (Eliason, 2021; McNichols, 2022). Meanwhile, the infrastructure to support civic engagement around these issues (e.g., civic groups, social media) have proven ineffectual, with many residents reporting feelings of distrust and exhaustion during interviews.

Visions of Wallingford is working to develop civic infrastructure that allows for a public sphere to emerge, by asking how neighbors can learn to create a collaborative place-story (Blood et al., 2012) through a collaborative filmmaking project (e.g., Baumann, Lhaki & Burke, 2020). The author began by conducting in-depth interviews in which participants mapped out personally significant locations. These maps informed themes for a series of guided walking tours (e.g., housing, plants, waterways, mosaic art), in which tour leaders, discussants, and other participants shared their own place-stories. Community members also helped to film the walking tours, content log the footage, and – with the help of a professional editor – assemble it into a documentary film. Throughout the entire process, families, retirees, people experiencing homelessness, construction workers, librarians, and myriad others were engaged as creative collaborators and encouraged to consider their own positionality with respect to the land they inhabit. The author is currently organizing public screenings, during which the film will serve as a catalyst for conversations about the future of the neighborhood.

Videos collected from the walking tours, the film assembly meetings, and the screenings are being treated as resources for data to be interactionally analyzed (Jordan & Henderson, 1995; Jones & Norris, 2005) as well as resources for the ongoing production of the film itself. In this way, the construction of educational theory is a parallel process to the construction of the film. For these dual goals, the project aims to stimulate citizen imaginaries by provoking self-reflection, challenging assumptions, creating beauty, entertaining, and giving pleasure for and with the publics that form throughout (Tobin & Hsueh, 2014).

Emerging findings suggest that participants are learning to see new possibilities with their neighborhood as they establish *polyoptic attunement*, or the multimodal, ecological coordination of attention (Marin & Bang, 2018) as visions are overlaid and hybridized. For example, during one of the film assembly meetings, a resident presented her summary of the plant-themed tour, based on her experience reviewing the footage. She was "kind of disturbed" that parents encouraged their kids to pick fruit from a cherry tree growing in a traffic circle, "but there wasn't any mention of, oh, somebody planted this tree." Another member at the meeting—who had been on that tour—responded, "I feel like I pay attention to that stuff. And I never even thought about that." This exchange led to a group visualization of possibilities for community care among humans and more-than-human life. In this instance, participants achieved polyoptic attunement as they engaged in public pedagogy.

Visions of Wallingford disrupts institutionalized civic engagement processes, which tend to perpetuate inequitable resource allocation in neighborhoods by amplifying voices of those with the material and identity resources which afford fuller participation (Fraser, 1990). Community members of different identities and ideologies engage in moments of dialogue, debate, and negotiation (Forester, 2012). In doing so, visions coalesce in both the film and throughout the filmmaking process, as the neighborhood expresses new possibilities for development. The project invites those interested in creating justice-oriented learning environments to similarly imagine how shared creative endeavors could stimulate new conversations and thinking about the challenges and opportunities that are closest to home.

Undoing acts of historical erasure: Breaking from dominant frames of White supremacy as civic engagement

Katie Headrick Taylor

Undoing acts of historical erasure is a form of civic engagement in which, especially White young people and adults, rarely participate. Instead, civics and social studies curricula (e.g., Sabzalian, Shear, & Snyder, 2021), as well as public spaces, too often *perpetuate* the historical erasure of Black, Indigenous, and People of Color in accounts of community and national development. How, then, might interactions and digitally mediated learning activities, that are intergenerational, interracial, and interinstitutional (e.g., public schools, public library, liberal arts college, and city government), restore/re-story the heterogeneity and pain of how places came to be? What new modes of community engagement are revealed and legitimated from such a learning context?

In a community-based project called Off the Map (OtM), mostly White high school students worked with Black and White retirees, librarians, and teachers to uncover and digitally preserve stories of school desegregation in an area of the Southeastern United States (Taylor, 2022). In the process, Black retirees described their memories of being made to attend all-White high schools and colleges; White retirees described their memories of being in schools with (very few) Black students. Present day high schoolers asked questions and documented these conversations for thematic leads into the public library's local archives. Synthesizing conversations and archival research, as well as observations from guided walking tours, young people created digital place-stories (Blood et al., 2012) for other residents of the area to experience via their mobile devices.

In this study, I begin with a grounded theoretical understanding that breaking from and reimagining dominant frames of White supremacy requires (predominantly White) people learning across lines of difference, be they racial, generational, gendered, and/or socioeconomic. Looking at video data and student-created artifacts, I used methods of video-based interaction analysis (e.g., Derry et al., 2010), as well as multimodal discourse analysis (e.g., Norris, 2004). These analytic methods further supported an interest in representational forms like mapping and app design: how do available tools and technologies also perpetuate the myth of a "single story" (Adichie, 2009)? The analysis followed the contestation, negotiation, and (re)construction of place-stories across the lifespan of the project (approximately six weeks).

Conversations with retirees represented for White students the first step toward undoing acts of historical erasure, especially in regards to students' preconceptions about the benevolence of school-based racial integration. In response to White students' provocations that "being able to attend [their] high school," must have been an "amazing opportunity" for Black students of the 1960s, Black retirees countered; they described being one of four or five Black teenagers in White high schools in the 1960s as "preparation for battle in Vietnam," "isolating," and learning that the "anticipation of violence can cause more stress than the actual violence does." White retirees described willfully ignoring the presence of Black peers in their high schools, downplaying any threat of violence remembered by Black elders. These exchanges unearthed so much pain, embarrassment, and outrage that one retiree said, "nobody wanted to talk about it."

Currently, some White students received alternate accounts of school desegregation as not just "acts of dissent" in the service of a community project, but—perhaps for the first time—a centering of being a Black person in a predominantly White community that has until recently only told (and taught) stories of White people in the curricula of civics and public space. Their digital place-stories represent a first attempt at circulating for public comment accounts of community development that acknowledge heterogeneity, violence, and pain. In this way, this project invites us to consider if civic engagement for White people might be about divesting from the myth of the “single story” and grasping stories about a nation “founded upon a triumvirate of horrors” (Castillo, 2022; p. 100).

Educating, coming out, and bringing hope: The online sociopolitical lives of undergraduate BIPOC youth

Molly Shea, Emma Elliott, & Christina Guevara

This study explores the intersection of learning, civic engagement, and wellbeing for eight undergraduate students during the 2021-2022 school year, which took place during an ongoing racial reckoning, a global pandemic, and online schooling. Thus, this study explored how students narrated their civic engagement and its relationship to their well-being during a heightened socio-political moment. Undergraduates in our study used social media to expand their understanding of themselves, create communities to support school-related struggles, and refigured their social media communities to better support their wellbeing. We found that young people were engaged in a political education online and in-person (through protests and community care actions) that shaped their understanding of the political moment and had implications for their sense of wellbeing.

This year-long, mixed methods study involved the development of a survey on students’ overall wellbeing and learning in an undergraduate lecture course (n=98). From the respondents we selected 8 participants and conducted 3 hour-long, semi-structured interviews with each participant throughout the year. We selected interview participants with a purposeful sampling strategy (Merriam, 2009). Preference was given to students from historically underrepresented communities and/or students who reported the largest changes in stress levels. Sample interview questions included, “How are you maintaining your health and well-being during this time?”, “How is your chosen community supporting you?”, and “How did your civic engagement detract from, support, or expand your sense of wellbeing?”. We then coded for themes and conducted a grounded analysis of how wellbeing, civic engagement, and learning informed one another.

We found that students engaged in online communities to teach, mentor and support others who may have been struggling with their sense of belonging in college settings. These activities were often done as part of a voluntary engagement with social media and took place outside of incentives from college coursework. For example, Sherria, a biracial Black student who grew up in predominantly White communities, was engaged in several in-person protests and helped create mutual aid pages for those in need. However, the activity she spent the most time supporting was using social media to educate people about racism. Here is one excerpt from our first of three interviews where she discussed taking action on a topic she cared about:

> I went to protests, but my biggest impact... was having... probably 100 conversations with people [online] over the past year about racism and how it impacts me and my family... educating people or trying to educate people sometimes just having like straight up arguments with people who I was close with but are no longer friends with... I'm having those hard conversations.

These “hard conversations” were taxing, and in her next interview, Sherria shared how she ended up “purge[ing]” many of the people from social media to preserve her wellbeing. The activity of educating others became a place of learning to take care of herself by shifting her social support systems. She found support from online communities of people who identified as People of Color, neurodivergent, and/or polyamorous. Sherria’s experience was unique, but mirrored how other students were learning about racism (to some degree) in classes but were also teaching and learning from others and reorganizing their online communities as issues of race became central conversations online.

A second example came from Dani, a college student who identified as a non-binary and biracial (Mexican and White). Just after the pandemic began, Dani became an online tutor at a local community college, Table Mountain, where they used to be a student. The tutoring group was struggling with engagement as courses moved online. The group was concerned that some students may not feeling welcomed. Dani decided to do something new for them and “come out” online. When Shea asked Dani how their civic activities changed during the pandemic, they cited their role as a tutor where they “came out” on the tutoring Discord page. Dani stated:

> Something I did as a tutor was I re-introduced myself in a very long post where I was basically coming out as all of my individual identities and trying to bring hope to anyone who might be like me or might see some of themselves in me… you know, I was once just like them, and now I’m here and I’m here to help as well” (interview, 12/9/21).

Dani shifted their sociopolitical engagement to “bring hope” and to reconceptualize a more caring pedagogy. Although Dani and their family were experiencing financial hardship and were immunocompromised, they were able to engage in sociopolitical activities through work. Dani had previously been “timid about community engagement” but through their work as a tutor and an employee at an interfaith synagogue, they realized that engaging with the community “felt good.” These experiences shifted Dani’s practices and solidified a sociopolitical engagement that spanned in-person and online activities.

The connections between sociopolitical discussions online and how undergraduate students develop civically engaged identities often remains invisible to researchers studying civic learning in school. The political importance of engaging with racism and gender politics online may have implications for constructions of civic life across contexts. These online spaces preserved social connections, deepened sociopolitical engagement, and often led to different forms of engagement that spanned online and in-person civic activities.

Developing a culture of place: Belonging, identity and socio-spatial learning

Kaleb Germinaro

Collaborative place-making fosters a sense of *identity-in-place* at the scale of the individual and the collective. Following Black Geographers like Katherine McKittrick (2020), this paper examines identity-in-place by asking “where we know *from*” and “how we come to know *where* we know from?” To consider these questions, this study follows a group of Black and Brown high-school-age girls developing identities-in-place during an out of school design-build program run by a local nonprofit organization called Sawhorse Revolution. Through a design process to build youth- and disability-friendly spaces, young participants learned architecture principles (e.g., accessible design and storying a space) and carpentry techniques. The design process also focused on developing young people’s sense of belonging and identification with specific Seattle-area locations and structures through field trips, arts-based design activities, and workshops about disability spatial justice.

As young people made sense of their belonging, they incorporated their individual and collective place-based identities related to becoming/being a spatial producer in the design process for a client group—Deaf Spotlight. This client represents the Deaf community while making space and advocating for those in the disability community. They center Deaf artists, filmmakers and performers through annual events and a film festival. The first 4 weeks included individual and collective identity-focused design sessions. Deaf Spotlight was picked by the youth within the middle of the 10-week program. The client picked activities for week 5, and subsequent weeks were focused on designing the space for the client by applying identity-focused design sessions. After distributing an RFP, Deaf Spotlight was selected as a means of disrupting spatial inequities, since the youth realized that both the organization and the Deaf community at large lacked a physical space in the city. Therefore, this study’s central question was: How do disciplinary-based spatial practices (e.g., designing and building) support the development of intersectional individual and collective identities?

Data consisted of participant observations, interviews, and video data of design sessions; thematic coding revealed three components of youth learning to build their own belonging that they took up in their own design process. These three components were: Memory, and resisting forgetting, to express un/belonging; relationality as a process for making space for their individual and collective space-making processes; and learning to story a space through design as detailed through pedagogical techniques. Using a grounded theory approach and thematic analysis (Glaser and Strauss, 1967; Harry et al., 2005), I identified identity narratives in the learning environment and analyzed how youth within the study learned their own belonging as they cultivated and understood their identities in relation across spaces (Gholson and Wilkes, 2017; Nasir, 2011). The youth within the study use their identity development as a cyclical everyday activity to design alternative futures individually and collectively (Gutiérrez et al., 2019) as they learn about the components of their belonging. In so doing, my analysis identified that as youth understood their identity-in-place across the individual and collective scales, they learned how and where they know from. They then extended this identity-in-place concept to the client through their design of a physical space. Further, their identities and cultivation of identities were actualized through a civic engagement process that connected to local movements of spatial justice and design activism for larger social movements that aimed to disrupt hegemonic power structures through space, a form of design activism.

Design activism is the process of positioning designers and their practices as central to activist work to address social injustices. The design activist approach also centers and emphasizes the needs of those receiving said design, rather than centering an aesthetic. In this study, young people went from engaging in activities that illuminated their individual design principles and desires, to negotiating a collective design as spatial re/producers and designers of a physical space for a group of people. Their efforts showcase that design activism is a mechanism that responds to the needs of those within a city, resisting luxury and exclusive design innovations that further render those within the margins as placeless (Summers et al., 2022). The development of their collective design was possible through the design principle of belonging. Belonging as a design principle allows for more equitable and just spaces that resist belonging to spaces not built for those who are othered and rendered placeless. Identity un/belonging is a political, challenged, and inextricably linked process to understand ways of knowing and being in the world. Supporting students in perspective taking and reasoning through a sense of identity-in-place requires multiple and diverse stories to be told, centered, and promoted in learning. Through design activism, young people wrestled with issues of power, historicity, and ethical responsibility to disrupt spatial hegemony.

We need more understandings of design activism and its relation to learning for how we engage and think about space. Design then serves as an activist tool that mediates learning on civic and spatial imaginaries of/for belonging. In this study, youth build their imagined futures of where/how they want to belong in real time. Throughout the program, youth moved their imaginary belonging through designing and building their imagined physical futures, informed by their sense of *identity-in-place*. Through this learning process, youth produced infrastructure that activated previously uninhabited space, activating public space in a way that works to repair unbelonging through design. This form of learning is consequential, employing learning as action to engage civic imaginaries and shift material conditions. As such, this paper's findings position youth as legitimate space- and decision-makers as they extend their belonging far past themselves. There is a need for more identity-centered inquiry as a means of deepening place relations and promoting identities connected across time and space.

Significance of contribution

This symposium's set of papers pushes on the notion of civic engagement to consider the multiple publics that communities engage in, how they do so, where they take place, and how this can shape our designs of learning environments that move beyond normative constructions of civic participation to a more generative one that supports the imagining of a more socially just future. Moreover, through the dialogue between papers, we hope the reader can wonder how those who are not invited into some normative notion of "civics" can speak and act powerfully to reimagine community values and practices. How are immigrants, Black and Brown youth, queer folx, and people experiencing houselessness claiming space, creating civic imaginaries, and fighting for dignity and belonging across contexts? And how does the field develop learning environments where White people learn to divest from the myth of the "single story" of civic identity to reimagine rightful presence (Calabrese Barton & Tan, 2020) in communities? Collectively, the studies in this symposium either design or interrogate learning environments where citizen imaginaries form, where individuals are driven to imagine answers that remove structural limitations and enable them to act as fully human and in solidarity with others. In the learning environments highlighted in these papers, a sense of belonging and agency are a central component of citizens' imagining or dreaming within their civic engagement trajectories. Together these papers offer new insight into civic engagement that suggests democratic ideals are not set in stone but instead should be in constant expansive development geared at more socially just communities and societies.

Abstract: While research has shown the value of learning through play and creative production, less is known about the use of playful and creative assessment for ongoing learning. We therefore use this symposium to address the following questions: how can educators use creative and playful assessment techniques and tools to engage students in processes of learning? And what types of learning do students encounter in these experiences? Additionally, how can researchers engage educators in creating playful assessments that address the needs of their students' learning context? In response, we present findings from four separate research projects that engage these intertwined forms of assessment in different contexts. In doing so, we produce a holistic understanding of designing and using creative and playful assessment for learning, one that positions this approach to learning design as a valuable and far reaching tool within learning processes.

Symposium focus: Constructing playful and creative assessments

Although common conceptions of educational assessment frame this process as a means for evaluating student achievement, Pellegrino et al. (2001) and multiple other scholars also argue that educators can and should use assessment as a tool for continued learning. While this assertion produces a binary distinction within the literature, with certain forms of assessment being labeled as formative (focused on learning) or summative (focused on evaluation), researchers also assert that the barrier between the two remains blurry and more accurately rests on the intentions of educators, evaluators, and students (Black et al., 2004; Knight, 2002; Shepard, 2000). Moreover, Kumpulainen & Wray (2001) argue that summative assessments of students' final tasks or products do not provide a full picture of learning. Researchers and educators should therefore look towards the processes of learning, such as play and creative exploration, as potential tools in a holistic approach to assessment (Kumpulainen & Wray, 2001). In doing so, the field can continue to explore how various assessment tools contribute to the ongoing learning of students and how educators can employ those tools for that outcome.

With this broad framing in mind, we use this symposium to address the following questions: how can educators use creative and playful assessment techniques and tools to engage students in the processes of learning? What challenges do they face in implementation and design? And what types of learning do students encounter in these experiences? Drawing on multiple bodies of literature (including game-based and arts-based learning), we focus on assessment through creative production and play for multiple reasons. First, both forms of (overlapping) assessment contain embedded and authentic assessment processes, allowing students to learn as they continue to engage in playful and creative practices (Halverson, 2021; Howard et al., 2022; Kim & Ifenthaler, 2019; Norris, 2008; Shute & Ke, 2012). Second, playful and creative assessment allows students to both develop and demonstrate learning beyond the intended curriculum, including the construction of agency, creativity, autonomy, collaboration, and other crucial skills within the contemporary moment (Díaz-Lefebvre, 2006; Halverson & Sawyer, 2022; Kim & Rosenheck, 2020; Pavlou, 2020). Finally, while numerous scholars have advocated for playful and creative approaches to learning for years (Gee, 2007; Papert, 1980), others have argued that further research into game-based and arts-based assessments in particular needs to occur (Halverson, 2022; Halverson & Sawyer, 2022; Kim & Ifenthaler, 2019; Sawyer, 2015). Scholars have only begun to scratch the surface of what creative and playful assessment can offer students. Further investigations into (a) the various forms of creative and playful assessment employed by educators and (b) what and how students learn within those experiences will contribute to our growing understanding of how these intertwined approaches to assessment can help students.

Taking this call for further research to heart, our symposium addresses this need by providing robust examples of playful and creative assessment for learning in a variety of US based contexts. While we draw on research from international scholars throughout, we situate this work within the US because of the growing divide between assessment and forms of play or creative exploration within formal learning settings (Zosh et al., 2017). Our work therefore explicitly challenges this distinction and provides opportunities to think with these two interrelated components of education in tandem. Across the four papers in this symposium, the panelists highlight the essential purpose of assessment–making students' thinking and learning visible–and the necessary conditions, including a mindset shift in the educational macrosystem, that will enable the success of assessments that go beyond ranking students' performances. Taking an ethnographic approach, Saplan opens by discussing the assessment approaches in out-of-school time arts education and the pain-points brought about by the traditional assessment mindset, even in this setting. Stoiber and Kim further illustrate the barriers to embedded, playful assessments by providing two concrete examples of assessment tools–one adopted and the other neglected, potentially due to their differential alignment with traditional assessment beliefs–in an inclusive artificial intelligence (AI) literacy curriculum. Lin, Anderson, and Woods follow-up with a potential approach–co-designing with teachers and educators through multiple design iterations, even in the early stages of this process–in an effort to strike a balance between playful assessments and practical constraints in high school geometry classrooms. Finally, Tofel-Grehl, Feldon, Searle, and Suarez demonstrate the powerful impact of creative assessments in a makerspace, where elusive constructs such as identity development can be made visible through authentic activities with maker materials. From theoretical insights to findings from different moments of the design and implementation process, this rich set of examples builds towards a holistic understanding of playful and creative assessment.

In presenting this symposium, we begin with a brief overview statement from the symposium co-chairs and individual statements from representative authors. From there, we move into a more informal style of presentation where audience members can try some of the assessment tools described in the papers and discuss empirical findings from the research conducted by participants. The symposium will then conclude with a discussion that will include comments from our discussant, pre-planned questions for the presenters, and an open question and answer session where audience members and authors can further explore playful and creative assessment together.

Promises and pain-points for creative and playful assessment in out-of-school arts learning environments

Kailea Saplan

Purpose and theoretical framework

Students across the United States are becoming increasingly diverse and entering the education system with rich cultural backgrounds and funds of knowledge that lay the foundation for how they learn (González et al., 2005; Llopart & Esteban-Guitart, 2018). Unfortunately, our current assessments do little to integrate or honor each student's unique ways of knowing and sense making. Exploring the nascent world of creative and playful assessment offers solutions for how to assess students in such a way that empowers them to equitably demonstrate what they know (Díaz-Lefebvre, 2006; Kim & Miklasz, 2021). Since American schools rarely afford opportunities for creative and playful learning, let alone creative and playful assessment, I sought to investigate the assessment practices of various non-school environments. In a secondary analysis of a qualitative research study, I explored creative and playful assessment in highly creative and playful learning environments, namely out-of-school time (OST) youth arts programs. The main research question guiding this analysis was: How do OST youth arts organizations integrate creative and playful assessment, if at all?

Methods, data sources, and analysis

Data sources for this study include: nine semi-structured interviews with educators and organization leaders of OST programs across the United States, and 12 focus group conversations featuring a combination of at least 3 types of stakeholders (e.g., arts educators, organization leaders, policy makers, researchers, or youth artists). This study was nested within a larger project about OST arts education and marginalized youth (Halverson et al., 2023), and is the result of multiple rounds of qualitative analysis including: (A) a round of emic, open-coding strategies (descriptive, concept, and in vivo coding) and memo writing to make sense of how the organizations generally operate and what promising practices and challenges they share; and (B) a round of more detailed analysis focused on how these organizations implement and describe assessment, using analysis matrices, memo writing, and concept and pattern coding (Merriam & Tisdell, 2016; Saldaña, 2016).

Specific to this study, I conducted a secondary analysis of stakeholders' discussions about assessment using both emic and etic coding strategies. Etic codes were drawn from literature on creative and playful assessment, and included concepts like the authenticity of the situations in which youth are assessed, the degree to which assessment proved flexible to youth's learning processes as they unfold, and the degree to which assessment allows a learner to demonstrate their competency in multiple ways depending on their own goals (Díaz-Lefebvre, 2004; Kim & Miklasz, 2021).

Findings

In this symposium, I highlight approaches to creative assessment that stakeholders identified, including approaches that are common in formal arts education assessment literature, like final showcases or performances and informal, formative critique (Deutsch, 2016). I also introduce approaches to assessment worth further exploration in OST arts learning, like stealth observations of youth building their public presence as an artist, and the use of stories as evidence of success. Additionally, I share two other notable findings that emerged in analysis. First, despite the creative environment of OST arts organizations, educators identified many obstacles to engaging in assessment that they found meaningful and authentic to arts practice. Second, although arts educators and organization leaders implement assessments that share many features of playful or ludic assessment (Kim and Miklasz, 2021), the assessments are rarely playful in terms of being fun for learners. These findings represent opportunities for assessment in OST arts organizations moving forward.

Discussion

Overall, my analysis revealed that while some OST arts organizations relied on creative praxes to assess youth in OST arts programs, stakeholders also revealed barriers to integrating less traditional assessments. Kim and Miklasz (2021) wrote that classroom educators sometimes experience pain-points when they attempt to integrate playful pedagogy that is incompatible with familiar assessment methods. This study suggests that pain-points also exist for OST arts leaders and educators, who feel constrained by certain notions about how assessment is "supposed" to function (e.g., assessment should function in a one-size-fits-all capacity; the core purpose of assessment is to compare youth). While creative and playful assessment in informal learning environments may hold promising solutions for equitable assessment, the pain-points that emerge in implementing those assessments must be understood and mitigated.

Examining barriers teachers face when adopting playful assessments for a middle school AI curriculum

Andy Stoiber & YJ Kim

Purpose

Playful assessments are a dramatic counterpoint for most classroom educators trained and experienced in teaching during a regime of standardized testing. Playful assessment centers and empowers learners to display what they know via modalities which are designed to leverage students' own interests and allow multiple paths to demonstrate progress.

This work examines playful assessments embedded in a middle school Artificial Intelligence (AI) curriculum, including: Computational Thinking, Design Thinking, Ethical Thinking, and AI domain knowledge. This paper focuses on challenges encountered during the implementation of our new assessment tools, and discusses barriers teachers face to embrace playful assessments.

Theoretical framework

In the wake of No Child Left Behind, educational psychologists found an improvement in learning when, instead of studying, students take tests and practice retrieval (Roediger & Karpicke, 2006; Karpicke & Roediger, 2008). This suggests that more opportunities for learners to reflect on their experiences and synthesize their thinking throughout a curricular unit significantly impacts student learning (Penuel & Watkins, 2019). Playful assessments diverge from this approach on principle, as Kim & Miklasz (2021) outline four dimensions of freedom playful assessments ought to embody: Freedom to (1) Experiment, (2) Fail, (3) Try on Identities, and (4) Freedom of Effort.

Methods, data sources, and analysis

Following these principles, we designed two playful assessment tools: 1) Game Cards + Profiles, inspired by Pokemon trading cards and Dungeons & Dragons character sheets, and 2) Kanban (a project management process popular across industries). These tools were introduced to teachers at five of our implementation schools to be used with the four-week-long AI curriculum. We present findings from this, our first design-implementation-iteration cycle of a design-based research study. We include four data sources: co-design sessions with two teachers, teachers' reflection videos, student responses to assessments, and classroom observations; data and transcriptions were analyzed using Grounded Theory (Strauss & Corbin, 1994).

Findings

The Kanban boards were adopted in some form by most teachers, while Game Cards + Profile were all but neglected. We speculate this cleavage flows from teachers' routines and value systems. Whereas the Kanban boards were modified into a set of worksheets due to teacher preference and classroom constraints, Game Cards + Profiles' concept and mechanics were perhaps too divergent from what teachers expect and are comfortable with when conducting assessment. This bias, perhaps rooted in the conditions of standardized testing, may impact their evaluation of how helpful playful tools can be; whereas tools described/designed in terms a teacher can relate to may make them more likely to adopt playful assessments. We will further describe our tools and the affordances and constraints of playful assessment and the significance of how teachers perceive them in the context of a project-based AI curriculum.

Discussion

Our work provides useful design insights for how to help teachers adopt playful assessment for middle school students. Despite teachers' recognition of its affordances, playful assessment requires teachers to actively challenge existing and familiar assumptions for conventional assessment approaches. This paper highlights these challenges and offers perspective for how we can support teachers with this innovative approach.

Situated experiences to assess new thinking: A puzzling approach to playful assessment

Grace C. Lin, Emma Anderson, & Peter J. Woods

Purpose and theoretical framework

While extant research advocates for gamification as an effective approach for developing assessments and learning contexts beyond traditional tests (López-Belmonte et al., 2020; Piñero Charlo et al., 2021; Sailer & Homner, 2020; Sakai & Shiota, 2016; Sun-Lin & Chiou, 2019), others have amplified the challenges of gamifying education without sacrificing the game's authenticity (Laato et al., 2020). A related tension exists within the complexities of assessment within project-based learning (PBL) (Wilson, 2021), as educators navigate the tensions between authentic projects and targeted assessment tasks (Fields et al., 2021; Grover et al., 2018; Lui et al., 2020). In this presentation, we argue that the integration of gamified assessments within PBL can attend to the issues of both, imbuing assessment games with a sense of authenticity while providing new tools for targeted yet contextual assessment within PBL curricula. To further explore this connection, we draw on Kim and Miklasz's (2021) framework for ludic assessment that sits at the intersection of learning sciences, assessment science, and game design. The playfulness of such assessments would engage students while supporting their learning and growth. They call attention to the pain points of educators and urge a broader, flexible view of assessments. In this presentation, we dive deeper into educator pain points, attempting to bridge the gap of traditional assessment and a truly ludic assessment.

Methods, data sources, and analysis

To more fully investigate the design of puzzle based assessments within PBL curricula, we draw on design-based research (DBR) as an overarching methodology (Anderson & Shattuck, 2012; Barab & Squire, 2004) with an emphasis on co-design (Roschelle et al., 2006) and rapid prototyping (Desrosier, 2011; Tripp & Bichelmeyer, 1990). This ongoing research initiative began when we formed a design collaborative by recruiting high school math teachers as design partners to help develop PBL Geometry curricula through monthly co-design sessions. We also worked with the collaborative to create the Situated Experiences to Assess New Thinking (SExTANT) materials, a series of puzzles designed for targeted assessment within our curricula that draw on the benefits of both PBL and gamification. For this presentation, we focus on the design of a tangram-based puzzle assessment of knowledge related to rigid transformations. The puzzle involves students using translations, rotations, and reflections to transform a letter or number made of tangram shapes into another letter as a means to decipher a secret message.

Data sources include collaborative meeting video recordings, teacher comments on design artifacts, teacher interviews, and researcher meeting notes and memos. As the primary objective of this phase of the project is to create the assessment (as opposed to theory building), we rely on a rapid qualitative analysis approach via the lightning report method (Brown-Johnson et al., 2020) wherein we organized notes (often in real-time) taken during meeting or interviews, synthesized feedback, decided on new modifications, and proceeded to enact design changes. In turn, our findings stem from our process-based methodology and provide insight both into our co-design process and the creation of puzzle based assessments.

Findings

Throughout our iterative process, the researchers, designers, and teacher co-designers (both the consultants and the implementation partners) collectively attempted to balance practical constraints and needs of the classroom while maintaining the playful, fun, and engaging aspects of the puzzle designs. In doing so, we uncovered the following tensions within the design process. First, designers and educators routinely iterated between playful designs and assessment efficacy. As seen in Puzzle Iterations 2 and 3 listed in Table 1, which outlines our meeting notes and design choices, collaborative members regularly debated how to balance the ability to recognize "individual understanding and contribution" with "the 'fun' and the magical" elements of puzzle design. Second, our team regularly navigated the tensions related to format, aesthetics, and materials. This tension clearly exists in Puzzle Iteration 4 and 5 (see Table 1), with the desire to move to a digital platform creating the need for a physical backup while simultaneously producing translation challenges within the design of the puzzle itself.

Table 1

Major Iterations in the Transformation of the Puzzle Assessment Design

Puzzle Iteration	Design Collaborative Feedback	Design Team Response
0	Expressed assessment needs and interest in puzzle as assessment	Conceptualized assessment ideas for Transformation module
1 – Tangram cipher puzzle where students first solve transformation steps to obtain cipher, use cipher to decode secret message, and then create their own cipher and message. The starting puzzle may be a letter (e.g., E) or a number (e.g., 4) formed by the seven tangram pieces. The steps of transformation will move the shapes to form another symbol.	Positive response toward puzzle; Timing may be an issue; Group work (small group or class level would work better, depending on class proficiency) Create your own would be ideal, but may work better as enrichment	Reconfigured puzzle so that student groups will be able to solve the puzzle within 1 class period. Created explicit group work instruction Removed the "create your own" activity as part of the assessment.
2 – Shortened tangram *group* puzzle embedded in a narrative where the transformed symbols would spell the solution to the narrative.	Concerns surfaced regarding how to tell individual understanding and contribution when the puzzle is meant to be solved as a group. The sentiment was that students may be able to spell the word without having solved all of the tangram pieces.	Reconfigured puzzles to make various pieces more individualized, resulting in the "blasted to pieces" version where each student only sees one piece of tangram shape at a time.
3 – Blasted to pieces version: each panel includes only one piece of the tangram shape. Students will have to transform each piece individually and then work together to materialize the transformed symbol.	The pendulum swung too far the other way. When you see only one piece with the instructions at a time, you lose sight of the "fun" and the magical. The resulting "puzzle"looks and feels similar to a traditional assessment.	Revert back to the shortened group puzzle. Re-emphasize the narrative as well as the group work instruction. Polish the tangram pieces to align with the narrative (i.e., tavern theme).
4 – Tangram *anagram* version. Students would each solve 1-2 symbols depending on class level.	Desire to move to a digital space	Explored and started building a puzzle version on Mathigon.

(More advanced class, groups of 3 where each student solves 2 puzzles.) The solved tangrams would each show a letter. The students would have to unscramble the anagram to get the solution to the narrative.		Physical print version relegated as "back-up." Updated facilitation notes for teachers.
5 – Digital Mathigon prototype	Difficulty level of puzzles and the resulting shape locations need to be adjusted.	Rewrote the mathematical instructions to address difficulty level and differing scales between initial prototype and Mathigon's tangram shape defaults.

Discussion

Though our study is still underway, we zoom in here on our co-design and rapid prototyping (Jones & Richey, 2000) process, one that helped teachers and researchers navigate the tensions between design puzzle assessments to formatively gauge student understanding of content materials and keeping students engaged in a PBL module. Our emergent findings thus provide a glimpse into the inner workings of a diverse team and shed light on the design tensions, challenges, and adaptations that emerged as we attempt to balance playful assessment with the needs of our teacher partners. In doing so, we offer an approach to co-design that can embody the gradual change needed to shift stakeholder mindset from the traditional to the ideal, flexible view of ludic assessments called for by Kim and Miklasz (2021).

The authentic maker assessment: Staying true to the spirit of making with a constructionist measure

Colby Tofel-Grehl, David Feldon, Kristin Searle, & Mario Suarez

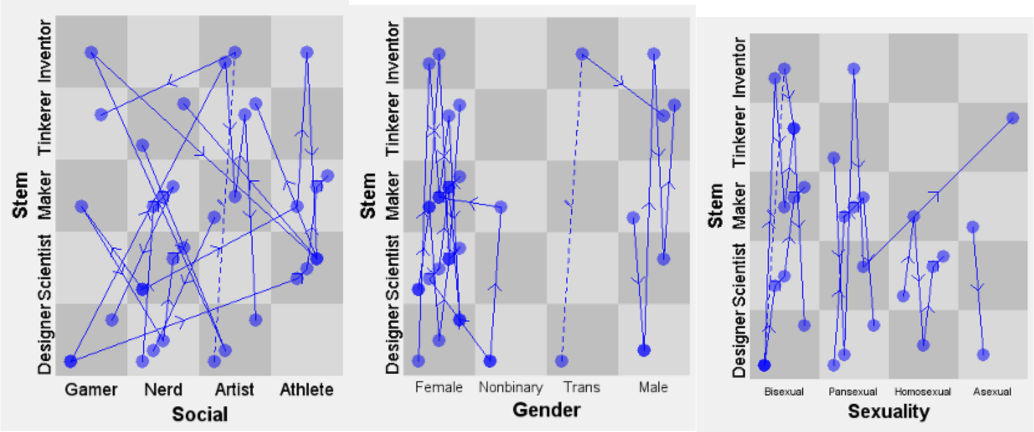
Purpose and theoretical framework

Making is a powerful tool for engaging historically marginalized peoples in STEM learning by creating an inclusive space for identities to be visible and actively incorporated into projects (Shaw et al, 2019; Peppler et al, 2016). Use of unconventional STEM materials (e.g., electronic textiles, recycled materials) and individuated designs also creates opportunities for diverse funds of knowledge to become a part of how STEM is perceived and enacted, linking developing knowledge to the values and needs of communities (Tofel-Grehl, 2022; Tofel-Grehl et al., 2017). However, measurement of the shifts that occur in the relationships between personal, cultural, and STEM identities have historically used methodologies at odds with the ethos of the maker movement, frequently relying on static categories of identity framed by the authors of validated surveys. Existing quantitative instruments are limited because 1) their unidimensional and non-intersectional conceptions of identity (e.g., targeting exclusively gender or race, but not both), 2) their stylistic incompatibility with Maker environments (i.e., hands-on, loosely structured Maker projects followed by a multi-page Likert instrument), and 3) their inability to incorporate locally meaningful identity constructs salient to specific cohorts of participants.

Methods, data sources, and analysis

Authentic Maker Assessment deliberately utilizes materials consistent with Maker activities to capture and quantify shifts in intersectional identities that occur through maker activities. Using a phenomenographic approach (Åkerlind, 2005; Marton & Pong, 2005) to collect qualitative data from groups of students and develop locally meaningful and emergent categories of identity, these locally constructed categories are then represented by pony beads of different colors. Each day, participating youth add beads they select from categories that best reflect how they are experiencing their identity at that time with remarkable variance from day to day (see Figure 1; Feldon et al., 2020). As participants construct these bracelets, they inherently provide longitudinal, multidimensional records of shifting identity facets meaningful to them. The cumulative results yield co-evolving and interacting categories of identity that are quantifiable through mixed-methods phenomenography (Feldon & Tofel-Grehl, 2018).

Figure 1
Pairwise mapping STEM identity to social identity, gender, and sexuality



Findings and discussion

In this paper, we share analytic strategies, evidence of measurement validity, and participants' views of communicating their identities using this approach based on multiple samples of youth participants across diverse geographies, affinity groups, and ages. Participants in summer schools and camps brainstormed different aspects of their identities that they wanted to think about and share. Facilitated discussion yielded aggregation of articulated identities into larger categories (e.g., gender identity, sexuality, social identity) with specific subcategories for each. The beads selected from each of the four broad categories and strung onto participants' identity bracelets acted as a running log of shifting identities and identity emphases throughout the camp, as well as a physical artifact for the student to display their identity within the group (see Figure 2). Daily photographs were taken of each participant's bracelet to allow for tracking of the dynamic identity shifts students experienced while attending the Maker camp. Metrics based on dispersion and duration of category selections over time yielded higher level integrated constructs suitable for statistical analysis of change and stability over time.

Abstract: This structured poster session brings together seven presentations from middle and low-income countries around the world. While research in the field of learning sciences provides some guidance as to how to design learning environments for transformative action, most of this research is conducted in economically wealthy parts of the world (United States, Europe, Australia). This session focuses on different approaches to critical pedagogy that lead to transformative action in unique cultural contexts across low and middle-income countries in the world. It also highlights the need for equitable partnership building between researchers, practitioners and community members that are engaged in transformative action.

Introduction

This structured poster session brings together seven research projects that have investigated the role of critical pedagogy in supporting transformative action within local communities in low and middle-income nations around the world. *The focus of this symposium* is the importance of transformative action as a framework to design learning environments for youth, so as to help them apply their knowledge to urgent problems faced by society (Curnow & Jurow, 2021; Gutiérrez & Jurow 2016; Kirshner, 2015). We present a set of papers committed to transformative action, in the tradition of Freirean pedagogy. Learning environments designed within the framework of transformative action challenge educators and students to critically think about issues such as: how can all voices and contributions in the learning environment be heard and honored; how can issues discussed in the learning environment center around social justice; how can knowledge generated in the learning environment be used by local communities so that the knowledge generation process has relevance to everyday life issues faced by the learners and their communities (Bangs & Davis, 2015; Jemal & Bussey, 2018). This work also builds on Freire's (1970) assertion that the educational process must interweave theory, reflection, and action as a means to advance the broader society towards social change and justice. This approach to the design of learning environments is particularly relevant in a moment in which the world is experiencing a series of concurrent crises—environmental, geopolitical, civilizational, economic, health—each with direct and profound effect on students. To respond to these challenges, school curriculum should not only give voice to students, but empower them as transformative agents in the face of political, racial, economic or cultural oppressions. Such curriculum can take the form of participatory action, service learning, arts-based learning, critical making, or others. The role of educators is a challenging one, as they must be agents who can help students parse through different sources of knowledge. The transformative action approach responds to research that suggests that emotional responses to situations perceived as oppressive and overpowering (e.g., systemic racism and other forms of discrimination, war, poverty, etc) might be alleviated by engaging students in some form of committed action (Charlés, 2010; Ridley et al., 2020).

While research in the field of learning sciences provides some guidance as to how to design learning environments for transformative action, most of this research is conducted in economically wealthy parts of the world (United States, Europe, Australia). There is a need and a responsibility for learning scientists to address learning in all of its forms and contexts, which can inform our deeper understanding of how learning occurs in diverse contexts and situations. We can also advance on the work of Freire and others in critical pedagogy, by examining these ideas in a set of studies. Putting such pedagogy into practice has been recognized as a great challenge, in part because of the need to engage student voice meaningfully and establish a democratic learning environment (Braa & Callero, 2006; Wink, 2005). These forms of engagement have proven to be a challenge even in high-income nations (Basu & Calabrese-Barton, 2010), with some hard-won advances made by educational researchers. But to succeed, teachers require substantial professional development, in order to engage students in autonomous, personally relevant forms of learning while still connecting with disciplinary content and practices, as well as critical thinking, inquiry, and creative expression. Lower and middle-income settings introduce an additional set of challenges, varying greatly in terms of their educational systems, local cultures, languages, and the specific issues that may be oppressive to students and local communities. The learning sciences bring a wealth of understanding about how to engage such diversity and sustain deeply situated learning, and the researchers in this symposium will present an array of studies that deliver on that promise. As a part of this structured poster session we provide examples of how critical action approaches were facilitated by teachers in Bengaluru, India; how educators at a tinkering lab in rural India connected materials and learning experiences in the tinkering lab to community problems; how science teachers in Guyana brought their socio-political identities to their classroom settings; how podcasting was used by youth in the Coeur D Alene nation to understand community based environmental problem solving; how education approaches in India need to include voices of marginalized (Dalit) students and their communities; how a youth led organization (Equal Education) creates powerful learning experiences for youth in South Africa; how education approaches in Brazil create a culturally relevant learning experience for learner.

Structure of the session

This session will be a structured poster event, with short (2-minute) presentations given by each project at the outset, followed by three 15-minute visiting rounds, where audience members choose one poster where they will join a discussion, and everyone switches to a new poster with each round. Each poster will include information about the partnership, relevant research, and findings about transformative action. At the end, the audience will return to a plenary mode for a 20-minute discussion led by Professor Chris Hoadley, from University at Buffalo. The audience will be engaged with a set of questions derived from our innovation sessions, described below.

This will be an innovative session, responding to the criteria listed in the Call for Papers. To *allow a wider level of hybrid activity* in support of all time zones, and *to allow for protracted discussion before and after the session,* we will engage all those registered for the conference (i.e., including those who signed up for online access) in a knowledge building activity before the session.

CALE: Empowering teachers in southern India in a professional learning community

Renato Carvalho, Preeti Raman, Jim Slotta, & Khyathi Vinay

This study was conducted in the context of a project called the Critical Action Learning Exchange (CALE). CALE is an international professional learning community (PLC) for educators dedicated to designing, enacting and sharing critical action curriculum that empowers students in responding to pressing, complex socio-environmental issues such as climate change, social justice, pandemics, and more. CALE draws upon the theoretical perspective of Critical Pedagogy, which is based on a philosophy of praxis that stresses the importance of an educative process that interweaves theory, action, and reflection as a means to advance the broader society toward social change and justice (Freire, 1970; Kincheloe, 2004; McLaren, 2000). This perspective is grounded on the concept of *conscientização*, which is described as “The process whereby people achieve an illuminating awareness of the socioeconomic and cultural circumstances that shape their lives and their capacity to transform that reality” (Freire, 1975). *Conscientização*, therefore, aims beyond “critical thinking” to include a sense of critical consciousness that enables students to make judgements on their current and ideal realities, and empowers them as agents for positive change. CALE applies Critical Pedagogy within a modern context of empowering teachers to help students overcome the sense of powerlessness regarding overwhelming socio-environmental issues, and feel empowered as agents capable of responding to those problems. Within CALE, teachers participate in professional development activities to develop understandings of Critical Pedagogy and collaboratively develop new critical action curricula. Over the past three years, we have designed the CALE activities, resources, and technology environments to support our programs, tested our design ideas through cycles of implementation with teachers, and continuously improved our various frameworks and design guides to help CALE become a sustainable community of practitioners (Authors, 2021).

In Summer 2022, we organized a workshop in Bangalore, India, with the participation of 15 educators. Participants explored four “critical action approaches” using carefully curated materials and exemplars. Teachers’ curriculum designs were guided by the CALE design framework for critical action curricula. This framework includes six components, divided into two axes. The "vertical" axis includes components intended to help students move deeper toward action—from knowledge, to criticality, to action. The “horizontal” axis increasingly expands the scope of the students' critical action—from the individual to the community and finally to the globe. Participants worked in small design groups and engaged in two cycles of peer review. This paper presents the specific features of our workshop, including materials and activities, as well as the pedagogical elements of provocation/activation and engagement through design. We investigate the efficacy of our model in supporting teachers' development of understandings of critical action pedagogy, as captured through teacher discourse, document and interaction analysis. We surveyed participants regarding their beliefs about professional development and their own practices, as well as their understandings of active learning and 21st-century competencies. Our data include teachers’ survey responses and products of their design work.

We start from the hypothesis that some factors make it difficult for teachers to implement this change, such as the curricular expectations, which demand that teachers cover a broad range of topics and discourage the time-consuming deep exploration of topics needed for critical inquiry. The CALE workshop model provides a series of pedagogical and technological supports to help teachers overcome those barriers. These include the exploration of pedagogical approaches, the CALE curriculum design framework, and a curriculum design template. While “lack of time” and “fear of change” continue to be barriers to the implementation of CALE curricula in classrooms in India, teachers in our study were hopeful and motivated to integrate critical action into their curriculum. We look forward to sharing teachers’ experiences and outcomes of enacting their curriculum designs in their classrooms.

Community based problem solving through technology design and collaboration in rural western India

Akshay Kedari & Devayani Tirthali

Rural students across the world find it challenging to develop interests and motivation in science and technology related topics (Harris & Hodges, 2018). Research focusing on students in rural schools showed that students, irrespective of their actual ability, tended to have weaker beliefs in their own academic ability and did not pursue additional educational opportunities compared to their suburban and urban peers (Young, 2000, Gilbert & Yerrick, 2001). In rural western India school is often perceived as an agent that introduces the youth to outside knowledge that is very different from the existing culture and tradition in the region (Jackson, 2003; Shiva, 2000; Goonatilake, 2001). As Pande (2001, pp 48) points out, “In their haste to run away from the village, the young men and women do not seem to have the time to understand their own village and their own people, nor do they receive any orientation towards this in school.” For example, in Maichun Village in the Kumaon region of India, Palta was a community activity that involved the entire village coming together and making compost for their agricultural fields. The practice not only strengthened community bonds but also provided quality fertilizer for agriculture. Jackson (2004, pp 96) observes that “The young youth in the village do not see compost as a resource for sustainable agriculture. In fact, they are ashamed of working on the land: the girls for aesthetic reasons (nail paint would be spoiled and the compost stinks- were some instant remarks from girls) and the boys for livelihood (what will we do in the village? We go to the city, earn money and live comfortably- the boys say). Several families in the village now complain of declining agricultural yields, so much so that “food is not even enough for six months in a year.” The example clearly points out that since most of the formal educational system does not focus on traditional practices, the sustainable livelihood in the village is impacted. Pande (2001, pp 51) also adds, “These impacts were too small to be noticed in the village in the early stages and when they became apparent and obvious for everyone to notice them, it requires resources, the time and knowledge to regenerate or improve them- a task that nobody in the village can do alone.” Therefore, it is an important undertaking to design a curriculum that focuses on connecting school related work with community-based practices. In this paper we discuss a project that was conducted in rural western India that focused on how to make science and technology relevant to students' everyday lives and how to increase student interest in science and technology related topics. The study was built around the recognition that scientific expertise resides not only within school walls but also within the community itself. The project started with asking students to work collaboratively in groups so as to select a problem in their community which they could solve by designing a technology based solution. The students were asked to work for about a duration of 6-months as a part of the tinkering lab they had in their school. The students were instructed to use as many tools as possible from the tinkering lab to design their prototypes. This project was carried out during the COVID-19 pandemic and therefore the curriculum that was implemented was designed taking into consideration that student attendance would not be consistent. The school shut down twice during the pandemic and a lot of the students did not have access to technology tools which made remote learning an impossible task. The project design reflected these concerns and designed a program that the students could attend face to face.

We measured student interest in science and technology related topics using a survey before and after the program. We also kept field notes during the 6-month period in order to document the process of how the students went about choosing, understanding and solving the problem that they perceived existed in their community. There were 13 students from 9th grade who participated in this project (4 girls and 9 boys). The topics that the groups chose were as follows: Group 1: The four girls decided to design an incinerator for disposal of used sanitary pads. This topic was chosen by the girls as availability and access to sanitary pads and a system for disposal of the pads is an urgent issue in rural India. The girls imagined this incinerator would be used in their community. Group 2: This group had 3 boys in it and they discussed the need to design a face lock system for doors in the community that they wanted to live in. The lock in the door would have a facial recognition software which would then provide optimal security for members of the community. Group 3: This group also had three boys and they worked on creating an automatic water tap in all the households so that there is less waste of water along with the convenience of having a water tap in the home. Group 4: The three boys involved in this group decided to design an electricity generator through the use of sewage water. The idea was to direct the sewage into a micro-turbine system that would then generate electricity. While most of the groups worked steadily towards their projects, group 4 struggled with conflict. The students in group 4 were not very interested in working on a project that involved community issues. The teacher had to step in several times so as to make sure the conflicts between the group members was at a manageable level. As mentioned above we administered a pre and post STEM interest survey. The STEM interest survey was adopted from a validated and reliable instrument designed to measure STEM interests among middle school students (Christensen & Knezek, 2017). We also used field notes to understand how students engaged with each of their projects.

Our findings suggest that we do not see significant shifts in terms of students' interests in STEM. While some students in the groups (n = 4) showed positive changes in their interest toward science in particular the shifts observed are not significant. However, our field notes suggest that the students were engaged throughout the process of the project. The COVID-19 pandemic also made it difficult for students to have steady engagement with the projects and may have contributed to showing no significant change in the interest levels. Given that this was our first attempt to make the ATAL tinkering lab relevant to the students' everyday lives we have several findings that will help us with our next attempt toward making the tinkering lab relevant to students' lives. Given that patience and perseverance are key factors to any kind of STEM work, in our next iteration we will emphasize that in any kind of STEM related work collaboration is a key aspect. Collaboration requires building trust, creating spaces for listening and being vulnerable. We will emphasize these important aspects of STEM related work. We are also in the process of thinking about how to emphasize patience and perseverance in our next version of making the ATAL tinkering lab relevant to students' everyday life.

The impact of the sociopolitical landscape on science teacher identity and science classroom discourse in Guyana, South America

Shakuntala Devi Gopal

Science education has historically had a tendency to call itself apolitical or neutral and consequently been unwelcoming to conversations surrounding injustice (Bazzul and Tolbert, 2019). However, funding agendas, cultural lobbies, and personal bias not only influence the direction and quality of science, but also what we teach about that science and then how that science is received by learners. This point is emphasized by Rodriguez (2017) who describes his own experience teaching students about the damage deforestation is causing to ecosystems and then later receiving angry phone calls from parents who worked in the forest industry. While he uses his story to examine the emotional demands of teachers who have social justice agendas, this research explores similar teacher narratives in Guyana in South America to highlight how teacher identity plays a significant role in how and what science is taught in the classroom, especially that with significant sociopolitical dimensions. This work specifically examines the sociopolitical factors that shape science teacher identity and how that identity informs pedagogical practices and classroom decision-making. Research on science teacher identity has established how identity can influence science teaching practices and pedagogical commitments (e.g., Helms, 1998); however, the relationship between science teacher identity and the increasingly sociopolitical nature of science education remains under-examined (Kokka, 2018). This relationship requires deep exploration given how important connecting science to society has become in order to prepare youth for the complicated world they will inherit. Youth must not only learn to decipher scientific complexities, but also the social, economic, and political factors that influence decision-making. For example, learning how dams can generate hydroelectric power in lieu of burning fossil fuels is not enough to make informed dam-related decisions as dams also disrupt marine ecosystems (Scheer & Moss, 2012) and can impair the livelihood of marginalized communities (e.g., Mapes, 2020). So, this research asks whether science teachers see themselves as responsible for developing youth "critical consciousness" (Freire, 1970) i.e., the ability to recognize social realities that perpetuate inequities (Jemal, 2017), and why not if not. Conclusions drawn rest on the stance that a) science education plays a significant role in cultivating critical thinking skills in youth (Bybee, 2013) and b) teachers effectively serve as "agents of political socialization" (Bar-Tal & Harel, 2001, p. 122) in terms of how they choose to frame issues in the classroom, and what kind of learning ecologies they sustain (Authors, 2015). Using a qualitative research design, this study examines whether secondary school science teachers (1) position themselves as responsible for engaging student criticality in the classroom, (2) see a direct connection between their work in the classroom and national socio-scientific challenges such as climate change i.e., see themselves as sociopolitical actors, and (3) see science education as supportive of activism. Holland et al.'s (2001) concept of figured worlds and Davies and Harré's (1990) conception of positioning theory were employed to explore the social reality that Guyanese secondary school teachers are embedded within that shapes and informs how teachers position themselves in relation to this sociopolitical work of science teaching. 25 secondary school science teachers participated in a three-part semi-structured interview design (Seidman, 2013) where they were asked about their teaching practices, commitments, and history, and also the connections they saw between politics and their work in the classroom. Data analysis took the form of coding and thematic analysis (Saldaña, 2016) in order to locate structures, or moral orders (van Langenhove, 2017) that characterize and shape figured worlds (Holland et al., 2001). Initial analysis has revealed unique social, political, and historical context that shape tensions science teachers must then navigate. For example, one science teacher reflected on her struggle to use the color green when designing her classroom during a science unit that focuses on environmentalism because this color has historically been associated with a particular political party. Her use of this color risks asserting a false political allegiance which could alienate students along political lines. Furthermore, because political parties in Guyana are ethnically divided, she risks stoking pre-existing ethnic tensions within her classroom. This paper will share similar stories that highlight the social and political complexities that must be considered in science learning environments that aim to develop youth critical consciousness.

Voices to hear: Telling stories, listening to the present, and imagining the future

Sameer Honwad

Voices to Hear (V2H), a design-based research project that utilized oral traditions of storytelling, engaged Native American youth ages 12-25 in learning about complex environmental challenges faced by the Coeur d'Alene (CDA) nation. We believe that by asking students to reflect on environmental decision-making processes in their communities they, and we, will advance the practice of merging two different knowledge systems (Eurocentric-mainstream/dominant science perspective, and Indigenous – traditional knowledge) to resolve environmental problems, and enable sustainable decisions in their everyday lives.

Research has shown that successful environmental decision-making in Indigenous communities across the world involves combining both traditional and Eurocentric science knowledge (Penashue, 2006). This project aimed to spotlight the historical atrocities that have led to several environmental, social, and political consequences, and also embolden students to consider the ways they can be activists and community leaders (Ginder & Kelly, 2013). By the end of a multi-week summer program hosted by the CDA Department of Education, students create podcasts about environmental issues affecting their community that are direct consequences of colonization and exploitative practices by non-Natives on Native land. Podcasts topics included exploration of the heavy metal waste in the Coeur d'Alene (CdA) river due to extensive gold and silver mining, and the absence of salmon, a culturally important food source, because of the construction of a dam by Western corporations.

We used making high quality radio podcasts as a pedagogical approach to help youth understand how to engage with complex environmental problems in their communities. The use of high-quality radio podcasts was the chosen storytelling mechanism for two key reasons. The first is accessibility—podcast production and distribution is inexpensive and an almost universal medium. The second reason is that podcast making connects deeply with Native oral traditions. Of the modern media, podcasting comes closest to the original form of human storytelling: stories told "in the dark" with the pictures formed in the listeners' imagination. At the same time, podcasts still uses the latest digital technology. While podcasting resonates strongly with oral story telling traditions, it also provides a mechanism for conducting scientific inquiry. The production of a five- or ten-minute high-quality audio documentary is a multilayered, labor-intensive process that emphasizes scientific inquiry, patience, and perseverance, requiring observation, data collection, analysis, and building a summary.

Through the podcasting process, students learned about environmental issues through the lens of different knowledge systems (Indigenous and Eurocentric) by hearing stories told by CDA Elders, explanations provided by natural resource scientists, and observations made by other community members. While the strength of podcast making is in resonance with Native American oral storytelling traditions for learning about and sharing with the rest of their community, the V2H process also provided a mechanism for conducting scientific inquiry and reflection on the inherent complexities of socio-scientific challenges. The podcasting process allowed youth to think about, ask questions about, and discuss the social and political dimensions of the environmental problems they explored. Podcasts were published on the CdA Department of Education website. This research examined student ability to systems think through the analysis of interviews, concept maps, and podcasts. Pre- and post-program data included student analysis of a pre-designed problem-based environmental story and concept maps as visual representation of the social, political, and scientific components that they saw as integral to solving the problem at hand. Data from podcasts focused on how students chose to represent local socio-scientific issues that are grounded in real-world complex systems.

We used the Core Values (CV), which draws on five core values (stewardship, membership, guardianship, scholarship, and spirituality) that reflect the worldview and heart of the CDA Tribal people, as the analytic framework. The core values as defined by the tribe are as follows: Stewardship: To care for all things with integrity, responsibility, accountability and social awareness in all spheres of life. Membership: Capable, decent, moral, ‘a good person’, a good citizen in your family, tribal, local and world community. Guardianship: Protecting tribal ways of knowing and being through the protection, care and responsibility for people, natural resources, culture, history, traditions, language and spirituality. Scholarship: Life-long, holistic learning with ideas rooted in tribal values, self-determination, self-government and sovereignty. Spirituality: Faith from which the Creator reveals the connection between all life.

The core values provide a culturally relevant framework to help us analyze and understand how CdA youth think and understand complex problems. Given the ways student participants were already embedded in a community with a rich cultural and environmental history, we aimed to leverage sociocultural worldviews and utilize pre-existing student schemas as cultural capital for systems thinking through our use of the CV framework. Framing the analysis within these core values highlights relationship, protection, and care. The V2H program enabled students to realize the interconnections within systems, as revealed in their interviews, stories, and the podcast narratives. The data showed that students value (1) caring that emphasizes responsibility, accountability, and social awareness in all spheres of life, (2) learning to understand the world by applying knowledge meaningfully in the community, and (3) care, responsibility, and protection for fellow people and natural resources. Meadows, Randers & Meadows (2004) posit that our increasing obsession with growth has resulted in the persistence of unsustainable environmental decision-making. We assert that CV, as a teaching framework, offers an ideal ideology approach to living that works to reinforce the notion that environmental systems are in a delicate balance which must be maintained in order for them to remain sustainable.

Making waves from the margins: Agency of students marginalized by caste in india

Ishita Pradhan & A. Susan Jurow

To design equitable learning environments, it is important to listen or read about the lived experiences in the voices of the people who are at the receiving end of oppressive practices. Educational experiences of students marginalized by caste system (Dalits) in Indian higher education have been documented well (Deshpande, 2006; Maurya, 2018; Pathania & Tierney, 2019; Singh, 2013), predominantly, these narratives did not include Dalit students’ voices. The narratives, especially those presented by privileged caste researchers, advance deficit views of students from marginalized caste backgrounds. In contrast, we center Dalit students’ voices to present their everyday experiences and interpretations of being in a space enduringly dominated by and imagined as a stronghold of privileged caste communities. Our initial question considered what it meant to engage with the dominant narratives about what it means to be a Dalit in spaces of higher education in India. As we gained insight into their everyday experiences of humiliation and marginalization, our research question shifted to ask: How does Dalit students’ agency manifest in everyday actions and towards what ends?

The study was conducted virtually in Spring 2021 due to the COVID-19 pandemic. It was initially designed as an interview study, where Authors conducted online interviews (~80 minutes) with 6 participants, who were a mixed group of Dalit students pursuing undergraduate, master's and doctoral studies in state and central universities across India, along with supplemental information from a focus group discussion (~90 minutes). Framing the participants as agentic individuals aware and in-charge of their voices (Trouillot, 1995), in control of their narrative, we approached the interviews as a co-constructive space where the participants recounted their experiences in their own words and Authors engaged in storying with the participants while reflecting on her personal experience of being a student in the Indian higher education belonging to the middle rung of the caste hierarchy.

The co-constructive nature of the interviews allowed Authors to listen to the participants deeply that helped Authors in discovering connections, reconsidering assumptions, develop and assess new ideas and pursue new directions in the inquiry of humiliation and agency manifested in the everyday campus life of Dalit students (Lareau, 2021). As a result of this deep listening, Authors identified a remarkable event during interviews, when one of the student participants spoke about a half naked protest at their university which received media attention from the local media channels. Authors subsequently searched through the YouTube channel of the local media outlet and identified publicly available videos where the student participant, along with fellow Dalit student activists, can be seen staging half naked protest for their rights. Therefore, for our research question, we use data from interviews, relevant information from the focus group discussions and YouTube videos to understand how Dalit students claim and articulate their community's humiliation (Nandy, 2009; Rawat & Satyanarayana, 2016) and use agency in everyday actions and towards multiple ends against the indignity and marginalization. The interpretive video analysis helps "seeing" frame by frame, gestures and actions to decode the social interaction (Knoblauch, 2012) among students, how they position themselves, each other and the institution in the act of protest and leverage embodied use of agency to transform the campus environment – implementing a university wide dress code, in this case. Using the framework of transformative agency (Engeström, 2015), initial analysis based on the interviews shows that Dalit students used their agency to organize change across multiple spaces and times. They strategically critiqued their everyday oppression and humiliation, and pushed the imposing limits of the institution to drive change in their learning ecology. Their bold actions brought awareness to caste-based atrocities and drove policy changes in their colleges. Students leveraged resources and tools such as, writing about caste inequalities and publishing in local magazines, collectively organizing events to celebrate lives of famous Dalit personalities, running study groups to discuss caste-based issues, use law (SC/ST Act) and access to local media outlets to challenge discrimination on campus. Their personal stories of organizing involved shifts in their sense of what was possible, what they were learning about higher education systems, and who they were becoming as historical actors (Authors, 2016).

The politics of "waithood" and designing for transformation: Learning to organize while confronting liminality in south africa

Tafadzwa Tivaringe & Ben Kirshner

Youth in South Africa have (re)emerged as powerful actors at the center of educational transformation. From organizing groups, such as Equal Education, to fallist movements, such as #RhodeMustFall and #FeesMustFall, young people are challenging unequal social structures and leading efforts to reimagine just and equitable education. While there is a growing body of research that documents such transformational efforts, less scholarly has attended to the kinds of learning environments that have (re)ignited political activism among this cohort of youth as well as their contemporaries in the global South, such as Nigeria, Brazil, Chile, and India (Espinoza & González, 2016; Kirshner et al, 2021; Tivaringe & Kirshner, 2021; Strong, 2018). Further, the scant body of work on designing transformative learning environments within the learning sciences has largely been situated in the global North, and is therefore yet to sufficiently grapple with the unique structural dynamics, cultural, economic, and political, that characterize the global South (Espinoza and González, 2016; Honwana, 2014; Honwana & De Boeck, 2005). This paper draws on ethnographic data of a South African youth-led organizing group, Equal Education (EE), which influenced the country's educational system by effectively compelling the government to adopt an equity-focused education policy. Building on our previous work that documented young people's framing strategies and learning trajectories (Kirshner et al, 2021; Tivaringe & Kirshner, 2021), we use this opportunity to carry out a focused analysis of the learning environment for a subset of the EE movement: post-secondary youth, here defined as high school graduates who are typically between 18-24 years. We exclusively focus on post-secondary youth because, as much literature on youth in the global South has shown, this cohort is often confronted with high levels of liminality, precarity, and marginality relative to peers in the global North. Conceptualized as "waithood" because so many post-secondary youth experience barriers to full employment, education, and economic independence (Honwana, 2014), this life stage and structural position presents unique opportunities and challenges for the design of learning environments that advance Frerian approaches to social change. Confronted with a common challenge of shifting governance and leadership from founders to local actors, we observed that EE created transformative learning environments for political education, called “youth groups”, in which post-secondary youth served as facilitators and community leaders. Youth groups, and indeed EE’s broader learning ecology, were characterized by pedagogical practices that emphasized distributed forms of authority, embraced equity-centered spatial arrangements (e.g., reading circles), and drew on the legacy of the anti-apartheid movement and everyday practices to resist inequality in the education system. The youth-led movement developed a specific cohort model for post-secondary youth that combined political education, skill development in facilitation and youth organizing, and community building. Given the effectiveness of these features in empowering youth to navigate liminality, transform EE into a more democratic organization, and advance justice in the country’s educational system, we argue that such a model has important implications on designing transformative learning environments across the globe.

Making as empowerment and community-building in the brazilian amazon

Paulo Blikstein, Raquel Coelho, José Valente, Eliton Moura, Joana Corrêa, & Romaro A. Silva

Despite Maker Education’s numerous contributions to education, such as the rekindling of constructionist, project-based STEM learning in mainstream systems, recent research has drawn attention to the fact that a considerable part of what happens in makerspaces reflect North American ideas, views, and epistemologies, having objectives implicitly rooted in the experiences of dominant populations (Buechley et al., 2008; Buechley, 2013; Vossoughi et al., 2016). Anthropologists, sociologists and historians have long documented varied and globally dispersed manufacturing and craft practices (e.g., Eglash et al., 2006; Mukhopadhyay, 2009). Inspired by works that merge such studies with considerations of making in education (e.g., Cavallo, 2000), and recent conceptualizations of cultural making, we designed a project in Brazil to engage with multiple communities to research their making practices and the diverse perspectives that underlie them. A team of 6 researchers was assembled, with deep ties to six Brazilian communities. The locations include two indigenous tribes, two *quilombola* communities (formerly enslaved people), a community of Afro-Brazilian weavers, and a Samba school. Our analysis for the symposium will focus on two communities of *quilombola* origin.

In the first community (clay pot makers in the Northeastern Amazon), the production of clay objects was deeply intertwined with spirituality. The collection of clay could only be done once a year under strict religious rules dating decades back. The interviews revealed that those rules served a variety of goals, from the practical (making sure the clay was collected exactly before the rainy season) to the political (assuring that the elders and the women remained protagonists in the process). The data also showed that the production of the clay pots was anything but routine or prescribed: despite the “official” production routine, each of the pot makers (“louceiras”) reported having their own set of steps, innovations, and new ideas to optimize the process or make it more interesting--and reported strong self-efficacy in the process. For example, some devised a technique to leave the clay sun dry for several hours, while others swore by a different procedure based on fire drying. The clay pot making process was just one cog in a much more complex set of practices that were a key component in the well-being of the “louceiras,” in which empiricism and religiosity were tightly connected: the spiritually-inspired procedures were seamlessly connected to highly empirical procedures. In a second quilombola community, a few hours away, women made cosmetics from native seeds. We also found seamlessly-integrated spiritual and empirical practices here with an additional and vital political component. The community leader reported that they had to organize and create an association to optimize production, which made them realize something entirely unrelated to cosmetics. Once they had an association, their voices coalesced into an amplified and powerful one. They were surprised to realize that, as a women's association, they could demand better local healthcare, transportation, and education from the local government. In this case, thus, the collective making of cosmetics indirectly empowered women to organize, find their voice and demand their rights. In the symposium, we will expand on such topics and discuss how making -- in its unsequestered version -- goes much beyond the creation of exciting objects, but is enmeshed in the spiritual and political realms of community life. However, the making that happens in most schools largely ignores that the production of artifacts in the world is connected to psychological, economic, and political aspects. We will discuss ways by which the creation of artifacts by diverse communities can inform and inspire how maker education is organized and conceptualized in our schools.

Abstract: Learning sciences researchers, in correspondence with the increasing usage of design-based research, increasingly tend to implement similar theories, curricula, tools, and even learners across different contexts like schools and out-of-school settings. Successfully navigating these movements and transitions involves understanding the dynamic relationship between our (researchers') imagined design's learning goals, and the goals and constraints of learners, educators, and other stakeholders mediating any implementation. In this symposium, we present a diverse breadth of work which highlight different design, analytic, and theoretical lenses to examine these transitions. This symposium aims to encourage researchers to consider such extensions of their work, and surface grammars of analyses that can help researchers involved in such work, through shared discussion across five different projects implementing and analyzing their different implementations in contrasting ways.

Introduction

As researchers and designers, we are often re-adapting similar activities for in-school and out-of-school settings. This is uniquely relevant to the learning sciences community for our inclination towards design-based research (Barab, 2006), and navigating and understanding the dynamic relationship between our (researchers') imagined design's learning goals, and the goals and constraints of learners, educators, and other stakeholders mediating any implementation (Fishman & Penuel, 2018).

We are especially interested in the journeys and challenges underlying projects that aim to implement similar designs, goals, or even concepts – broadly conceived of as any intervention (or reform) – in school settings as well as out-of-school settings. Building on Engeström's argumentative grammar for formative interventions (2011) – "(a) activity system as a unit of analysis, (b) contradictions as a source of change and development, (c) agency as a layer of causality, and (d) transformation of practice as a form of expansive concept formation" – we want to collate how this can provide an analytic lens to examine transforming the same intervention across different settings. In this symposium, we want to discuss different instances of interventions or developments that are conceived for, or repurposed across settings, and the different ways this adaptation is done.

This aims to build on prior work around how different out of school spaces are in general recognized for their affordances and limitations. In the span of work in this symposium we discuss a breadth of different agents and phenomena that can be noticed and inform our understanding of how moving across settings changes learning.

We present these submissions in a particular order which build upon and vary from each other in the scale and kind of trans-context phenomena they highlight, especially through the lens of Engeström's argumentative grammar (a, b, c, d) for formative interventions and activity systems (2009).

Tools

Our first entry highlights the design variations as enacted in *tools and materials* that are necessitated through the variations in *rules* imposed across different settings. This work also highlights how the division of roles (in terms of informal educators, teachers, and other enactors of curricula) remixes materials in ways that we should anticipate and design for. This analysis shows signs of thinking about interventions as serving and being transformed in different activity systems, and especially surfaces how (grammar feature b) contradictions in settings can be a source of change and development.

Learners

Our second submission focuses on the learning that is enacted as learners themselves move across settings – and how their participation in creative activities in out-of-school spaces is often rooted in and initiates from identities rooted in the more familiar school settings. This is not seen as a drawback but provides a lens to pay attention to how learners' movement and increasing familiarity with different identities itself is a productive form of learning. This piece surfaces a valuable lens of (grammar feature c) agency as a layer of causality, centering *youth/learner subjectivity*, but as always constituted through features of the new and old settings like overt and implicit community and rules present across these spaces.

Teachers and Families

Our third submission highlights a critical way of deepening the traditional *divisions of roles and labor* across *community* members. Providing out of school events that allow teachers to connect with their students' families helps teachers gain new lenses to consider their students' broader ecosystems, recognizing a fuller *agency* from their *parents*, and also engaging in these activities with parents – a peer group that they typically see as disconnected from their contexts – also deepens how they are able to perceive the disciplinary practices relevant to their instruction and teaching.

Institutions and Materials as Bridges

Mirroring and extending our first entry, the fourth submission presents a focus on materials as constructed in response to different components of activity system(s) (like institutional rules, community members and division of roles) but as a bridge across contexts as learners move between and across settings (grammar feature a). At an overt intersection of the different lenses highlighted above, this work aims to support learners moving across settings and focuses on how to enable productive movements of the same in response to the complex interconnected and interacting networks that bridge these different settings.

Expansive conceptual development and transformation

Our last submission presents a heavily community centered re-adaptation of broad learning principles and ideas with varying amounts of similarity and connection between the same (including very adjacent and connected settings as well as completely distal and disconnected re-adaptations). This work surfaces how we as researchers can pay attention to community grounded translations and interpretations of our own ideas as a source of learning and transformation for our understandings and identities.

Structure of Symposium

Given this surfaced progression and contrast of ideas and analytical lenses across our works, we imagine presenting our works in short presentations of less than 7 minutes each (35 minutes). Following this, we aim to do a collective brainstorm including symposium participants and the discussant on how these different lenses can be applied to the other projects (approximately 25 minutes), and if there is a productive shared synthesis of these lenses that can be a product for all presenters as well as other learning science researchers to use in their projects considering cross-context learning experiences. Our discussant Nichole Pinkard brings tremendous experience to the space and discussion of creating and studying ecologies of learning for (marginalized) youth across a wide variety of contexts, which can powerfully enhance this discussion through surfacing many other practical concerns from the field, as well as theoretical perspectives which can enhance our analyses. We imagine the last 10 minutes for open-ended question and answer between the audience and the panelists.

Intersecting Sports and Technology Across Schools, Parks, and Community Centers

Vishesh Kumar & Marcelo Worsley

Our work aims to design culturally sustaining computing education experiences for youth engaged in sports and physical activity, through the use of various sports technologies and physical computing tools (Kapor Center, 2021). This work is rooted in enabling richer exposure and access to technology as users as well as manipulators and producers to youth involved in athletics spaces which are often seen as disconnected from most academic endeavors (Hodge et al., 2008). Relatedly, this also connects to expanding conceptions of computing practices and learning experiences – enabling youth to see competence in technology and computing as possible within the context of their sports practices, as well consider computing itself as a domain not exclusively for people with academic competence (Kendall, 2007).

Our implementations of these activities have spanned a variety of contexts including schools, parks, community centers, and a variety of other pop-up summer and afterschool programs. Our curricular activity design tends to span a variety of modalities including discussions about sports activities and related technologies familiar to youth; engaging in familiar physical activities (like running laps around a track, or shooting hoops on a basketball court); repeating these activities with technological tools (like step counting wearables, or automatic sensor embedded score tracking balls); and then recreating these tools using programmable modules (like creating step counters using easy to program microcontrollers like micro:bits). Implementing such activity sequences in different settings has posed a variety of contrasting design constraints leading to minor and major variations in our curricula.

In Schools

Space: While finding classrooms and *spaces* to engage in conversations about and with different computing technologies *which also support free movement* for learners in a cross-contextual challenge, it is a more pressing constraint in schools. Schools tend to make stronger divisions between regular classroom spaces and educational conversation being engaged with “sitting down” learners, and physical education conducted in a dedicated gym space which is minimally oriented for extended discussions and conversations, and mostly centered around following drills and exercises or engaging in free play.

Time: This separation of space and practices also adds to the additional challenge of moving between different kinds of activities. For instance, schools would rarely allow students to access their laptops in a gym space, and moving large groups of students from a classroom to the gym takes a significant amount of time. This immediately affects the shape of our original curricular designs. Additionally, the nature of “dedicated discipline centered time periods” (while not unique to school and similar to many other educational programs) also poses a challenge in implementing deeply multidisciplinary curricula in schools.

Capacity: Additionally, being able to find *partner teachers*, specifically a library teacher who already engaged in computing exercises with her students, and a PE teacher willing to adapt her classes while also deeply collaborating with the library teacher at the same school – mediated through our researcher support – was an extremely critical component of a successful school implementation of our activities. Since the ideas of using such sports technologies as well as wearable computing tools for programming are unfamiliar in traditional PE or computer science teaching professional development, it is key to recognize and prepare for in-classroom small scale innovations being impossible without constant correspondence and partnership with teachers, as well as great flexibility in the expectations around the material covered since school teachers need to prioritize the requirements of the district, of their own school, and also their own prior expertises and preferences.

Assessment: Relatedly, these systemic requirements also frequently constraint or reshape the kinds of assessment and data collection made possible to identify student learning. While our partner teachers went above and beyond in responding to classroom survey and assessment design alongside us, we found it important to prioritize centering teachers’ professional goals and requirements to also contain student participation around assessment through modalities and language that they are more familiar with and often presented with. These modalities help the assessment serve the teacher first, and also respond to other structural constraints like the time allotted and available, and student orientations to classroom activities in the spans they are asked to complete assessments.

Out-of-Schools

Moving these curricula to out of school contexts showed how the features described saliently above vary in out of school settings. Also, this transition also surfaced the role of *interest*, or learner *engagement* as a much stronger affecting factor that we did not directly or overtly experience in our work at schools.

Space: In informal settings, while our unique needs of a gym-like space alongside technological resources and tools presents a key constraint regarding the spaces we partner with, we have experienced fewer challenges rooted in the separation of space (for instance bringing laptops or tablets on the basketball courts) across out of school spaces.

Capacity: Not dissimilar to the nature of overworked teachers with limited capacity for adaptation and novel implementations, most programs and out of school spaces catering to under resourced youth (a primary goal and design constraint in an equity and justice centered project like ours) have a lack of access to well-equipped facilitators and mentors to implement curricula, especially for extended periods of time. While this varies, many out of school spaces also have a lesser capacity than teachers to have sustained relationships with students and a recognition of their broader contexts. We do not have any specific response to this difference and are currently considering different ways of building deeper relationships in these spaces (Thompson et al., 2021) with youth, their families, facilitators in the space, and the activities they experience.

Interest (and assessment): Tied to the nature of formal assessments in schools, youth interest and engagement in out-of-school settings is often significantly changed through the different nature of assessments with significant stakes. School grades tend to often be valued as a social authentic marker of learning and competence from youth, which necessitates most school students to pay attention to the teacher in a way that is rarely induced in out of school settings. Here, some youth are extremely intrinsically driven to some specific activities that they attend for (for instance passion about specific sports at a sports after school program), and some are socially driven either through peers or parental decisions; or are intrinsically demotivated regarding any specific activity (for instance talking about STEM at a sports camp which can continue to excite some learners but also polarize and induce disinterest in others). So far we respond to this diversity of youth participation by including space for prolonged participation in any of the intermediate activities for whichever youth have strongest affinity for. For instance, if some youth are strongly engaged with their favored sports experience augmented through our sports technology, and indicate disinterest from the following activity of programming the same technology, we try to let those learners continue playing the sport they are more interested in. This often creates a tension between other learners not wanting to sit down and code while their friends are still playing, but also creates space for and draws learners who might be particularly excited about the programming exercise after having used a technology.

Dreaming Beyond the Specter of Schooling in Expansive Co-Design Spaces

Michael Alan Chang & Thomas M. Philip

Towards dismantling dominant power hierarchies in schooling, researchers have sought to engage youth as key actors in re-imagining schools (Cammarota & Fine, 2008; Flores, 2008). Despite researchers taking critical approaches to participatory design, youth commonly advocate proposals that ultimately bolster standardized academic outcomes (Kirshner, 2010). In this paper, we share our journey running an out-of-school *Learning Futures Workshops* (LFW) with high-school aged youth of color. The LFW supported youth in dreaming expansively about schools and identifying how emergent artificial intelligence (AI) technologies could make those expansive dreams a reality. In this work, we frame co-design spaces as figured worlds (Holland et al., 2001) in order to better understand how youth conceive of new interventions and reforms for *ideal schools* based on identities situated in well-established cultural contexts, such as *existing schools*. Over the course of our workshop, we altered our co-design figured world to offer youth an expansive set of identities to draw from, and show how this created opportunities for youth to author new possibilities for schooling beyond the grammar of schooling. The conceptual exercise of moving from existing settings to the ideal settings posed challenges and opportunities that we detail here.

Figured worlds are described by Holland et al. as “a socially and culturally constructed realm of interpretation in which particular characters and actors are recognized, significance is assigned to certain acts, and particular outcomes are valued over others” (2001). We conceptualize out-of-school co-design spaces as a particular kind of figured world where the valued goal is to construct new figured worlds. Because co-design spaces are unfamiliar for most youth, where participants actively try on identities, including established identities practiced in *existing* figured worlds. These identities practiced within existing figured worlds exist within the context of a *space of authoring*, or a toolbox of practices and discourses that participants are constantly orchestrating. These spaces of authoring open and constrain possibilities around how actors respond to events within existing figured worlds; it is in this way that co-design participants develop their identities as agents of change, and determine how and in what ways existing figured worlds can be transformed to realize their hopes and dreams.

Early in our LFW, we found that youth primarily drew from their well-established, durable identities from the figured world of schooling. The figured world of schooling, sometimes described as a grammar of schooling (Tyack and Tobin, 1994), is characterized by a series of historically robust instructional practices that serve to reinforce a hierarchy amongst students. Drawing from their identities as high achieving students, youth conceived of an AI-based agent that keeps “other” (e.g., lower-performing) students on-task, thus reinforcing the existing systems of authority that are common within the figured world of schooling. These AI possibilities initially advocated by youth were strongly in tension with our critical goals, where we hoped to create a space where young people could re-imagine powered relationships within classrooms.

In an effort to surface expansive possibilities, we brought youth to a number of relatable sites of everyday collaboration, including a cooperative house occupied by seventy university students. In the cooperative house, youth were introduced to *community agreements*, where all house members collectively constructed a set of beliefs about how they would occupy a shared space. By making the figured world of the cooperative house salient to the co-design space, facilitators opened up a variety of tools and practices that youth could deploy to author novel, liminal identities within ideal imagined figured worlds. Youth subsequently imagined a new AI-based technology that supported them in classroom conflicts, where the norms for the conflict would be jointly constructed and agreed upon by the members of the classroom community. In this manner, we demonstrate how imagining within co-design spaces is deeply shaped by identities in practice that youth invoke across a large swathe of figured worlds. While the specter of schooling looms large over this process of re-imagining schools, we demonstrate how broadening the imagined spaces of authoring can open expansive possibilities for dreaming across disparate worlds.

“They Are Whole People”: Consequential Transitions for Pre-Service Teachers Participating in a Family Creative Computing Program

Melissa Braaten, Ronni Hayden, & Ricarose Roque

Introduction

Our design work focused on the different roles in a learning ecology and the consequential transitions of roles and practices across settings. In this particular case, we focus on pre-service teachers (PSTs) as they participated as facilitators in a culturally expansive and creative computing environment within an intergenerational, out-of-school setting. This paper presents findings from a project that documented the experiences of PSTs as they prepared for, facilitated, and reflected on their practices to support families from non-dominant communities in an implementation of the Family Creative Learning (FCL) program, a series of workshops that engaged families to create projects based on their families’ stories. We use the concept of “consequential transitions” which emphasizes that “transitions are consequential when they are consciously reflected on, often struggled with, and the eventual outcome changes one’s sense of self and social positioning” (Beach, 1999, p.114).

Data sources and analysis

We recruited PSTs from an elementary science education course taught by one of the authors at a school of education at a university in the Mountain West region of the US. Two PSTs signed up, Christine and Esmeralda (pseudonyms), who were completing their final semester of student teaching in local elementary schools in an urban area. Both Christina and Esmeralda grew up in the same urban area. Prior to the workshops, we supported PSTs in preparatory sessions where they engaged in case studies of past facilitator experiences, documentation practices, and activities with the computational tools that families would be using.

The FCL workshops were hosted at a public library in the same urban area and families were recruited from the local neighborhood by library staff. During the workshops, we collected ethnographic data that included observation through written field notes, photo and video documentation, and project artifacts. Our design team, including PSTs, recorded debriefs following each workshop that included discussions of facilitation practices and suggested design improvements for the next workshop. We also conducted post-workshop interviews with pre-service teachers and family members who had participated through the last workshop.

Findings

Through reflections in their field notes and post-workshop interviews, both Christine and Esmeralda came to understand families’ identities and their own identities as teachers in more expansive ways than what was available in school settings. They voiced how in school opportunities to build relationships with adult caregivers and families were very limited (e.g. brief parent-teacher conferences to discuss children’s progress). At best, teachers get to know parents as “so-and-so’s mom or so-and-so’s dad” rather than full people. Within FCL workshops, PSTs were engaging with children and parents across various activities and working with family members to create projects based on their family stories. Both PSTs shared a shift in perspectives in how they saw parents and families. For example, after observing and later supporting a father-daughter pair to negotiate ideas for their project, Christine shared her realizations that parents were fully human, people who have their own interests and identities and who need to be seen and heard too by their children. Esmeralda noticed the structures and facilitation practices within FCL that supported families to “come as they are” with their values, stories, and languages appreciated and welcomed. These structures included meaningful activities that allowed younger children to participate, facilitators like herself who spoke the families' languages, and activities that supported parents to explore their own ideas and curiosities with the tools.

In addition to developing more expansive views of families, teachers also engaged in STEM and tech-related identity work. Christine shared she felt a sense of accomplishment, not about a specific moment of coding, but about envisioning how a whole creative computing experience could be used to reconfigure relationships between teachers, families, and STEM-centric school activity. Esmeralda reflected on the power of seeing "so many smiling faces when it came to coding" and shared "personally my feelings towards coding have changed and it's really cool that I get to see families…producing some really beautiful projects that have to do with coding."

Implications and contributions

We found the concept of "consequential transitions" in noting the powerful shifts experienced by PSTs when reflecting on: (1) their perspectives of families as "whole people," not just knowledge about family engagement; (2) their own selves in STEM and computing; (3) their ability to name and identify what structural features of FCL supported them in their engagement with families. Our inclusion of pre-service teachers has implications for the kinds of experiences that are provided for PSTs during their education, especially experiences with families and with out-of-school organizations to engage in alternate possibilities, perspectives, and roles as educators. In our next steps, we plan to document the pre-service teachers' experiences as they move back and forth between their field experiences in classrooms and move onto their professional careers as teachers. Despite these powerful transitions, after they completed their SoE program, Christine and Esmeralda reflected having a hard time imagining what they could implement in practice in their school experiences from their FCL experiences. We recognize PSTs themselves are in less powerful positions as newcomers to systems and structures that dominate interactions between teachers and families. We plan to design scaffolding experiences for PSTs as they transition into school experiences from FCL.

Connecting OST and In-School Settings to Support Learning Transitions

Kylie Peppler, Maggie Dahn, & Mizuko Ito

Introduction

Learning sciences research often views learning ecosystems as a constellation of in- and out-of-school partners. Less frequently do we theorize or design for transitions between in- and out-of-school experiences. In the example of STEM learning, considerable interest is placed in learning experiences that spark STEM interest. But, once interest is sparked, how do we design and develop sustainable ecosystems (which necessarily must span in- and out-of-school experiences) to support learning across a lifetime? This paper examines the work of an interdisciplinary team of educators and learning scientists leveraging the research-based connected learning framework (Ito et al., 2013, 2020) to identify effective community-based strategies for STEM transitions across settings, and using design based research to amplify and spread effective practices across coordinated state networks.

A key element of connected learning environments is how educators and program leaders make connections across settings so that youth can build on their interests to access additional programming, interest-driven communities, and future learning pathways. Through specific design principles and strategies, including (a) coordinating learning between settings, (b) brokering new learning opportunities, (c) using openly networked infrastructures, and (d) making learning visible, this project iteratively co-designed and developed strategies for educators and program leaders to more effectively support youth in connecting their early interests into lifelong and lifewide learning. These design principles for connecting learning across settings take shape through specific choices educators, program leaders, and youth make to support learning in and across their respective settings, whether or not those choices are an explicit part of a program's design. Examining the transitions between learning experiences provides the field with a more equity-oriented and learner-centered approach to supporting young people's learning across settings and over time.

Data sources and analysis

This project examined the transition between learning experiences within the context of middle school girls' learning trajectories across STEM learning settings. In partnership with STEM Next-affiliated Afterschool State Network alliance (which includes in- and out-of-school partners) and the coordinated initiative, Million Girls Moonshot (MGM), we were able to view coordination across settings and the broader ecosystem and trajectory of STEM learning. We systematically studied how five state networks (i.e., Nebraska, Alabama, Pennsylvania, Florida, and Massachusetts) built upon and improved girls' transitions between STEM experiences, which involved interviews with 25 field leaders and youth from across the network, and multiple cycles of iterative co-design with network and program partners. At the start of the project, networks identified strategies they would like to use to connect youth to future learning opportunities. Partners iteratively worked with the research team over the course of a year to refine and implement strategies for making STEM transitions between settings. Two exit and interest surveys with over 70 network members helped capture the impacts of this work on over 5,000 youth.

Findings

Eight initial examples for successfully promoting STEM connections surfaced within the network as a result of our DBR approach to community-engaged design, falling across the four design principles of the *making connections* area of the connected learning framework: (1) a wraparound model to bring together cross-sector organizations; (2) coordinating between out-of-school (OST) and school programs; (3) coordinating between community and OST programs to support community-based STEM projects; (4) supporting brokering work of near-peer mentors; (5) helping adults broker connections to STEM-based entrepreneurship opportunities; (6) helping adults get family and youth buy-in into STEM programs; (7) developing an openly networked infrastructure to help youth find STEM programs; and (8) supporting youth in using an open portfolio for STEM work.

Key findings included: (1) Through implementation and refinement of these making connection efforts, the state networks reported gains in connections to future STEM learning. Networks reported a 37% increase in the number of new connections made to future STEM learning during Phase 1 of the project–over 864 connections to future STEM learning opportunities. (2) The participating state networks saw a marked increase in capacity. While deploying these new and refined approaches, networks reported a 39% (n =+1,235) increase in youth participants, drawing in over 51% (n = +647) more girls. (3) The national MGM networks and programs employ a wide range of nascent practices for making connections that can be leveraged for higher impact. Practices are interconnected and mutually reinforcing, and network administrators self-reported intense motivation (i.e., each strategy is of interest to more than 75% of the state network) to adopt and/or refine one or more ways for making connections highlighted in this project.

Implications and contributions

This paper centers on advancement of theory and knowledge of how connecting learning across settings can broaden access and deepen engagement with STEM for girls. As the field continues to make progress on how to design culturally relevant STEM learning environments for historically marginalized groups, what has received less attention is how to effectively connect and coordinate between these efforts. Typically, STEM programs, both in and out of school, lack connections and coordination across programs and settings. This study offers critical insights and models for how to support inclusive and equitable STEM ecosystems that knit together culturally relevant approaches, focusing specifically on the connections between programs and settings. It also contributes to theory and evidence for how to build effective alliances, networks, and initiatives that serve educational equity and inclusion goals.

Constructionism through the Prism: A Spectrum of Education Implementations in Thailand

Deborah Fields & Paulo Blikstein

Sometimes an educational reform is not a specific technology, activity, or curriculum but rather a philosophy. Such is the case in our study of the implementation of constructionism in Thailand. In the late 1990s, an emerging organization in Thailand, the Suksapattana Foundation (meaning “study and development” in Thai), initiated four years of collaborative work with Seymour Papert in an effort to learn and apply constructionism in their country. While they partnered with Papert and leaders visiting from MIT for four years, they continued implementing constructionism in creative ways across many local sites for the next 20 years and continuing.

In this paper we consider the range of implementations of constructionism specifically in education contexts: public and private, formal and informal. Pizmony-Levy (2011) provides a useful metaphor for considering the ways that local implementations can vary: educational reforms are refracted through the “prism” of individual nation-states, local ministries, and institutions (p. 604). Applied to implementation of constructionism in Thailand, we ask, *how was the educational philosophy of constructionism refracted through local institutions in developing different “colors” of implementation? What, if anything, was held in common across implementations? What institutional and individual factors shaped each implementation?*

Part of a larger study of the Suksapattana Foundation's (SF) implementation of constructionism since 1997, we draw on interviews with 23 people (several more than once) from five sites along with several leaders of the foundation, totalling 47 hours of interview data gathered in-person from 2017-2020. Analysis focused on each individual institutional case of implementation of constructionism, attending to origins, endings, transition points, leaders, influences of various institutions (school, educational ministry), and explicit and tacit applied values of constructionism. Below we briefly describe diverse, 6-20 year long constructionism interventions across different areas of Thailand.

Primary School 1: "Traditional" constructionism implementation

One teacher who attended some constructionism workshops using Microworlds was inspired to implement it in her classroom. With some used computers provided by the SF, she began to teach units on Microworlds (and later Scratch) with her 5th grade class. Over time the entire school slowly adopted the idea and embraced the idea of doing creative projects under the ethos of "constructionism." We call this the traditional model because it most mirrors constructionism implementations around the world which tend to focus on students using digital technology to create interest-driven projects (Holbert et al., 2020).

Primary School 2: Teacher Agency

Here the main instigator was a principal who took to heart the idea of learner agency and met with her teachers to engage in conversation about how to implement constructionism. The teachers chose to group by grade level and work together to do an implementation each year. For instance, the third grade decided to use one month to focus on student projects around cooking traditional foods. When the principal left, constructionism implementation ended, but at least one teacher deeply internalized it and has applied it in other work.

Primary School 3: Indigenous Knowing

A leader of the SF was visiting a school in the Hill Tribe area of Northern Thailand, one locus of the country's indigenous population. Here he met a teacher who had self-developed a beautiful pedagogy where students learned math and Thai (a second language for most students) by studying rice fields and other local work. The leader recognized constructionism in this teacher's work and simply celebrated and acknowledged it, helping the teacher win some awards that led to local recognition and acceptance of his unusual pedagogy.

Summer Technology Workshops

A former principal created a small foundation to support teachers and students in Southern Thailand by sponsoring summer workshops. These focus on creative uses of digital technology, such as maker education, and do not require changing the school curriculum since they take place over the summer. The SF helps provide or connect leaders for some of these workshops.

Private School: Radical Constructionism

Frustrated by the resistance of many schools to providing time and flexibility for teachers to implement constructionism, some SF leaders created their own private school where learner interests and student-created projects were the entire focus of all learning. Teachers were hired from other careers (not from teaching colleges) to disrupt traditional norms of top-down, hierarchical teaching models. As the school grew, it moderated some of this radical implementation through interactions with parents' college entrance worries and school certifications, but as of 2020 still reserved at least 3 days a week for student projects.

Across these implementations we see a great deal of flexibility and innovation. The pioneers of constructionism might be a teacher, a principal, or foundation leaders. Leaders met resistance from existing school models, policies, curricula, and traditions. They each found different niches of application, from what would easily be recognized elsewhere as "constructionist" with digital tools to more ground-up approaches that focused not just on learner agency but teacher agency and tapping into local and traditional knowledge. Researchers were not a part of any of these implementations, though the SF played a variety of roles, from introducing leaders to the constructionist philosophy, to providing materials, to connecting people with resources, to simply celebrating and publicly acknowledging good pedagogy that defied local norms. Perhaps what stands out the most is that nowhere did SF tell leaders what constructionism was or how it should be implemented. Like Papert and Harel (1991), they instead engaged leaders in developing their own (constructionist) projects and valued leaders as learners with agency, interests, and local needs. The Thai constructionist community provides a provocative case of culturally responsive revision and application of an educational reform by people from across the society of a Global South, developing country.

Engaging With Glucose Equilibrium Mechanistic Accounts: Type 1 Diabetes Case Study

Ilana Dubovi, Tel-Aviv University, ilanadubovi@tauex.tau.ac.il

Abstract: Reasoning about mechanisms is a core of science education, however, more research is needed into the degree of mechanistic details that should be unpacked to support learning. In this study, we analyze two case studies of laypersons with diabetes engaging with agent-based models that represent glucose-equilibrium processes. Our analysis revealed that incomplete mechanistic representations triggered a sense of dissonance but involved strong emotional engagement. Implementations are discussed.

Introduction

Type 1 diabetes mellitus (T1DM) is one of the most common chronic diseases and is caused by the destruction of the pancreas's ability to naturally produce insulin. To what degree laypersons who are diagnosed with T1DM engage in mechanistic reasoning is not fully understood. Mechanistic reasoning focuses on the process that underlines cause-effect relationships and thereby takes into account *how* the activities of components of a constituent system affect one another. Koslowski (1996) proposed that mechanistic reasoning "explains the process by which a cause brings about an effect" (p. 13). Russ et al. (2008) distinguished between causal inferences of input-output relations, the "causal intuitions", which emerge very early during the course of human development, and the mechanistic conception of a specific process within particular domains (p 422). For instance, in relation to glucose equilibrium and T1DM, the effect of insulin injections upon reduced blood glucose levels would be a causal intuition. While a particular explanation of how insulin mediates the glucose uptake into the muscle cell, which in turn goes through a breakdown process (glycolysis) to produce energy, would be a deep mechanistic explanation that identifies the causes and *how* they are processed. Unpacking mechanistic accounts and their causal interactions is extremely important to learning and teaching (NGSS Lead States, 2013), however, more research is needed as to how many "black boxes" should be unpacked (Haskel-Ittah, 2022), namely, how much mechanistic detail is required. The current study, therefore, explored the mechanistic reasoning structures by studying the learning processes of T1DM patients who used computerized agent-based models which simulate glucose-equilibrium processes (Dubovi et al., 2020). The aim was to outline how laypersons with T1DM who are experiencing bodily diabetes "episodic feelings" engage with mechanistic accounts of their medical condition and to what extent (Nemirovsky, 2011).

Methods

Two male adult patients were recruited during their routine visits to the diabetic clinic. The first participant (P1) was 38 years old and diagnosed with T1DM since the age of 8. The second participant (P2) was 41 years old and diagnosed with diabetes since 14 years of age.

To explore how T1DM patients engage with mechanistic accounts related to their disease, they were introduced to computerized agent-based models which represent the main organelles and molecules that participate in the metabolic processes and insulin mechanisms that maintain blood glucose levels. The models were developed by Dubovi et al. (2020) with NetLogo (Willensky, 1999). The learning process was video recorded and lasted on average for 56 minutes. While exploring the models, participants were asked to apply the "think-aloud" protocol (Ericsson & Simon, 1998) by talking through their step-by-step interaction with the models. Their think-alouds were transcribed and coded for their learning practices, the difficulties they encountered, and their areas of individual interest.

The video recordings were analyzed for facial expressions, using the Affectiva Affdex algorithm provided by iMotions 9.0 (https://imotions.com) to obtain in real-time the 7 basic emotion likelihoods for joy, anger, surprise, contempt, fear, sadness, and disgust.

Results & discussion

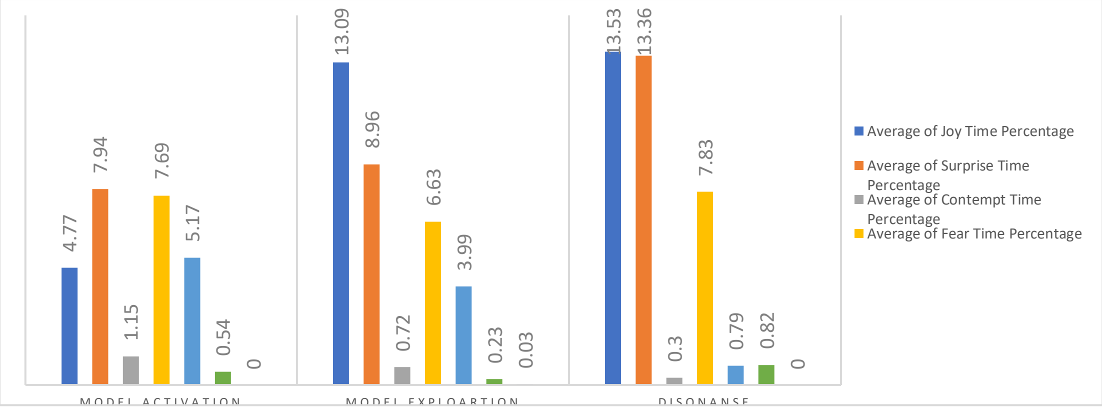
The following exploration practices were identified: (1) The agent-based models integrated three main representations: the microworld, the graphs/plots, and buttons to manipulate the models. P1 attended mainly to the microworld of the agent-based models, while P2 mainly observed the graph representations. (2) While each screen included an agent-based model and the instructions beside it, both participants attended first to model manipulation and exploration, and only when they had finished did they proceed to reading the instructions and scaffolds.

The think-alouds analysis revealed that the participants experienced a strong sense of dissonance between the model visualizations compared to their own mental models which were grounded mainly on their individual embodied experiences. For example, P2 outlined that in the model the impact of the short-acting insulin injection “felt” too fast with a too small impact on blood glucose levels; in contrast, the effect of physical activity on the glucose levels “felt” too strong. This sense of dissonance might be explained by incomplete mechanistic details that were represented in the models which in turn revealed a gap between P2's embodied experiences and the visualized processes. It should be noted that during those moments of dissonance, an emotional engagement that was measured by facial expressions extraction (see Figure 1) demonstrated a relatively high frequency of emotions such as surprise and joy. Surprise is included in a notable list of basic emotions, which has been related to triggering cognitive mechanisms, fostering attention and improving learning processes (Brod et al., 2018).

Overall, it can be suggested that moments of dissonance can be reduced by tuning the degree of mechanistic information details to the learner’s previous experiences with the phenomena. For example, to help learners understand better why physical activity bring a such strong impact on glucose levels, the models should include more complete mechanisms on how physical activity increases the expression of GLUT4 transporters on the cell membrane which in turn enhances cellular glucose transport into muscle cells. On another hand, further research should explore to what extent these moments of dissonance should be mediated, because as we show, moments of dissonance are important to emotional of joy and surprise, which in turn might promote deeper learning.

Figure 1

Changes in participants’ emotional engagement across different phases of the agent-based models.



Note. The figure shows the percentage amount of time the participants displayed each emotion.

Designing Worked Examples for Dynamic Learning Technologies: The Effects of Action and Self-Explanation

Avery H. Closser, Purdue University, aclosser@purdue.edu
Hannah Smith, Worcester Polytechnic Institute, hsmith2@wpi.edu
Erin Ottmar, Worcester Polytechnic Institute, erottmar@wpi.edu
Jenny Yun-Chen Chan, The Education University of Hong Kong, chanjyc@eduhkk.hk

Abstract: The worked example (WE) effect has predominantly been explained by cognitive load theory. Less research has considered how embodiment may inform the design of WEs. We present a pilot study on the effects of *viewing* versus *mirroring* WEs in a dynamic online environment. A total of 64 ninth-grade Algebra I students were randomly assigned to a condition in which they viewed or mirrored WEs and were or were not prompted to provide explanations. Students showed learning gains with the largest gains among students prompted to give explanations. These findings support the worked example effect and provide preliminary evidence that may inform how WE s are designed for online math environments.

Introduction and theoretical perspective

Worked examples (WEs) provide a step-by-step solution to a problem. Studying WEs in algebra increases learning more than solely problem solving (Barbieri & Booth, 2020), known as the worked example effect (Sweller, 2006).

Prior research has explained the worked example effect through cognitive load theory and shown the effectiveness of providing WEs with self-explanation prompts on learning in algebra (Renkl, 2014). Such WEs provide minimal content that avoids redundant information, splitting attention, or unnecessary elements that do not contribute to learning. Alternatively, theories of embodied cognition posit that students' physical experiences and interactions influence their cognitive processes, including mathematical thinking and learning (Nathan, 2021). In this vein, *interacting* with, instead of just studying, WEs may better support learning.

We present a pilot study testing how principles of cognitive load theory and embodied cognition may extend to WEs with and without self-explanation prompts in Graspable Math (GM: Weitnauer et al., 2016), an online, interactive algebra notation tool. GM was developed from theories of embodied cognition to allow users to physically manipulate notation through gesture-actions that emulate mathematical properties in a physical-to-virtual embodied experience with mathematical terms. To identify effective ways to present algebraic WEs in dynamic online learning environments like GM, we ask: 1) *Do students learn more from viewing or mirroring WEs in an online learning environment?* 2) *Do students learn more from studying WEs with or without self-explanation prompts?* 3) *Is there an interaction between WE presentation and self-explanation prompts?*

Methods

The sample included 64 ninth-grade Algebra I students (M = 14.2 years of age, SD = .5) who participated in the intervention and completed at least half of the pretest and posttest. Our sample included: 34 (53%) female, 27 (42%) male, two (3%) non-binary students, and one student not reporting gender.

We used a 2 (Presentation: view or mirror) × 2 (Self-explanation: prompt or no prompt) between-subjects design. Teachers assigned the study as three 30-minute in-class activities. On Day One, students completed an eight-item pretest to measure their algebra knowledge (e.g., $5 - 4(2b - 5) + 3b = 15$). The pretest and posttest were used in a previous study with a similar population (Smith et al., 2022). Here, the reliability coefficient was KR-20 = .74 (pretest) and KR-20 = .77 (posttest), showing acceptable reliability. On Day Two, students were randomized to a condition in GM. Students completed a brief training tutorial on GM followed by four pairs of WEs and practice problems on equation solving. The WE presentations and instructions varied across conditions but the problems were consistent. The WEs and paired practice problems were presented in the same order across the four conditions with each WE followed by a paired practice problem. On Day 3, students completed a posttest that matched the pretest structure (e.g., $30 - 4(b - 5) + 1b = 20$).

Conditions

Students were randomly assigned to one of four conditions in which they would: 1) *view* WEs, 2) *view-and-explain* WEs, 3) *mirror* WEs, or 4) *mirror-and-explain* WEs. Students in the *view* condition saw two presentations of each WE on-screen. The WE on the left side of the screen showed the major problem derivations in a static image. The right side of the screen showed a looping video of the problem being transformed in GM. The looping video ensured that students in all conditions saw the dynamic problem-solving process; however, students in view conditions watched the video whereas students in the mirror conditions generated the process themselves through GM gesture-actions. Students in the *view* condition were prompted to "*Study the worked example. Once you feel comfortable with the steps taken to solve for the variable, select the solution below as your answer*." Similarly, students in the *view-and-explain* condition were prompted to study the same WEs and select the solution. They were also prompted to provide an explanation: "*Study the worked example. Use the box below to explain each step in the worked example. Once you have explained the steps, select the solution to the equation*."

Students in the *mirror* condition saw a static image of a WE at the top of the screen, and an interactive problem equation presented below. They were instructed to manipulate the equation using GM to match their solution steps with the WE: "*Use the worked example as a guide to complete the problem below using the Graspable Math Canvas. You may reset the problem as needed*." Students in the *mirror-and-explain* condition were also prompted to provide an explanation: "*Use the box below to explain each step in the worked example*."

Results

A 2 (Time: Pretest vs Posttest) × 2 (Presentation: View vs Mirror) × 2 (Self-Explanation: Prompt or No Prompt) repeated measures ANOVA revealed a main effect of time ($F[1,60]= 56.93$, $p < .001$, $\eta_p^2 = .487$): students improved from pretest ($M = .39$, $SD = .25$) to posttest ($M = .60$, $SD = .30$). There was no main effect of mirroring vs. viewing worked examples ($F[1,60]= 0.82$, $p = .37$, $\eta_p^2 = .013$). There was a marginal effect of self-explanation prompts ($F[1,60]= 2.80$, $p = .10$, $\eta^2 = .045$). There was also a marginal Time × Self-explanation prompt interaction ($F[1,60]= 3.74$, $p = .06$, $\eta_p^2 = .059$). Post hoc comparisons with Bonferroni corrections revealed that all students performed comparably at pretest and significantly improved from pretest to posttest ($p < .001$); however, this effect was larger for students in the self-explanation prompt conditions. Students who received self-explanation prompts demonstrated larger growth (pretest: $M = .41$, $SD = .26$; posttest: $M = .68$, $SD = .25$; $p < .001$) than those who did not receive self-explanation prompts (pretest: $M = .36$, $SD = .24$; posttest: $M = .52$, $SD =.32$; $p = .001$).

Discussion

This pilot study investigated how features of WEs impact learning in a brief randomized controlled trial. On average, students improved from pretest to posttest, demonstrating learning gains across conditions. There was no evidence to suggest that viewing or mirroring WEs was more effective; however, students who studied WEs with self-explanation prompts learned more than those who studied WEs without self-explanation prompts.

Students improved about 20% from pretest to posttest, supporting the worked example effect. Similarly, Smith et al. (2022) saw comparable learning gains after students studied one of six WE presentations. These findings suggest the WE format may not matter as much as just engaging in WE practice. As such, researchers and educators may have more flexibility in designing WEs for online contexts. Further, the results support prior research on self-explanations in WEs (e.g., Renkl, 2014): self-explanations are helpful regardless of the WE format. Looking ahead, we will conduct the experiment with a larger sample. While the small sample size renders the results somewhat inconclusive, this pilot study demonstrates how educational technologies open new doors to designing WEs. As K-12 education increasingly uses online tools, it is essential to consider how we can leverage multiple theoretical perspectives to design materials that support student learning and online practice.

Abstract: Neuroscientific studies in educational contexts increasingly reveal insights into mathematical cognition. However, means for, and results from, group-wide brain activation synchrony analyses when engaging in mathematical reasoning are absent. Thus, we developed a method to investigate population-wide brain activation synchrony and applied this function to examine expertise-dependent differences when interacting with geometric or symbolic math demonstrations. The results revealed greater synchrony when interacting with geometric than symbolic demonstrations, and for students with less formal math education. This indicates the presence of group-wide expertise-dependent brain activation pattern differences upon interacting with different math demonstrations. Furthermore, the results demonstrate the functional validity of a novel method for brain activation synchrony analysis.

Introduction

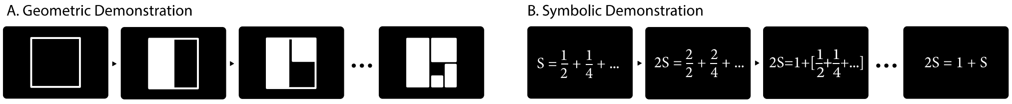
Neuroscientific approaches to investigating cognitive mechanisms of learning in laboratory and classroom settings constitute an essential part of the learning sciences research. At present, there is a lack of neuroscientific studies of group-wide brain activation patterns to shed light on (mathematical) cognition. In other contexts, whole-brain analyses revealed the importance of theta synchrony for memory encoding and retrieval (Solomon et al., 2017), and brain-to-brain group synchrony analyses were shown to be a predictor for classroom engagement (Dikker et al., 2017). However, these studies mainly consider isolated electrodes or individual brain waves, whereas approaches tackling the whole picture of electrode activation, including various locations, brain wave frequencies, and group-wide pattern similarity comparisons, are missing.

This paper reports participant-overarching EEG-based brain-synchrony patterns of students with different levels of math education interacting with geometric or math symbolic demonstrations. We propose and describe a new method to explore EEG-based estimations of brain activation patterns over large population samples. Additionally, we provide an open-source *R*-package to apply this function to other datasets.

Methods

The study participants were 46 university students (26% female, 74% male, 0% non-binary; Age: $M = 22.3$ years, $SD = 2.4$ years). They were grouped into novices and experts based on their educational background (i.e., the number of math courses in their study discipline). All participants were right-handed and did not report hearing difficulties or neurological disorders. The study was approved by the local ethics commission. The stimuli shown during the study consisted of geometric (i.e., figurative) and symbolic math demonstrations. The latter depicted step-by-step explanations of mathematical calculations of variable difficulty. The participants were asked to attentively follow eight randomly and vicariously solved math demonstrations (four symbolic, four geometric) on a screen (Figure 1). Meanwhile, their brain activation levels were measured by EEG (ANT NEURO EEGO MYLAB electrode cap with 128 EEG channels).

Figure 1
Exemplary geometric (A) or symbolic (B) math demonstrations consisting of consecutive slides



A participant's average frequency signal of all electrodes was used as a reference to standardize the recorded signals. Artifacts related to eye movements were removed by conducting an independent component analysis decomposition. Welch's analysis was conducted upon high- and low-pass filtering to assess the signal power at the different frequencies, serving as the basis for investigating between-participant brain synchrony. The novel brain-synchrony function's underlying idea combines clustering algorithms and correlation analyses. First, within-participant correlation scores are calculated for each EEG channel as the basis for *k*-means clustering. Applying the Kelley-Gardner-Sutcliffe penalty function, the channels are hierarchically grouped in clusters.

Repeating this procedure for all participants results in multitudes of specific sets of channel clusters. In the next step, all channel combinations are summarized over all participants in a contingency table, revealing how often two specific channels are assigned to the same cluster in all individual participants. Lastly, a *p*-value-corrected χ^2-square test for each channel comparison is conducted to examine which channels' recorded brain waves consistently correlate over the population. The specifically-for-this developed function is openly available as *R*-package under https://github.com/samueltobler/brainwavesync.

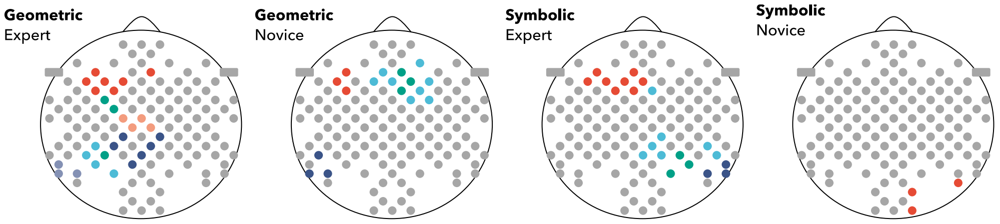
Applying this *brainsync* function (described above) to the priorly Welch-transformed data sets, we obtained brain-synchrony patterns for the four conditions of brain wave frequencies between 0 and 50 Hz (α = 0.001 with FDR-adjusted *p*-values). The results of the analysis were descriptively analyzed.

Results

The analysis revealed four very distinct patterns of brain activation synchronies in the four different conditions (Figure 2). Looking at all experts with geometric demonstrations indicated several electrode clusters of similarly recorded brain activation patterns, primarily found in the left prefrontal and parietal brain regions. In contrast, novices seeing the same demonstrations showed the largest brain activation synchrony in prefrontal and right frontal brain regions. When viewing symbolic math demonstrations, all participants shared fewer brain activation patterns. Furthermore, experts displayed the most brain activation synchrony in prefrontal brain regions, whereas nearly no synchronous activity was found among the novice participants.

Figure 2

Brain activation synchrony clustered in the different experimental conditions and sub-groups



Note. Different colors indicate condition-related cluster-belongings.

Discussion and conclusion

Prior research suggested the feasibility of population-wide brain synchrony analyses for identifying cognitive mechanisms associated with learning in various conditions. Regrettably, previous approaches to examine such synchronous activities are lacking. In contrast, the present novel function identified several electrode clusters of brain activity synchronies in various subgroups. The synchrony pattern with geometric demonstrations in prefrontal regions indicates commonly shared synchrony in brain regions associated with working memory tasks (e.g., Sauseng et al., 2010), and those in the parietal areas related to the more regulated activation of regions necessary for low-dimensional structure generalization and object interpretation (cf. Summerfield et al., 2020). The activation synchrony that is only present in the expert group might be attributable to different prior knowledge influencing the processing of the geometric demonstrations. In contrast, insufficient prior knowledge might constitute an additional challenge for generalizing structural information. The lack of identifiable brain activation synchronies might be caused by the variability of activation patterns, also stemming from diverse behavioral reactions. Future work should investigate whether such cluster analyses can reveal additional insights when considering various moderating factors, including math anxiety or prior knowledge. The study's primary limitation is the lack of prior mathematical knowledge assessment. Comparing individual students based on actual performance instead of inscribed courses may result in more precise results.

How and for Whom Does DragonBox12+ Support Math Learning? The Relation Between In-Game Progress and Math Performance

Jenny Yun-Chen Chan, Education University of Hong Kong, chanjyc@eduhk.hk
Chloe Byrne, Worcester Polytechnic Institute, cmbyrne3@wpi.edu
Janette Jerusal, Worcester Polytechnic Institute, jjerusal@wpi.edu
Allison S. Liu, Worcester Polytechnic Institute, aliu2@wpi.edu
Erin Ottmar, Worcester Polytechnic Institute, erottmar@wpi.edu

Abstract: Using data from 183 U.S. seventh graders, we examined whether students' DragonBox12+ progress related to their later mathematics achievement, and whether students' prior achievement moderated this relation. Higher in-game progress was associated with higher end-of-year mathematics achievement, and this association was stronger among students with lower prior mathematics achievement. These findings advance research on how and for whom DragonBox12+ supports mathematical learning, and have implications for practices using game-based technologies to supplement instruction.

Introduction and methods

Grounded in theories of game-based learning (Plass et al., 2015), DragonBox12+ (hereafter DragonBox) is a commercially available application that allows students to dynamically manipulate engaging characters on-screen as they learn algebraic principles in a playful context. Aligned with seventh grade math standards in Common Core, students isolate a box containing a dragon, similar to solving for *x* in algebraic equations. Although developers of DragonBox claim that it may help students improve their algebraic performance (Siew et al., 2016), the empirical findings are mixed (Long & Aleven, 2017). Recent analyses in a year-long randomized controlled trial (RCT) suggested that DragonBox positively impacted seventh graders' algebraic performance (Decker-Woodrow et al., in press). However, it is unclear whether the positive effect was associated with, or independent of, students' progress within DragonBox. Further, prior work has focused on students' algebraic performance (e.g., Long & Aleven, 2017; Siew et al., 2016), but the broader impacts of playing DragonBox on students' general math achievement remains unknown. Here, we investigate the effect of students' DragonBox progress as well as the moderating effect of prior achievement on later math achievement. Our research questions (RQs) and their corresponding hypotheses are as follow:

1. Does students' progress in DragonBox predict their later math achievement? Based on relevant research (e.g., Hulse et al., 2019), students who solve more problems in DragonBox may score higher on the end-of-year math achievement.
2. Does the relation between progress and end-of-year math achievement vary by students' prior achievement? We explore this relation, and do not have an a priori hypothesis.

The data were collected as a part of an RCT involving a pretest, nine 30-minute intervention sessions, and a posttest during the 2020-2021 academic year amidst the COVID-19 pandemic. The RCT was conducted in collaboration with a large, suburban school district in the Southeastern U.S. to test the efficacy of three educational technology interventions on seventh graders' algebraic performance (Decker-Woodrow et al., in press). Using this dataset, our current analyses included 183 students (male=52%, female=48%; White=60%, Hispanic=25%, other=15%) who played DragonBox and had math achievement scores from the end of fifth and seventh grade.

DragonBox has ten chapters, each with 20 problems. DragonBox progress was measured as the total number of problems students completed in the game throughout the full intervention (*M*=103, *SD*=49). This measure of in-game progress was the focal predictor for RQ1.

The end-of-year assessment measured students' mathematical understanding in a broad range of topics, including ratios, equations, geometry, and statistics. The assessment included a variety of tasks (e.g., computation, word problems) and answer formats (e.g., multiple-choice, graphing). The assessment scores ranged between 265 and 740. We used students' seventh-grade scores (*M*=549, *SD*=56) as the outcome variable for both RQs. The interaction between fifth-grade scores (*M*=561, *SD*=58) and in-game progress was the focal predictor for RQ2.

Results and discussion

We found that students' in-game progress predicted their seventh-grade scores above and beyond the covariates (e.g., biological sex, race, fifth-grade score), *B*=0.17, *p*=.012. For students with average in-game progress, increasing their progress by one problem was associated with a 0.17-point increase in their seventh-grade scores. Adding the Fifth-grade Score × In-game Progress interaction revealed that the effect of in-game progress varied by students' fifth-grade score, *B*=-.002, *p*=.035. Specifically, the positive association between in-game progress and seventh-grade scores was stronger among students with lower vs. higher fifth-grade scores.

Given that prior studies on DragonBox focused on students' algebraic performance (Decker-Woodrow et al., in press; Long & Aleven, 2017; Siew et al., 2016), the current study was the first to report DragonBox's impacts on general math achievement. We found that on average, students' end-of-year math achievement scores decreased over time, potentially owing to the negative impacts associated with educational disruptions during the COVID-19 pandemic (Engzell et al., 2021; Kuhfeld et al., 2022). Despite the learning loss, we found a positive effect of in-game progress; solving more problems in DragonBox might have mitigated the decrease in students' math achievement. Further, this positive effect was stronger among students with lower math achievement.

One explanation of this finding is that simply engaging students in math through playing DragonBox may help foster a positive attitude towards math and support their later performance, especially among students with lower math achievement. Prior work has shown that the game-based approach can increase students' engagement with learning (Mora et al., 2015), and that playing DragonBox fosters students' positive attitudes towards math (Dolonen & Kluge, 2015; Long & Aleven, 2017; Siew et al., 2016). Future work should replicate the current finding and delineate the mechanisms through which in-game progress and prior achievement influence students' math attitudes and performance. Doing so will help identify ways that game-based approaches support different aspects of mathematical learning and inform practices that maximize their benefits across students at varying levels of achievement.

In sum, understanding how and for whom game-based tools are beneficial can help researchers and educators effectively support students' mathematical learning. Game-based tools may be one way to engage students in math and help decrease learning gaps from pandemic-related disruptions in education. Our findings contribute to the research on when and how to use game-based tools to support mathematical learning during the pandemic and beyond.

Teachers Using Perspective-Taking to Develop Deeper Understanding of Their Emotions and Informed Views of Teaching and Learning in a Knowledge Building Environment

Mei-Ju Chen, National Tsing Hua University, meiju@mx.nthu.edu.tw
Chao-Yu Guo, National Chengchi University, chaoyu@nccu.edu.tw
Huang-Yao Hong, National Chengchi University, hyhong@nccu.edu.tw

Abstract: This study explores how in-service teachers worked collaboratively to discuss their views of teaching/learning while reflecting on teaching-related emotions via perspective-taking (PT) in a knowledge building (KB) environment. Data mainly came from online activity logs and discussion. The main findings from mixed-methods analysis indicate that after engaging in PT in a KB environment for a semester, teachers were able to develop more positive emotions towards their teaching practices, while also developing more informed pedagogical views.

Introduction

Facing the challenge of the 21st century education that responds to the economical, technological, and societal shifts at an ever-increasing pace, teachers play a key role in improving students' capabilities. This challenge requires them to perform increasingly more complex teaching tasks that demands high cognitive and emotional load (Buchanan, 2020). Currently, as often seen from formal teacher training and development, the main trend of teacher development still tends to employ an outside-in approach that focuses on how to develop teachers' professional expertise via enhancing their teaching knowledge and skills (Grainger, 2020). There is a general lack of studies focusing on inquiring into how to help teachers develop their expertise from an inside-out approach, such as reflecting on their own practice to better understand their own pedagogical views and the related emotions derived from the conflicting views of teaching and learning (Korthagen, 2017). To this end, this study is interested in examining a reflective approach, called perspective-taking (PT), to help teachers look at the inner-side of their teaching experience, by reflecting on their own pedagogical views while developing deeper self-understanding and more positive teaching emotions (Jaber, 2021).

Perspective-taking (PT) is a way of viewing experience from differing stances (e.g., 1st-, 2nd-, & 3rd-person PT). PT helps people to form some self-distance (Orvell, et al., 2022) when looking at themselves, so as to critique and revise their experience. So, PT may be used to help teachers reflect inwardly and facilitate their professional growth via self-awareness and emotional clarity. Unfortunately, when reviewing existing literature about PT and educational studies, PT is mostly used as a strategy to build students' multiple views and cultural understanding, and rarely used as a tool to help teachers' professional development. PT, however, can be useful for effective professional development as it provides an opportunity for re-thinking teachers' own teaching concerns, personal strengths and mission, emotional fluctuation, within an authentic teaching context (Fullan, 2007). Many studies also showed that teachers' emotions affected their pedagogy and the students' performance, and their views of learning also influenced their practice, and that teachers' emotions, learning perspectives, and practice are related and important for teacher growth (Buchanan, 2020; Jaber, 2021). Consequently, we intend to apply PT to help teachers engage in self-reflection and self-exploration regarding teaching views and emotions. This study also intends to engage teachers in community-based professional development by means of a collaborative knowledge building (KB), which is defined as sustained production and improvement of ideas of value to a community (Scardamalia, 2002) and it is posited that engaging participants in PT in a KB environment would help them rethink about their psychological well-being, while building collective knowledge for public good, and developing a deeper understanding of the conceptions of knowledge creation. A computer-supported KB platform called Knowledge Forum (KF) is employed in this study to foster online discussion and to provide a virtual place for teachers to practice their PT via exploratory and self-distanciating discourse. Building on the above review, the main research question is: Does engaging participants in PT while discussing critical teaching incidents (CTIs) in an online knowledge building environment help them develop more informed views of teaching and learning and more positive teaching emotions?

Method

Participants were 51 in-service teachers enrolled in a master degree program in a national university in Taiwan. The duration of the study was a semester (18 weeks). We introduced PT as a means for participants to engage in reflective discussion about CTIs occurred within their teaching practices. Knowledge Forum (KF)--a knowledge building environment—was used to record all online activity and content. The course was divided into three stages to guide participants to shift their perspectives, from I-PT, to Other-PT, to Back-to-I-PT, when discussing CTIs.

Four KB principles (Scardamalia,2002) was used as teaching guidance: (1) “Authentic problems, real ideas” was applied to help participants identify their target critical incidents for discussion; (2) “Idea diversity” was used to encourage participants to read and respond each other’s online notes and to promote social collaboration; (3) “Rise above“ was used to guide participants to review all the self-reflections and peer-responses; (4) “Knowledge Building discourse” was employed to encourage constructive and collaborative discourse with partners. Data mainly came from online discussion notes, and analysis focused on: (1) online activities which examine the number of notes contributed, read, and modified in KF, as well as the number of words written per note; (2) content of discussion that reveals participants’ views of teaching and learning, and related teaching emotions (using key concepts in notes as unit of analysis). Cohen’s Kappa (k) was used to compute inter-coder reliability (= 0.74). Wilcoxon signed-rank test was employed for analysis of above three views from the three stages.

Findings, discussion, conclusions and implications

According to the analysis of online activity logs and discussion notes in KF, we found the following four main findings: (1) There is an increasing trend from stage 1 to 3 in terms of number of words written per-note, indicating that under principled guidance, participants progressively became more thoughtful and reflective on their critical teaching incidents during discussion. (2) In terms of participants’ teaching emotions, z-test showed that from I-PT to Back-to-I-PT (stage 1 to 3), there was a significant increase in more positive emotions ($z=-5.592^{**}$, $p<0.01$), but no significant change in negative emotions. This suggests that PT activity in a KB environment was effective to cause emotional reflection among teachers. The persisting negative emotions only imply that there were still conflicting views between teaching and student learning that requires further deeper thinking. (3) In terms of teaching views, from stage 1-3, there showed a significant increase in student-centered view ($z = -7.472^{*}$, $p < 0.05$), while there was a significant decrease in teacher-directed view ($z = 5.119^{**}$, $p < 0.01$). This suggests that the participating teachers are exploring possibilities for student-directed learning, thereby implying the development of a more informed teaching views. (4) In terms of the learning views, from stage 1-3, there showed a significant increase in creation-oriented learning view that is deemed essential for the 21st century education ($z = -2.428^{*}$, $p < 0.05$); and, in contrast, there showed a significant decrease in acquisition-oriented learning view ($z = 5.064^{**}$, $p < 0.01$), while there was no significant difference in terms of participation-oriented view. As creation-oriented learning view is more compatible with a student-centered teaching view, this may explain why there is an increasing trend of positive epistemic emotions as well from stage 1 to 3.

To sum up, this study used KB principles to guide and engage the participants in taking different perspectives to discuss some past teaching critical incidents in a KB environment (i.e. KF). The study intends to shift the focus of teachers’ professional development from externally acquiring core teaching knowledge, to internally reflecting on one’s epistemic views and emotions. The main finding suggests that incorporating PT activities to discuss critical incidents in a KB environment seems effective. Accordingly, we conclude that PT as a pedagogical means can help enable teachers to form some self-distanced perspectives to reflect deeply on their teaching experience as tacit knowledge with a more objective, holistic, and diverse views. At the same time, our finding also suggests that the application of KB principles can help the participating teachers more effectively engage in the collective discussion and reflection activities online to better understand themselves as teachers and integrate differently teaching and learning perspectives more coherently and deeply. In addition, KF provides a computer-supported collaborative environment that helps engaged the participants in community-oriented (rather than individual-based) PT reflection. Future research could explore the integrated use of PT and KB in greater depth by including a control group to better validate that this is an effective way of promoting teacher professional development.

Figured Worlds of Emerging STEM Education Researchers

Shams El-Adawy, Cydney Alexis, Eleanor C. Sayre
shamseladawy@ksu.edu, calexis@ksu.edu, esayre@ksu.edu
Kansas State University

Abstract: Various experiences bring STEM (Science, Technology, Engineering, and Math) researchers to discipline-based education research (DBER), but there is little research on their conceptualization of and navigation into this new area of research. Pairing phenomenography with the figured worlds framework, we discuss how emerging STEM education researchers identify within DBER and negotiate how this new research field fits with their primary one. Our findings highlight salient negotiations they are encountering in their DBER engagement, which provides us with insights into the opportunities needed to better support their professional development.

Introduction

DBER, discipline-based education research, is an interdisciplinary field that investigates discipline-specific learning and teaching that is often paired with more general research on human learning and cognition (National Research Council (U.S.) et al., 2012) and has substantial overlap with the learning sciences. DBER draws from learning practices from disciplinary science, whereas learning sciences provides a complementary perspective by drawing from the psychology of learning, cognition, and development. Our work investigates how emerging STEM education researchers, particularly classically trained STEM faculty transitioning to DBER, identify and/or imagine their positioning in DBER. Their positioning has not been examined before; rather, prior work focuses on the way emerging STEM education researchers' projects evolve. Taking an identity and positioning frame to better understand the adjustment of new DBER scholars, we address the following research question: How do emerging STEM education researchers currently perceive their DBER role? We interview emerging STEM education researchers and present a preliminary analysis that focuses on how they negotiate DBER into their professional lives.

Theoretical framework: Figured worlds

Figured worlds is a theory that captures how individuals imagine or identify their identity and position within a particular context that is social, cultural, and historical (Holland et al., 1998). Figured worlds allow us to examine identity formation as an evolving narrative or storyline constructed due to interactions within a sociocultural space. The identity formed within a figured world comes from participation in its activities and from processing the meaning of one's identity in a given socio-cultural context. The framework draws attention to how people process entry and growth as learners in a new sociocultural space; how they make sense of the space's norms; how they situate themselves and the contributions they bring; and how they perceive the power dynamics at play (Urrieta, 2007).

Context and methodology

A significant portion of our study data was collected in a professional development program named "Professional Development for Emerging Education Researchers" (PEER), which was designed to help STEM faculty, postdocs, and graduate students jumpstart their transition into DBER (Franklin et al., 2018). Our 28 interview participants included researchers with a disciplinary emphasis in mathematics, physics, and biology. We analyzed our data using a phenomenographic approach, which is a research methodology examining how individuals experience a phenomenon (Marton, 1986). Through the repeated reading of the interviews, categories of experiences were identified, followed by the creation of definitions and codes. The first author gathered all the categories, codes, and quotes, refining definitions and codes continuously. The analysis was collaboratively discussed until consensus developed among the project's research team.

Analysis: Central theme of negotiation

A significant theme identified is how emerging STEM education researchers negotiate their position and identity in DBER vis-à-vis their home discipline.

Negotiating positioning in DBER and DBER collaborations

Some negotiators seek to balance improving their teaching and engaging in DBER. A full professor of mathematics at a regional undergraduate serving US institution reflects on the ways to position himself in DBER as a collaborative field. He wonders, *"What's the way to work with education research or what's the overlap"* between doing DBER himself or collaborating with DBER researchers as an engaged instructor, and how he can be *"part of that community."* He is trying to figure out how to collaborate with education researchers in productive ways but is unsure of what expertise DBER values and what a classically trained STEM researcher can contribute. This navigation of norms of collaboration and scholarship in an interdisciplinary field is daunting to emerging scholars in the field, even for experienced researchers in other areas, which impacts how this negotiator positions themselves in DBER and how they see it as a figured world.

Negotiating identity in DBER

This type of STEM education researcher is negotiating which aspects of their professional life drive their DBER engagement. One of the participants who is a math instructor at a US public research institution reflects on her professional identity as having tension between mathematics and mathematics education research: "*I was a mathematician, but no, I'm not a mathematician anymore. Oh, and maybe I'll be a math ed researcher? No, I'm not really a math ed researcher either."* This researcher no longer identifies with her past experiences, which influences her lack of identification as a mathematics education researcher. Her DBER identity becomes a mediating force that causes her to reconsider and renegotiate her professional identity**.**

Negotiating tension between DBER and traditional STEM disciplines

This type of negotiator highlights how some STEM faculty are skeptical of DBER results. One tenured math professor in a mainly undergraduate US institution stresses that some senior mathematicians and faculty *"don't value math education research."* She imagines senior mathematicians saying "*you can't possibly capture what I know from my decades of experience. Like, math education researchers just can't do it."* Part of her mathematics figured world includes devaluing education research results, as embodied in these imaginary-yet-powerful experienced mathematicians. As this type of negotiator imagines herself engaging more in DBER, she highlights the challenge of navigating tensions between DBER and classical STEM disciplines.

Discussion and conclusions

This analysis of interview data examines how STEM education researchers conceptualize themselves as they negotiate their DBER figured world. They imagine how they can integrate their expertise into this collaborative and interdisciplinary space, as they take up new research identities. They experience a tension between education research and practitioner expertise, which highlights the challenge of committing to DBER as a classically trained scientist. To help build capacity and acclimate new researchers, support could include explicit discussions about these negotiations to help researchers imagine their figured worlds. Helping STEM education researchers manage the tensions between DBER and classical research fields can promote persistence and strengthen ties. In turn, knowledge-sharing around these challenges can help researchers transition smoothly.

Finding a Sense of Belonging: Linguistic and Social Marginalization in Education in Rural India

Jessica Chandras, University of North Florida, j.chandras@unf.com
Sameer Honwad, University at Buffalo (SUNY), sameerho@buffalo.edu
Devayani Tirthali, Independent Researcher, dgt2103@columbia.edu

Abstract: In India, significant challenges exist in education for students from marginalized language communities. India is incredibly linguistically diverse but education is offered in only twenty-three languages. We explore the case of Banjara students, a marginalized Tribe in Maharashtra, who speak a different language at home than their non-Banjara peers. This study examines Banjara experiences of the language gap between school and broader communities to develop ways to address closing the gap in the future.

Introduction

India is the world's largest democracy and socio-culturally one of the most diverse nations in the world, with 122 official regional languages spoken across approximately 1.3 billion people (Guha, 2017). The diversity comes with challenges related to socio-linguistic inequities. One of the ways in which social inequities get perpetuated is through language use in classrooms (Mohanty, 2019). In India, school-based curriculum is often taught in one of the twenty-two official state languages or in English (Annamalai, 2001). Even after the recent emphasis on Indian languages to 'decolonize' education, the use of official state languages as language of instruction, recreates the colonial power structures that prioritize monolingual monocultural practices, suppressing the marginalized communities and their languages (Panda, 2023). Students who do not speak the regional or state language at home and in their communities find the learning process challenging when they attend school (Groff, 2017). In Maharashtra, a western Indian state, Marathi is the dominant regional language used for official transactions and education in addition to English. Students from marginalized communities who do not speak the dominant regional language at home or in their communities often do not find a sense of belonging in the classrooms. In this study, we explore the case of Banjara students, a socially marginalized Tribe in Osmanabad District in Maharashtra. Banjara students speak a different language at home (Banjara) than their peers who use Marathi, Maharashtra's state language and language of instruction in government-funded schools in the region. Banjara communities across India were previously branded as "Criminal Tribes" during the British colonial period due to the notion that their nomadic lifestyle and occupations were socially deviant. The community continues to face marginalization and social, economic, and educational disenfranchisement which is compounded by Banjara youth's inability to communicate in the state language when entering school (Ramaswamy & Bhukya, 2002l; Schwarz, 2010). As they progress through their schooling, Banjara-speaking students distance themselves from their language because learning Marathi in school is both a means to assimilate to educational norms and mediate their experiences of social marginalization and stigma.

In the Osmanabad District in Maharashtra, Banjara children attend schools in or near their home communities, called tandas, where teachers are non-Banjara speaking. Students therefore must adapt from their mother tongue at home to Marathi in school, even if they attend school with their Banjara-speaking peers. This poster describes the learning challenges Banjara students face where there is no formal or official support provided to help them bridge the gap between the language spoken at home and the language of instruction in school. The poster details findings from a first phase of a broader research project on how Banjara students (6th through 10th grade), and community members understand the problem that Banjara students face. Future phases of the study will progress to understand what solutions community members, teachers, school administrators and students themselves think to close the language gap between schools and communities.

Theoretical background

We ground this work in learning sciences theories that help us understand how to design educational research projects for learners who live in Indigenous and colonized spaces (Smith, Tuck & Yang, 2018). A major problem within Indigenous communities is that youth have limited access to resources in the formal education system that allows them to merge their ethnic identity with the content that is being taught (Kovach, 2010). Learners from Indigenous cultures construct concepts taught in the classroom in parallel with Indigenous concepts, with very little interference and interaction between the two (Jegde, 1995). It is important to note that many learners from Tribal communities desire to break the cycle of assimilation and associated loss of culture (Nelson, Adger, &

Brown, 2007). The project described in this paper is the first step to understand how to create a sense of belonging for learners from the Banjara community in western India.

Research design

We collected data using qualitative ethnographic methods in June 2022. We conducted 34 interviews with 7 parents, 17 educators, and 11 students. We also conducted approximately 35 hours of observations in educational spaces and tandas.

Analysis and findings

Most school materials and instruction is in Marathi, with some textbooks and lessons in Hindi and English as well. Banjara students note a stark transition in terms of language when they begin school. It is usually in school where they learn Marathi, but not necessarily from lessons or teachers. In narratives of assimilation to educational and societal norms and expectations for success, students describe a slow and often painful process lacking in scaffolding or resources to aid in the linguistic transition. Pratiksha, among other quotes on a poster, discusses how informal assistance to learn Marathi came from her peers.

> "In the first grade I couldn't speak any Marathi, and in second grade I could speak a little bit, and then in third grade I could speak just a little more. I just didn't know how to speak and I couldn't understand. [...] The teacher used only Marathi and my friends would say, "Why don't you raise your hand in class, is that because you can't speak Marathi?" "Yes, that's why." So, my friends used to write things down for me and I would remember them and repeat them. I couldn't read and I couldn't even speak. And everyone used to put their hands up (when the teacher asked questions). And I couldn't, but slowly Marathi came."

Language assimilation is a gradual process that generations of Banjara-speakers experience where students from Banjara communities must adapt to speaking, reading, and writing Marathi. A mother from one of the most disadvantaged Banjara tandas, said, "If we speak Marathi at home, [children] will also speak Marathi." When a schoolteacher asked her to speak Marathi at home, her response was, "If the teacher asks, we have to obey." Parents motivate younger generations to assimilate to the linguistic norms needed for jobs that offer more economic advancement. There is a recognition of values assigned to languages that brings into focus how the Banjara language is of limited use in broader society. Banjara-speaking students concurrently articulate both an ambivalence towards and an awareness of dynamic intersections of power with impacts of overlapping caste and class categories in socially and linguistically stratified settings. Balaji Dada, a Banjara educator, said, "Our language will just keep us in our group." Remaining in a tanda and using Banjara means that one remains limited in jobs.

Discussion

Implications of this study demonstrate that a production of identities for Banjara youth includes negotiating their social statuses within a structure of linguistic hegemony for social advancement through assimilation to the majority language group. To be educated in the Banjara community in the Osmanabad District in Maharashtra carries an expectation of suffering through a difficult transition of learning Marathi independent of others and independent of assistance from authority figures such as teachers. Banjara-speaking students concurrently articulate both an ambivalence and an awareness towards dynamic intersections of power with impacts of overlapping identity categories where language is mapped onto identity and belonging in socially and linguistically stratified settings (Bucholtz & Hall 2005). We have explored Banjara student's perceptions of identities and orientations to education in this phase of research. In next phases, we plan to explore classroom discourse directly and develop interventions for educators.

Supporting K-12 Computer Science Formative Assessment Evaluation & Teacher Assessment Literacy

Shuchi Grover, Looking Glass Ventures, shuchigrover@acm.org
James W. Pellegrino, University of Illinois Chicago, pellegjw@uic.edu

Abstract: As K-12 computer science (CS) education expands, there is a growing recognition of the need for formative classroom assessment practices. Grover's recently developed formative assessment framework for K-12 CS provides guidance, however tools for *evaluating* formative assessment remain a gap—as evidenced in feedback to our formative assessment literacy PD efforts. This paper examines the suitability of Pellegrino et al.'s validity framework for instructionally relevant assessment for use in K-12 CS classrooms and teacher PD.

Background & motivation

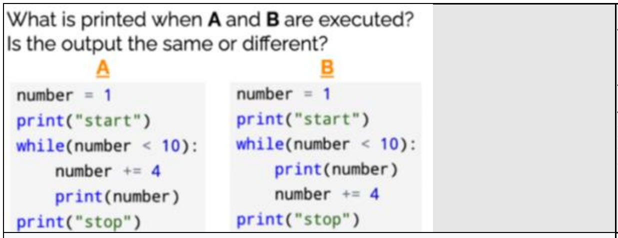
Teachers across the US are now teaching coding and computer science (CS) as part of a rapidly growing "CS for All" movement aimed at teaching CS to all K-12 learners. There is healthy progress on many aspects of this endeavor, including the creation of tools, curricula, teacher professional development (PD) programs, and research on CS teaching and learning (for students and teachers) and implementation. However, gaps remain in teacher preparation, key among which is the ability to measure student learning in the classroom for the purpose of improving learning outcomes for all students (Vivian et al., 2020).

Formative assessment is assessment ***for*** learning, or measurement that helps monitor student learning and inform subsequent teaching moves. There is compelling evidence that attention to classroom formative assessment can produce greater gains in student achievement than any other change in what teachers do (Wiliam & Leahy, 2012). Professional learning of classroom assessment practices is *formative assessment literacy*. Teachers new to a content area and/or teaching practice face many challenges when it comes to engaging in appropriate assessment practices in their instruction (deLuca & Klinger, 2010). In order to address this need, we drew on a formative assessment framework for K-12 CS (Grover, 2021) to design and pilot a CS assessment literacy PD module, Formative Classroom Assessment for Teachers (FCAT), that is now publicly available as a "PD-in-a-Box" and in active use by various CSTA chapters in the US. Feedback on our three-session FCAT pilot and a CSTA conference workshop (total N=~500 teachers) was overwhelmingly positive, suggesting that FCAT succeeded in meeting its goals in helping teachers develop a foundational understanding of formative assessment (Grover & Twarek, 2023). However, several teachers requested tools to evaluate formative assessments.

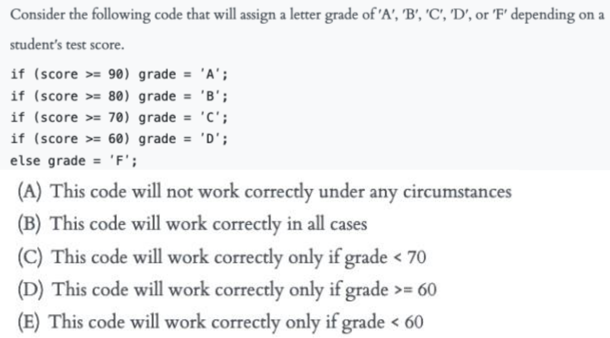
Table 1
Evaluating K-12 CS classroom assessments on cognitive, instructional & inferential validity

Example Assessment	Evaluation/Analysis
 What is the value of the variable **steps** after these two blocks are executed? set steps to 10 move (steps + 10) steps A. 0 B. 10 C. 20	Cognitive: This is a good assessment as it clearly targets when/how variable values change/are updated. Instructional: Variables are a key concept. Inferential: Excellent diagnostic question and points to what must be done if students do not get this right. (For example, step through code and inspect variables, demonstrate the use of a 'set' and 'change' block).

 Look at the code below and predict where the bee sprite will appear. What will the program show?
`var bee = createSprite(200,200);`
`bee.setAnimation("bee");`
`bee.x = 350;`
`bee.y = 350;`
`drawSprites();`
(A) a bee sprite in the middle of the screen
(B) a bee sprite in the bottom right corner
(C) two bee sprites, one in the middle and one in the bottom right corner
(D) three bee sprites, all in different places
(E) nothing, there will be an error
	Cognitive: This assessment targets knowledge of the coordinate system for the Code.org programming environment "stage" as well as basic Javascript animation functions; neither is a generic domain skill for programming (same for Scratch stage-related Qs)
	Instructional: Presumably this content is covered when introducing learners to the programming environment
	Inferential: Weak. Since this assessment involves an understanding of basic Javascript functions to create and animate a sprite, as well as the x/y coordinate system of the stage, an incorrect answer could point to a lack of understanding of either of those.



What is printed when **A** and **B** are executed?
Is the output the same or different?
A
`number = 1`
`print("start")`
`while(number < 10):`
`    number += 4`
`    print(number)`
`print("stop")`
B
`number = 1`
`print("start")`
`while(number < 10):`
`    print(number)`
`    number += 4`
`print("stop")`
	<u>Cognitive</u>: This assessment targets how: while loops work, expressions control loops, and update of variables.
	<u>Instructional</u>: Loops are a key concept in programming
	<u>Inferential</u>: Even though 2 concepts are targeted, the responses provide a clear indication of where a student is lacking understanding. It targets a common misconception students have about 'while' loops



Consider the following code that will assign a letter grade of 'A', 'B', 'C', 'D', or 'F' depending on a student's test score.
`if (score >= 90) grade = 'A';`
`if (score >= 80) grade = 'B';`
`if (score >= 70) grade = 'C';`
`if (score >= 60) grade = 'D';`
`else grade = 'F';`
(A) This code will not work correctly under any circumstances
(B) This code will work correctly in all cases
(C) This code will work correctly only if grade < 70
(D) This code will work correctly only if grade >= 60
(E) This code will work correctly only if grade < 60
	<u>Cognitive</u>: This is a good assessment as it targets if statements and flow-of-control. *However*, there is a possible confound with understanding of the mathematical relational operator (>=) which many K-8 students finding confusing.
	<u>Instructional</u>: Conditional logic is a key part of teaching intro programming and it scores high on this feature.
	<u>Inferential</u>: If words like 'greater than or equal to' were used instead, it would be an excellent diagnostic question with clear follow-up feedback if students do not get this right. (code-tracing with various values of score including edge cases).

A framework for evaluating formative assessments for K-12 CS classrooms

Pellegrino, DiBello, and Goldman (2016) draw on contemporary thinking on validity of assessments to propose a framework for conceptualizing and evaluating the validity of classroom *assessment that is intended to function close to instruction*. It includes 3 validity components/dimensions: **Cognitive**: how well does assessment align to a domain knowledge/skill in ways that are not confounded with other aspects of cognition such as language or working memory load?; **Instructional:** how well is an assessment aligned with curriculum and instruction, including students' opportunities to learn?**;** **Inferential**: how well does the assessment accurately provide information & feedback about student performance for diagnostic purposes and follow-up action? Table 1 shares analyses of sample assessments relative to the three validity dimensions described. The contrasting cases of good assessments (grey) versus those needing improvement serve to highlight variations in assessment quality.

Based on our evaluation effort, we found the 3 validity categories useful & straightforward to use. However, we also concluded that (1) some assessments, especially those pertaining to the syntax and specifics of a programming language, are necessary for formative feedback but are not aligned to a CS domain skill or K-12 CS standard. It would be helpful for CS teachers to draw this distinction as they evaluate items; (2) evaluation on **instructional** is contextual (*was this topic taught in this particular classroom?*) when done in the abstract (as we have) but it would be easy for a teacher to evaluate an assessment on this component. We believe that this evaluation framework should be a part of K-12 CS teacher assessment literacy PD such as FCAT and any K-12 CS formative assessment framework would also be more robust with the inclusion of these evaluative elements.

Engagement With an Online Syllabus: Preferences for Design and Interactivity

Emre Dinç, Jennifer Sisco Babb, Maria Scalzi Wherley
ezd287@psu.edu, jls164@psu.edu, mrs110@psu.edu
The Pennsylvania State University

Abstract: We examined the impact of design and interactivity on undergraduates' engagement with an online syllabus. We found that appealing design and interactivity elements, such as embedded videos and tabs, influenced student engagement. Age, race, gender, and disability accommodations did not affect engagement. A course overview video is recommended.

Introduction

Traditionally, a syllabus provided a schedule and policies but now has taken various forms: "a contract between the instructor and the student," (Parkes & Harris, 2002, p. 55) or a welcoming document for fostering belonging and enthusiasm (Gin et al., 2021). But it is common that students do not read syllabi, as they are often lengthy and boring (Ludy et al., 2016). Attempts at engaging syllabi vary from newspaper-style handouts (Dobersek et al., 2019) to *liquid*, online syllabi featuring design, video messages, and supportive language (Pacansky-Brock et al., 2020). The use of videos is recommended (Johnson, 2022), particularly a warm introduction from the instructor demonstrating an interest in students' learning. In this study, six formats of a single online syllabus were used, with consistent information, language, and tone, but varying in design and interactivity. We examined students' perceptions and interest in the syllabus and their engagement with the different versions. The conceptual framework was based on syllabus studies related to design (e.g., Ludy et al., 2016) and interactivity (e.g., Kim & Ekachai, 2020). We considered images, color, and static charts as design elements, and accordion and tab structures, interactive charts, and embedded videos as interactive elements. We asked, *How do syllabus design and interactivity influence students' engagement with an online syllabus?*

Method

The study was conducted in an asynchronous online geology course at a public university. 515 students participated in six sections. Drupal, Rise, and Canvas were used (see Table 1 and Figure 1). Participants completed pre- and a post-surveys. Impression (Ludy et al., 2016), interest (Keller, 2010), and engagement (Schaufeli et al., 2002) scales were adapted. Dependent samples t-test, one-way ANOVA, and multiple regression analyses were conducted. Qualitative data was analyzed using a coding scheme based on our conceptual framework.

Table 1
Syllabus Information for Different Sections

	Syllabus design	Syllabus interactivity	Course content is in	The syllabus is in
Section 1 (n = 90)	text only/no design	no interactivity	Canvas	Rise
Section 2 (n = 76)	text only/no design	with interactivity	Canvas	Rise
Section 3 (n = 105)	design included	no interactivity	Canvas	Rise
Section 4 (n = 101)	design included	with interactivity	Canvas	Rise
Section 5 (n = 89)	text only/no design	with interactivity	Canvas	Canvas
Section 6 (n =54)	text only/no design	no interactivity	Canvas	Drupal

Quantitative results

Only Section 5 had a significant improvement in students' perception of the syllabus being easy to navigate and comprehensive. The overall impression score significantly improved only in Section 5. Section 6 had the lowest means on all impression subscales, while Section 5 had the highest means on the subscales of easy-to-navigate and comprehensiveness. Before the study, there were no significant differences in impressions between sections. However, after using the assigned syllabi, Section 4 found their syllabus to be significantly more visually appealing than Section 6 found theirs. Age, gender, disability accommodation, and race did not significantly affect student engagement with the syllabus. Referring to the syllabus, preference for design and interactivity, the impression of and interest in the syllabus, and the text/video format of the course overview and instructor introduction significantly affected engagement.

Qualitative findings

We examined qualitative data from three sections (Sections 1, 4, and 5) based on the quantitative results. 16 participants' post-survey responses per section were included. Participants in only Section 4 were shown videos. Including videos in a syllabus resulted in positive perceptions and a preference for the inclusion of videos in a syllabus. Sample quote: "I think making a syllabus more interactive [with videos] is a great way to get students involved in reading it [the syllabus]" (Section 4). Participants who did not experience course overview videos in this study expressed concerns about the use of video in the syllabus. Sample quote: "When I refer back to the syllabus, I want to find a certain section to read quickly, not comb through a 5-minute video" (Section 1). Participants in all the three sections praised the inclusion of design in their syllabi, citing increased visual appeal, ability to skim quickly, engagement, and interest. Participants in Section 4 were particularly positive about the efficacy of design in their syllabus. Sample quote: "All of the words [text-only] can seem overwhelming at times, so it might be beneficial to include more images" (Section1). Participants from sections 4 and 5 found their syllabi more interesting and enjoyable than those from Section 1, possibly due to the interactivity included in Sections 4 and 5. Sample quote: "It [a syllabus with short videos, images, and colorful infographics] is more interesting and visually appealing than a wall of text that makes everything seem of equal importance" (Section 1).

Figure 1

Design and Interactivity Samples from the Online Syllabi of Sections 1, 4, and 5

Section 1 Section 4 Section 5

Conclusion and recommendations

Design and interactivity in an online syllabus significantly affect students' engagement with the syllabus. We recommend including colors, images, videos, accordions, and tabs. We found that age, gender, race, and disability accommodations did not have a significant effect on student engagement with the syllabus. We suggest that further research is needed, given the diverse student population in higher education. Our study suggests that students prefer instructor introductions that are presented via text. We recommend including a short course overview video.

The Marketization of Education: A Microanalytic Analysis

Etan Cohen, The Ben-Gurion University of the Negev, etancohen@gmail.com
Tal Carmi, The Ben-Gurion University of the Negev, talcarmi.mail@gmail.com
Adam Lefstein, The Hebrew University of Jerusalem, adam.lefstein@mail.huji.ac.il

Abstract: The neoliberal turn inspired processes of marketization, meaning that Discourses originating in the business sector are applied to educational contexts to construe education as a competitive market selling products and services to consumers. But *how* does marketization occur? In this poster we use linguistic-ethnographic methods to explore how the marketization of educational discourse played out in the context of a learning community comprising educational practitioners who were exploring the notion of teacher inquiry and who were led by an organizational consultant who encouraged them to adopt a business Discourse. Our findings revealed an initial resistance to this Discourse, an incompatibility between business and educational Discourses, and the means by which the business Discourse ultimately took hold.

Theoretical background

A figured world is "a picture of a simplified world that captures what is to be taken for typical" (Gee, 2011, p. 71) that is construed by individuals and communities to make sense of their social surroundings and their positions within them. The education system is one example of a figured world that can be construed in various ways. Big-D Discourses are "ways of combining and integrating language, actions, interactions, ways of thinking [etc.] … to enact a particular sort of socially recognizable identity" (Gee, 2011, p. 201). Discourses are reflexively linked to figured worlds, meaning that they are co-constitutive (Gee, 2011). Individuals draw on the resources that are available to them through their social identities and discursive repertoires to construe figured worlds. Concurrently, the way in which figured worlds are construed foregrounds certain Discourses that are taken as normal. Figured worlds and Discourses are fundamental elements of learning, when it is viewed as a situated activity that is defined in terms of identity and community (e.g., Lave & Wenger, 1991).

Fairclough (1993) argued that the adoption of a neoliberal Discourse can fuel a process whereby the figured world of education is construed as a free market driven by profit and competition. In Israel, where we conducted our study, the high-tech sector is especially influential. Several scholars have therefore focused on the ways in which Discourses imported from high-tech have shaped Israeli education. For example, Ramiel (2019, p. 11) argued that redefining Israeli learners as *users* "universalizes the teacher, student and schools, […] tends towards 'global uniformity' or a 'one size fits all' approach [and] unifies all students under an uncritical technological solutionism" (see also Tamir & Davidson, 2020). In this poster, we explore some micro-processes underlying one attempt to introduce a business Discourse imported from high-tech in order to marketize education. Specifically, in this case study we investigated one community's learning trajectory, asking how a business Discourse came into play, what figured worlds interlocutors construed in response to it, the challenges that they encountered, and how, ultimately, the business Discourse shaped the learning process in consequential ways.

Methods

Context

The data for this poster were collected as part of a Research-Practice Partnership between our University and the INBAR Institute (we use pseudonyms throughout), a "national intercollegiate center for the research and development of curricula and programs in teacher education" (INBAR website). Recently, the Institute's leadership was dissatisfied with intra-organizational coordination and knowledge management. To improve them, INBAR established a learning community comprising nine professionals representing six different units who met bi-weekly, to explore the notion of *teacher inquiry*. In addition to the shared bi-weekly meetings, the team also met for a series of three two-day seminars, which marked the beginning, middle, and end of their yearlong collaboration. These seminars were led by Eric, an experienced organizational consultant who used to work as a software developer. In the sessions he led at the seminars, Eric imported discursive tools from high-tech that were business-oriented to improve the group's work and outcomes. We identified these sessions as a unique opportunity to analyze the marketization of education.

Analysis

We drew on linguistic ethnography, which combines the rigor of linguistics with the situatedness of ethnography (Rampton et al., 2015). This involved a review of our entire corpus of field notes, selection of a sequence of interactions that was especially *telling* (Tabak & Baumgartner, 2004), detailed transcription, and discourse analysis methods to investigate the emergence of interactive meaning in the sequential unfolding of the interactions. Our turn-by-turn analysis of the sequences drew on Gee's (2014) approach to discourse analysis, and particularly on the view that in addition to conveying ideas, language also functions as means of engaging in socially recognizable activities and identifying as certain types of people. Hence, we asked about each turn at talk: (1) What ideas the interlocutors were conveying; (2) what socially recognizable activities they were engaged in (or were encouraging others to engage in); and (3) what socially recognizable identities they assumed.

Data sources

As participant-observer, Etan attended all team meetings, documenting them through video recordings and field notes, and conducted 16 semi-structured interviews with the team members. Our analysis focuses on a sequence of three interactions that was purposefully selected because it was especially telling vis-à-vis our research questions. We also note that our interpretations embodied a broader ethnographic analysis and reflected our understandings of the entire data set and Etan's experience as participant-observer.

Findings

In this section, we analyze a sequence of three brief interactions that occurred during the second 2-day seminar in February 2022, which portrays a shift in the learning community's Discourse. Prior to the seminar, the Discourses employed by the community and the identities assumed by its members were primarily academic: they spoke in terms of theories, data, and research methods; and conducted literature reviews and interviews to advance their goals. Yet Eric, the group moderator, encouraged them to forgo their academic Discourse, and adopt elements drawn from a business Discourse that he associated with high-tech culture, instead. The first interaction in this sequence of three shows that when these efforts were abstract and overt, the group resisted them. The second interaction reveals some tensions and obstacles that emerged when there were multiple and incompatible Discourses at play. And finally, the third interaction shows how the use of a cognitive tool ultimately mediated a process of marketization, as the team adopted a business Discourse to engage in their educational pursuits.

Discussion and conclusion

In this poster, we focus on the marketization of education, and singled out one process by which the figured world of education came to be reconstrued as a business. While far from exhaustive, our microanalytic account showed how one learning community grappled with an attempt to shift its knowledge building activity away from an academic Discourse, and towards a business one that was imported from the high-tech sector. Despite initially resisting the effort to marketize their discourse, the community ultimately succumbed, begging the question: Why?

Our data suggests that one possible reason for this outcome may be that the community resisted the business metaphor only so long as it was advanced overtly and in the abstract (interaction 1). However, adoption of the Business Model Canvas to advance the team's knowledge was a far more subtle proposal, and thus less contentious. Although it initially generated some confusion (as outlined in interaction 2), it was seen as a productive way to move forward nonetheless (interaction 3), which significantly impacted the team's work.

Exploring the AI Experiences of Rural Students and Teachers: A Sociocultural Perspective

Jessica Vandenberg, North Carolina State University, jvanden2@ncsu.edu
Danielle Boulden, North Carolina State University, dmboulde@ncsu.edu
Veronica Catete, North Carolina State University, vmcatet@ncsu.edu
Wookhee Min, North Carolina State University, wmin@ncsu.edu
Bradford Mott, North Carolina State University, bwmott@ncsu.edu

Abstract: Artificial intelligence (AI) education is especially needed for young rural students who have limited access to high-quality learning opportunities. We are developing an AI-centered learning environment that introduces rural middle grades students to AI concepts through digital game design activities. We interviewed students and teachers on their understanding of and background with AI. The results will guide the design of our professional development for teachers and game design activities for students.

Introduction and theoretical framework

Artificial intelligence (AI) education is increasingly seen as a critical endeavor for students to be successful in the world and workplace of the future where AI will be ubiquitous (Touretzky et al., 2019). It is essential to expand efforts to increase students' interest in AI and provide youth with early AI learning experiences, especially middle grades students who are developing their perceptions and dispositions toward STEM (English, 2017). Rural schools, which represent approximately 80% of North Carolina schools, are smaller and more isolated than their urban and suburban counterparts and face challenges with attracting and retaining high-quality teachers and student access to advanced coursework in STEM (Assouline et al., 2017). Game design holds potential for cultivating student interest and knowledge in computing (Comber et al., 2019), and game-based learning shows potential for teaching AI concepts to K-12 students (Lee et al., 2021). Our AI-centered learning environment, called AI PLAY, introduces AI concepts to middle grades students (ages 11-14) and teachers through camps and school-based programs in rural North Carolina. In this work, we present our initial findings from student and teacher interviews on their understanding and use of AI.

Sociocultural theories posit that all learning must consider social and cultural dimensions of human interaction and that these dimensions become internalized as children learn and mature (Vygotsky & Cole, 1978), indicating that childrens' surroundings—be they human or environmental—shape their knowledge and experiences. Our context, computer science (CS) in general and AI in particular, is not broadly accessible to all students. Rural students often have restricted access to innovative educational opportunities and their families and teachers are more likely to not have had these experiences either. As such, a goal of our work is to augment rural students' social capital by fostering their skills to learn and use CS and AI now and in the future.

Methods

We conducted interviews and focus groups with rural participants: nine students and two teachers. All interviews were conducted and recorded via Zoom video conferencing. We utilized a semi-structured protocol that queried participants on their background knowledge of AI, experiences with coding, and gaming interests. Two members of the research team individually open-coded the transcripts and met to discuss the codes. A third team member facilitated collapsing codes into themes, which we report below.

Findings

Teachers

Our teacher participants taught at rural, low-income schools and their courses focused on prescribed curricular materials that did not specifically target goals for in-depth CS or programming concepts. Both teachers acknowledged providing some time for their students to experiment with coding using physical computing with drones or robots, with one describing these experiences as an "incentive." Both teachers had either limited or dated prior training with CS and programming. When asked about their knowledge of AI, both teachers candidly expressed that they knew very little; however, they were receptive to professional development (PD). One teacher noted "[AI is] obviously kind of trending in that direction in the future, so I think it's important for students to learn about it." Both teachers felt that students would be motivated by an engaging game design-based learning experience to learn about AI.

Students

When asked to share what AI is, students' responses included the following, under the theme of *programming and general computer usage*: "stuff that's online," "computers [are] robots," and "a coffee machine." Under the theme of *AI awareness and understanding*, students' responses ranged from superficial awareness (i.e., "smart computers") to more pronounced understandings of AI (i.e., "the doorbell camera… will pop on" and "drones can water plants"). When asked to share their background with programming and gaming, most students knew of Scratch and many had coded a game using Roblox. Students mentioned learning about programming from a parent, YouTube, or simply from playing online, and not in school. All students indicated they played digital games and when asked their interest for learning about AI through digital game design, students expressed a high degree by saying "if you know how to code you could essentially get a job that involves coding" and "it'd make the game more funner (sic) to play."

Discussion, conclusions, and future directions

We approached understanding what rural middle grades learners and educators know about AI by interviewing students and teachers. Despite having a limited number of participants, we surmise that their experiences are common across rural areas of our state. Sociocultural perspectives help us understand the role of a person's immediate environment—people and devices—in what they know. We know that rural schools and families often lack access to the internet, suitable devices, and diverse learning opportunities. The students in this initial study have more of an understanding of AI, albeit often superficially, than their teachers, which has prompted us to consider the accuracy of what students know about AI and CS. North Carolina does not certify middle grades teachers as CS teachers; as such, middle grades students tend not to have teachers with specific training in CS and programming. One of our goals is to augment the training middle grades teachers receive in service of exposing more students to advanced technologies, programming, and AI. Additionally, teachers' awareness of what students could learn about AI was limited and therefore, any professional development must explicitly teach these concepts to teachers. Students had high enthusiasm for playing and designing digital games; therefore, teaching advanced technologies through game design holds great potential for their learning and potentially their career trajectories. These initial findings are essential as we design a set of prototype activities on core AI concepts for students and PD activities and resources for teachers.

Analyzing Collective Imagination: A Complex Systems Approach

Brandon Reynante, Stanford University, reynante@stanford.edu

Abstract: Typical approaches for investigating collaborative learning and problem-solving neglect how individual interactions give rise to emergent group-level behaviors. In this study, I adopted a complex systems approach to analyze collective imagination during a collaborative fiction writing activity in a high school classroom. I qualitatively coded discourse data at two levels of analysis: individual talk turns and collective imagination episodes. I employed nonlinear computational analysis techniques to examine the multilevel time series data.

Introduction

Imagination is a complex form of mental activity where consciousness transcends the here-and-now of proximal experience to mentally represent objects, ideas, images, and world states not currently present (Vygotsky, 1980). It is both an individual cognitive process as well as a situated and distributed social process (Kolovou et al., 2021). Movement towards a shared imaginary space has been suggested to coincide with collaborative emergence: a flow of ideas among individuals who are directed toward the same imagined object (Kolovou et al., 2021).

Typical approaches for investigating collaborative learning and problem-solving neglect the dynamics of how individual interactions give rise to emergent group-level behaviors, which generally exhibit nonlinearity where patterns at the macro-level have different properties from the constituent parts (Hilpert & Marchand, 2018; Jacobson et al., 2019). Quantitative linear cause-effect models are only apt for contexts where a linear relationship among components exists (Hilpert & Marchand, 2018). Qualitative methods are better suited for examining nonlinearity and emergence, but the vast amount of data and reliance on textual description can obscure dynamic patterns (Jacobson et al., 2019). There is growing recognition of the importance of using a complex systems approach for investigating learning and collaboration (Jacobson et al., 2019; Hilpert & Marchand, 2018).

In this study, I adopted a computational complex systems approach to analyze a collaborative fiction writing activity in a high school classroom. Specifically, I sought to investigate the following hypotheses:

H1: Group interaction processes will exhibit characteristics of a complex dynamical system.

H2: The emergence of collective imagination will be associated with a flow of ideas among participants.

Methodology

Participants and context

The participants were students in an environmental science class at a public high school in Northern California. They were taking part in a learning experience that integrated engineering and fiction writing to develop stories depicting sustainable climate futures. There was a total of 48 students split into 12 groups of 3 to 5 students each. Participants self-reported demographic information (gender: 65% female, 35% male; age: M = 17, SD = 0.8; race/ethnicity: 71% White, 12.5% Hispanic/Latinx, 12.5% Asian, 2% Native American, 14.5% did not respond). I focus on a single group of four students during a collaborative writing activity to demonstrate the methodology.

Data collection

Dynamic behavior of group interactions can be observed in microgenetic time series data where many measures of the same variable are taken in close proximity over time (Hilpert & Marchand, 2018). Since group-level behaviors emerge from and influence individual-level interactions, one should examine multiple levels of analysis (Hilpert & Marchand, 2018). I considered both individual-level talk turns and group-level collective imagination episodes. To capture this time series data, I audio recorded and transcribed all group utterances.

Data analysis

I used qualitative methods to code the collaborative discourse data and computational nonlinear analysis techniques to examine the coded discourse. Utterances were coded at two levels of analysis (see Table 1). At the level of an individual talk turn, I coded utterances using a collaborative problem-solving scheme. At the level of a discursive episode, I used a binary code for whether two or more members were in a state of collective imagination. Every talk turn received an individual discourse code and a group-level collective imagination code. Two researchers independently coded the entire transcript (~350 utterances) and achieved a pooled Cohen's Kappa of 0.91, indicating excellent inter-rater reliability.

Table 1

Codes for individual-level discourse and group-level collective imagination

Code	Description
1. Team Process (TP)	Utterances that regulate how members organize themselves to get work done.
2. Information Sharing (IS)	Utterances that request or provide simple information about the task itself.
3. Knowledge Sharing (KS)	Utterances that request or provide knowledge beyond simple information.
4. Idea Request (IR)	Utterances that request ideas for addressing the task.
5. Idea Proposal (IP)	Utterances that propose ideas for addressing the task.
6. Idea Elaboration (IE)	Utterances that elaborate on a previously stated idea.
7. Idea Analysis (IA)	Utterances that seek to clarify, evaluate, or (not) support an idea.
8. Acknowledgment / Agreement (AA)	Utterances that recognize receipt of information or that express (dis)agreement.
9. Tangent / Off-task (TOT)	Non-task related utterances.
10. Exclamation / Incomplete (EI)	Exclamations emphatically express emotion.
Collective Imagination (CI)	Two or more members have disengaged consciousness from the proximal experience and are directed toward the same imagined intentional entity.

Regarding H1, one characteristic of a complex system is chaotic dynamics—that is, a balance of randomness and order in system behavior (Hilpert & Marchand, 2018)—which I evaluated using Shannon information entropy, a widely used indicator of disorder (David et al., 2022). To examine H2, I employed two techniques: state-space grids and lag sequential analysis (David et al., 2022). State-space grids are a graphical representation of a system's trajectory as it moves through the range of possible system states defined by the relationship between two categorical variables that are synchronized in time. Lag sequential analysis (LSA) can be used to identify sequential patterns of behaviors. One indicator of the degree of association between two time series in LSA is Yule's *Q*, which yields values between +1 (complete positive association) and -1 (complete negative association).

Results and discussion

Entropy values of the discourse code time series (Figure 1, left) range between 1.5 and 2.1, indicating neither random nor deterministic behavior (David et al., 2020). Thus, H1 is supported: the group interaction exhibits characteristics of a complex system. The state-space grid trajectory (Figure 1, right) shows that collective imagination was most highly associated with idea proposal (IP), idea elaboration (IE), and idea analysis (IA). Significant positive Yule's *Q* values were also found for IP ($Q = 0.49$), IE ($Q = 0.92$), and IA ($Q = 0.36$). Thus, H2 is supported: collective imagination is associated with a flow of ideas. While this study focused solely on a single group interaction, the results demonstrate the utility and novelty of the approach.

Student Motivation in Unplugged Computational Thinking Activities in Upper Secondary Science Education

Niels Bonderup Dohn, Aarhus University, dohn@edu.au.dk
Nina Bonderup Dohn, University of Southern Denmark, nina@sdu.dk

Abstract: In this case study, we investigate the use of unplugged Computational Thinking activities to learn topics within biology and chemistry. The tasks involved constructing decision trees, and thus algorithmic thinking. The students found the activities interesting but also difficult. At the same time, there are signs of utility value because the constructed decision trees could be used for solving exam tasks. Even though the construction of decision trees seems to be a promising way to include CT in science teaching, it may be difficult to do so in every science subject.

‘Unplugged’ computational thinking in upper secondary science education

Computational thinking (CT) is a set of computer science concepts and practices that can be applied to many different disciplines for problem solving and understanding (Grover & Pea, 2013). Incorporating CT into science education may help foster students to learn science content and practices (Wilensky & Reisman, 2006). A large strand within the literature emphasizes that CT can be performed ‘unplugged’, that is, without the step of coding the designed algorithm into a computer program (Caeli & Yadav, 2020). The claimed pedagogical advantage is that students become familiar with the steps of the problem-solving method without the additional complexity of having to learn a code language. This is particularly relevant when CT is utilized to learn other disciplines than computer science. However, there are only a few studies of unplugged CT activities in upper secondary science education, and the few that are published focus on students’ understanding of for instance conceptions of natural selection (Peel et al., 2019). So far there has been very little focus on students’ motivation in relation to unplugged activities. Accordingly, we know very little about the extent to which students want to deal with unplugged CT in science education. In this case study, we therefore investigate students’ motivation in two unplugged CT-activities at the upper secondary level. The study is part of a larger, four-year multiple-case study on embodied CT.

Methodology

This study involves one teacher and his Year 11 biotechnology class, which he taught both in biology and chemistry. The class size was 26 students. The teacher developed two unplugged activities on constructing decision trees, which involves algorithmic thinking, a central element of CT (Grover & Pea, 2013). Tasks were solved in small groups of students. In biology, the task was to construct a decision tree algorithm to be able to distinguish between 7 different inheritance paths in genetics: 1) autosomal dominant, 2) mitochondrial inheritance, 3) dominant X-linked, 4) Y-linked dominant, 5) recessive X-linked, 6) co-dominant, and 7) autosomal recessive. The students had to construct relevant questions for a given inheritance, which could be answered with yes/no, for example: Do all children with trait X also have at least one parent with trait X? Does a father with trait X always have daughters with trait X? The decision tree then had to be tested on several family trees that had been used in previous exam tasks. In chemistry, students were tasked with constructing a decision tree for identifying chemical substances. Classical chemical analysis relies on chemical reactions between the material being analyzed (the analyte) and a reagent that is added to the analyte that is easily detected. For example, the product could be colored or could be a solid that sediments from a solution. The task was to design a decision tree to identify an unknown positive or negative ion from a scheme of precipitation reactions where certain mixtures of readily soluble salts resulted in the formation of a precipitate and eventual color. The next step was to test the algorithm on 10 unknown solutions in the laboratory and count how many reactions they minimally had to make to ensure correct identification. Finally, students calculated goodness-of-fit of their proposed algorithmic model.

The two sessions each lasted 90 minutes. To evaluate students’ motivation, we used self-report with open questions supplemented by classroom observations and informal interviews. In the self-report, produced in a pen-and-paper format, students were asked to describe their positive and negative experiences with the activity and to comment on whether the activity made the content easier to understand. Thus, we did not directly prompt for expressions of motivation so as not to provoke biased responses from the students (e.g., to give answers that they believe the researchers want). Observations, conducted by the first author, were focused on situations in which students were engaged but also on situations where students appeared confused, frustrated, or demotivated. Students who appeared to display particularly high or low motivation were interviewed on how they experienced a given situation, and why it was or was not motivating. The interviews were short, lasting 1–2 minutes.

The analysis was data-driven, as we searched for signs of how involvement impacted students' self-reported understanding of the science content and of motivation. In our search for signs of motivation, we did not limit ourselves to one theory but were open to statements being interpreted inductively in different directions, especially interest (Hidi & Renninger, 2006), self-efficacy (Bandura, 2001), and utility value (Eccles & Wigfield, 2020). The following exemplifies our analysis: In the statement "The activity was fun, especially at the beginning when you had to make the system", we interpret 'fun' as a sign of enjoyment, which is proxy for interest and intrinsic motivation. In the statement "I personally think it was boring" we interpret 'boring' as an epistemic emotion and sign of absence of interest. "It is something we can use in the future" indicates experienced utility value.

Results

The tasks were challenging to most students and required them to engage in a "detective task" (their wording). In biology, the students found it difficult to come up with enough relevant questions regarding inheritance for their decision trees. Several groups initially used trial-and-error. By the end of the lesson, half of the students had a decision tree that worked for all seven types of inheritances, while a third succeeded in making parts of an overall algorithm. When an algorithm worked on a random inheritance path, there was great cheering in class. In chemistry, several groups sat for a long time and discussed while other groups started right on with chemical analysis in the laboratory. As soon as the students had constructed an algorithm that they were convinced was correct, they showed great commitment in the laboratory. However, some students were also frustrated by lack of reaction (nitrate does not react with the tested positive ions, but the students had not realized this and tried adding nitrate).

The results suggest that students find CT-activities with decision trees fun and interesting, allowing them to address curricular content in new ways. Many praised the logical thinking behind the tasks. Wordings like "new", "alternative", and "different" are proxies of interest and intrinsic motivation (Palmer, 2009). At the same time, many students also reported that the CT-activities were challenging and confusing and thus frustrating, indicating attributional thinking on task difficulty with possible consequences for competence beliefs (self-efficacy). According to students' expressions, it required a deep understanding of the biology/chemistry concepts involved to be able to create a meaningful algorithm. Finally, there are signs of experienced utility value (c.f.: Eccles & Wigfield, 2020) because the constructed decision trees were evaluated as useful for solving exam tasks.

Although the two learning tasks required algorithmic thinking, it is uncertain to what extent such decision tree tasks can be implemented in every science topic, which may be a limitation as regards the general aim of introducing algorithmic thinking into upper secondary science education.

Abstract: We consider how a teacher-designed unit, *Rainbows*, became a longitudinal tool within an elementary science teacher PD community. *Rainbows* allowed teachers to enact roles of teacher, designer, facilitator, and PD designer. *Rainbows* also oriented new teachers joining the community and served as a trace of the community's practice over time.

Background and conceptual framing

Professional development (PD) fosters learning when teachers navigate the complexities of their work. Research demonstrates that one element of effective PD is its sustainability over time (Darling-Hammond et al., 2017). However, longitudinal PD communities inherently change, necessitating support for integrating new members and developing all members' practice over time. Drawing on the lens of communities of practice (CoP; Lave & Wenger, 1991), we frame learning as participating in community practices that are mediated by "novel cultural tools that trans[form] the action" over time (Wertsch, 1998, p. 42). This analysis considers how a teacher-designed unit known as *Rainbows* became a multimodal cultural tool that transformed the practices of a CoP of elementary science teachers. *Rainbows* was a phenomenon-first based science unit focused on light and color. As *Rainbows* evolved over time, it reflected new shared understandings of what it means to teach science. It also created opportunities for members to take up new roles and for new members to join the community. As teachers engaged with *Rainbows*, they enacted roles of teacher, designer, facilitator, and PD designer. We ask how *Rainbows* became a trace of learning and shared practice within our PD community.

Study context and analysis

Data came from a multi-year, design-based research study of an elementary science PD community focused on using representations and modeling to support student thinking. Year 1 included 9 teachers (Cohort 1 or C1) who participated in an initial summer workshop, academic year science lesson enactments, and 4 video club meetings (Sherin & Van Es, 2009). Year 2 was impacted by COVID-19; no new members joined. In Year 3, 7 of the C1 teachers returned and took on leadership roles. Six new teachers (Cohort 2 or C2) joined the community. All 13 teachers participated in Year 3 summer workshops and academic-year science lesson enactments and video clubs. We focused on moments where *Rainbows* was an explicit part of PD activities. Using content and thematic analysis (Morse, 2012), we analyzed how *Rainbows* evolved to transform community practices and participation.

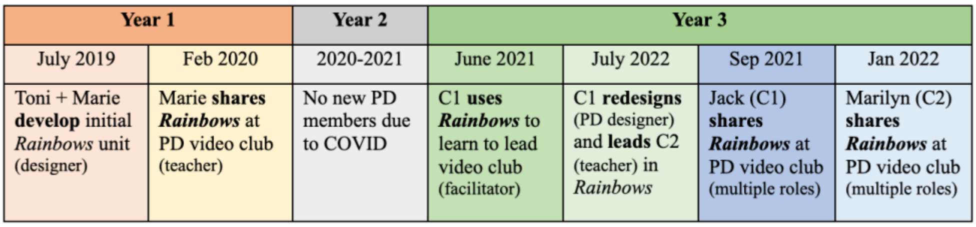
Findings

Figure 1 traces how *Rainbows* supported teachers' participation over time. The initial development of *Rainbows* (Year 1) helped 4th grade teachers Toni and Marie M. (self-chosen pseudonyms) enact roles as designers and teachers to take up new pedagogical practices. In summer Year 3, C1 took up new roles as facilitators and PD designers by engaging with the *Rainbows* unit in new ways. *Rainbows* also apprenticed C2 members into the community. During academic Year 3, *Rainbows* supported longitudinal learning for community members as reflective practitioners.

Year 1: Tool development and teacher learning

During Year 1 summer PD (July 2019), Toni and Marie took on the role of designer as they planned a unit for 4th grade standards on light and color. While they initially struggled to apply phenomenon-first approaches, their collaboration culminated in the original *Rainbows* unit, which both teachers implemented during the 2019-2020 school year. Marie reflected on students' learning in *Rainbows* during a PD video club, noting that practices such as modeling helped students "construct some type of meaning" about science phenomena. *Rainbows* served as a tool during Year 1 to introduce teachers to pedagogical approaches as they enacted roles of designers and teachers.

Figure 1
The Rainbows Unit Over Time



Year 1		Year 2	Year 3			
July 2019	Feb 2020	2020-2021	June 2021	July 2022	Sep 2021	Jan 2022
Toni + Marie **develop** initial *Rainbows* unit (designer)	Marie **shares** ***Rainbows*** at PD video club (teacher)	No new PD members due to COVID	C1 **uses** ***Rainbows*** to learn to lead video club (facilitator)	C1 **redesigns** (PD designer) and **leads** C2 (teacher) in *Rainbows*	Jack (C1) **shares** ***Rainbows*** at PD video club (multiple roles)	Marilyn (C2) **shares** ***Rainbows*** at PD video club (multiple roles)

Summer year 3: New roles and new members

In June 2021, C1 teachers prepared to take on a new role of facilitator for incoming C2 members. A video clip of Marie teaching *Rainbows* became a tool that C1 teachers used to learn how to facilitate the familiar community activity of video club. C1 teachers also took on a new role of PD designers as they collectively re-designed *Rainbows* to integrate their learning from the PD community. They enacted their role as facilitators as they implemented their adapted *Rainbows* unit and led video club activities with new C2 teachers in July 2021. These experiences allowed incoming C2 teachers to become oriented to pedagogical practices valued by the PD community (e.g., modeling, phenomenon-based approaches). During summer 2021, *Rainbows* became the bridge between C1 in their roles as PD designers and facilitators and C2 in their roles as teachers and designers.

Academic year 3: Longitudinal learning and practice

Rainbows supported teachers in developing their practice over time. Both Toni and Marie continued to revise *Rainbows* and enacted the unit yearly with their students. Other C1 teachers also adapted and implemented *Rainbows*, as did C2 teachers in Year 3. Teachers from both cohorts brought implementations of *Rainbows* to video clubs, where classroom video and student work supported the whole community's learning about how representations and modeling support students' science thinking.

Discussion and implications

Analysis demonstrates how *Rainbows* was taken up by our PD community as a cultural tool that shaped practice and participation. As it was adapted for different purposes, the unit supported access to shared and developing understandings of practice and to roles of learner, teacher, designer, facilitator, and PD designer. It also challenged traditional power roles by redistributing power across researchers and teachers. We argue that *Rainbows* was significant in part because it was created by C1 teachers, rather than researchers. In further analyses, we hope to extend explanations for how and why tools like *Rainbows* support teacher learning in longitudinal PD communities.

European University Cyprus

Abstract: This study explores the introduction of faculty Professional Learning Communities (PLCs) in order to enhance instructors' teaching competencies in higher education. The study identified faculty PLCs structures that encourage evidence-based reform in faculty members' teaching practice. Data were collected from 127 faculty using an online questionnaire. Analysis identified factors relating to the willingness to engage in faculty PLCs and sources of information for shaping teaching reform. We discuss the implications of possible new directions of supporting faculty in their efforts to enhance their teaching competencies. Policy implications point to a novel approach to supporting faculty for enhancing their teaching competencies.

Theoretical framework

Professional Learning Communities (PLCs) refer to small teams of instructors with shared interests and visions that meet regularly, exchange expertise, and work collaboratively with the goal of improving their teaching practice (e.g., Margalef & Roblin, 2016). PLCs are viewed as continuously collaborating groups of like-minded colleagues, sharing and engaging together in the practice of learning for improvement in daily business, connected by similar values, opening up to one another trustfully about routines and obstacles, discussing openly and thus contributing to each colleague's concern (e.g., Stoll et al., 2006). In the context of PLCs, professional learning takes the form of an ongoing, sustained, intensive and collaborative approach to improving teachers'/instructors' effectiveness in raising student achievement and enhancing student learning experiences.

Although a recently growing number of studies have investigated the use and function of PLCs at primary and secondary education levels, there is to date relatively little evidence whether changes occurred within PLCs in higher education can be sustainable beyond the faculty participation in PLCs (Tinnell, Ralston, Tretter & Mills, 2019). Faculty PLCs are playing an increasingly important role in higher education, connecting faculty with their students and colleagues (Cox, 2001), and placing an emphasis on evidence-based changes in teaching (Ralston, Tretter, & Kendall-Brown, 2017).

Purpose and research questions

This study explores the potential introduction of faculty PLCs ay to enhance instructors' teaching competencies. The current study focuses on a "young," small, private university in Cyprus. Our purpose in this paper focuses on identifying faculty PLCs' structures that encourage long-term sustainability of evidence-based teaching reform in faculty members' teaching practice. Data collected aimed to investigate the characteristics of productive and sustainable faculty PLCs. Toward this end, the study seeks to answer the following two research questions: (1) Which factors are related to the faculty's willingness to engage in PLCs? (2) Which sources of information are considered important in shaping their teaching?

Methods

Data were collected from 127 faculty at the end of the Spring semester of 2022 through an online questionnaire (https://qr.page/g/4vSda0UjlIh). Working from the literature on PLCs and faculty PLCs, we identified several main themes related to the ways that are supportive of the productive work of PLCs, as well as aspects that may encourage or discourage faculty to participate in long-term changes in their teaching competencies. The questionnaire examined the current state of faculty PLCs at the University in order to identify good practices and needs for supporting and sustaining faculty PLCs as tools for professional learning, growth, and development.

Results

Analysis of the data indicated factors that relate to the faculty members' willingness to engage in PLCs as well as sources of information that participants in the survey highlighted as important in shaping their teaching. Factors included: (i) sharing teaching experiences with colleagues, (ii) gaining valuable information from hearing about colleagues' experiences, (iii) sharing experiences about student results, (iv) experimentation with new ideas, (v) meetings with colleagues, (vi) reflecting with colleagues about common teaching issues, (vii) working in a small group of colleagues on improving teaching, (viii) reflecting on own teaching. Factor analysis indicated that 8 items included in the questionnaire loaded in one factor and with a good Cronbach's alpha score (α =0.85).

Further, a series of exploratory bivariate analyses were performed using gender, mode of employment (full-time or part-time faculty), rank, and the academic school that the participants belong to. The analysis showed that the demographic variables did not distinguish different modes of willingness. In effect, this possibly suggests that there was a uniform approach and positive willingness to engage in faculty PLCs. Interestingly, this willingness to engage in faculty PLCs did not relate to the workload of the teaching staff. Willingness to engage in PLCs was positively related to the perceived importance of teaching among other academic activities.

An important finding related to the sources of information that participants highlighted as important in shaping their teaching. These related to both informal and formal feedback instructors get from their students, student learning results from exams and/or assignments, discussion of feedback from students with the program coordinator or the department chair and other colleagues, and participation in workshops and/or seminars. Finally, the participants suggested several thematic areas for faculty PLCs that would be of interest in the future. These were (i) pedagogical principles & methods of teaching (including inclusive learning & differentiation), (ii) digital tools & emerging new technologies for teaching & learning (including in-class activities for enhancing student engagement during lectures), (iii) evaluation and assessment strategies and approaches, and (iv) interactivity between the students, the instructor & the course materials.

Discussion

Overall, the study revealed participating instructors' very positive inclination to engage in PLCs. Factors connected to that willingness were in line with the literature about important characteristics for productive instructors PLCs, related to e.g., having shared values and vision, adopting a collective responsibility for student learning, and actively and regularly engaging in individual and group professional learning (Bolam et al., 2005; Hord, 1997; Stoll & Earl, 2003; Vescio, Ross & Adams, 2008). Of course, it needs to be acknowledged that the lack of differentiation identified in the ways faculty responded to the questionnaire could be influenced by a self-selection bias of the people who have opted to participate in the study in the end.

An additional important finding relates to the ranking of the items identified by participants in the study as sources of information that shape their perceptions of teaching. Participating instructors seem to feel that collaborative pedagogical reflection is valuable for their teaching duties, although prior research has suggested that the notion of community-wide collaboration is usually absent from higher education meetings, curricular planning, and pedagogical discussions (e.g., Massy, Wilger, & Colbeck, 1994).

Taken all these together, the findings point towards new directions in faculty professional development, away from traditional approaches of lectures or seminars, focusing more on peer interaction and support, and student data focusing on learning outcomes aligned with the increasing research interest in the field. At the same time, findings point to a direction for further, more detailed investigations about the impact of faculty PLCs on higher education (Richlin & Cox, 2004; Tinnell et al., 2019).

Abstract: Auditory space, an underrecognized dimension of placial space, is key to understanding and designing unique learning environments. In this single case study, we analyze an interview with two afterschool music program teachers. We found that as students learn music, co-created auditory space progresses from merely consuming music or making individual sounds, to listening to and playing with one another, and finally collaboratively composing songs. Implications for attending to sound when designing learning environments.

Introduction

Sounds, like birds in nature or traffic on the street outside your home, play a particular role in situating our understanding of physical space and place (Lochhead, 2019). Likewise, music plays an important role in setting cultural space and place (Low, 2014), the rhythms and melodies of a neighborhood market, a holiday festival, the radio on a car ride with your mom. Music researcher Judy Lochhead (2019) describes music as *placial*, emphasizing its role in our lived relationship with the physical space where "aural dimensions are often unarticulated" (p. 696). Like Lochhead, we use the anthropological term *placial space* to indicate the complex combination of physical and relational space in learning environments. In classrooms, physical attributes like desks and other learning tools unite with interpersonal interactions to create new spaces and sites for learning (Massey, 2005). While sharing physical markers with in-school contexts, afterschool spaces often offer more relational flexibility through casual relationships with teachers and less stringent structures and rules for behavior.

From a theoretical standpoint, we consider placial space to be something in the process of becoming, interactionally constituted, and both physically and socioculturally formed (Massey, 2005). The arts, particularly music, set placial space in unique ways through playing, composing, and movement practices. Arts learning is both individual and social, a representational process described as an expression of collective meaning-making or emergent student voice (e.g, Peppler et al., 2022). Like other sites for learning, arts and music-making spaces can be described as co-created (e.g., Dahn et al., 2023) and "made meaningful through peoples' engagement with them" (Taylor & Phillips, 2017, p. 596). While there are unique sounds that overlay our sense of physical space in a learning environment, little is known about the ways educators describe and interact with sound in a classroom or afterschool setting, or how they use music production as a tool for demonstrating or externalizing learning. In this poster, we consider the ways music overlays a learning setting by asking the following questions: *How do teaching artists describe auditory space in relation to placial space in an afterschool music program? How do auditory space and music learning interact throughout the duration of the music program?*

Methods

Our poster is part of a larger study based on semi-structured interviews conducted with pairs of teaching artists and classroom teacher collaborators. For this single case study (Cresswell & Poth, 2018), we focused on a teaching artist duo, Nick and Michelle, who taught a high school music afterschool program in the 2021-22 school year. Interview questions included thinking about designing for space in their classroom environments, and the role of student agency in co-creating space. We analyzed the interview by coding for mentions of physical space, relational space, music, and other sounds. We then created a qualitative timeline identifying cooccurrences of descriptions of music and sound with placial space. Finally, we analyzed the timeline for the trajectory of change in participation and musical representation from the beginning, middle, and end of the music program.

Findings: Changes in music learning and auditory space

Teaching artists described auditory space in relation to placial space in a few key ways. At the start of the program, students entered the physical space of the music room with one wall lined with keyboards, guitars, and drum sets, and another wall set with rows of chairs with music stands. The center of the room was set for a teacher to act as conductor and accompanist, with a laptop and pickups for amplified sound output. The teaching artists encouraged students to tinker with the instruments and explore the sounds they make explaining, "the approach to space is really open ended and experimental, experiential, and then students gradually [decide] this is where I want to organize my space." The placement, physical feel, and sound of the instrument affected a student's choice of what to play and where to play it in the music classroom. Michelle emphasized the affordances of the afterschool space in responding to student needs, "[we] get input from students of what they want, what is a space for them where they feel comfortable doing what they want to do." That co-creation of auditory space, driven by listening to student interests, also played out in repertoire selection, where students brought in song requests, learned covers, and eventually wrote and recorded their own song.

As the program progressed, the students went from recognizing and experimenting with sound, to understanding the ways sound interacts in auditory space, Nick described the placial space shifting as the program progressed based on sound production and the students' need to hear one another as they learned to play together. "It has to do with the bands and being able to hear the drums when you're playing, or like being able to hear the bass." Musically, drums and bass set beat, rhythm, and tempo, driving students nearer to one another so they can follow along together. Nick then explained, "It was also about individual students feeling comfortable, scooting closer to each other gradually." While the students engaged in the physical and auditory creation of space, their relationships to one another within the space led to an added sense of belonging.

Toward the end of the program, the physical space shifted as the group left the music room to record their original song in a second space at the school, an intimate recording studio filled with professional recording equipment like a soundboard and microphones. "This professional setup felt like an escalation for everybody." One student sat in the lead engineer's chair and directed the other musicians. Nick explained to the students, "'you're pressing record. You're gonna let them know when to start playing the piece.' So there was an interplay in that space and ownership too." Musically, playing and singing their own original song connected the auditory to their roles, directing the collaboration or playing the music, in the physical space.

Nick described working in the recording studio as a powerful turning point in their music learning and song playing, "when we came back to the music room, it was like there was a whole new set of confidence that the students exhibited. We put together twice as many songs in three weeks after the studio than we did in the six months before the studio. I think that shifting space was really powerful." Michelle explains that relationships also grew, "after the recording was done there was this different camaraderie and they were all closer than they had been before. There was an ease with the way that they spoke and moved around the room that was different." Student learning was entrenched in the combination of sound and placial space.

Conclusion

Teaching artist descriptions situate co-created auditory space as key to the placial learning environment. In the context of collaborative songwriting, students' arts learning is evidenced through a shift in participation and investigative process—a progression from music and sound consumption to an external representation of their understanding of how music works as they learn to write melody and lyrics, produce and record, and finally, put the pieces together to create cohesive, collaborative, original songs. Considerations of aural aspects of placial space have implications for other learning spaces, layering sound into designs for future learning environments and considering possibilities for sound in mediating learning processes.

Critical Race Theory and the Use of Media

Isis Howard, Arizona State University, ilhoward@asu.edu

Abstract: Politics worldwide have become increasingly polarized, limiting education policies, particularly discourse on race and gender. This theoretical essay examines the relationship between Critical Race Theory (CRT) and current education policies as acts of white fragility and suggests that using media to talk about race at an early age can support the ability to think about and discuss race. Based on tenets of CRT, the author presents two illustrative analyses of media objects for use in K-8 classrooms.

Introduction

In recent decades, politics worldwide has become increasingly more polarized with the upsurge of Far-Right Movements in countries such as the US, UK, Brazil, India, and more. These extremist politics have led to policies that limit education freedom worldwide. Particularly in the US, Republican party members are using critical race theory (CRT) as a scapegoat to push the dominant narrative of a post-racial society. Several states have proposed or passed policies restricting CRT or gender studies. As learning sciences and other related fields continue to advance theories and methods to be more inclusive of the experiences and knowledge of historically marginalized communities, these policies threaten the equitable educational experience for all youth by limiting racial and gender discussions. Discussions about race and gender are essential for children and youth socialization, and media is a tool that can be used to supplement these discussions. *Media* here is defined as a societal tool used to express information or entertainment using various mediums, such as TV shows, newspapers, magazines, books, and social media. As educational freedom continues to be attacked by policy makers, what does the research on CRT, white fragility, and media tell us about how to foster children and youth's understanding of race and gender in critical and responsive ways? To explore this question, I present two illustrative analyses of how media can be used in the classroom to facilitate critical discussion about race and other forms of oppression using the tenets of CRT.

Critical race theory

CRT was introduced into education in the '90s to intentionally examine education through a racial lens, focusing on how race is a significant determinator of educational difference (Howard & Navarro, 2016). Five main core tenets of CRT are commonly referenced (Carlton Parsons, 2017): (1) Racism is seen as systemic, not as an individual act, (2) Challenges the dominant ideology of race-evasive society, (3) Examines the historical and contextual of systems, (4) Highlights the lived experiences and experiential knowledge of minority communities, and (5) Seeks the elimination of racism and other forms of oppression. CRT is not taught in pre-college classrooms to the extent that far-right policy makers lead the media to believe. Instead, tenets of CRT are used to support the teaching and learning process by highlighting minority lived experiences, allowing students to reflect on their political identities and teachers to reflect on how their own experiences impact their classroom environment (Blaisdell, 2021; Carlton Parsons, 2017; Vakil, 2020).

Race-evasiveness does not make race go away

A key theme of CRT is that racism is a systemic societal issue. In a racial-evasive society, race is theoretically not acknowledged as a factor of one's ability and opportunity, but failing to acknowledge these factors leads to inequality. This system then reinforces the dominant narrative without taking action to deconstruct it. In failing to recognize and uphold differences, the race-evasive reaction to criticism is victimization. This reaction is ingrained within white fragility in that it denies other races and gender and fails to examine the intersectionality of their privileges and oppression. *White fragility*, initially coined by DiAngelo (2018), is the defensive reaction of white people toward discomfort when discussing race that challenges their dominant worldview (Applebaum, 2017). Racial-evasiveness and white fragility are concepts that limit societal transformation as they support the existing power structure of racism. White fragility and discomfort are products of a race-evasive society that ignores the issues of race and gender until late adolescence or early adulthood - much too late. However, such fragility and discomfort can be seen as performative acts, thereby rendering them changeable. Educators can thus provide opportunities for students to address the issue of race and racism (Applebaum, 2017) to counteract these reactions and promote healthy racial and gender socialization.

Methods

I contend that media can be used to alleviate the feeling of discomfort when talking about issues of race and gender. Using media to analyze social norms and supplement racial discourse can benefit youth socialization (Stout et al., 2020). In the next section, I propose two pedagogical examples of how media can support critical race pedagogies to facilitate the discussion of race and systemic oppression. Media examples were chosen for their fictional narrative worlds that mirrored issues of race and gender in modern society.

Illustrative analysis 1: Race in manga

I present an illustrative analysis of a middle school grade-level manga, *As a Reincarnated Aristocrat, I'll Use My Appraisal Skill to Rise in the World* by Natsumi Inoue, and how tenets of CRT are presented in the text. The story is set in another world that has a government monarchy. The main character, Ars Louvent, is reborn into aristocracy and quickly finds that he needs to find capable people to serve him as he prepares for a war in the future. As the main character brings capable people to his side, he deconstructs the dominant norms of his society by recruiting a darker-skinned character and other characters of oppressed backgrounds. Some of the core tenets of CRT are evidenced in the text. For example, the text highlights the first tenet, "Racism is Ordinary," by creating a society where one race is inherently better. People in the south are seen as dumb and are to be enslaved. This idea is embedded in every part of Inoue's fictitious society; thus, they are not treated with the same rights. If they are not enslaved, they normally live in poverty as they cannot get jobs like average citizens. Practitioners can use this example to relate to the history of oppressed peoples throughout the world and history. By first relating these topics to a fictional narrative, students may find it easier to identify and discuss these social norms without participating in white fragility.

Illustrative analysis 2: Gender norms in children's media

Here I present an illustrative analysis of gender roles in children's media, examining how these roles are presented through the tenets of CRT and other critical pedagogies. Children's media marketed to elementary-age students are often used to reflect moral stories that help children understand the norms of society. As societal attitudes change, the media begins to reflect those attitudes. This can be reflected by the recent increase in media that deconstruct traditional gender norms. For example, the book *Pink is for Boys*, by Robb Pearlman, deconstructs gender norms in a simple way to visualize matter by equating colors to both genders. This book highlights two essential tenets of CRT: challenging the dominant ideology and eliminating all forms of oppression, as it dismantles traditional gender stereotypes of genderism. Educators can use this book to help children reflect and counteract the dominant gender norms at an age-appropriate level without going into complex details of oppression.

Conclusion

As this new age of conservatism continues encroaching on our educational freedoms, enacting pedagogies that support children and youth's racial socialization becomes increasingly critical to prepare students. As practitioners continue to navigate these spaces, using media as a pedagogical tool to discuss race through the tenets of CRT can help encourage students to be better equipped to engage in productive conversation around race and to make more informed political decisions. Discussing race should not be discomforting, but it will always be discomforting if it is never discussed, and acts of white fragility will continue to run rampant.

Assessing Scientific Reasoning: A Delphi-AHP Approach

Shiyu Liu, Ocean University of China, shiyuliu@ouc.edu.cn
Xi Chen, Qingdao Engineering Vocational College, chenxi@qdec.edu.cn

Abstract: The present study aims to develop a framework for assessing scientific reasoning using the Delphi-AHP methods. Twenty experts were surveyed for two rounds, during which they proposed assessment indices and ranked their importance. Based on pairwise comparison of expert ratings of the indices, we constructed a final framework which consisted of three Tier 1 indices, eight Tier 2 indices, and twenty Tier 3 indices. This work brings an innovative perspective into scientific reasoning assessment.

Objectives

Scientific reasoning ability entails a necessary set of skills in scientific endeavors (Fischer et al., 2014). It is an important cognitive element indispensable to classroom learning as well as daily life. As students' level of scientific reasoning is an important indicator of educational quality across the globe, how to effectively evaluate scientific reasoning has received great attention. Given that existing assessments usually focus on certain aspects of scientific reasoning (e.g., Luo et al., 2020), there is a great need of tools that can evaluate scientific reasoning in a systematic approach. The present study aims to develop an integrated framework for assessing scientific reasoning based on the AHP method, which can provide a more comprehensive evaluation of students' scientific reasoning competence.

Methods

To establish an assessment framework of scientific reasoning, we adopted the Delphi and analytical hierarchy process (AHP; Saaty, 1980) methods. The Delphi method is used to repeatedly obtain expert opinions until there is a comprehensive consensus (Delbecq, van de Ven, & Gustavson, 1975). AHP is a mathematical method which uses a pair-wise comparison approach to build a hierarchy, which provides a quantitatively justified criteria system for selecting the most qualified candidates as well as gathering information on students in educational circumstances (Thomas & Kirti, 2008).

The present study was carried out in four steps. First, content analysis was conducted on previous literature to analyze and synthesize existing definitions, theoretical frameworks, and models about scientific reasoning. Then, assessment criteria were developed based on the content analysis, recently released educational standards internationally, as well as the frameworks of international large-scale assessments (such as PISA and TIMSS). Next, a preliminary three-tier framework was proposed to categorize the essence of scientific reasoning, each of which included specific criteria with detailed descriptions. Given the domain-specific nature of scientific reasoning, we confined the current investigation to high school biology. To ensure the objectivity and feasibility of the framework, we used the Delphi method for two rounds, where we surveyed twenty experts to determine the evaluation criteria for scientific reasoning. All experts were either experienced scientific reasoning researchers or biology teachers with over 10 years of teaching experience. After the framework was constructed, the AHP method was applied to rank the ratings that experts provided for each criterion using pairwise comparison. Last, to evaluate the feasibility of this framework in real educational settings, a twenty-item questionnaire was developed based on the framework for high school students to report their perceived level of competence in each scientific reasoning element.

Results

Based on content analysis of extant literature, a preliminary model of scientific reasoning was constructed, with three Tier 1 indicators and nine Tier 2 indicators. Two rounds of Delphi consultation were conducted. During the first round, the reconciliation coefficient (which should fall into the range of 0 to 1) was 0.171. Experts reached an agreement on establishing the Tier 1 criteria, but not on Tier 2 criteria. In particular, the Tier 2 criterion of "scientific modeling" was suggested to be taken out as it overlapped with other criteria. During the second round, the reconciliation coefficient reached 0.573, indicating a relatively high degree of agreement among experts. Based on the ratings as well as suggestions from experts, we finally modified the preliminary model into a framework with three Tier 1 criteria, eight Tier 2 criteria, and twenty Tier 3 criteria.

The AHP method was used to rank the ratings from experts for each criterion. To ensure the reliability of ratings, we calculated the Consistency Ratio (CR), which reflects the level of experts' familiarity with the topic and their judgment. When CR is higher than 0.7, reliability is at a high level. In this study, CR was 0.915, which means the final rankings among the experts was very high. See details of the final rankings in Table 1.Last, we distributed the questionnaire that was developed based on this framework to 163 high school students (82 males and 81 females), and results showed that the Kaiser Meyer Olkin (KMO) value was 0.924, and the Bartlett Test of Sphericity $\chi2$ was 1618.634 (df = 190), p < 0.001. The questionnaire had a relatively high reliability and validity, indicating that the framework was applicable for classroom use.

Table 1
Weight Distribution of Indicators

Tier 1	Weights	Tier 2	Weights	Tier 3	Weights
Generating Hypotheses	0.222	Identify Problems	0.289	Be aware of problems	0.469
				Construct contextually relevant problem representations	0.531
		Ask Questions	0.399	Ask contextually relevant scientific questions	0.443
				Ask explorable scientific questions	0.557
		Make Assumptions	0.312	Formulate a scientific hypothesis related to the problem	0.500
				Develop testable scientific hypotheses	0.500
Experimentation	0.394	Design Experiments	0.635	Design scientifically sound experiment protocols	0.358
				Design a complete and feasible experiment plan	0.334
				Be aware of controlling variables	0.308
		Collect Evidence	0.365	Classify and organize experiment data	0.389
				Clarify the meaning of data representation	0.253
				Observe and analyze the experimented phenomena	0.358
Scientific Argumentation	0.384	Evaluate Evidence	0.419	Evaluate scientific arguments from different sources	0.267
				Analyze the limitations or deficiencies of experiments	0.232
				Evaluate and interpret the results of scientific investigations	0.501
		Draw Conclusions	0.356	Draw conclusions in response to scientific questions	0.273
				Conclude based on scientific evidence	0.243
				Summarize and apply scientific findings	0.484
		Exchange Evaluation	0.225	Communicate and share each other's scientific reasoning process	0.587
				Rationally evaluate others' scientific reasoning process	0.413

Discussion

Assessing students' scientific reasoning competence has been a crucial yet challenging task for educational researchers and practitioners. The present study introduced the Delphi and AHP methods into this line of research for the first time. The proposed framework transferred the reasoning processes into measurable indices, which can be directly applied in classroom settings.

Perceived Helpfulness of Phatic Expressions in Online Help-Giving Interactions

Amos Jeng, Nigel Bosch, Michelle Perry
amosj2@illinois.edu, pnb@illinois.edu, mperry@illinois.edu
University of Illinois Urbana-Champaign

Abstract: In this survey study, we assessed how students rated the helpfulness of replies to online requests for help with and without *phatic expressions*, or comments serving a purely social purpose. We found that students perceived help-giving replies with neutral and self-oriented phatic comments to be less helpful than those discussing course content alone. In contrast, students perceived help-giving replies with greetings, salutations, and other-oriented comments to be equally helpful to those discussing course content alone.

Introduction

When struggling students seek academic help in online learning environments, it is important that they perceive the help they receive from others to be effective. In the online context, these perceptions of support have been found to be related to academic resilience (Permatasari et al., 2021), and students who have negative experiences with help-seeking are less likely to seek further help in the future (Mare & Sohbat, 2002).

In the present study, we contribute to literature on online collaborative learning by examining whether *phatic expressions*—comments that serve a social rather than informative purpose (Maíz-Arévalo, 2017)—contribute to or detract from the perceived helpfulness of replies to requests for help posted to an online college course discussion forum. Although existing work has shed light on behaviors that yield effective academic helping interactions in online courses (Nandi et al., 2012), little is known about the helpfulness of comments that serve a purely social function in these settings. On one hand, phatic expressions do not convey information about course content and thus do not directly address a help-seeker's academic problem. On the other hand, these expressions may help learners connect with others and thus increase their willingness to accept others' support.

Maíz-Arévalo (2017) previously identified four different types of phatic expressions that are used in online communicative settings: greeting/parting tokens, self-oriented comments, other-oriented comments, and neutral comments (see Table 1). Our investigation explores how the inclusion of each of these types of expressions predicts the perceived helpfulness of help-giving replies posted to an online discussion forum. Our research question is: *How do phatic expressions contribute to or detract from the perceived helpfulness of replies to requests for help posted to a college course discussion forum?*

Table 1
Types of Online Phatic Expressions (Maíz-Arévalo, 2017)

Type of phatic expression	Definition	Example
Greeting/parting token	Greetings and farewells to open/close messages	"Hi there"
Self-oriented comment	Comments that refer to the speaker	"I've had a busy week"
Other-oriented comment	Comments that refer to the addressee	"Thanks for your question"
Neutral comment	Comments on the "context shared by interlocutors" (Maíz-Arévalo, 2017, p. 440)	"Lots of posts on the forum today"

Methods

Participants and procedure

This study utilized a repeated measures survey design and was completed online during the Spring 2022 semester. Participants were undergraduate students enrolled in a large introductory statistics course at a public university in the midwestern United States. During the survey, participants rated the helpfulness of 16 replies to requests for help posted to an online statistics course discussion forum, on a scale from 1 = *Not helpful* to 5 = *Very helpful*. For each of the 16 replies, participants were randomly shown one of two possible versions of the same reply: (a) a version that only discussed course content (e.g., "For any z-score that is huge, to the point where it's off the chart, you can assume the p-value is going to be pretty much 0") or (b) an edited version that discussed the same course content and also included a phatic expression (e.g., "This is a very good question. Basically, for any z-score that is huge and off the chart, you can assume the p-value is pretty much 0"). The order in which the 16 replies were presented was randomized for each participant.

Of our 16 help-giving replies, 5 included greeting/parting tokens in the version of the reply with a phatic expression, 4 included self-oriented comments, 4 included other-oriented comments, and 3 included neutral comments. We dummy coded phatic expression type (i.e., the type of phatic expression associated with the version of each reply shown to each participant) into 4 variables ("greeting/parting token," "self-oriented comment," "other-oriented comment," and "neutral comment") at the individual rating level, with "no phatic expression" as the baseline group for comparison.

Originally, 345 participants completed the survey. We excluded 6 participants who demonstrated response bias by providing the same helpfulness rating for all 16 replies. Our final sample consisted of the remaining 339 participants. All participants were compensated with extra credit.

Data analysis

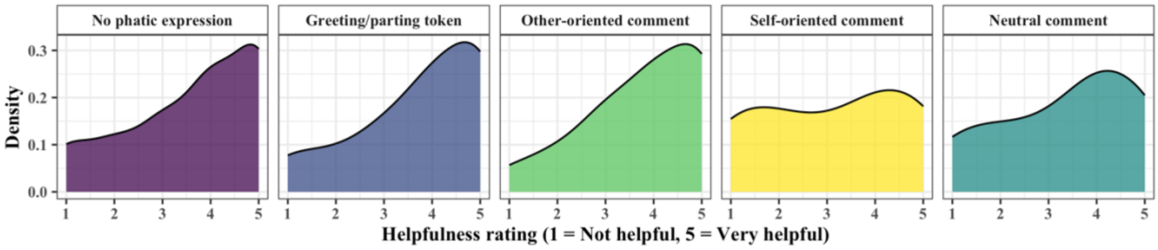
We analyzed the data with linear mixed model analysis because we could not consider multiple ratings from the same participant or for the same help-giving reply to be independent of one another. We included helpfulness rating as our dependent variable, participant ID and help-giving reply (post ID) as random effects, and the different types of phatic expressions as fixed effects. We centered and standardized helpfulness rating prior to analysis.

Results and discussion

Participants perceived help-giving replies with neutral (β = -0.16, *SE* = 0.05, *p* = .002) and self-oriented (β = -0.18, *SE* = 0.04, *p* < .001) comments to be significantly less helpful than replies discussing course content alone. In contrast, participants perceived replies with greetings/parting tokens (β = 0.03, *SE* = 0.04, *p* = .49) and other-oriented comments (β = 0.02, *SE* = 0.04, *p* = .96) to be equally helpful to replies discussing course content alone. Figure 1 is a density plot displaying the distribution of helpfulness ratings by the type of phatic expression used.

Figure 1

Distribution of Helpfulness Ratings by Type of Phatic Expression



Overall, our findings suggest that the ratings associated with help-giving replies were not improved by the inclusion of phatic expressions. In fact, self-oriented and neutral comments appeared to have a negative impact on perceived helpfulness. Participants may have perceived such expressions as adding little to the content of the help-giving reply and thus a potential waste of the help-seeker's time. However, our findings suggest that students can include other-oriented comments and greeting/parting tokens in their online help-giving replies without detracting from the message's overall perceived helpfulness. These expressions have the common characteristic of acknowledging the addressee's presence; it is possible participants saw them as worth including in help-giving posts because while they are not helpful in terms of conveying course material, they can provide social support by making students feel encouraged, appreciated, or seen by others. That being said, a limitation of our survey design is that it is possible our participants may have felt differently about the use of phatic expressions in more authentic contexts. Thus, future work should examine how online help-giving replies that include different phatic expressions are perceived by the students who receive them after seeking academic help.

Predictors of Sense of Belonging to One's Course Community for Online and In-Person Learners

Amos Jeng, Aparajita Vemuri, Michelle Perry
amosj2@illinois.edu, avemuri2@illinois.edu, mperry@illinois.edu
University of Illinois Urbana-Champaign

Abstract: In this survey study, we examined the factors contributing to a sense of belonging to one's course community for college students enrolled in either the online or in-person version of the same introductory statistics course. We found no significant overall difference in online vs. in-person students' sense of belonging to their course community. However, online first-generation college students reported lower belonging to their course community than any other combination of course version and college-generation status.

Introduction

In educational settings, a sense of belonging refers to "the extent to which students feel personally accepted, respected, included, and supported by others in the school social environment" (Goodenow, 1993, p. 80). Research has shown that among college students, a sense of belonging to college settings is associated with important learning outcomes, including engagement, persistence, and well-being (Gopalan & Brady, 2020). Thus, it is paramount that researchers gain a full understanding of the factors that contribute to students' feelings of belonging in college, so that we are positioned to support student success.

Online students, specifically, may struggle to develop a sense of belonging to their course communities, due to the oftentimes lack of real-time, in-person interaction in such settings (Peacock et al., 2020). Nevertheless, few studies have investigated sense of belonging in the context of online learning. For this reason, the present study aims to expand our understanding of how online vs. in-person students of diverse backgrounds experience a sense of belonging to their course community. Our research questions (RQs) are as follows: (1) *Among college students, does course version (online vs. in person) predict sense of belonging to one's course community, holding course grade and demographic characteristics constant?*; and (2) *Among college students, are the associations between course grade and sense of belonging to one's course community, as well as demographic characteristics and sense of belonging to one's course community, moderated by course version?*

Method

Participants and procedure

We employed a cross-sectional survey design that was completed online during the Spring 2022 academic semester. Participants (N = 327) were students enrolled in either the in-person (n = 155) or online version of a large introductory statistics course taught at a public university in the midwestern United States. We collected data during the last month of the semester, so that participants would have had the chance to establish a sense of belonging to their course community. During the survey, participants completed a four-item measure assessing their sense of belonging to their course community (adapted from Goodenow, 1993; α = .73) and provided information on their course version (online vs. in-person), current course grade (out of 100), and demographic characteristics (race/ethnicity, gender, and college-generation status). Participants were compensated with extra credit in the course.

Data analysis

Participants could respond with "Prefer not to say" when providing their grade and demographic characteristics; we estimated missing values for these variables with multiple imputation, creating 50 imputed data sets in total. Next, we used multiple regression to address our RQs. In Model 1, we regressed sense of belonging to one's course community on course version, course grade, and demographic characteristics, thus addressing RQ1. In Model 2, we added interaction terms to examine whether the associations between (a) course grade and belonging and (b) demographic characteristics and belonging were moderated by course version, thus addressing RQ2.

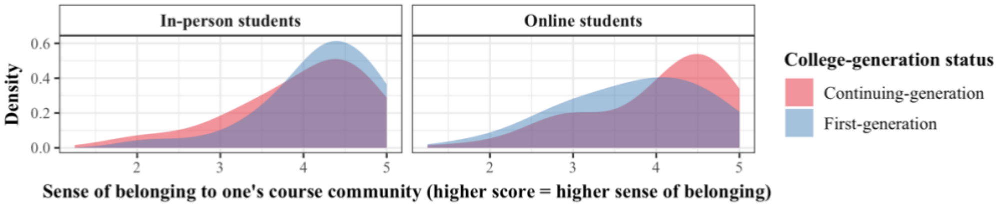
Results

Model 1 explained a significant pooled 13.34% of the variance in sense of belonging to one's course community (F[8, 318] = 6.12, p < .001). We found a non-significant difference in online and in-person students' reported degrees of belonging to their course community ($B = -0.13$, $SE = 0.09$, $p = .14$). Additionally, a higher course grade was associated with a significantly higher sense of belonging ($B = 0.02$, $SE = 0.004$, $p < .001$). Also, students identifying as men, on average, reported a significantly lower sense of belonging than students identifying as women or non-binary ($B = -0.20$, $SE = 0.10$, $p = .047$). Finally, students in the "Other race" category reported significantly higher degrees of belonging than students identifying as White ($B = 0.68$, $SE = 0.25$, $p = .01$). No other significant associations were observed in Model 1 ($ps > .05$).

The change in our pooled R^2 from adding the interaction terms in Model 2 was statistically significant, $\Delta R^2 = .04$, $F(7, 311) = 2.23$, $p = .03$. The association between college-generation status and sense of belonging to one's course community was moderated by course version ($B = -0.53$, $SE = 0.52$, $p = .01$). Specifically, online first-generation students experienced lower belonging to their course community than any other combination of college-generation status and course version. No other significant interactions were observed ($ps > .05$). Figure 1 shows the distribution of our sample's sense of belonging scores by college-generation status and course version.

Figure 1

Distribution of Sense of Belonging Scores by College-Generation Status and Course Version



Discussion

In this study, we found that online students do not necessarily experience a lower sense of belonging to their course community than their in-person counterparts. We believe our study's specific course context may have contributed to this finding; the large nature of the class, as well as its lecture-style format, may have limited the amount of in-person interaction available to students enrolled in the in-person version of the course. This lack of in-person interaction, in turn, could have limited in-person students' abilities to develop a sense of belonging above and beyond what was experienced by the online students.

Moreover, although online and in-person students reported similar overall degrees of belonging to their course community, we found that the disparity in feelings of belonging between continuing-generation and first-generation students was significantly larger for students enrolled in the online, compared to the in-person, version of the course. This finding aligns with previous research demonstrating that first-generation college students are often less likely than their continuing-generation counterparts to be socially integrated into their campus community (Stebleton et al., 2014); it is possible that the isolating nature of online learning compounded this sense of isolation for our online first-generation participants, which yielded a lower overall sense of belonging to the course community. This result points to the importance of supporting the academic and social integration of first-generation college students enrolled in online courses.

Overall, our findings suggest that a student's sense of belonging emerges out of multiple intertwined influences that span students' social identities, academic performance, and course context. Future research should continue to account for the ways in which associations between student characteristics and sense of belonging may depend on one's specific course context.

All Rhodes Lead to Creativity

Sunny Pei, Jonan Phillip Donaldson, Jay Woodward
sunnyzhp22@tamu.edu, jonandonaldson@tamu.edu, drjay@tamu.edu
Texas A&M University

Abstract: This paper took a look at the ways that individuals interacted with and conceptualized creativity. Utilizing authentic artifacts taken from senior level creativity students as well as articles centered around creativity written by experts from a broad range of expertise, two conceptualizations were found using network analysis, titled the Complex-Originality-Connections conceptualization and the Solutions-Tool-Freedom conceptualization. The two conceptualizations emphasized different perspectives, and no noticeable difference was found between student and expert level individuals.

Introduction and background

The study of creativity is a field composed of numerous and distinct groups of people from different backgrounds in the academic sphere. From psychologists and educators to businesses, engineers, and chemists there are a plethora of diverse perspectives (Sawyer, 2011), but a unifying framework–Rhodes' 4P–provides a lens by which creativity has often been viewed through the categories of person, product, process, press (Rhodes, 1961). Virtually every profession demands the ability to introduce novel and useful changes to our work and surroundings which is imperative for innovation, growth, and happiness. The questions of what creativity is, how to measure it, how it impacts people, what it arises from, and how to nurture it are more prevalent now than ever (Runco, 2017). Today's changing global climate, rapid technological advances, and increased globalization demands that learning scientists design and facilitate learning that will allow people to thrive in contexts that require heightened levels of creativity (Pierroux et al., 2022). Complex conceptual systems theory (Donaldson & Allen-Handy, 2020) argues that conceptualizations are complex systems, and that practices are emergent from these conceptualizations. Our study does not attempt to define creativity, but rather to gain a deeper understanding of how people conceptualize it as this is a necessary step for facilitating development of creative potential and practices.

Methods

Data in this study came from academic articles from creativity researchers as well as authentic artifacts produced by undergraduate university students in a senior-level creativity course. The artifacts were produced by teams and could take either of two distinct forms: games or assessments. Regardless of the medium, both represented original designs that were grounded in fundamental concepts from the creativity literature. We collected and analyzed the papers produced by each team in which they described their product and provided justification for their design choices. For the academic journal articles, we searched for papers that focused on discussing either creativity or subjects relating to creativity filtered by highest cited through the Web of Science database. The results were further filtered to exclude papers that featured the same authors or were published in the same journal, save for the *Creativity Research Journal* and *Thinking Skills and Creativity* to ensure representation of the broad diversity of perspectives used by creativity researchers ending with 50 articles. These papers were then coded using MAXQDA Analytics Pro to capture and categorize all uses of metaphors, non-metaphor characterizations, practices, and value statements. Once completed, Pearson correlations were calculated within each coding category and imported into the UCINET network analysis software. Girvan-Newman cluster analysis was used to identify clusters. Clusters of metaphors were interpreted as conceptual metaphors, clusters of non-metaphorical characterizations were interpreted as conceptual stories, and clusters of value statements were interpreted as worldviews. These clusters were named and collapsed in MAXQDA. New network maps of correlations between these elements were analyzed using Girvan-Newman cluster analysis to characterize the different complex conceptual systems representing unique conceptualizations of creativity.

Findings

When analyzing both student submissions and professional publications, we found two conceptualizations of creativity through network mapping of correlated conceptual elements at the $p<0.001$ level, each of which was aligned with particular clustered aspects of the creativity landscape framework: The Solutions-Tool-Freedom conceptualization and The Complex-Originality-Connections conceptualization. There were no differences in conceptualizations between the creativity experts (articles) and the creativity students (artifacts).

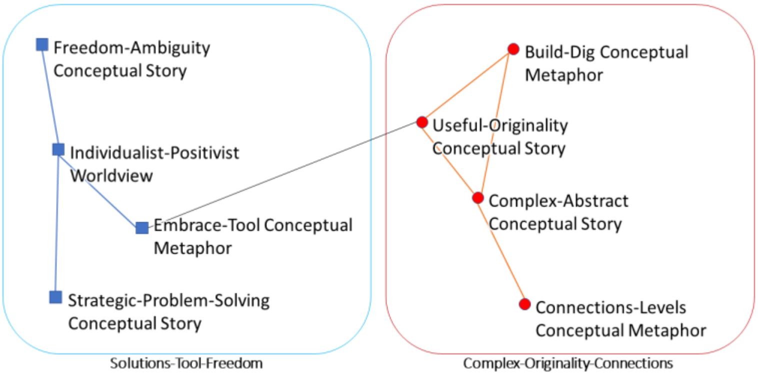
The Complex-Originality-Connections conceptualization (Figure 1, circle-nodes cluster) found that when people viewed creativity as all encompassing and difficult to define, they would use metaphors which had more physicality and spatial connotations, particularly when discussing creativity. Also contained within this conceptualization is the notion that creativity is a combination of divergent and convergent thinking in order to come to create a product or idea that is both relevant and useful, but also new and original.

The Solutions-Tool-Freedom conceptualization of creativity (Figure 1 - square-nodes cluster) found that when the concept of creativity was focused more on an individual characteristic, they would use metaphors that involved the personification of ideas. Additionally, this cluster more heavily emphasized the aspect of freedom and the ability to choose or, failing that, the importance of having a rebellious streak to go against the established norms. This is most heavily emphasized with the inclusion of an individual-focused worldview.

As mentioned above, the Individualist-Positivist worldview is part of the Solutions-Tool-Freedom conceptualization. In our study, we did find another worldview–the Collaborative-Interaction worldview–which did not cluster with any conceptualization of creativity. We interpreted this as suggesting that the Collaborative-Interaction worldview was ubiquitous.

Figure 1

Network map of elements in the two conceptualizations of creativity



Implications and discussion

The conceptualizations we found were aligned with important creativity theories and frameworks. Our finding of no difference in conceptualizations between the creativity experts and creativity students suggests that having students work in teams to design creativity games or assessments is a powerful means of structuring learning in creativity courses. Using the 4 Ps framework proposed by Rhodes (1961), we can observe that the two clusters emphasize different perspectives that are aligned with both the assignment itself and articulated tenets of creativity. The Solutions-Tool-Freedom conceptualization favored the person-centered and product-specific aspects of creativity. When it comes to designing new practices to improve and encourage learning, these individuals that have this conceptualization might approach the question by emphasizing the importance of individuals and evaluating based on the product produced, while underestimating the importance of supportive environments and collaboration. The Complex-Originality-Connections conceptualization emphasized the process and press aspect, while possibly overgeneralizing experiences and creating routine practices that may fit the requirements of most but allowing the few to fall through the cracks.

Embodied Math Learning Through Design Friction: An Argument in Favor of Flawed Tools

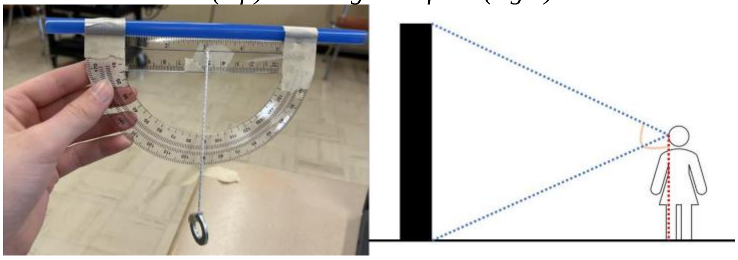
Peter J. Woods, University of Nottingham, peter.woods@nottingham.ac.uk
Amelia M. Farid, Massachusetts Institute of Technology, afarid@mit.edu
Grace C. Lin, Massachusetts Institute of Technology, gcl@mit.edu
Emma Anderson, Massachusetts Institute of Technology, eanderso@mit.edu

Abstract: This work explores the affordances of *design friction* – a term drawn from technology scholarship to denote embedded obstacles in tool use – in educational tools for mathematics learning. We present a case study analysis of a project-based learning geometry unit implemented in two classrooms. Analyses show that as students created a map of their local surroundings using a crude sextant rife with design frictions, they constructed powerful embodied understandings of mathematics.

Background

While most new technologies intentionally minimize design frictions, or "interactions that hinder people from painlessly achieving their goals when interacting with technology" (Mejtoft et al., 2019, p. 41), some scholars have argued that design frictions can interrupt mindless technology use, inspire reflective practices on the part of users, and produce clearer understandings of the technology's functions (Heeden, 2020; Sung, 2021). In turn, this body of research alludes to the learning potential of engaging design frictions, including those embedded within educational tools. We therefore use this poster to investigate how design frictions produce opportunities for embodied math learning. To do so, we draw on research that positions embodiment within human-tool interaction (Clark, 2008; Okita, 2015) and recognizes knowledge construction in mathematics education as an embodied process (Abrahamson & Sánchez-García, 2016; Ma & Kelton, 2018; Vogelstein et al., 2019). How design friction contributes to or detracts from embodied math learning, however, remains largely unexplored. To this end, we now turn to new empirical research to explore the intersection of design friction and embodied learning.

Figure 1
Crude sextant tool (left) and diagram of use (right)



Methods

Our findings come from case study research (Yin, 2019) into the initial implementation of a Project-Based Learning (PBL) unit in two geometry classes (with 20 students each) at a public US high school in a large, northeastern city. The unit aimed to develop trigonometry understandings by guiding students to create a map of their local surroundings without the aid of GPS or distance measuring tools (such as a tape measure), instead using a crude sextant (made out of a protractor, a drinking straw, a string and a weight) to measure various angles formed between themselves and external objects (see Figure 1). Because the sextant provided the angle formed between the object, the viewer's eye (acting as the vertex), and the ground (see Figure 1), students could use right angle trigonometry to determine distance. Due to numerous unintentional design frictions, the crude sextant students created proved difficult to use for multiple reasons: differences in posture produced inconsistent results, the string used to measure the angle would often swing back and forth, the protractors used by most students list two supplementary angles at every measure, and more. To collect data on this tool's use, we conducted 30-minute mid- and post-interviews with the teacher of both classes (Sam), two 30-minutes focus group interviews with seven students total, and collected/analyzed materials created by the students during the unit, thus ensuring reliability through triangulation (Denzin, 2012). To analyze the data, we employed a combination of descriptive and pattern coding techniques (Saldaña, 2015) to understand where participants encountered design frictions in the tool and how navigating those frictions created opportunities for learning mathematics.

Findings

Analyses revealed embodied mathematical understandings students developed when navigating design frictions in the sextant. One student, Laura, struggled to interpret the two vertically aligned supplementary angle measures displayed on the protractor: “It's hard to figure out which one’s the right one. If it's going up to 90, then I would be like, ‘OK, I am looking down.’ But if it was higher than 90, I was looking up.” By not readily providing users with an exact value, the sextant prompted students to consider the physical manifestations of contextualized angle measures and how they themselves embodied aspects of the problem (i.e. they represented one side of a right triangle). Similarly, Sam described the following issue that occurred when students tried to determine the distance to an object that was not on the ground: “when they were pointing their compass at the object, [they] had to take that into account how far above the ground that was. So I asked them ‘how could you work around it?’” In recognizing this problem, Sam locates a design friction with the tool (the sextant only gives limited information that may not be applicable in all instances) and identifies an embodied trigonometry problem (essentially, how to find the measurements of a trapezoid using trigonometry) that again positioned students within the problem.

Participants also discussed how design friction led to deep statistical thinking when developing techniques for increasing the sextant’s accuracy. As Laura described, “when [the string] was swinging back and forth, you couldn't really [record the angle measure] once. I did it a couple times to make sure that I was getting at least close numbers because it kept swinging.” In responding to the constant swinging of the string, Laura engages multiple mathematical thinking practices: checking one’s work by comparing that answer to contextual details (such as other recently recorded angle measurements), determining whether additional data is needed, and calculating averages to produce a more accurate solution. Sam engaged in a similar process when working with students: “I was having them [record measurements] a couple times and they would get different angles. I'd have them calculate the trig, see which one was farther away from the actual and say, ‘why do you think that was?’” In this example, Sam helped students better understand how to use the tool and check for accuracy. In doing so, he engaged them in statistical practices as they solved trigonometry problems.

Discussion and conclusion

Although the scope of this research does not translate into broad claims, our findings reveal one instance where design friction within an educational tool created opportunities for embodied mathematics learning. By not efficiently providing learners with the needed measurements, the crude sextant pushed students to situate themselves *within* trigonometry problems and use that embodiment to find solutions (such as by aligning specific values with “looking up” or “looking down” to work towards an answer). Drawing on these findings, we argue that education designers and researchers should further explore the use of design frictions in intentionally pushing students towards new and specific forms of mathematical thinking.

Comparison of Self-Regulation Process Patterns Between High and Low Achievers in TPACK Development

Yunian Zhang, Lingyun Huang, Boyin Chen, Minhong Wang
dianazhang@connect.hku.hk, lingyun.huang@hku.hk, bychen@connect.hku.hk, magwang@hku.hk
Faculty of Education, University of Hong Kong

Abstract: The study explores teachers' self-regulated learning (SRL) process patterns in technological pedagogical content knowledge (TPACK) development. SRL processes were analyzed through think-aloud protocols. TPACK achievements were assessed by the quality of participants' lesson plans. Preliminary results showed high achievers performed a more recursive sequential regulatory pattern, while low achievers showed a more linear one. Teachers with a more successful SRL model could achieve better TPACK performances. These findings could contribute to detecting the relations between SRL and TPACK.

Introduction

Technological pedagogical content knowledge (TPACK) represents teachers' knowledge of integrating technology into different knowledge dimensions to scaffold students in constructing new knowledge (Mishra & Koehler, 2006). Recent research finds that developing TPACK should consider authentic instructional tasks and teachers' self-regulated learning abilities (Huang & Lajoie, 2021). Self-regulated learning (SRL) refers to the self-regulatory processes that enable learners to transform preexisting abilities into task-related behavior to attain goals, reflecting the degree to which learners are metacognitively, motivationally, and behaviorally active participants in learning processes (Zimmerman, 2000).

SRL supports TPACK development by engaging teachers in cognitive and metacognitive regulatory activities in a goal-oriented process (Poitras et al., 2017). Previous studies have found that learners with more SRL competence, especially metacognitive regulatory abilities, could achieve better TPACK performance (Huang & Lajoie, 2021). For example, the authors presented several self-regulatory process models SRL in response to different TPACK levels (Huang & Lajoie, 2021). One common feature of these significant studies is that SRL is measured through log data collected during learning. While log data are more objective, easy to be gathered, and informative of contexts where self-regulation occurs (such as time, sequences, etc.) (Azevedo & Gašević, 2019). Think-aloud protocols are another optimal option for capturing SRL processes accurately and dynamically, giving researchers access to learners' thought processes through their verbalizations in a learning task (Greene et al., 2010). Thus, the purpose of this study is to know how teacher performs self-regulation in TPACK learning. We collected and analyzed teachers' think-aloud protocols and created the SRL process patterns with a process mining algorithm. To gain the nuanced differences, we retrieved the SRL data from high achievers (5 participants had the best TPACK performances) and low achievers. This paper will present the preliminary results, given data analysis is still in progress. In this research, we aim to (1) identify SRL process patterns while teachers are involved in lesson design with TPACK, (2) compare patterns' differences between high and low achievers, and (3) better understand the role of SRL in TPACK.

Method, analysis, and results

Twenty-eight third-year student teachers from a normal university in China voluntarily participated in this study. They were asked to design a technology-integrated English lesson on nBrowser (c.f. Poitras et al., 2017), which is an open-ended learning environment that adaptively fosters SRL and TPACK development. Meanwhile, they needed to verbalize their thoughts during the whole process of recording their think-aloud data. Each of them met the experimenter and implemented the study individually.

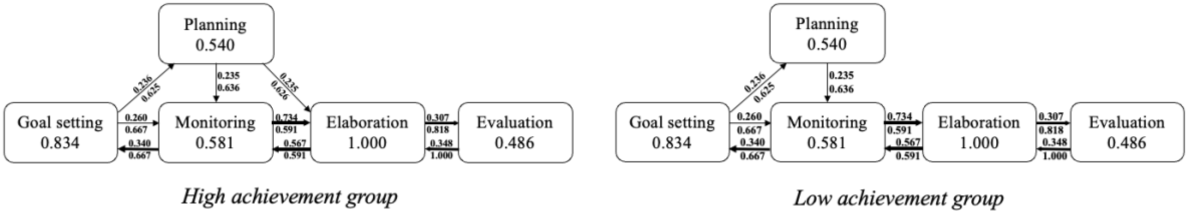
Pre-implementation began with the introduction of nBrowser and think-aloud training to familiarize participants with the platform and verbalization of thoughts. Then they had 45 minutes to design the lesson. Their lesson plans served as one indicator of TPACK achievements. The recorded think-aloud data were coded using an SRL coding scheme adapted from Azevedo et al.'s scheme (Azevedo & Gašević, 2019) and analyzed using Fuzzy Miner (Günther & van der Aalst, 2007), which is an algorithm to place the unstructured events into interpretable models. The alogorithm uses two fundamental metrics, *significance and correlation*, for computing a process model for the given data set. Thus, we could identify participants' SRL process patterns in TPACK development from unstructured think-aloud data. TPACK achievements were assessed by evaluating their lesson designs according to the criteria documented by Author et al.(2021).

We created a high-achiever sub-cluster (top 5 participants) and a low-achiever sub-cluster (last 5 participants) based on their TPACK achievements. The two preliminary process maps generated by Fuzzy Miner were described and presented in Figure 1. Even though both maps contained identical five events, their occurrence and relationships were quite different. In the high-achiever group, all SRL events were connected, forming an iterative and recursive sequential model. It showed that participants enacted the primary sequence of events: Goal-Setting-Planning-Elaboration-Evaluation. Regarding the event connections, Elaboration was strongly and significantly mutually connected with Monitoring. It is also connected with Evaluation with moderate strength and significance. The event of Monitoring was highly directed to Goal setting, but the magnitude of the connection from Goal setting to Monitoring was weak.

The process pattern in low achievers was more linear and straightforward. The primary common path of the pattern was a loop consisting of Goal setting, Monitoring, Elaboration, and Evaluation. There also existed a weak loop of Goal setting, Planning, and Monitoring. The connections between Elaboration and Monitoring/Evaluation had the highest significance in this pattern. But the lack of connections between Planning and Elaboration revealed that they less regulated their planned strategies, which was the main difference from higher achievers. It suggests that participants might finish their lesson design with fewer considerations of monitoring and evaluating specific plan strategies.

Figure 1

The SRL Process Patterns of the High (Left) and Low Achievers (Right)



High achievement group

Low achievement group

Discussion and conclusions

This study identified two distinct SRL process patterns of high and low achievers in TPACK learning. The results showed that high achievers' SRL pattern was more goal-oriented and recursive. Participants designed their lesson starting with constructing instructional goals, monitored and evaluated comprehension and modified learning. This aligns with previous evidence that teachers' SRL promotes TPACK (Huang & Lajoie, 2021). However, since it is a preliminary analysis based on partial data, we need more data to confirm such findings and to gain a holistic understanding of the relations between teachers' SRL and TPACK development. Despite so, the findings add solid evidence to the literature and provide implications for teachers, educators and school administrators regarding the importance of self-regulation in teachers' learning and professional development.

Thinking About Values and Ethics of Transdisciplinary Science Activities: A Case of Palestinian Arab Young Learners

Areej Mawasi, Technion, areej.mawasi@ed.technion.ac.il
Ruth Wylie, Arizona State University, ruth.wylie@asu.edu

Abstract: Learners' values and ethics systems shape how they engage with learning activities. We explore how ten young Arab Palestinian learners think about ethics and values when they talk about transdisciplinary science activities and roles. We argue that meaning-making related to values and ethics presents opportunities for young learners to draw upon their existing cultural resources as they engage in transdisciplinary activities and think of values and ethics.

Introduction and background

Many existing frameworks of science ethics center on ideas and perspectives around practices that exist within Western Science practices (Kimmerer, 2013; Medin & Bang, 2014). Conceptions of ethics through Western epistemologies often ignore the perspectives and ethical systems of nondominant communities (Bang et al., 2016) and may be in tension with the values of nondominant learners, thereby interfering with their engagement in science. Here, we report findings from interviews with ten Palestinian Arab learners, analyzing how they perceive and describe values and ethics. We build on Bang et al.'s (2016) work to conceptualize our findings as *axiological ways of thinking, doing, and being,* where axiologies are defined as "values, ethics, and aesthetics—that is, what is good, right, true, and beautiful—that shape current and possible meaning, meaning-making, positioning, and relations in cultural ecologies" (Bang et al., 2016, p. 1-2). We chose an axiological framing (Bang et al., 2016; Tolbert & Bazzul, 2020) because we identified that learners think in expansive, complex, and value-laden ways about ethics, aesthetics, and relations with humans and others when describing their experiences. Here, we ask: What values emerge when learners articulate their beliefs and perceptions about their science-related activities?

Methods

Context

Ten learners (5th and 6th grades) participated in four days of activities (~8 hours total) led by two educators from Al-Rowad for Science and Technology, an organization that supports Arab learners' participation in science and technology in Israel. Each day, learners completed a hands-on activity associated with a scientific phenomenon. The activities were transdisciplinary, combining science with art, engineering, and math through features like colors, shapes, and measurement. Following the four days of instruction, the first author, Areej (a member of the local community who speaks the local language) conducted interviews to explore learners' perceptions of their engagement in activities. Interviews were conducted individually and mainly in spoken Palestinian Arabic, the local language of the youth participants.

Interviews and data analysis

We used interviews to explore learners' beliefs and perceptions of transdisciplinary science activities. As an instrument, the interviews afforded us a space to engage learners in meaning-making about their activities in the program, as well as everyday science-related activities. The interviews lasted 48.4 minutes on average (SD=8.9min). We recorded and then transcribed the interviews. The interview protocol addressed a variety of questions related to students' perceptions of the activities and roles of scientists, artists, engineers, and inventors. This paper focuses on questions and stances related to values and ethics, such as the notion of responsibility when doing a science activity and understanding learners' ethical thinking (e.g., Imagine your invention caused an issue in your house. Who would be responsible for that?).

The interview data was coded across two cycles, and then an interpretive approach was applied (Saldaña, 2015). The applied codes were in English and selected examples were translated for discussion among authors. The first coding cycle focused on identifying places where students talked about responsibility in doing science. During the two coding cycles, we noticed learners were thinking in more complex ways about ethics than we had initially anticipated; therefore, in the second cycle, we expanded the coding into a "values" category to capture instances when learners talked about responsibility, harm, ethics and morality, design aesthetics, and the utility of science.

Findings

Ethical thinking is evident in learners' meaning-making related to their beliefs and perceptions of their learning activities in the program and other related activities in their everyday. We describe our findings through five themes: ethics, responsibility, utility, aesthetics, and relations.

Learners conceptualized *ethics* in multiple ways when describing people's roles and actions. These include ethics as: a characteristic of a scientist, the recognition of the consequences of actions, causing no harm or damage, and undertaking good or bad actions. For example, one student, explicitly mentioned ethics when responding to the question, "What characteristics should you have to become a scientist?" saying, "intelligence/smart, ethics, and patience."

We derived the *responsibility* category from our interview question about who should take responsibility if a hands-on science artifact that learners built as part of the program, or an invention they created, were to cause damage or harm (e.g., to humans, more-than-human beings, or objects). We identified that learners' perceptions are often connected to their experiences in school. For example, learners focused on the figure of a responsible student and the ethical valence of listening to one's teachers and following rules of discipline. We acknowledge this question threatens to narrow thinking about ethics by tethering it to issues of responsibility and consequences, yet there is evidence in our findings for learners' expansive thinking about ethics beyond this framing.

Through learners' stances about *the perceived utility of science activities*, they articulated how they would use the artifacts created through those activities, in varied ways that include: displaying the artifact, using it for personal play or with other family members, drawing on it, engaging family members in conversation about it, and observing changes in it. These examples demonstrate that learners had their own unique perceptions of how to use the products of hands-on activities, beyond viewing them as scientific artifacts. Overall, we found that learners perceived the utility of the activities they completed by making connections to values they describe (e.g., relations with family members, using artifacts in a beneficial way, considering the artifact as an aesthetic object).

In the analysis, we found learners describing the ethical features of artifacts and materials they engaged with in terms of design. The category of *aesthetics and beauty* emerged from learners' descriptions of their process, how materials or design manifest visually, and the learning experience as a "beautiful" one.

Finally, it is evident in the findings that learners' engagement with transdisciplinary science activities is contextualized in *relation to others* as well. This was particularly clear when learners described everyday experiences with humans and more-than-human beings, as well as perceptions of their activities. *Relationality* is not always characterized in a positive light; it also included examples where learners wrestled with ideas (e.g., using animals in scientific research) or described inequitable and fraught interactions among people.

Discussion

The findings suggest that learners' axiologies are interconnected and interact with learners' cultural resources and everyday experiences. These resources and experiences are essential for how they engage with learning activities and the possibilities they can imagine for themselves. In some cases, we identified tensions between values inherent to learners' worldviews and values inherent in science practices. Such tensions reflect how learners could be wrestling with contradictions between their own thinking and dominant science practices or normative ideas. These tensions also suggest complexities within the dynamics of childhood-adulthood, nature-human, and cultural values-dominant values when it comes to what counts as science knowledge and practices (e.g., Kimmerer, 2013). We see the complexity of ethical thinking among young learners as an invitation to consider values of relations, care, and aesthetics as fundamental to their engagement in learning environments.

“You tried one hundred thousand times”: A Learner’s Resisting Behavior(s) towards Self and Collective Rights to Participate Equitably

Areej Mawasi, Technion, areej.mawasi@ed.technion.ac.il

Abstract: The context of this poster work is an out-of-school transdisciplinary science program for young Arab learners. Here, I focus on moments of resistance to norms during participation in learning activities that included discussions and hands-on tasks. I present two examples of an interaction analysis where resistance as a form of self-determination creates learning opportunities for the individual learning and their peers collectively to participate, resist, and express themselves.

Introduction

Out-of-school learning environments can provide learners with opportunities to engage in activities where they do hands-on activities, discuss with one another, and explore materials they are not used to at school. This poster explores a learner’s engagement in a transdisciplinary science program activity to examine how it supports (or not) their acts of self-determination as reflected through resistance to activity norms and expressions that have individual and collective ends. Although prior work in the Learning Sciences addressed dynamics and interactions in STEM environments, less work has been focused on the enactment of self-determination of nondominant learners and its collective outcomes for classroom learning (Davis et al., 2020). Focusing on an episode of resisting norms during activities, I present two examples about the behaviors a young 5th grade Arab Palestinian learner. Throughout the learners’ interaction dynamics, I consider relationality building with peers as an ethical process that have implications for learning collaboratively with others (e.g., Vossoughi et al., 2020). I argue, the learner’s resisting behaviors reflect his active role as an actor in addressing power dynamics towards shifting it.

Methodology: Activities, participants, and major procedures

This study is part of a larger project aims to better understand the engagement and participation of young Arab Palestinian learners within a community-based organization’s transdisciplinary science program in Israel (Mawasi, 2021). This poster draws on interaction analysis from the third day of the program, when learners built an Illuminating Board artifact. I chose to focus on the two hours activities during this day because it afforded various activity contexts (i.e., building, testing materials, drawing, discussions) and learners became more familiar with the space norms, educators, and their peers. Ten fifth- and sixth-grade learners (five girls, five boys) participated in the program (Winter break of December 2019). Two educators were present in the space. Through the analysis, the focus on Rami’s case (pseudonym) was by noticing his interaction with peers when offering help, participation in discussion, and a mixed usage of play talk and scientific vocabulary. This interactivity also extended to ways the learner was using materials in the space to build his artifact, including, building step-by-step, testing materials, expressing with materials, and inviting other peers to join him for such activities. Finally, the observation in videos for the learner behaviors included his interaction with educators as well.

For this poster, I draw on videos of the third day activity of the program: recordings of 14 videos with segments of 7.75 minutes on average (~2 hours). These videos focused on Rami’s behavior when doing the hands-on activities. At the same time, I supplemented these videos with notes and photographs that I took in the space, and other video-camera angles that recorded the whole classroom as a supplement. Throughout the interaction analysis I developed analytical memos and notes that were also supported by screenshots from videos.

Figure 1
Calling for equitable participation: Rami (red) pointing his hand towards Faris (red)

This study focuses on Rami’s interactions with peers, educators in the setting, and materials. The interaction analysis of videos considered talk (e.g., playful talk, science vocabulary), hands gestures (e.g., pointing towards others or materials, building artifact with carefully), and moving in the space (e.g., standing, moving from his chair to white board) in the space (Erickson 1986, 2006; Jordan & Henderson, 1995; Vossoughi et al., 2020). I started this study with a broad question on how learners engage and interact in this learning setting. I wrote memos and analytical notes to identify Rami's behaviors with peers, materials, and educators. Then, I used Davis et al. (2020) as a framework to identify and expand Rami's acts of self-determination. This included, moments of resistance, expressions, humor and play, and interaction with others and materials.

Findings: Resisting for self and collective right to participate equitably

While Rami contributed to discussion, in some cases, he resisted existing norms and inserted his own right to participate and other participants rights to participate as well. This particularly was during two moments where he argued for fairness in participation among learners: one with the teacher and one with another student in the classroom. In one example, the teacher did not give Rami as much time as another student, Faris (pseudonym), to draw on a big Illuminating Board, consequentially, Rami attempted to take materials from the teacher without permission and then by end of the day activities, Rami expressed his frustration by writing the word "#Tuz #طز" (an Arabic expression that reflects frustration) on his own board. In a second example, this frustration about fair participation, was enacted not for himself, rather, for supporting other peers. In a discussion about the spectrum of light, students raised their hands to answer teacher questions, as a common norm of this setting. Faris from the back interrupted while raising his hand and said "me, I want to say something." The teacher said, "Can we try to listen to Noura, let's have turns, I will listen to you, I will listen." Faris insisted, "teacher no, let me." Rami turned to the back and pointed at Faris, he said, "you tried one hundred thousand times." While Rami was exaggerating, he was referring to that Faris had the opportunity to answer and talk in discussions many times, while others did not, and now Faris should give other people the opportunity to answer (see Figure 1). Faris put his face down. Noura (pseudonym) began to talk; Rami moved his face to his left side to listen and looked towards Noura. Faris looked towards Noura too, at the same time he was still moving his body up for teacher attention. Here, Rami's act of self-determination was to suggest to Faris to be respectful to others, which created an opportunity for Noura to talk and join the discussion.

Conclusions

The findings demonstrated varieties in how self-determination was enacted in the two examples by Rami. In the discussion flow, Rami's acts of self-determination were reflected in asking for fairness in participation, wondering out loud with peers in discussions, and expressing his frustration on his own artifact. The findings suggest, in alignment with Davis et al. (2020), these moments enabled Rami to navigate his learning trajectories, help others, express himself, and participate in the learning space practices to explore new ways of learning beyond disciplining norms. These behaviors were made possible by asserting his (and other learners) right to participate equitably in discussion and activities while exchanging this political view with educator in the space. Finally, these activities are contextualized in the evolving history of the learning that was happening in the program among learners and with teachers. Future work may consider examining the impact of teacher specific instructional moves and pedagogy on creating opportunities for the learner to engage in resisting, expressions, and playfulness.

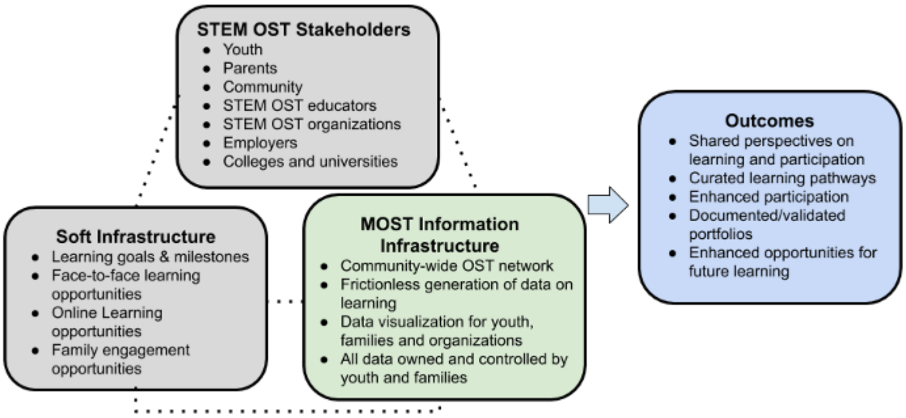
Abstract: This poster explores a method for documenting learning in out-of-school-time (OST) settings such that the values of youth and OST providers are preserved and highlighted. OST learning documentation can serve a variety of purposes, including as evidence of college readiness. The poster presents a prototype of a personal learning record for OST learning and discusses tensions and opportunities for such a record of learning and explores key tensions in creating such a representation.

Introduction

There are many reasons to document youth learning in out-of-school time (OST) or informal settings. These include helping guide youth to future learning opportunities, helping youth pursue work, or as part of pursuing future formal education such as college (Keune et al., 2022). Such documentation could also be valuable to OST organizations, both for program improvement and for obtaining funding. There are also a range of tensions that emerge from the process of attempting to document youth OST learning. What counts as learning? What kinds of knowledge are privileged? And how do we avoid damaging the motivations youth have for engaging in OST activities with the addition of formal assessment and documentation of learning (Torrance, 2012)?

This poster presents work-in-progress from an NSF-funded project exploring the documentation of learning in OST contexts as part of expanding college access. The poster contains a prototype record of learning intended to be used alongside traditional college application materials. It also describes the research on OST learning used to inform the prototype and invites discussion of pathways forward in this design space. A goal of the project is to center and elevate an OST STEM learning ecosystem (Pinkard, 2019) in which the views, values, and goals of different stakeholders are valued and represented (see Figure 1).

Figure 1
An OST STEM Learning Ecosystem



Design of the study

This project explores the learning experienced by youth in three different OST contexts, selected in part for their divergent goals and *modus operandi*. One is a community-based program in the U.S. Pacific Northwest for mixed income, refugee, and immigrant youth. Another is a middle-grades coding program in the U.S. Midwest designed to enhance learner self-concept around computing. And the third is a university-sponsored college preparatory program in the U.S. Midwest designed to enrich learning for high school students and prepare them for success in higher education. To investigate learning, we interviewed both youth and their caregivers and OST providers. We also interviewed college admissions personnel from a broad range of institutions to understand how they currently view OST learning and how different representations of OST learning might elevate its role in the college admissions process. Using inductive coding, we investigated each of these interviews to surface themes and patterns. We then shared these observations with OST youth, families, and providers to understand how they recognized their learning in our data, and with college admissions personnel to understand how they might view our data about learning in their work. From here, the project team worked with our partner the [redacted for review], an organization focused on the development of mastery-based transcripts for use in formal K-12 education, to extend their transcript concept into the OST space. This prototype (see Figure 2), which we refer to as a personal learning record instead of a transcript, was then shown to OST providers to see if they viewed it as useful and representative of their activities, with youth and families, to see if they viewed it as representative of their values and learning, and with college admissions personnel to see if they viewed it as useful in their holistic review processes. Detailed findings and a discussion of the tensions described above are presented in the poster.

Abstract: Possibilities to support lifelong learners with learning analytics (LA) tools must be examined. We investigated what type of support user expect from LA guidance tool. Qualitative analysis identified five key themes important for users in the context of LA-supported lifelong guidance: Education and work information provision, diversification of understanding about available career paths, sense making, self-reflection, and transition support. The results highlight potential directions for developing LA guidance tools.

Introduction

The world of work is becoming increasingly unpredictable, leading to a growing number of occupational, industrial, and geographical transitions (Sullivan & Al Ariss, 2021). From the individuals' perspective this requires lifelong learning, building on past experiences, information about self and the world in order to make decisions and to find paths towards desired educational and occupational outcomes. Emerging technologies represent a major knowledge gap in this context as little is known how they can be utilized to support individuals through lifelong learning and work. Previous research has argued that LA holds potential to support humans through life transitions (Poquet et al., 2021). Through LA tools based on accumulated individual data it is possible to utilize individuals' previous learning information for lifelong guidance purposes. This process could be further optimized through individuals' needs and preferences. For instance, empirical research showed LA tools to be used for academic advising support within higher education institutions (Gutierrez et al., 2020). However, user needs and expectations in the context of lifelong guidance remains unexamined. In this research we investigate possible contributions of LA to lifelong guidance through the inquiry of users' expectations for and feedback about the LA lifelong guidance tool. We aim to better understand what type of support individuals expect to help them move through life transitions. This work contributes to better understanding future development directions of emerging technologies for guidance purposes.

Materials and methods

Participant group (N = 106) comprised of 42% men and 57% women; age mean 21.7 years. Basic education was completed by 72.6%, vocational education and training by 17% and higher education by 9.4% of the users. The users used a LA lifelong guidance tool, which suggested study programs and places based on user's interest, likes and dislikes in education. Users' expectations and feedback were gathered in a questionnaire and analysed inductively using qualitative content analysis to identify prominent themes in connection to the LA tool use.

Results and discussion

Results revealed five key themes important to users in the context of LA lifelong guidance (Figure 1), adding additional layer of understanding how LA could be used to benefit lifelong learners.

Quality career information on educational opportunities, and job market situation came out to be essential for the users. In agreement with previous research, provision of career information is a fundamental requirement of career guidance technology.

> Participant 1: *If you don't know about training/education, you get information and get acquainted with different levels of education or training, you get information on where to ask for more.*

Diversification of understanding of possible career paths was key expectation from the users' perspective. LA can respond to this need by helping users to re-evaluate their backgrounds and interests in different contexts. Results of this study provide promising direction for this possibility, which must be further researched. Developments in this direction could also facilitate career guidance objectives for social justice.

> Participant 2: *[The LA tool] provides a wide variety of educational opportunities that you may*

not have considered.

Sense making support was expected helping to understand and analyse provided information. Although traditionally this has been attributed to counsellor's work, availability of human support is often limited. Clear need has emerged not only to provide information but to support further analysis and interpretation for actionable career path insights.

Participant 3*: [I would use it] to compare study fields and different levels of education.*

Self-reflection support was expected to better understand career interest and options in the context of own life. Previously LA has been used to facilitate self-reflection in institutional learning context, however, it must be further explored in the lifelong guidance perspective. For instance, interest should be clearly reflected in the provided career recommendations.

> Participant 4: *[There should be] questions about career aspirations, life wishes and dreams (family, career, childlessness).*

Supporting transitions – the users note both technical LA tool support for transitions (e.g., applying to study programs) as well as psychological benefits (e.g., getting confidence needed to make decisions). Accordingly, LA could support users to set short- and long-term goals, progress into and out of education, into the world of work and between jobs. Although current maturity level of the LA guidance tool was limited, results present an interesting possibility. Thus, the category contains both kinds of answers.

Participant 5*: You get assurance of what to start doing.*

Figure 1
Identified types of support users expected from the LA tool

AI-Integrated Virtual Students for Teacher Training: Comparing Simulation-Based Classroom Dialogue With the Real Thing

Alex Barrett, Fengfeng Ke, Chih-Pu Dai, Luke West, Saptarshi Bhowmik, Nuodi Zhang

Abstract: This paper reports on a study of AI-integrated virtual student agents designed for preservice teacher training. Eight preservice teachers engaged in a simulated science class where they conducted multiple lessons with the virtual students. Simulation lesson discourse was transcribed and compared to that of in-service teachers conducting lessons with real students. Results indicate that the virtual student authentically replicated declarative and interrogative patterns of discourse, but preservice teachers asked fewer questions than their in-service counterparts.

Introduction & theoretical background

Providing preservice teachers with authentic experience has been a focus for teacher educators. One way to accomplish this is through simulated teaching. Artificial intelligence (AI) can be used to render simulation-based virtual agents that reflect the cognitive-affective states of real students. However, AI-integrated virtual student agents need to be scrutinized for authenticity.

For agents to be perceived as authentic, cognitive-affective student models can be integrated into a language model (Dai & Ke, 2022) to generated discourse that is similar to that of real students. The difference between AI-generated discourse and that of human students remains an open question. This invites the use of discourse analysis as a tool for analyzing dialogue systems, which is a common tool for evaluating conversation agents to gain insight into the accuracy of the conversation agent's logic and the behavior of the human interlocutor (Hobert, 2019). A surface level inquiry into the function of statements made by the agents with preservice teachers on the one hand, and in-service teachers with real students on the other, can illuminate patterns of discourse that provide insight into both the agent's functionality and preservice teacher performance.

We therefore analyzed the classroom dialogue of preservice teachers and AI-integrated virtual students from a discourse perspective with the goal of comparing simulated and real classroom discourse, assessing both authenticity and efficacy for teacher training. The research question guiding this study is how do the mean frequencies and ratios of statement function (declarative, interrogative, imperative, and exclamatory) compare for teachers and students within and between actual and simulated classrooms?

Method

This split-plot study involved eight pre-service STEM teachers recruited from a teacher training program at a U.S. university. Participants underwent four-hour teaching practice sessions that included preparation, delivery, and reflection of teaching a STEM topic exemplified in Ambitious Science Teaching (Windschitl et al., 2018), a K-12 STEM teaching framework initiative. Lessons were delivered by the preservice teachers in *OpenSimulator*, a 3D virtual world, to AI-integrated virtual student agents. The agents were programmed with a generative, pre-trained transformer-based deep neural network model trained on authentic STEM classroom dialogue (see Bhowmik et al., 2022).

The text-based interactions between the preservice teachers and the AI-integrated virtual student agents resulted in a transcript of over 12,000 words for analysis across 12 separate teaching sessions. Additionally, 24,000 words were manually transcribed from actual teacher-student dialogue for comparison.

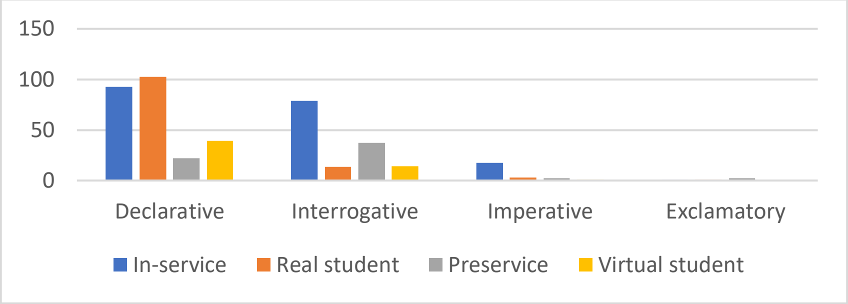
Data were analyzed by coding the transcripts by frequency of statement function based on the four typical function types: declarative, interrogative, imperative, and exclamatory. Frequencies were averaged per teaching session and ratios were calculated to allow comparisons between class contexts (actual and simulated). Select comparisons among these figures were made using an analysis of variance (ANOVA).

Results

Figure 1 depicts mean frequencies of statement type from the actual and simulated classroom sessions. In the simulated classroom, preservice teachers, on average, used significantly fewer declarative statements than the virtual student (F (1, 22) = 7.36, p = .013), but significantly more interrogatives (F (1, 22) = 8.22, p = .009). Imperative use was non-significant between preservice teachers and the virtual student (p = .181). For both simulated and real contexts, exclamatory statements were too infrequent to warrant comparisons. In-service teachers in an actual classroom context, on average, also used significantly more interrogative statements (F (1,

16) = 14.24, *p* = .002), and spoke more per turn at talk (*F* (1, 16) = 11.77, *p* = .003). However, unlike in the simulated classroom, in-service teachers did not have a significant difference in declarative statement use from real students (*F* (1, 16) = .185, *p* = .673), and used imperatives significantly more (*F* (1, 16) = 14.13, *p* = .002).

Figure 1
Mean frequencies of statement types in dialogues from simulated and actual classrooms.



Note. Actual classroom sessions tended to be almost twice as long as simulated sessions and therefore between-group comparisons in this figure should be avoided.

Table 1 shows the teacher-to-student mean ratios for statement functions for dialogues that took place in both the simulated and actual classrooms, allowing for between-group comparisons. For declarative statements, the mean teacher-to-student ratios were non-significant between simulated and actual contexts (*F* (1, 19) = 1.24, *p* = .280), as were the imperative ratios (*F* (1, 8) = .10, *p* = .765). Mean interrogative ratios, on the other hand, were significantly different between contexts (*F* (1, 19) = 9.95, *p* = .005).

Table 1
Teacher/student mean ratios for statement types from simulated and actual classrooms.

	Declarative	**Interrogative**	**Imperative**	**Exclamatory**
In-service teacher / Real student	0.93	16.89	1.02	-
Pre-service teacher / Virtual student	0.71	4.04	1.36	-

Conclusion

To summarize, within both contexts, students used more declarative statements than teachers, and teachers used more interrogatives than students. Between contexts, teacher-to-student interrogative ratios were much larger in real classrooms, with in-service teachers using them almost 17 times more than students, compared to preservice teachers' four-fold use. These findings can aid in better coaching of preservice teachers and in further developing the AI-integrated virtual student agent.

Voices From the Field: Teachers' Perceptions of Who Teacher Leaders are and What They do

Mahtob Aqazade, Rice University, mahtob.aqazade@rice.edu
Adem Ekmekci, Rice University, ae16@rice.edu

Abstract: Teacher leadership is important for providing high-quality education. However, there is little consensus on what constitutes teacher leadership. We explored perceptions of eight teachers about teacher leadership. The following themes emerged to describe teacher leaders: being a model, lifetime learner, experienced teacher, listener, aware of everyone's needs, communicator, and collaborator as well as assisting teachers and improving students' learning. Those who participated in a teacher leadership program were engaged in professional development beyond school-level.

Introduction

Providing teacher leadership opportunities may be a potential solution to support building knowledge and sustaining a community of highly qualified teachers. To conduct rigorous research on the impacts of teacher leadership opportunities, many scholars attempted to describe teacher leadership and what teacher leaders do. However, many studies still failed to provide an encompassing definition of teacher leadership (Nguyen et al., 2019; Wenner & Campbell, 2017; York-Barr & Duke, 2004). The conceptualization of what constitutes teacher leadership is widely varied across literature (Neumerski, 2012; Nguyen et al., 2019). Broadly, some definitions of teacher leadership include going beyond classroom walls by "maintaining K-12 classroom-based teaching responsibilities, while also taking leadership responsibilities outside of classroom" (Wenner & Campbell, 2017, p. 140). However, these definitions mainly represent the perspectives of researchers that are external to the practice. Therefore, it is important to explore the teachers' perceptions regarding teacher leadership. Such exploration can advance the current teacher leadership frameworks and models (e.g., Teacher Leadership Exploratory Consortium, 2011) by bringing in the practice side of the coin and bridging research and practice. Handful of studies investigated how teachers' perceptions of teacher leadership (e.g., obtained through teacher leadership inventory survey; Angelle & Teague, 2014) relates to other factors such as self-efficacy, age, gender, educational qualifications, and teaching experience (Aliakbari & Sadeghi, 2014; Angelle & Teague, 2014) or the schools' culture and context (Bradley-Levine et al., 2014). These studies are limited by self-reported surveys of teacher perceptions and do not necessarily focus on defining teacher leadership. In this paper, through in-depth interviews, we aim to explore how master teacher fellows (MTFs) described the characteristics of teacher leaders and what teacher leaders do in comparison to non-MTFs. The following research questions framed our work: How do teachers perceive teacher leadership (characteristics and what do teacher leaders do)? Do perceptions of MTFs and non-MTFs differ in this regard?

Methods

We conducted one hour-long semi-structured Zoom interviews with eight mathematics teachers (three male, five female; six White, one biracial, one African American) with 10 to 25 years of teaching. In this paper, we focused on the following interview questions "What do you think the characteristics of a teacher leader are? What do you think teacher leaders do?" We used deductive, thematic data analysis (Saldaña, 2021) and drew from York-Barr and Duke's (2004) review summary.

Results

There were no noticeable differences between MTFs' and non-MTFs' descriptions of teacher leader characteristics. We found four common themes: being a (a) model, (b) lifetime learner, and experienced teacher, (c) listener and aware of everyone's needs, and (d) communicator and collaborator. Both non-MTFs and MTFs indicated that being a model for teachers and students is one of the teacher leaders' characteristics. For instance, a non-MTF, said, "A leader also sets the example by continuing to learn and change and to teach other people what to do." An MTF thought "they [teacher leaders] set an example for other teachers" and "model what they should be doing." To become a model for other teachers and students, teacher leaders need to also continue to learn and develop their knowledge of teaching and learning. Both MTFs and non-MTFs highlighted the importance of "continu[ing] to learn and change," "grow[ing] from what I was learning," and "learn[ing] from each other…grow[ing] together." An experienced and knowledgeable teacher can offer "suggestions on how to better fit into the faculty climate," provide "content-focused coaching," or "share ideas" about teaching and learning as well as understand and make use of students' assessment data. MTFs and non-MTFs described that teacher leaders need to listen and become aware of everyone's needs. It is only by being a good listener, a teacher leader can "understand what is needed and assist newer people in achieving certain levels." As a teacher leader, a non-MTF, said, "I need to listen to other people…to my students when they tell me things. I need to listen to other teachers when they tell me about the problems and the struggles that they are having." Being a good listener is one step toward being an effective communicator and collaborator. The communication skills and ability to collaborate were other characteristics of teacher leaders. For example, an MTF explained, "being able to communicate with a teacher without them feeling like they're inadequate, or they don't know what they do…always trying to be positive with them and just trying to build them up…"

The teachers describe the characteristics of a teacher leader in relation to their leadership responsibilities. These responsibilities illuminated what teacher leaders do or are expected to do, which were centered around different approaches to assisting teachers and improving students' learning. For example, an MTF said, "I think a teacher leader is someone who, you know, who assists teachers, works collaboratively with teachers to better craft their teaching, you know, through content-focused coaching." MTFs more often thought of these leadership responsibilities in a broader range and were more engaged in their school and district PD programs compared to non-MTFs. For example, an MTF took part in designing questions "for the high school level, national level."

Significance, contribution, implication

In this paper, we found four common themes highlighting the characteristics of teacher leaders: significant experience and extensive knowledge, lifelong learning, and communication and collaboration skills (in line with prior studies; e.g., Katzenmeyer & Moller, 2001; York-Barr & Duke, 2004). Further, teachers described what teacher leaders do by primarily focusing on what York-Barr and Duke (2004) referred to as the professional development of colleagues. However, in comparison with non-MTFs, the MTFs' engagement in leadership activities were beyond their schools. The implication of this study is particularly important for those who plan and support teacher leadership programs. The results of this paper contribute to the conceptualization of what constitutes teacher leadership from teachers' perspectives and provide practitioner insights into models and frameworks for teacher leadership.

Science and Mathematics Teacher Retention: A Collective Analysis and Comparison Between Master Teachers and Other Teachers

Adem Ekmekci, Rice University, ae16@rice.edu
Mahtob Aqazade, Rice University, mahtob.aqazade@rice.edu
Rebecca McGraw, University of Arizona, rmcgraw@arizona.edu

Abstract: Teacher retention has been a continuous challenge in the U.S. In this paper, we compared 84 Master Teaching Fellows (MTFs) and 83 non-MTFs in their self-efficacy, leadership skills, school-work environment, diversity dispositions, and professional network size. Using multinomial logistic regression, we also explored if these factors related to their retention. Results indicate that MTFs: (1) have higher levels of self-efficacy and diversity dispositions, and larger leadership networks; and (2) are more likely to shift to leadership positions. Findings provide insights for developing teacher leadership programs.

Introduction

Teacher turnover presents significant challenges for U.S. public schools for over decades, particularly for science and mathematics in high-need schools. Factors such as self-efficacy, leadership, autonomy, and social networks may help mitigate the adversities feeding into teacher turnover. In fact, because of the positive impacts of self-efficacy on instructional approaches and constructive learning, greater student motivation, and collaborating with other teachers (e.g., Boice, et al., 2021), many argue that higher self-efficacy can also yield other positive outcomes such as teacher retention (e.g., Polizzi et al., 2021). Related to leadership, mounting evidence suggests that K-12 school-based leadership can be one of the most successful forms of support to develop and sustain highly qualified teachers (e.g., Berg et al., 2014). Additionally, principal autonomy support and teacher-school fit have been associated with teachers' sense of belonging and job satisfaction (Youngs et al., 2015), which can, in turn, relate to teacher retention. Research indicates that teachers who have more connected networks are more likely to persist in teaching and develop leadership identities (Alemdar et. al., 2022). Professional social networks are important assets for teachers in several ways including informal professional development by learning from each other, supporting each other on non-teaching related factors such as cultural and administrative, and developing strong teacher identities (Polizzi et al., 2021). Moreover, research indicates that teachers who have more connected networks are more likely to persist in teaching and develop leadership identities (Alemdar et. al., 2022). The following research questions formally guided this study: (1) How do Master Teachers (MTFs) compare to non-MTFs in terms of their self-efficacy, leadership skills, diversity dispositions, school-work environment, network size, and retention? (2) To what extent do these factors relate to their retention? Is there a difference between MTFs and non-MTFs regarding this relation?

Methods

Data were collected from 84 MTFs and 83 non-MTFs across the nation (30% male and 70% female; 88% White and 12% from minoritized backgrounds). We define MTFs as science and mathematics teachers who participated in a five-year National Science Foundation Noyce Master Teaching Fellowship Program and taught in high-needs schools. Teachers completed self-reported comprehensive surveys comprising demographic and professional background questions; 4- or 5-point Likert-scale items about teaching self-efficacy (Klassen et al., 2009), leadership skills (Watt et al., 2010), person-organization (P-O) fit (Youngs et al., 2015), teacher autonomy (Baard et al., 2004), and diversity dispositions (Schulte et al., 2008); and social network (Polizzi et al., 2021). We used multinomial logistics regression analyses with retention as a four-level nominal outcome (stayer: continue teaching in the same school, mover: change schools, shifter: take a leadership position; and leaver). We explored the impact of independent variables on three retention levels compared to stayers.

Results

Findings indicated that MTFs' teaching self-efficacy (t (165) = 2.23, $p = .03$) and leadership network size (t (165) = 3.18, $p < .001$) are significantly greater than non-MTFs. Although not statistically significant, MTFs' availing diversity dispositions are slightly higher than non-MTFs (t (165) = 1.81, $p = .07$). There was no statistically significant difference between MTFs and non-MTFs on other factors. Regarding retention, there was no difference between MTFs and non-MTFs for being a mover or leavers. However, significant differences occurred between the two groups about staying (t (165) = -3.22, $p < .001$) and shifting (t (165) = 2.24, $p = .03$) to a leadership position. Interpreted collectively, we can infer that MTFs are more likely to assume a leadership role. Regarding the relation between retention and independent variables, results indicated that higher level of engagement in teacher leadership and lower degrees of P-O fit were associated with shifting to a leadership position (see Table 1). Leadership network size is positively associated with shifting to a leadership position. Lastly, leavers, compared to stayers, tend to have slightly higher levels of self-efficacy. The relationship between the independent variables and retention did not differ by MTF-ness.

Discussion and conclusions

Our study revealed that MTFs tend to have higher levels of self-efficacy and availing diversity dispositions and larger leadership networks. Another significant difference between MTFs and non-MTFs is the likelihood of shifting to a leadership position. One important area of discussion is whether a teacher's shift to a leadership position hurts the teacher retention. Perhaps, shifting results in impacting other teachers and contributing positively to teacher retention. Shifters indeed feel having more impact on other teachers and students when they assume a leadership role (Ekmekci et al., 2022). These findings favoring MTFs provide evidence for the impact of NSF Noyce programs on teachers. Additionally, teacher leadership activities had a significant impact on shifting and P-O fit had a negative impact on shifting. In brief, long-term professional development for developing teacher leaders seems to produce positive outcomes for teacher self-efficacy and leadership. Thus, school and district administrators should promote and encourage teachers to engage in leadership activities.

Gatekeeping of Emerging Discipline-Based Education Researchers

Christopher A. F. Hass, Kansas State University

Abstract: Discipline-based education research (DBER) is a field which attracts many faculty who are not previously trained in education research. We conducted interviews with 27 emerging discipline-based education researchers to better understand their experiences and needs entering the field. Many of our participants have experienced gatekeeping during their journey into DBER. Using Barzilai-Nahon's Theory of Network Gatekeeping, we discuss some of the impacts of gatekeeping on emerging DBERers.

Introduction

Discipline-based education research (DBER) has become more formally established in recent years, gaining support and formal recognition from STEM disciplinary societies. DBER presents a unique challenge as research on tenure-stream DBER faculty shows that many do not follow the typical pathway into education research. Instead, faculty move into education-focused positions without significant prior background (e.g., science faculty with education specialties (SFES) discussed by Bush et al., 2017). Emerging DBER faculty often feel unprepared for research in education or find themselves lost and anxious as they try to engage with education research. We discovered that perceived gatekeeping–the process by which people with power in a community control or limit others' access to that community and its resources–significantly impacts new researchers. As new members of the education research community, these emerging DBERers find themselves daunted by the task of engaging with the education community. Many of them have experiences which negatively impact their engagement, however many of them also discuss experiences which have supported their move into education research. Here we discuss some of those experiences and call upon the education research community to consider how we might reach out to and include these new and emerging DBERers.

Theoretical framing

DBER has not focused on theoretical investigations of gatekeeping. Following Barzilai-Nahon's review in which they note the lack of consistent, broadly applicable theories of gatekeeping (Barzilai-Nahon, 2009), we use Barzilai-Nahon's (2008) Theory of Network Gatekeeping (TNG), which they produced as a synthesis of the fragmented literature, as a theoretical lens to analyze and discuss gatekeeping within DBER. Importantly, our approach to gatekeeping does not require that it be necessarily a bad thing (gatekeeping is an ordinary part of research communities, e.g. peer review), nor does it require gatekeeping to be malicious. In fact gatekeeping can be a healthy and normal feature of research communities.

Several important features of the TNG were utilized in this study (Barzilai-Nahon, 2008). The *gate* is a point of entry (physical or conceptual) through which a person or their ideas (the *gated*, emerging DBER faculty) must pass to join the DBER network (community). *Gatekeeping* is the process of controlling passage through the gate. *Gatekeepers* (members of the DBER community) are those who are responsible for deciding who or what can pass through the gate. The TNG also provides four attributes of the gated to explain the ways gatekeepers prioritize allowing entry of the gated (*gatekeeping salience*): power in relation to the gatekeeper, information production ability, relationship with the gatekeeper, and alternatives in the context of gatekeeping (for example, if you try to publish and get rejected, is there a publication alternative available to you). These attributes can occur in any combination, and any given instance of gatekeeping could involve some or all of them.

Methods

Authors 1 and 2 conducted semi-structured interviews, about one hour in length with 27 emerging DBERers. These interviews included 8 major questions, each with optional follow up questions. Our interviewees are 23 faculty (a mix of tenure and non-tenure track faculty), but also include 3 graduate students and post-doctoral researchers, as well as one high school teacher working on their master's degree. These interviews focused on the participants' experiences becoming involved in DBER, their career experiences, and their research goals and projects (in various stages of maturity) in DBER. We were particularly interested in the challenges participants faced and things that had supported them in overcoming those challenges, as well as their thoughts on their identity and place within or adjacent to DBER.

The first author conducted an initial analysis of the transcripts to find interviews where the interviewees had a clear discussion of their experiences navigating entry into the DBER community and gatekeeping (or lack thereof) that they had experienced. These gatekeeping experiences could include both direct events (e.g. someone actively blocking an individual's participation), indirect experiences (e.g. a lack of connections, or extensive use of jargon), or even imagined gatekeeping (e.g. concerns about stigma and expectations in the field). We found 12 interviews with strong discussions of gatekeeping for our thematic analysis (Clarke et al. 2015). The second author examined these themes, and agreement was reached between the two authors through discussion and refinement of themes. Poster presents the most prominent themes we have found for the community's consideration.

Themes of gatekeeping

We found three themes, each of which is grounded in the four attributes of the gated as defined in the TNG (Barzilai-Nahon, 2008): **qualification**, participants feel underqualified for DBER; **alienation**, educators feel out of place or excluded by established researchers in DBER; and **connections**, the importance of closer relationships with existing community members for becoming a part of the community. In an example of qualification, Cole (chair of a mathematics department) said: "here's [the interviewer] working on his PhD to be able to do this kind of research" and continues "I also think that research should be done by professional researchers, right?" These participants are capable of engaging in DBER scholarship (TNG, *information production ability*), however their perceived lack of qualification acts as a barrier to entry into the DBER discourse (TNG, *gatekeeping*). Alex highlights alienation (assistant professor of mathematics) when describing conversations with researchers at the Research in Undergraduate Mathematics Education (RUME) conference: "I have a lot of intuition that I feel comfortable talking about, and sometimes the RUME scholars are like, 'but this is the only thing that's been studied and because people have thought about this way in the past, this is sort of how the conversation has to go" (TNG, *power in relation to the gatekeeper*). In an example of connections Samuel (graduate student in Physics Education Research) said: "I've been in physics education research for probably about three years and we have a DBER group on campus that I'm in with other people, and I've found these to be enjoyable, effective places where I can learn about education research" (TNG, *relationship with the gatekeeper*).

This poster presents the themes to the audience, as well as excerpts from the data to explain our reasoning and ideas. We hope to highlight some of the negative experiences associated with gatekeeping in our field, the impacts they have on EDBERs, and talk about what we can do as a field to mitigate those negative impacts while sustaining the positive and necessary aspects of gatekeeping.

McGill University

Abstract: This study explored the relationship between dynamic changes of emotions and flying performance in a simulation. K-cluster analysis found a high (n=12) and a low-performing group (n=7) according to flying performance (precision and error). Groups experienced different sequences of emotions. Both groups had sequences among neutral-anger, and neutral-happy. High-performers had more sequences among disgust-fear, whereas low-performers had more sequences between disgust-anger. Aviation trainees experience dynamic changes in the emotions, which can impact performance outcomes.

Introduction

This study aims to understand the relationship between the dynamic changes of emotions and flying performance in a simulation. We aim to contribute to the literature by (1) using new approaches to account for multidimensional measures of performance, considering individual variability (i.e., precision) and accuracy approaching the target metric (i.e., error), and (2) understanding the emotional experience of aviation trainees, accounting for dynamic sequences of emotions with different performance levels.

Emotions and performance in aviation training

Research and education in aviation training aims to facilitate effective psychological processes that ensure proficient performance. Aviation training is increasingly interested in understanding the nuances of emotions in pilot trainees' performance, yet such research is still in its early stages (Murray & Martin, 2012). Additionally, flying performance was conventionally evaluated through instructor observations, however, recent approaches suggest using aircraft logfiles can increase consistency and decrease evaluation time (Li & Lajoie, 2021).

Theories of emotions in learning

Since emotions are short states that are triggered by specific events, such emotions can dynamically change throughout a learning activity. Therefore, recent research is exploring the interaction between dynamic emotional changes during learning on performance. Affective changes are expected to impact the cognitive processing of learners', facilitating, or blocking achievement of the learning goal (D'Mello & Graesser, 2012). When solving the problem in a functional way, learners are expected to have changes among confusion, frustration, and engagement (D'Mello & Graesser, 2012). If the learners are unable to solve impasses, they can stay in a sequence of frustration, resulting in boredom, disengaging from the task (D'Mello & Graesser, 2012).

Research question and methods

We pose the following research question: Do aviation trainees, grouped according to their performance, differ in the sequence of emotions they express during a flying task?

19 undergraduate and graduate students (M_{age}=24.36, σ=5.814) performed flying maneuvers in X-plane (Laminar Research, 2022), a flying simulation software designed to mirror real planes. Flying performance metrics (speed, altitude, heading) were obtained from logfiles and used to calculate precision and error: a larger number in precision (i.e., more variance) was interpreted as more movement, a larger error (calculated with root mean square error) would imply more distance to the objective set in the instructions.

Participants' facial expressions were video recorded and analyzed with specialized software (FaceReader 6.0, 90% accuracy rate, Noldus, 2015). Emotions (i.e., neutral, angry, sad, happy, disgust, surprise, and fear) are recorded in a sequential manner to assess the significant sequences of emotions. Interpreting results, we considered expression of happiness aligned with enjoyment and engagement/flow, anger with frustration, disgust with confusion, fear with anxiety, and sadness boredom (Harley et al., 2015).

Results

A 2 k-cluster analysis was conducted to group students according to performance scores, which required three iterations to create differentiated clusters. Z-scores were used to interpret each cluster. Cluster 1 (n=12) was labeled as high performance since trainees had low variance in precision (Z_{speed}=-0.57, $Z_{heading}$= -0.43, $Z_{altitude}$=-

0.58) and error (Z_{speed}=-0.51, $Z_{heading}$= 0.41, $Z_{altitude}$=-0.61). Cluster 2 (n=7) was labeled as low performance since trainees had a higher variance in precision (Z_{speed}=0.99, $Z_{heading}$=0.73, $Z_{altitude}$=0.99) and error (Z_{speed}=0.88, $Z_{heading}$=-0.70, $Z_{altitude}$=1.05).

A lag sequential analysis was performed to understand the difference in the sequence of emotions, using the Generalized Sequential Querier program (GESQ, Bakeman & Quera, 1995). Sequential transitions can be seen in table 1 for high-performers and table 2 for low-performers. Results show that 8 out of 42 potential sequences were statistically significant for high-performers, and 9 out of 42 sequences were significant for low-performers.

Table 1

The Sequential Transition Matrix of Emotions of High Performers

Z	Angry	Neutral	Surprise	Happy	Fear	Disgust	Sad
Angry	-8.24	9.47**	-0.59	-2.39	-1	0.82	-1.43

Table 2

The Sequential Transition Matrix of Emotions of Low Performers

Z	Angry	Neutral	Surprise	Happy	Fear	Disgust	Sad
Angry	-12.62	8.71**	3.9	-1.65	-3.76	5.04**	0
Neutral	11.65**	-16.86	-0.15	6.51**	3.89**	0.37	0
Surprise	1.94	3.13**	-3.66	-3.16	4.74**	-3.91	0
Happy	-4.23	7.59**	-2.41	-3.34	-2.08	1.33	0
Fear	-3.39	2.49	6.43	-2.08	-1.29	-2.31	0
Disgust	4.72**	1.23	-3.52	0.02	-2.3	-3.81	0
Sad	0	0	0	0	0	0	0

Note. *p < .05; ** p < .01; *** p <.001

Conclusion

The findings contribute to the literature by deepening the understanding of emotions in aviation training. Our findings confirm that trainees experience dynamic emotional changes during the flying task, and patterns vary according to performance. Trainees had significant bidirectional sequences between neutral and anger and neutral and happy. This finding aligns with the model of affect dynamics in which learners return to equilibrium after impasses (D'Mello & Graesser, 2012). Trainees who were more precise in their movements and were closer to the target metric (less error) had more sequences between disgust and fear. Conversely, trainees who were less precise and had more error experienced more loops between disgust and anger. High-performers were more likely successful in a high-concentration task after facing impasses (disgust/confusion) and expressing an activating emotion (fear/anxiety) that led them to solve the task. Low-performers experienced more frustration (anger) after facing impasses. These results emphasize the importance of understanding the relationship between emotions and performance in aviation training. We believe these results can be transferred to learners in high-stakes professions.

Digital Clinical Simulations and Video Debriefs to Promote Equity Mindsets: Insights From a Mixed-Methods Staggered Randomized Experiment in an Online Course

Joshua Littenberg-Tobias, WGBH Educational Foundation, joshua_tobias@wgbh.org
Justin Reich, Massachusetts Institute of Technology, jreich@mit.edu
Preeti Ramen, Massachusetts Institute of Technology, preetirmr@mit.edu

Abstract:. We developed a digital clinical simulation (DCS) and an asynchronous video-based simulation debrief (VD) and studied their effects within the first unit of an online professional development course (N = 767). Although we found no statistically significant differences in equity beliefs between participants in the two experimental conditions of the study (DCS-only and DCS + VD) and the control condition after the first unit, there were significant shifts overall by the end of the online course.

Introduction and background

Given the importance of DEI issues in education, finding a method for delivering high-impact, low-cost, scalable professional learning is an important goal. Digital clinical simulations (DCS) employ rich digital media to immerse participants in educational scenarios and prompt them to make improvisational decisions at key moments (Hillaire et al., 2021). These simulations afford opportunities for educators to practice how they would act in uncomfortable situations in low-stakes environments for students (McGarr, 2021). This study focuses on how a DCS and VD affected participants' views on educational equity within an online asynchronous professional learning course for teachers. We examined the "Jeremy's Journal" simulation which focuses on differentiating between equality, treating all students the same, and equity, modifying the learning environment based on student needs and sometimes providing more support and flexibility to some students (Milner, 2012). Participants played the role of a 7th grade ELA (English Language Arts) teacher of an outgoing but struggling student named Jeremy. Participants made decisions during the week on how to support Jeremy in his learning and, at the end, had to decide whether to accept his request to be excused from a weekly quiz (Figure 1). Participants then completed a six-minute video debrief depicting teachers debriefing the simulation during a live facilitated session. Interspersed within the segments were cutaway scenes of teachers reflecting on their experience in interviews (Figure 1).

Figure 1
Simulation Images and Video Debrief

Enact

Monday

A snapshot of Jeremy's journal is shown below:

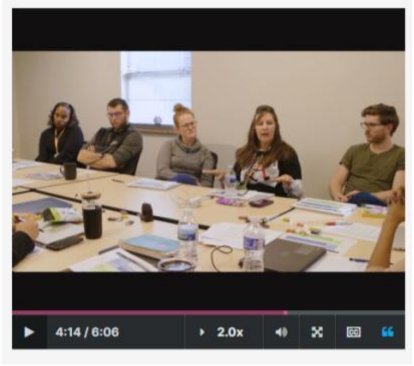
I never had a brain until Freak came along and let me borrow his for a while, and that's the truth, the whole truth.

-Freak the Mighty by Rodman Philbrick

Monday
Looks like a run-on. Thats it. All done
Scribble time.

Cause is subject and verbs
Hyperbole EXAGGERRRRAATTIOOON that
CANNOT POSSIBLY be true
His hands were as big as frying pans

Based on the class responses and Jeremy's journal entry, how do you want to respond?



"And no matter what looks like for that student they also have the same goals, but how do we help them get there. Building on talking to them, you start to see that maybe they need something different." *Debrief Participant*

Methods

Our data comes from the second run of a massive open online course (MOOC) for educators on a popular online learning platform (N = 787)—68% identified as female, 74% as White, and 84% identified as fluent English speakers. Most participants reported working in K-12 schools (54%). The demographics of participants in the analysis sample roughly reflected the demographics of educators and those in education-aligned industries. We used a staggered randomized multiple baseline design (Levin et al., 2018) to measure participant attitudes on an equality-equity survey measure (see Littenberg-Tobias et al., 2021 for survey items). The survey measure was randomized within the course structure (Figure 2). Although all participants eventually received the entire treatment through this design, we sought to estimate the immediate effects of both on participating in a DCS and combining a DCS with a video debrief. We also measured participant attitudes on the same measure after completing the course. Multilevel linear growth models were used for all analysis.

Figure 2
Study Design

	Time 1	Time 2	Time 3	Time 4	Time 5
Control	Survey	Intro videos	Survey	Jeremy's Journal	Video debrief
DCS	Survey	Intro videos	Jeremy's Journal	Survey	Video debrief
DCS + VD	Survey	Intro videos	Jeremy's Journal	Video debrief	Survey

Results

There were no statistically significant differences in participants' mindsets between the control group and those that had completed the digital clinical simulation (DCS) and those who had completed both the digital clinical simulation and the video debrief (DCS + VD). However, when we examined overall growth after completing the course, we did observe significant shifts toward equity beliefs ($\beta = 0.133$, t= 2.402, $p < 0.05$, ES= 0.25 SD)

Discussion

These findings raise important questions about when and how teachers change their beliefs about equity. As other studies have found shifts toward equity are not linear, and there may be diversions, half-learnings, and setbacks along the way (Self & Stengel, 2020). Changes in mindsets may not be therefore may not be immediately detectable on surveys even though participants may be beginning to shift in their beliefs. In future research, we intend to explore how different methods of feedback affect shifts in participants' equity attitudes to better understand how online instruction can be designed to best foster more equitable teaching practices.

Developing Pre-Service Teachers' Epistemic Cognition Through Learning Pedagogical Knowledge

Miho Kawasaki, Jun Oshima, Ritsuko Oshima
kawasaki.miho@shizuoka.ac.jp, joshima@inf.shizuoka.ac.jp, roshima@inf.shizuoka.ac.jp
RECLS Shizuoka University

Abstract: We examined a course designed for pre-service teachers to develop their epistemic cognition on teaching practices through collaboratively learning pedagogical knowledge. Pre-service teachers' epistemic cognition was evaluated by asking them to interpret a teaching practice recorded in a video, before and after the course. Three patterns of epistemic cognition were identified using clustering analysis. Characteristics of each pattern were discussed for further refinement of the course design.

Background and research purpose

For educating students to develop their epistemic cognition, teachers must develop not only their own epistemic cognition on content knowledge, but also another type of epistemic cognition to improve their teaching practices (Mor-Hagani, & Barzilai, 2022). Recent studies have focused on how in- and pre-service teachers develop their epistemic cognition on teaching practices. Barnes et al. (2020), for instance, approached in-service teachers' epistemic cognition, by asking them how they evaluate students in their classroom. Referring to the "Aims, Ideals and Reliable Process (AIR)" model (Chinn et al., 2016), Barnes et al. (2020) found that teachers missed pedagogical knowledge to justify their teaching processes. In another study, Hartmann et al. (2021) designed an instruction based on an activity of multiple text integration, to elicit pre-service teachers' epistemic cognition on their teaching practices. They confirmed the effectiveness of the multiple text integration. Pre-service teachers who competently integrated multiple texts could appropriately demonstrate their epistemic cognition on teaching practices in their essays. Although studies have examined in- and pre-service teachers' epistemic cognition on their teaching practices as a unique nature of the profession, few studies have conducted design-based research to examine how acquisition of pedagogical knowledge facilitates teachers' epistemic cognition.

In this study, we, therefore, designed a course for pre-service teachers to learn pedagogical knowledge, based on the learning sciences. We examined how their learning facilitated their epistemic cognition on their teaching practices.

Method

Course description

Eighteen pre-service teachers took the course as part of their teacher certification program. They learned pedagogical knowledge based on the learning sciences through three modules: (1) knowledge-centered approach, (2) collaborative learning, and (3) self-regulated learning. In each module, we designed learning activities based on the framework of the preparation for future learning (Mylopoulos et al., 2016) and multiple text integration (Hartmann et al., 2021). Pre-service teachers were instructed to elicit their ideas related to the study topic in a module and collaboratively elaborate ideas based on their experiences. After listening to a lecture, they further engaged in multiple text integration through jigsaw activities (Miyake, & Kirschner, 2014). Each module took a day, and the course was conducted as an intensive summer course over three days. The course was co-designed by the three authors, who also taught the course.

Collected data and analysis

Pre-service teachers' epistemic cognition on teaching practices before and after taking the course

The same video recording was used to evaluate pre-service teachers' at the beginning and end of the course. The comparison between the pre- and post-test allowed us to examine the growth of their epistemic cognition consequent to taking the course. The video was an 11 minute-long summary of a science lesson on weather and air pressure. Eighth-grade students collaboratively engaged in problem-solving using their learned knowledge, coordinated by an experienced female teacher. At each test, pre-service teachers watched the video twice, and responded to the following questions in their worksheets: (1) what they noticed as instructional goals of the lesson, (2) what they noticed as effective processes to achieve the goals, and (3) what behaviors they noticed as students achieve the goals.

We developed a coding scheme to evaluate pre-service teachers' descriptions of the lesson's *Aims*, *Reliable Process*, and *Ideals*, based on the pedagogical knowledge that they could have learned through the three modules of the course. In terms of the lesson's aim, we assessed whether the overall goal of the lesson was described. For the processes and ideals, the descriptions were evaluated from the viewpoint of the three modules, with 1 point for each valid description, 0.5 points for partially accurate description by two independent raters (Cohen's k ranged from .5 to .7 for three components of AIR). The average scores were used as AIR model scores.

Data analysis

Pre-service teachers' epistemic cognition on teaching practices was coded as a sequence of *Aim*, *Ideals*, and *Reliable Process* scores. After standardizing the scores, we conducted an exploratory clustering analysis, to identify pre-service teachers' AIR model patterns of their teaching practices. Finally, we conducted an ANOVA on pedagogical scores, with AIR patterns as an independent variable, to examine how identified AIR patterns were related to the pedagogical knowledge scores in these three modules.

Results and discussion

In the clustering analysis of pre-service teachers' AIR model scores at the post-test, we found three clusters, each of which had unique score patterns. A 3 × 3 (Clusters × AIR components) ANOVA on the standardized scores revealed a significant main effect of Cluster, $F(2, 15) = 6.31$, $p < .05$, $h_p^2 = .4568$, and a significant interaction effect, $F(4, 30) = 17.09$, $p < .01$, $h_p^2 = .6949$. Multiple comparisons by HSD method showed that: (1) mean *Aim* score of Cluster 1 was significantly lower than those in other clusters, (2) mean *Ideals* score of Cluster 2 was significantly lower than those of the other two clusters, and (3) mean *Reliable Process* score of Cluster 2 was significantly higher than those of the other clusters. Based on the results, we named Clusters 1, 2, and 3 aIr, AiR, and AIr, where small characters represent significantly lower scores compared with other group(s), and capital characters represent significantly higher scores.

The aIr group of pre-service teachers had "Ideals" performance by students in the video, but did not specify *Aim* (i.e., why the performance is important to see from the perspective of learning deeply) and *Reliable Process* (i.e., how students should learn to attain the "Ideals" performance). We consider that the aIr pattern of teachers' epistemic cognition is typical for beginner teachers, and they are stuck with what is important at students' performance level but do not connect the performance with the theories behind it.

The differences in patterns of epistemic cognition should be further examined by conducting design conjectures (Sandoval, 2014) to analyze what mediating processes were facilitated by our design elements, so that we can further refine our instructional design.

The Talk Move Patterns of Teacher-Student Interactions in K-12 Mathematics Lessons: An Analysis Based on the TalkMoves Dataset

Deliang Wang, Yang Tao, Gaowei Chen
wdeliang@connecct.hku.hk, ttaotaoy@connect.hku.hk, gwchen@hku.hk
The University of Hong Kong

Abstract: The paper compared the talk move patterns of teacher-student interactions at the primary, middle, and high school levels. Specifically, this paper employed the sequential analysis method on 200 transcripts from a mathematics classroom discourse corpus *TalkMoves*. The preliminary results showed that although teachers from all three levels encouraged the whole class to participate, asked students questions, and required them to explain, students at different educational levels responded to teachers' talk moves differently. Students from primary and middle schools were more responsive than those in high schools.

Introduction

The academically productive talk (APT) advocates teachers adopting talk moves (i.e., specific dialog acts) to effectively elicit learners' participation in the discussion (Michaels et al., 2008; Resnick et al., 2010). To unravel key characteristics of talk moves supporting productive classroom discussions, researchers have made dedicated efforts to investigate teacher-student interaction patterns (e.g., Tytler & Aranda, 2015). Most studies, however, have focused on a single level of education. Few attempts were made to compare discourse patterns among different grade levels. The comparison of classroom discourse at different educational levels could not only inform researchers of generic patterns that advance knowledge acquisition but also assist teachers in mastering pedagogical approaches tailored to the needs of specific groups of students, especially for those teachers who straddle educational levels. Thus, this current research is intended to fill this gap by analyzing and comparing the talk move patterns of teacher-student interactions in mathematics lessons at the primary, middle, and high school levels.

Method

Data preparation

This paper employed the *TalkMoves* dataset as the data source for analysis and comparison. The *TalkMoves* dataset contains 567 transcripts from K-12 mathematics lessons (2022). Based on the APT framework, teacher utterances were labeled with *no talk moves* (T.N), *keeping everyone together* (T.K), *getting students to relate to another's ideas* (T.G), *restating* (T.RS), *revoicing* (T.RV), *pressing for accuracy* (T.PA), and *pressing for reasoning* (T.PR). Student utterances were labeled with *no talk moves* (S.N), *relating to another student* (S.R), *asking for more information* (S.A), *making a claim* (S.M), and *providing evidence* (S.P).

Before performing the analysis, data preprocessing measures were taken. Firstly, the data in the *TalkMoves* corpus were collected from 1990 to 2021. Considering instructional approaches three decades ago may be different from current pedagogies, this paper selected the latest transcripts recorded in 2019, 2020, and 2021. Secondly, each transcript in the corpus was either from an entire or partial mathematics lesson. Given that some partial sessions may have various durations, this paper uniformly chose transcripts from full mathematics lessons with a duration of around 55 minutes. After preprocessing, the paper finally obtained 122 transcripts from primary schools, 53 transcripts from middle schools, and 25 transcripts from high schools. The number of utterances was 72,237 for primary schools, 29,216 for middle schools, and 10,438 for high schools.

Data analysis

The lag sequential analysis (LSA) was mainly used to compute the probability of an action followed by another action and evaluate whether the probability is statistically significant (Bakeman & Gottman, 1997). Thus, this paper adopted this method to compare talk move patterns of classroom discourse among different grades and selected significant teacher-student talk move sequences to draw the sequential transition diagram (as shown in **Figure**). The values near the arrows and the arrow thickness represented the z-score and significance level, respectively. When the Z-score was equal to or above 1.96, the sequence of starting-following talk moves was statistically significant.

Preliminary findings

REF _Ref118971562 \h Figure 1 indicates how students at different educational levels responded to teachers in mathematics lessons. There were three teacher-student talk move sequences shared by the primary, middle, and high school levels, respectively, namely *keeping everyone together* → *relating to another student*, *pressing for accuracy* → *making a claim*, and *pressing for reasoning* → *providing evidence*. These three sequences implied that despite different grades, teachers all encouraged the whole class to participate, asked students questions, and required them to explain, demonstrating that teachers effectively used talk moves to contribute to learning communities, knowledge, and thinking.

However, students at different educational levels responded differently to teachers' talk moves. Specifically, students from primary and middle schools were more responsive than those from high schools. For example, when teachers attempted to *get students to relate to another's ideas*, primary and middle school students replied by *relating to another student, asking for more information, and providing evidence*, while high school students only responded by *relating to another student.* A similar situation occurred when teachers tried to *keep every student together*.

Automatically Assess Elementary Students' Hand-Drawn Scientific Models Using Deep Learning of Artificial Intelligence

Tingting Li, CREATE for STEM Institute, Michigan State University, litingt1@msu.edu
Feng Liu, Department of Computer Science and Engineering, Michigan State University, liufeng6@msu.edu
Joseph Krajcik, CREATE for STEM Institute, Michigan State University, krajcik@msu.edu

Abstract: Because of the complexity of scoring open-end tasks, machine learning (ML) has been utilized for automatically assessing students' constructed responses. However, most existing research focuses on grading text-based responses. No studies have investigated the automatic scoring of hand-drawn models created by elementary students. In this study, we applied ML to automatically score hand-drawn scientific models developed by elementary students for evaluating knowledge-in-use. We first developed algorithms using human-scored responses and then validated these algorithms with new data. We also implemented a data augmentation technique to enhance accuracy. Our findings demonstrate the potential of the developed algorithm to achieve high performance in automatically scoring hand-drawn models.

The Opportunities and Challenges of Scientific Modelling

Scientific modeling is a powerful approach for engaging students in science learning by enabling them to create multiple representations that explain or predict natural phenomena based on evidence (Li et al., 2021). However, the complexity and diversity of these models make their evaluation time-consuming and demanding (Zhai et al., 2022). Researchers have sought solutions by developing automatic scoring methods for students' written text-based constructed responses at the secondary or postsecondary levels (Mislevy et al., 2020). Yet, modeling still presents significant challenges for automatic assessment due to their tangible representations of intricate cognitive processes (Li et al., in press). This complexity is further amplified in hand-drawn scientific modeling tasks that measure complex constructs like knowledge-in-use. Students' hand-drawn models exhibit greater abstraction and within-class variation, reflecting their individualized interpretations of the same objects (Xu et al., 2021). Consequently, automatic scoring becomes more complex than other image classification tasks, as these drawings vary in style, skill, and detail compared to photographs (Lu & Tran, 2017). Because modeling is an essential scientific practice and scoring hand-drawn models is challenging and time-consuming, a need exists for automated assessment technology explicitly designed for students' hand-drawn models. This study explores: *How accurate is the neural network-based machine learning evaluation of hand-drawn scientific models developed by elementary students compared to human evaluators?*

Methods

This study utilized efficacy data from the ML-PBL project (Krajcik et al., 2023). Post-unit assessments were developed using a modified design process (Harris et al., 2019), employing 4-point holistic rubrics. Item validation was conducted using item response theory. We focus on three 3rd-grade modeling tasks. Task sq_v3, from the first unit, asks students to model the impact on squirrels if all trees were removed. Tasks ty_v4 and ty_v9, from the second unit, address "force and motion." Task ty_v4 requires students to create models explaining factors affecting toy car movements and collisions, while task ty_v9 involves designing a model to prevent car collisions. Students completed post-unit assessments, which were scanned and converted to PDFs for scoring. Six raters learned to score the items, and inter-rater reliability (IRR) checks were conducted to ensure consistency. A baseline 0.70 ICC coefficient was used to verify consensus between pairs of raters (0.68-0.87) (Koo & Li, 2016). Illustrating with task sq_v3, the dataset contains 2076 hand-drawn models by 2134 students across two years, distributed across 107 unique classes from four Michigan regions.

Machine Learning Algorithm Development and Validation

We developed Convolutional neural network (CNN)-based algorithms to score student hand-drawn models and compared the predicted scores to human expert scores (Krizhevsky & Hinton, 2012). A 10-fold cross-validation method validates the CNN-based scoring model. The 2076 student models were randomly divided into ten groups, with 10% for testing and 90% for training. The training set was further split into validation and actual training sets at a 1:4 ratio. As a result, we had 487 training samples, 382 validation samples, and 207 testing samples in each fold. We utilized the ResNet-18 architecture for feature extraction, implemented our model in Pytorch, and used an Adam optimizer with a learning rate of 1e-4 for both networks. The networks were trained for 200 epochs using an NVIDIA GeForce GTX 1080Ti graphics card, and data augmentation techniques were applied during the training process.

Findings

We calculated human-machine scoring agreement (HMA) accuracy for training and testing stages to determine the percentage of HMA. After each epoch, validation accuracy is computed, and network weights are saved. The highest validation accuracy weights are used to calculate test accuracy after training epochs (Lu & Tran, 2017). Average validation accuracies across folds were calculated during iterative training. In the testing stage, the validated CNN-based model assigned scores to a new testing group. A data augmentation model was compared to one without data augmentation. For task sq_v3, average training stage validation accuracies ranged between 38.31% and 64.12%. Table 1 presents the testing stage average test accuracies for task sq_v3, comparing data augmentation and non-data augmentation models, using data augmentation to reduce overfitting improved scoring performance, achieving a 62.32% +/-1.63% scoring accuracy. Task ty_v4 test accuracies were 73.25% ±1.47%, while task ty_v9 had a slightly lower accuracy of 53.29%±1.21%.

Table 1
Machine-human scoring agreement (test accuracies/ %) for tasks

Modeling tasks	With data augmentation techniques	Without data augmentation techniques
sq_v3	62.32±1.63	43.95±1.63
ty_v4	73.25±1.47	55.78±1.35
ty_v9	53.29±1.21	39.96±1.09

Discussion

This study explores ML for scoring hand-drawn models measuring knowledge-in-use, offering insights into factors affecting machine scoring. Automatically scoring hand-drawn models is challenging due to the variety of forms and artistic styles, the difficulty of machine classification using holistic rubrics (Nehmn & Haertig, 2012), and the complexities of automatic handwriting recognition with misspelled labels. The findings can help improve support for developing scientific models for deeper learning through timely assessment feedback.

Teaching, Learning, and Mentoring for Racial Equity: A Multi-Dimensional Case Study

Joy Esboldt, University of California Berkeley, esboldt_joy@berkeley.edu

Abstract: Scholars still have much to learn about how teachers learn about and teach for racial equity nested within multiple relations of power. Drawing on two illustrative moments within a qualitative case study, this study examines the co-construction of racial equity discourses and enactments within an equity-oriented induction mentoring program. I demonstrate how interpersonal dynamics coupled with organizational elements and the sociopolitical context constrained educators' engagement with liberatory equity discourses and enactments.

Introduction

As teacher-facing racial equity initiatives expand in some parts of the county and societal racial discourse shifts, scholars still have much to learn about how teachers *learn* about racial equity and *enact* their learning within racialized ecologies, organizations, and the larger sociopolitical environment (Nasir et al., 2016). This paper examines how teachers' racial equity learning and enactment are shaped by the social relations, organizations, and sociopolitical landscapes in which they work, and how their learning and enactment creates and/or forecloses opportunities for justice-oriented transformations. This study draws on recently reconceptualized sociopolitical theories of learning, which attend to learning ecologies as racialized, racializing, and situated within relations of power (Nasir et al., 2020). This multidimensional framework analyzes moment-to-moment micro interactions, and the dynamic macro sociopolitical environment and meso racialized organizations in which they occur, to explore the complex and constrained phenomenon of teacher learning within conditions that govern, constrain, and enable particular ideas, ideologies, identities, and interactions (Philip & Gupta, 2020; Ray, 2019).

Methods

This qualitative case study comes a larger Research-Practice-Partnership and focuses on a novice teacher-mentor pair within the New Educator Equity Mentoring Program, it draws from over 120 hours of observations and interviews. Reflective of district demographics, both the mentor (Evelyn) and teacher (Ashley) are white, and all the students are students of color (majority Latinx). Both educators expressed prior interested in racial equity and met each week to reflect and co-plan. Throughout data collection, I formalized transcripts, fieldnotes and content logs for all observations and interviews. I wrote analytic memos on themes while in the field and again at the end of data collection (Bogdan & Biklen, 2016). I used recursive inductive and deductive coding on MAXQDA, including index codes such as *discourses of equity, resources, social identities,* and *contestations*. I created additional analytic codes while reviewing data. After consolidating codes, I used critical discourse analysis with illustrative moments to investigate how racial (in)equity is noticed, given meaning, negotiated, and enacted (Fairclough, 2013; Hall, 1996).

Findings

Findings suggest that interpersonal dynamics coupled with organizational discourses and tools within larger neoliberal reforms constrained educators' engagement with transformative equity meanings. Even with various race-explicit discourses and different conversational processes (Horn et. al, 2017) power-avoidant discourses emerged as dominant.

Moment 1

In winter, Evelyn (mentor) raised the topic of "Black student engagement," as part of the district's initiatives for *Black Excellence.* Evelyn observed there was a "very subtle" lack of positive behavior narration with Josh, the one Black student present during an observation, and encouraged Ashely to do more. The mentor repeatedly qualified her observations and then rushed to the next topic. As the only observed discussion on antiblackness, this narrow focus failed to attend to interracial student tension in Ashley's class (including the frequent use of the n-word by non-Black students and the reliance on Black girls to correct it), nor the district's plans to close several majority Black schools and the subsequent grassroots resistance. This moment offered affective instruction for Ashley to expect emotional configurations that centered her comfort in interpersonal conversations about race (Vea, 2020) and foreclosed on an opportunity to build political and micropolitical racial literacy (Pham, 2022).

Moment 2

In spring, the teacher and mentor planned for table groups, starting with ideas of heterogeneity and collaborative learning. However, through interpersonal affective affinity, celebrating the others' ideas, student ability quickly emerged as the most important aspect for grouping, further facilitated by the easily available organizational tools of ranking students by standardized test scores. On the first day of table groups in the classroom, the teacher repeated neoliberal logics of ability and (un)desirability (Sengupta-Irving, 2021) to students directly as she justified the new seating arranged as based on "those with higher scores" and "those with lower scores," assuring students their "grade won't be affected by [their lower performing groupmates]." Students adopted related labels for themselves and other as students within their group, categorizing students who are "smart," "does their work," and "doesn't do their work."

Discussion

These moments illustrated the multiple discourses that teachers navigate in their learning and teaching and the interpersonal, organizational, and sociopolitical influences that shape how educators negotiate these discourses. Specifically, dominant ideas of equity embedded within mediational and discursive tools constrain transformative meaning making in interaction. Depoliticization of technical practices, hierarchies of learners, and dominant logics of ranking emerged through tool use in ways that went unquestioned and ultimately reproduced the status quo. These illustrative moments demonstrate how the (un)available organizational resources within the structural conditions and interactional arrangements may stymie more transformative learning and practice.

Scholarly significance & conclusion

Overall, this study expands understandings of teacher racial equity learning as critical and constrained actors. Specifically, by attending to the organizational tools that educators interactionally negotiated within their sociopolitical landscape, we gain a greater understanding of the complexity of teacher learning around racial equity. Rather than focusing on individuals or professed beliefs, this work demonstrates how dominant ideologies were reconstructed interactionally through engagement with seemingly "neutral" tools in ways that held implications for students' classroom opportunities. Mentoring and teacher learning communities offer integral teacher learning support. Yet, everyday tools and protocols ideologically structure the affordances and constraints of learning. Advancing this understanding supports the resistance of neoliberal deprofessionalizing reforms on teachers by underscoring the complex, situated, and dynamic process of learning and enactment within multilevel environments.

Innovate to Mitigate: Teacher Role in a Student Competition

Gillian Puttick, Brian Drayton, Santiago Gasco
gilly_puttick@terc.edu, brian_drayton@terc.edu, santoago_gasca@terc.edu
TERC

Abstract: The Innovate to Mitigate (I2M) project poses challenges for secondary-school students to design feasible, innovative strategies that mitigate CO_2 emissions and thus global warming. Design is informed by research on problem-based learning, pedagogy for which poses demands on teachers. This paper presents preliminary evidence about how I2M teachers supported student teams to engage in science and engineering practices.

Introduction

The Innovate to Mitigate (I2M) project (https://terc.edu/innovatetomitigate) poses design challenges in climate change mitigation for middle- and high-school students. Student teams propose a mitigation strategy, describe how they consider it an innovation, and how feasible it might be to implement. The design of the challenge is informed by research on problem-based learning and on participatory pedagogy (Tucker-Raymond et al., 2021). Our initial research (Puttick et al., 2017; Drayton & Puttick, 2018) suggests that this open challenge can galvanize creativity and engagement among young people, and support "3-D learning" (NRC, 2012). In this paper, we present preliminary findings about the experience of four teachers as their students participated in the 2021-2022 I2M challenge. We ask: (i) How did teachers perceive their role in supporting student teams engaged in open-ended design challenges that mitigate global warming?

Building teacher capacity to support problem-based learning

In PBL contexts that drive towards pre-determined learning goals, the challenges that face teachers result from the tension between grounding student work in a general question that has multiple possible investigation methods and is not bounded by a curriculum, and this desired "end point." In the I2M challenges, unbounded by content learning goals, the science practices (NRC, 2012) themselves are the articulated learning goals. In this context, the teacher acts as facilitator, asking meta-cognitive questions to guide students. We expected that teachers would need assistance in supporting PBL and in helping students to understand science as an "evidence-based, model and theory building enterprise" (NRC, 2012).

Context and methods

Teachers support students through several phases: Submitting an abstract that outlines a mitigation strategy online for public discussion, revising based on these discussions and developing a prototype over the next 3 months, and finally submitting a short video and paper. At 3 transition points, teachers were oriented to (i) the purpose of participant crowdsourced conversations to improve designs, (ii) mentoring strategies and supporting distributed expertise, and (iii) supporting student epistemic agency using "science-as-practice" (Stroupe, 2014).

Participants

The four experienced teachers in the study signed up 10 student teams. Ms. Rotham, a mathematics teacher at a parochial high school, was recruited as mentor by a transfer student in 12th grade, who had participated in I2M previously. Ms. Schaaf, an environmental science teacher in a large urban school district, had 5 teams participating in independent study for an upper-level course. Ms. Staples, a language arts teacher at a private school, had two middle school teams in her special needs class. Ms. Hayter, a science teacher in a large urban school district, had two middle school teams participating in an after-school club.

Data sources and analysis

Data included transcripts of teacher post-interviews that focused on teacher role, challenges faced by students and teachers, perceptions of student learning, motivation, and school-related constraints on participation. Three researchers independently applied a concept-driven framework to code all data (Spencer et al. 2014). Codes were teacher role (general aspects of teachers' role in supporting students), PBL (affordances and challenges of PBL), science practices (NGSS science practices). Researchers iteratively discussed coded data. After coding was stable, a researcher wrote an interpretive research narrative pertaining to each code. The research team discussed narratives to test inferences, identify area requiring further analysis, and maximize the value of the data.

Findings

Across diverse learning contexts, all 4 teachers described how supporting student engagement in practices primarily centered on various aspects of working with data, and on constructing arguments. Not surprisingly, younger students needed support in how to take and record data. Ms. Hayter reported, "I kind of gave them a little template […] any time that they tested, we would take pictures and then we would write a little tidbit about what happened." Ms. Rotham's independent study students needed help identifying variables, "they were challenged as to what are the variables we're measuring, what's the independent variable." Both Ms. Hayter and Ms. Rotham reported that they also provided guidance about what to do with data once it was in hand. As Ms. Hayter put it, "there's a difference between data information, so you can have all these numbers, but actually putting meaning to it..." Furthermore, students needed to understand how to use data to build a persuasive scientific argument. For example, Ms. Rotham reported that she pushed her students to collect data from the prototype they were building, "you can't just build something and say it works," in other words, the claim needed substantiation.

For the senior independent study students, providing empirical rationales for their claims (Sandoval & Millwood, 2005) was a challenge. Ms. Schaaf observed, "[it was] a little bit of a learning curve for them, because I don't think they're used to defending their arguments." She reported that she pushed them on this, asking, "how can you support the claim that you're making…? Where is it coming from?"

Comments from three of the four teachers centered on the need to cede control (Puttick et al., 2015). Ms. Hayter's comment was representative, "So [I was] very much hands-off. So that was a bit of a change for me where it's not on giving them as many instructions," while Ms. Staples spoke about being challenged by the science, "I spent quite a bit of time studying so that I could help them understand the chemistry or the physics or whatever."

Discussion and significance

Working with the wide range of subject areas and possible technologies that were determined by student project choice, teacher moderation was focused on the practices. This mostly freed the teachers to cede authority (Puttick et al., 2015) and effectively support student directed PBL. The teachers made effective strategic use of targeted procedural questions, suggestions of resources, and project management strategies to support students' agency and capacity to conduct investigations. Within each context, McNeill et al. (2017) in a study focused on argumentation, found that teachers' decisions sometimes focused on surface features of argumentation rather than understanding it as an epistemic practice (Stroupe, 2014). Our preliminary data indicate that these teachers understood this deeper meaning of argumentation as a science practice. Teachers' guidance of argumentation practices will be one focus of future research.

What Data is in K-12 Data Science? An Analytic Approach to Understanding the Data Used in K-12 Data Science Courses

Rotem Israel-Fishelson, Peter F. Moon, Rachel Tabak, David Weintrop
rotemisf@umd.edu, pmoon@umd.edu, retabak@umd.edu, weintrop@umd.edu
University of Maryland

Abstract: To help students understand the role of data in their lives, it is important to introduce them to foundational data science. This paper presents an analysis of the data used in YouCubed's Explorations in Data Science curriculum. This work provides an analytic understanding of how data science is situated in students' lives and provides insights into ways curricula are preparing them for a data-rich world.

Introduction

As the role that data play in society grows, it is increasingly important to introduce foundational concepts and practices of data science to K-12 students (LaMar & Boaler, 2021). The last five years have seen the emergence of several year-long data science curricula (e.g., IDSSP Curriculum Team, 2019) that are playing an important role in defining what constitutes data science at the high school level. Given the ubiquity of data in the lived experiences of today's high school students, there is a tremendous opportunity to situate data science instruction in ways that draw on learners' interests, experiences, and cultures. Understanding the types of datasets being used in data science curricula and their alignment with the experiences of learners is an open question. In this work, we propose an approach for answering the overarching question: *What data is being used in K-12 data science curricula?* The proposed approach attends to what data is used, when it is from, its size, and how it relates to learners. To demonstrate this approach, we analyzed the YouCubed Explorations in Data Science curriculum (YouCubed, 2022), a year-long, freely available, and widely used data science curriculum. This work seeks to shed light on the nature of the datasets that are at the heart of a high school data science curriculum. In doing so, it contributes to our understanding of how best to introduce K-12 students to data science.

Analytic approach

To understand the data in K-12 data science curricula, we developed an analytic approach that attends to four interrelated measures (below). These measures were then applied to the 56 datasets identified in YouCubed.

- Topic - the ideas and topics represented, based on the Bootstrap:Data Science curriculum (Schanzer et al., 2022): *Sports, Politics, Media & Entertainment, Environment & Health, Education, Nutrition,* and *Other*.
- Recency - when the data is from, ranked by the following coding scheme: *Fresh* (just-created data), *Recent* (data from the last 3 years), *Past decade, Older than a decade,* and *Not relevant* (fictitious data/ no date).
- Size - the number of observations or entries in the dataset. We classified the datasets into five sizes: very small (<25), small (25-100), medium (100-1,000), large (1,000-10,000), and very large (>10,000).
- Proximity – how the datasets relate to learners, adopted from Lee and Delaney (2022). We used a slightly modified 5-point scale, ranging from 0-4, with 0 describing content-agnostic data, 1 describing fictional data, 2 describing data about a topic that might be familiar to some but not all students, 3 describing data on niche topics, and 4 capturing data that students collected about themselves and their peers.

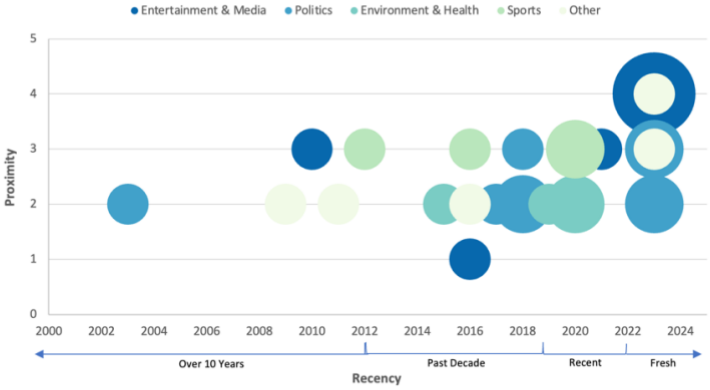
Findings

Our analysis revealed that the most common topic, comprising 16 of the 56 datasets, was Entertainment & Media. The next most common were Politics (12 datasets), with topics such as demographics and economics, followed by Environment & Health (9 datasets), and Sports (5 datasets). Regarding recency, the results show that most datasets are relatively recent, with 25 of 56 being from the last 3 years, with 13 of those datasets coded as *fresh,* meaning the data was/will be collected by the students. In analyzing datasets' sizes, we found that most of them were relatively small, with 13 Very Small datasets and 18 Small. In addition, the curriculum includes 10 Medium, 2 Large, and 4 Very Large datasets. Our analysis reveals that the curriculum includes datasets that fall across the full range of proximity levels, with a majoring of datasets rated as 2 or 3, meaning they are using real data. Specifically, 28 datasets are not related directly to the lives of students (level 2), and 18 datasets cover topics rated as more directly relating to students (level 3). In investigating the intersection of multiple categories, we found that datasets dealing with Entertainment & Media and Environment & Health tend to be relatively small. At the same time, topics related to Politics include very large datasets. In looking at the interaction of Proximity and

Topic, we can see that some topics like Politics and Environment & Health had a high level of datasets ranked as Level 2, which means they used real data but were not closely associated with the students' knowledge or interests. On the other hand, most Entertainment datasets were categorized as Levels 3 and 4 representing data that was either collected by the students or directly related to their personal lives. This analysis shows the types of topics that are close to students and identifies opportunities for potentially revising datasets within a curriculum to help make datasets and materials of greater interest to students. The final intersection we highlight is the relationship between Proximity and Recency, which sheds light on the question of whether more recent datasets are more *proximate* to students. Figure 1 illustrates that the answer to this question is generally yes. This can be seen in the trend where the higher the proximity level, the more recent the data is. This trend exists across all analyzed topics.

Figure 1

The Proximity of datasets in the YouCubed Explorations in Data Science curriculum, organized on a timeline. The bubble size represents the number of datasets with that Proximity/creation date.



Discussion and conclusion

This work presents a set of analytic lenses to deepen our understanding of the data used to introduce K-12 students to the field of data science. In attending to the topic, recency, size, and proximity of the data, we get a picture of what data are used in the YouCubed curriculum and see how it succeeds in incorporating datasets that are recent, *proximate*, and span various topics. At the same time, the analysis reveals opportunities for improvement, such as possibly revisiting the dataset coded as Politics to either make them more proximate to the learner, more recent, or replace them with datasets from other categories. This proposed analytic framework can be useful to curriculum developers to ensure that their materials incorporate various topics that are relevant to learners. Similarly, an educator could use this coding scheme to identify potentially problematic or less interesting datasets to make a more engaging curriculum. For researchers, this framework may be useful to understand the characteristics of a curriculum or as a way to compare different curricula. As the presence and importance of data in society continue to grow, it is important that all students develop a basic understanding of data science. A key aspect of this is developing effective, engaging, and equitable data science learning opportunities, which includes creating curricula with datasets that engage students. This paper builds on prior research to further develop an analytic framework that researchers, designers, and educators can use to ensure that K-12 data science curricula prepare students to be data-literate citizens.

Online Family Jewish Learning: Cases of Non-traditional Partnerships

Shai Goldfarb Cohen, Ben-Gurion University of the Negev, goldfars@post.bgu.ac.il

Abstract: With the focus of online tools as a tool to connect people, most of whom are strangers, through the study of Jewish texts, this poster presents a phenomenon of family members practicing online *havruta* (paired couple) learning together. My research questions were: How does online family *havruta* learning function as a learning space? And, how do learners experience such learning? Generating data from six semi-structured interviews, these cases show how learners explore Jewish texts as they deepen their relationships. Their actual family relations reflected a broader definition of Jews as a single people constituting one albeit large, extended, historical, and global family. Thus, these cases can be viewed as metaphors for online communal learning, specifically, Jewish learning communities.

Introduction

Learning with a sibling or parent through the Jewish pedagogy of *havruta* (paired couple) surfaces new and interesting dimensions of the relationships involved in the learning process of text study. Six adult learners shared their personal stories with me about their experiences of *havruta* learning with family members. In these cases, the learners played different roles both as learners and teachers as they went back and forth between them. They experience online Jewish learning platforms to connect with a family member through Jewish text study as they take advantage of the tools available to do so. For family members, learning together seemed to be a safer space for them to disagree and switch between being a learner and a teacher at times. In these case studies, texts, learning, and argumentation are all central elements of what it means to participate in an ongoing discussion and negotiation of the Jewish textual meanings and the ways that can be applied today.

Theoretical framework

Textual interpretation in Jewish learning and teaching

The practice of interpretation is an essential part of Judaism. It was central to the Jewish canon formation and it is the heart of more modern Jewish learning traditions as well. Shulman (2008) argues that there are three signature pedagogies for Jewish education which embody the three dimensions of performance, setting, and interactions as they all emphasize the act of interpretation. One of these pedagogies is *havruta*. Havruta provides "a setting for mutual and reciprocal coaching, scaffolding, challenge, and debate" (p. 11). The negotiation and exchange of ideas is an essential part of the *havruta* learning practice which originates from traditional Jewish Torah studies called *beit Midrash* (literally "House of Learning"). There, the construction and reconstruction of the meaning of the text are integral parts of the learning process (Kent, 2010).

Jewish Education in the Age of Google

In their report, *The Future of Jewish Learning Is Here: How Digital Media Are Reshaping Jewish Education*, Kelman et al. (2019) find that as online learning becomes more accessible, Jewish learning opportunities and experiences are also shifting. These changes include the proliferation of more approachable learning materials, the creation of new social connections, and the engagement with Jewish content in new ways that reflect learning in the 21st century.

As transnational people, Jews have long used technology to distribute learning across great distances. Today, most distance learning is internet-based. Such new media also provide novel ways of reading ancient Jewish texts as well as new learning practices. Shifts in a set of paradigms are likely to change Jewish education in the 21st century, pushing it to become more learner-centered, relationship-infused, and life-relevant (Woocher, 2012). In the "age of Google" (Rubin Ross, 2017), there are also innovative shifts in the roles of learners, teachers, community, text, and social justice, parts of a broader change in Jewish education generally.

According to Woocher (2008), both "virtual" and "real" networks shift existing social ties, creating new connections and new types of communities that otherwise would not exist. Part of the transition to a digital age includes technological and cultural transformations, like "the transition from oral tradition to written text, and then from written to printed text" (Woocher, 2008, p. 190). Given the changing landscape of Jewish learning in the digital age, this study aims to deepen our understanding of contemporary online sacred text study, specifically with family members.

Methods

This qualitative study generated data from six semi-structured interviews with users of online Jewish learning platforms, investigating how they collaboratively interpret sacred texts with family members. To find and recruit participants, I posted a call for participation on social media platforms, such as *Facebook*. Some of the questions included questions about the reasons for learning with a family member, what this kind of learning partnership enabled and/or disabled, and how it is different from learning with a partner who is not a relative.

To analyze the data, I began open-coding, seeking themes related to the participants' learning experiences such as collaboration, interpretation, and digital learning. Second, I used *in vivo* coding, in which codes refer to phrasing from the language of the qualitative data record, the terms used by the participants themselves. Through this thematic analysis, I unearth how adult learners use online tools to learn and connect with family members through Jewish text study.

Discussion and Conclusions

The online space and digital tools enabled learners not only to stay connected on a personal level but to bypass the bickering that could punctuate their differences; the focus on the text allowed them to find common ground, and the online tools allowed them simultaneous access to the text. For example, Mary shared her learning experience with her sister who came from a different professional background as a teacher. This allowed them to maintain ‘learning mindsets’ or a ‘growth mindset’ (Dweck, 2007). They came into the *havruta* learning sessions being equal learners in this virtual space as they overcame the differences between them to learn Jewish texts together. Sometimes by being aware of these differences, they learned more about their sisters, about themselves, and the Jewish texts and their multiple meanings than simply participating in text study.

Others, like Jennifer, understand this learning practice as a way to unite with another person and become one with the text. For her, as a Jewish educator by profession, being a student in her *havruta* studies surfaced another identity. In her learning experience, Jennifer went back and forth between her identity as a teacher/expert/mother and a learner/novice/daughter. She enjoyed the unique learning moments in which she was the learner and was seeking additional opportunities to expand that experience with other learners. She also understood that it was “less critical *what* we're studying [than] *that* we're studying.” The digital tools available provided Jennifer and her family, like other learners, the power to study Jewish texts not only for personal growth, but also as a family value, ritual, and tradition that connected to the historical bases of Jewish communal learning.

Some participants also talked about moments of disagreement. For example, Alyssa understood that as an adult, she held different views than her father and *havruta* partner but debating and disagreeing regarding various topics was a powerful instrument for the Jewish people as a group and family members in particular. Meeting with her father virtually enabled Alyssa to experience such personal exploration through Jewish text study with a loved one. Like Alyssa, other learners were also able to collaboratively explore sensitive issues while also learning as equals through text study; thus, the hierarchical power relations involved in the father-daughter arrangement, for example, were somewhat equalized through *havruta*.

At present, this study is still underway, making it difficult to document its significance. However, this research already broadens the existing literature on Jewish learning practices by exploring how online environments shift the roles of participants learning with relatives and the possibilities for meaning-making as they take advantage of Jewish sacred textual interpretation that is more accessible and more engaging.

Moving From the Spontaneous to the Intentional: More Evidence of How Children Use Visual Marginalia to Self-Regulate Their Learning

Nadia Dario, Kristine Lund
nadia.dario@ens-lyon.fr, kristine.lund@ens-lyon.fr
CNRS, École Normale Supérieure de Lyon, Université de Lyon 2

Abstract: In this poster, we introduce the concept of Visual Marginalia (VM) and present our second study on this topic, carried out in Italian primary and secondary schools. Results give more evidence to our Visual Marginalia elaboration Model (VMeM) confirming how VM involve base and explicit intentionality and ongoing self-regulation processes that affect students' emotions, attention, motivation, memory, and knowledge integration and reorganization and revealing a new type of VM, Dynamic Visual Marginalia.

Introduction

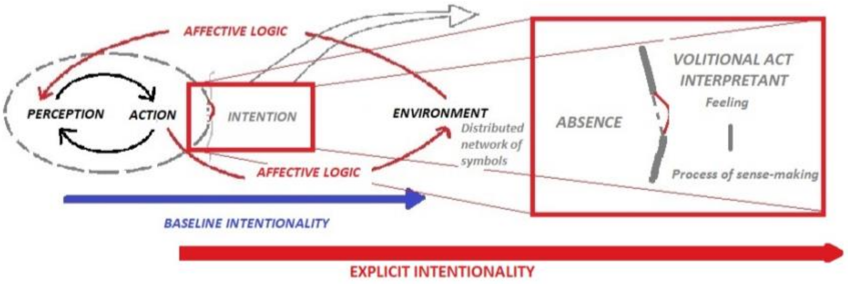
Humans leave traces of their existence over time, such as in cave paintings and graffiti. Marginalia refers to the graphical and textual elements produced by a reader in the margins of books. Great thinkers like Einstein and Bruner have produced Marginalia. Recently, we introduced the term Visual Marginalia to describe all visual self-expressions like para-writings, para-drawings, and creative modifications of book texts produced by students during the teaching-learning process (Dario, Lund, & Tateo, 2022; Dario & Tateo, 2022). According to our developmental approach, we study Visual Marginalia not as static but «in their making» (Valsiner, Chaudhary and Benetka, 2017). The second study, reported here, used a new methodology to capture VM elaboration in real classrooms (See Dario, Lund, & Tateo, 2022). Results showed more evidence for our Visual Marginalia elaboration Model (VMeM), which categorizes and confirms that VM connect intentionality and students' self-regulation. We also discovered a new type of VM, called Dynamic Visual Marginalia, which evolves from one type to another, illustrating the canalization of emotions and the maintenance of attention.

The relationship between intentionality and self-regulation

This poster demonstrates how students constantly move between different levels of intentionality deeply related to self-regulation (See Results and Interpretation). In Figure 1 we illustrate how baseline intentionality and explicit intentionality work.

Figure 1

Baseline and Explicit Intentionality



In particular, we argue that the VMeM model (Figure 2) shows spontaneous VM (e.g. scribbles and stylizations) which are governed by baseline intentionality and regulate emotional states, listening and memorization while deliberate VM (e.g. doodles and annotations) are controlled by explicit intentional actions and involve also comprehension and support self-initiated, self-planned, and self-sustained learning processes.

Study design

The study replicated the methodology used in Dario, Lund and Tateo (2022) that involved mixed methods to grasp the phenomenon of VM in its development during the teaching-learning process: we first organized kick-off meetings with principals and teachers, giving teachers a brief questionnaire. Then we video-recorded face-to-face lessons during the Covid-19 pandemic in 2022, collecting any VM that were produced by students, and conducting self-confrontation on-line interviews. We used the Big Blue Button Platform where we shared a screen with two windows: one with a wide-angle lens camera showing a recording of the lesson the students participated in; the other with an Interactive Whiteboard showing the VM where students moved a pointer to explain how they made it and what the production helped them deal with.

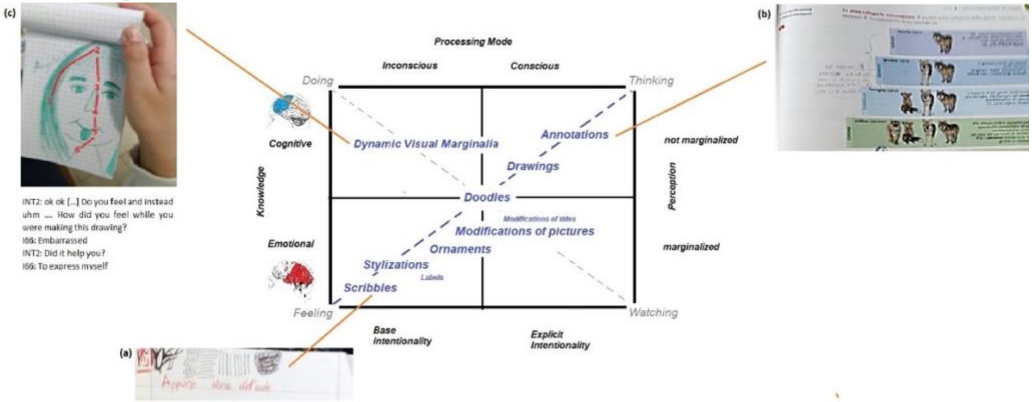
We had 67 students (ages 6-12) and 6 teachers, from primary and secondary schools in Northern Italy. All were native Italian speakers and did not have behavioral or learning difficulties. Each participant took part voluntarily, and parents provided authorizations.

Results and interpretation

Our poster will present VM forms (scribbles, stylizations, ornaments, modifications of titles and images, doodles, drawing realistic elements, annotations) however students often move from one kind to another, creating Dynamic Visual Marginalia. Here we report three examples of VM. The first is a scribble (Figure 2a), a combination of repetitive lines and scrawls, governed by a baseline intentionality, reflecting the student's sense of boredom and lack of interest during a pause in the art lesson.

Figure 2

VMeM and VM examples



INT2: ok ok [...] Do you feel and instead uhm .... How did you feel while you were making this drawing?
I66: Embarrassed
INT2: Did it help you?
I66: To express myself

In Figure 2b, while the teacher is explaining, the student seizes the initiative (explicit intentionality) to jot down an answer to a possible test question, taking into account the effect of her learning on the upcoming exam performance and her capacity for self-direction, self-planning, and knowledge retention.

In Figure 2c, a student produced a Dynamic Visual Marginalia dealing with her embarrassment during a sex education lesson. She drew a spontaneous scribble (hair) and transformed it into a girl, symbolizing her own sense of distaste. This VM helps the student to control her emotions (See text under Figure 2c) and promotes critical thinking. She thought the lesson was poorly done and the teacher was embarrassed. This knowledge produced in her a further sense of disgust.

Conclusion

This poster shows how VM are semiotic and self-regulatory tools with varying levels of intentionality that anchor learning to the context and help the learner to develop agency. Furthermore, we suggest that teachers accept VM as valuable tools and integrate them into the design of learning activities instead of discouraging their production.

Supporting Teacher Reflection in Video-Coaching Settings

Sara van der Linden, University of Twente, sara.vanderlinden@utwente.nl
Susan McKenney, University of Twente, susan.mckenney@utwente.nl

Abstract: While video coaching has the potential to support teachers' learning, limited support is available for coaches who want to use video in their own schools. This study reports on one educational design research project (consisted of four sub-studies) that aimed (1) to conceptualize teacher reflection in video-coaching settings, (2) to articulate support to improve teacher reflection, and (3) to reify (make concrete) the articulated support. Findings related to the three research objectives are discussed.

Research background and objectives

Video coaching is a professional development approach in which teachers or coaches record teaching episodes and engage in video-based one-to-one or group-based discussions in a sustained manner (van der Linden & McKenney, 2020). While there is a need for more high-quality coaches, there is very limited insight into ways to support these coaches (Tekkumru-Kisa & Stein, 2017), especially in their own schools. A number of gaps in research can be observed in this regard. First, there are questions about the conceptualization of teacher reflection in video coaching settings, because comprehensive reviews on teacher video coaching are lacking. And despite the fact that productive teacher reflection is crucial for teacher professional learning (Darling-Hammond et al., 2017), it remains an ambiguous concept (Clarà, 2015). Second, while literature on coach moves (e.g. Borko et al., 2014) provides an extremely valuable basis for the enactment of coaching sessions, additional support for coaches to lead video-coaching initiatives within their own schools is lacking. Third, the literature currently lacks practical tools for coaches improve the quality of reflective conversations. Therefore, this study aimed to (1) conceptualize teacher coaching in video-coaching settings, (2) articulate support, and (3) reify the articulated support.

Method

This study reports a synthesis of findings from one educational design research (EDR) project. EDR was deemed as an appropriate approach because of its intention to simultaneously develop theoretical insights and practical outputs for real-world use (McKenney & Reeves, 2019), which matches the nature of the three aims. The study consisted of four sub-studies (A, B, C, D), each aligned with one of the main educational design-research processes (i.e. analysis, design, construction and evaluation, respectively), and contributed to one or more research aims, see Table 1. This study foregrounded qualitative methods due to its overall explorative approach, although mixed methods were also used. Participants consisted of teacher reflection experts from research and practice (C) and participants with insight into environments where coaching takes place (D). The results of two sub-studies have been published already (van der Linden & McKenney, 2020; van der Linden et al., 2022) and those of two others are currently under review. The proposed poster uniquely synthesizes findings across the four sub-studies, in light of the three overarching research objectives.

Findings and discussion

Addressing the first research objective, a conceptual model representing teacher reflection in video-coaching settings has been developed, based on video coaching literature (A), reflection literature (B), and expert insights on what aspects should be included in a teacher reflection observation instrument (C). Three types of reflection were identified as central to teacher video-coaching, namely reflection on action as a retrospective process, reflection for action as an anticipatory process, (A, B), and reflection in action as knowing-in-action (B). In addition, the literature and expert insights emerging from sub-studies B and C yielded two perspectives on knowledge development, namely a deliberate perspective, which foregrounds collective knowledge on teaching as a frame of reference, and an aware perspective, which foregrounds knowledge development within practice and through interaction. Moreover, three phases of reflection were distinguished based on reflection literature (B), namely, (1) preparation, (2) image forming, and (3) conclusion drawing. Finally, the non-recurrent aspects of reflection include "attention" (i.e., focus) and "reasoning" processes (i.e., nature of talk, study A, B), and study B added "determining" as a concluding process, see Figure 1A.

Figure 1
Conceptual model (A), and the ReflAct Tool (B).

With regard to the second research objective, guidelines for supporting the improvement of teacher reflection in video-coaching contexts were articulated based on instructional design literature (B), teacher reflection expert insights (C), and the proof-of-concept (D). The four-components-instructional-design model (van Merriënboer & Kirschner, 2017) was selected to support the complex learning of united reflection in study B, and a blueprint for supporting reflective practices in video-coaching settings was put forward in this study. Experts deemed a formative assessment observation instrument as most needed (C), and this approach was described as a way to help coaches to get insight into the current situation, the desired situation, and ways to close this gap in study D.

Finally, an online tool, ReflAct (Figure 1B) reified the articulated support using the observation instrument from study C, which formed the basis for a computer-supported process that helps coaches to evaluate the current quality of reflection, gain insight into the desired state, and provides pre-programmed tailored advice how to improve the next conversation. Both studies C and D contributed to quality criteria for a viable tool to improve teacher reflection in video-coaching settings. Sub-study C did this through expert evaluations of the clarity of the developed indicators of the observation instrument, whereas sub-study D did so through a proof-of-concept study where experts used the prototype and commented on added value, compatibility, clarity, and tolerance. This study showed (amongst other things) that the prototype formative assessment tool for teacher reflection has the potential to provide added value in terms of effectiveness through coach development and calibration, through mirroring (i.e., insight into the current state) and advising (i.e., guidance on next steps).

The conceptual model could support teachers' attention problems of practice, by asking how core practices *have served* (united reflection-on-action), *will serve* (united reflection-for-action), *and are serving* (united reflection-in-action) the specific student population and the teacher. The support guidelines foreground approaches to develop this reflective ability that is needed to focus on problems of practice. The ReflAct tool provides initial directions for formative evaluation of video-rich reflective talk in ecologically valid ways. The conceptual model, support guidelines, the ReflAct tool and its underlying quality criteria will be illustrated on the proposed poster to guide a productive discussion with participants at the ISLS on the following additional topics: contextual variety and potential influence on the viability and institutionalization of video coaching interventions.

Elaborateness of Explanations to Understand AI Recommendations

Lydia Harbarth, University of Duisburg-Essen, lydia.harbarth@uni-due.de
Daniel Bodemer, University of Duisburg-Essen, bodemer@uni-due.de
Lenka Schnaubert, University of Nottingham, lenka.schnaubert@nottingham.ac.uk

Abstract: Successful human-AI collaboration requires an understanding of the AI system which can be achieved by human-interpretable explanations. In an experimental study ($N = 109$), we found more elaborated explanations to foster causability and trust, whereas adaptability of elaborateness provides no further benefit. Although cognitive load was not affected by explanations, its causal role requires further investigation. Future research should integrate learning sciences with explainable AI research to consider system and human aspects of understandable AI.

Introduction and research questions

Artificial Intelligence (AI) is increasingly used in the workplace. While the focus often lies on the optimization of work-related processes, there is an inherent link to learning. Especially within (but not limited to) the introductory phase of AI-workplace-integration, users not only have to understand complex content, but also need to learn about the AI system and its functioning in order to interact successfully with it. Research in explainable AI shows that transparency supports the understanding of AI systems as well as trust (Molina & Sundar, 2022). However, only because a system is explainable per se does not mean that the user actually understands it. We thus need to distinguish between the explainability of a system, actual explanations provided, and the users' processing of said explanations. Taking this one step further, we need to consider a system's ability to explain its functioning ("explainability", Adadi & Berrada, 2018) and the human perspective on the ability of these explanations to foster the users' understanding of the causal chain of system functioning (i.e., "causability", Holzinger et al., 2020). The latter depends on individual characteristics as different users may need or prefer differently elaborated explanations (e.g., Putnam & Conati, 2019). For example, novices may need more elaborate information than expert users, and the possibility to adjust the level of elaboration may provide even further benefits for learning processes. When designing human-computer interaction, there is always a trade-off between amount and complexity of information and the capacities of human information processing (e.g., Sweller, 2010). Thus, when designing explanations, human working memory capacities need to be taken into account to enable adequate resources for germane cognitive processes via balancing extraneous and intrinsic load. In sum, careful design is necessary to foster understanding of and trust in AI systems while considering individual learner characteristics, needs, and information processing, which can be achieved by using human-interpretable explanations. In our study, we thus investigate the effects of different types of instructional material (in terms of level and adaptability of elaborateness of explanations) on system causability (i.e., perceived appropriateness of explanations for understanding the system) and trust in the system. As additional information may strain cognitive resources but may also support learners during information processing, we exploratively investigate the role of cognitive load.

Experimental study

In a between-subjects online experiment, $N = 109$ participants (age: $M = 26.89$, $SD = 11.35$) were confronted with 12 scenarios and had to decide whether to play golf based on multifaceted weather data while guided by a bogus AI system. Participants were randomly assigned to one of three conditions: (1) high level or (2) low level of elaborateness of explanations or (3) the possibility to flexibly adapt the elaborateness by toggling between high and low. Afterwards, all participants conducted questionnaires regarding – amongst others – cognitive load (Klepsch et al., 2017), system causability (Holzinger et al., 2020), and trust (Jian et al., 2000).

While the level and adaptability of elaborateness of explanations did not affect trust in the system directly, mediation analysis showed that including causability as a mediator explained some of the variance of trust ($R^2 = .23$, $p < .001$) with the level of elaborateness (but not adaptability) affecting trust via changes in causability (CI[0.01; 0.43]). Direct effects on trust remained non-significant. This data indicates that explanations do not affect trust in AI directly but that the relationship between explanations and trust may rather be explained by causability. More elaborate explanations may increase their perceived appropriateness to help understand the system which, in turn, may increase trust in the overall system. The possibility to toggle between low and high elaborated explanations, however, did not provide further benefits regarding causability or trust. When examining how elaborateness of explanations, trust, and causability are related to cognitive load, we found negative correlations between cognitive load (i.e., extraneous and intrinsic load) and causability and also trust ($- .71 \leq r \leq$

-.42). This means that high load (induced by the content or presentation of the learning material) is associated with lower perceived appropriateness of explanations regarding system recommendations as well as lower trust.

Conclusion

Our study shows that while explanations may not affect trust per se, trust can be increased when learners perceive provided explanations as appropriate to understand the output of AI systems (causability). While the relationship between trust and the ability of explanations to foster actual understanding still needs to be considered, a learner's perspective seems to be an important part of the equation. Regarding the level of elaborateness of explanations, our findings are in line with research on transparency and traceability (e.g., Molina & Sundar, 2022) and also in line with the idea that (perceived) quality of explanations is a feature of trustworthy systems (Holzinger et al., 2020) that should be utilized to develop explainable AI. Regarding adaptability, however, research shows positive effects on understanding (Holzinger et al., 2020), while in our study, adaptability did not provide further benefits regarding understanding or trust. One reason may be that our scenario did not require such a feature. As adaptability is especially important when explanations may not only benefit but potentially also harm learning (for example by adding unnecessary load) its gain may increase with task complexity. Our results indicate that load is not affected by the explanations we provided, but cognitive load as well as the need for additional information may severely depend on learner characteristics like expertise (Putnam & Conati, 2019). Thus, adaptable explanations may have more merit when learners are confronted with a complex task and may gradually reduce their levels of support with developing expertise. Additionally, future research should examine which elements of an explanation need to be made adaptable (e.g., content features) to optimize effects. Thereby, cognitive load should be considered as it is connected to causability and trust in AI, although the causal relationships are yet unclear. Mistrust has previously been linked to cognitive load (Samson & Kostyszyn, 2015) and it may be worth exploring this relationship also in the context of human-AI collaboration. Understanding AI and using it in a responsible way is important in working and learning contexts (e.g., in vocational training), where end users are often no technology experts and may have varying knowledge regarding AI and its functioning. As AI algorithms are difficult to understand even for experts, it is thus crucial to gain insights on how to develop human-interpretable explanations and how to adapt them to learners' needs. Our study emphasizes considering both sides of the medal when analyzing understanding of AI: the system side and the human side.

Abstract: An important goal of 21st century education is preparing students to comprehend and integrate information from multiple documents to make informed judgments as lay people. This paper describes student use of a computer-supported collaborative learning (CSCL) system called EDDiE (Electronic Documents Disagreements Evaluation) that embeds epistemic scaffolds into a shared workspace designed to support students as they analyze, evaluate, interpret, and integrate evidence from multiple documents. In this study, the EDDiE system successfully promoted student discourse related to evidence analysis, evaluation, interpretation, and integration, and lay use of evidence. Findings indicate that students need further instruction and scaffolding to distinguish among the quality, amount, and strength of evidence and to support the development of epistemic criteria for evaluating the quality of document sources.

Introduction and theoretical framework

A crucial goal of education is to enable students to aptly comprehend and integrate information from a diverse range of oft-conflicting information sources (which we refer to as "documents") to make informed judgments (Barzilai et al., 2020). Because many issues faced by citizens hinge in large measure on evidence (such as evidence bearing on the efficacy of COVID-19 vaccines or on the reality of climate change), the competencies needed to reason well about evidence are of crucial importance. Prior research on efficacious digital tools to support student engagement with multiple documents include prompts to support students' metacognition (Stadtler & Bromme, 2007), as well as epistemic scripts or scaffolds which guide learners through the key activities of knowledge production (Weinberger et al., 2005). Digital epistemic tools have been effectively used to support students' engagement with and integration of information from multiple documents, such as through the use of document maps that enable the user to link sources and claims (Barzilai et al., 2020).

This paper reports on how students worked with a CSCL system designed to incorporate competencies for both experts and lay people to reason about evidence identified in the Grasp of Evidence (GoE) Framework (Duncan et al., 2018). The system, called EDDiE (Electronic Documents Disagreements Evaluation), is a browser-based application that provides a shared workspace for multiple students to read, discuss, and analyze a set of documents together (Mochizuki et al., 2022). EDDiE supports students as they engage in the five dimensions of reasoning about evidence specified by the GoE framework as they read and analyze the documents on EDDiE's collaborative graphic organizer, referred to as the *analysis tableau*. EDDiE incorporates epistemic scaffolds that encourage collaborating students to discuss evidence along each of the five dimensions and supports learners in using the results of evidential reasoning to resolve disagreements among documents to reach a sound conclusion.

Methods

Context, participants, and data collection procedures

This design-based research study was conducted in 2020 in the context of an online, Zoom-based undergraduate course on the design of learning environments at a private university in Japan. The participants were 7 male and 6 female undergraduate students majoring in informatics. Prior to data collection, participants watched a video demonstrating how to use each feature of EDDiE without providing substantive instruction on appraising evidence or resolving disagreements. Students also received a visual aid summarizing the features and functions of EDDiE.

The participants were divided into groups of three and assigned one or two trained student facilitators. The participants were provided with five Japanese documents (approximately 200-400 words in length when translated into English), that provided a variety of claims about different diets, described positive and negative effects of these diets, and provided evidence from relevant scientific studies and experts. Each document was presented as a digital media or blog post that included the source information and descriptions of one or more nutritional studies ranging in quality, strength, and number. The documents varied in the strength, quality, and number of expert sources referred to within each document. The students were given approximately 80 minutes to read and analyze the five documents together using EDDiE to reach a joint conclusion about the best diet(s) to follow based on the information provided across all five documents.

Data analysis

Three groups were selected for data analysis because they completed the task in full with minimal intervention by the facilitator. Data sources included English translations of the transcript of each group's discussion and the final version of the EDDiE tableau that the participants collaboratively created over the course of the discussion. Qualitative coding was conducted using NVivo. In the first phase, the first author conducted deductive coding to identify the presence or absence of the features of student discourse that EDDiE was intended to produce related to the analysis, evaluation, and integration of evidence as well as lay use of evidence. Inductive coding was also conducted to identify emerging patterns related to collaborative student discourse related to evidence or the features of EDDiE. The codebook was then reviewed and revised in collaboration with two additional researchers. In the second phase, the full dataset was recoded using the revised codebook. The coded data was then organized and analyzed in accordance with the five dimensions of the Grasp of Evidence framework with an additional category for portions of the discussion related to resolving disagreements among multiple conflicting documents.

Results

Analysis of student discourse demonstrates that the features of the EDDiE system that were most successful included the epistemic scaffolds for *evidence analysis* and *evidence evaluation* (e.g., the evidence circles feature), which functioned together to promote productive collaborative discussions about how various methodological features contribute to the overall quality of evidence, drew students' attention to methodological features they may not have otherwise examined, and encouraging collaborative judgments about which methodological features constitute a strong empirical study. However, although the epistemic scaffolds intended to support students' *lay use of evidence* (e.g., document author circles) produced extensive discussion about quality of document sources, students struggled to identify appropriate criteria to gauge which sources were more trustworthy than others. In addition, while the EDDiE graphic organizer was an effective scaffold for eliciting student discourse about reasons to explain disagreement, such as how differences in research methodology may explain conflicting evidence, students sometimes provided explanations that were ill-supported by the evidence across the five documents.

Discussion

While the epistemic scaffolds of the EDDiE system function to support students as they engage in the *analysis*, *evaluation*, *interpretation*, *integration*, and *lay use of evidence*, the findings identify specific areas where further scaffolding or other instructional supports are needed to further improve student comprehension and integration of information from multiple documents. Proposed revisions to the EDDiE system include: (1) opportunities to develop richer, more nuanced criteria for source credibility; (2) scaffolds to encourage the use of student-generated disagreement reasons as a springboard for thinking about how to resolve the disagreement between documents; and modifications to support students in distinguishing among the quality, amount, and strength of evidence. Classroom instruction that focuses on developing effective epistemic criteria for evaluating the quality and strength of evidence as well as the evaluation of the quality of document sources and expert judgments has the potential to support students' epistemic growth in conjunction with the use of the EDDiE system.

Re-Envisioning Bibliometric Analysis as a Tool for Transforming the Field

Dalila Dragnić-Cindrić, Judi Fusco
daliladc@digitalpromise.org, jfusco@digitalpromise.org
Digital Promise

Abstract: New digital technologies can help create equitable educational outcomes. We used bibliometric methods, a powerful tool for analyzing large bibliographic datasets, with an open-source software to map the computer-supported collaborative learning literature. Applying a diversity, equity, and inclusion lens, we considered the strengths and weaknesses of this method and analyzed the resulting literature map. We offer recommendations to researchers using similar approaches and re-envision the transformational potential of bibliometric analysis.

Introduction

This conference theme, "Building knowledge and sustaining our community," calls for envisioning a new role of technology for building knowledge and community. We connect to the conference theme by focusing on bibliometric literature analysis and using this method as a tool that can point the way toward increasing diversity, equity, and inclusion (DEI) in a scholarly field and its community. Bibliometric analysis (BA)–a method for mapping and synthesizing scholarly fields–propagated in recent years with technological advances and the increasing accessibility of bibliographic databases (BDs) such as the Web of Science (WoS; Block & Fisch, 2020). We consider this method in the context of our literature synthesis. Due to space limitations, we provide high-level information about our work here and share additional details in the poster at the conference.

Our research project aims to map and synthesize literature on computer-supported collaborative learning (CSCL), identify topics relevant to K12 practitioners for translation from research to practice, and determine if new research is needed. The project has three phases; in this paper, we discuss Phase 1, literature mapping. In our work, we take a DEI lens and work to transcend the bounds of bibliometric analysis, re-evaluate it, and re-envision it as a tool for transforming the field. We focus on the following two questions: RQ1) what does a map of CSCL literature look like? and RQ2) what does the map reveal about DEI in this field?

Methods

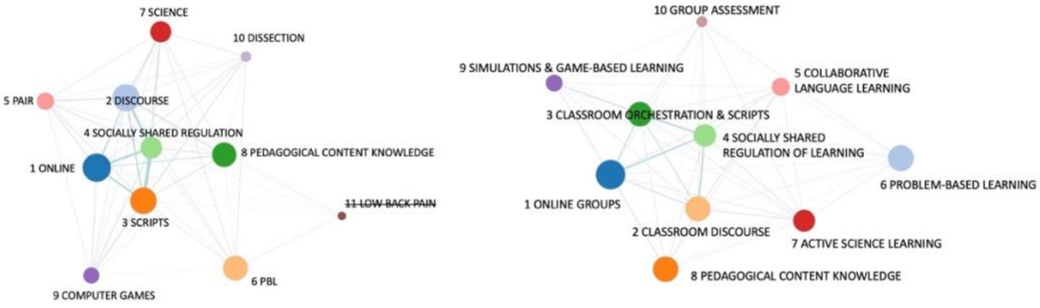
Bibliometric methods are quantitative methods used to analyze bibliographic datasets (e.g., author and journal names, article titles, abstracts, keywords, publication years) available through BDs (e.g., WoS). These methods identify topic clusters and links between them, impactful authors, articles, and publications, and reveal author networks; they have the potential to uncover academic silos and point to research gaps (Block & Fisch, 2020). WoS provided the relevant meta-data for our search on K12 STEM collaborative learning.

Our whole corpus included 16,470 publications. We analyzed this corpus using the existing open-source BiblioMaps tool (Grauwin, n.d.), utilizing the bibliographic coupling (BC) method. BC is based on the overlap between the references of each pair of publications. The resulting visual representation shows structures of nodes or topics in the literature. Our goal was to identify key research topics relevant for K12 practice, so we worked to refine the initial software-generated CSCL literature map (Figure 1, on the left). We determined the top 10% most relevant publications of our search was most appropriate (Figure 1, on the right). We independently reviewed publications in each node and excluded irrelevant nodes (i.e., low-back pain). Next, we evaluated node names and determined names that would be informative to researchers and teachers. To ensure that the map created through the BA reflected current knowledge, we compared the map topics to those in the recent "International handbook of computer-supported collaborative learning" (Cress et al., 2021). We noticed that two of the topics in the Handbook, DEI and argumentation, were not on our map. We decided to include these two topics in the project. Throughout the process of map curation, to ensure the map's trustworthiness, we engaged in peer-debriefing sessions with researchers not involved in this project to review the map and our curating decisions.

Results

In response to the RQ1, we found the initial whole corpus, software-generated literature map gathered publications into 21 topics and 151 subtopics based on the shared references. The initial map of the top 10% most relevant publications (11 topics, 40 subtopics) included some nodes with uninformative names and unrelated literature. Related to our RQ2, our analysis revealed a relatively small sub-node of works (27 publications) focused on equity, with the majority of publications originating from the U.S. The fact that DEI was not included at the node level in the map means that it did not share enough citations with the publications in other nodes.

Figure 1
The initial map (left) and the final map (right) of CSCL literature (top 10% most relevant publications)



Discussion

Our bibliometric research led us to concur with Gomez et al. (2021) that despite deep concerns with DEI within the CSCL field, the existing literature does not reflect a global effort to address DEI as a focal point of CSCL studies. Until a larger number of studies focus on DEI and become linked to the existing publications, bibliometric methods will not reflect changes in the literature structure. Researchers using the existing bibliometric tools should be aware of the following three caveats concerning DEI that became evident during our study: a) level of access to BDs, b) biases and lack of algorithmic transparency in the BDs and software tools, and c) accessibility of the research literature. First, as each bibliographic study starts with extracting data corpus from a BD, the level of institutional access to a BD might differ for researchers by the institution. Hence, researchers with different access levels would obtain different outputs from a BD for the same search terms. Second, there are proprietary search algorithms used by BDs to determine publications' rankings in search results. The criteria for the rankings are obscured, so it is not possible to identify biases that might influence the results. The third caveat is the ability to access the research literature. Researchers from under-resourced institutions may have less access to publications behind paywalls and may be unable to cite such works. Without these citations, their work will not be included in BC analyses because its references will not connect it to 'mainstream' research. Considering these caveats, we posit that the first step towards the transformative use of bibliometric analysis is the acknowledgment that software-generated literature maps reflect inequities, biases, and issues of power that are present and evident in the structure of scholarly fields and in the tools used in them. One recommendation to researchers who want to use bibliometric methods to do more than describe a field's structure is to center DEI in their work by reflecting on what is and is not present, whose voices are included or not, and what literature is yet to be created. Our list of caveats is not all-inclusive. Rather, it is meant to start a conversation about envisioning more equitable tools, approaches, and partnerships.

Angry but Hopeful: Emotions About Climate Change on TikTok

Prasina Parameswaran, Ha Nguyen
prasina.parameswaran@usu.edu, ha.nguyen@usu.edu
Utah State University

Abstract: Articulating emotions can help youth to contextualize seemingly distant issues such as climate change and invite dialogues. In this work, we examine how youth express emotions about climate change on social media. Our analyses of 171 TikTok videos with description tags related to climate change revealed multiple emotions, such as joy, optimism, anger, fear, sadness, and sarcasm. These findings help to frame climate science education to elevate individuals' emotions and experiences towards climate-minded actions.

Introduction

TikTok—one of the fastest growing social media platforms among youth aged 13-24 (Li et al., 2021)—provides a site for youth's self-expression. We focus on youth's emotional expression on TikTok in the context of climate change. The research illuminates how to frame climate education for youth, to motivate their uptake of sustainable actions. We focus on emotional expression as it can be conducive for learning (Curnow et al., 2020; Pekrun & Linnenbrink-Garcia, 2014). Students experience positive and negative emotions, from enjoyment and curiosity to anxiety and confusion in learning settings, and these emotions contribute to academic and personal growth (Pekrun & Linnenbrink-Garcia, 2014). Within climate science contexts, youth also articulate a range of emotions, from anxiety to optimism, to make sense of climate news and climate action (Ojala, 2012; Zummo et al., 2020). Emotional expression also helps to relate youth-created content to other social media users and facilitate learning and social movements (Kluttz & Walter, 2018). Prior work has examined climate change discussions without an explicit focus on categorizing emotions (e.g., Hautea et al., 2021). Our work examines (1) how emotions are displayed in climate change discussion, and (2) which emotion types might be associated with more user interactions. Generative interactions may indicate productive framing for climate change conversations.

Methodology

Data included 171 videos published between September 2020 and August 2022 on TikTok, a platform for creating and interacting with short-form videos. The sample was randomly drawn from a larger corpus of 500 videos, which we pulled from publicly available data under hashtags related to climate change, such as #climatechange, #climateaction, #sustainability, etc. In the current analysis, the videos showed varying number of interactions, likes (*M* = 149,057.60, *SD* = 608,408.18), shares (*M* = 4072.5; *SD* = 13,045.85), and comments (*M* = 2576.86; *SD* = 13,119.35). The large standard deviations suggest the sample's representativeness to not only include videos that are popular on the platform. Before data collection, we received confirmation from the university's IRB that the research did not involve human subjects, because the data were publicly available.

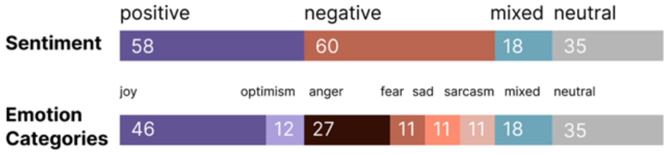
Our qualitative analysis of the videos focused on emotions, drawing from video creators' facial expressions and gestures, video captions, and on-screen text (Hautea et al., 2021; Li et al., 2021). We went through two coding stages. First, the first author watched 50 videos and developed first-level, low-inference codes of emotions (e.g., "hopeful", "happy", "angry"). Second, the authors collaboratively discussed the first-level codes to refine the coding scheme. We developed two layers of codes: sentiments (positive, negative, and neutral) and emotion categories that captured nuances in the sentiments. The categories drew from emotion frameworks to include joy, sadness, anger, and fear (Jack et al., 2014). We added codes for "sarcasm" and "optimism", as these emotions were identified as critical to climate change discourse (Curnow et al., 2020; Ojala, 2012). To establish inter-rater agreement, the two authors separately coded 69 videos each (40% of the corpus) and achieved 88.5% agreement on sentiments and 86.9% on emotion categories. The first author coded the rest of the data.

Results

For RQ1, we noted a range of sentiments in the videos: positive (*n* = 58; 34%), negative (*n* = 60; 35%), a mix of positive and negative sentiments (*n* = 18; 11%) and neutral (i.e., no sentiment; *n* = 36; 21%; Figure 1). Positive videos showcased *joy* (e.g., uplifting environmental news, appreciation of climate activists, and personal sustainability practices, among other themes; *n* = 46, 27% of total videos) and *optimism* for climate solutions (*n* = 12, 7%). For example, videos coded with optimism focused on concrete actions, such as using renewable energy sources, regenerative agricultural practices, and local produce. These videos emphasized climate optimism, or belief that human agents (e.g., youth, scientists, policy makers) have clear directions to address climate change.

Figure 1

Distribution of Sentiment and Emotion Categories



There were also videos with negative sentiments that expressed *anger* (*n* = 27; 16%), *fear* (*n* = 11; 6%), *sadness* (*n* = 11; 6%), and *sarcasm* (*n* = 11; 6%). In one video coded with anger, a creator combined footage of himself picking up plastic on the beach and images that showed the harmful impact of plastic waste on the marine ecosystem. The creator used strong language to express his emotion (e.g., "sea turtles, whales, dolphins are trapped in them, killing them."). Combining visuals also helped to show sarcasm. One video displayed footage of a creator reacting to statements from corporations (e.g., "we can achieve net zero by 2050") by raising his eyebrows and looking down. These expressions suggested sarcasm: Despite their statements, corporations had not taken meaningful action. Videos that showed fear were also related to the lack of climate action. Meanwhile, those that displayed sadness focused on climate-induced biodiversity loss and violence against climate activists.

We observed videos showing both positive and negative sentiments, most commonly a mix of fear and optimism. For example, one video displayed a creator's fear (the onscreen text read "feeling hopeless about the future"). Her expressions and body movements gradually changed, however. She started dancing and putting her hands up while the onscreen text stated: "seeing young people come together to take action and make change".

To answer RQ2 about effective emotional framing to generate interactions with other users, we ran analyses of variance (ANOVA) to examine the relation between videos' sentiments and the number of likes, comments, and shares. We did not find significant associations (likes: $F(3, 167) = .76$, $p = .52$; shares: $F(3, 167) = 2.41$, $p = .07$; comments: $F(3, 167) = 1.30$, $p = .28$). This suggests that the average interaction counts (as indicators of a video's popularity) did not significantly differ for videos with different sentiments.

Discussion and conclusion

We found that youth more often display emotions than no emotions, with similar amounts of positive and negative sentiments. Researchers have emphasized the role of negative emotions in inviting conversations about civic topics (Curnow et al. 2020). Youth also express hope to cope with climate anxiety (Ojala, 2012). Emotional expression may provide opportunities to connect with a broader audience and contextualize climate change discussion to facilitate sustainable practices. Our future work involves examining the videos' comments, to understand how audience relates to emotional display and engage in conversations that may enrich learning.

Abstract: Social justice-oriented design has influenced design practice and research in various design fields. While the number of justice-oriented research and practices increases, it remains unclear how to incorporate justice-oriented design into the actual design process, particularly for projects that involve specific marginalized groups. This poster introduces social justice-oriented design guidelines with applied case examples.

Introduction

There is an increasing interest among learning scientists in contributing to social changes and promoting social justice (e.g., Reynante, 2021). Social justice-oriented design is to create an equitable social environment through design processes and products. To raise designers' awareness of social justice issues, several justice-oriented frameworks have been proposed. For instance, inclusive design and universal design encourage user experience designers to consider the full range of human diversity and increase the inclusiveness and accessibility of their design solutions. Other frameworks also emerged, such as culturally responsive and sustaining education framework (NYSED, 2018) focusing on creating curricula affirming students' linguistic and cultural identities. These frameworks highlight the essential components of social justice-oriented design and provide directions for designers to promote social justice. However, it is not necessarily clear how they can be applied to design for/with particular marginalized cultural groups. Designers need guidelines and methods to incorporate culture and values into their design products (Moalosi, Popovic, & Hicking-Hudson, 2010).

The purpose of this poster is to introduce justice-oriented design guidelines that we created and used and to demonstrate how they guided our design of a simulation for domestic violence victims on a US Department of Justice (DOJ) funded research project.

Conceptual framework

The conceptual framework used in the present work was built based on the literature on critical theory (e.g., Horkheimer, 2002) and social justice-oriented design studies (e.g., Bellini et al., 2022) as well as six dimensions of justice-oriented design (Dombrowski, Harmon, & Fox, 2016). *Critical Theory as a philosophical foundation*. Critical theory encourages people to reflect and critique the current power structures with considerations of historical, cultural, and ideological contexts. According to critical theory, inequality occurs when certain groups' interests or needs are less valued by others and thus have less access to resources such as education, healthcare, and food security. Designers can lead social change by recognizing inequality that exists and address inequalities with possible solutions. In our project, critical theory led the design team to focus on the lived experiences of Korean immigrants who suffer from domestic violence and to identify the resources they need to change unjust situations. Grounded in their cultural and linguistic uniqueness, they prefer to approach Korean church leaders (if they seek help), which led to the design of a simulation that engages Korean church leaders in the community's domestic violence prevention. *Social justice-oriented design*. Social justice-oriented design is rooted in critical theory with the purpose of promoting equity and fairness among people, regardless of the social groups to which they belong. It focuses on the injustice caused by social or cultural norms that may limit the agency of community groups. Many social justice-oriented design projects aim to reduce the harm caused by unjust practices influenced by those norms or traditions. In addition, justice-oriented design emphasizes increasing the cultural inclusiveness of the design products. Those studies explored the meaningful design collaboration or co-design process with people from diverse ethnic backgrounds (e.g., Chauhan et al., 2021) and investigated the cultural needs of user groups to include their values, cultural norms, and into the design products (e.g., Reynante, 2021). *Six dimensions of justice-oriented design*. The conceptual framework of Dombrowski, Harmon, and Fox (2016) highlights the six design dimensions of social justice-oriented design: transformation, recognition, reciprocity, enablement, distribution, and accountability.

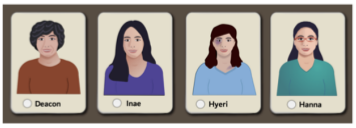
Design guidelines

Figure 1 illustrates the social justice-oriented design guidelines we created and used in our project for social justice among victims of intimate partner violence, along with two design examples. Our poster will showcase design cases that illustrate how each guideline informed the project design.

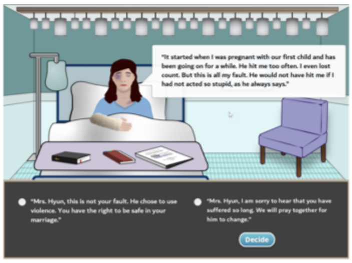
Figure 1

Simplified Presentation of Design Guidelines and Example Design

- *Guideline 1: Inequality Identification.* Designers focus on the larger contexts to identify the inequality issues that may marginalize or produce disadvantages for a certain group.
- *Guideline 2: Cultural Recognition*. Recognize the cultural norms, values, and assumptions that may cause the inequity. Particularly, the design team can conduct literature review or user analysis to identify cultural related factors that contribute to inequity.
- *Guideline 3: Ideation*. Based on the inequality and inequity identified, conceptualize the pathway to the ideal just situation that can be created by design. This may lead to the possible design solutions or interventions that improve the unjust situation.
- *Guideline 4: Culturally Responsive Design*. Incorporate cultural factors into the intervention design process that may lead to equitable engagements: a) create culturally responsive functions and features that lead to equitable engagements, b) incorporate cultural norms and values into the design of the content, c) create graphics that carry symbolic meanings resonating with the target users, and d) incorporate cultural attractors into the design of the interface elements that match expectations of a specific culture.
- *Guideline 5: Equitable Distribution.* Consider the equitable distribution of the design solution, including opportunities and access to related resources: a) collaborate with community partners to help distribute the design, b) provide alternative access to the related resources, c) consider the language needs of the user group.



Ideation: conceptualize four simulated virtual cases to change the unjust situation



"It started when I was pregnant with our first child and has been going on for a while. He hit me too often. I even lost count. But this is all my fault. He would not have hit me if I had not acted so stupid, as he always says."

● "Mrs. Hyun, this is not your fault. He chose to use violence. You have the right to be safe in your marriage."

● "Mrs. Hyun, I am sorry to hear that you have suffered so long. We will pray together for him to change."

Culturally Responsive Design – incorporate cultural norms and values into the design of narratives

Preliminary impact findings

We have implemented the simulation designed using those guidelines in collaboration with victim service organizations and church leaders. We found that religious leaders who participated in this program increased in their knowledge and self-efficacy in domestic violence prevention (Choi et al., 2022).

Positive Education to Promote Flourishing: PERMA Framework Applied to College Students

Jing-Hua Chen, Army Academy R.O.C. Taiwan, jinghua@aaroc.edu.tw
Huang-Yao Hong, National Chengchi University, Taiwan, hyhong@nccu.edu.tw
Meiju Chen, National Tsing Hua University, Taiwan, meiju@mail.nd.nthu.edu.tw

Abstract: This study aims to promote students’ autonomy and self-facilitation of well-being through positive education as an instructional approach. The participants were divided into an experimental group (*n* = 45) and a control group (*n* = 49). Data include online behavioral logs and a survey. The findings showed:1) Students practiced proactively positive psychology interventions (PPIs) and worked interactively with one another in an online platform. 2) PPIs were found significantly effective in increasing subjective well-being, and in reducing depressive symptoms.

Introduction

It has been estimated that there is between 12 and 46 percent of university students experiencing mental health problems (Harrer et al., 2019). Mental illness is associated with issues in academic contexts, including lower academic engagement, underachievement, and dropout (Ishii et al., 2018), as well as higher levels of academic dissatisfaction (Lipson & Eisenberg, 2018). School-based positive psychology interventions (PPIs) are a new curriculum for students to learn some coping skills with an aim of promoting their well-being（Shankland & Rosset, 2017). PPIs are aimed at increasing positive feelings, behaviors, and cognitions, while also using theoretically and empirically based pathways or strategies to increase well-being (Liau et al., 2016). The PERMA framework proposed by Seligman (2011) considers well-being to be broadly comprised of five elements: Positive emotions refer to hedonic feelings of happiness, such as feeling contentment and joy; engagement refers to feeling completely absorbed and engaged in life and connected to activities/organizations; positive relationships refer to feeling socially integrated, cared about and supported by others, and satisfied with authentically connected to others; meaning or purpose refers to believing that one’s life is valuable and feeling connected to something greater than oneself; and a sense of accomplishment includes making progress toward goals, feeling capable (Au et al., 2018).

This study employs Knowledge Forum (KF)–an educational software designed to help and support knowledge building communities. A main tool feature that KF uses is scaffolding (Scardamalia, 2004). In this study, the components of the PERMA model were directly employed as scaffolds in KF. This study is based on the PERMA model, designed and implemented school-based positive psychology interventions (PPIs) for 16 weeks, and employed an online Knowledge Forum learning environment for students to practice PPIs. Accordingly, the research questions are: (1) Can students practice proactively PPIs and work interactively with one another in an online KF? (2) Can the PERMA model activities (designed as KF scaffolds) improve college students' well-being?

Method

45 Taiwanese college students in an experimental group took a positive psychology course with PPIs treatment. In contrast, 49 Taiwanese college students in a control group took a psychology course with no PPIS treatment. The members of the experimental group, who practiced PPIs with the help of the PERMA framework, planned about good memories, character strengths, gratitude, and resilience and worked online in KF for note-creating, modifying, reading, and replying using the PERMA scaffolds during the 16-week course. Finally, the teaching assessment is to understand about student's learning engagement and process, as well as the effects of treatment for promoting students’ well-being and decreasing depressive symptoms. Regarding the data sources, the first pre-post survey items were taken from *Taiwan Subjective Well-Being Scale—Short Form (TSWBS-SF)* with 15 items (such as “I feel joyful all the time”) (Yu et al., 2017). *Taiwan Depression Scale (TDS)* with 22 items (such as “I am stressed”) (Yu et al., 2008). Second, online activity logs were concerning notes created, modified, read, and replied to by students in KF were also gathered.

Results

First, Table 1 shows how the students of the experimental group practiced proactively PPIs online in KF. Students were found to consistently work with ideas by creating, revising, and reading notes over four activities in a semester. Students spent most of the time on the activity of good memories. And one particular student was found to have a total of 21 notes-created and 17 notes-replied to others, showing that this student actively participated in KF activities and interacted intensively with others. The overall results show that students were able to progressively increase their interactive engagement as reflected in their built-on notes about practicing PPIs. The finding also suggests that students were able to work collaboratively as a community in this course. Students who created notes in KF used the PERMA model as scaffolds, such as “When you can face every day of life with gratitude, you will be happier” (positive emotions, P), “ Thanks to my family for their support and encouragement when I encounter setbacks (Relationships, R)”. Second, Table 2 shows the scores of subjective well-being（t（92） = 3.6，*p* = .001，*d* = .74）, and depression（t（92） = -2.83，*p* = .006，*d* = .58） were significantly different between the experimental group and the control group. The survey results indicated PPIs practiced in KF are related to improving mental health and decreasing depressive symptoms.

Table 1

Descriptive Analysis of the Experimental Group’s Activities in KF (N = 45)

KF Activities	Good Memories		Character Strengths		Gratitude		Resilience	
Activity Frequency	Total	Percentage	Total	Percentage	Total	Percentage	Total	Percentage
Creation	148	11%	105	18%	54	20%	66	17%
Modification	266	21%	192	32%	84	30%	112	28%
Reading	864	68%	295	50%	140	5%	216	55%

Table 2

Independent Samples t-test in the Experimental Group and the Control Group

Items	M(SD）		df	t-value	*p*	ES（*d*）
	Ne = 45	Nc = 49				
Subjective Well-being	46.87（ 7.98）	41.06（ 7.66）	92	3.60	.001	.74
Depression	13.18（11.53）	20.31（12.81）	92	-2.83	.006	.58

Discussion, summary and conclusion

With the help of positive education as an instructional framework, the participants wrote the PERMA plan and shared ideas online, while interacting with peers in the scaffolded KF environment. During the 16-week practice, they were constantly immersed in the PERMA activities. Finally, the survey results also showed statistically significant differences in the mental scales. It is shown that PPIs can effectively improve college students’ flourishing and reduce depressive symptoms. Positive education as an instructional approach can promote students’ autonomy and self-facilitation of well-being. However, during the practicing PPIs sessions, participants were encouraged to share their thoughts and experiences, and there was an associated risk that participants might disclose information about their health and mental health. The teacher who manages the PPIs had the responsibility to comfort students and help them avoid being negatively affected.

Exploring Physicality in Out-of-School Time Learning

Lo Lee, Denise Jones, Steve Cederquist, Xingjian Gu, Barry Fishman, Leslie Herrenkohl
lololee@umich.edu, jonesdee@umich.edu, cedsteve@umich.edu, xjgu@umich.edu, fishman@umich.edu,

University of Michigan, Ann Arbor

Abstract: Bodily experience in learning has been an ongoing discussion in Learning Sciences. Informed by prior research on the value of embodiment, we explore bodily experience slightly differently by highlighting place-based physical attributes of youth in an out-of-school time (OST) context. Through interviewing students, parents, and OST providers, we discuss how such physicality imbued with interaction within space can capture and foster OST learning and engagement over time, supporting how parents and providers perceive OST STEM education.

Introduction and background

Learning is considered an embodied process where the body is key to acquiring knowledge and constructing shared meaning (Abrahamson & Lindgren, 2014). A vast literature on embodiment exists in Learning Sciences. For example, Lyons (2018) studied the use of technology in museums to help people make sense of exhibits and gain playful and collaborative experiences. Vossoughi and colleagues (2020) illuminated how children organized learning for the self and others using received embodied assistance in an OST tinkering program. There is another stream of inquiry where scholars probed how mobility affected learning. Marin and Bang (2018) investigated how learning occurred by observing children and parents walking in the forest. Informed by prior work, we explore bodily experience, including senses, by highlighting place-based physical attributes as physicality—how youth's bodily interactions with space may support their engagement in OST learning. This poster comes from a larger research project where we work with students, parents, OST providers, and college admission officers to discuss how OST STEM learning can be documented via personal learning records. Our goal is to show the potential of utilizing physicality as a way of knowing *how* youth engage in OST STEM activities.

Methods

This poster reports preliminary data from interviewing 24 youths, 10 OST providers, 10 OST alums, and 4 parents from one specific OST venue, *STEM Space*. STEM Space is an OST program affiliated with a public university in the Midwestern United States to offer free college preparation guidance and academic resources for middle and high schoolers living nearby. All our recent interviews were done remotely and audio recorded. We followed semi-structured protocols to request participants to share their experiences with OST STEM learning, participation, and programming. We analyzed the interview data using qualitative content analysis (Hsieh & Shannon, 2005). As the initial step, we transcribed audio recordings into verbatim transcripts and interpretable content logs. Codes were derived from the data inductively. Each document was coded by at least two researchers following the social moderation process (Frederiksen et al., 1998; Herrenkohl & Cornelius, 2013) to address discrepancies in coding. Although social moderation is time-consuming compared to other evaluation approaches, such as intercoder reliability, we select this strategy to ensure that all possible themes are captured and recorded. We also created memos to document thoughts during data analysis and assigned pseudonyms to each participant.

Findings and discussion

Among the 48 participants, the most frequent example of physicality occurred when students recalled their college campus trips. For example, when asked about what she found valuable when participating in STEM Space, Toni said that she was impressed by her trip to the university with which STEM Space was affiliated.

> I highly enjoyed the trips. I love going to other places and seeing the college. […] I love seeing the museums; I love seeing the areas; all those experiences are very nice to me. I have never been to a big campus […] Finding those spaces I could go to, like "this will be my space; that will be my space," just understanding what I am comfortable with is very good. (Toni)

This view is echoed by several other students, including Karla, Alicia, Veronica, Shelia, Lydia, Tanya, and Melanie. Apart from youth, several parents and OST providers shared the same positive perspective of these college and field trips and summer camps. One illustrative parent example is Beth, a mother whose two daughters have both taken part in the STEM Space program for years. When asked whether she thought her children learned something about STEM, Beth appreciated that the Earth Camp included "a lot of hands-on experimentation" and the learning supplies sent by STEM Space: "I thought it was well planned because the kids are just sick of Zoom. […] The teacher had set it up was very much hands-on […] that really, really worked." In a similar vein, we saw appreciation for physicality from OST providers. Jessica, an experienced OST provider in charge of earth and environmental sciences outreach programs for high schoolers, recalled how she employed physical activities to encourage problem-solving and peer cooperation in her program.

> The first thing we do is go to the adventure center on campus; there are high ropes course and the climbing wall. We tell them [youth] to focus on cooperation and problem-solving, and we've never had interpersonal conflicts with our groups. At night, we often sit by a bonfire on the beach […] where we will have our counselors talk about their paths […]. (Jessica)
>
> I don't want them [youth] to memorize anything; I don't want them to pass a test. […] I want them to feel "I can take an intro course; I'll be empowered to feel a little bit better about it; I can travel to some of these spaces and feel comfortable." […] I want them to feel comfortable hanging out with the kids who feel comfortable in these spaces. (Jessica)

Here, Jessica raised an essential point where she brought the meaning of sense of belonging to the fore in an OST setting. According to her, the feeling and the sense gained through physical events with peers made these OST learning activities profound. Plus, Jessica interpreted her OST STEM program as a springboard to promote skills like problem-solving, teamwork, and reflection. Particularly, what Jessica portrayed that she hoped to bring to youth, i.e., confidence and community building, are well mirrored in her design of physical activities in the program. Based on the data, we contribute to a different lens to discuss bodily experience inseparable from how we interact with space, including sight, hearing, touch, and beyond, and what it means for human learning. Like how body language is considered vital to facilitate knowledge acquisition, we suggest that physicality can capture other dimensions of learning, making it valuable as an innovative information channel to unpack OST learning.

Conclusion

In this poster, we present physicality, which highlights place-based physical attributes, as a potential lens to gauge *how* youth participate in OST activities. We show that although physicality may be hard to quantify, it can be a useful naturalistic indicator of student learning and engagement over time. It helped youth envision and prepare for the future, supporting what parents and providers perceived OST STEM education. A deeper look at the literature is needed to solidify the theoretical underpinning of this line of conversation. We plan to continue data collection and analysis while iterating the qualitative coding to generalize relevant results to put into practice.

Abstract: This sequential mixed methods study applies Lewin's (1947) force field theory as a framework to explore the childhood experiences and current perceptions of pre-service elementary teachers from rural communities regarding social justice advocacy. Results of the quantitative portion of the study indicate that their elementary teachers supporting diverse students may be a supporting factor in multiple ways. The qualitative study is underway, but initial outcomes may provide insights for pre-service teacher programs.

Background and research purposes

Rural schools face unique challenges regarding social justice advocacy (Cuervo, 2016), as teachers struggle to transfer what they learned about social justice advocacy from their pre-service training to their classrooms (Ajayi, 2017). Rural elementary pre-service teachers are more likely to resist learning about and applying practices to support diverse students due to limited exposure to diversity and a lack of awareness about systemic oppression (Han et al., 2015). The intersection of culture, learning, and equity has been a focus of the learning sciences for decades (Nasir et al., 2006). While several learning scientists have focused on social justice training for teachers (e.g., Darling-Hammond, 2002), this focus has not shifted towards social justice advocacy development for elementary teachers in rural communities. Rural schools are becoming more racially diverse (Cuervo, 2020) and these demographic shifts and unique student needs require training for teachers to not only teach diverse groups but also to advocate for students from all backgrounds. Researchers have been calling for better pre-service education on social justice for years (Cochran-Smith et al., 2009). However, many teacher preparation programs offer limited exposure to the history, needs, and methods of social justice advocacy (Cuervo, 2016). This study explores supporting and inhibiting factors that affect SJA for elementary teachers in rural communities.

Given the challenges and opportunities around social justice advocacy unique to rural elementary pre-service teachers, we employed force field theory (Lewin, 1947) to frame and conceptualize our work. Force field theory rests on the idea of an equilibrium between the driving and constraining forces faced when working toward positive change. These forces can affect behaviors in individuals and groups regarding change. Based on this framework and the existing literature on rural pre-service social justice advocacy, we devised three research questions: 1) What are rural pre-service teachers' perceptions of the need for social justice advocacy in rural elementary schools? 2) What were rural pre-service teachers' experiences with social justice advocacy when they were students in rural elementary schools? 3) What are rural preservice teachers' perceptions of barriers and supports for social justice advocacy in rural elementary schools?

Summary of quantitative data, findings, and discussion

To address these questions, we developed a sequential, exploratory mixed-methodology design (Plano-Clark & Creswell, 2008). This approach allowed for an overview of the phenomena in a rural Appalachian state through a quantitative survey and a detailed understanding of cultural, contextual, and educational supports and barriers from qualitative interviews. The survey was based on existing instruments for social justice (Ajayi, 2017; Whitaker & Valtierra, 2018). Questions were adapted to address the research questions and suit the sample. To improve content validity, all questions were peer-reviewed by an expert in survey research. The timeline was sequential, with the quantitative survey first, informing the qualitative interview protocol. The qualitative interviews will provide insights into the distribution of a phenomenon within a chosen population (Denzin & Lincoln, 2007). The survey and interviews were implemented independently but with some interactivity, as the survey results informed the interview questions (Greene et al., 1989). The results of the quantitative and qualitative studies will be presented in a mixed manner, showing areas of convergence and elaboration.

There were 58 participants who completed the survey. Results of the demographic questions showed 83.1% of respondents were between 18 and 22, 15.3% were 23-27 years old, and 1.7% were in the 39 to 49-year range. Results for gender were 86.4% female, 11.9% male, and 1.7% non-binary. The racial breakdown of participants was 93.4% White, 3.3 % Asian, and 1.6% Black or African American.

To address our aims, we examined the analysis of covariance models based on two independent variables: 1) whether students' hometown is classified as rural and 2) whether students indicated an interest in teaching in a rural setting. We examined whether these factors explained variation in 1) pre-service teachers' experiences with prior teachers' supporting social justice advocacy, 2) pre-service teachers' perceived need for social justice advocacy training, and 3) pre-service teachers' perceptions of others' support for social justice advocacy in their hometown. Findings indicated that 1) students who indicated an interest in teaching in rural settings also reported higher levels of social justice advocacy on the part of their prior teachers, and 2) students from rural hometowns reported lower support from others for social justice advocacy. These findings suggest that prior teachers' support of social justice advocacy when the pre-service teachers were in elementary school may be a promoting factor for pre-service teachers' social justice advocacy, while past experiences with less support may serve as a barrier to advocacy.

ANCOVA models were based on two factors/IVs (and controlling for the other): 1) whether students' hometown is classified as rural and 2) whether students indicated interest in teaching in a rural setting. We prioritized three variables as outcomes: 1) prior teachers' support valuing (i.e., when I was growing up, elementary teachers in my hometown valued supporting diverse students…); 2) perceived need for social justice advocacy training (i.e., social justice advocacy training for teachers in my hometown is needed); and 3) perceptions of others' support for social justice advocacy (i.e., social justice advocacy in elementary classrooms in my hometown would be supported by…).

These findings suggest that prior teachers' support of social justice advocacy may be a promoting factor, while past experiences with less supportive elementary teachers may serve as an inhibiting factor to advocacy. Differences were not observed in perceived need for social justice advocacy training based on rural teaching interest or rural hometown, but the means were high across groups (i.e., students reported a high need for social justice advocacy training irrespective of their hometown or location of interest for teaching). As rural schools face high teacher attrition (Frahm & Cianca, 2021), this could be something for rural school leaders to consider in recruiting new teachers, retaining teachers, and facilitating community support for social justice. The qualitative portion of this study will give in-depth insights into the specific supporting and inhibiting factors for rural elementary teachers as they try to engage in social justice advocacy.

Thinking Artistically: Artistic Compositions of Interactions as a Lens for Understanding Learners Engagement

Areej Mawasi, Technion, areej.mawasi@ed.technion.ac.il
Shagun Singha, Arizona State University, ssing257@asu.edu

Abstract: This poster considers the usage of *artistic thinking* to analyze interactions in learning environments. Using a moment-to-moment video analysis, several interaction dynamics were noticed among learners and with materials in a community-based science learning setting. Through two cases of six artistic compositions created from video-analysis data, we argue that visual artistic thinking serves as an investigative tool to gather and relay range of social and historical meanings of learners' engagement with peers and materials.

Introduction

Interactions as a collective of actions and reactions between individuals or artifacts are communicated through various modalities (e.g., speech, gestures, gazes, movement) when represented. A growing body of work in the Learning Sciences has been building on multimodal analysis to understand learning processes and interactions in learning environments (Vogelstein et al., 2019; Vossoughi et al., 2020). Work in the field also attuned to the ethical implications for what video analysis can communicate about learners and learning (Vossoughi & Escudé, 2016). For instance, shifting from a technocentric video analysis towards centering learners' dignity and relations building (Vossoughi & Escudé, 2016) can create opportunities to examine interactions while engaging in perspectives taking, consider power dynamics of actors, pay attention to evolving relations, and examine the embodied interactions and movement in the space. That is, the medium of image becomes not only an examination of a sequence of events, but also, the structures of interactions they communicate. Building on prior work, we consider the ways thinking artistically invites us to examine how interactions are arranged, represented, and in motion (Saldana, 2014). The purpose of this approach is to examine a range of perspectives represented in data and expand the modalities through which actions and behaviors observed are represented (Saldana, 2014). This poster explores the possibilities for how thinking artistically through artistic compositions of illustrated interactions can expand our understanding of learners' interactions in learning environments.

Methods

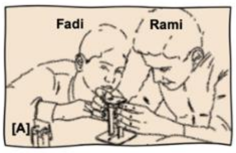
This poster is derived from a larger study conducted within a four-days transdisciplinary science program in a community-based organization of Al-Rowad for Science and Technology with Ten young Palestinian Arab learners (5th-6th grade) (Mawasi, 2021). Data used in this poster are from a moment-to-moment interaction video-analysis notes (~2 hours) (Jordan & Henderson, 1995). The analysis examined learners' human interactions and with materials. Specifically, the analysis focused on the third day of activities for learners' engagement in the space. This poster discusses examples of interaction analysis illustrations from videos screenshots and notes.

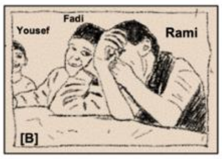
Findings

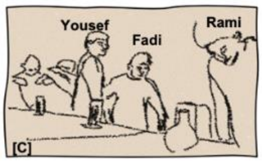
Case 1: Help and invitation for joint activity vs. noticing a different student dynamic in the background

The main participant this case focuses on is Rami (pseudonym). Across three activity contexts Rami took a different position (see Table 1): (A) Rami helped Fadi and demonstrated how to build a piece in the artifact. (B) Rami whispering to Fadi. Fadi keeping one eye towards Rami, one towards the teacher. No interaction with materials here. (C) Rami standing and invites Yousef and Fadi to look with him at the effect of light on his clothes. While in the background, two students have a different dynamic, and they are not part of the triad engagement.

Table 1
Interactions among peers and with materials across three activity task contexts





Case 2: Enacting power over artifacts

The teacher assistant gave Faris and Karam the light so they test it together (1st second). Faris took it to himself and began to test it (3rd second)). Karam attempted to take it, yet, Faris kept pushing it away. Even when Karam succeeded to hold the light, still, Faris kept holding the light towards himself (5th second).

Table 2

Evolving dynamics of gazes and gestures across time of interactions with artifact (light) and between actors

 Second 1	 Second 3	 Second 5

Discussion

In conclusion, artistic compositions refer to the use of creative expressions (used in visual and performative arts) to explore interactions between individuals and their environment. Such compositions offer insights into the ways in which humans interact with their surroundings and how these interactions evolve over time. By engaging with artistic compositions, researchers can attune to the fluid roles, actions, and positions of actors in learning environments thus remaining receptive to emotional experiences and diverse interpretations of learning. Artistic approaches can also be viewed as investigations into the arts themselves, aimed at comprehending the intricate layers of meaning embedded within an art form that is relevant to the learning process. Artistic approaches build on existing multimodal methods by providing additional lenses through which to examine learners' interactions with one another and artifacts. This is significant because traditional fieldwork approaches view the learning process through a single lens, which limits our understanding of the complexities of the learning experience (Leavy, 2020). The two cases illustrate the usefulness of artistic compositions in examining fluid roles and power dynamics in learner interactions with one another and with artifacts. This poster emphasizes the importance of using artistic approaches by employing visual compositions as artistic forms to gain insight into the intricate dynamics of these interactions and recognize the subtle power dynamics that are embodied within them at a micro-scale. This highlights the value of incorporating diverse methodological tools to enrich our understanding of complex phenomena in the field of education.

Computational Thinking and Robotics in Mixed Environments

Tanya Chichekian, Université de Sherbrooke, tanya.chichekian@usherbrooke.ca
Joel Trudeau, Dawson College, jtrudeau@dawsoncollege.qc.ca
Tawfiq Jawhar, Champlain College, tawjaw@gmail.com
Yi-Mei Zhang, McGill University, yi-mei.zhang@mail.mcgill.ca

Abstract: This study examined how educational robotics fostered college students' computational thinking skills in virtual and physical learning environments. Students from a traditional (*N* = 33) and an active-learning (*N* = 35) classroom completed surveys, problem-solving tasks, and robotics navigation challenges in virtual and physical learning environments. After one semester, students' computational thinking skills increased, but varied based on gender and performance in the problem-solving tasks. Students in the traditional classroom benefited from the virtual learning environment.

Theoretical framework

Recently different models for computational thinking (CT) have been proposed (Weintrop et al., 2016), each emphasizing concepts, practices, and perspectives to varying degrees. From an educational perspective, a CT model should include concepts that go beyond knowing a programming language and emphasize the pedagogical aspect of teaching CT (Hsu et al., 2018) with classroom activities designed for problem-solving and solutions that are reusable in different contexts (Shute et al. (2017). One way of fostering the development of CT is through educational robotics (Chevalier et al., 2020). Whereas earlier studies on educational robots (Touretzky, 2013) have focused on teaching programming, others have taught a broader set of computer science concepts and skills such as "computational thinking" requiring students to practice their abilities in abstraction, algorithm design, debugging, and generalization (Bers et al., 2014). This study is framed under the theory of constructionism (Papert & Harel, 1991), whereby knowledge is actively constructed through collaborative learning and interaction with the environment. In this approach, learners typically work on authentic problems in small groups which are beneficial at increasing students' understanding of complex systems and promoting interest, engagement, and motivation (Jacobson & Wilensky, 2006). The integration of robotics activities aimed at introducing CT concepts before learning about programming are still scarce. The current study investigates how a series of robotics activities fostered college students' CT in virtual and physical learning environments.

Research method and design

A series of robotics learning activities with Arduino microcontrollers were implemented to a physics curriculum with the goal of expanding students' CT by prompting them to think simultaneously about the completion of a robot navigation challenge in mixed learning environments: (1) as part of a simulation in a virtual platform and (2) in a physical environment (i.e., physics labs). The following research questions guided this study: (1) How do robotics learning activities foster students' CT attitudes? (2) How does instructional approach influence students' applicability of CT in virtual and physical learning environments? Based on prior research demonstrating learning gains after interacting with digital applications (Dalgarno & Lee, 2010) and simulation environments (Chichekian et al., 2022), it was expected that students who participated in the robotic activities would display increases in their CT over time. It was also hypothesized that the virtual simulation platform would be more useful for students exposed to a traditional teaching approach given limited exchanges and feedback from peers and the teacher.

Sample and context

College students (*n* = 68) between 17 and 19 years old were recruited from two Engineering Physics courses. Students were randomly assigned to two classes: 1) a teacher using an active-learning instructional approach (*n* = 35, 12F, 23M) and 2) a teacher using a traditional instructional approach (*n* = 33, 11F, 19M, 3 missing). Two-third of students (*n* = 44) had no prior coding experience and the remaining (*n* = 20) reported some knowledge of Arduino, HTML, Python, video game programming, hackathons, code academy, but no formal training.

Robotics labs

The robotic labs introduced students to Arduino programming and a final autonomous navigation challenge: Using sensor feedback, program a robot that can navigate a complex path in the shortest possible time. Students learned about hardware basics, how to test the Arduino IDE with the UNO board, and how to wire up a simple "move the robot task". They learned how to apply programming basics to learn how the hardware can be used and designed an algorithm that would use the data from the ultrasonic sensor as feedback to control the robot. The virtual challenge consisted of programming a robot to navigate a path in an optimal time, whereas the physical challenge aimed at optimizing and generalizing a solution for a hardware challenge that accounted for new changes.

Data sources

A survey composed of three subsscales measuring CT attitudes was derived from Part 1 of the *Callysto Computational Thinking test* (Cutumisu et al., 2019) and administered at the beginning (T1), during mid-term (T2), and at the end of the term (T3). This nine-item scale ($\alpha = 0.81$ at T1, $\alpha = 0.89$ at T2, and $\alpha = 0.81$ at T3) assessed students' ease using digital technology (3 items, e.g., "I find it easy to use new technology"), their problem-solving processes (3 items, e.g., "When I am solving a complex problem, I try to break it up into smaller or simpler problems"), and their attitudes toward coding (3 items, e.g., "I am comfortable writing code to solve problems.") Scales ranged from 1 (strongly disagree) to 7 (strongly agree). Assessments on the virtual and the physical robotic challenges were scored on a total of 10 based on the robot's success in navigating the challenges.

Data analysis

A one-way repeated measures was conducted to assess how the robotics activities fostered students' CT attitudes. Paired sample t-tests within male and female students were also conducted to assess the changes in CT attitudes over time. A moderation analysis assessed how the instructional approach moderated the relationship between students' performance on the robotics challenge in the virtual and physical learning environments.

Results

There was a significant increase in students' CT attitudes over time, $F(2, 65) = 15.60$, $p < 0.001$, specifically between T1 ($M = 4.97$, $SD = 0.91$) and T2 ($M = 5.31$, $SD = 0.92$), $t(66) = 3.46$, $p < .001$ and between T2 ($M = 5.31$, $SD = 0.92$) and T3 ($M = 5.59$, $SD = .0.68$), $t(66) = 2.69$, $p = .009$. Males and females experienced significant increases from T1 to T2, $t(41) = 2.23$, $p = .032$ and $t(22) = 2.53$, $p = .019$, respectively; females also experienced significant increases from T2 to T3, $t(22) = 2.23$, $p = .033$. Compared to their peers, students in the active-learning context scored significantly higher on the physical challenge ($M = 8.41$, $SD = 1.17$ vs. $M = 7.30$, $SD = 1.44$, $t(65) = 3.47$, $p = 0.001$), but significantly lower on the virtual challenge ($M = 9.65$, $SD = 0.87$ vs. $M = 10.06$, $SD = 0.17$, $t(65) = -2.73$, $p = 0.010$). Generally, as students scored higher on the virtual challenge, their grades on the physical challenge increased significantly, $b = -5.71$, $t(63) = -5.02$, $p < 0.001$. The virtual simulation benefited students in the traditional context who experienced a more significant increase in their scores on the physical challenge, $b = 7.26$, $t(63) = 6.79$, $p < 0.001$ compared to their counterparts, $b = 0.78$, $t(63) = 4.02$, $p < 0.001$.

Discussion and conclusion

Overall, the robotics activities had a significant positive effect on male and female students' CT over time, especially for females who reported a significant increase from mid to end of term which was not the case for males. The virtual simulation environment provided leverage for students to receive constructive feedback on their algorithms, test, debug, and rerun their code, and, ultimately, generalize, and apply their solutions to the physical navigation challenge. This learning experience was an optimal scenario for students in the traditional classroom as receiving real-time feedback from the simulation and incremental support when learning how to translate an algorithm into a programming language somewhat compensated for the minimal opportunities to collaborate outside of class. The individualized contribution to student learning from virtual and physical learning environments is indicative that contextualized learning activities should be designed separately and independently because although they are interrelated, they are operationalized and conceptualized as distinct.

Exploring the Effectiveness of a Spherical Video-Based VR Intervention for Test Anxiety in an English as a Foreign Language Setting

Volker Eisenlauer, Vanessa Spilles, Maximilian C. Fink, Bernhard Ertl
volker.eisenlauer@unibw.de
Universtität der Bundeswehr München, Germany

Abstract: Immersive virtual reality (VR) experiences enable learners to become familiar with test situations and thus become more resilient to emotional stress relating to test taking. This qualitative study aims at understanding the educational emotions triggered via and within a spherical video-based VR intervention for test anxiety in an English as a Foreign Language (EFL) setting.

Introduction

This poster is directed to gain an understanding of educational emotions triggered via and within a spherical video-based VR intervention for test anxiety in an English as a Foreign Language (EFL) setting. More specifically, it aims at (1) specifying the emergence and nature of emotions experienced when undergoing the intervention, (2) comparing screen-based and head-mounted-display (HMD)-based VR experiences in terms of perceived immersion, and (3) assessing the perceived effectiveness of spherical videos for getting acquainted with test situations and managing negative emotions when takings tests.

Taking key issues relating to test anxiety and educational emotions and VR into account (in particular (Pekrun 2006, Scherer et al. 2001 and Sherman & Craig 2019), we developed the *VR Test Anxiety English* prototype training world with the help of a 360-degree video camera and corresponding film editing software. In close collaboration with the language center staff, the typical phases of the oral English language performance test (LPT) were identified and structured into consecutive film shots. Using a 360-degree camera enabled us to capture typical stimuli of a real exam situation shaped by existing physical examination environments, fellow test takers, and examiners. Users may experience the different phases of the exam in a sensory and concrete way either by turning their heads when wearing the HMD or by clicking and dragging the material when accessing it on a desktop PC or tablet. A brief version of the learning environment can be accessed at https://youtu.be/rjjYdtNyl8w (Eisenlauer & Sosa 2022).

Research design

The sample comprised 10 students of University of the Bundeswehr Munich, Germany. All participants had prior experience of taking oral English exams at the university's language center. The participants were divided into two groups. One group first explored the test situation on a desktop PC and then accessed the material via an HMD; the other group first used an HMD and then a desktop PC. Following the intervention, participants underwent a guideline-based, problem-centered interview including 29 open-ended questions divided into four thematic clusters. After transcribing the interviews, the data were organized using MAXQDA. The interpretation and analysis of the data was based on Mayring's (2015) qualitative content analysis.

Data analysis and discussion

Concerning educational emotions before exams in general, only two of the 10 participants reported experiencing high levels of emotional tension. However, those who indicated low or average levels of test anxiety in general reported feeling comparatively more tension in exam situations with a high perceived subjective value (Pekrun, 2006). Concerning the subjective perception of the oral English LPT examination, eight participants indicated that they considered the exam to be controllable as they were introduced to the examination procedure as well as possible examination topics. The two participants with high test anxiety associated the oral English LPT examination with feelings of insecurity triggered by uncertainty over the examiner's questions as well as by linguistic barriers. It is also noteworthy that these two participants reported that tensions would have a negative effect on their motivation. They described negative emotions resulting in the attitude that one can never be prepared enough to pass the exam. Most participants (8 out of 10) reported that prior introduction to the examination form and procedure would have positive effects on the test results. In accordance with previous findings (Pekrun & Götz, 2006), the data confirm that test preparation establishes the backbone of the perception of a situation's controllability and thus can relieve tension.

Regarding the extent to which participants immersed themselves in the spherical media VR intervention, the analysis indicates a significant difference between the different media interfaces. All participants rated the

HMD-based VR experience as realistic, whereas only two participants described the desktop PC-based environment as realistic. The high authenticity via HMD was linked to head movements corresponding to the viewing directions and the authentic presentation of an examination setting and other test takers. Regarding the intervention on a desktop PC, the contents were experienced “as a video” [#Test Person 6] and external stimuli diverted attention from the simulation to the physical environment. The majority of participants reported that they could immerse themselves in the VR training world via HMD. One participant stated, “you really felt put back in this test situation so that you already started to think about possible answers to what [the teacher] asked here, because you were already a bit more in it than in the video” [#Test Person 9].

Considering educational emotions, six participants described experiencing test anxiety-specific feelings when watching the test simulation via the HMD. The experienced emotions were not perceived to be as intense as in a real exam situation, but participants still noticed signs of a faster heartbeat or sweaty palms. Equivalent feelings were not described regarding the intervention via a desktop PC. According to three participants, negative emotions in the HMD setting were especially caused by negative feedback on the performance given at the very end of the simulation by one of the examiners: “when the negative result was presented, it was somehow as if I had not passed” [#Test Person 1]. The different reactions to the negative feedback are in line with previous findings that emotions are caused by a person’s current interpretation of a situation (Scherer et al., 2001).

Concerning the effectiveness of the VR intervention, six participants stated that the controllability of an exam situation can be increased with the help of a simulated VR environment. Watching the test simulation helped the participants familiarize themselves with the exam procedure and thus made the exam situation feel more relaxing: “Habit makes serenity, so if I practice something often, I become more relaxed in it. It doesn’t matter what kind of training it is; the more often you do it, the more the skills come, the more habit comes, and from that comes serenity” [#Test Person 9]. The participants evaluated the intervention as an effective training tool for getting acquainted with the test situation. To inhibit the emergence of test anxiety, they saw the need to provide more possibilities for interaction; for example, “what I was missing for a real exam preparation would be this interactivity, for example, in the selection of topics, that you actually have two realistic topics in the situation and you can choose with the help of VR glasses” [#Test Person 10].

Summary and conclusion

In line with previous research (Alsina-Jurnet et al. 2007), the study provides evidence that the VR intervention had a stronger emotional appeal to students with high test anxiety than to those with low test anxiety. The test simulation served as an effective tool for enhancing the controllability of the situation but was only partially effective for reducing or preventing test anxiety. Though anxiety-related emotions could be triggered via and within the VR intervention, the feelings were perceived not to be as strong as they would be during a real test situation. Among other reasons, an explanation for this may be the limited interactivity. That is, the spherical media-based VR intervention afforded the immediate experience of an existing physical examination setting and examiners, but there were no options for user-driven activities, such as responding to questions or giving an oral presentation. The processing and interactive visualization of spherical media with help of a game engine or authoring tool establishes an efficient way for enhancing the immersion in VR environments to address and research test anxiety in future studies.

Student Help-Seeking Through Utilization of Professor Office Hours

Megan Botello, Teomara Rutherford
mbotello@udel.edu, teomara@udel.edu
University of Delaware

Abstract: Help-seeking is an important self-regulation skill required for students' academic success, but students struggle asking for help when they need it. In this exploratory study, researchers interviewed professors, surveyed students, conducted observations, and analyzed course material to investigate (a) messages professors send through the structure of their course and how these associate with students' values for office hours and help-seeking behaviors, and (b) how students report knowing when to ask for help, where they turn for it, and their motivation to seek it. Findings showed that students view office hours as a last resort. Professors who promoted resources (e.g., office hours) had higher office hours than their colleagues.

Purpose

Self-regulation skills, such as help-seeking, are important for effective learning, but many students have poor help-seeking behaviors, such as knowing they need help or how to ask for help when they need it; this is especially true among college students in mathematics (Ryan & Pintrich, 1997). Although many resources are available to these students, few students utilize these resources (Gueudet & Pepin, 2018). One resource that is particularly underutilized is office hours. This may be because of students' lack of value for help-seeking and office hours as a resource (Briody et al., 2019). This is an area that is under-researched and motivates this exploratory study, which investigated the following research questions:

1. What messages do mathematics professors send through the structure of their courses and how do these messages associate with students' values for office hours and help-seeking behaviors?
2. How do undergraduate mathematics students report knowing when to ask for help, where to turn for it, and their motivation to seek it?

Perspectives

Self-regulated learning (SRL) is a major predictor of academic success (e.g., Davis & Hadwin, 2021). To successfully regulate their learning, students need to know when they need to seek help. However, students in college often struggle when deciding what to do when they need help, and reaching out to professors can be daunting (Newman, 2002). Students' values of learning affect behavior towards learning (Eccles & Wigfield, 2002). If professors could help their students increase their value perceptions for help-seeking, this may lead to an increased interest in learning the content resulting in greater student success in academic endeavors. Prior research has illuminated some ways to facilitate help seeking: professors can provide support for autonomy, provide opportunities to practice SRL through course content, and can buffer the fears of students asking for help by being responsive to student needs (Newman, 2002). One study (Briody et al., 2019) found that although students desired interaction with and had positive experiences with their professors, they were hesitant to contact faculty. Many of these students described their professors as "busy" or "important" and described their own needs as "silly" and "dumb." The researchers explain the need for a shift of power in the faculty-student relationship and identify ways that faculty can increase faculty-student interaction by making opportunities available to students to practice communication in the classroom and relationship building.

Method

Introductory math professors at a mid-Atlantic public university and their students were invited to participate in this IRB-approved study via email. Four professors (professors A-D) and 17 students participated. Two of the professors were men; none disclosed their race. Of the students, 71% were female, 53% were White, 6% Asian, 6% African American, and 6% Indian; 29% did not disclose their race. Students were distributed between classes. Faculty participated in a 20-minute interview; students participated in a survey. Questions captured professor and student perspectives of students' willingness to ask for help, utilization of office hours, and communication between faculty and students. The syllabi and canvas pages for each professor's course were reviewed for office hour information and other resources and to see how professors communicated to their students. One observation per class was conducted to note how students and professors interacted. Observations described student engagement, interactions with the professor and their peers, and the professor's promotion of resources. All data was coded qualitatively. The presence and frequency of codes were compared across professors.

Results

RQ 1: What messages are mathematics professors sending through the structure of their courses, and how do these messages associate with students' values for office hours and help-seeking behaviors?

Professor A promoted office hours to his students weekly. He encouraged students to contact him through email and ranked office hours as the number one resource for students to seek help before use of other resources. He offered office hours twice a week both online and in-person. He promoted peer interaction through the physical structure of his classroom (round tables and tutoring promotion via posters). This professor had the highest office hour attendance (nine students per month). On the other hand, professor D viewed office hours as unhelpful and as a last resort. She did not promote office hours and only offered them online, once a week. She also did not promote peer interaction like the other professors did (no group work and individual desks). She had "generally no one" show up at her office hours. The stark difference between professor A's and D's perceptions, actions, and office hour attendance implies that the potential messages that these professors send through their course structure and promotion of office hours conveys the value of office hours and help-seeking to their students.

RQ 2: How do undergraduate mathematics students report knowing when to ask for help, where to turn for it, and their motivation to seek it?

Each student completed a questionnaire to describe their perceptions of office hours and other resources. Students explained what evidence they use to determine whether they were struggling in math class. Students responded that they use exam scores, assignment grades, or class grade to make this determination. Students were asked what they preferred to do if they needed help on their math homework. Their responses were: figuring it out themselves (29.4%), using an online source (35.3%), using a tutoring service (11.8%), asking a friend/classmate (17.6%), or asking a professor (5.9%). One student said, "I think I will review the class video page and if I am still stuck I'll just struggle on my own." Overall, most students preferred figuring out their work themselves or turning to an online source if they needed help rather than asking a professor. When asked under what circumstances they would find themselves attending office hours, most students stated if they were concerned about their grade, or if they were very confused on a concept. One student reported that office hours would be their last resort, stating they would go "if no one else I knew could help me and the question was impossible to figure out." Lastly, students were asked what has kept them from attending their professor's office hours. Responses ranged from not needing to attend due to good grades, the preference to go to tutoring instead, the lack of time or conflicting schedule, anxiety, not feeling their questions were important enough, or simply forgetting.

Significance

A few implications can be inferred from the results. For example, the student surveys provided insight on why or why not students attend office hours, such as the impact their grades have on their decisions to seek help. This study also provides information on how students feel about the value of resources provided to them. Students prefer seeking help from their peers, which is a finding that aligns with previous work (e.g., Newman, 2002). This means one way to promote help-seeking in the classroom includes facilitating peer engagement to create a positive learning climate where students are encouraged to seek help from each other. Furthermore, practices of Professor A could be beneficial to consider as he had much higher office hour attendance than his colleagues. Previous research suggests professors can promote competence through meaningful activities where students can practice the skills of self-monitoring as well as questioning peers and asking for feedback from them (Newman, 2002). These practices will encourage help-seeking behaviors and normalize them as part of the learning process.

Complexities and Contradictions in a Teacher's Activation of Epistemological Resources and Their Consequences for Student Framing

Sherry A. Southerland, Jennifer Schellinger, Lama Jaber, Sierra Morandi
ssoutherland@fsu.edu, jls09h@fsu.edu, ljaber@fsu.edu, smorandi@fsu.edu
School of Teacher Education, Florida State University

Abstract: This research employs the lenses of epistemological resources and framing to examine the complexities of one teacher's efforts to position his middle-school biology students as sensemakers. Through interviews, classroom observations, and document analysis, we trace the teacher's activation of varied epistemological resources and how such resources positioned students' efforts throughout the lesson. While the launch of tasks was framed as an opportunity for "doing science," this framing became less stable when the teacher engaged with students in small group work and during the wrap up that were focused on the "right answer." Specific phases of the lesson served as a context that influenced the epistemological resources activated, helping us understand the varied, dynamic, and sometimes contradictory nature of the teacher's moves and their consequences on students' framing of their efforts.

Introduction

Science education reform efforts envision classrooms as sensemaking spaces where students explore natural phenomena to refine their understanding of scientific ideas and practices (NRC, 2012). Engaging students in science learning through sensemaking is "notoriously challenging" as teachers must "navigate an unpredictable terrain of student ideas" (Watkins & Manz, 2022, p. 1). With these considerations in mind, this research examines the complexities of one teacher's efforts to position his middle-school students as sensemakers in science.

Methods

Data for this case study were drawn from a year-long professional development (PD) project designed to foster teachers' abilities to support student sensemaking about science through talk. We focus on one middle school biology teacher, Jerry, and his middle school students' framing of his instructional practice. We focus on Jerry and his class because we observed that while he provided space for students' sensemaking and employed the tools introduced in the PD, his teacher-led wrap ups discussions centered on providing canonical knowledge. We wondered about the factors influencing his varied instructional moves and their consequences.

Data sources included classroom video observations of three lessons (*Cell Structure, Cell Reproduction, and Mechanism of Evolution*), classroom artifacts, teacher surveys, and a series of open-ended and structured stimulated recall teacher and student interviews. To begin our analysis, we examined the kinds of student thinking required by the task, using the categories described by Tekkumru-Kisa and colleagues (2022). Classroom videos from three, multi-day lessons were segmented to broadly characterize the different lesson phases (launch, small group work, round robin, wrap up discussion, and write up). Within each segment, we analyzed Jerry's instructional moves for evidence of epistemological resources underlying his instructional decisions. Drawing from Elby and Hammer (2010), we recognized two epistemological resources at play in Jerry's instructional moves: k*nowledge as propagated stuff* and *knowledge as constructed*. Drawing from Berland and colleagues (2016), we examined classroom videos and interviews for evidence of students' framing as "doing school" or "doing science," noting instances of interruptions of, or shifts in, how students framed their efforts during a lesson segment.

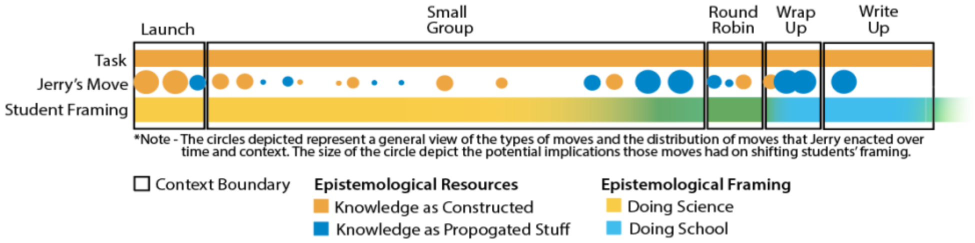
Results

Analysis of the three lessons revealed consistent patterns in Jerry's instructional moves, patterns which speak to the activation of different resources around knowledge and learning in different contexts. We came to understand that different phases of the lesson represented distinct contexts for Jerry, and influenced his activation of resources around knowledge, knowing, and learning, including those related to *knowledge as propagated stuff* and to *knowledge as constructed* (Elby & Hammer, 2010). Figure 1 depicts how the activation of these resources varied across phases of the lessons. Student interviews suggest that despite the varied framings across the lesson phases, some of the students recognized that their classroom experiences were distinct from those scientists engage in, and even given these complex dynamics, understood that scientists construct knowledge through such negotiations.

Our analysis sheds light on the dynamic nature of epistemology and framing in one teacher's efforts to engage his students as sensemakers in science. This analysis across three lessons identified variabilities in Jerry's moves across lesson phases. The launch of the task and much of Jerry's moves in small group work activated the resource of "knowledge as constructed", and many of his moves were consequential for students' framing of their efforts as "doing science" as they engaged in sensemaking about a phenomenon. The launches are particularly interesting as they highlight the role of the tasks in supporting Jerry's attempts to position his students as sensemakers. Their role in the launch and small group work was consequential for cuing "knowledge as constructed" as the prominent epistemological resource that Jerry tapped into. However, toward the end of the small group discussions, we begin to see that Jerry made very different sorts of moves that aligned with a view of "knowledge as propagated stuff". In the latter phases of the lesson, these moves were consequential for how students took up the framing of "doing school".

Figure 1

Graphic Representation of the Interplay Between the Epistemological Resources Underlying Jerry's Moves and the Task, and Students' Framing of their Efforts across the Lesson Phases, Generalized from Three Lessons.



*Note - The circles depicted represent a general view of the types of moves and the distribution of moves that Jerry enacted over time and context. The size of the circle depict the potential implications those moves had on shifting students' framing.

Conclusions

Our findings highlight the fine-grained epistemological elements that the teacher activated in different contexts and phases of the lessons examined and their consequences for students' framing of their efforts. This resource activation explanation for one teacher's moves helps account for the frequently documented shifts that occur when teachers navigate the unpredictable challenge of new practice. While this research examines the epistemological resources employed by just one teacher, this close speaks to the need to support teachers to explicitly make connections between resources, moves, and student framing. These findings are tentative and require further investigation. If the utility of the resource framework holds up, it suggests that PD should be structured to help teachers examine the consequences of their enactment of specific teacher moves throughout stages of a lesson to help them learn to activate more productive resources to engage students in sensemaking.

Technology-Mediated Lesson Study: Facilitating Three-Dimensional Science With Rural Science Teachers

Michelle Hudson, Rebecca Sansom, Heather Leary, Josh Stowers, Tracy Poulsen, Clara Smith
michelle_hudson@byu.edu, rsansom@chem.byu.edu, heather.leary@byu.edu, josh_stowers@byu.edu,

Abstract: Rural science teachers have fewer collaborative and professional learning opportunities. To bridge the geographic isolation of these teachers, a professional learning model called Technology-Mediated Lesson Study (TMLS) has been developed. TMLS engages teachers with a team of colleagues in iterative, collaborative cycles of lesson design, teaching, observations via technology, and lesson redesign aimed at high-impact professional learning and enactment. This poster presents qualitative findings from the first year of the program.

Introduction

Science education in the United States is transforming toward a model that comprises three dimensions (3Ds): science and engineering practices, crosscutting concepts, and disciplinary core ideas (SEPs, CCCs, and DCIs; NGSS Lead States, 2013). Central to the new standards is the principle that students must make sense of science in a way that combines the three dimensions for richer, more authentic learning experiences. In one western state, urban school districts have implemented these standards for several years, including training teachers in 3D science teaching; however, most rural teachers in the state have received very little training on the new standards.

Isolation is a significant problem for many rural teachers in that they are often the only teacher of a particular subject or the only science teacher in a school. As a result, they have fewer or no opportunities for meaningful collaboration, even though collaboration is a crucial characteristic of effective professional learning (Svendsen, 2020). When professional learning is up-to-date, ongoing, collaborative, practice-based, and connected to local contexts, it is more effective at changing teaching practices (Desimone, 2009; Kennedy, 2016). Lesson study is an established professional learning model that has shown success in meeting teachers' professional learning needs by improving collaboration, helping teachers examine their practice, and enhancing student learning (Kanellopoulou & Darra, 2019). Traditionally, lesson study is conducted in small groups that meet in person to create lessons, review each other's teaching, and revise lessons together; however, the very fact of rural teachers' isolation makes such in-person collaboration impossible.

Technology-Mediated Lesson Study (TMLS) was developed to utilize technology to connect otherwise remote teachers in a novel professional learning model that engages teachers in iterative, collaborative cycles of lesson design, teaching, observation, and lesson redesign with a team of colleagues, resulting in high-impact professional learning and enactment. Through this process, teachers meet and collaborate through technology-mediated methods; they work together to improve their 3D science teaching skills and develop high-quality 3D science lessons aligned with state standards. These lessons are now ready to be shared with other teachers in the state and across the country.

Primary goals and conceptual framework of TMLS

This research has three goals: first, *principles*: an innovative model for rural teacher professional development via technology-mediated lesson study that supports translating professional learning into classroom practice through social support systems; second, *people*: building expertise, capacity, and collaboration among teachers to support 3D science teaching; and, third, *products*: creating and disseminating high-quality 3D science lesson plans aligned with state standards and the Next-Generation Science Standards to be shared with teachers across the country.

The research design is built on an ecological model described by Sallis et al. (2008) and is applied to changing teaching practices to incorporate three-dimensional science teaching. The program targets, first, personal factors (e.g., attitudes, self-efficacy) by supporting rural science teachers' development of knowledge, self-efficacy, and positive attitudes about 3D science teaching; second, social factors (e.g., peer, administrator, and student expectations) via cohorts of subject-region teams to provide a sense of community and support for the instructional changes needed for the new state standards; and, finally, contextual factors (e.g., physical, material, and time resources) to support and evaluated these lessons in a variety of settings and teaching conditions.

Research method

Twelve rural science teachers were given in-person professional developmental instruction in the principles of 3D science and the lesson study process. Groups of four teachers were formed and each developed high school biology lessons aligned with state standards incorporating 3D science elements. One teacher in each group recorded themselves teaching the lesson to their students by using a Swivl robot. Other group members reviewed and commented on each lesson and then met virtually via video conferencing to discuss the lesson they watched and revise the lesson plan. This process was then repeated for each subsequent teacher, taking turns teaching the revised lesson and coming together as a group to review and revise the lesson. Qualitative discourse analysis was conducted on TMLS meeting observations and personal interviews.

Results

Qualitative analysis of personal interviews and observation of lesson review meetings indicates that new collaborations resulting from involvement in the TMLS process positively affect making new professional collaborations and connections. This improved collaboration was also seen by observing group meetings to review lesson plans. Group conversations showed a willingness and openness to work together and enthusiasm that they are “able to focus just on the content of the lesson rather than on other school issues” (e.g., discipline problems). Through interviews, teachers indicated that the TMLS process changed their thinking regarding 3D science. One participant said, “Anytime you can build a lesson plan and then implement that lesson plan, I think that's going to encourage growth. Watching all of the other teachers on Swivl and…going through that process helped a lot in just in my own instruction.” These results show that creating, discussing, and revising a lesson plan that uses 3D science principles with a group of other science teachers can help improve how each teacher views their ability to teach with these principles in their classes, and those involved in the TMLS process are incorporating 3D science principles in their teaching beyond the lessons they created as a group.

Conclusion

Technology-mediated lesson study assists rural science teachers in developing new connections with other teachers they otherwise would not have any contact with, and preliminary data from interviews and observations of group discussions indicate that the teachers value these connections as well as the TMLS process. These otherwise isolated teachers are finding new collaborations with colleagues from around the state. Some participants indicated wanting to incorporate the TMLS process with others in their schools, suggesting they see the value of co-creating lessons. Data also suggests that the TMLS process—including watching others teach—is helping teachers learn 3D science better and improve how it is incorporated into their classes. Participants specified that this process has allowed them to thoroughly think about all aspects of 3D science for the first time and helped them improve incorporating these principles when developing new lessons. Future studies will further explore how the TMLS process helps connect rural science teachers on an ongoing basis and how teachers can integrate 3D principles to change how they teach science.

Exploring 6th to 8th Graders' Math Play Processes and Strategies

Chih-Pu Dai, Fengfeng Ke, Yanjun Pan
cd18m@fsu.edu, fke@fsu.edu, yanjunpan@gmail.com
Florida State University

Abstract: Students' math problem-solving processes and strategies during math gameplay are poorly understood given its complexity. This ethnographic study examined gameplay sessions with 150 students over nine months in three design-based implementations. Findings revealed three preliminary patterns: 1) students' explanatory math play developed overtime; 2) students' cognizance to make sense of math in real-world context; and 3) students managing struggles to be productive.

Introduction and background

Math problem solving is complicated. Prior research has demonstrated that digital game-based learning (DGBL) environments can be effective platforms for doing math (Tokac et al., 2019). In DGBL, when working on in-game tasks, learners are naturally engaged in exploratory- and discovery-oriented problem solving. Game mechanics, game rules, and game tasks can facilitate learners to generate, test, and experiment hypotheses during the math problem solving processes (Ke et al., 2019). These processes are complicated and can be arduous and frustrating. *Math play* is a core to learners' engagement in game-based math problem solving; in which learners immersing in iterative rounds of math hypothesis testing and exploration, encompassed by failure or struggle (Williams-Pierce & Thevenow-Harrison, 2021). During *math play*, learners gradually develop problem-solving skills and epistemological sense toward math—by reorganizing and building up experience and by integrating new information into knowing (Kolodner, 1983). Notably, productive struggle is an important component in *math play*. Warshauer (2015) illustrated four types of struggles in middle school math classrooms: 1) get started, 2) carry out a process, 3) uncertainty in explaining and sense-making, 4) express misconception and errors.

Although research in the learning sciences has shed light on the processes of student learning in math (Warshauer, 2015), the processes and strategies that students use while playing math learning games are still vague. This murky area can hinder our understanding and theory development that fully benefit learners when they are engaging in DGBL. The purpose of this study is thus to identify the processes and strategies that middle school students' use during game-based math problem solving. Our focal research question is *what is math play and its associated strategies as perceived and enacted by middle school students in an architectural math game?*

Method

We used an ethnographic method to examine the phenomenon embedded in 6th through 8th graders' math gameplay sessions. The students played *E-Rebuild*, a math DGBL designed based on common core state standards for middle school students, and the math concepts in the game were chosen accordingly (Ke et al., 2019). The study is ongoing, we collected data from two schools with seven teachers and their 150 students through nine months long-term ethnographic participation in three design-based implementations. This study used data collected with participatory observations, interviewing, in-field notes, game artifacts, and computer logged gameplay-learning analytics. Multiple data sources ensured trustworthiness through triangulation. Open coding and constant comparative techniques (Glaser & Strauss, 1967) were iteratively conducted to construct meaning of the processes and strategies used by the middle school students during game-based math problem solving.

Results

Students' explanatory math play developed overtime

In the math gameplay-learning trajectories, students often revisit levels that they have successfully completed. Sometimes, students also tried to help other students when other students are dealing with the game math tasks that they have completed before. This iterative process has led to reorganizing and rediscovering for math conceptual development and shaping in students' memory. Students were unsure about the underlying concept related to their solution. But as they iteratively experimented with the same type of problems by trying different acts or solutions, they started to develop conscious perspectives and were able to explicate with math thinking.

For example, in one class, Ryan (pseudonym, 6th grade) was trying to solve a math task focusing on geometry and angle (folding a square-shaped paper to a target 3D shape). He approached the task without math understanding: "*Is that (angle) 45°? Cause it's half of 90...or 40?*" After three failed attempts, he used an in-game learning support and figured out the solution, but he was still pondering about the accuracy of the solution: "*I don't think it will work*." He tried the solution anyway, completed the level, and even earned all the badges. Facilitator ("F" hereinafter): "*Do you know why it is 90°?* Ryan: "*I don't know (smiling).*" After two weeks (five gameplay sessions), he helped a peer with the same level, he put "180°." This time, he failed to help his peer to solve the level. After another three gameplay sessions, Facilitator asked: "*have you learned anything?*" Ryan voluntarily mentioned this level, and was able to explain the embedded math concept by transitioning between gestures and the game interface: "*I learned the angles. It's 90° (using his hand to gesture the folding of a 90° angle).*" Computer-logged task performance data suggested that Ryan has retried and failed at least three more times with this exact level in-between different gaming sessions, until completing the final successful attempt. In this example, Ryan's math play evolved as he experienced gameplay purposefully and mathematically.

Students' cognizance to make sense of math in real-world context

Observations, interviews, and logged data of a student, who has been slacking in in-game task performance and kept gaming the system, revealed that students' meaningful math play occurred when they were cognizant of the math concepts and when they integrated real-world contextual sense-making into gameplay:

1 F: What do you like?
2 Beau (6th grade): Basketball.
3 F: Do you see any math in basketball?
4 Beau: Yes. *The arch.*
5 Other students: That's science.
6 Beau: *That's math*, you need to know *the arch*, get the ball in there.
7 F: Oh nice, did you see any connections between that and this game?
8 Beau: Oh, the basketball level, I painted the basketball court already.
9 F: Is that your favorite level?
10 Beau: Yes.

Students managing struggles to be productive

As observed, students experienced iterative struggles along the math play trajectory, they managed the struggle with diverse strategies. For example, some students were observed to manage in-game struggles *with more careful problem analysis or information processing*; for instance: "Tyson (7th grade) completed a hard level with all the badges. He cheered and thrown his hands in the air in excitement." F: "how did you feel about it?" Tyson: "it was kinda *stressful*." F: "what guided you to the completion of the level?" Tyson: "well, I was trying, and *it was always wrong*, because *I didn't notice* that 85% (discount in purchasing the materials)… I think I just kinda did it."

Discussion and conclusion

In this study, we elucidated the processes of and strategies used by middle school students during math play. The three highlighted preliminary patterns in this study demonstrate the scholarship of math play, reorganization and rediscovery for math conceptual understanding during math play, and strategic, productive struggle management in DGBL (Kolodner, 1983; Warshauer, 2015; Williams-Pierce & Thevenow-Harrison, 2021). We maintain that these patterns are important insights for designing meaningful and constructive game-based math problem-solving experience, or math play, for middle school students.

Abstract: In this poster we are reporting the first iteration of a Design-Based Research project exploring how Object-Based Learning assists business students in developing a deeper understanding of the dynamics of leadership. Some students visited the on-campus Chau Chak Wing Museum while others engaged online with a selection of artefacts, artworks and specimens that represented different types of leadership characteristics in different cultural contexts over time. Students worked in small groups with a carefully curated group of objects to reflect on and explore what it means to be a leader for good. We conclude with an analysis of students' reflections following the workshops and invite feedback for further iterations.

Introduction and context

In a world of increasing complexity and rapid change, being a leader for good has been identified as a critical skill for graduates at the University of Sydney Business School. Conventional approaches to teaching leadership in business schools have often stressed the role of the charismatic individual, often a white man, as a transformational leader providing a compelling vision for the future that others follow (Collinson & Tourish, 2015). To support diverse expressions of leadership, we designed a new course on leadership and action research. In this course, students work on real world problems and develop solutions that are data informed, and a final individual leadership portfolio that outlines their leadership understanding, capacity, skills and approach. However, students often struggle to identify and articulate their unique and individual understanding of leadership that consider their diverse cultural and personal experiences. To help students explore leadership beyond popular tropes and challenge the normative and gendered discourse on leadership, we designed a series of Object-Based Learning (OBL) workshops. OBL is the active integration of curated objects into the learning environment to facilitate the acquisition of cross-disciplinary knowledge (Chatterjee & Hannan, 2015). The diversity of collections at the Chau Chak Wing Museum, along with the dedicated Academic Engagement Curators served to amplify this message. In the workshops, students were encouraged to examine the complexity of leadership dynamics and to question the assumption that power should be vested in the hands of few. It is not common for business courses to incorporate OBL in lessons and there is no direct link between objects and leadership in general. However, museum objects can stimulate discussion and debate and as such are excellent focal points for enhancing student engagement with the concept of leadership.

Research design and methods

In this study we are employing Design-Based Research (DBR) to explore how OBL can be implemented in Business education. DBR is an interdisciplinary mixed-method approach that studies learning activities in a naturalistic setting and facilitates data collection through a variety of methods (Barab, 2006). In our study, we are collecting data through observation of the OBL workshops, students' post-workshop reflections, and analyzing student leadership portfolios. DBR facilitates the cyclical enhancement of the learning tasks, materials, tools, and patterns of communication (Reimann, 2011). We are reporting the first iteration of OBL implementation, with the aim of applying further enhancements in future semesters. In total, 45 students were enrolled in this course during the semester with 27 students attending in-person classes and 18 attending online classes through Zoom. Following the OBL workshops, we collected student reflections using Padlets.

OBL workshops: Structure and content

We designed two OBL workshops to explore the concept of leadership. Each workshop was designed and delivered by the museum Academic Engagement Curators in two modes: in-person in the museum's learning spaces and online through Zoom. A variety of objects were selected for the workshops, including the Tin Sheds Poster Collection (Figure 1a) and other objects that represented a range of cultures, knowledge systems and social hierarchies, ranging from First Nations traditions and activists to ancient Roman Emperors and animal specimens. For example, students were challenged to connect a magpie specimen to concepts of leadership (Figure 1b). Students discussed and reflected on characteristics and qualities of a leader after being introduced to a recent

Conversation report that a group of Australian magpies, fitted with tracking devices by scientists hoping to collect behavioral data, surprised the researchers by working collaboratively to remove the devices from one another.

The activities were designed to take the students through the stages of familiarization, deep observation, critical analysis, application, and synthesis, which roughly mapped to five levels of Bloom's Taxonomy. In the familiarization stage, the students engaged in quick observation of the selected objects. Next, the students conducted deep observation of one object as a group and each student shared one unique observation, covering the visual elements. The purpose of deep observation is to build a robust and multi-perspective foundation of information on which to base the next phases. The critical analysis phase focused on purpose, motive, audience, message, and an evaluation of the effectiveness of each. Finally, the students applied their learnings by creating their own poster to communicate the main message of their own research projects (Figure 1c). In the final discussion, students connected the objects to the concept of leadership and examined how each contributed a different perspective on what makes a leader.

Figure 1

(a) (b) (c)

Student reflections and future directions

In total 27 students responded to the reflection questions on the Padlets. We used thematic analysis (Fereday & Muir-Cochrane, 2006) to identify broad themes on 1) OBL deepening understanding of leadership, 2) facilitating communication, and 3) questioning prior assumptions on leadership. While a detailed discussion of the results is out of the scope of this poster, they indicated a strong support for the three aspects queried. Students commented on how the activities helped them draw “deeper meaning” and see leadership “in a new way”. One student added that the workshops “Deepened my understanding of creative visual cues in influencing others and conveying a message, qualities which are important to becoming an effective leader”. Students stated that the objects acted as “a stimulus which helped direct discussions” and make an abstract concept such as “leadership more concrete”. The workshops helped students question their prior assumption about leadership with one student stating “my understanding of leadership expanded to include the importance of symbolism” and another student added “the new perspectives provided alternative for views of leadership (ie. Spiritual) which I had not considered before”. While still in its early stages, the outcome of this project indicates that students were able to think critically and creatively about leadership, and most importantly, they were able to question their own assumption and formulate new and more inclusive conceptualizations of leadership characteristics (Chatterjee & Hannan, 2015). In further iterations of this project, we will incorporate more objects that represent wider perspectives from diverse cultures and throughout different points in time. In addition, we will analyze the student leadership portfolios for any evidence of the change in conceptualization about leadership for good.

A Teaching Routine for Working With Existing Data in Science Classrooms

William R. Penuel, University of Colorado Boulder, william.penuel@colorado.edu

Abstract: Working with existing data is central to science investigations, but students and educators have generally not had experience using existing data sets to answer their own questions. We introduce a teaching routine that makes explicit critical steps in the process of working with data to gain insight into real-world phenomena. We intend the routine to support both curriculum developers and teachers in designing and enacting lessons to support students in engaging productively with scientific data, focusing on steps that are not commonly encountered in science classes.

Working with existing data in science classrooms

Exploring real-world phenomena using existing scientific data is a powerful context for engaging students in meaningful disciplinary practices in science. (NASEM, 2019). Working with already-collected data adds complexity to the already complicated task of data analysis. While research has identified many of the supports students need for working with data (Manz et al, 2020; Rubin, 2020; Feldman et al, 2000), working with data that was collected by someone else in a different context adds considerable complexity. In this paper, we report on work in progress on a teaching routine for developers and teachers seeking to support students in working with existing data in classroom investigations in science. Teaching routines are “recurring patterned sequences of interaction that teachers and students jointly enact to organize opportunities for student learning.” (DeBarger et al., 2010, p. 225). Teaching routines can function as resources for curriculum writers as they construct sequences of lessons to engage students in science practices, as well as helping teachers adapt instruction to students’ emergent ideas.

Project context: EMBEDS

The Exploring the Mathematics of Biological Ecosystems with Data Science (EMBEDS) project investigates the potential of integrating “data excursions” for developing high school students’ competencies with data practices and data modeling into phenomenon-based instructional materials. These “data excursions” allow students to interact with datasets collected by scientists related to ecosystem dynamics to query their contexts, change the way they are aggregated and represented, and explore patterns they reveal.

An example of one such excursion we have developed takes place within a unit on ecosystems being developed for OpenSciEd, a free, phenomenon-based set of instructional materials aligned to the Next Generation Science Standards. The overarching unit question pertains to how the creation of the Serengeti National Park impacted local ecosystems. Early in the unit, students try to determine whether large increases in wildebeest and buffalo populations between 1960-75 could have been caused by an increase in available food. After learning that scientists had no data on food–but had to rely instead on rainfall as a proxy–students use CODAP (a free educational data analysis tool) to explore data on rainfall in different regions of the Serengeti during that time period.

As our project unfolded, we decided that it would be helpful to articulate a teaching routine to guide the design of our excursions and to help teachers support students’ work with existing scientific data. The routine makes explicit aspects of investigating scientific phenomena that students do not typically encounter, such as the idea that a given dataset may not be able to answer the question at hand because it was collected for a different purpose or that measurements may have been made differently by different scientists.

The data routine

Our project is studying how a data routine can support sensemaking about phenomena in science. Our high-level conjecture guiding this inquiry is that:

> *Lessons (excursions) organized around the elements of the data routine can support students’ ability to use existing multivariate datasets to help explain complex ecosystems phenomena.*

We further hypothesize that certain elements of the routine may be particularly consequential in their impact on students' facility with data, e.g. predicting what patterns in the data would imply particular answers, deeply investigating the way in which data were collected and how measures were defined, and working with a tool that facilitates the creation of multiple linked representations that support students' data fluency. We intend the Data Routine to be a resource that other design research projects might explore, particularly those connected to curriculum efforts in science, social science, and the emerging field of data science. An important set of questions pertains not only to its flexibility in other disciplinary contexts, but also what kinds of outcomes might be supported by its use, and what other embodiments might be necessary to achieve those outcomes.

Table 1
Elements in the Data Routine

Element	Student Actions
Framing Questions	● Students come to a consensus on question(s) to address related to the anchoring phenomenon and possible answers to their question(s). ● Students decide what kinds of data they need to answer their question(s). ● Students identify multiple plausible answers, and for each, students make predictions about what the pattern in the data would look like, if each answer were true.
Orienting to the Data	● Students orient to the data (what is each case? what are the variables?), discuss the source of the dataset, query who collected the data, by what methods and why, and evaluate its reliability, ● Students evaluate whether the dataset might help answer their questions, if it can answer a different related question instead, or is not relevant to their question.
Exploring the Data	● Students discuss ways to explore the data to help answer their questions. ● Students create initial representations and notice and record patterns they see. ● Students make initial claims based on patterns in the data, including how confident they are in the presence of variability.
Sensemaking about the Data	● Students present their claims and relevant representations to support them to others. ● The class engages in a discussion to decide what claims can be supported from the data and articulates limitations of the data. ● The class discusses whether they can reach consensus on an answer to the question(s) and identifies remaining and additional questions that arise from their analysis.

University of California, Irvine

Abstract: This study is part of a series of in situ design-based research investigations within a large public university in California, assessing undergraduate science instruction while distance learning. It has become increasingly important to identify sustainable learning alternatives to support online teaching and learning while integrating educational technologies informed by evidence-based practices of pedagogical learning experience design (LXD). Consequently, this design-based research efficacy study aimed to test the effectiveness of embedded video questions in supporting or hindering students' learning experience. Results showed that learners who experienced the embedded-video questions had significantly higher quiz grades, page views, and course participation as well as increased levels of online engagement and self-regulation, while experiencing lower levels of mind-wandering and cognitive load. Implications on how institutions may iteratively design and effectively foster successful science online teaching and learning with the deployment of innovative "edtech" tools grounded in pedagogical learning experience design are discussed.

Introduction

Embedded video questions are a type of educational technology design feature that adds interactive quizzing capacities while students watch an asynchronous video. As a video plays, students watching the video are complemented with questions that aim to stimulate deeper or more active information processing (Christiansen et al., 2017; Kovacs, 2016; van der Meij et al., 2021). This is like an Audience Response System (ARS) during traditional in-person lectures where an instructor utilizes a live polling system in a lecture hall, such as iClickers, to present questions to the audience (Pan et al., 2019). However, in an online learning environment, students are assigned videos to watch on their own time and a series of questions appear on the screen that review concepts immediately, check for misconceptions, and foster a deeper conceptual understanding. Research on the use of embedded video questions has already shown promising empirical results in the field, such as stimulating students' retrieval and practice, facilitating recognition of key facts, and prompting behavioral changes to rewind, review, or repeat the materials that were taught (Cummins et al., 2015; Haagsman et al., 2020; Rice et al., 2019). Embedded video questions have also been shown to transition learners from passively watching a video to actively engaging with the video content (Dunlosky et al., 2013; Schmitz, 2020), a critical factor when considering the expediency from in-person to online instruction due to the pandemic. As a result, there is a myriad of affordances that showcase the positive effects of embedded video questions on students' learning experiences such as their engagement, mind-wandering, cognitive load, and self-regulation. As we introduce a new "edtech" design of embedded video questions to an undergraduate-level biology course, we evaluate the efficacy of our designs by examining the impacts of students' engagement, mind-wandering, cognitive load, and self-regulation as a result of our LXD. This design-based research (DBR) in situ approach applies theories of learning to evaluate the efficacy of design and instructional tools with learners "in the wild" (DBR Collective, 2003; Siek et al., 2014) to test the effectiveness of embedded video questions in supporting or hindering students' learning experience. The following research questions guide this study: RQ1) What is the effect of the treatment condition on learners' quiz grades, page views, and participation rate? RQ2) What is the effect of the treatment condition on learners' engagement, mind-wandering, cognitive load, and self-regulation? RQ3) To what extent is the effect of the treatment condition related to learners' quiz grades, and is this relation moderated by learners' self-regulation, cognitive load and mind-wandering?

Methodology

In this study, 183 undergraduate students majoring in Ecology and Evolutionary Biology at a Southern California School of Biological Sciences participated. The student demographics included 1.2% African American, 72.0% Asian/Pacific Islander, 10.1% Hispanic, 11.3% white, and 5.4% multiracial, with 69.0%

females and 31.0% males. Students self-enrolled randomly into one of two course sections with different quiz implementation methods: 1) end-of-video questions (N = 92) and 2) embedded video questions (N = 91). Survey data were collected before (Time T1) and after (Time T2) a 10-week intervention period. The study used a quasi-experimental design, where the quiz delivery method varied. In the first condition, students received quiz questions after watching assigned video scaffolds. In the second condition, questions were embedded within the video player, time-stamped to match the content. Both conditions had the same instructor, content, and conceptual questions, with the only difference being the timing and placement of the quiz questions.

Findings

A MANOVA found significant differences between learners with and without video-embedded questions in quiz grades, pageviews, and participation ($F(3, 150) = 188.8$, $p < 0.000$). Univariate tests revealed significant differences in quiz grades ($F(1, 152) = 6.91$, $p < 0.05$, $\eta 2 = 0.043$), pageviews ($F(1, 152) = 26.02$, $p < 0.001$, $\eta 2 = 0.146$), and participation rates ($F(1, 152) = 569.6$, $p < 0.001$, $\eta 2 = 0.789$). Bonferroni comparisons confirmed these differences, showing that learners with video-embedded questions had significantly higher quiz grades, pageviews, and participation. A second MANOVA compared learners with and without video-embedded questions on four variables: engagement, mind-wandering, cognitive load, and self-regulation. It revealed significant differences ($F(4, 177) = 5.09$, $p < 0.001$), indicating that students with embedded video questions had higher engagement and self-regulation while experiencing lower mind-wandering and cognitive load. A multiple regression model found that learners' treatment condition significantly predicted quiz grades ($\beta = 1.15$, $SE = 4.72$). Additionally, cognitive load ($\beta = -0.340$, $SE = 0.096$) and self-regulation ($\beta = 0.448$, $SE = 0.063$) had significant main effects, while mind-wandering ($\beta = -0.121$, $SE = 0.185$) did not. Interaction effects between treatment conditions and self-regulation ($\beta = 0.747$, $SE = 0.099$) and cognitive load ($\beta = 0.564$, $SE = 0.150$) were also significant. Together, these variables explained approximately 27.1% of the variance in quiz grades ($R2 = 0.271$, $F(3,155) = 5.62$, $p < .001$).

Results showed that learners who experienced the embedded video questions had significantly higher quiz grades, page views, and course participation. Findings further indicated that these learners also experienced significantly higher levels of self-reported online engagement and self-regulation, while reporting lower levels of mind-wandering and cognitive load. These results are in line with the literature on the affordances of embedded video questions for fostering conceptual knowledge, increasing attentional awareness, and providing interactive learning opportunities that boost the retention of course content (Cummins et al. 2015; van der Meij et al., 2021). Additionally, it suggests that learners' improved quiz performance may be linked to their self-regulation and cognitive load. These questions engage students actively, promoting information retrieval and reflection, possibly contributing to a testing effect facilitated by our embedded video question design. The embedded video question platform offers a medium to facilitate cognitive processing such that learners are recognizing and aligning what they know and identifying what they do not know.

Self-Regulated Learning in Online Continuing Education: Managing Learning Time is a Key Challenge

Katharina Teich, Linda Froese, Vanessa Loock, Nikol Rummel
katharina.teich@rub.de, linda.froese@rub.de, vanessa.loock@rub.de, nikol.rummel@rub.de
Ruhr University Bochum

Abstract: The self-paced format of online courses requires learners to act highly self-regulated while managing their learning time. In contrast to the ample research on self-regulated learning (SRL) in online higher education, research on adult online SRL is scarce. In this paper, we present results concerning adult online learners' time management, a specific aspect of SRL. A re-analysis of survey data of 60 adult learners indicates that time management is a particular challenge in this context.

Introduction

Compared to traditional in-person learning environments, online courses offer a high level of independence in terms of when, what, and how to learn. This makes them particularly appealing to adult learners who often attend continuing education and training (CET) courses besides their regular working hours. However, this high level of independence can also entail particular challenges, as learners must be highly self-regulated and take responsibility for managing their own learning process (Kizilcec et al., 2017). Especially time management can be a critical self-regulated learning (SRL) issue in the context of work-related CET online courses, because adult learners often have to balance work, family commitments, and learning.

So far, research on adult learners' SRL, specifically in the context of work-related CET online courses, is scarce (Jossberger et al., 2020; Schulz & Roßnagel, 2010, Fontana et al., 2015). A notable exception is the SRL framework for work-related training developed by Sitzman and Ely (2011), which incorporates strategies from Zimmerman's SRL model (Zimmerman, 1989) and provides first insights into relevant SRL strategies for adult learning. To address this lack of research that captures the attributes of how adult learners self-regulate during online learning, we conducted a secondary analysis concerning SRL strategies by re-analyzing an existing dataset consisting of survey responses of adult learners who participated in a CET online course. In this paper, we focus on *time management* as one particularly important aspect of SRL in the context of CET online courses. We investigated how adult learners managed their learning time (RQ1) and further analyzed how time management was related to learning outcomes (i.e., quiz results) (RQ2). With our analyses, we aim to provide initial insights into how adult learners manage their learning time in CET online courses and, thus, to contribute to extending SRL models accordingly.

Methods and analysis

For the analyses we present in this paper, we re-analyzed a dataset that comprised survey data of $N = 60$ adult learners who participated in four iterations of the same CET online course. The analysis presented in this paper is part of a larger study with the aim to (a) extend current SRL models and (b) investigate support that addresses particular SRL challenges in the context of CET online courses. The original surveys encompassed various measures. To answer our first research question, we identified measures within the surveys that corresponded to the definition of the SRL strategy of time management outlined by Sitzman and Ely (2011). According to their definition, self-regulated learners manage their learning time by setting a schedule for when they learn, taking time to learn, and monitoring their own learning time, for example, when it comes to meeting appointments. To investigate these aspects of SRL in the CET course, we computed descriptive analyses on adult learners' amount of *learning time* spent on each module of the course in comparison to the estimated learning time provided by the course organizers. Furthermore, we quantitatively investigated measures inquiring *when learning activities mainly took place*. Given that the CET course was to be completed during working hours, a significant part of learning should ideally occur during this time.

To investigate our second research question, we evaluated how the SRL strategy of time management is related to *learning outcomes*. For learning outcome measures, we analyzed quiz scores participants achieved in six quizzes that were part of the CET online course. As it was possible to achieve different highest scores in each quiz, we standardized all quiz results to z-scores. We then computed Spearman correlation coefficients between the quiz results' scores and the scores for time management, since the variable *quiz results* was not normally distributed.

Results and discussion

Concerning our first research question (RQ1), the comparison of adult learners' amount of learning time per module and the estimated learning time provided by the course organizers indicated that adult learners managed their learning time sufficiently as they did not exceed the estimated learning time. Course organizers estimated that learning one module would take an average of 178 minutes. Participants spent M = 164.96 minutes per module. However, results also show that even though the course was supposed to be a completed during working hours, participants mainly learned in the evenings (59 %) and generally in their free time (98 %). This indicates difficulties with integrating learning time into working hours.

Regarding our second research question (RQ2), the analysis of learning outcomes revealed that learning best takes place in the evening in the context of adult online learning. We found that learning in the evening (p = .047, ρ = 0,323*) is significantly associated with learning outcomes. Additionally, we found a negative, but not statistically significant correlation between learning during working hours and learning outcomes. Even though this finding should be viewed with caution, it could indicate that learning during working hours may not be as effective compared to learning in the evening.

According to our findings and in line with previous theoretical considerations, adult learners from this online CET course faced difficulties with time management, more specifically, with incorporating time for learning into their work schedule, which is usually intended by employers that offer work-related CET online courses. Yet, our analysis revealed that learning in the evening separated from the work context was positively and significantly related to learning outcomes and hence fosters learning. This result contradicts previous assumptions and thus could be an initial indication that future research needs to rethink time management strategies in the context of adult online education.

In conclusion, the analyses presented in this paper provided initial insights into adult learners' time management as an important aspect of SRL in the context of work-related CET online courses. However, it should be noted that our findings may be somewhat limited by re-analyzing an existing dataset with regard to our research questions. In the future, it would be desirable to conduct further studies designed specifically to assess the SRL strategy time management in order to replicate our initial findings.

Examining the Effect of Automated Assessments and Feedback on Students' Written Science Explanations

Abstract: Writing scientific explanations is a core practice in science. However, students find it difficult to write coherent scientific explanations. Additionally, teachers find it challenging to provide real-time feedback on students' essays. In this study, we discuss how PyrEval, an NLP technology, was used to automatically assess students' essays and provide feedback. We found that students explained more key ideas in their essays after the automated assessment and feedback. However, there were issues with the automated assessments as well as students' understanding of the feedback and revising their essays.

Introduction

Engaging students in authentic science practices is central to learning and understanding science (NGSS, 2013; Braaten & Windschitl, 2011). At the core of such practices is writing scientific explanations, which researchers say should: (1) use data and/or evidence to make claims, and (2) connect scientific principles to evidence to explain the observed phenomenon (Berland & Hammer, 2012; Berland et al., 2016; Krajcik et al., 2014). Natural Language Processing (NLP) technologies can support students in writing science explanations by providing automated feedback (Gerard & Linn, 2016). This study investigated the role of an NLP technology, PyrEval, (Gao et al., 2018; Passonneau et al., 2018), to assess students' written science explanations. The research questions guiding our study were:

1. How does automated feedback help students explain key ideas in their science essays?
2. What are the opportunities and limitations of using automated feedback in classrooms?

Methods

Participants and context

A total of 264 students from three 8th-grade public middle school classrooms in the Midwestern US participated in this study. Students learned the science of roller coasters by conducting experiments in a simulation and writing essays to develop a roller coaster design based on the science they were learning. Students wrote a design essay (E1) after conducting their first set of experiments, which was sent to PyrEval for feedback. Next, students conducted additional experiments and wrote a second design essay (E2) that built on ideas and feedback in E1. They received feedback from PyrEval on their E2, based on which, they were given the opportunity to make revisions and resubmit their final design essays. We called this essay 2 revised (E2R).

PyrEval uses a wise-crowd model, where samples used to match key ideas, referred to as content units (CUs), are taken from a range of student essays. It automatically parses students' essays into propositions and creates a model of important propositions derived from a small set of reference responses. It then creates a vector representation for propositions and compares them to recognize paraphrases of similar content. In our study, 15 CUs were identified as the most important ideas for students to learn during the unit, which PyrEval applied to automatically assess students' essays.

Results and discussion

We used the number of CUs identified by PyrEval in student's essays as the measure for our analysis. We conducted a repeated measures analysis to examine changes in students' essays from E1, to E2, to E2R after receiving feedback for students who completed all three essays (*N=228*). We summed the 15 CUs into a CU total score for each student's essays and used these as dependent outcomes. Our analysis showed that students included significantly more CUs in E2R (*M=5.05, SD=3.02*) than E2 (*M=4.77, SD=2.93*), and significantly more CUs in E2 than in E1 (*M=3.68, SD=2.40*) ($F_{1,228}=82.1889$; $p<.001$; $\eta p^2=.267$). We also ran Wilcoxon signed-rank tests to understand the changes in students' essays for each CU from Essay 1 to Essay 2 Revised. We found significant differences between E1 and E2R for 6 of the CUs; this means more students included these CUs in E2R, compared to their E1. Conversely, there were no significant differences for the remaining CUs.

Our analysis showed that students included significantly more CUs from both E1 to E2 and E2 to E2R. This indicates that students included more ideas in their essays after receiving feedback, a finding also observed in other studies (Gerard et al., 2019; Tansomboon et al., 2017; Zhu et al., 2020). Our study provides evidence that PyrEval was able to expedite the 'scoring' of students' essays, which otherwise would have taken a long time to do manually for teachers, as has been observed in other studies evaluating NLP technologies to automatically assess students' science writing. However, there were some challenges: *First*, there were some challenges with PyrEval correctly identifying CUs. PyrEval looks for ideas, or CUs, in individual sentences. When students' ideas were scattered across multiple sentences or even paragraphs, the technology may not have been able to recognize the CUs. Students often write long sentences to explain and repeat ideas over several sentences, which often lack precision. They also sometimes forget to include punctuation. We found that PyrEval had difficulty recognizing ideas in sentences longer than 25 words. *Second*, we found that it is challenging to translate automatic assessments into comprehensible feedback for students.

Clearly, writing and revising explanations is not an easy task for middle school students. Using the findings from this study, we plan to make changes to our approach to ensure that we provide adequate scaffolding to students. We plan to improve PyrEval's ability to recognize CUs in students' writing by refining the NLP model, based on this year's classroom dataset. Additionally, our plan is to provide teachers with more information about students' progress through a teacher dashboard by summarizing trends about students' progress at multiple points in the unit, prior to and after essay writing. This high-level overview will allow teachers to see trends across their classes, enabling them to dynamically make titrated instructional decisions to ensure students get the support they need when they need it.

Exploring AnnotateEdTech as an Online Collective Third Space for Developing Teachers' Learning and Humanizing Practices With Technology

Charles Logan, Northwestern University, CharlesLoagn2025@u.northwestern.edu

Abstract: Online collective Third Spaces can support educators' learning about surveillance-based educational technologies while simultaneously helping educators to develop humanizing practices with technology. In this paper, I discuss AnnotateEdTech, an online collective Third Space that brings together educators to use social annotation to critique educational technology companies' claims about their products. I share one case of an AnnotateEdTech gathering and discuss how participants' annotations are evidence of their learning and humanizing practices with technology.

Introduction

Students and educators in the United States are increasingly forced to learn and teach beneath the harmful gaze of surveillance technology. Hoadley and Uttamchandani (2021) offer several recommendations for addressing surveillance-based educational technology. The authors advocate for a humanizing approach to technology that considers how technology can "support learning and thriving by disrupting inequity through supporting identity development, self-expression, authorship, collaboration, and activism" (Hoadley & Uttamchandani, 2021, p. 15). The authors also argue for more opportunities for teachers to learn about these technologies.

AnnotateEdTech is a promising design innovation to support teacher learning that aligns with Hoadley and Uttamchandani's (2021) suggestions for humanizing approaches to technology; it can also be understood as a collective Third Space (Gutiérrez, 2008). AnnotateEdTech is an online professional development experience that brings together participants to use the social annotation tool Hypothesis to analyze, question, and critique the claims educational technology companies make about their products on their websites. In this short paper, I will offer a brief description of AnnotateEdTech and how it might help educators document and disrupt the creep of surveillance-based educational technologies.

Collective Third Spaces and transformative teacher learning

Gutiérrez (2008) describes a collective Third Space as a learning environment that challenges participants to reflect on who they are and imagine what they might accomplish individually and together. The learning that occurs "becomes situated, reciprocal, and distributed, leading to new forms of learning" (Gutiérrez, 2008, p. 159). While Gutiérrez (2008) discusses how a collective Third Space nurtures learning for youth from nondominant groups, other educators have used the design to support teacher learning. For example, the Marginal Syllabus is an online professional development project for K-12 teachers, university students, and university researchers that uses the social annotation tool Hypothesis to facilitate discussions about educational equity scholarship (Kalir & Garcia, 2019). The success of the Marginal Syllabus points to a need for more examples of online collective Third Spaces that realize the possibility of social annotation for educator learning.

AnnotateEdTech as a collective Third Space for teacher learning

AnnotateEdTech is founded on the belief "that annotation expresses power in ways that are productive, networked, and situated in social contexts" (Kalir & Garcia, 2021, p. 132), qualities that mirror a collective Third Space's situated, reciprocal, and distributed learning.

I first decided to create AnnotateEdTech as a way for educators to critique the narratives produced by online proctoring companies. According to companies like Proctorio and ProctorU, their software can help identify students who are cheating on an exam. Critics have labeled it a dehumanizing technology (Hoadley and Uttamchandani, 2021). To better comprehend how a group of educators worked together to understand and counter online proctoring's harms, I explored the following research question: What elements of humanizing approaches to technology did educators practice through their social annotation of online proctoring websites?

Research context and methods

Context

I worked with members of Ethical EdTech to facilitate the first AnnotateEdTech. My co-facilitators and I promoted the first AnnotateEdTech through Ethical EdTech's listserv and Twitter. On November 16, 2020, 16 higher education faculty and staff joined an hour-long Zoom call and annotated 12 websites belonging to three online proctoring companies. Participants created 96 annotations using the social annotation tool Hypothesis.

Methods

I began by developing more specific definitions of identity development, self-expression, authorship, collaboration, and activism, grounding my definitions in relevant literature when necessary. For example, I turned to Engle & Conant (2002) for help conceiving of *authorship* as producing knowledge through asserting agency to define, address, and resolve problems. Next, I conducted deductive coding (Miles et al., 2020) using my more refined definitions of humanizing approaches to technology.

Findings

The annotator with the username rstarry critiques Proctorio's claim that their technology promises "total learning integrity" (Figure 1). The annotation, playful and stinging, is a GIF from the film *The Princess Bride*. The annotator's memorable self-expression communicates the doubt and exasperation they experience as they learn more about the discourse tactics used by online proctoring companies to frame and sell their products.

integrity

AnnotateEdTech

Linkletter Nov 16, 2020
Public

ID verification

Proctorio has been aggressive with critics and reporters in claiming that they do not use facial recognition technology. But as has been documented, they have been marketing the product as *using* facial recognition technology.

In their bid response to California State University's request for proposal, they repeatedly stated that they use facial recognition technology.

It's all very confusing. Almost like they want to have it both ways - silence critics and make BANK.

AnnotateEdTech

(a) (b)

In Figure 2, the participant Linkletter authors an annotation to illustrate Proctorio's hypocrisy regarding its claim that their proctoring software does not use facial recognition technology. Linkletter refutes the claim by sharing evidence to the contrary: the second and third hyperlinks connect to tweets and a request for proposal, respectively, that show Proctorio refers to its use of facial recognition technology. Linkletter uses the networked nature of social annotation for distributive learning, a key characteristic of collective Third Spaces.

Discussion and conclusion

The harmful effects of surveillance-based educational technology require immediate action. Taking inspiration from the possibilities of a collective Third Space, I have argued for designing online collective Third Spaces to support teachers' learning and foster their humanizing practices with technology through social annotation. My initial findings show how fellow teachers work together to understand and resist the narratives sold by online proctoring companies. Online collective Third Spaces can be a nourishing context for teachers to enact and hone humanizing learning practices with technology.

Learners' Emotion Responses: Interactive and Constructive Learning

Andrew C. Jung, Department of Computing Sciences, University of Hartford, jung@hartford.edu
Jinsook Park, Department of Mathematics, University of Hartford, jpark@hartford.edu
Suk Jin Lee, TSYS School of Computer Science, Columbus State University, lee_suk@columbusstate.edu

Abstract: We aim to use computing technologies to develop a better understanding of the level of stress/anxiety students experience during different modes of tasks in a STEM-focused interdisciplinary university class setting. Various types of classroom tasks are used to identify students' emotional responses as a means to ultimately shape classroom experiences and improve learning. The results of this projects will provide guidance for developing instructional materials to enhance students' learning.

Introduction

In order for college students to gain robust critical and creative thinking skills to solve complex problems, it is important to provide a motivating environment where students can enjoy learning and desire to develop these skills appropriately. Instructors put in a multilateral effort to design instructional materials with diverse strategies. Research shows that students are more actively engaged and interested in a subject when presented with interactive and constructive classroom activities (Chi & Wylie, 2014; Hake, 1998). As instructional materials are implemented, however, students may experience positive or negative emotional changes during activities. Anxiety and stress levels in class may negatively affect students' learning, resulting in decreased academic performance. We aim to use computing technologies to develop a better understanding of the level of stress/anxiety students experience during different types of tasks in a STEM-focused interdisciplinary university class setting. We consider various types of classroom tasks within passives, active, interactive, and collaborative modes and identify students' emotional responses as a means to ultimately shape classroom experiences and improve learning.

Interactive and constructive course design

The course is intended for first year students who are not majoring in Computer Science or Engineering. The course is designed to provide students with ample hands-on activities, discussion, demonstrations, and projects to enhance students' learning performance by practicing active learning strategies. The goal of the course is to enhance students' computing capabilities, which are necessary for computational thinking. This course includes industry 4.0 technology such as Robotics and Internet of Things (IoT) with a goal of increasing active learning and engagement. We will define classroom activities as follows:

Table 1
Classroom Activities

Category	Type of Activity
Active	Present and/or explain the works and artifacts
Interactive	Discussion with Instructor and Collaborator
Constructive	Doing Hands-on Activities
Passive	Listening Lecture

The guiding research questions that will frame the proposed research are:

1. What emotional responses will students elicit during different modes of activities?
2. How do changes to the mode of classroom activities and students' associated emotions impact learning?

This study will identify the mode of activities to which students respond more positively or negatively while learning actively. We will design the class activities with four different modes: active, interactive, constructive, and passive). A primary focus will be placed on investigating how students' emotional responses will range during these four modes. For example, hands-on practice following an instructor's explanation of the concept has shown to be an effective way to reinforce course concepts. Even though there are established positive effects for students, it is unclear how students feel during activities. The second research question seeks to understand how students' emotions affect their learning outcomes. We will compare the relationship between the result of artifact analysis and their emotional data. The following table presents the method that we will use to investigate each of these questions:

Table 2
Research Questions and Methods

Question	Methods	Data
1. What emotional responses will students elicit during different modes of activities?	Design four modes of activities in the instructional design and compare surveys and artifact data	Survey and artifact data
2. How do changes to the mode of classroom activities and students' associated emotions impact learning?	Conduct qualitative analysis to investigate relationships between students' emotions and artifact analysis.	Survey and artifact data

Method

Settings and Participants. The sites for this study are one liberal private university in the Northeastern United States and one state university in the Southern United States. These sites are different geographically, structurally (public vs. private), and demographically. The participants will be undergraduate students taking the interdisciplinary course in Fall 2023, which we designed as a general education course for each university. We will ask all students at the beginning of the semester to participate in the research as participants, with a maximum of ten participants at each university.

Data Collection and Analysis. The JAWS and Watson's emotion detection questionnaire will be employed, but we will modify the criteria to adapt to the educational environment (Van et al, 2000; Watson & Friend, 1969). Participants will participate in one pre-survey to identify his/her perception on the mode of the activities. Participants will also be required to respond to a survey after each class within 24 hours. Each participant's survey result will be compared with artifact data (Sladana, 2011). First, we will analyze preliminary survey data using inferential statistics to determine the statistical significance and the practical significance and use a chi-square test of independence to check whether two variables (the mode of activities and emotional response from survey) are likely to be related to or not. Second, we will analyze artifacts such as students' work and video-recordings to gain more understanding of the contexts and students' tasks using dyadic analysis, in which two researchers will exchange and develop ideas in the process of analysis. Physiological data (heartbeat and EDA) will be obtained while students perform each activity during class hours in real-time using the E4 wristbands. Two video cameras will record participants' group(s) during class time to track their responses by the mode of activities. The timestamps of E4 data (heartbeat and EDA) will be compared to video recording timestamps to verify the different modes of activities. Each participant's survey result will be compared with his/her data from E4 to analyze the consistency of the responses.

Discussions

The primary focus of the course objectives and activities is to increase student engagement and the development of logical thinking and creativity. The results of this project will provide other instructors with tools to develop instructional materials that enhance students' learning in consideration of emotional responses to class activities. This project will provide instructors with a better understanding of the relationship between various types of activities and related emotional responses and how they affect learning; therefore, instructors, especially for STEM areas, will gain guidance for designing and developing instructional materials that enhance learning. The proposed interdisciplinary course can be utilized as an example for STEM instructors to design and develop their own interactive and constructive courses.

Restorying Through Design Intersecting Oppressions in Computing Education Using Black Feminist-Womanist Methodologies

Mia S. Shaw, University of Pennsylvania, mshaw12@upenn.edu

Abstract: Despite the push for engaging nondominant youth in learning computing, researchers have stressed the importance of supporting youth in understanding the sociopolitical and ethical dimensions of the design of emerging technologies. This poster presents the design and implementation of an informal workshop in which a racially/ethnically-diverse group of nondominant, 14-15-year-old youth designed interactive artifacts that reimagined or “restoried” dominant narratives about computing technologies. Through centering Black women’s knowledge and experiences with intersecting oppressions, this study framed African-American women’s quilt-making as a *restorying through design* methodology rooted in Black feminist-womanist theories. Reporting on the design experiences of 4 Black participants (i.e., 3 girls and 1 boy), I asked, *How might restorying through design using Black feminist-womanist methodologies reveal intersecting oppressions throughout computing education and culture?* Data collected and analyzed included participants’ quilt artifacts, exit ticket/final survey responses, and observation field notes. Findings demonstrated how white supremacy, heteropatriarchy, and capitalism can shape Black women’s experiences in computing education and with computational technologies. Implications for this study include the affordances and challenges of centering Black feminist-womanist methodologies in computing education.

Introduction and background

Despite the push for engaging nondominant youth in learning computing, researchers have stressed the importance of supporting youth in understanding the sociopolitical and ethical dimensions of emerging technologies. While seeming innocuous and neutral, new technologies risk uniquely marginalizing nondominant communities by reflecting and reproducing existing systems of power and injustices across society (Benjamin, 2019). However, in K-12 learning environments, youth are rarely supported in learning about the intersections of technology, ethics, and politics, as computer science (CS) and engineering curricula tend to promote narratives that reflect dominant epistemological beliefs of technology as neutral, objective, and democratic (Ko et al., 2020; Vakil, 2018). Therefore, innovative approaches are needed to support youth in making explicit connections between not only the personal, sociocultural, and political dimensions of computing, but also the speculative dimension regarding what computing and technologies *could* be.

Given that codes—both technical and sociocultural—have histories and can act as narratives telling us what to expect (Benjamin, 2019), this study drew from narrative scholarship to support youth in engaging in speculative literacy practices of interrogating and reimagining technology’s relationship to systems of power. Rooted in recent configurations of restorying describing how nondominant youth use digital tools to reshape narratives from marginalized perspectives (Thomas & Stornaiuolo, 2016), I offer *restorying through design* as an approach for supporting nondominant youth in designing computational artifacts while also interrogating and reimagining dominant narratives about computing technologies. Due to Black women’s unique knowledge and experiences with intersecting oppressions such as racism, sexism, and classism (Collins, 2002; Phillips, 2006), this conceptualization of *restorying through design* is grounded in Black feminist and womanist theories and practices.

Methodology

Using design-based research (Design-Based Research Collective, 2003), I designed and implemented a two-part, 45-hour workshop with an informal STEM program at a local science museum. Honoring the histories and storytelling practices of Black women, I centered quilt-making as a Black feminist-womanist methodology that African-American women used to restory their lived experiences (Cash, 1995). During the workshop, 16 high-school-aged youth from diverse backgrounds—14 of whom consented/assented—designed artifacts that “restoried” dominant narratives about computing technologies. More specifically, participants designed interactive quilt patches using electronic textiles, which are fabrics embedded with microcomputers, lights, and sensors stitched together using conductive thread and can be programmed to perform a wide array of actions (Buechley, Peppler, Eisenberg, & Kafai, 2013). In addition to designing interactive quilt patches, youth also participated in guided discussions interrogating dominant narratives about computing technology, particularly through engaging in restorying practices of naming and historicizing their everyday realities (Stornaiuolo & Thomas, 2018). To that point, I asked: *How might restorying through design using Black feminist-womanist methodologies reveal intersecting oppressions throughout computing education and culture?*

This study focused on the *restorying through design* experiences of 3 Black girls (Larry, Nia, and Britney) and 1 Black boy (Minaj). Data collected included participants' quilt artifacts, exit ticket/final survey responses, and observation field notes, and using conjecture mapping (Sandoval, 2014) and grounded theory (Charmaz, 2006), findings demonstrated how white supremacy, heteropatriarchy, and capitalism can shape Black women's experiences in computing education and with computational technologies. Implications for this study include the affordances and challenges of integrating Black feminist-womanist epistemologies and methodologies in computing education.

An Analysis of the Design and Pedagogy of *DragonBox Algebra*

Jeremy Bernier, Man Su, Lin Yan, Brian Nelson
jeremy.bernier@asu.edu, mansu@asu.edu, lyan27@asu.edu, brian.nelson@asu.edu
Arizona State University

Abstract: Game-based learning has been applied to solving algebraic equations with the games *DragonBox Algebra 5+* and *12+*. The developers claim that players can learn to solve algebraic instruction just by playing the games, yet there is little research to verify this. Additionally, existing literature does not speak to the experience of playing *DragonBox Algebra*. Here, we present a preliminary analysis and discussion of the design and pedagogy of *DragonBox Algebra* via the Design, Play, Experience framework. We provide a discussion of the design elements and the pedagogy apparent from the game, the publicly-stated pedagogical principles, and the extent to which they align with relevant learning theories.

Introduction

Serious games are games which are designed to achieve some purpose beyond providing entertainment (Winn, 2009). The design elements of a serious game, then, are critical to consider in analyzing and understanding the effectiveness of serious games (Winn, 2009). Therefore, as the first part of a larger research project, we carefully considered the design elements of a commercial serious game, *DragonBox Algebra* (DBA). In our poster, we will briefly present our analysis of the most salient design elements in the game, as well as the extent to which those elements align with the pedagogical principles stated by the designers (Kahoot!, n.d.) and theories of learning. In particular, we note that while the designers articulate a belief in the efficacy of discovery learning, the design of their app seems to be more strongly informed by behaviorist learning principles.

Game-based learning (GBL) is a popular approach in mathematics education (Byun and Juong, 2018). The commercial serious games *DragonBox Algebra 5+* and *12+* together are an example which applies GBL to the essential skill of solving algebraic equations. The Google Play store description of the 5+ version claims that "[c]hildren as young as five can begin to grasp basic processes involved in solving linear equations in an easy and fun way, without even realizing that they are learning." Despite the strong claims made by the developers, quantitative research paints a more nuanced picture (Long & Aleven, 2014; Siew et al., 2016; Supriandi et al., 2020). While some of these studies suggest playing DBA alone or in conjunction with instruction produces positive results (Siew et al., 2016; Supriandi et al., 2020), Long and Aleven (2014) found that it was less effective than gamified and non-gamified versions of an intelligent tutoring system for solving linear equations.

Analytic framework

We determined that Winn's (2009) DPE framework would be an appropriate analytical tool in our work with *DBA* because it is intended to be used both in the design *and* analysis of serious games. Under the DPE framework, Design, Play, and Experience represent three interrelated but distinct components of a game: "[t]he designer designs the game; the player plays the game; which results in the player's experience" (Winn, 2009, p. 1014). Across these three components, the DPE framework includes four "layers" of game elements: Learning, Storytelling, Gameplay, and User Experience (Winn, 2009). The full framework is depicted in Table 1 below.

Table 1
The DPE framework (Winn, 2009)

	Design	Play	Experience
Learning	Content and Pedagogy	Teaching	Learning
Storytelling	Character, Setting, and Narrative	Storytelling	Story
Gameplay	Mechanics	Dynamics	Affect
User Experience	User Interface	Interactivity	Engagement

The design of DragonBox Algebra

DBA is organized into chapters, each with 20 levels. Figure 1 below shows two example levels. The content of *DBA* is the rules and methods of solving algebraic equations. Throughout the game, players are introduced to concepts and skills that are key to solving and simplifying algebraic equations. *DBA* relies on just-in-time information (Kester, et al., 2001) and immediate feedback in order to develop players' ability to solve algebraic equations. Additionally, the game minimizes formal mathematical notation when introducing new rules. These pedagogical elements draw from the seemingly contradictory approaches to learning of discovery learning (Hammer, 1997) and behaviorist (Skinner, 1961) learning pedagogies.

The characters, setting, and narrative of DBA are minimalistic. The player is able to choose an avatar for themselves and each chapter is defined by a dragon which lives in the titular DragonBox. The setting and narrative are sparse. Mechanically, the game is oriented around the player using "powers" which correspond to rules for solving algebraic equations. Players use the powers, at first individually, and then in conjunction, in order to get the DragonBox alone on one side of the screen. In terms of the user interface, the game is designed for tablets and mobile devices and optimized for touch screen interface.

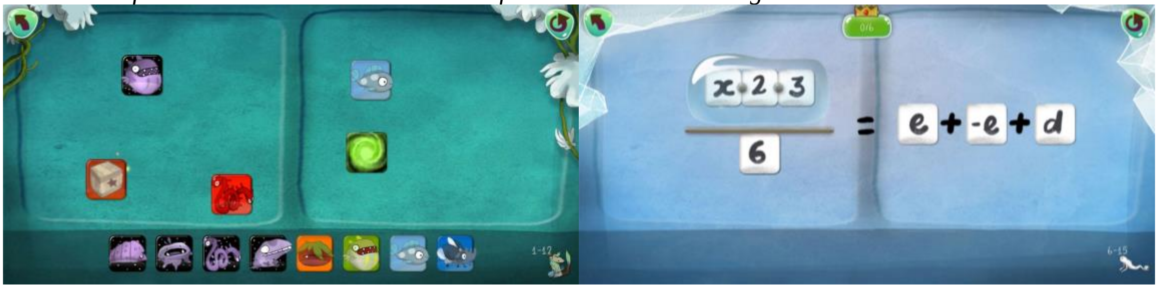
Screenshots from DBA 12+ - Ch 1 Lvl 12 on left and Ch 6 Lvl 19 on right.



Next steps

We present our poster without making definitive claims on the effectiveness of *DBA*, as it represents only the first step of our work. Our next step is to consider the remaining elements of the DPE framework using data from learners in 5th through 9th grade, analyzing how these learners Play the game in response to these design elements and what sort of Experience they have as a result of this.

Districts Helping Districts: Facilitating a Community of District Leaders to Develop Computing Pathways

Kelly Mills, Merijke Coenraad, Pati Ruiz, Quinn Burke
kmills@digitalpromise.org, mcoenraad@digitalpromise.org, pruiz@digitalpromise.org,
qburke@digitalpromise.org
Digital Promise Global

Abstract: We explore how to best facilitate a community of district leaders from six districts across the United States as part of a research practice partnership to design and implement K-12 computing learning opportunities. We found that developing a shared vision, conducting a needs assessment, and encouraging follow up interactions were helpful in facilitating a community of collaborative learning for district leaders.

Introduction

Educational systems are working diligently to adopt policies and practices to increase offerings for computing education in order to equip all learners with essential skillsets to succeed in our increasingly technological world and workforce. In the United States, district leaders have been uniquely challenged to restructure K-12 systems to provide computing learning opportunities for all learners. While states have adopted standards and frameworks as a guide to design and implement computing learning opportunities, district leaders must adapt these resources to be used within the unique contexts of their school communities, considering their students and families, available resources, competing priorities and ongoing initiatives. In previous work, our team has partnered with districts to develop inclusive computing pathways (Mills et al., 2021). As this work scales, we seek to understand how collaboration between school districts in unique contexts can support them to design and implement K-12 computing learning opportunities, which may also inform supports for other shared problems of practice.

We conceptualize the group as a community of practice (CoP; Lave & Wenger, 1991) where all districts learn from each other. Indeed, in our prior project, we led an RPP that interconnected districts in three states and we were consistently surprised at how helpful districts were to each other despite varied locales. While CoPs have been successfully facilitated for many geographically dispersed professional groups, we seek to expand knowledge about these collaborative learning networks between educational district leaders focused on computing pathways. In this study, we explore how to best facilitate a community of district leaders from six districts across the United States as part of a research practice partnership. Specifically, we ask "What practices support district leaders to productively collaborate as part of a community of practice to design and implement inclusive computing pathways?"

Methods

We engaged in a research-practice partnership (Coburn et al., 2013) between 2018-2021 to develop computing pathways in districts from three states ("core districts"). Collaboratively, we developed a toolkit articulating a shared process, best practices, and useful resources for districts to develop computing pathways (Mills et al., 2021). In 2021, we piloted this toolkit in four additional districts ("pilot districts"). In November 2021, all districts attended an in person convening to share processes and strategies for their computing pathways. All districts indicated that they learned significantly from other districts and would benefit from continued connection. Therefore, they began participating in a CoP with 2-3 members of each leadership team to address problems of practice at the leadership level, such as scaling implementation, generating buy-in, and securing continued funding. Researchers adopted a design-based research approach, entailing iterative cycles of design and analysis, to adopt best practices to facilitate the community of district leaders.

Districts attend bi-annual, in-person convenings (three to date: November 2021, June 2022 and November 2022) and participate in regular virtual calls. Participants (N=21) include district leaders (n=6), curriculum/instructional specialists (n=6), building leaders (n=3) and practicing teachers (n=6). We used qualitative research methods (Miles, Huberman, & Saldana, 2014) to analyze project artifacts, meeting notes and field note observations from each of our meetings within the networks including the collection of design and planning documentation, identifying features of the peer-collaborative networks and supports that they provided.

Findings

We describe how three facilitation practices of the district leader CoP contributed to collaborative learning related to developing computing pathways. One practice that contributed to community building was developing a shared vision among district leaders. Given the nature of this project as an RPP, district leaders were included in the proposal process and helped to develop short-term and long-term goals of what they sought to get out of the CoP, management practices, and the expertise they brought to and wanted to receive from the CoP. This established a shared purpose amongst the group to disrupt patterns of inequity in computing education in all districts and share resources and best practices – particularly around professional development, teacher recruitment and retention, and computational thinking integration. Another facilitation practice that enhanced collaborative learning was co-designing and conducting an assessment of the current district landscape and needs. Discussing specific indicators across districts enabled them to provide consultancy to each other as they develop strategies and processes to scale their computing pathways and disrupt inequity within them. Finally, districts indicated that they learned from connecting with other districts about specific issues outside of the cadence of regularly scheduled virtual and in-person convenings. We attribute these interactions to the facilitation practice of encouraging follow up activities (e.g. email communication, meetings, resource sharing) between districts that are addressing similar challenges and creating shared platforms for interactions that were not moderated by the research team.

Table 1
Demographics of Each District and What They Hope to Share and Learn in CoP

District	Context	Demographics	Hope to Share in CoP	Hope to Learn in CoP
Core 1	Urban 28 schools 14,000 students	Title I: 37% Black: 19% Latinx: 12%	-Equity-focused data analytics	-Navigate competing initiatives
Core 2	Suburban 34 schools 28,000 students	Title I: 17% Black 9% Latinx: 12%	-Shared leadership with school/classroom	-Teacher professional development
Core 3	Rural 18 schools 7,000 students	Title I: 71% Black: 33% Latinx: 2%	-Teacher buy-in -Content integration	-Assessment of implementation
Pilot 1	Large Urban 329 schools 269,098 students	Title I: 58% Black: 39% Latinx: 35%	-Teacher support for existing CS/CT initiatives	-Evaluation/observation tools -Alignment with industry certification
Pilot 2	Suburban 5 schools 3,606 students	Title I: 13% Black: 3% Latinx: 31%	-Elementary integration	-Middle and high school integration
Pilot 3	Rural 2 schools 1,019 students	Title I: 3.9% Latinx: 7%	-Alignment with existing initiatives -Teacher buy-in	-Teacher resources for integration -Professional learning

Conclusion and implications

Although each district made many different choices about their computing pathway, we discovered many commonalities in best practices for pathways development that were invaluable and warranted fostering for future district-to-districts connections. Specifically, we found that developing a shared vision, conducting a needs assessment, and encouraging follow up interactions were helpful in facilitating a community of collaborative learning for district leaders. In future iterations of our CoP, we will facilitate “on the ground” learning among district leaders, traveling to one district for classroom visits and student/teacher conversations in order to experience an existing computing pathway and collectively consider where their own goals and plans may overlap or differ. Through our ongoing process of design and refinement, we plan to use our learning to develop empirically-supported resources, tools, and measures to support a growing network of school districts nationwide to engage in sustained, regular conversation and collaborative problem solving about computing pathways.

Sewing and Weaving Data: Analyzing Fiber Crafts as Context for Performing Data Processing and Storing

Anna Keune, Technical University of Munich, anna.keune@tum.de

Abstract: Fiber crafts, including sewing, are connected to the history and future of computing. Yet, they are underrepresented in computing education. This qualitative study analyzed performed an iterative thematic analysis of artifact analysis sessions in which computer science experts examined middle school students' craft projects for evidence of challenging computer science concepts. This paper shows a weaving and sewing craft as context for performing data processing and storing with implications for computing education.

Introduction

Tangible manipulatives enable exploration of unfamiliar concepts through culturally-relevant body-based interactions (Horn, 2018). Using tangible manipulatives to facilitate computational learning is particularly compelling for students who are new to computing because the tools can readily provide access to complex computational ideas at an early age (Bers, et al., 2019). Materials like looms and fabric are traditionally associated with practices of people who are underrepresented in computing and are strongly connected to the history of computing (Abbate, 2012) as well as more recent computational development (Devendorf & Di Lauro, 2019). Yet, fiber crafts are often overlooked in computing education–apart from examples that the present study leans on an seeks to expand. Within educational research, electronic textiles (Buechley, 2006) have consistently proven to be a cogent context and notable exception for introducing youth—especially girls—to STEM disciplinary concepts, including accounts of circuitry learning (Pinkard et al., 2017). Fiber crafts have the potential to disrupt how we think about computing education especially because they introduce materials that are typically linked to decorative practices (Kafai et al., 2021; Keune et al., 2020).

Work is needed in the learning sciences to consider how the specific materials of fiber crafts (in this study weaving and fabric manipulation) align with computational ideas. Understanding how fiber crafts are aligned with computation can inform the creation of more diversity-oriented contexts. To investigate fiber crafts as a context for computing, I asked: *How do weaving and fabric manipulation support engagement with computation concepts (especially data processing)?* This qualitative study aligned fiber crafts with computational ideas through artifact analysis sessions of fiber artifacts by computer science experts. Craft projects were translated into pseudocode, a description of an algorithms in plain language, to illustrate computational concepts required for the crafts. The findings provide empirical evidence that crafts require engagement with processing and storing data with material parts and other computational concepts relevant for computational learning.

Methods

This qualitative study investigated fiber crafts for computational learning. The context of the study were university settings within which artifactual analysis (Pahl & Rowsell, 2019) of craft projects were conducted with computer science instructors at research-focused universities who were identified through university websites and recruited via email. Data sources came from the recorded artifactual analysis sessions with the instructors and focused on the instructors' experiences teaching computer science courses followed by a close look at fiber crafts artifacts to surface how fiber craft projects included computation. The analytical focus lay on understanding how the aspects mentioned by the instructors related to K12CS concepts (i.e., algorithms, variables, control structures, modularity, and troubleshooting) and beyond (e.g., data processing, memory). The explanations further served to translate the fiber crafts artifacts into pseudocode to highlight computational concepts. Some of this translation process was started by the instructors but expanded to illustrate how the crafts' material doings relate to computation.

Findings: Processing and storing data with material parts

Findings showed that instructors aligned the crafts with processing and storing data through material parts. The instructors recognized weaving as the organization of data in memory and the production of fabric rows as the exploration of data structures that were written into the memory of the fabric. One example of this was the gap that crafters produced by weaving with two separate shuttles, as if processing "two data structures at once," as one instructor explained. To produce the pattern, crafters wove mirroring row-by-row patterns. In the example project, the crafter passed blue yarn from right to left and yellow yarn from left to right to the center of the threads on the loom. When heddle positions changed (i.e., the loom threads changed positions), both yarns were moved in opposite directions toward the outer edges of the loom. The data that was stored within the fabric functioned like memory of the state of the computer and one instructor explained: “The state of the computer basically means, what is in the memory right now . . . This is useful for tracing what the algorithm did over time.” According to the instructor, the fabric showed the evolution of the computer state over time, one horizontal thread at a time. Typically, this kind of memory gets overwritten in the computer.

The instructors also recognized the organization of data in memory with fabric manipulation. The crafting process in fabric manipulation depended on the number, location, and distance of visible intersection points on the matrix that were sewn together. Instructors identified the intersection points as variables that crafters had to engage to produce a pattern. For example, an instructor explained: “The dot . . . can be represented as a variable. And their coordination change[s] over time as you’re sewing. Or their relation[ship], their distance changes, so they move around.” The instructor proceeded to write a list of variables that would be filled as crafters selected which intersection points on the matrix (i.e., dots) to sew together. The sewing process changed the position of the intersection points as well as the distance between points, which produced folds. The instructors recognized the produced fabric folds as writing data to memory. One of the instructors said: “This is how the processor and memory work together. All they know about are locations of data, [its] coordinates, and what operations we can do on this data.” Instead of producing machine-state memory, the graphic sewing pattern presented data that could be transposed onto the fabric through the language of stitches.

Discussion

Looking across how fiber crafts that the computer science instructors identified as computational presents fiber crafts as a promising context for computational learning, especially learning about data storage and processing. The machine state memory woven into the fabric made it possible for crafters to retrace, undo, and redo parts of their fabric designs. This further suggests alignment with troubleshooting that would need further investigation. Additionally, altering matrix structures can show how structures–whether grid points on fabric or thread arrangements on looms–direct performance. The contrasting engagement across two matrix-based crafts highlights the potential of designing for matrix play as a way to make computing a linear as well as a spatial artifact transformation process. Matrix play can make it possible to think three-dimensionally from the start, which can be useful for programming and algorithmic thinking that takes place in three-dimensional space with structures and matrices rather than on a flat plane (e.g., computational architecture, construction engineering).

Does the Emergency Switch Make a Difference in STEM Motivationally Supportive Instruction? Comparing Instructors' Motivational Support Across Pre-Pandemic In-Person and During-Pandemic Online STEM Learning Environments

Qiyuan Zheng, Kristy A. Robinson
qiyuan.zheng@mail.mcgill.ca, kristy.robinson@mcgill.ca
McGill University

Abstract: Due to the global pandemic, universities experienced an emergency switch from in-person to remote teaching, which likely prompted changes in instructors' motivationally-supportive instruction. The present study investigated how instructors supported students' motivation through relevance statements, supporting autonomy, and showing their enthusiasm in pre-pandemic in-person and pandemic online STEM learning environments. Findings from lecture recording segments in 2019 and 2020 demonstrated instructors' in-class motivational support differed across the two learning conditions.

Introduction

Prior empirical studies offered a promising clue that teachers' teaching practices can have a positive influence on students' motivation outcomes in postsecondary school contexts, but little is known about how teachers supported students' motivation in different contexts (Canning et al., 2019). Previous findings indicated that teachers might change their instructional strategies in different learning environments or over time (De Meyer et al., 2016). Hence, it is imperative to detect what specific strategies they chose in different environments corresponding to the changes in instructional practices.

Due to the outbreak of the pandemic, the major delivery method in university-level STEM education has experienced an emergency change from in-person to online. The sudden shift in the learning environments, together with the COVID stress (Arslan & Allen, 2021), exacerbated the challenges for both students and instructors. Therefore, there is a need to explore whether instructors have offered adaptive motivationally supportive instruction in class to tackle the negative impacts brought by the social circumstances.

To build a foundation of knowledge about instructors' in-class motivational support in two learning environments, this study focused on capturing evidence of instructors' in-class motivational support observed from the lecture videos. Toward that end, the proposed study addresses the following research questions: a) How did instructors support students' academic motivation in pre-pandemic in-person and pandemic online university-level STEM courses? b) What similarities or differences can be observed in instructors' in-class motivational support across pandemic online and pre-pandemic in-person learning environments?

Theoretical framework

Classical motivation theories, including self-determination theory (Ryan & Deci, 2000) and situated expectancy-value theory (Eccles & Wigfield, 2020), have offered theoretical guidance for supporting students' motivation from different but associated perspectives. Grounded on those theories, autonomy-supportive teaching, relevance statements, and teacher enthusiasm in class are effective in motivating students. Comparing instructors' motivational support between online and in-person learning environments by analyzing the observational data and investigating how instructors' instructional strategies might change under the transition of learning environments filled the research gap by regarding instructors as important socializers and demonstrating how instructors' motivational support worked in real-world educational settings.

Research design

The lecture video recording data was gathered during two separate years for one introductory chemistry course at a large university in Canada during Fall 2019, when instruction was conducted in person in a large lecture hall, and Fall 2020, when instruction was conducted online via Zoom platform due to the COVID-19 pandemic.

For analysis, lecture recordings were divided into segments of approximately 10 minutes each, then matched across 2019 and 2020 by the topic and instructor. This resulted in a total of 173 video segments, 107 from Fall 2019 and 66 from Fall 2020. Preliminary analyses started with descriptive statistics using the dataset directly obtained from the coding results so as to gain an overview of instructors' motivational support in two semesters. To further investigate the differences and similarities across two learning environments, this study conducted a repeated-measures MANOVA and paired sample *t*-tests as post-hoc tests to examine the specific differences of every coding item under the three main measures.

Findings and discussion

From the qualitative evidence, instructors' motivational support varied in different environments. For example, the most frequently used domains in relevance were connecting to routine activities and everyday life (32%) in 2019. However, instructors often connected the content to previous knowledge (28%) in 2020, while connecting to the routine events (21%) ranked second. Results also revealed the similarities across the two years. For instance, no evidence has been found that instructors have built connections between chemistry learning and students' career choices, displayed patience, and responded to students' negative emotions in both teaching scenarios.

Overall repeated-measures MANOVA demonstrated that instructors supported students' motivation differently by using differing amounts of relevance statements, autonomy support, and enthusiasm across the two learning environments. Specifically, instructors made more relevance statements and demonstrated more enthusiasm in the pandemic online learning environments than in pre-pandemic in-person learning environments. Instructors' autonomy-supportive teaching obtained higher scores in pre-pandemic in-person learning environments than in the pandemic online learning environments. Paired-samples *t*-tests were conducted to explore which detailed supporting strategies have the most salient differences. For relevance statements, bridging to understand a concept in the current chemistry class and providing explanatory rationales for procedure across two semesters experienced a significant change, meaning that instructors were more likely to connect the current learning materials to prior knowledge and identify the value and utility for students in 2020 online learning environments. Significant differences were also detected in the specific sub-facets of autonomy supportive teaching, where the rating scores were significantly higher for caring about students during in-person schooling.

In alignment with prior studies (e.g., De Meyer et al., 2016), this study revealed a homogenous conclusion that instructors' motivationally supportive strategies varied based on the learning environments. However, differently, instructors tended to have more relevance statements and show enthusiasm, but less autonomy-supportive in pandemic online schooling. Considering that the Zoom platform has become a lifeline for students and instructors during the global pandemic, this emergency and necessity might have various impacts on instructors, including negatively affected their motivational job characteristics but improved their teaching abilities (Beardsley et al., 2021). Thus, further research is needed to identify the differences and similarities of motivational support among pre- and post-pandemic, and during-pandemic online teaching. By examining the final grades across two semesters, students in pandemic online learning environments achieved higher academic performance in their final grades than in the pre-pandemic in-person settings ($M_{2019} = 80.06$, $M_{2020} = 91.84$). It worth noticing that even though global pandemic introduced additional challenges for instructors to support students' motivation in online learning, adjusting the utilization of various motivationally supportive strategies and making the maximum use of them appears to be possible.

Given the differences and similarities between pre-pandemic in-person learning environments and pandemic online learning environments in undergraduate STEM disciplines, it is essential to provide STEM faculty with a holistic overview of how they supported students' academic motivation. Such rigorous descriptions might also encourage them to implement more targeted and effective in-class motivationally supportive instructions in both learning conditions.

Developing Undergraduate Students' Competence in Reasoning About Bodies of Evidence

Hiroki Oura, Tokyo University of Science, houra@rs.tus.ac.jp
Toshio Mochizuki, Senshu University, tmochi@mochi-lab.net
Clark Chinn, Rutgers University, clark.chinn@gse.rutgers.edu

Abstract: Citizens are vulnerable to biased claims in social media based on *cherry-picked evidence*—i.e., claims supported by one or two studies when most studies support a different claim. We report results of an instructional study that investigated whether undergraduate students can improve their reasoning about such bodies of evidence and thereby make epistemic judgements that give preference to claims supported by larger bodies of evidence rather than one or a few studies. Results show that students who received instruction were more likely to prefer claims supported by larger bodies of evidence and also rated sources that cited such evidence as more trustworthy.

Introduction

Citizens often face situations in which they need to seek answers on a topic (such as the safety of vaccinations) but soon discover that information sources present conflicting claims (Lewandowsky et al., 2017). However, sources often present an incomplete picture of what the evidence says—citing just one or two studies when there may be dozens or even hundreds of relevant studies. Furthermore, when sources present just one or two studies, they may misleadingly cherry pick one of the few studies that support one position, ignoring the majority of studies on the other side. Our previous research has demonstrated that Japanese undergraduate students frequently favor positions supported by single studies over positions studies by a large majority of all studies, and they also pay little attention to whether evidence is cherry picked or not (Oura et al., 2022). In this study, according, we developed and examined a one-week instructional program to foster a preference for basing judgments on larger bodies of evidence rather than on just one or two studies.

Method

Participants were 150 undergraduate students in an online introductory education course at a public university in Japan. The students engaged in all procedures individually. The design was experimental with two conditions (no-instruction versus instruction), and students were randomly assigned to one condition. The experiment consisted of two instruction and one assessment phases as follows. The first instruction set aimed to develop students' competence in basing epistemic judgments on larger bodies of evidence instead of one or two pieces of evidence. To this end, we developed three documents (A, B, and C) on the topic of whether a drug (called "IFC") has a positive effect on curing a tropical form of hepatitis. In Document A, an expert author claimed that it is effective based on two described medical experiments. In Document B, another expert made the same claim based on the description of one experiment. In contrast, the expert author of Document C made a conflicting claim that IFC has no effects on curing hepatitis, based on a meta-analysis. Students in the *no-instruction* condition read and summarized each of these three documents. In contrast, students in the *instruction* condition were given PFL-based instruction with an invention task followed by formal instruction (Schwartz & Martin, 2004). Specifically, they were first asked to read the three documents and rank them based on the strength of evidence each presented; then they developed as many characteristics and criteria for the strength of evidence as possible. After the invention task, they were given text-based formal instruction in which one student and teacher discussed conversationally how to evaluate the strength of evidence.

The second instruction set aimed to develop students' competence in evaluating the trustworthiness of authors who cite evidence to support their claims. We developed four tweets (A, B, C, and D) by four different authors on the topic of whether sucratame, a "fictitious" artificial sweetener, increases the risk of cancer. The author of Tweet A claimed that it increases the risk of cancer based on "one large-scale study." The author of Tweet B claimed conversely that it does not increase cancer risk based on "most of studies" with no specific studies cited. In contrast, the author of Tweet C claimed that it increases cancer risk based on 25 studies in which 72% of them showed some increase of cancer risk. Lastly, in Tweet D, the author claimed there was no increase of cancer risk based on "a study conducted in 2008" stating that he "read various studies." As with Instructional Set 1, students in the *no-instruction* condition read and summarized major points of the four tweets. In contrast, students in the *instruction* condition read and ranked the four tweets in terms of strength of evidence and built on their previous list of invented criteria to decide which claim is supported by stronger evidence. After the invention task, they were given text-based formal instruction in which the same student and teacher discussed how to evaluate the trustworthiness of authors based on their expert knowledge in the focal topic.

Our assessment examined whether students could make judgments about claims based on larger bodies of evidence (i.e., all the studies available), rather than on one or a few studies, which might further be cherry picked. For the assessment, we developed three documents (A, B, and C) making conflicting claims on the relationship between rewards and work performance. The author of Document A, a business journalist, claimed that rewards increase work performance (*pro-rewards* claim) based on two studies whose evidence supported their claim. In contrast, the author of Document B, a business researcher, made a conflicting claim that rewards decrease work performance (*anti-rewards* claim) based on a meta-analysis analyzing 91 studies. Document C, by an experienced business journalist, also made the *anti-rewards* claim but based this conclusion on a single study. The assessment was conducted one week after the two instruction sets. Prior to reading the three documents, students answered two pre-survey items to measure their prior positions on both pro-rewards claim that rewards increase work performance and the anti-rewards claim that rewards decrease work performance. After this pre-survey, students read the three documents and answered seven post-survey items to measure their post positions on both claims, the strength of evidence on both positions, and the author trustworthiness on each document. All the responses were on 7-point Likert scale (1 = strongly disagree and 7 = strongly agree).

Results

There were no significant differences between the conditions in the variables before reading the three documents. Prior to reading the documents, students in both conditions strongly endorsed the *pro-rewards* position and were strongly against the *anti-rewards* position. In contrast, significant differences were found for most post measures with the p-value thresholds adjusted by the Bonferroni correction. Specifically, students with instruction rated the *pro-rewards position* significantly lower than no-instruction students ($\eta^2 = 0.07$). They also rated the anti-rewards position higher than no-instruction students ($\eta^2 = 0.03$), although this difference was not statistically significant. For strength of evidence, in comparison with no-instruction students, instructed students gave significantly lower ratings for *pro-rewards strength of evidence* ($\eta^2 = 0.11$) and significantly higher ratings for *anti-rewards strength of evidence* ($\eta^2 = 0.06$). For ratings of trustworthiness of the three sources, instructed students gave significantly lower ratings for *trust in Documents A and C* (both of which cited just one study) ($\eta_A{}^2 = 0.15$, $\eta_C{}^2 = 0.14$); they gave significantly higher ratings for *trust in Document B* (that reported a meta-analysis) ($\eta_B{}^2 = 0.07$).

Discussion

The instruction produced important changes in students' epistemic judgments. In comparison with uninstructed students, instructed students found Document B—the one document that presented a synthesis of research (a meta-analysis) rather than one or two studies—more trustworthy, and the documents that presented just one or two studies less trustworthy. In addition, in comparison to uninstructed students, they viewed the evidence for the pro-rewards position to be weaker, and the evidence for the anti-rewards position to be stronger. These results indicate that students can improve their reasoning about larger bodies of evidence our instruction based on Preparation for Future Learning, which scaffolded students to attend more to the bodies of evidence rather than one or two studies only. Further research also is needed to investigate ways of instruction in other situations, for example, when descriptions of evidence are insufficient when reading multiple documents.

Building a Science Concept Recognition System Using NLP From Elementary Students' Science Storybooks

Lingchen Kong, Wallace Nascimento Pinto Junior, Jinnie Shin
l.kong@ufl.edu, wallace.pintojun@ufl.edu, jinnie.shin@coe.ufl.edu
University of Florida

Abstract: Despite the benefits of reading instructions, limited studies exist on recommending suitable learning resources for children's science education. To create a recommendation framework, identifying science learning resources that encompass science concepts that are adequate for the grade level is vital. In this study, we collected 52 science books for grades 3 to 5, extracting science concepts using named-entity recognition algorithms. Our findings could identify close to 3,000 science concepts entities across various science topic categories.

Introduction

Troubling trends in recent statistics and research evidence stress the need for improvement in reading comprehension skills for upper elementary school students in the U.S. (NAEP, 2022). The 2017 administration of NAEP revealed that 65% of 4th-grade students are not proficient readers. Studies further indicate that close to 15% of grade 5 students' achievement in science can be attributed to their reading comprehension of science passages (Taboada, 2012). Taken together, these results underscore the critical need for effective reading instruction for science performance. As an indispensable tool for doing and learning science as noted by the Next Generation Science Standards (NGSS) and The Common Core State Standards (CCSS), reading enhances the content understanding, promotes inquiry and conceptual change, contributes to knowledge building, and cultivates scientific habits of mind. However, providing appropriate science resources that satisfy students' needs is a challenging task. Oftentimes, the issues stem from the inability to locate appropriate science storybooks in a timely manner (Goldman & Bisanz, 2002), and the difficulties in connecting various science concepts to specific book contents (Pearson et al., 2010). To identify the appropriate resources that introduce adequate and diverse conceptual information for children's science learning, our study focuses on analyzing children's books to understand the underlying science topics. We demonstrated the use of the natural language processing approach, named entity recognition algorithm (Shelar et al., 2020) that is specifically trained to extract science concepts. The following research questions were addressed to guide the study:

1) *What are the common science concepts introduced in science storybooks for grades 3 to 5 students?*
2) *To what extent the use of the natural language processing approach, specifically the entity recognition algorithms, can identify and extract varying science concepts from storybooks?*

Methods

Our analysis was conducted in three stages. First, a total of 52 STEM-focused children's books for grades 3 to 5 were randomly extracted from publicly available repositories using a Python package, *PyPDF2*. To reduce the noise in the text data, we skipped the publication content (e.g., year, author, publisher) that commonly presents in the first two to three pages. We then preprocessed the data by applying sentence tokenization, removing redundant space, punctuations, symbols, and stop words, and applying lemmatization. Second, we created bi- and tri-gram models to train a science concept extractor using the named entity extraction approach. Given that most science concepts are presented in noun phrases, we utilized Part of Speech (POS) tagging to match all possible noun phrases as our science concept candidates, then computed the word similarities for each candidate using the science glossary resources. If the maximum similarity score exceeds the conventional cut-off of 0.3 (Rekabsaz et al., 2017), we categorized it into the concept category with the highest score. Table 1 provides an example of the glossary resource we created that was used to identify the science concepts from the children's books. Last, we compared the results with the naive named entity extraction results qualitatively. A quantitative evaluation involving two human raters will be provided.

Table 1
An Example of Science Concepts and Definitions

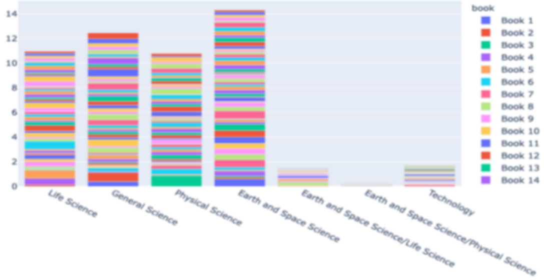
Source	Grade	Year	Category	Term	Definition
STEMscopes Alabama	5	2015	Earth and Space Sciences	Atmosphere	The layer of gas surrounding planet Earth, held in place by gravity and composed of a limited number of elements, primarily nitrogen and oxygen.

Results

A total of 3,620 unique science concepts were identified (see Figure 2b) from the children's storybooks. Figure 1a shows the proportion of science concepts identified from the 52 training books. We calculated the proportion of concepts in each science category and added them to determine the dominant representation of science concepts among the training sets. Results indicate that children's books frequently introduced science concepts from the "earth and space sciences" category (27.5%), followed by general science (23.9%), life sciences (21.1%), and physical sciences (20.7%). Relatively small concept entries were identified from the earth and space sciences/life sciences (0.29%) and earth and space sciences/physical sciences (0.0%), and technology (0.33%) categories.

Figure 1

(a) Science Concepts Categories in Storybooks (left) and (b) Total number of science concepts identified (right)

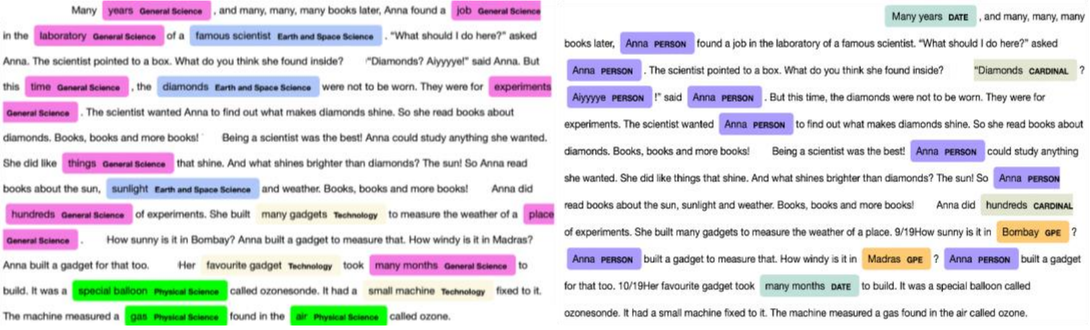


Category		
Life Sciences	Frequency	N books
General Science	738	48
Physical Sciences	965	48
Earth and Space Sciences	769	49
Earth + Life sciences	900	52
Earth + Physical Sciences	94	23
Technology	19	16
Total	135	35

We also compared our concept extraction approach with a widely adopted named entity recognition system (Spacy; Vasiliev, 2020) to show the shift in focus of entity extraction. Figure 2 shows this side-by-side comparison where our approach categorized words such as "years" and "months" as general science concepts, while the entity recognition algorithm classified them as "date" information. We believe this is because general science concepts often include concepts that are related to experiments and collecting information over a period (years or months) to draw conclusions. Further quantitative evaluation will be conducted and provided to support the accuracy and effectiveness of our approach.

Figure 2

An Example science concept (left) and named entity extraction (right) results.



Many years General Science , and many, many, many books later, Anna found a job General Science in the laboratory General Science of a famous scientist Earth and Space Science . "What should I do here?" asked Anna. The scientist pointed to a box. What do you think she found inside? "Diamonds? Aiyyyye!" said Anna. But this time General Science , the diamonds Earth and Space Science were not to be worn. They were for experiments General Science . The scientist wanted Anna to find out what makes diamonds shine. So she read books about diamonds. Books, books and more books! Being a scientist was the best! Anna could study anything she wanted. She did like things General Science that shine. And what shines brighter than diamonds? The sun! So Anna read books about the sun, sunlight Earth and Space Science and weather. Books, books and more books! Anna did hundreds General Science of experiments. She built many gadgets Technology to measure the weather of a place General Science . How sunny is it in Bombay? Anna built a gadget to measure that. How windy is it in Madras? Anna built a gadget for that too. Her favourite gadget Technology took many months General Science to build. It was a special balloon Physical Science called ozonesonde. It had a small machine Technology fixed to it. The machine measured a gas Physical Science found in the air Physical Science called ozone.

Many years DATE , and many, many, many books later, Anna PERSON found a job in the laboratory of a famous scientist. "What should I do here?" asked Anna PERSON . The scientist pointed to a box. What do you think she found inside? "Diamonds CARDINAL ? Aiyyyye PERSON !" said Anna PERSON . But this time, the diamonds were not to be worn. They were for experiments. The Effects of AI Feedback on Students' Epistemic Emotion and Performance in Engineering Design: An Exploratory Study

Juan Zheng, Lehigh University, juan.zheng@lehigh.edu
Rundong Jiang, Institute for Future Intelligence, rundong@intofuture.org
Shan Li, Lehigh University, shan@lehigh.edu
Jiayan Zhu, Lehigh University, jiz621@lehigh.edu
Charles Xie, Institute for Future Intelligence, charles@intofuture.org

Abstract: One of the affordances of AI (Artificial Intelligence) for professionals is that AI can explore a much wider solution space to arrive at creative solutions that surprise them. This study explored the epistemic emotion of surprise and its effect on students' performance as they used AI feedback to assist their engineering design. Specifically, we examined 43 high school students' emotional reactions and their changes in design solutions after receiving AI feedback. Multinominal regression was performed to find that AI feedback did not have a significant influence on the level of surprise students experienced. However, most students made more positive changes to their designs when they found that AI feedback was much better than their original solutions. This study suggests that integrating AI elements in engineering design could help students optimize their designs.

Introduction

There is a trend of integrating AI elements into STEM (i.e., science, technology, engineering, and mathematics) education for cultivating students' cross-disciplinary knowledge and creative thinking to solve authentic problems in real life. However, students find it challenging to understand how AI works and how AI feedback could benefit their learning process (Touretzky et al., 2019). This is particularly true in the context of engineering design. Engineering design involves the integration of relevant STEM knowledge and the constant development of design outcomes (Zheng et al., 2020), during which surprise may occur and may affect students' iterative modification and refinement. However, there is limited research exploring students' epistemic emotions in engineering design. Thus, this study aims to examine the occurrence of the epistemic emotion of surprise and its effect on students' learning and performance when they use AI feedback in engineering design.

Methods

Figure 1
Interface of Aladin

This is part of a larger study where 43 students from two suburban Midwestern high schools learned science concepts, performed engineering design, and utilized AI feedback in a simulated learning environment (i.e., Aladdin). In the current study, students were asked to redesign a profitable solar farm, which generated more annual revenue from the produced electricity and less annual cost caused by installing and maintaining solar panels. In Aladdin (see Figure 1), students can have access to a variety of construction, visualization, and analysis tools (Zheng et al., 2020). More importantly, AI feedback leads students toward a comprehensive understanding of all design variables. The AI feedback is produced through an evolutionary computation process that systematically searches through various variables or parameters to identify optimal solutions under certain criteria and constraints (Xie et al., 2022). As displayed in the bottom left of Figure 1, the AI presents a dynamic graph to show how AI achieves the optimal design through a series of evaluations and generations. Students were encouraged to refine their designs after receiving AI feedback. We then used two open-ended questions to examine students' feelings of surprise. i.e., *If you are surprised by how AI changed the design variables, can you explain why? If you are not surprised by how AI changed the design variables, can you explain why you are not surprised?* To categorize students' responses, we designated them as "surprised" if they reported solely surprised variables, "not surprised" if they reported exclusively unsurprised variables, and "partially surprised" if they indicated surprise towards some design variables but not others. Finally, students' performance change was calculated by subtracting the student's final design profit (after receiving AI feedback) from the student's original design (before receiving AI feedback).

Results

After receiving AI feedback, most students were partially surprised (N = 24). However, some other students felt either not surprised at all (N = 8) or totally surprised (N = 11). Students felt totally surprised when the AI design was much better than their original design, whereas some other students were not surprised when the AI design only made a slightly more profit or made the same profit. For example, student CP5S9 said, *"I am surprised because I didn't realize how much the tilt angles could change through the seasons. There is a sort of spot that is the greatest, but that more appropriately has the tilt angles."*. In contrast, student *CP5S7* commented, *"I am not surprised because the AI did not change anything to my final design."*. In addition, we found that students' performance change was positively correlated with AI feedback. The majority of students made more positive changes to their design when they found that AI design was much better than their original design.

Discussion and conclusion

This study explored the epistemic emotion of surprise and its effect on students' learning and performance when they received AI feedback in engineering design. We found that AI feedback did not have a significant influence on the level of surprise students experienced. This unexpected finding may be due to students' different epistemic beliefs on AI feedback. Students' epistemic belief is a significant antecedent of epistemic emotions (Muis et al., 2018). Students who valued AI feedback would be surprised when AI provided limited design suggestions about their design. Meanwhile, students who had high belief in their original design may not feel surprised at a mild change made by AI.

Furthermore, most students made more positive changes to their design solution when they found AI feedback was much better than their original solution, whereas a few students failed to make significant changes to their final design. This finding suggested that a larger change made by AI induced more effort from students in iterative design and better final performance. Therefore, instructors and designers should present AI feedback in a way that highlights the improvement made by AI to maximize its utility. In addition, some students still need assistance in understanding AI feedback and making corresponding changes to their original design. This suggests the necessity to increase students' AI literacy so that students can use AI feedback effectively (Long & Magerko, 2020). In summary, the findings of this study corroborate the effectiveness of AI feedback on students' design performance, regardless of the level of surprise experienced by students. More research is needed to investigate the interplays of epistemic beliefs, epistemic emotions, and AI feedback in engineering design.

Do Thinking Styles Change With Task Complexity in Problem-Solving?

Juan Zheng, Lehigh University, juz322@lehigh.edu
Shan Li, Lehigh University, shla22@lehigh.edu
Xiaoshan Huang, McGill University, xiaoshan.huang@mail.mcgill.ca
Tingting Wang, McGill University, tingting.wang4@mail.mcgill.ca
Susanne P. Lajoie, McGill University, susanne.lajoie@mcgill.ca

Abstract: In this study, we analyzed the differences in the three types of thinking styles (i.e., analytical thinking, dichotomous thinking, and metacognitive thinking) between tasks of varying complexity. The participants consisted of 31 medical students who were asked to think aloud while diagnosing two virtual patients in an intelligent tutoring system. We applied text mining on the participants' think-aloud transcripts to extract the metrics of analytical thinking and dichotomous thinking. We manually coded monitoring and self-reflection activities from the think-aloud transcripts as indicators of metacognitive thinking. The results showed no significant differences in participants' analytical and dichotomous thinking between a difficult and an easy task. However, participants demonstrated a significantly higher level of metacognitive thinking in a difficult task than in an easy task.

Introduction

Researchers and educators unanimously acknowledge the crucial role of thinking styles in learning and problem-solving. Despite its central importance to learning, the conceptualization and instrumentation of thinking styles/ skills are rarely treated explicitly by researchers. In this study, we take the initiative to examine the three types of thinking styles, i.e., analytical thinking, dichotomous thinking, and metacognitive thinking, based on several considerations. First, the three types of thinking styles, especially analytical and metacognitive thinking, are considered vital to our research context of clinical decision-making (Li et al., 2020). We are particularly interested in dichotomous thinking, which was deemed useful for quick decision-making (Oshio, 2012). Moreover, the three types of thinking styles involve strong linguistic components; therefore, standardized analytical techniques can be developed and applied to study those thinking styles of different samples.

In this study, analytical thinking is defined as the degree to which people use formal, logical, and hierarchical thinking patterns in problem-solving (Pennebaker et al., 2014). Pennebaker et al. (2014) proposed a categorical-dynamic index (CDI) to quantify analytical thinking across contexts. In terms of dichotomous thinking, it refers to a style of thinking that tends to be over-generalized and be in extremes (Boyd et al., 2022). Dichotomous thinking is also referred to as black-or-white thinking, right-or-wrong thinking, and all-or-none thinking (Oshio, 2012). Metacognitive thinking is the ability to "think about one's thinking". Metacognitive thinking involves monitoring one's thought processes and the resources, constraints, and progress in a learning or problem-solving condition. Through monitoring, learners establish the basis for self-reflection, whereby they (1) ask questions to themselves to check their understanding of learning products, (2) make attributional judgments about their performance, and (3) express their views, concerns, and emotions toward the task.

To our knowledge, no effort has been made toward examining the changes in the three types of thinking styles in tasks of varying complexity. Therefore, the overarching goal of this study is to examine whether and how task complexity affects the three types of thinking styles in clinical reasoning.

Methods

The participants comprised 31 medical students (67.7% females) from a large North American University. The average age of the participants was 23.45 (*SD* = 3.02). Participants were asked to diagnose two virtual patients in BioWorld, an intelligent tutoring system designed to foster self-regulated learning and clinical reasoning skills of medical students (Li et al., 2020). BioWorld is an inquiry-based learning environment, which allows participants to gather evidence, make inferences, and raise hypotheses in the process of diagnosing virtual patients.

Prior to the task, participants completed a consent form and a demographics questionnaire, followed by a 15-minute training session to help them get familiar with the BioWorld environment and think-aloud protocols. Participants were tasked to solve the *Pheochromocytoma* case (difficult) and *Diabetes* case (easy) independently, during which they were instructed to think aloud.

We analyzed participants' thinking styles (i.e., analytical thinking, dichotomous thinking, and metacognitive thinking) based on their think-aloud transcripts. Specifically, we used LIWC (Linguistic Inquiry and Word Count), a text-mining tool (Boyd et al., 2022), to extract students' analytic thinking and dichotomous thinking. Analytical thinking was assessed by the categorical-dynamic index (CDI), which captures the degree to which learners use formal, logical, and hierarchical words. Regarding dichotomous thinking, it was assessed by participants' use of absolutist language such as all, none, and never. Moreover, we used two strategies (i.e., topic representations and verbs) to segment the think-aloud transcripts into 2,792 meaningful idea units. We coded whether or not each unit involved metacognitive thinking (i.e., monitoring and self-reflection). In total, there were 1,048 units coded as involving metacognitive thinking. The inter-rater reliability was .813. We used paired t-tests to compare the differences in the three types of thinking styles between the two task conditions.

Results

As displayed in Table 1, there were no significant differences between the two tasks in analytical and dichotomous thinking. Nevertheless, the difficulty task yielded a significantly higher level of metacognitive thinking (*M* = 18.32, *SD* = 7.88) than the easy task (*M* = 14.23, *SD* = 6.85), *t* (30) = -2.97, *p* < .01.

Table 1
Paired t-tests for comparing students' thinking styles in the two task conditions

Thinking styles	Easy task		Complex task		t-test
	M	*SD*	*M*	*SD*	
Analytical thinking	16.47	12.12	16.01	9.84	.20
Dichotomous thinking	0.99	0.47	1.04	0.62	-.62
Metacognitive thinking	14.23	6.85	18.32	7.88	-2.97**

Note: ***p* <.01

Discussion and conclusion

We found that the participants did not differ significantly in analytical thinking and dichotomous thinking when solving a difficult and an easy task. However, the level of participants' metacognitive thinking increased significantly as the task complexity increased. One possible explanation is that analytical thinking and dichotomous thinking might be more trait-like personality variables, whereas metacognitive thinking is a more state-like construct. In this regard, task complexity could hardly affect how an individual typically thinks (i.e., thinking patterns). Future research is needed to investigate the nature of the three types of thinking. Moreover, there are two approaches to clinical reasoning: analytic reasoning and non-analytic reasoning (Li et al., 2020). At the heart of analytic reasoning is the objective analyses of a patient's symptoms, medical test results, and the probabilities of different diagnostic hypotheses. In non-analytic reasoning, physicians and medical students use personal experience and intuitive knowledge to diagnose patients. The two approaches of clinical reasoning also provide a potential explanation for our research findings. Despite differences in task complexity, participants' preference for a specific approach to clinical reasoning might to be relatively stable. As a result, no significant differences were observed in their analytical and dichotomous thinking skills.

This study has methodological importance and practical implications. First, this study represents an initiative to simultaneously examine different types of thinking styles in empirical research. While the basic notion that thinking styles are important to learning is not new, the attention given to thinking styles has often been in an abstract sense. We provided a clear definition of the three types of thinking styles. Furthermore, the techniques presented for capturing the three types of thinking styles inform future research of different disciplines and contexts. Pedagogically, findings from this study highlighted the important role of metacognitive thinking in tasks of varying complexity. For optimal teaching and learning, more focus might be needed on the scaffoldings of metacognitive thinking than analytical and dichotomous thinking.

Assessing Computational Thinking Attitudes in Empirical Research: A Systematic Review

Zexuan Pan, Hao-Yue Jin, Maria Jose Martinez Rodriguez, Yajie Song, Maria Cutumisu
zexuan4@ualberta.ca, hjin2@ualberta.ca, mariajo1@ualberta.ca, yajie6@ualberta.ca, cutumisu@ualberta.ca

Abstract: This study investigates how affective, behavioral, and cognitive components of computational thinking (CT) attitudes are measured in empirical studies. Findings show that (1) surveys were the most commonly used tools for measuring CT attitudes; (2) all three components were measured in CT studies; and (3) the affective component of CT attitudes was less likely to be measured compared to the behavioral and cognitive components. This review reframes the assessments of CT attitudes and provides a reference for researchers interested in measuring the attitudinal dimension of CT. Future studies are suggested to explore the alignment among the three components and the relationship between different components and CT skills.

Introduction

Computational thinking (CT) has been regarded as an essential ability for individuals in this technological age (Wing, 2006). Compared to the mastery of CT knowledge and CT skills, participants' CT attitudes have seldom been explored in the existing literature (Tikva & Tambouris, 2021). CT attitudes can be conceptualized as either the dispositional dimension of CT or the psychological antecedents/consequences of CT-related activities (e.g., programming, robotics, game play; Hooshyar, 2022). Regardless of conceptualization, a systematic understanding of CT attitudes is needed, as participants' internal states play a vital role in CT development (Tang et al., 2020; Tikva & Tambouris, 2021).

The current study aims to investigate how CT attitudes are measured in empirical studies. The following questions guide this study: What assessment tools were used to measure CT attitudes? What components of attitudes were measured in CT studies? What were the most frequently measured components of CT attitudes?

Methods

The present literature search was conducted using the Boolean expression "computational thinking" AND "(attitud* OR disposition* OR perspective* OR perception* OR affect*)" in six databases. First, the researchers screened the titles and abstracts of the 920 records (372 duplicates), excluding the publications that were not related to CT or not empirical (n = 379). Second, the researchers reviewed the full text of the remaining 161 publications independently, extracting those that met the inclusion criteria (n = 25). The reasons for exclusion were: publications that (1) measured STEM attitudes instead of CT attitudes (n = 76); (2) did not include the measurement of CT attitudes (n = 31); and (3) did not include details about the CT attitudes instrument (n = 29). The present study adopts Ostrom's ABC framework (1969), which has been used to explore students' states about digital data (Chi et al., 2018), to analyze the CT attitudes measured in empirical studies. In the ABC model, three components, namely affective, behavioral, and cognitive, are identified to represent different aspects of attitudes.

Findings

Assessment tools of CT attitudes

In the selected studies, surveys were the most commonly used tools for measuring CT attitudes (n = 20). Example items included "I think learning CT is interesting and valuable", "I can use CT to understand the problems in the real world", and "It is worth learning CT well". In addition to Likert-scale items, open-ended questions were used in two studies. While surveys typically served as the single assessment tool of CT attitudes, interviews, observations, and participant work samples were usually combined to provide evidence of CT attitudes (n = 4). Besides statistical analysis and qualitative content analysis, machine learning techniques were also employed to explore participants' CT attitudes (n = 1). The change in CT attitudes was assessed in seven studies, with the primary purpose of evaluating the benefits of CT instruction/intervention. The attitudinal change was measured by comparing participants' responses on the pre- and post-surveys (n = 6) or was inferred from participants' verbal responses and engagement patterns (n = 1).

Components of CT attitudes

The affective, behavioral, and cognitive components of attitudes were all measured in CT studies. In 17 of the selected studies, all of the affective, behavioral, and cognitive components were measured using surveys (n = 15), written reflections (n = 1), or multiple qualitative tools (n = 1). In six studies, only two components of attitudes were measured using surveys (n = 5) or multiple qualitative tools (n = 1). Two studies measured the single component of attitudes. Compared to the behavioral component (n = 24) and the cognitive component (n = 24), the affective component of attitudes was less likely to be measured (n = 17).

The *affective* component was typically measured by the items related to participants' interest, enjoyment, and confidence in learning, applying, and teaching CT, such as "I am interested in integrating CT in my teaching", and "I am excited to express new ideas through programming". The *behavioral* component was typically measured by the items related to participants' likelihood and tendency to apply CT (e.g., "When I am solving a complex problem, I try to break it up into smaller or simpler problems"), perceived capacity of applying and teaching CT (e.g., "I can use CT to understand the problems in the real world"), willingness to learn more about CT (e.g., "I will actively search for more information and learn about CT"), and intention to integrate and teach CT (e.g., "I will voluntarily teach kids CT if I were given the opportunity"). The *cognitive* component was typically measured by the items related to participants' perceived CT ability and knowledge (e.g., "I know how to connect new problems with acquired coding knowledge"), perceived importance and usefulness of CT (e.g., "It is important for everyone to take the CT course"), and CT teaching self-efficacy (e.g., "I know the steps necessary to teach CT effectively").

Discussion, implications, and conclusions

Although all three components were measured in CT studies, few studies examined the alignment and synergy among them. According to the principle of attitude consistency (Haddock & Maio, 2004) and findings from a meta-analysis (Glasman & Albarracín, 2006), a strong alignment among multiple attitudinal components can predict and guide future behaviors. In CT research, examining the alignment among the three attitudinal components may be conducive to predicting participants' future CT learning and teaching behaviors. Additionally, while the majority of the selected studies included CT-related activities and assessed both CT skills and attitudes, few of them investigated the relationship between CT skills and attitudes. Future studies are suggested to examine how each component of CT attitudes is associated with CT skills, which may help to design effective CT interventions and create personalized CT learning opportunities. Theoretically, this review examines the assessments and instruments used in CT studies, potentially advancing the operationalization and understanding of CT attitudes. Practically, this review presents a summary of the measurement of CT attitudes and serves as a reference for designing the assessment tools for the attitudinal dimension of CT.

A Design-Based Training on Teachers’ Math Knowledge for Teaching

Yanjun Pan, Fengfeng Ke, Chih-Pu Dai, Luke West, Jiabei Xu

Abstract: The current in-situ, descriptive case study explored the nature of the teachers’ involvement in game-based math task analysis and design, in relation to their potential portrayal and evolvement of pedagogical content knowledge and epistemic beliefs for teaching. Data were collected from 12 in-service math teachers at three suburban middle schools, through in-field observation, screen video archives, and semi-structured interviews. The study findings indicated that teachers’ design reflected their math knowledge for teaching. In addition, teachers were given opportunities to develop pedagogical content knowledge and epistemic beliefs for teaching.

Introduction

There is an increasing recognition of viewing teachers as designers (Li et al., 2019), particularly as learning experience designers. Strong evidence of the existing studies suggests that training teachers as designers of the learning environment and experience not only play a prominent role in teachers’ professional development (Bressler & Annetta, 2021; Li et al., 2019), but it also provides their students with opportunities to enhance creativity and problem-solving competence when teachers infuse design thinking in their lessons (Retna, 2016). Specifically, prior studies suggest that there are implicit and explicit associations between teaching and design. For instance, Henriksen et al. (2017) explored how teachers applied design techniques to their professional practices through an in-depth qualitative analysis of a graduate-level teacher education course. They found that design thinking is one of the most essential factors that determines creativity capacity to address teaching challenges in the real classroom practices.

Unfortunately, prior research suggests that teachers cannot automatically transfer the obtained knowledge of design into classroom practice (Bressler & Annetta, 2021). Therefore, we conducted the current study to explore the implementation and impact of a design-based training program that aimed to make teachers cognizant of designers of an active learning experience. We conjectured that having teachers experience the design process will activate their reflection on design and teaching. We engaged and studied teachers in test-playing and designing game-based mathematics tasks, aiming to make and examine the practice of design as both the means and outcome of teacher training. Specifically, the current study explored the nature of the teachers’ involvement in game-based math task analysis and design, in relation to their potential portrayal and evolvement of pedagogical content knowledge and epistemic beliefs for teaching.

Methodology

We adopted a descriptive case study approach (Yin, 2017) to explore how in-service teachers designed and developed a learning environment, in relation to their pedagogical content knowledge and epistemic beliefs for teaching. We enrolled 12 in-service math teachers at three suburban middle schools in the southeast United States. We held an 8-hour workshop which included the program orientation, the game test-playing, and the post-game discussion. We collected data via (a) screen video archives, (b) in-field observations, and (c) semi-structured focus group interviews to reach triangulation. We conducted systematic coding followed by thematic analysis for the qualitative data (Attride-Stirling, 2001). After transcribing all the screen-recorded videos and interviews, we developed an initial open-ended coding protocol highlighted notable patterns of coded narrative and the associations between contexts and learners’ actions. Meanwhile, a cross-case pattern analysis of the individual case was conducted to verify the validity of the coding system.

Findings

Learning environment design reflected teachers’ math knowledge for teaching

The first major theme emerging was in relation to math knowledge for teaching. Two subthemes were as follows: (a) systemic thinking incorporated by horizon content knowledge, and (b) interface design by considering students’ cognitive load.

Systemic thinking incorporated by horizon content knowledge

When a dyad of teachers at School C were engaged in designing the game-based math tasks for students, they intended to design multiple consecutive game levels for different graders (from 5th grade to 8th grade) with the same scenario. They increased the level of complexity by considering students' knowledge level at each grade. One of the two teachers articulated their design philosophy in the interview: "*We are actually doing a whole level [for students in different grades] because…um… we said for sixth graders they can use all four quadrants and solve one-step equations. And then the eighth grader does the reflection of the axis, so we can build each grade on that level*."

Interface design by considering students' cognitive load

Our data indicated that teachers paid attention to students' cognitive load and were able to apply the cognitive theory of multimedia learning to design instructional content when they were engaged in game-based math task analysis and development, particularly for the interface design of the learning environment. For instance, many participants commented on an example of interface design that violated the contiguity principle of multimedia learning, "*When you are looking at it, without the number system, and then when you get back without having that image and you go to the 'Challenge Me', that's too difficult*." In addition, they were able to point out which design followed the principle, "*I like this better with the explanation (i.e., texts) and the picture (i.e., graphics)*."

Evolution from uncertainty to certainty about using games for math teaching

According to the analysis of the teacher-researcher interactions during the game testing play, we found teachers' epistemic belief of using games for math teaching evolved from uncertainty to certainty. At the beginning stage, teachers demonstrated their uncertainty about using games for math teaching since they may not embrace game-based contextual math problems as a type of word problems that they used in the traditional classrooms, by commenting: "*We haven't really seen a word problem (in the game)*." On the contrary, at the final phase (i.e., the post-game discussion), many participants expressed their appreciation of using a game to help students learn mathematics and discussed how they will use it in practical teaching. "*I am teaching fractions. The problem that I come across is that whenever they are having to do the procedures of finding the denominator, having to line up, having to take a mixed fraction and make it into a proper fraction, the procedures of that and having that actually do these full steps are… that's the hardest thing to have them really buy into [the other female teacher: that's true] umm. I think this [E-Rebuild] can help*."

Discussion and conclusion

The findings indicated that teachers better developed their knowledge for design and teaching when they were actively engaged in test-playing and designing game-based math tasks for their students. In particular, their design solutions reflected their math knowledge for teaching. This is in line with the prior studies suggested that there were associations between teaching and design (e.g., Henriksen et al., 2017). Furthermore, we found that teachers were given opportunities to build new pedagogical content knowledge for teaching and to help develop their epistemic beliefs of teaching. Therefore, the design-based workshop could be a potential way of knowledge building and skill development for effective teaching practices.

Identifying Pre-Service Teachers' Cognitive Engagement Patterns Using Time Series Clustering in a Programming Activity

Hao-Yue Jin, Yajie Song, Zexuan Pan, Maria Cutumisu
hjin2@ualberta.ca, yajie6@ualberta.ca, zexuan4@ualberta.ca, cutumisu@ualberta.ca
Faculty of Education, University of Alberta, Edmonton, Canada

Abstract: Learners' cognitive engagement has been identified as a key factor affecting learning outcomes. However, limited research has focused on how dynamic cognitive engagement patterns influence learning outcomes. In this study, ninety-three pre-service teachers participated in an online computational thinking (CT) activity. Four patterns were identified using time series clustering: (1) low-engagement; (2) high-engagement; (3) early-engagement; and (4) late-engagement. The findings revealed that high- and late-engagement learners displayed significantly higher CT skills than low-engagement learners.

Introduction

Cognitive engagement is defined as the psychological investment students make toward learning, which ranges from simple memorization to the use of self-regulatory strategies for deep understanding (Fredricks et al., 2004). Several studies found that students exhibiting higher cognitive engagement are more likely to achieve higher learning performance (Putwain et al., 2018). Learning analytics techniques using log data have been applied to identify learners' engagement patterns in recent years to provide feedback to learners, instructors, and administrators (Abdullah et al., 2020).

Computational thinking (CT) is regarded as a thinking process of "formulating problems and solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent" (Wing, 2011). Cognitive engagement could influence CT because individuals who are more engaged in a learning task could potentially recognize patterns more readily and devise appropriate solutions. Therefore, this study developed an online CT activity and collected pre-service teachers' answers to several learning tasks. This study aims to: (1) extract learners' cognitive engagement from their responses; (2) group learners based on their cognitive engagement; and (3) investigate whether there is any difference in learning outcomes among learners with different cognitive engagement patterns. This study addresses the following research questions:

RQ1: Which types of cognitive engagement patterns can be identified in the learning activity?

RQ2: How do learners that display different cognitive engagement patterns vary in their learning outcomes?

Method

Ninety-three pre-service teachers were recruited from the Faculty's Research Participant Pool program at a large research-intensive University in Western Canada. The consent form and surveys were both administered online using the Qualtrics platform and distributed through the SONA system according to the ethics protocol Pro00112720. The participants completed the online consent form and pre-survey for an average of 20.1 minutes. To prevent fatigue, participants completed the intervention and the post-survey one week after the pre-survey, for an average of 45 minutes.

During the CT training section, participants were provided with four block-based programming learning tasks that included multiple-choice, sorting, and ranking items. After completing each task, participants were asked to briefly explain their responses.

The data sources consisted of the explanations that the participants were prompted to provide after each learning task. The Interactive, Constructive, Active, Passive (ICAP) cognitive engagement framework proposed by Chi and Wylie (2014) was adopted as the coding scheme because it is often applied in analyzing discussions in online courses. However, there were no interactive behaviors among participants or between participants and researchers. Thus, engagement was coded as constructive ('2'), active ('1'), and passive ('0') in this study.

A K-means time-series clustering technique was conducted to group participants by pattern similarity using R. The elbow method was used to determine the optimal value of K (i.e., 4 in this case) and then the K-means clustering algorithm for K = 4 was applied to the data. Then, a one-way ANOVA was conducted to examine the differences in learning outcomes (i.e., CT skills) among the four groups.

Results

The time-series clustering classified the participants into four groups: (1) Early-Engagement Learners: the learners displayed active or constructive engagement in the first two learning tasks, but they switched to passive engagement in the last two learning tasks; (2) High-Engagement Learners: the learners mostly displayed constructive engagement across all four learning tasks; (3) Late-Engagement Learners: the learners were more likely to display passive engagement in the first two learning tasks, but they tended to display active or constructive engagement in the last two learning tasks; and (4) Low-Engagement Learners: the learners mostly displayed passive engagement across all four learning tasks.

The results of a one-way ANOVA analysis revealed significant differences in pre-service teachers' CT skills across cognitive engagement patterns ($F = 3.13$, $p = .030$). The multiple comparisons on CT skills of different groups of participants revealed that high- and late-engagement learners significantly outperformed low-engagement learners. However, there was no significant difference among early-, late-, and high-engagement learners.

Discussion and conclusion

In this study, learners were categorized into early-, late-, high-, and low-engagement groups based on their written responses following several learning tasks and their CT skill differences among these groups were compared.

The cognitive engagement patterns identified are consistent with those identified in a study by Kuromiya et al. (2021), given that high-engagement groups significantly outperformed the low-engagement group on CT skills. This result suggests the importance of engagement for learning in CT activities. It was expected that high-engagement learners would achieve higher learning performance (Martin & Dowson, 2009). Thus, passive engagement learners could be identified as at-risk learners, so that teachers could provide them with appropriate guidance (Chamberlain et al., 2014) or apply load reduction instruction (Martin et al., 2021) to boost these learners' engagement and to eventually help them succeed in the learning activity. In contrast to other studies showing that early-engagement learners performed better than late-engagement learners (Kuromiya et al., 2021), the present study found that late-engagement learners performed better on CT skills compared to early-engagement learners. This could be explained by the duration of the learning process. For example, in Kuromiya et al.'s (2021) study, students' engagement during the summer vacation was measured using log data. In their study, early-engagement students completed the assignment and generated interaction data mainly in the first half of the vacation. The current study revealed that, although the late-engagement group was more likely to engage passively in the early stage of the learning activity, this group gained similar CT skills as the groups who engaged actively or constructively all the time. One potential reason could be that the difficulty of learning tasks was increasing and learners engaging in more difficult tasks were more likely to perform better (Lynch et al., 2013). Future studies could explore the interaction effects of task difficulty and cognitive engagement on learner performance.

A Systematic Review of Automated Feedback Generation in Empirical Educational Research

Yajie Song, Hao-Yue Jin, Zexuan Pan, Maria Cutumisu
yajie6@ualberta.ca, hjin2@ualberta.ca, zexuan4@ualberta.ca, cutumisu@ualberta.ca
Centre for Research in Applied Measurement and Evaluation, University of Alberta, Edmonton, Canada

Abstract: Automated Feedback Generation (AFG) has gained much attention as a way to revolutionize online feedback provision. This paper reviews 30 publications to systematically analyze the effectiveness of AFG in empirical educational research. Pre-defined templates, natural language processing, and comparison with correct answers are commonly used AFG methods. Results show that AFG positively impacts student learning and feedback quality. However, gaps in current AFG research were identified, and suggestions for improvement include expanding the use of AFG from higher education to K-12 education.

Introduction and conceptual background

Feedback is defined as "information about one's performance or understanding provided by an agent, which can be a person, book, experience, or computer" (Hattie & Timperley, 2007). Behaviourist learning theory argues that students should be provided with feedback and reinforcement to nudge their behaviours in a desirable direction (Chen, 2011). Several studies have acknowledged the benefits of feedback on student achievement. For example, students who receive immediate, tailored feedback display significantly larger learning gains than those in traditional group-based instruction (Wu & Chang, 2020). However, students claim that the quality and the quantity of feedback they receive are often not matching their expectations (Krause et al., 2005). Concomitantly, it is impractical for instructors to provide individualized feedback to each student, given the ratio of students to teachers, especially in massive online learning environments (Wu & Chang, 2020). Thus, AFG has the potential to solve these issues, as it could help scale instructors' efforts to design and deliver feedback to students that would address their individual misconceptions and knowledge levels.

The existing literature reviews on AFG have some limitations, such as restricted search databases, specific time spans, and insufficient focus on AFG methods, feedback types, and appropriate domains. To fill these gaps, the present review aims to answer the following research questions: (1) What are the characteristics of the existing applications of AFG? (2) What methods are often used to generate feedback automatically? What are the effects of different methods of AFG on learning outcomes?

Methods

This systematic literature review follows the PRISMA framework (Page et al., 2021) to screen and select studies. The databases selected for this review are ScienceDirect, SCOPUS, ERIC, and SpringerLink, which cover a broad range of topics, from education and computer science. The search string used was (automat* OR immediate OR individual OR formative OR adaptive OR intelligent OR student OR learner) AND (feedback OR hint) AND generat*, with no restrictions on domain or time span. Results were limited to peer-reviewed publications in English. Multiple rounds of exclusion resulted in 30 eligible studies for final coding. This review only includes empirical studies in education, focusing on the effects of AFG tools on learning.

Results and discussion

Characteristics of the existing applications of AFG

This review found that most AFG tools predominantly target higher education levels (N = 22), with less focus on primary and secondary education. The reason for this finding could be that most AFG tools are designed for programming and essay-writing domains, and students often start learning these two skills in higher education through formal courses. However, applying AFG in K-12 will benefit far more students as well as their teachers. The current success of AFG in its relatively short development history indicates unlimited future possibilities, such as designing scalable just-in-time adaptive formative feedback that addresses and combats student misconceptions and helps instructors identify and approach material that is more difficult for students to understand.

Methods and effects of AFG

Pre-defined templates commonly used for AFG have been employed by Quigley and Kiely (2021) to fill in a pre-defined feedback matrix using MS Excel functions and present it to students. Another method employed a graph to represent problem-solving steps, such as the procedural knowledge model (i.e., probabilistic graph) used by Fossati et al. (2015) to extract student interaction history with the system. Another method is to compare student submissions with correct answers, where correct answers are obtained from previous student submissions (Price et al., 2017) or provided by instructors (Kim et al., 2016). NLP methods are also prevalent in AFG applications, as most feedback is text-based. Most studies found positive evidence (N = 28) of their tools for student learning based on the quality of provided feedback. Two studies found no evidence or contradictory results about their tools facilitating student learning. Some reasons might be the small sample size (N = 18; Lodder et al., 2021) or teachers being skeptical about the feedback provided by their tools, even though students perceived feedback as being helpful (Gu et al., 2021). Nineteen studies reviewed present experimental evidence for the effects of their tools on student performance.

Contributions and implications

This study provides a comprehensive overview of empirical studies on AFG and suggests directions for future improvements, especially in the context of classroom formative assessments. The present study extended the existing AFG reviews by adding more databases for the search, removing domain restrictions, and summarizing AFG methods and the effect of feedback on learning for the two most frequently applied domains: programming and essay writing, thus informing further AFG development. The findings of this review can inform the development of new AFG tools and improve the implementation of existing tools for feedback generation, with the potential to ultimately enhance student learning outcomes. The findings of this study can contribute to ongoing discussions on how to leverage technology to improve education and the learning experience, making it a valuable addition to the conference program.

Integrating Perspectives to Promote Knowledge Integration: How Knowledge Integration, Learning Progressions and Instructional Science Can Complement Each Other

Marcus Kubsch, IPN – Leibniz Institute for Science and Mathematics Education, kubsch@leibniz-ipn.de

Abstract: Science education aims at equipping students with an integrated knowledge base that enables them to comprehend phenomena and draw evidence-based conclusions. The knowledge integration perspective, however, is domain-independent and lacks insights that offer guidance for designing learning environments. This conceptual paper seeks to bridge knowledge integration with learning progression and instructional science, exploring the potential for better understanding science learning and creating effective, evidence-based learning environments that support integrated knowledge development and knowledge-in-use.

Introduction

Modern science standards and international organizations emphasize K-12 students demonstrating knowledge-in-use where learners apply their knowledge to explain phenomena and draw evidence-based conclusions (Harris et al., 2019). Knowledge-in-use is based on well-developed knowledge networks that are organized around core ideas (Linn et al., 2015). Designing instruction that fosters integrated knowledge requires combining domain-specific content models and domain-general instructional models (e.g., Koedinger et al., 2012). The challenge lies in meaningfully connecting these perspectives. This contribution aims to bridge these perspectives by exploring how knowledge integration, learning progressions, and instructional science complement each other.

Promoting knowledge integration in the science classroom

The goal of science learning is to engage learners with scientific phenomena so that they can develop a scientific understanding of the world and apply their knowledge to the problems they encounter. To this end, students need to develop knowledge-in-use (Harris et al., 2019) which rests on a well-integrated knowledge base (Bransford et al., 2000). The idea of integrated knowledge draws from the notion of semantic networks that represent explicit declarative knowledge in long-term memory. One way to promote a normative understanding of scientific phenomena are guided-inquiry activities which confront learners with novel (normative) ideas that challenge their current (often non-normative) understanding. In the best case, this process leads to conceptual change in which learners restructure their semantic network of ideas. Linn et al. (2015) propose that knowledge integration is more likely if teachers can elicit students' existing ideas about a phenomenon, help students add new, normative, ideas, help learners distinguish between their own and the normative ideas, and finally reflect on their ideas. The knowledge integration perspective is a domain-general approach; it does not define which ideas constitute resources or can be considered non-normative. Additionally, it emphasizes adding ideas to existing knowledge networks but does not offer guidance on identifying core ideas, a sequence for integrating these ideas to develop scientific understanding, or appropriate instructional activities that lead to integrated knowledge. To gain insights into the structure of a domain, the ideal sequence for teaching concepts, and the most effective instructional activities, one can turn to research on learning progressions, while research on instruction can provide insights into suitable instructional activities that promote a sustainable integration of new ideas.

Learning progressions in science education hypothesize how students' understanding of concepts develops with instruction (Corcoran et al., 2009). These progressions have starting and endpoints with intermediate stages in between. Lower anchors represent prior knowledge, while upper anchors denote desired competence. Although learning progressions assume a limited number of potential trajectories and outline expected knowledge and skills transitions and potential instructional approaches, they lack specifics on effective instructional activities, which can be found in instructional science. Knowledge integration and knowledge-in-use are central to science education, with learning progressions guiding the scope and order of knowledge and skill integration. *Instructional science* provides insights into learning activities that help learners acquire and integrate new ideas by focusing on cognitive-constructive processes, learning strategies, and the effectiveness of pedagogical interventions (Linn et al., 2015). Techniques like self-explanations, peer-tutoring, and concept maps have been shown to be effective learning techniques that serve these goals (Dunlosky et al., 2013; Rittle-Johnson et al., 2017). However, not all learning activities suit all learners; instructional designers must consider learners' cognitive development when selecting appropriate activities (Rittle-Johnson et al., 2017).

Synergies between the perspectives

Science learning aims to engage learners with scientific phenomena, develop scientific understanding, and apply knowledge to real-world problems. Students need knowledge-in-use (Harris et al., 2019) which relies on well-integrated knowledge (Bransford, 2000). Integrated knowledge stems from semantic networks representing declarative knowledge in long-term memory. In classrooms, guided-inquiry activities confront learners with normative ideas that challenge their often-non-normative understanding, thus potentially promoting conceptual change. Knowledge integration is more likely when teachers elicit students' existing ideas, introduce normative ideas, help differentiate between them, and encourage reflection (Linn et al., 2015). In the following we highlight potential synergies between the three fields of research and identify open questions for future work. A first synergy exists between knowledge integration and learning progression research. The knowledge integration perspective emphasizes accumulating ideas but lacks specifics on which concepts (i.e., ideas and their relations) learners should integrate in their knowledge. Learning progression research can provide insights into the core ideas and the sequence in which these ideas may be best presented to learners so that they can construct an integrated knowledge base. Learning progression research, in turn, benefits from instructional science's which provides insights into learning processes and instructional activities that are suited for learners on different developmental levels. Viewing learning and teaching from these three perspectives allows us to react to challenges that learners experience on different levels. For example, we may select alternative instructional activities for individual learners, revise the structure of a learning progression, or modify the placement of the progression within the curriculum. Furthermore, incorporating learning process measures that are employed by research on instructional science into the evaluation of learning progression can help disambiguate results and compare effectiveness across different classrooms. For instance, the learning processes promoted by different instructional activities within the same learning progression may provide alternative explanations for learners' performances. Lastly, the knowledge integration perspective can benefit from instructional science's micro-level view, helping select appropriate activities to trigger different knowledge integration processes. This integration expands the scope of instructional science with expertise from knowledge integration and learning progression research.

Conclusion

This article advocates for synergies between knowledge integration, learning progression research, and instructional science to holistically design science education. These perspectives offer different lenses for understanding prior knowledge, topic sequencing, idea connections, and instructional activity design. Closer collaboration between these fields can enhance validity and generalizability of findings, requiring meaningful connections between theoretical models and consideration of macro- and micro-perspectives. To better understand science learning and provide evidence-based guidance, interdisciplinary work between these research areas is necessary.

Abstract: The study focuses on how learning sciences and visual learning analytics can be used to design, and to improve, online workforce training in advanced manufacturing. We analyzed the data from a cohort of 900 professionals enrolled in an online training course regarding additive manufacturing. The results inform strategies for instructors to better align the course assignments, learning objectives, and assessment measures and argues for a synchronized data structure for use across online learning platforms.

Introduction

Research on pedagogy and practice for effective online instruction has boomed in recent years, abruptly accelerated by the COVID-19 pandemic (Anang, 2020). At the same time, educators and trainers are woefully underprepared for the needs of designing for this space. What is needed are more systemic approaches to scaffold high-quality online learning outcomes, grounded in the science of how people learn (National Academies of Sciences & Medicine, 2018) and how to design for online skill development for the future of work. This study builds upon prior approaches in learning sciences to support learning in the workforce through research partnerships with industry partners (e.g., Dede, 2006). Particularly, educational data mining (EDM) and learning analytics (LA) as a set of emerging practices have been used to examine learners' trajectories, activities, proficiencies and provide useful information for instructors to understand employees' learning (Ginda et al., 2019). To combine the latest understandings from the learning sciences with data visualization to scale high-quality learning outcomes to the gamut of online skills development offerings required by rapidly accelerating industry developments, this study illustrates the potential of applying learning design to a course focused on upskilling employees of a large aerospace manufacturer, offered via a leading research university's Massive Open Online Course (MOOC) platform. In line with current learning theory, an iterative approach to design-based educational research was applied to design online certificates and tested a learning objective-based approach to professional online education. Our aims are to support not only the intersection of the learning sciences and workforce training research, but also to the scientific process of exploration, discovery, confirmation, and dissemination. In this study, we ask: How can visual learning analytics (VLA) reflect students' engagement, learning outcomes, and the intersection of both with learning objectives? By answering the research question, we aim to provide a course design guide that incorporates the findings of students' engagement, learning outcomes, and learning objectives to inform the design of online courses.

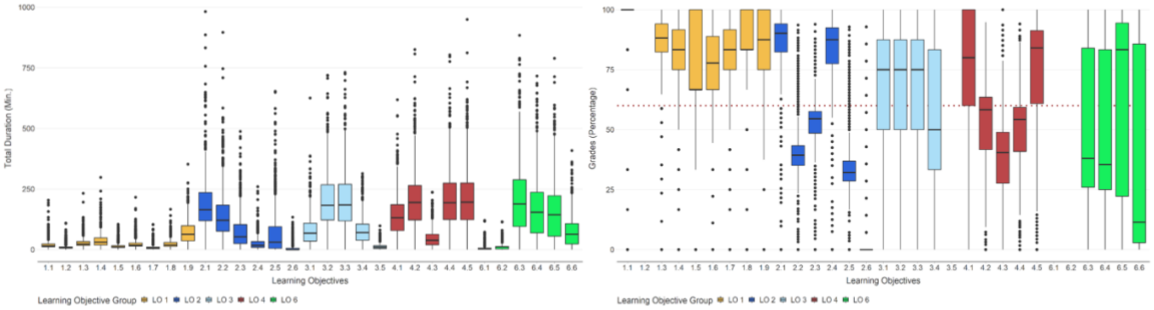
Methods

A nine-week online course focused on Additive Manufacturing (AM) was developed by aerospace employers as well as experts and scholars in AM and launched in 2017. We worked with the company to examine the learning outcomes and trajectories of 900 engineers to advance the upskilling process. We captured log file data from the course's learning management system (i.e., time an individual spends on videos or assignment), and analyzed employees' performances with course activities from week 1-6. In this poster, we removed the data from week 7-9 because employees used a 3D CAD modeling design platform, OnShape, which provides little information on the course site regarding learning activities and performance. We then qualitatively coded 31 learning objectives from weeks one to six to examine the relationship between the content of course modules and assignment and employees' performances. We visualized the results to cross compare the performance data and learning objectives. The purpose of the analyses was to examine if the content of the course modules and assignment were well designed to evaluate employees' learning which can be reflected on their performances.

Results

To understand how the instructional design supported employees' learning, the study examined the learning modules with learning objectives analysis, and then applied visual analytics and qualitative coding to investigate the relationships between learning objectives, performance, and engagement. Overall, our linear regression modeling confirms that time spent engaging course content positively correlated to student performance (r^2 =.4527, $p < .01$, n = 880). While these results are not surprising, it is an important measure to run at the end of any course to ensure that students, regardless of background knowledge, can perform well if they invest an adequate amount of time in the course. Examining the intersection of student performance, assessment measures, and intended learning outcomes yielded additional insights into how students engaged with the content. First, by providing VLA dashboards, this analysis helps to establish where students spent their time in the course content and more accurate estimations of time toward completion of each module. Second, the VLA clarified the amount of time it should take for students to accomplish a specific learning objective. Figure 1a presents the time students spent on each learning objective. This view makes salient how much time proportionately is dedicated to a learning objective, either in terms of time each student spent to complete a task, or how much extra time is dedicated in terms of learning activities to specific learning objectives. Furthermore, analyzing overall distribution of student performance within each LO and longitudinally can yield additional insights (see Figure 1b). For instance, certain LOs produce very low scores, instructors can look for correlation between performance and time spent. If more time spent on a LO leads to a low score, instructors can infer that students are putting forth effort, but the course content could be improved in future iterations.

Figure 1



(a) Engagement Time by Learning Objectives

(b) Percentage Grades by Learning Objectives

Discussion

This study examined the learning processes and outcomes of aerospace engineers through an online course which focused on the topic of additive manufacturing. Based on the analyses of learning objectives, processes and outcomes, the results informed modifications of future course content and assessment. This work took a fair amount of time to develop the training and courses, and it could be automated if the MOOC platform was designed with simple supporting workflows aimed to articulate learning objectives and tag them in the course assignments and assessment metrics. These key components could be fixed in advance and improve the overall course. Although the data and analyses were drawn from a single case, they provided a springboard to establish field standards across online courses and platforms in using LA and data structure for the purposes of adaptive assessment. To move forward, the process of upskilling employees requires close collaboration of learning scientists, data scientists, security experts, learning platform developers, and industry to design and develop learning materials and environment which lead to measurable improvements in work performance. This study helps to connect learning sciences to the increased focus on the upskilling issue in the workforce by applying EDM and LA approaches through practices.

“Our Result Corresponds With Our Assumption”: Students’ Biased Interpretation of Data Gained Through Mathematical Hands-On Experimentation

Ramona Hagenkötter, Valentina Nachtigall, Katrin Rolka, Nikol Rummel
ramona.hagenkoetter@rub.de, valentina.nachtigall@rub.de, katrin.rolka@rub.de, nikol.rummel@rub.de
Ruhr-University Bochum

Abstract: The present paper explores whether students who subjectively confirmed their initial assumptions during mathematical hands-on experimentation interpret their results in a biased way that confirms their initial assumption. We also assess whether these students judge their own performance higher than students who experimentally disconfirmed their initial assumptions. Our results indicate biased interpretation for the majority of the students who subjectively confirmed their initial assumptions. Furthermore, these students tend to judge their own performance higher.

Introduction

The implementation of inquiry-based learning methods in the classroom and the goal of improving students’ scientific literacy is increasingly emphasized in STEM education. With regard to mathematics education, mathematical hands-on experimentation seems to be a promising possibility to implement the phases of inquiry learning. Specifically, the steps of mathematical hands-on experimentation are highly comparable to the following core features of the inquiry learning process, namely hypothesis generation, experimentation, data interpretation, conclusion, and reflection (Pedaste et al., 2015). During mathematical hands-on experimentation, students have to make assumptions, plan and conduct an experiment, deduct a mathematical model from the real world (e.g., by noting the measured values and transferring them to a coordinate system), answer mathematical questions within this mathematical model, interpret the mathematical results in the real situation, validate the solution, and reflect on their approach (Geisler, 2021). However, research on inquiry learning in science contexts has demonstrated that students tend to stick to their initially generated hypotheses, leading to a biased interpretation of their data and, thereby, an impaired effectiveness of inquiry learning (e.g., De Jong & Van Joolingen, 1998). Based on the commonalities between inquiry learning and mathematical hands-on experimentation and, especially, against the background that students often only rarely work with real data in mathematics classes but rather with artificially generated data which already fit an intended model (e.g., Engel, 2010), it is likely to assume that the issue of biased data interpretation is also relevant for mathematical hands-on experimentation. Therefore, the present paper explores whether students who subjectively confirm their initial assumptions during mathematical hands-on experimentation tend to (mis)interpret their collected data in a way that confirms their initial assumptions (research objective 1). According to the cue-utilization framework (Koriat, 1997), an additional problem might be that students who subjectively confirm their initial assumptions may use this success as an inappropriate cue to assess their performance, leading to overly high self-confidence. Thus, we further investigate how students judge their own performance when they have either subjectively confirmed or disconfirmed their initial assumptions (research objective 2).

Methods

To achieve our research objectives, we analyzed the lab booklets of 28 students ($M_{\text{age}} = 15.04$, $SD = 0.43$, 64% male, 32% female, 4% divers) who either subjectively confirmed or disconfirmed their initial assumptions during mathematical hands-on experimentation. These students are a subsample (i.e., those who actually compared their experimental results with their initial assumptions) of three German secondary school classes that participated in a day-long project in an out-of-school lab at a large German university between August and September 2022. The students visited the out-of-school lab with their whole classes together with their mathematics teacher. In the first learning phase of the day-long project, the students had a total of 55 minutes to work in groups of three on a mathematical hands-on experiment on beer foam decay following the steps mentioned above. In addition to filling in the lab booklets, we asked the students to provide us with judgments of performance after the learning phase. For this purpose, the students had to rate on a scale from 0% to 100% how well they can do certain mathematical activities similar to the activities of the learning phase, especially the interpretation and validation of the results.

For the present analyses, we focus on the phases in which the students were asked to analyze and interpret their results and to compare them with their initial assumptions. We classified the students into the following categories: *subjective (partial) confirmation of the initial assumptions* (*n* = 16) and *disproof of the initial assumptions* (*n* = 12). The students who subjectively (partially) confirmed their initial assumptions during mathematical hands-on experimentation formulated, for example, the following conclusion in their booklet: “Our result corresponds with our assumption”. In contrast, the students who experimentally disconfirmed their initial assumptions, for instance, concluded: “[Our assumption] was completely wrong”.

Results and discussion

With regard to research objective 1, our results show that twelve out of the 16 students who subjectively (partially) confirmed their initial assumptions through their experiment made assumptions that did not fit the actual decay process of beer foam. Thus, only four out of the 16 students confirmed their initial assumptions correctly, while the majority of the students confirmed their initial assumptions incorrectly. We identified such an incorrect confirmation, for example, in a group of three students who focused their interpretation on very general aspects of their results that were consistent with their initial assumption. These students initially assumed that “the foam decreases proportionally”. The results of their experiment clearly showed no linear decay, but instead an approximately exponential decay. However, the students did not describe the actually observed beer foam decay, but only their graph in a very general way as follows: “We have noticed that the graph has decreased.” Thus, the students ignored that the decay process did not correspond with their initial assumption of a linear decay and they erroneously concluded that the results of their experiment support their initial assumption: “assumption confirmed through experiment!” With regard to research objective 2, descriptive statistics show that the students who subjectively (partially) confirmed their initial assumptions reported higher judgments of performance (*M* = 69.35, *SD* = 18.42) than students who experimentally disconfirmed their initial assumptions (*M* = 63.07, *SD* = 18.15).

Although the small sample size of the present paper limits the scope and generalizability of our findings, the results indicate that students tend to interpret their results in a biased way and, consequently, falsely confirm their initial assumptions during mathematical hands-on experimentation. Our results further suggest that subjectively confirming the initial assumptions can lead to a higher judgment of the students’ own performance than disconfirming. This is especially problematic because the majority of the students who subjectively confirmed their initial assumptions falsely confirmed them due to biased interpretation. It is likely that these students overestimated their own performance which can have detrimental effects on learning outcomes (see, e.g., Dunlosky & Rawson, 2012). Further research is needed to investigate ways that help both to prevent students’ biased interpretation and to foster students’ use of appropriate cues for judging their own performance.

Abstract: Today's challenges are better faced together than alone, highlighting that collaborative working and learning are of particular importance in the 21st century. However, research shows that graduates often do not feel well-prepared in this regard. Appropriate measurement approaches might be helpful for students to reflect their collaborative learning processes and to monitor their skill development. The current study describes the process of constructing an instrument for evaluating the quality of peer collaboration in higher education. Based on theoretical conceptions and in-depth observations of student groups, ten initial Behaviorally Anchored Rating Scales (BARS) were developed. Containing unequivocal behavioral anchors for high, medium and low levels of collaboration, the instrument has the potential to support evaluation processes in higher education. The contribution discusses enriching aspects of the approach but also what is still missing, and depicts potential fields of application.

Introduction

Collaboration is one of the most desired skills in the 21st century. Therefore, students transitioning from higher education into the workforce will be expected to collaborate with others in order to solve complex problems. However, the study by Wilson et al. (2018) highlights that many undergraduate students do not feel well prepared to work collaboratively and do not develop appropriate skills to do so. The existing soft skills gap between graduates' competencies and organizational demands (Abbasi et al., 2018) supports these findings. With regard to this, suitable measurement approaches would help students to reflect their own as well as the groups' learning processes and to monitor their skill development. Behaviorally Anchored Rating Scales (BARS) might be a promising approach to this end. BARS include behavioral anchors as response options that represent different quality levels of a construct with high values representing highly effective behaviors (Debnath et al., 2015). While they are particularly developed and used in terms of job performance ratings (Bernardin et al., 1976), their application in the context of performance in higher education courses also led to promising findings in terms of utility and applicability (e.g., McIntyre & Gilbert, 1994). Moreover, BARS have been found beneficial in similar areas of application, namely for the assessment of team member effectiveness (Ohland et al., 2012) and team adaptation processes (Georganta & Brodbeck, 2020). Respecting the promising findings on their feedback potential (Hom et al., 1982) and their use for self- and peer-evaluation purposes (Ohland et al., 2012), BARS might be a beneficial complementation to existing rating schemes primarily used by trained observers (e.g., the rating scheme for assessing collaboration processes by Meier et al., 2007). Hence, the aim of the current study is to construct an initial system of BARS for evaluating peer collaboration in higher education.

Method

Different procedures and formats for developing BARS have already been used (Bernardin et al., 1976) indicating that the development process is very flexible (Debnath et al., 2015). The procedure described in the current study is comparable to the one used by Georganta and Brodbeck (2020, Study 1). Based on a systematic literature review, we identified four core facets of collaboration including several sub-facets (Schürmann et al., 2022). Second, this coding scheme was pre-tested and used to derive and classify behavioral anchors from observations of student collaboration. The pre-study showed that the facets were suitable and applicable. Additionally, the findings enabled a deeper understanding of favorable behaviors and led to the enrichment and refinement of example indicators for each facet. In line with the method used by Georganta and Brodbeck (2020) the definitions and examples guided the following development stages and serve as description of each sub-facet in the BARS. Next, critical incident analysis (Flanagan, 1954) and frequency analysis were combined in order to derive and classify behavioral anchors for each of the ten sub-facets. Therefore, the video recordings of two collaborating student groups were observed. The recordings stemmed from an experimental field study where 38 undergraduate psychology students (in 14 teams of two to three) participated in a collaborative problem-solving task in a digital setting. In order to maximize variance, a group with a low level of collaboration and a group with a high level of collaboration (based on self-reports) were selected. Comparing two contrasting cases aimed to identify example behaviors from poor to excellent. The observation was systematically conducted by one rater (second author) using a combination of bottom-up and top-down approach to integrate quantitative and qualitative insights on the student peer collaboration. Critical incident analysis (Flanagan, 1954) was used to develop behavioral examples reflecting a spectrum from desirable to undesirable behaviors for each sub-facet. This process was supported by using frequency analysis to examine the prevalence of behaviors in both groups.

Results and discussion

In line with Ohland et al. (2012), we decided to use a 5-point scale with anchors for high, medium, and low levels of the respective sub-facets of collaboration. The “5”, “3” and “1” ratings each comprise four behavioral anchors, reflecting excellent, satisfactory and poor behaviors, respectively. Level “2” and level “4” do not contain behavioral anchors but can be chosen if behaviour is demonstrated which fits to both adjacent levels. In total, ten initial BARS (one for each of the sub-facet) for measuring student peer collaboration were developed. These scales are both based on theoretical concepts and derived from observations of natural and typical collaborative behavior. With respect to the second, combining critical incident analysis and frequency analysis turned out to be a suitable and fruitful approach as qualitative and quantitative data could be integrated and synthesized. While the frequency analysis provided indications of the differences between groups in terms of the distribution of facets, the critical incident technique helped to clarify these analysis results more precisely. Besides these strengths, there are also noteworthy limitations with regard to the development process. The observation and the assignment of the behavioural examples to the sub-facets were primarily done by one rater limiting objectivity and reliability. Although the current version needs to be further developed and evaluated to prove its psychometric characteristics, it already has the potential to be used beneficially. For example, it could be given to students as an instrument to support joint reflective processes about their collaboration (i.e., groups use it as self-evaluation instrument to detect areas of improvement). Thus, students might feel better prepared to work collaboratively and to develop appropriate skills to do so. Supplementary, this approach would allow to get insights into whether students are comfortable or having problems with using the BARS format. Taken together, future research is encouraged to investigate the potential of BARS in higher education context.

Expanding the 'Personally Meaningful': Engaging in Sound Making to Support Engineering Practices

Santiago Hurtado, Technical University of Munich, s.hurtado@tum.de
Anna Keune, Technical University of Munich, anna.keune@tum.de

Abstract: Personally meaningful design activities, such as sound making, can provide contexts for engineering education. Sound is personally meaningful because it connects to histories of a person's experiences and represents them. Building on constructionist perspectives, this qualitative study investigated engineering practices while youth created sound with conductive materials inspired by personally meaningful objects. Findings suggest that personally meaningful design activities should include materials with personal histories.

Introduction

The STEM field faces dropout issues internationally (e.g., Chen et al., 2018). Alternative approaches to STEM (Science, Technology, Engineering, and Mathematics) education are needed to counteract this trend. We focused on engineering education, which can be a path toward STEM education (Simmaro & Couso, 2021). Engineering education in K-12 is still not widely implemented, but early exposure could provide youth with positive experiences to inform their decisions to choose to stick with STEM. A promising approach toward early engineering education is through personally meaningful projects (Papert, 1980). Personal projects provide meaning beyond intended use, they evoke experiences that tie domain learning and interests (Turkle, 2007). One meaningful context in this area is sound making. Sound can have personally meaningful properties because we experience sound in everyday life and attribute meaning to sound through memories and emotions (Cambrón, 2005). Sound can become an object-to-think-with that provides a link between abstract and sensory knowledge at the intersection of cultural presence, embedded knowledge, and the potential for personal identification (Papert, 1980, p. 11). Despite these promises, we know little about the utility of sound making for engineering learning. Thus, we asked: *How does sound making tie personally meaningful objects and engineering practices in middle school students, and what electronic kits can support this better?* This qualitative study investigated the engineering design practices as youth engaged in sound making with electronic maker kits and conductive and non-conductive materials inspired by personally meaningful objects. We understand sound as vibrations transported through waves that can carry meaning. We found that sound making can evoke engineering design practices especially when it is possible to combine several conductive materials and build on personally meaningful objects. We close with implications for designing for engineering learning through sound making.

Methods

To address the research question, we used a qualitative approach with two groups of ten-year-olds in two 75-minute-long sessions for each group at a makerspace in Bavaria. The first group consisted of five girls and five boys and the second of seven girls and four boys. Every participant brought a personally meaningful object to the workshop (e.g., toy car, plant, house keys). Participants used the Playtronica Playtron, MIDI controllers that can be connected through smartphone or computer to play an instrument, and Squishy Circuits kits, which included battery packs, buzzers, motors with propellers, and switches, usually connected through conductive playdough. All participants had access to additional materials, including graphite pencils, copper tape, conductive thread and paint as well as other non-conductive craft materials. The participants had to produce sound with their personally meaningful object, electronic kits, and crafting materials. The data sources were: (1) Videos captured with three cameras (280 minutes) to show the interactions of all participants and (2) semi-structured interviews (123 minutes) that asked about their experiences with sound making, engineering, and crafting throughout the sessions. To answer the research question, we analyzed the video data and interviews following an iterative thematic approach to understand the engineering design practices (see National Research Council, 2013) that participants performed while creating personally meaningful sound. Additionally, the engineering design practices were coded as instances to compare how students engaged with the kits.

Findings

We found that engineering design practices through personally meaningful sound making were supported differently. Due to space constraints, we focus on Squishy Circuits. We identified two themes with Squishy Circuits: (1) Physical sound tinkering as conducive of engineering practices, which involved creating sound with movable objects powered with Squishy Circuits, and (2) filtering sounds as conducive of engineering practices, which involved using the buzzer as a main sound maker, but tinkering through filtering it with materials on top of it to modify its sound (e.g., foam, paper, dough, fabric). Squishy Circuits allowed youth to experiment with materials and to approach their sound creating task in different ways. They were able to design, iterate their designs, come up with new designs, and showed understanding of how materials worked and were connected.

Barney, a boy in the first group, brought a fidget spinner to the course as his personal object. He aimed to recreate its plopping sound. He tried replicating the sound of removing the lid of a metallic container remotely by using the Squishy Circuits propellers to create air pressure from inside. Barney iterated by adding propellers, battery packs, and adjusting the placement of the materials. When this did not work, he tried alternatives and understood that his design would not allow for his desired result due to not being airtight, the lid being too heavy, and the propellers not having enough force. Barney finished his project tapping the side of the can with the propeller and added the possibility of putting an ear inside the can for extra detail on the sound (see Figure 1). He showed engineering design principles through planning of his design, developing possible solutions, iterating multiple times on these solutions, and constructing explanations of the materials and their interactions. Barney used his personal object to guide his design and engage him to stay with it until the end.

Figure 1

Barney's four material explorations for his artifact representation: (1) Squishy Circuits buzzers with playdough, (2) xylophone being hit by the propeller, (3) propeller inside a plastic bottle, and (4) metallic can.

Discussion

This study points to the possibility of sound making with construction kits that connect to a range of materials as for engineering engagement. Also, providing a spectrum of materials for playing with resistance and conductivity as well as including physical materials enables experimentation with a range of sounds (e.g., tapping, sliding). This study suggests considering personal histories when designing personally meaningful activities. Beyond design activities being personally meaningful because people can choose what they want to design, bringing material objects (e.g., a plant, house keys, a toy car) from a persons' past and designing with them as an inspirational source can expand the personally meaningful toward including personal histories in activity designs. Such sound making can provide opportunities for early engineering education.

Expansive Learning in a Team of Middle Leaders Responsible for a Public School Network: Enthusiasm vs. Control

Viviana Hojman, Universidad del Desarrollo, vhojman@udd.cl
Micaela González, migonzalezp@udd.cl
Rodrigo Jara, rodjarab@udd.cl

Abstract: This article describes an intervention that was carried out with an intermediate leadership team of an department of education responsible for a group of schools in a low-income community in Chile. The intervention takes the form of a Change Laboratory. The results indicate that the team was able to identify a major tension and has since sought and tested new ways of thinking and solutions through collective agency.

Introduction

Faced with an educational system that perpetuates social inequalities, there is a pressing need for change and improvement initiated by the educational community itself. Therefore, a training intervention based on the Change Laboratory (CL) strategy was conducted in a low-resource community in 2022. The goal of this intervention was to strengthen intermediate leaders who bridge State agencies, such as the Departments of Education (DAEM), and the educational communities. The current study outlines an intervention-action conducted with an intermediate leadership team responsible for seven public schools and four kindergartens in the Education Department. The context and conditions of the leading middle team, their transformation demands, and their need for expansive learning are briefly described. Then, we will explain the concepts of activity theory and the change laboratory that inform the process. Next, we will outline the objectives and methodology utilized. Finally, we will present the preliminary findings and conclusions, as well as the references cited in this report.

Context and challenges of the intermediate leader team

The municipality where we conducted our work has a population of nearly 100,000 residents (INE, 2021), and their economic resources distribution is widely heterogeneous. This disparity extends to educational institutions in the region, resulting in significant inequality in the quality of education that students receive (Herrera, Munizaga, López, Jorquera, & Hernández, 2008). The DAEM of the municipality addresses this issue. The department is tasked with directing and promoting leadership, ensuring the attainment of learning goals, facilitating school relations, and managing available resources (PADEM, 2022). In this specific case, the DAEM collaborates with nearly 800 professionals who ensure the education of more than 3000 students and more than 400 preschoolers, all of them managed by an intermediate team composed of 12 people. The presented intervention targets these professionals and seeks to strengthen the relationships they have with other professionals in the municipal system in order to face the new educational needs in a post-pandemic context, among which it is possible to count serious problems of non-attendance (MINEDUC Study Center, 2022) and dropout (Murillo and Duk, 2020), emotional exhaustion and stress (ECLAC and UNESCO, 2020), and teachers' mental health (Caballero-Domínguez and Campo-Arias, 2020). With the emergence of new demands, it has become clear that the education system needs to change in several aspects that seem unsustainable. Given these new social scenarios, an educational intervention like CL became the most appropriate way to address concerns. The proposal is to provide a mediated space for creating expansive learning and collective agency.

Activity theory, laboratory of change, objectives and methodology

The Cultural Historial Activity Theory (CHAT) enhances comprehension of individual and collective transformation processes. Its minimum unit of analysis is the Activity System (AS), a triadic system comprising a subject, an object, and the activity that mediates the relationship between them (Leontiev, 1978/1984). In this theory, a community is formed through the sharing of rules and generation of a division of labor among community members (Sannino & Engeström, 2018). Mobilization of the SA is driven by internal contradictions, which manifest as dilemmas, conflicts, and paradoxes rather than direct observation. In the attempt to resolve these contradictions, new modes of action emerge (Engeström & Sannino, 2011).

Starting from the premise that the CL adopts a dialectical approach, the current study is qualitative and exploratory, situated within a dialectical epistemology that aims at capturing the richness, depth, and quality of the produced outcomes (Virkkunen & Newnham, 2012). The purpose of this study is to facilitate a collaborative transformation process to promote innovative solutions with a mid-level leadership team of the DAEM through a

CL. To this end, an initial organizational immersion was executed to collect relevant data. Following this, seven group work sessions and two follow-up sessions were conducted. Twelve participants were selected based on their association with the creation of conditions for educational improvement and their voluntary participation.

Data collection was conducted using semi-structured individual and group interviews, participant observation, artifact collection, and field notes. The CL sessions were video- and audio-recorded and are part of the material analyzed. The data analysis took place at two different levels: (1) the material used as working data for the CL sessions, and (2) the information chosen for the production of scientific knowledge framed in the CHAT and CL toolkit (Virkkunen & Newnham, 2012). For the analysis of initial data, weekly meetings were conducted, while work meetings with international experts will be held for the second stage to contribute to knowledge construction and scientific dissemination. Regarding ethical considerations in this research, the research design was sent to the university's ethics committee before the fieldwork began, and approval for the research and related documents was granted.

Preliminary results and conclusions

Early in the process, a tension emerged that the team saw as a dichotomy: either the leader would be charismatic and foster the professional growth of his team, or he would focus on defining and fulfilling rules. As a result, they perceived a trade-off between motivating their team and improving control of the institutional organization.

In the initial sessions, a historical reconstruction of this tension was developed, analyzing it from public policies to the teacher-student relationship within their educational community. Thus, in the fourth session, they initiated the construction of two tools to resolve this dichotomy: the first tool aims to increase student attendance while minimizing teacher absenteeism by making the community interested in attending school; the second tool aims to establish a management system that incorporates the purpose and strategies of community mobilization.

Although we have not completed the process, we can claim that this approach offers ways to address traditional actions that perpetuate the main tensions of the educational system, proposing the generation of new solutions focused on the main tensions or contradictions. Simultaneously, it permits the development of practical and pertinent solutions, crafting tools for the community. In the context of educational research, participating in interventions and research in change labs can provide valuable insights and opportunities for problem-solving utilizing theory and methodology, resulting in the acquisition of rich data sets. These experiences may even inspire the development of new longitudinal interventions and research..

Systematic Literature Review With PRISMA and NLP on Co-Creative Learning in Higher Education

Marije Bent, Aeres University of Applied Science, m.bent@aeres.nl
Erick Velazquez-Godinez, The Computer Research Institute of Montreal (CRIM),
erick.velazquez-godinez@crim.ca
Frank de Jong, Aeres University of Applied Science, f.de.jong@aeres.nl

Abstract: Teachers in higher education design and develop (blended) lessons and learning activities. At the same time, it proves difficult for teachers to develop competences in designing lessons. This poster is a literature study method with a focus on co-creation process of designing lessons by teachers following the PRISMA method and an examination trough a Natural Language (NLP) analysis. The NLP analysis added a different dimension to explore conceptual development in factors underlying the co-creation in the existing literature.

Introduction

Teachers create and develop lessons and curricula, which might be strongly supported by knowledge creation, collaboration, thinking and creativity through dialogue. Designing lessons requires more innovative and creative behavior from teachers. Until now, it is not investigated how teachers act while being collectively creative, albeit without identifying important roles that could support co-creation within the creative process Factors like openness to the unexpected, curiosity and confidence in risk-taking during work affect de creatively designed lessons and the design competences of teachers. These factors should be explored, given the critical importance that the lesson designs of teachers play in transforming schools and classrooms.

In the present systematic literature review (LR), we investigated the underlying factors needed to co-create, for example, to design more creative lessons. These determined factors, such as shared vision, dialogue and inquiry, collective action and reflection are investigated. To enlarge and support this method of reviewing, an analyzing technique from Natural Language Processing (NLP) (Velazquez et al., 2017), is added to investigate and visualize new models and incorporate them into a LR. The possibilities of computational analytic techniques, such as NLP, opened new opportunities for modelling and coding methods with big data, such as a large number of journals and articles (Wise & Schwarz, 2017).

Methodology

The Preferred Reporting Items for Systematic Reviews (PRISMA) guidelines (Page et al., 2021) provides a standard peer-accepted methodology when followed strictly, it contributes to the quality of the selection of articles used and the revision process and its replicability (McInnes et al., 2018).

The articles, collected following the guidelines of PRISMA, are analyzed further to extract information such as location and topics. Using Topic Modelling, we are able to automatically discover topics in the selected articles. We ran a series of experiments to find the more coherence topics in our dataset. We used the topics distribution over each article to determine its principal topic. Thus, articles can be grouped by the topics generated automatically. Topic modelling is commonly used to analyze large volumes of data in relation to specific settings (e.g. conversations about collective learning) (Wise & Schwarz, 2017).

Data sources and search strategies

The literature was systematically collected on the databases (EBSCO Host (including ERIC, PsychInfo, PsychArticles, and Academic Search Premier; ERIC *n*=83) and (Google Scholar *n*=8) between the years 2012 and 2022. These databases are chosen because of the focus on education. To identify as much as eligible studies as possible, the search terms were modified together and combined with the Boolean operators as follows: (("knowledge building" OR "co-creation" OR "collective learning" OR "collaborative learning" OR" joint work")) and ("higher education" AND "instructional design").

Constitution of the corpus of analysis

First, we converted the original format of the publications into text files to use them for the topic modelling technique. During such a process, some noisy characters may have been included in the text. Then we applied the topic modelling technique. We use the Latent Dirichlet allocation (LDA) algorithm. While working with topic modelling, a capital question is how we determine the better number of topics for a model. As in previous research (Bent et al., 2021), we automatically determine the number of topics by measuring the semantical cohesion of the group of words in each topic. Semantic word representations were used, also known as embeddings from Spacy.oi, to assess the semantic cohesion. For the computation part, we used two measures, one based on the average of word semantic similarity and a second one based on the average distance of the words in the topic. We created 20 models starting with two topics.

Findings

To determine the support of PRISMA by NLP, the studied articles and outcomes from the PRISMA method (Table 1) are related to the four topics (Table 1).With the topic modelling method, the articles were ranked on which factor, from high to low the support the topic they are related to.

Table 1
Four determined topics

Topic	Words_raw (first 10)	Topic name	Description
1	Learning, education, teacher, teaching, students, teachers, research, technology, design, development,	Learning and technology	Learning and technology and learners
2	Learning, knowledge, collective, team, teacher, collaboration, individual, social, study, teachers	Collective learning	Collective learning and teachers
3	Education, learning, vocational, knowledge, students, epistemic, vet, teachers, educational,	Epistemic learning	Epistemic learning VET education
4	Learning, teachers, research, school, students, teacher, study, virtual, world, development	Learning and development	Learning and research and development

The findings show that the found concepts from the PRISMA method are related to the classified topics. For example, the NLP analysis showed that the designs of the articles in topic 1 are more related to literature reviews or methodological reviews. The articles ranking on topic 1 showed indeed more on technology and education like topic 1 suggested, but while going deep in the table of the PRISMA method also about professional learning. It seems to show a greater understanding of the concepts found in the PRISMA method.

Conclusion and discussion

PRISMA fosters a broad set of criteria for literature review and the need for expanding the possibilities to find more concepts (Gough et al., 2012) and a better understanding of answering questions. Using topic modelling to discover more concepts to find design factors needed to co-create for creative lessons helps to see if more patterns are found. In the determined principles of co-creation such as shared vision, dialogue and inquiry, collective action and reflection emerge in topic were there seems a connection between reflection in the manual findings and that technology could also be related. This supports determining better to find patterns needed for finding factors. The subjectivity of manual reviewing decreases with the support of machine learning.

Fostering Productive Uncertainty Management in Engineering Problem-Solving Through Reflective Prompts

Vivek Sabanwar, Chandan Dasgupta, Kavi Arya
sabanwarvivek7@iitb.ac.in, cdasgupta@iitb.ac.in, kavi@cse.iitb.ac.in
Indian Institute of Technology Bombay, Mumbai, India

Abstract: Engineering problem-solving often involves managing uncertainties arising from various unanticipated issues and novices tend to ignore them or manage them unproductively. They require support to articulate uncertainties and build tolerance to manage them. The current study explores the role of reflective prompts in uncertainty management among novices. The analysis presents a promising role of prompts in not only acknowledging uncertainties but also in acknowledging relevant and productive uncertainties.

Introduction

Engineering practitioners typically encounter complex ill-structured problems in which they face unanticipated issues leading to uncertainties (Jordan & McDaniel, 2014). Thus, managing these uncertainties productively (Manz, 2018) become an integral part of engineering design. However, the skill to think, reason and manage uncertainties is found to be uncommon and challenging to learn (Dym et al., 2005). And previous work has shown that novices tend to ignore uncertainties or jump to conclusions immediately contrary to experts who manage uncertainties productively by acknowledging, maintaining and prioritizing them (Kaur & Dasgupta, 2022). In this regard, novices require support to identify and articulate uncertainties and build tolerance towards them. This requires higher-order thinking skills such as critical evaluation of the situation to identify productive uncertainties. Previous research finds reflective prompts to foster these skills in science projects by facilitating critical thinking and knowledge integration for sensemaking among middle school learners (Davis, 2003). Current work explores the role of such reflective prompts in fostering productive uncertainty management among undergraduate engineering students as they solve an engineering problem.

Method

Study design

A quasi-experimental study was designed to investigate the role of reflective prompts. Two teams of undergraduate engineering students were given the task of programming an educational robot to interface the line and color sensors. They had to program the robot to autonomously follow a black line path on a 7x7ft arena and correctly identify color patches along the nodes (black-colored square markers on the path). Teams were also given additional tools and equipment such as studs & screws, black chart paper, clamps, etc. for effective sensor interfacing. All the participants were from third-year electronics engineering with a similar academic performance history (CGPA>8.5) and a basic understanding of microcontrollers. They were provided a workshop of two hours to get them acquainted with the robot as they had no prior experience working on such a task. They were also provided code on analog to digital conversion (ADC), LCD, color sensor initialization, etc. to help them solve the task in the given time. The major challenge for students in this activity was thus integrating various elements and calibrating sensor values to solve the task. One team (prompts team), consisting of three boys and one girl received the prompts while solving the task. They received prompts such as "we have the following components" or "we wonder.."or *"regarding this we think.."* to trigger reflection (Davis, 2003). The other team (no-prompts team), consisting of one boy and two girls did not receive prompts. This team did not receive prompts but was given direct instruction to help them solve the task and overcome frustration if the team struggled too long with an issue.

Data collection and analysis

Both teams were given 90 minutes to complete the task and their audio and video were recorded to capture their activities. Qualitative content analysis (Mayring, 2015) was done on transcribed data using coding schemes from existing literature to identify uncertainty (Jordan & McDaniel, 2014), its category (productive or unproductive) (Manz, 2018) and the reflective behavior of participants (Davis, 2003). Due to poor audio quality during the first 23 minutes for the no-prompts team, their activities from 24th minute onwards only are analyzed.

Findings

Team activities

Both teams could not complete the task in the given amount of time. They faced a major problem of line following with the robot failing to identify nodes along the line. Within this larger issue, both teams faced various uncertainties and attempted to manage them. For example, teams faced uncertainties regarding the behaviour of the robot on the line and around the node as it misses the line or regarding the effect of velocity on line following. We found the no-prompts team to face more uncertainty episodes (28) than the prompts team (16). However, the no-prompts team spent less average duration per uncertainty (1.7 minutes) and more duration on uncertainty management (2.6 minutes). This is in comparison to an average of 2.4 minutes per uncertainty and 1.9 minutes of uncertainty management for the prompts team. Thus, we found that ***the prompts team did not jump to conclusions immediately but spent more time identifying uncertainties before attempting to manage them.*** We found some of these uncertainties and uncertainty management activities to be productive while others to be unproductive. The categorization is based on the discussion with subject matter experts regarding best practices to solve the given task. Uncertainties such as anticipating robot behaviour in the arena, changing value of the threshold, etc. are identified as productive as these relate to relevant aspects of the problem. Uncertainties such as changing the given ADC conversion or LCD code and changing the velocity are categorized as unproductive to solving the given task as they do not relate to relevant aspects of the given problem. We found the no-prompts team engaged in productive activities, for approximately 35% of the recorded duration. In contrast, the prompts team engaged in productive activities, for approximately 56% of the duration. ***Thus, the prompts team engaged more in productive activities compared to the no-prompts team.***

Role of prompts in productive uncertainty management

We analysed different episodes of prompting the team to further understand the role of prompts in productive uncertainty management. During the prompting episode at around 33rd minute, the team members identified black chart paper as potentially useful material (acknowledging uncertainty). In the episode at around 63rd minute, the team develops an understanding that ambient lighting may affect node detection and in the episode at around 77th minute, the team refers to the previous understandings (2nd episode) and relates it to the given material (1st episode) and follows a new approach, of using the given material to tackle the issue. Thus, at the end of 3rd episode, the prompts team understands the role of ambient lighting in line and node detection and decides to use the black chart paper to cover the sensors to avoid noise due to lighting. ***Through this analysis of prompting episodes, we see that reflective prompts are found to affect the team's approach to help them acknowledge and manage uncertainty productively.***

Conclusion

The current work identifies the potential role of using reflective prompts in productive uncertainty management. We found prompts to help teams identify productive uncertainties and spend more duration in productive activities towards managing them. Further research on evaluating the role of prompts from a lens of epistemological and positional framing of participants will lead this exploration towards generalization.

Characterizing Students’ Performances for Interactive Instructional Decisions Making to Meet Individual Needs

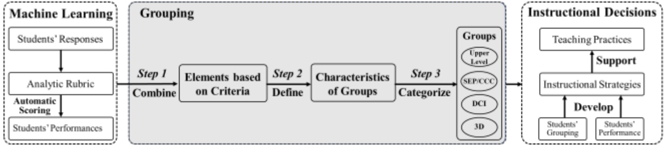
Mao-Ren Zeng, Peng He, Namsoon Shin, Joseph Krajcik
tsengma1@msu.edu, hepeng1@msu.edu, namsoo@msu.edu, krajcik@msu.edu
Michigan State University

Abstract: With the increasing emphasis on the goal of knowledge-in-use in science learning and the growing research of machine scoring on science assessment, teachers can provide feedback to meet an individual student’s needs. The results were used to characterize students’ performances and interpret students’ challenges in knowledge-in-use. This study presents an approach of using the information of machine learning assessment to provide student difficulties for supporting teachers’ decision-making and providing feedback on students’ needs.

Conceptual framework: Characterizing students’ knowledge-in-use

Providing timely feedback on students’ performances is essential in successful knowledge-in-use teaching. However, teachers face challenges assessing and providing student feedback, particularly in large and diverse settings. Researchers have used machine learning to assess students’ responses to knowledge-in-use tasks (Zhai et al., 2021) and have shown the effectiveness of machine learning in scoring tasks and providing timely feedback to learners. However, only a few studies examine supporting teachers in making instructional decisions and designing instructional strategies based on students’ performances via machine learning. To overcome this barrier, this study characterizes and categorizes students’ performances on knowledge-in-use assessments to reduce the cognitive load on teachers interpreting the results from machine scoring. Figure 1 illustrates the process we used to build a system for characterizing and grouping students’ performance on knowledge-in-use assessments to support instructional decision-making. Our approach has three phases: machine learning, grouping, and instructional decisions. This paper focuses on the *grouping phase*. The research questions are: (1) How to characterize students' responses to knowledge-in-use science assessment to allow teachers to more efficiently and productively provide feedback to meet student needs and promote student learning? (2) How do students perform when applying scientific knowledge and scientific practices on knowledge-in-use assessments?

Figure 1
The Framework of Process of Grouping Based on Machine Learning Assessment



Method

Subjects and procedures

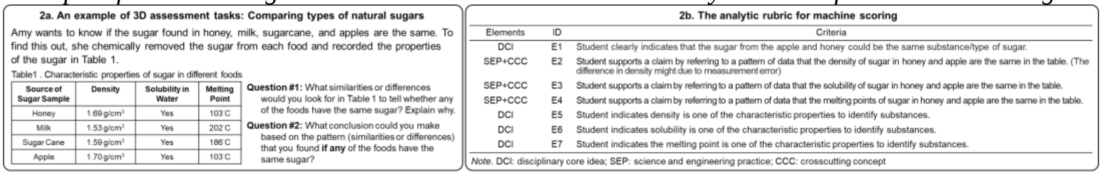
The participants were middle school students (11-13 years old) in the U.S. who completed knowledge-in-use assessment tasks from the Next Generation Science Assessment [NGSA] portal. The NGSA tasks, designed as formative assessments, assess students’ proficiency in using knowledge to make sense of phenomena. We selected three tasks aligned with the middle school physical science standards (Figure 2a). We randomly collected 1,200 students’ responses for each task from the database. Then, we used analytic rubrics for human and machine scoring of responses. The interrater reliabilities using Kappa values are higher than 0.7 between humane raters and 0.89 between the human and machine scoring. Finally, we followed a process for grouping (Figure 1) to categorize students’ performances based on students’ challenges in applying three dimensions -disciplinary core ideas [DCIs], science and engineering practices [SEPs], and crosscutting concepts [CCCs]- and present this information to teachers.

Analytic rubric

We developed analytic rubrics to measure different aspects of knowledge-in-use assessment tasks (He et al., in press). There are seven elements in the analytic rubric, and each element presents an aspect of knowledge in use learning (Figure 2b). The analytic rubric allows for characterizing proficiency in the DCIs, SEPs, and CCCs.

Figure 2

Example of the Knowledge-In-Use Assessment Tasks and the Analytic Rubric for Machine Scoring



2a. An example of 3D assessment tasks: Comparing types of natural sugars

Amy wants to know if the sugar found in honey, milk, sugarcane, and apples are the same. To find this out, she chemically removed the sugar from each food and recorded the properties of the sugar in Table 1.

Table1 . Characteristic properties of sugar in different foods

Source of Sugar Sample	Density	Solubility in Water	Melting Point
Honey	1.69 g/cm³	Yes	103°C
Milk	1.53 g/cm³	Yes	202°C
Sugar Cane	1.59 g/cm³	Yes	186°C
Apple	1.70 g/cm³	Yes	103°C

Question #1: What similarities or differences would you look for in Table 1 to tell whether any of the foods have the same sugar? Explain why.

Question #2: What conclusion could you make based on the pattern (similarities or differences) that you found **if any** of the foods have the same sugar?

2b. The analytic rubric for machine scoring

Elements	ID	Criteria
DCI	E1	Student clearly indicates that the sugar from the apple and honey could be the same substance/type of sugar.
SEP+CCC	E2	Student supports a claim by referring to a pattern of data that the density of sugar in honey and apple are the same in the table. (The difference in density might due to measurement error)
SEP+CCC	E3	Student supports a claim by referring to a pattern of data that the solubility of sugar in honey and apple are the same in the table.
SEP+CCC	E4	Student supports a claim by referring to a pattern of data that the melting points of sugar in honey and apple are the same in the table.
DCI	E5	Student indicates density is one of the characteristic properties to identify substances.
DCI	E6	Student indicates solubility is one of the characteristic properties to identify substances.
DCI	E7	Student indicates the melting point is one of the characteristic properties to identify substances.

Note. DCI: disciplinary core idea; SEP: science and engineering practice; CCC: crosscutting concept

Characterizing student performances on knowledge-in-use assessment

To support teachers with meaningful information based on students' performances, we combined the elements within the analytic rubric based on the use of scientific ideas (DCIs). For example, we combined E6 and E7 using expert reviews and statistical analysis. First, from a content perspective, density (E5) is a critical and more challenging property for students. Second, based on the results of statistical analysis, the Kappa value of the agreement between human and machine scoring increased when E6 and E7 were combined. Similarly, we made the two elements with SEP and CCC (E3 and E4) into a new element. We used these new elements to classify students' performances and defined the characteristics of groups according to performances on the updated analytic rubric. In the last step, we categorized students into four groups: students needing support to (1) move upper level, (2) use SEP and CCC, (3) understand DCI, and (4) use DCI, SEP, and CCC. For example, if a student responded that Apple and Honey are the same, they considered that the density, solubility, and melting point provide characteristic properties to identify substances. Moreover, the student shows that Apples and Honey have the same melting point and solubility. The student performed adequately based on elements of DCIs but insufficiently on the elements of SEP and CCC because they did not discuss the data related to the density. Thus, we categorized this group as needing support on SEP/CCC.

Results

The pattern of the distribution indicates that students who need support on the DCIs, SEPs, and CCCs had the highest percentage across the three tasks. For example, more than 80% of students were categorized into the group needing the DCIs, SEPs, and CCCs support, and the remaining students were grouped across the DCI group (10.01%), the upper-level group (3.08%), and the SEP/CCC group (0.05%) in task one. Although the percentage of groups differs among the three tasks, the distribution pattern is similar. The results indicated that students need help integrating the dimensions in solving problems or explaining phenomena. Students need support in using the dimensions, and teachers need to design effective strategies to promote students' proficiency.

Discussion and conclusion

We illustrated our approach for characterizing and grouping student performance on knowledge-in-use tasks: (1) combining the elements of the analytic rubric, (2) defining the characteristics of groups, and (3) designing the process of categorizing students. This approach can provide teachers with students and the whole classroom's performances categorized by areas needing support so that teachers can adjust their instruction to support student and class needs in a timely manner. We presented preliminary results of human and machine scoring to show the process of grouping. We are conducting further research to explore how groupings and associated information on students' performances support teachers and what and how additional information generated from machine learning scoring of assessments can be provided and used for making instructional decisions.

Proof of Concept and Design Principles for Culturally-Sustaining Educational Assessment

Daniel Hickey, Chamian Lam, Qianxu (Morgan) Luo, Joshua Quick
dthickey@iu.edu. lamcha@iu.edu, luoqian@iu.edu, jdquick@iu.edu
Indiana University

Abstract: Despite broad scholarly agreement supporting culturally-responsive education, uptake remains sporadic because of multiple forms of resistance. We contend that educational assessment is a crucial locus of resistance *and* inclusivity. We introduce an approach to formative and summative assessment that responds to multiple forms of resistance and is organized around four levels of increasingly formal assessment. We present new assessment design principles based on an initial proof of concept from a graduate course on assessment.

Introduction

Despite recent suppressive legislation, there is broad support for asset-based responses to diversity and discrimination in education. These include *culturally relevant education* (CRE, Aronson & Laughter, 2016), and *culturally sustaining pedagogy* (CSP, Paris, 2012). But uptake of asset-based responses has been sporadic in K-12 schools (Neri et al., 2019) and universities (Hanesworth et al., 2019). We argue that educator-created assessments are a significantly under-explored obstacle. In response, we offer a conceptual contribution and initial evidence for *culturally sustaining educational assessment* (CSEA).

Potential resistances to more inclusive educational assessment

Neri et al. (2019, p. 202) argued that school resistance to CRE is a "multi-level" problem that stems from (a) limited understanding and belief and (b) a lack of know-how. We agree, extend the argument to higher ed, and suggest that these challenges persist in the design of inclusive assessment. A second source of resistance is the aforementioned legislation limiting or prohibiting the discussion of race and gender. We assume that this resistance is likely higher when grading, assessment, and testing are involved. A third source is the challenge of creating "culturally valid" assessments, partly because educator-chosen representations that reflect the life context and values of minoritized youths may be rejected by those learners (Solano-Flores & Nelson-Barber, 2010). A fourth related source of resistance is that some students may feel pressured to speak for their communities.

Our final potential source of resistance is the most complicated and potentially contentious. This resistance is rooted in Paris' (2012) argument that pedagogy should “support young people in *sustaining* the cultural and linguistic competence of their communities while simultaneously offering access to *dominant cultural competence*" (p. 95, emphases added). We acknowledge the long history of blatantly racist use of standardized tests (Cunningham, 2019) and worry that prevailing summative assessments can encourage erasure and assimilation. But we also agree with Paris that all students must have access to the valued opportunities for educational advancement, admissions, and employment that are constrained by existing assessments created without attention to systems of power and privilege.

Introducing culturally sustaining educational assessment

CSEA emerged in an extended program design-based research of online courses and assessments (Hickey & Rehak, 2013; Hickey et al. 2020). This work embedded situative educational design principles for *productive disciplinary engagement* (PDE, Engle & Conant, 2002) within a situative multi-level assessment framework (Hickey & Zuiker, 2012). This resulted in a comprehensive framework that aligns learning across four increasingly formal levels of assessment that capture learning over increasingly lengthy timescales. These include (1) very informal *immediate* instructor analyses of student discourse, (2) informal *proximal* engagement reflections, (3) semi-formal *proximal* self-assessments, and (4) formal *distal* automated multiple-choice achievement tests. Iterative refinements in a range of online settings aimed to (a) maximize public interaction via threaded discussions of course resources and student work, (b) minimize private instructor-student interaction, (c) avoid dreary discussion forums that are removed from student work, and (d) preserve the validity of scores at each level as evidence of learning by avoiding teaching directly to those assessment items.

Starting in 2019, we began extending this framework to sustain diverse cultures in a way that helped all students master targeted course concepts, with the five potential sources of resistance in mind. This work was primarily carried out in an online course on educational assessment taught for many years by the first author and completed by the second and third authors as Ph.D. students. The course is a useful testbed because it typically includes students who identified with minoritized communities and who identified as politically-conservative (and sometimes expressed resistance to CRE, Hickey and Lam, 2022). We gradually extended the course using Agarwal and Sengupta-Irving's (2019) critique of PDE for ignoring the influence of power and privilege and their suggestion to include sociopolitical uncertainties (SPUs) that invite (without requiring) minoritized students to position themselves as having valuable experience and (therefore) expertise.

Our presentation demonstrates how each of the four assessment levels was extended to be more culturally sustaining. These included (1) adding an SPU in each assignment as one of two student-choice options and encouraging students to share unique expertise in informal instructor feedback, (2) adding a prompt for *cultural engagement* in the reflections, (3) including facts (but not opinions) regarding most of the SPU in the self-assessments, and (4) including facts (but not opinions) regarding some of the SPUs in the achievement tests.

We summarize evidence from 2022 as initial proof of concept. This includes analyses of 155 weekly e-portfolios (including instructor and peer comments), self-assessment and test performance, an interview with one of two African-American students in the course, and responses from the anonymous course evaluations.

We concluded that the expansion of CSEA in the 2022 section was promising, but more work is be needed for truly honest and productive dialogue (e.g., Vakil et al., 2016). We further concluded that these initial results support our proposed CSEA design principles:

1. **Include optional SPUs that invite, but do not require, students who identify with minoritized communities to position themselves as having valued relevant experiences and expertise.**
2. **Instructors' informal assessment of disciplinary discourse should position *all* students as having valued experiences and expertise and carefully introduce additional SPUs.**
3. **Encourage students to reflect on how social and cultural factors impacted their engagement without requiring them to speak for their community.**
4. **Instructors should read cultural reflections and directly respond to particularly compelling ones in public or private feedback as appropriate.**
5. **Include formative self-assessments for all controversies to efficiently foster familiarity.**
6. **Include exam items that assess the achievement of some (but not all) of the controversies and SPUs and ensure that those items function appropriately.**

The Perceived Benefits and Pitfalls of a Hybrid Course Learning Modalities From a Self-Determination Theory Perspective

Amit Shlomo, Rinat B. Rosenberg-Kima
a1@campus.technion.ac.il, rinatros@technion.ac.il
Technion, Israel Institute of Technology

Abstract: This study aimed to shed light on students' learning preferences post-COVID19. One hundred and thirty-four undergraduate university students attended physics hybrid courses and could participate by attending synchronously face-to-face, synchronously online, or asynchronously online. Most students initially preferred to arrive face-to-face but shifted to online modalities and were generally inconsistent in their attendance. The perceived benefits and pitfalls of different learning modalities were identified, and their relationships to self-determination theory are discussed.

Introduction

While some studies pre-COVID-19 show that most students preferred learning F2F (e.g., Jaggars, 2014), current studies suggest that the pandemic online learning experience may have changed their preferences (e.g., Castro & George, 2021).

Research shows that students' motivation is a critical factor in engagement in online learning. Self-Determination Theory (SDT) regards the conditions that can affect an individual's self-motivation. SDT points to three basic psychological needs are autonomy, competence, and relatedness (Ryan & Deci, 2019).

This study aims to analyze students' learning modality preferences by answering the following questions: (1) How would students learn, allowing them to choose between synchronously F2F, synchronously online, or asynchronously online?, (2) What are the reasons for students' preferences, and their relationships to SDT?

Method

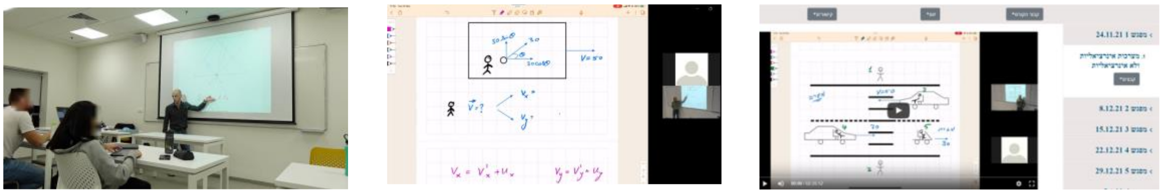
Participants

One hundred and thirty-four university undergraduate students in Israel enrolled in one of the hybrid physics courses and signed a consent form. One hundred and four answered all the questionnaires (51 males, 53 females, age mean=22.85, SD=2.07).

Material

Students could choose to participate in one (or more) of three learning modalities (F2F, Zoom, lessons' recordings) and could change their learning modality during the course (see Figure 1).

Figure 1
Photos/Screenshots of: (a) Synchronous face-to-face lesson, (b) Synchronous online lesson via Zoom, (c) Webpage for an asynchronous online lesson.



(a) (b) (c)

Research tools

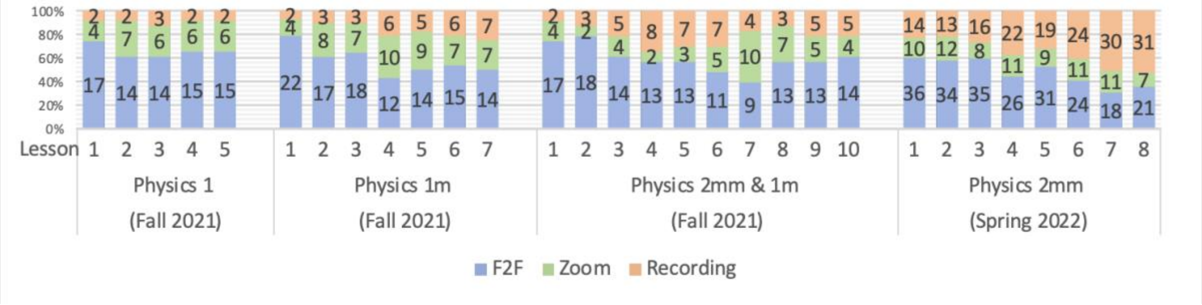
Students filled out a questionnaire including (a) learning attendance modality per each lesson and (b) open-ended questions regarding their reasons for their attendance, i.e., for each learning modality they attended they were asked: "what were the reasons for attending via F2F/zoom/lesson recording?". Thematic analysis was conducted on their answers (Braun & Clarke, 2006). In addition, the participants filled out a demographic questionnaire.

Findings

At the beginning of the course, most students arrived F2F, but the number of participants attending via zoom and recordings increased throughout the semester (see Figure 2).

Figure 2

Students' attendance sorted by courses with the same amount of lessons and hours. Physics 1/1m is Mechanics. Physics 2/2mm is Electricity & Magnetism.



At the end of the course, students answered open-ended questions regarding their learning attendance.

The benefits and pitfalls of learning F2F. Students reported several benefits of learning F2F: (a) increased concentration, (b) decreased distractions, (c) better understanding, (d) increased sense of commitment, (e) Social learning support, and (f) educational atmosphere. Nevertheless, students also reported pitfalls of learning F2F: (a) losing track of the lecturer, (b) losing concentration, and (c) no time/space flexibility.

The benefits and pitfalls of synchronous learning via Zoom. Students reported several benefits of learning via Zoom: (a) learning individually, (b) reduced travel time, flexible space, and (c) health benefits. Nevertheless, students also reported pitfalls of learning via Zoom: (a) decreased concentration, (b) increased distractions, (c) discomfort asking questions, and (d) technological problems.

The benefits and pitfalls of asynchronous learning via lesson recordings. Students reported several benefits of learning via lesson recordings: (a) controlling the pace of the lesson, (b) time/space flexibility, (c) allowing repetitions after the synchronous lesson, (d) lowering pressure during the synchronous lesson, (e) health benefits. Nevertheless, students also reported pitfalls of learning via lesson recordings: (a) requires self-discipline, (b) lack of social support.

Discussion

Students' initial preference for learning F2F is consistent with other pre-COVID19 studies (e.g., Jaggars, 2014). Nevertheless, their pre-learning preferences are not entirely met with their actual attendance; some students shifted to online learning modality, and some were inconsistent in their learning modality choice.

Overall, six main categories were found through all benefits and pitfalls. SDT can be linked to the themes: Attention, self-discipline, and learning efficiency can be linked to competence, self-support to relatedness, and time/space flexibility and health to autonomy.

The research is limited to students learning in a technological institution, and students had a particular motivation to participate in the course (they were willing to pay to join the course).

In conclusion, the era of post-COVID19 has transformed online learning into a necessity for all higher education. The benefits and pitfalls of each learning modality should be considered in designing learning modality post-COVID19. For students to choose between the benefits and pitfalls of each learning modality, it may not be trivial.

Visualizing Funds of Identity: Using Network Software to Model Collective Identity in a Classroom

Christina Stiso, Menxi Zhou, Selena Steinberg, Joshua Danish, Kalani Craig
cstiso@indiana.edu, mz13@iu.edu, ssteinb@iu.edu, jdanish@indiana.edu, Craigkl@indiana.edu
Indiana University

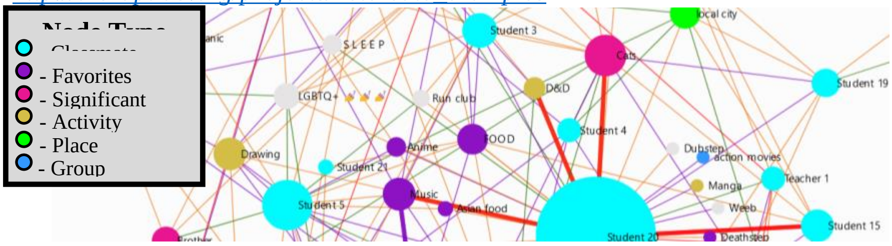
Abstract: Funds of Identity is a valuable way of understanding the resources learners bring to the classroom from home and that are relevant to them. In the present study, we supported learners in using the Net.Create network visualization software to support 5th- and 6th-grade students in representing their collective funds of identity as part of a data literacy unit. We present analyses showing how this tool supported their articulation and a summary of the ideas they viewed as central to their identity.

Introduction

Identity is a central concept in many learning theories, for instance, the funds of identity (FOI) framework proposed by Esteband-Guitart and Moll (2014). Funds of identity refer to the subset of their background knowledge that students find relevant to their own lives in their current context. While it is crucial that teachers understand their students' FOI to develop dignity-affirming instruction, teachers struggle to elicit this kind of information (Neri et al., 2019). In this study, we attempted to extend the theoretical notion of FOI in two ways, one practical and one theoretical. Practically, we show how network visualizations can help make identities - a key component of FOI work - visible in new and interesting ways. Theoretically, we expand the conception of a fund of identity as something that can be understood as shared or emergent. This allows us to lay the groundwork for theorizing the concept of collective funds of identity, a concept developed in collaboration with Dr. Rebecca Colina Neri.

A network visualization is a graph composed of 'nodes' which are connected to each other via lines, called edges (see Figure 1 for an example). They are often used to understand complex datasets where the relation between entities is important - for instance, a social network like Twitter. Net.Create is an online tool designed to create network visualizations (Craig, 2017; Craig et al, 2021). It supports simultaneous editing by many users, making it ideal for in-classroom use. Other analyses (Zhou et al., 2023) have shown how Net.Create can mediate students' understanding in classroom activities; the present analysis focuses on how these interactions support identity exploration.

Figure 1
An anonymized section of the identity network visualization made by participants in the class. The labeled circles are nodes, the lines between them are edges. Full graph: http://theraptlab.org/projects/netcreate_examples



Methods and design

The research team designed and led a six-day unit on networks and data literacy in a combined 5th- and 6th-grade classroom. The classroom was in a private school located in the midwestern United States. 11 students self-identified as female or girls, and 11 identified as male or boys between the ages of 10 and 12. Most students self-identified as White or American, 1 identified as 'Latina', 1 as 'Mexican', and 1 as 'Mixed'; English was the primary language spoken at home by all participants. From this intervention, the team collected video recordings (both classroom interactions and post-activity debriefs), physical artifacts, and digital networks created by students.

Each day, students participated in several activities designed to engage them with the concepts of network science, such as centrality, gravity, or betweenness (Hammer & Berland, 2014). Some of these activities used the Net.Create software while others used physical materials such as yarn to represent edges; most were playful. In addition to the other activities, students worked in pairs using the Net.Create software to iteratively construct a network visualization of their likes, interests, and connections. The categories (node types) in this network were based on the categories used in the FoI Literature (Esteban-Guitart & Moll, 2014). While individual students were only supposed to add and connect themselves to things that they personally liked, the eventual effect was something that showed collective as well as individual interests. For instance, students were able to see which people and things were more central to the classroom network - pet ownership was very central, something that several students claimed to not have been aware of before the activity.

Findings

Our analysis indicates that students, generally, articulated a greater number of network science concepts after engaging in network visualization activities (Zhou et al, 2023). Importantly for the present analysis, the identity network created by the students shows some of the key interests that students have and are comfortable sharing in their classroom such as interests in cats, drawing, and a wide range of foods. When asked in the post-interviews and during the implementation whether they felt the identity network 'represented' them *as a class*, students almost universally agreed (8 of 9 groups), leading us to infer that these entities are representative of actual interests. However, when asked if they felt the network represented them as an individual they were less positive.

Using interaction analysis of post-implementation interviews, paired with an analysis of the network artifacts, we also found that students felt like they learned a lot about their collective identity and how it may be represented through the network visualization activities. Much of this was specific facts, e.g., a lot of people in the class like cats or listening to music, but several students went further indicating that the network increased their sense of belonging. One student stated "I never knew how connected we all were…[or that] I had so many connections to people I don't even talk to" while another claimed that the amount of overlap in the classroom connection made them realize "if we just talked to each other more we'd be friends". When asked if the network helped them learn anything about themselves, one student said they "found out stuff I didn't think I was into", but then when they saw those things in the network they realized that not only did they like those things, others in their class also did.

Conclusions and significance

Eliciting identity in a way that is useful to an instructor is difficult (Neri et al., 2019). The use of network visualization software offers a promising classroom-based approach to eliciting students' individual and collective funds of identity in a manner that has the potential to support greater asset-based instructional work by teachers, though additional work is needed to better document how this representation both does and does not reflect learners' ideas and identities.

Fostering Subjective Understandings: Exploring the Role of Place and Transdisciplinarity in a US Teacher Education Program

Kathryn Lanouette, Esther Kim, Gladys Krause (1)
lanouette@wm.edu, ejkim05@wm.edu, ghkrause@wm.edu
William & Mary

Abstract: Education in the United States is often siloed by discipline, making transdisciplinary teaching and learning supporting social justice challenging. Drawing from a multi-year collaboration centering place, dominant narratives, and mapping in an elementary teacher education program in the mid-Atlantic region, we examine prospective teachers' justice-oriented inquiries posed across varied settings. We find that place-based pedagogies, collaborative cross-discipline teaching, and a question posing focus fostered transdisciplinary sensemaking, but also note limitations promoting further study.

Introduction

Within STEM education, there is an ongoing siloing of disciplines from Kindergarten through higher education, resulting in prospective educators often having limited opportunities to consider broader historical socio-political dimensions that shape disciplinary teaching and learning (Sengupta-Irving & McKinney de Royston, 2020). Takeuchi et al. (2020) argue that a *critical transdisciplinary* approach is essential to disrupting disciplinary hegemonies, to making possible forms greater than the sum of the disciplines centering equity and justice. We report on years 1 and 2 of a multi-year design-based research project that supported prospective teachers in experiencing and designing for transdisciplinary learning, building on our collective work as professors teaching Science, Social Studies, and Mathematics Methods, respectively, in an elementary teacher education program.

Theoretical framework

We draw on the work of Sylvia Wynter (1995), a Jamaican transdisciplinary scholar in U.S. Black Studies. Her essay *1492: A new world view*, uses *subjective understanding*, to offer an alternative perspective on Columbus. Subjective understanding refers to how sub-goals are a necessary part of the path to the ultimate goal. Applying this to Columbus, Wynter examines the many disciplinary frameworks (theology, social discourse, science, geography, politics) that made Columbus, the resultant narratives, and all the tragic consequences possible, that is, a subjective understanding of Columbus. This understanding of disciplinary learning and social justice aligns with Takeuchi et al.'s (2020) conceptualization of *critical transdisciplinarity*, which entails "interrupt[ing] disciplinary hegemonies to … lead to the emergence of new concepts, representations, and applications, that ideally should also re-center voices from the margins" (pg. 218).

In our collaborative methods classes, transdisciplinary learning and teaching took on three elements: 1) our own collaborative teaching as a model for our students, 2) using a variety of disciplines to answer larger questions about how injustices are made possible, not simply weaving together disciplines, and 3) centering historical and current narratives in local places as visible constructs that can be deconstructed and reconstructed by teachers and students.

Methods

Drawing on Soja, we understand "spaces as simultaneously sites of injustice and emancipation" (pg. 27), becoming particular places through "a simultaneity of stories-so-far" (Massey, 2005, pg. 5). We conjectured that a constructed and contested place would be generative for supporting prospective teachers in moving beyond *what is* towards *how it came to be*, in turn making visible dominant narratives across a range of phenomena and disciplines. To that end, we designed a three-class sequence as part of the methods courses, centering activities around a revered Colonial Site adjacent to the university campus and several public schools.

In the first class, prospective teachers were supported in considering the complexities of place for teaching and learning. In the second class at the Colonial Site, prospective teachers had extended time to explore their emergent questions and identify primary sources at the Colonial Site. Prospective teachers worked in pairs, spending 45 minutes freely walking around the grounds and recording emergent questions that intersected with science, math, and social studies disciplines. In the third class back in the campus classrooms, prospective teachers added their questions and images to a collaborative ArcGIS map, a participatory Geospatial Information System (GIS) mapping tool, enabling the sharing of questions, specific locations, and related media in their lesson plan designs. Prospective teachers then worked in groups of 3 or 4 to imagine transdisciplinary lesson designs anchored around questions that might surface dominant and nondominant narratives (e.g. whiteness, erasure of Black and Indigenous voices) through a transdisciplinary approach.

Participants and data sources

Participants included two cohorts of prospective elementary teachers, comprising 43 Masters (MA) and Bachelors (BA) students in total. Data sources include researchers' field notes for each class session, video recordings (e.g. GoPro video outside, whole group video), and digital/paper artifacts (e.g., brainstorming place from Day 1, pairs' questions and source note sheets from Day 2, collaborative question mapping using ARCGIS maps and poster lesson plans from Day 3).

Analytic methods

In this analysis we ask: Which subjective understandings became visible and which remained hidden in this transdisciplinary learning and teaching sequence? Using thematic analysis (Saldaña, 2016), we focused on prospective teachers' questions emerging across the three class sessions. We coded artifacts and video in two waves, focusing on (a) what disciplines were leveraged in questions and (b) if or how questions attended to the construction of the Colonial Site, demonstrating subjective understandings.

Results

Prospective teachers incorporated all three disciplines in their lesson plan questions centering social studies due to the nature of the site. Notably, prospective teachers generally generated math questions and activities by calculating costs or measurements, not engaging with socio-political or historical inquires (Gutstein, 2012). As an example, one pair developed an overarching question of "How communities interact with gardens?" For social studies, the pair emphasized social and economic inequities by asking "Who benefits from the garden? Who owns the garden?" They also included the question "Who works in the garden?" to attend to the reality of enslavement. With regards to science, the same group focused on how humans and more-than-humans shape the environment and each other by asking "How do gardens change the natural landscape? How do humans and animals interact or affect the gardens and one another?" The pair also posed mathematical questions, focusing on measuring the size of the garden and other spatial arrangements removed from historical, social or political inquiries.

In terms of the visibility and invisibility of subjective understandings emergent in prospective teachers' questions and lesson design plans, we found that every group developed lesson plan question ideas on Day 3 that acknowledged the presence of socio-economic and historical inequities, drawing together several disciplines. Yet rarely did their questions move deeper into *why* and *how* they came to be, that is, the subjective understanding that Wynter details in *1492*. Across the multiple groups that fully or partially attended to subjective understandings, we observed that the theme of change and continuity over time facilitated an initial responsiveness not only to the constructedness of the Colonial Site, but to how knowledge in science, history, and as disciplines are also simultaneously constructed and deconstructed.

Conclusion and contributions

We join scholars and educators attending to the complexities and possibilities of supporting *critical transdisciplinary* teaching and learning, with a focus on equity and place in teacher education. We offer empirical evidence of how such transdisciplinary sensemaking might emerge within a closed time period, centered around a contested place and involving cross-disciplinary faculty collaborations, with key areas identified for further support in future iterations.

#Antiracist: White Teacher Agency and Learning on Twitter

Amanda N. Coviello, University of Wisconsin-Madison, acoviello@wisc.edu

Abstract: This study draws on interviews with three White teachers to answer the question: How do White teachers agentically pursue their own antiracist learning and development through their use of Twitter? My analysis shows how participants use Twitter to interrogate their own whiteness, hold themselves accountable, and find support for vulnerability and discomfort—creating rich opportunities for transformative antiracist learning.

Introduction

Many teachers rely on resources found outside of schools and even outside of their local communities to supplement their professional development, especially where controversial topics such as race, racism, and antiracism are concerned. In this paper, I highlight teachers' agency in self-directing their antiracist learning and development on Twitter, guided by the question: How do White teachers agentically pursue their own antiracist learning and development through their use of Twitter? The three study participants described rich possibilities to build supportive race-conscious learning communities beyond what is available within the confines of school- and community-based learning spaces.

Prior research and theoretical framework

Using Whiteness Studies (Leonardo, 2009), and sociocultural learning theories (Vygotsky, 1978), this study views White racial identity development as a process of unlearning (Tatum, 1992) supported by participation in social activities that challenge to previously held ideologies (Leonardo & Manning, 2017). Following these frameworks, antiracist learning requires trusting and supportive relationships that hold teachers accountable to their antiracist development as well as humanizing support and guidance in which White teachers are situated as valued members of an antiracist community as they navigate the vulnerability of unlearning (Leonardo, 2009; Leonardo & Manning, 2017; Picower, 2021). Prior research suggests that White teachers often resist the necessary and uncomfortable work that antiracism requires (Picower, 2009). Other studies emphasize the success of specific programs and in-person communities that not all teachers have access to, and in which teachers have little responsibility or agency for directing themselves (Picower, 2021). Without discounting the literature describing White resistance to antiracist learning, this study investigates teachers' agency in seeking support to develop their understanding of and commitment to antiracism. There is growing recognition that teachers are agentic sense-makers who make meaningful decisions impacting their own development (e.g. Anderson, 2010; Louie, 2017). Social media may be a particularly valuable resource for teachers pursuing antiracist learning and development, as they may use online platforms to self-direct their own learning and build supportive communities (Carpenter & Krutka, 2014). The present study offers new insights into the possibilities of sites like Twitter for supporting White teachers' self-directed antiracist learning.

Methods

This analysis focuses on three participants, Mark, Erica, and Pam (pseudonyms), that all self-identified as committed to antiracist education and agreed that Twitter influences their antiracist development. These three participants also participated in "Accomplices" (a pseudonym), a private Twitter group of White educators, which became a central interest of my analysis. Interviews were conducted and recorded via Zoom in Spring 2021. Using a form of stimulated recall interviews (SRI; Dempsey, 2010), I prompted participants to provide detailed descriptions of their experience on Twitter by situating that experience in their recent activity. Following SRI protocol, I used participant observation to gain knowledge of participants' behavior to inform the questions that I asked. Although excluded from my analysis, these observations provided a sense of how participants typically used Twitter. Interviews focused on how participants made decisions about who they perceived as guides and sources of support for their antiracist learning. To analyze the interview data, I used open coding to identify common themes first focusing on the tools and activities that participants described (e.g., following, likes, hashtags) and the people that they named as influential to their development. Informed by the literature, further analyses focused on how participants made decisions about whom they perceived as guides and whom they turned to for support. I also looked for indications of how these decisions were made with a consciousness of the racial dynamics of Twitter-based relationships and how this consciousness influenced how they used Twitter.

Findings and implications

Three themes emerged from my analysis: 1) participants valued Twitter as a space to find new sources of guidance that could offer resources for making sense of antiracist teaching and that challenged their previous ideologies; 2) beyond only engaging with other users as sources of guidance, participants also developed personal relationships with users that supported their growth by holding them accountable and offering a space to share vulnerabilities; and 3) each participant described the ways they confronted their own racial biases and white socialization as a result of their engagement with networks of teachers on Twitter.

In making decisions about whom they perceived as guides and chose to follow, each participant named race as a key factor. Specifically, Black women were named as important sources of knowledge along with other White teachers who functioned as role models for their antiracist development. Although they did not always interact with these guides in ways the guides noticed, the guides were nonetheless meaningful resources to participants. Furthermore, participants made critical decisions about who would best support their development based on the content of the user's Tweets and their reputation within antiracist Twitter circles. Eventually, each participant became a member of a private DM group, Accomplices, for White teachers committed to antiracism. The community they built through Accomplices provided a space to work through their discomfort and hold each other accountable without expecting people of Color to do so. Critical to their online relationships was a sense of accountability and trust that developed over time and shared values that allowed them to express vulnerabilities and challenge one another.

Through access to guidance and the communities that they became a part of, participants described their Twitter activities as helping them become more conscious of systemic inequities and the ways that they themselves have been socialized by whiteness. This was especially true for one participant (Erica) who described having limited interest in her own antiracist development prior to encountering discussions of antiracist education on Twitter. This points to the unique ways that platforms like Twitter can make unexpected resources for learning visible to teachers. They also named ways that their conversations on Twitter inspired them to incorporate lessons that examined racial biases (Mark); explicitly address implications of recent events of racist violence (Pam) and help their students (preservice teachers) to find resources and communities of support that would encourage their antiracist development (Erica). While conscious of their positionality and aware that they always have more to learn, each participant expressed that Twitter helped them to feel a sense of empowerment to challenge racist systems in their daily lives.

These findings demonstrate the possibilities for White teachers to actively pursue antiracist (un)learning in transformative ways. Rather than avoid discomfort, the teachers in this study frequently sought out discomfort and built relationships with people who would hold them accountable to their antiracist development. Furthermore, this study describes teachers' agentic use of technological resources to access new sources of guidance and support and suggests that sites like Twitter may provide opportunities for White teachers to participate in new social activities that help reveal the ways that they have been socialized by whiteness. More research is needed to investigate the themes described in this study such as the role of White teachers in acting as antiracist guides for other White teachers and how such learning is taken up in practice. By examining teacher learning in informal and self-directed spaces, we can better understand the types of activities that both support teachers' development and invite their active participation. Additionally, by examining the increasing use of technology and social media as a resource for expanding opportunities to engage in antiracist learning, we can learn more about future possibilities for teachers to build the kinds of national and cross-racial coalitions that are necessary to dislodge the foothold of white supremacy in education.

A Pilot Study of Chinese Academic Motherhood, Strategic-Decision-Making, and Course Design

Ling Che, Susan M. Bridges
cheling@connect.hku.hk, sbridges@hku.hk
The University of Hong Kong

Abstract: Academic motherhood remains an area to be explored more deeply in China. This pilot study of online course (re)design during the COVID-19 pandemic is timely given shifts in China's Family Planning Policy. The Learning Design Components framework guided interview analysis of two mothers' strategic decision-making in (re)designing university courses. While their motherhood experiences during campus closures were challenging, their vicarious observations of their children's teachers' online pedagogy supported new strategies their adoption to empower undergraduates.

Introduction

Studies into Chinese academic mothers emerged after the late 1970s alongside policy reforms. Historically, female academics in China have had different career profiles and access. Before 1949, they were subject to compulsory termination upon marriage. While this improved with the creation of the People's Republic of China and the Cultural Revolution, access to qualifications for career advancements remained limited, as reflected in minimal research outputs (Tang & Horta, 2021). Ward & Wolf-Wendel (2004) indicated that a sense of accomplishment, self-esteem, respect, flexible schedules, improved efficiency and autonomy, and even being a better mother for some were positive aspects of academic motherhood. However, they also idenfied gender inequity, heavy workload, time shortage, and sometimes even guilt of not being a 'good mother' because of juggling work and life as challenges. Chinese academic mothers' work-life conflicts have their own specific characteristics, especially given their social context and China's family policy changes from one child (1980) to two children (2016) to three children (2021) per family. Research into Chinese academic motthers' course design experiences for online teaching and returning to campus during the COVID-19 pandemic will bring new insights into their academic lives. By investigating Chinese academic mothers' home-teaching and child-rearing experiences, this study aims to address the issues of school-society disconnect in a networked society (Tabak et al., 2019).

Conceptual framework

During the global pandemic and campus closures, academics adapted to emergency remote teaching, acquiring the expertise to (re)design courses and teach online from their homes. Rapanta et al.'s (2021) Learning Design Components (LDC) framework reflects the centrality of strategic decision-making for successful online course design and conceptually guides this research. Specifically, strategic judgments are influenced by institutional decision-making and long-term planning (macro-level professionalisation), cognitive apprenticeship (meso-level empowerment), and pedagogical and instructional approaches (micro-level flexibility). Meso-level empowerment scaffolds teacher expertise through co-design and coordination across formal and informal communities of practice, with the final design and its implementation reflecting the teacher's strategic decisions. The guiding question adopted in this pilot study is: *How does being an "academic mother" influence Chinese university educators' strategic decision-making in their course (re)design processes during the COVID-19 pandemic?*

Methodology

From the respondents of an ongoing online survey, two academic mothers from Liaoning Province, China were selected for case analysis based on their teaching discipline (English) and child profiles (Tracy - one 15 year old high school son; Rachel - two sons (15 year old middle school; 8 year old primary school). Tracy is a newly promoted professor and course coordinator, while Rachel is a lecturer and course team member. The differences in academic rank and child profiles indicate differences in workloads and priorities; however, both have courses of a similar size that required a shift to fully online delivery. Both joined in-depth, open-ended audio-recorded interviews (~30 min each) which were conducted in Mandarin via WeChat™ and translated into English. Thematic analysis of interview transcripts focuses on the student empowerment dimension of the LDC framework to explore the strategic judgements of both course designers (Braun & Clarke, 2006).

Results

Academic mothers and their child(ren) in this project all reported experiencing online and/or hybrid teaching during COVID-19 campus closures in China. Overall, both Tracy and Rachel's reflections illustrate the mutual effects of their dual identities of "mother" and "course designer". They indicated burdens of "workload," "lack of rest, and research productivity"; however, both dedicated time and space to course (re)design as they valued the quality of their online teaching during the pandemic. For example, Tracy equipped her course with an online "quiz" for formative testing of students' speaking. Specifically, academic motherhood during home lockdowns provided opportunities for them to observe "from the other side of the screen" and both cases reflected that this enhanced their empathy, encouraging them to create supportive classroom environments, a key facet of LDC empowerment. The emic, almost ethnographic observation of Tracy's son's home zoom classes provided an insight into "behind-the-scenes" activities facilitating new understanding and approaches:

> We can't see what students are like behind the screen in online classes. But if I observe my child in his online class, I will know his role as a student and how he interacts with teachers. It inspires me to motivate, interact, and be thoughtful with my students. (*Tracy, Nov 2022*)

Similarly, Rachel gained insights into students' home learning from her son's experience and found that it supported her interactions with her students and motivated her students' autonomy in the class:

> My son would lie to his teacher when he sneaked away by repeating "hi" to indicate a bad network. When my student did the same in my hybrid class, I would jokingly say, rather than being angry, "I can't ask him questions due to a bad network". (*Rachel, Nov 2022*).

Discussion & conclusion

Pilot analysis of these two cases indicates some positive outcomes from academic mothers teaching online from home during campus closures in China. Although the additional workload was acknowledged, both chose to prioritize their teaching over work-life balance and research productivity. As academic mothers teaching working online for the first time, they were able to adopt, adapt, and explore new strategies to empower students for synchronous online classes. From an LDC perspective, their observations of their children's classes and engagement in learning online at home scaffolded their learning and enhanced their adaptive expertise. While many university systems sought to support teachers formally, their "spontaneous", informal learning by observation supported their online (re)designs and provided a new dimension to their professional development in a networked society (Tabak et al., 2019). In both cases, they viewed this professionalisation as a rewarding aspect of academic motherhood. Their flexibility and creativity reflect Darling-Hammond and Bransford's (2005) notion of teachers' "innovation expertise" with creative solutions to online teaching challenges. Their decisions to appropriate the teaching practices of their children's online teachers and to support student empowerment by adopting more empathetic approaches led to transformations in their practice. Despite the challenges of caring for children whilst teaching online, they felt their motherhood experience positively influenced their strategic decision-making as teachers and course designers.

Unsettling Socio-Emotional Learning:
Perspectives From Working With Resettled Refugee Youth

Sarah Priscilla Lee, Stephanie T. Jones, Vishesh Kumar, Marcelo Worsley
spl@u.northwestern.edu, stephanie.jones@u.northwestern.edu, vishesh.kumar@u.northwestern.edu,
marcelo.worsley@u.northwestern.edu
Northwestern University

Abstract: The COVID-19 pandemic ushered in significant shifts in how youth experience both in-school and out-of-school learning. One of the most notable changes was in where and how group interactions took place. This paper argues that in the transition from in-person to virtual programming, socio-emotional learning (SEL) requires additional planning and intention. We explore how facilitators and refugee youth negotiate SEL in a virtual summer program. Our findings reveal authentic SEL when facilitators use an ethic of care through technological troubleshooting. We also present nuances that youth offered to SEL, which trouble uniform depictions of what SEL might mean. From this, we share implications for further SEL work and intergenerational learning supports that extend beyond the challenges posed by a global crisis.

Introduction

Resettled refugee youth face significant challenges acclimating to a new society, including language barriers, unfamiliar social norms, values, belief systems, practices, institutional environments, and unwelcoming contexts of reception (Bennouna et al., 2021). The COVID-19 pandemic exacerbated the challenges that refugee youth face. Attending to, and supporting, socio-emotional Learning (SEL) skills serve as a powerful tool to support acclimation, sense of belonging, and continued learning in a new place (d'Abreu et al., 2019). This poster shares facilitative moves in a segment from a virtual summer program that centered Socio-emotional Learning for refugee, immigrant, and asylum seeking youth (grades K-12). We utilize discourse analysis to explore facilitator and children interactions as they read a book "Pete the Cat and His Magic Sunglasses". We highlight findings that demonstrate how facilitators can embody and implement authentic SEL and moments when youth expanded what counts as SEL.

Background

SEL is widely described as "the process through which children and adults understand and manage emotions, set and achieve positive goals, feel and show empathy for others, establish and maintain positive relationships, and make responsible decisions" (CASEL, undated). The layered traumas, grief, uncertainties, and isolation due to the COVID-19 pandemic, in the midst of increased racialized violence, has amplified calls for re-imagining teaching and learning that centers care and socio-emotional development (de Royston et al., 2020; Bang, 2020; Bang et al., 2021). Despite the promises of SEL to support students' learning and center relations of care, SEL curriculum often follows rigid scripts, which has negative consequences for the health and wellness of students of color (Camangian & Cariaga, 2021; Simmons, 2019; Simmons, 2020). Authentic SEL responds to students' cultural contexts, affirms those contexts, and addresses traumas. Facilitators need training that supports them with modeling and embodying SEL through an ethic of care.

Contexts, participants, and data

Researchers and participants

Participants are from a research practice partnership (Coburn & Penuel, 2016) started in 2017 with Refugees Around the World (RAW), a nonprofit refugee organization located in a large midwestern city. For the past several years, the research team has partnered with RAW to support after school and summer programming for local youth. Additionally, the research team takes on the responsibility of training summer interns for their work with the youth. An intern, Jamie, and the youth program coordinator, Myra, co-facilitated a session with five kindergarten-aged children. Jamie read aloud a book "Pete the Cat and His Magic Sunglasses" with an animated video to accompany the reading.

All participants use she/her pronouns and pseudonyms are used for participants and the organization. Jamie was not formally a teacher and was in a masters program for social work. Myra had led youth programming at RAW for one and a half years and has a background in trauma-informed and culturally-responsive pedagogies. The researchers were second and third-year Learning Sciences graduate students.

Methodological framework

Using discourse analysis (Gee, 2004; Rogers, 2011) we examine the interactions between facilitators and kids as they read and discuss the book "Pete the Cat and His Magic Sunglasses". Two vignettes highlight contrasting forms of 1) supporting youth as they struggled with the logistics of participating virtually, and 2) not fully acknowledging emotional sensemaking from youth that diverged from the learning material and facilitator's expectations.

Findings

Two findings demonstrate how facilitators and kids engaged with SEL. In the first finding, we notice moves enacted within the constraints of the virtual platform to model and embody SEL within an ethic of care. In the second finding, we share tensions around cultural framings that surfaced during a discussion of the book.

Discussion

The book and discussion serve as the primary artifact that Jamie used to implement her sensemaking around SEL with the kids. The discussion surfaced negotiations and tensions around cultural framings and assumptions tied to SEL goals in this session. In the second case, we see Myra's interventions to troubleshoot microphones as a move to value each kid's participation and part of a larger effort to lower the barrier to participation. Beyond a set of skills that can be developed, SEL is an embodiment of empathetic response and attending to oneself and others. Zoom required a level of slowed down attention from Myra and other facilitators, which reflected their goals of a SEL rich summer experience.

Implications

Existing scholarship argues that intergenerational, home contexts might offer a space and relationships to engage in authentic socio-emotional learning.

Conclusion

We see glimpses of possibilities for enacting authentic SEL that engages students, facilitators, and family members in embodying SEL skills beyond scripts. Future training for facilitators needs to articulate the dominant cultural framings of SEL that perpetuate ideas of SEL as scripts, and support sensemaking toward SEL rooted in relationships that attend to the layered contexts for youth.

Supporting Culturally Relevant Computer Science: Evaluating Lesson Plans With a Research-Practitioner Partnership Rubric

Sarah Lilly, University of Virginia, scl9qp@virginia.edu
Jennifer L. Chiu, University of Virginia, jlc4dz@virginia.edu
Eric Bredder, University of Virginia, eb8ga@virginia.edu
Anita Crowder, CodeVa, anitacrowder@codevirginia.org

Abstract: This poster explores how teachers in a research-practitioner partnership utilize a rubric to evaluate lesson plans in terms of their integration of culturally relevant computer science. Results include that teachers felt able to include opportunities for cultural competence but indicate that additional support is necessary to include opportunities for cultural critique and conceptions of knowledge. The poster will highlight additional supports that teachers may need to develop culturally relevant computer science lesson plans.

Introduction and background

State and national frameworks in the United States (e.g., K-12 Computer Science Framework, 2016) task teachers to offer opportunities for equitable access to computer science (CS) to their students (Madkins et al., 2019). To promote equitable CS, we support teachers to integrate culturally relevant computer science education (CRCSE) through a research-practitioner partnership (RPP; Chiu et al., 2022). We broadly define CRCSE as a pedagogical strategy for teachers to leverage students' cultural identities and resources within the contexts of classrooms (e.g., Madkins, 2019), drawing on concepts of academic success, cultural competence, and sociopolitical consciousness (e.g., Ladson-Billings, 1995).

Elementary teachers may need support to develop CRCSE lessons, because they may not have a background in CS, may have limited experience with CS pedagogical practices, or may need support to draw upon their students' cultural assets within CS (e.g., Morales-Chicas et al., 2019; Yadav et al., 2021). RPPs can support elementary teachers to equitably teach CS within their culturally diverse classrooms by providing ongoing professional development (PD) tailored to fit the specific needs of their teachers through strong practitioner involvement. For example, PD through RPPs can help teachers to increase their confidence in teaching with CS (Rich et al., 2021) and empower teachers with the agency to develop tools for their own classrooms (e.g., Christian et al., 2021).

Yet few studies have explored how RPPs can support elementary teachers to build knowledge of CS practices, concepts, and pedagogical strategies (Henrick et al., 2019), particularly culturally relevant CS. The purpose of this work is to support elementary teachers to develop and implement culturally relevant curricular materials that integrate CS into core content areas. Specifically, this study explores how teachers utilize an RPP-developed rubric to evaluate their lesson plans to (1) support culturally relevant CS lesson development and (2) privilege the voice of teachers in considering the areas in which they find successes and the areas in which they indicate that additional support is needed. We explore the research question: To what extent do teachers evaluate their own integrated CS lesson plans as reflecting culturally relevant pedagogical strategies?

Methods

This study uses an embedded, single case study methodology (Yin, 2018) to consider artifacts from a five-day, summer PD workshop conducted by an RPP for elementary teachers. The purpose of this workshop was to help 3rd-5th grade teachers outside of the RPP develop culturally relevant lesson plans that integrate CS. Workshop participants included eight teachers, five teacher-leaders from the RPP, three researchers, and two non-profit leaders. Prior to the workshop, the RPP collaborated to create the lesson plan rubric. The rubric operationalized cultural relevance through cultural competence (maintaining students' cultural integrity during teaching and learning processes), cultural critique (helping students recognize, understand, and critique current social inequities), conceptions of self and other (commitment to the belief that all students can achieve), social relations (enhance student-teacher and student-student relationships and collaborative learning opportunities), and conceptions of knowledge (scaffold learning using artifacts endemic to your students' racial and ethnic identities and local/global culture and history). The rubric also enabled teachers to select the extent to which their lesson plan offers these opportunities for cultural relevance (yes, no, maybe) as well as to explain their reasoning. In the PD, the eight teachers worked to create their own lesson plans with support from the teacher-leaders, researchers, and non-profit leaders. The eight teachers were then encouraged to self-evaluate their lesson plans using the RPP rubric. The poster includes these artifacts (i.e., lesson plans and rubrics) and information about PD activities. For analysis, lesson plans and rubrics were blinded. Five RPP researchers together analyzed the teachers' rubrics in aggregate to note themes in how teachers used the rubric, areas of cultural relevance in which teachers felt they were doing well, and what additional supports they may need.

Results

Findings reveal that five teachers (pseudonyms used below) were able to use the rubric developed by the RPP to evaluate their CS lesson plans for opportunities of cultural relevance. Four out of the five teachers felt successful in the area of providing opportunities for cultural competence. For example, Ms. Vittitow noted in her explanation of their lesson plan that she will, "Play a video that explains the history of the term *debug* - the video offers students background knowledge and shows the important role women have in technology." Ms. Vittitow also noted that students will, "Create their own division story problems. This allows students to draw from their own experiences and cultures to create practical problems." In these ways, Ms. Vittitow felt that she was able to offer cultural knowledge relevant to the students' identities and build upon students' background knowledge. However, none of the teachers felt that they addressed providing opportunities for cultural critique in their lesson plans, and they were mixed in whether their lesson plans provided conceptions of knowledge. For example, Ms. Sunshine noted that she would "provide a program for students to express their knowledge on how to build/create a graph" and students would "use their knowledge to create a bar graph." However, Ms. Sunshine did not feel that she demonstrated that knowledge is shared and constructed together or provided pathways to connect to students' identities, culture, and history.

Discussion

Findings demonstrate that teachers generally felt as if their integrated CS lesson plans provided opportunities for students to connect to their own experiences and cultures but did not provide as many opportunities for sociopolitical consciousness. This poster will invite a discussion about the extent to which these kinds of rubrics can be helpful by providing more detail about the teachers' lesson plans and rubric ratings. The poster will also contain future plans of the RPP to continue to support these teachers to plan and implement CRCSE lessons. Results contribute to understanding how RPPs can support teachers' learning of CRCSE lesson planning.

Students’ Attitudes Towards Mathematics During Math Walks

Saki Milton, Marc T. Sager, Candace Walkington, Maximilian K. Sherard, Anthony Petrosino
slmilton@smu.edu, msager@smu.edu, cwalkington@smu.edu, msherard@smu.edu, apetrosino@smu.edu
Southern Methodist University

Abstract: Math walks are informal learning activities where students create mathematical meaning from their everyday surroundings. In this qualitative study, we observed 5th–8th-grade students (N = 52) across three urban informal learning sites (a community center, a zoo, and an aviation museum) as they created their own math walks exploring geometric concepts. In a post-survey questionnaire, students described their attitudes toward math using affective language motivated by three psychological factors: autonomy, competence, and relatedness. Implications for informal math learning are discussed.

Conceptual framework

Recent informal learning science literature (Guzey et al., 2016) maintained that situated learning has been used to broadly study students’ attitudes toward STEM (science, technology, engineering, and mathematics) as they participate in authentic learning activities (Brown et al., 1989). The construct of attitudes toward math has been extensively studied in formal schooling scenarios, revealing that students typically express their attitudes toward math using affective descriptive language (Chew et al., 2019; Russo & Minas, 2020). Those studies showed that students’ attitudes toward math can range from being “positive” to “ambivalent” to “negative” and usually vary in strength along that spectrum. But, how do students express their attitudes toward math in informal learning environments? Math walks, or informal learning activities where students walk around their communities and form math connections with the art, nature, etc. within their surroundings, are being used as a way to improve students’ attitudes towards mathematics (e.g., Wang et al., 2021). We used self-determination theory (Deci & Ryan, 2012) to examine how students expressed their attitudes toward mathematics based on three psychological factors that motivate behavior: autonomy, competence, and relatedness (Russo & Minas, 2020). As such, our research question was: How do students describe their attitudes toward mathematics after participating in and creating a series of math walks?

Methods

Over 3–4 sessions, we examined a diverse group of learners in grades 5–8 (N = 52) at three informal learning sites (a community center, a zoo, and an aviation museum) in a large urban city in the southwestern U.S.A. Across the sites, learners were mostly female (71%), Black (49%), and Hispanic/Latinx (27%). Grade level breakdown was 33% (5th grade), 37% (6th grade), 19% (7th grade), and 11% (8th grade). Students self-organized into groups of 3–4 paired with one researcher who video-recorded the group’s daily interactions. After they finished the math walk activities, they took a paper-based survey, which included two open-ended questions: (1) What did you like about your experience creating your math walk? and (2) What do you wish had gone differently? In isolating students’ attitudes toward math, we used thematic analysis (Braun & Clark, 2006) to contextualize students’ written feedback on their experiences and iteratively coded responses as either positive, ambivalent, or negative. Then, like Russo and Minas (2020), we categorized the statements into three themes representing the psychological motivators: autonomy (choice over how they approached the task), competence (feeling they have the necessary success skill), and relatedness (collaboration with their peers during the task).

Results

Students’ affective attitudes toward math walks

Analysis of the data revealed that affective attitudes (how they felt) toward mathematics after the math walk experience (see Table 1) were predominantly positive across all sites, with 69% (*n* = 27) of students reporting positive sentiments. Positivity language included phrases such as "I liked...," "I enjoyed...," or "It was fun...." For instance, a 5th-grade female community center participant expressed her satisfaction by saying, "What I liked about creating my own math walk is when I got to go and find an area that was math related." Students who expressed ambivalent or negative feelings were evenly split at 15.4% (*n* = 6). For example, a female 8th-grader at the aviation museum reported mixed feelings, saying, "It was okay. It really doesn't matter to me. It was boring sometimes, and then it wasn't boring." Meanwhile, a male 8th-grader at the zoo expressed a desire for "things being more related to math." We coded this as a negative feeling because a specific learning need was unmet. Unanswered questions were excluded from the analysis.

Table 1
Summary of Students' Affective Attitudes toward Mathematics during Math Walks

Positive	Ambivalent	Negative
27 (69.2%)	6 (15.4%)	6 (15.4%)

Psychological motivators for students' positive attitudes toward math

Next, we described the student attitudes and found that they primarily attributed positive attitudes due to their perceived ability to demonstrate *competency* in math (n = 23). For instance, one fourth-grader at the zoo wrote, "I liked finding similarities between math and animals." Other students used language that emphasized *relatedness* (n = 11) when expressing their attitudes toward math during the math walks at their sites. Two documented responses were:

> *"I like that we got to be in a group and express our ideas in math."* –4th-grade male zoo participant
>
> *"I also enjoyed how we worked in a group because groups make me feel more comfortable."* –5th-grade female student community center participant

Finally, eight students (n = 8) discussed the importance of *autonomy* when completing their math walks. "Being able to pick our stop was my favorite part," explained one 8th-grade male who attributed his positive attitude toward the math he was learning to his enjoyment of autonomy during the tasks.

Conclusion

Our analysis revealed that student-created math walks are promising tools for practitioners to gauge students' affective attitudes toward mathematics and the possible reasons behind those attitudes. Although most students expressed positive attitudes toward mathematics, some reported negative or ambivalent feelings. The impact of math walks on students' perceived competence requires further exploration to inform the development of math walk activities and theories of change for informal math learning. These preliminary findings are based on data collected in the first year of our five-year study. Future implications include students' transferability of positive attitudes towards mathematics developed in informal learning environments to formal learning environments (i.e., schools) and teachers' experimentation with math walks to improve students' attitudes toward mathematics.

Issues in Infrastructuring OST STEM Learning for Selective College Admissions

Steven Cederquist, Barry Fishman, Leslie Rupert Herrenkohl
cedsteve@umich.edu, fishman@umich.edu, leslierh@umich.edu
University of Michigan - Ann Arbor

Abstract: We report findings from interviews with college admissions personnel (CAP) as part of a larger infrastructure project examining opportunities to enhance the value of out-of-school time (OST) STEM learning in the U.S. college application review and admissions process. Our findings report on how CAP employ holistic review practices with information on both formal and OST learning experiences in the context of STEM admissions to render admissions decisions.

Introduction: Expanding the college admissions infrastructure

Our focus in this study is to explore the dimensions of the existing infrastructure of college admissions and to better understand how the existing infrastructure affords *some* students admission to selective colleges and universities in the United States but not others. Following Star and Ruhleder (1996), and later Penuel (2018), we understand infrastructure to be primarily relational. As such, we study infrastructure by examining the materials, standards, and work practices that support coordinated and distributed work with diverse stakeholder groups: in this study, the context of holistic review in selective college admissions in U.S. colleges and universities. This study builds off previous work by Cederquist, Fishman and Teasley (2019) which explored the potential of digital credentials as an innovative college admissions data source. This study expands our understanding of how college admissions professionals (CAP) make holistic admissions decisions and the role information on out-of-school time (OST) learning plays in selective admissions with a focus on access to STEM programs in post-secondary education. Through this work we are developing a platform (a kind of mastery-based record of OST learning) in partnership with the Mastery Transcript Consortium (MTC), OST program providers, and OST students and their families, to document the learning occurring at these sites. Our findings point to the potential benefits and challenges of incorporating mastery-based transcripts of OST learning into the college admissions process and unique challenges to inclusiveness presented by STEM admissions standards and practices.

Methods and participants

This is a qualitative study of how CAP conduct holistic review and the information they use to understand readiness for learning at their institution. We recruited 12 participants using snowball sampling methods: all have first-hand experience reviewing college application materials and making holistic admissions decisions in real admissions scenarios. The participants represent a range of institution types: private liberal arts colleges (n=4) and both public and private research universities (n=8). The institutions also represent a range of selective (n=8) and open (n=4) institutions (selective meaning a 60% admission rate or lower). Our sample size limits the generalizability of our findings, but our objective in this study has been to surface issues for future inquiry.

Conversations with participants followed a semi-structured interview protocol and addressed the following topics: 1) participant roles and responsibilities, 2) how CAP identify promising applicants in undergraduate admissions, 3) how information on formal and informal (OST) learning is used in holistic review, and 4) how STEM readiness standards influence holistic review. Data collection consisted of audio and video recordings of interviews and digital transcripts autogenerated by the video-conferencing platform. We prepared data for analysis by cross-referencing audio recordings with written transcripts to correct transcription errors. Data cleaning coincided with creating content logs for each interview. Content logs allowed us to document our initial reflections on each interview. We inductively coded both content logs and transcripts in an iterative fashion to develop emergent themes into a codebook that will guide future rounds of inquiry and design work.

Findings and discussion

CAP review files for evidence of academic and nonacademic fit. A judgment of academic fit is made from verifiable curricular information reported by the applicant's secondary school: academic transcripts and standardized test scores. CAP use school profiles and personal knowledge of specific schools to contextualize academic rigor. Nonacademic fit is understood through information submitted by an applicant or someone in their network: personal essays and letters of recommendation. When discussing OST learning, CAP often referenced lists of "extracurricular" activities produced by the Common App, a platform that allows students to scale the submission of applications through a common portal, an affordance CAP believe has further complicated review: i.e., as application submission increases, quality decreases. Finally, some admissions systems allow students to submit their own supplemental information: e.g., research reports or creative writing.

Time and application volume are common factors that interact within holistic review. Standardized academic transcripts afford quick analysis and comparison between applicants. When applicants attend the same school, comparison is quite straightforward. When transcripts vary in format, curricula, and reporting metrics, comparison becomes more difficult. The opacity of grades further complicates understanding what students know: i.e., what is the difference between an A and an A- in terms of effort? Limited time also means CAP usually do not review supplemental student work. In addition to not having time, CAP believed they do not have the content knowledge to make informed judgements on the quality of the work. Nonetheless, student work was often described as a strong signal of student passion, interest, and character.

Trust in data sources and concerns of equity influence how CAP understand nonacademic fit. Because essays, extracurricular lists, and reference letters are the responsibility of the applicant, CAP view this information as less reliable than academic information as students have control on what to include, exclude, and how to frame achievement. Extracurricular lists are read to understand the motivation behind interests: alignment of engagement across activities is significant here. CAP believe a successful essay communicates an applicant's authenticity. This could be understood as engagement driven by intrinsic motivation, an understanding of self, or a commitment to others beyond oneself. CAP also acknowledge how inequitable access to resources that can improve college applications impacts the quality of student-submitted information.

We found that two factors primarily complicate STEM admissions: 1) a perception of STEM curricula as rigid and hierarchical pathways, and 2) competition for limited seats drives up admissions standards. When standards rise, the question becomes who merits admission most. This is difficult to answer, but it is encouraging that some CAP believe readiness for STEM can be understood through multiple dimensions, those both academic and nonacademic. Still, there is an understandable reluctance to admit students who do not meet minimum academic requirements. CAP acknowledged potential equity issues with emphasizing academic information in STEM admissions but note that a student's background information, essays, and letters of recommendation (when genuine) provide alternative sources of information on an applicant's potential for success. The objective then is to determine why the student did not meet academic standards and if they could still do the work. Evidence comes from school profiles, examples of managing personal responsibilities, evidence of engaging in group work, or evidence of a broader impact the student might have on the institution's community. Ultimately, when academic information is not *the* determining factor, but rather a floor that must be reached, holistic review is a matter of determining how each student *distinguishes themselves* as opposed to how each diverges from the academic norm.

Conclusion and future work

The next phase of research will include the development of a prototype mastery-based transcript. Design research work on the prototype will include human-centered design studies with CAP that mimic the holistic review process. Our goal in this design work is to understand issues of usability while being sensitive to the values underlying holistic review. Our findings suggest a focus on features that support sensemaking of student work and contextualizing extracurricular activities is needed, as these issues align with two features of mastery-based transcripts: the ability to embed and curate student work and the ability to capture work pursued outside formal classrooms.

We also would like to acknowledge Prof. Stephanie Teasley for their contribution to earlier versions of this paper.

Schoolyard SITES: School-community Partnership to Learn about Teaching Locally-Relevant Citizen Science

Lara Gengarelly, University of New Hampshire, lara.gengarelly@unh.edu
Sameer Honwad, University at Buffalo, sameerho@buffalo.edu

Megan Glenn, Erik Froburg, Malin Clyde, Haley Andreozzi

University of New Hampshire

Abstract: Schoolyard SITES is a community partnership STEM teacher professional development program and research study at University of New Hampshire. The program partners elementary teachers with UNH Extension science volunteers to bring locally-relevant citizen science projects to K-5 students. Our research study examines the community-based partnership PD model and its impact on school teachers' self-efficacy and their success in engaging students in the NGSS science practices through citizen science projects.

Introduction

Currently K-12 science instruction is changing in the United States. As described in the *Framework* (National Research Council [NRC], 2012) and outlined in the *Next Generation Science Standards* (NGSS Lead States, 2013), the national K-12 science education recommendations emphasize active learning that engages students in the science practices while learning disciplinary content. Furthermore, a fundamental principle of the *NGSS* is that K-12 students engage in science learning that is relevant to their everyday lives, hence demanding real-world, problem-based learning (NRC, 2012). Given this new vision of K-12 science education, teachers' approach to instruction is expected to significantly change. Therefore, there is an increasing demand, nationally and in New Hampshire, for professional development (PD) that builds both K-5 teachers' science content knowledge and their ability to integrate the science practices into the classroom (Osborne, 2014).

Schoolyard SITES (Schoolyard Science Investigations by Teachers, Extension Volunteers, and Students) is a community partnership STEM teacher PD program and research study at University of New Hampshire (UNH). The program partners elementary teachers with UNH Extension science volunteers to bring locally-relevant citizen science projects to their students. We designed Schoolyard SITES to address identified needs of elementary school teachers, for PD in *NGSS*. It also capitalizes on emerging trends in citizen science programs and their associated learning outcomes (National Academies of Sciences, Engineering, & Medicine, 2018).

The study focused on the following research questions: 1. What collaborative components do teachers and volunteers focus on while working on a successful interdisciplinary collaboration? 2. What are the changes that are observed in elementary school teachers' self-efficacy teaching science and ability to integrate NGSS science practices through a locally-relevant citizen science project?

Schoolyard SITES model & activities

The Schoolyard SITES professional development model is a 3-pronged collaboration among elementary teachers, Extension science volunteers, and professional development/citizen science professionals. This 3-way collaboration is central to building both content knowledge and teacher self-efficacy. The teachers, volunteers, and professional development specialists create a synergy of skills, expertise, and content knowledge. The Schoolyard SITES PD workshop series emphasizes a collaborative learning approach that supports the development of a partnership between teachers and project volunteers. The PD framework is structured such that elementary teachers share their knowledge of instructional planning and pedagogy, while at the same time the volunteer shares their knowledge of specific, local life or Earth science topics and their passion for the scientific enterprise. Participants learn together as a team, and gain experience with scientific investigations and content that they will use later in their classrooms. With support from the volunteer, teachers design and teach a citizen science curriculum for their students that is relevant to the school district's curriculum and elementary school site.

Methods

We used a mixed-method research approach that incorporated pre- and post surveys and interviews plus document analysis of curriculum units produced as a result of the teacher-volunteer partnership. The online surveys and interviews (face-to-face) were administered before the first workshop and after participants taught the curriculum project in the elementary classrooms. The survey and interview instruments addressed volunteers' and teachers' process of collaboration, teachers' self-efficacy teaching science and integration of the eight NGSS science practices. The pre post surveys included the reliable and validated Science Teaching Efficacy Belief Instrument (STEBI-A)(Riggs & Enochs, 1990). Document analysis of collaboratively designed curriculum units were conducted to assess the extent to which the eight NGSS practices were represented in the projects.

Findings & analysis

Teacher-volunteer partnership

After going through the collaborative process, the teachers (100%, n=12) reported that they continue to feel that collaborating with community members is an important endeavor. All volunteers (100%, n=7) reported in their pre-surveys that collaborating with community members was an important endeavor and in the post survey most of the volunteers (86%, n=6) reported that they continue to feel that collaborating with teachers is an important activity, while one (14%, n=1) was unsure. Overall, the teachers were able to give more nuanced or very detailed explanations for each of the collaborative components after completing the Schoolyard SITES program. For example, we found that most teachers (n=11) in their pre survey suggested that listening is important part of a collaborative process but did not provide details. In the post survey most teachers (n=12) were able to illustrate with at least one example how listening is an important part of the collaborative process.

Teacher self-efficacy

The average self-efficacy score for the teachers before the Schoolyard SITES program was 50.8. Following the program, the average self-efficacy score for the teachers was 54. The change in self-efficacy for individuals differed. Some individuals demonstrated a larger change in efficacy than others. This variability among the 12 teachers attributed to the 'borderline' difference between the average pre (50.8) and post (54) scores (t-Critical two-tail = 2.20, $p = 0.06$, n=12) for the cohort collectively. In general, however, the majority of teachers (75%) demonstrated an increase in self-efficacy.

Integration of NGSS practices

All participating teachers (n=12) reported moderate or very improved integration of NGSS science practices after the Schoolyard SITES program. The top NGSS science practices reported were students' carrying out investigations, analyzing and interpreting data, constructing explanations, and engaging in scientific argumentation. The curriculums designed by the teacher-volunteer teams included the eight NGSS science practices. The practices of asking questions (SEP1), planning and carrying out investigations (SEP3) and data analysis (SEP4) were featured in all of the team's written curriculum units. In addition, scientific argumentation (SEP7) and communication (SEP8) were also integrated into most of the units.

Discussion

The Schoolyard SITES model emphasizes a pathway for how citizen scientist volunteers and teachers can build a sustainable partnership so as to engage elementary students in citizen science and authentic science practices. The study sheds light on how collaborative behaviors (e.g., listening, compromise) play a role in the partnership. We observe that all teachers and community volunteers understand that school-community partnerships are important, and our findings suggest that teachers increase self-efficacy and improve their integration of NGSS practices in the classroom after participating in the Schoolyard SITES community-based partnership PD model.

Abstract: The shift to remote teaching during COVID-19 raised awareness of inequities built into traditional teacher education, as well as limitations to the inclusiveness of teacher educators' accepted practices. Findings from student (n=170) and instructor (n=30) questionnaires are presented from a mixed-methods study that explores how the pandemic experience affected teacher educators' equitable teaching practices, and the impact of their modeling on the future instructional priorities of their in-service and pre-service students.

Introduction

Teacher educators must always be concerned both for their students' learning, and their students' own future teaching. Moreover, teacher educators not only teach through the material they cover, but also through the modelling they provide (Moore & Bell, 2019). The shift to remote teaching during COVID-19 raised awareness of inequities built into traditional teacher education, and limitations to the inclusiveness of teacher educators' prior accepted practices. Snapshots of students' homes and lives, realizations about what tools and conditions for learning were(n't) at students' disposal, and insights about assumptions baked into traditional program structures all fostered new awareness of barriers to equitable participation and learning in teacher education. Many of these equity issues were not actually new during COVID-19, only more visible. Long-standing inequities related to race, gender, socio-economic status, diverse learning needs and mental health challenges were well-documented before the pandemic (e.g., Linden, Boyes, & Stuart, 2021); but the necessity to re-design courses to accommodate COVID-19 protocols provided an opportunity for teacher educators to rethink traditional assumptions and practices, some of which had treated such inequities as normal and acceptable.

Many faculties of education in Canada have made commitments to pursue equity and inclusion in their programs and practices, and have made some progress meeting them. However, it was uncertain to what extent such progress could or would be maintained under the limitations of remote teaching conditions. Our study generated data about the equitable and inclusive practices that teacher educators at one Canadian faculty of education implemented during emergency COVID-19 remote teaching, and the insights their pre-service and in-service students took away from this modeling for their own teaching practice.

Methods

This data comes from a multiple-case study of teacher educators' design choices intended to address challenges of equity and inclusion. We took a sequential mixed-methods approach, using instructor questionnaires to inform case selection. Student questionnaires were not linked to specific courses or instructors, but were used to provide a general backdrop for the instructor data. Both questionnaires were administered in Fall 2021 and included a combination of selected-response and open-ended items. Questions focused on innovations that respondents deemed successful, that is, their "best" pandemic learning or teaching experience. The student questionnaire (n=268, 11% of enrolled students enrolled in summer 2021) captured the challenges students faced, their opinions regarding strategies their instructors used to support them, and the lessons they learned from those strategies for their own future teaching. The instructor questionnaire (n=30, 22% of instructors in summer 2021) captured how instructors ascertained what challenges students faced, the strategies they used to respond to them, and their opinions about which of these strategies were most effective. Descriptive statistics, such as frequency counts, percentages and means are provided for some of the selected response items. We also present responses to an open-ended question posed to students: "If you already teach or plan to teach, in what ways has your experience as a student in this course influenced your thinking about your own flexible and equitable practices as a teacher?" Responses from current teachers seeking graduate degrees and intending (pre-service) teachers (n=170) were coded by the first two authors into 12 categories related to three themes (student needs and voice; flexibility and designing for difference; communication and organization). Percent agreement across all coding categories was 95%. Finally, the first two authors coded teacher educators' responses to the question, "What teaching strategies that you typically use to promote learning and/or equitable participation in this class were hampered by pandemic conditions?" in five categories with 94% agreement. Consensus discussions were held to finalize all coding.

Teacher educators' adaptations

The most common challenges teacher educators noted among their students were non-school commitments, (e.g., childcare, work, 92%), general worries or stressors (e.g., crowded conditions or isolation, 91%), and mental health concerns (83%). Instructors' awareness of students' mental health needs and complex life circumstances drove greater flexibility in the form of reduced synchronous class time (88%) or better access to alternatives to that class time (e.g., pre-recorded or live-recorded lectures, 54%), more flexible deadlines (77%), reduction or elimination of late penalties (62%), more choice around how students demonstrated their learning (54%), and more opportunities to revise work (58%). Such adaptations mirrored those at other institutions (e.g., Goin Kono & Taylor, 2021; Johnson, Veletsianos, & Seaman, 2020). Our teacher educators also demonstrated care by regularly checking in with their students (81%). However, teacher educators found these approaches insufficient to address the social challenges of pandemic teaching and learning. In the open-ended responses, two-thirds of teacher educators described difficulty with one or more of the following: fostering productive group work (40%), circulating among groups (20%), fostering community or connection with students (27%), facilitating discussions (20%) and "reading the room" (17%), all of which could potentially hamper equitable participation for students. Nevertheless, most students from marginalized and equity-seeking groups (87%) or those who were uncertain of their writing, reading and presenting (67%) felt their learning experiences in their "best" pandemic class were *not* affected by such status. Thus, despite struggling with the affordances of the remote teaching format, instructors appeared to have been successful in creating space for diverse students to participate comfortably.

Current and intending teachers' learning from those adaptations

When asked how their experience as learners would affect their future teaching, most students either did not answer (35%) or provided short, general statements (51%), e.g., "Importance of flexibility and understanding." A few (28%) provided more detailed plans, such as, "Having varied assessments where students can display their learning. Flexible deadlines and connecting with students who may not participate as much. Having different forms to participate in class to manage anxieties."

A commitment to flexibility and/or designing for difference was most common (41%). Some students simply indicated they would be flexible (26%), such as, "Being flexible and comfortable with change." Others would give students choice in assignments or assessments (9%) or explicitly design for difference (14%), such as, "Should I become a teacher, I plan to put an emphasis on inclusivity and working with the UDL guidelines, as well as guided instruction." Very few intended to make learning materials available in multiple forms (3%).

About a quarter of students (24%) mentioned increased awareness of or attention to students' needs and voices. Some (18%) indicated more awareness of students' needs than before. A few noted the importance of being kind, patient and open-minded (9%), the need to be aware of the mental and physical demands of the learning context (6%), to listen and attend to students (8%) and to give them voice (4%). On rare occasions students expressed more nuanced insights such as, "It has made me realize that my students may struggle without speaking up, and as an instructor, it is important that I look out for signs of non-verbal struggle such as a sudden change of grades. Otherwise, it can create a vicious cycle where the student begins to fail, is too depressed or unwell to mention or care about it, and goes on and on."

Besides two students who indicated a desire to incorporate Indigenous perspectives and/or pedagogies in their teaching, none explicitly mentioned ways in which they might attend to the needs of marginalized or equity-seeking groups; though general statements regarding opportunities for all student voices to be heard or to engage in inclusive practices may be based on such concerns.

Promoting Students' Productive Vocabulary Growth and Knowledge Advancement Through Knowledge Building

Chunlin Lei, Shanghai University of International Business and Economics, leichunlin@suibe.edu.cn
Junjie Zhang, the University of Hong Kong, zjjedu@connect.hku.hk
Qian Cheng, Shanghai University of Finance and Economics, cheng.qian@mail.shufe.edu.cn

Abstract: This knowledge building study was conducted in an English-as-Foreign-Language context and examined both students' productive vocabulary growth and collective knowledge advancement. Analysis of the lexical frequency profiles indicated students used greater number of sophisticated, academic and domain words across time. Inquiry threads analysis also suggested a higher level of knowledge advancement over time. This study has implications on how to design learning environments to facilitate language learning and idea improvement.

Introduction

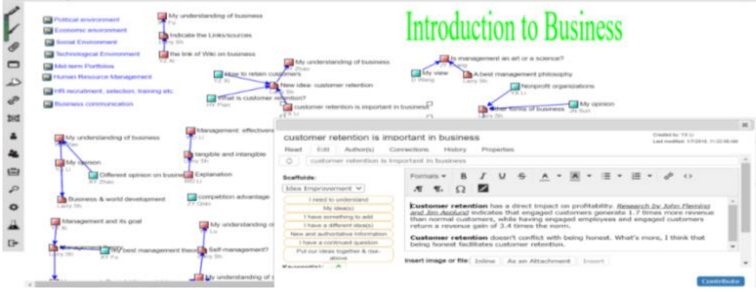
Very few knowledge building studies have focused on vocabulary growth in the process of collaborative inquiry. The one exploring this area was conducted in an English-speaking country (environment) and included Grade 3 kids as the participants (Sun, Zhang, & Scardamalia, 2010). This study is conducted in a university in Chinese mainland, where English is used as a medium of instruction (EMI) for delivering content subject, and a dual goal of developing both students' content knowledge and English language proficiency is expected to achieve.

Knowledge building is a social process through which learners work collaboratively and continuously towards idea improvement. To support the process, a networked technological platform, Knowledge Forum (KF) is used and students can compose ideas and build on, annotate, or rise above their early understandings. Through progressive and productive discourse moves, an idea or concept gets nurtured, enriched, revised or refined. In the second language acquisition or foreign language learning field, a content and language integrated learning (CLIL) approach is increasingly employed in recent years. The CLIL approach emphasizes both content knowledge and language acquisition; and more importantly, language is acquired or learnt through negotiation of meaning. This pedagogical approach is acting concordantly with the knowledge building model in that meaningful interactions of ideas are fundamental to learning, not matter it is language learning or subject knowledge learning. This study is conducted in an English-as-foreign-language context, and addresses two RQs: (1) How is the students' productive vocabulary developed in the knowledge building process? (2) What characterizes students' collective knowledge advancement; is it connected to student' vocabulary growth?

Research design

The participants were 30 Year-1 students (M=6, F=25) majored in English for International Business. In an 18-week length of a course entitled *Introduction to Business*, students were engaged in collaborative inquiry about business concepts in class and continued their discussion in KF after class (see Fig.1). Students were encouraged to write KF notes in English and try to use business domain words they learnt in and outside class.

Figure 1
KF View and An Open KF Note



Customer retention has a direct impact on profitability. Research by John Fleming and Jim Asplund indicates that engaged customers generate 1.7 times more revenue than normal customers, while having engaged employees and engaged customers return a revenue gain of 3.4 times the norm.

Customer retention doesn't conflict with being honest. What's more, I think that being honest facilitates customer retention.

The data of the study included all KF notes and analyses followed two major strands. One is productive vocabulary growth which is measured by "Lexical Frequency Profiles" (Laufer and Nation,1995). The measure provides an analysis of the percentages of word families at various frequency levels in a piece of written work, e.g., the first 1000 and the second 1000 frequent word families, and Academic Word List. In addition, a Business Domain Word List is also developed for this study to understand students' mastery of subject specific words. The second strand is to identify students' conceptual understanding and knowledge advancement via inquiry thread analysis (Lei and Chan, 2018). An inquiry thread was categorized low-, middle-, and high-level of knowledge advancement (LKA, MKA and HKA). A LKA thread is often short, consisting of students' quick or instinctive ideas about a business topic without referencing to authoritative sources of information; a MKA thread draws a pool of students' ideas, yet repetitions occur frequently and showing a lack of community awareness; a HKA thread demonstrates a question-explanation intertwined process, showing students' identifying and addressing knowledge gaps, negotiating meanings, and formulating more sophisticated views on business concepts.

Findings

Development of students' productive vocabulary use

The students composed a total of 746 KF notes (M=24.9 and SD=6.14) over 18 weeks. To examine the development of students' vocabulary growth, the dataset was divided into Phase 1 (from Week 1 to Week 9) and Phase 2 (Week 10 to Week 18). Using software including RANGE and SPSS, the study showed a comparison of lexical frequency profiles based on counts of word types in Phase 1 and Phase 2(Table 1).

Table 1

Comparison of Lexical Frequency Profiles Based on Counts of Word Types in Phase 1 and Phase 2

	Phase 1Mean (SD)	Phase 2Mean (SD)	T-test
First 1,000 words	73.69% (4.93%)	66.44% (4.69%)	T=7.75; p<0.001
Second 1,000 words	7.14% (2.00%)	8.24% (1.93%)	T=2.05; p<0.05
Academic words	11.48% (3.65%)	14.10% (3.38%)	T=3.34; p<0.01
Not in the list	7.70% (3.83%)	11.21% (3.88%)	T=5.23:p<0.001
Domain words	8.59% (1.55%)	10.44% (2.00%)	T=4.53, p<0.001

Students' collective knowledge advancement

Inquiry threads generally reflect the developmental trajectories of an idea or a business concept; how it gets shared, evaluated, enriched, revised or refined through the efforts of a learning community is a process of collective knowledge advancement. After assortment, a total of 29 inquiry threads emerged from the data. We then further classified the threads into Phase 1 (n=16) and Phase 2 (n=13) threads. In line with the coding scheme mentioned in the research design section, we coded all the threads into low-, middle-, and high-level of knowledge advancement which is shown in Table 2 as follows.

Table 2

Distribution of Low, Middle and High Level Knowledge Advancement Threads in Phase 1 and Phase 2

	Phase 1 (No. and %)	Phase 2 (No. and %)
L-level KA	9 (56.35%)	3 (23.1%)
M-level KA	4 (25.00%)	3 (23.1%)
H-level KA	3 (18.75%)	7 (53.8%)
Total (No. and %)	16 (100%)	13 (100%)

Conclusion

This study indicated students were able to use greater number of sophisticated, academic and business specific words as they were more engaged in knowledge building process across time. As well, student' collective knowledge advancement experienced a developmental trajectory, moving from a relatively low level to a high level.

“Using the Master’s Tools” to Integrate Play With Kindergarten Mathematics: Creative Insubordination Through Playful Resistance

Brittany Caldwell, Anita A. Wager
Brittany.caldwell@vanderbilt.edu, anita.wager@vanderbilt.edu
Vanderbilt University, Peabody College

Abstract: In this study, we focused on the challenges that kindergarten teachers discussed related to curriculum, lack of teacher autonomy, and administrative control. We explored teachers' resistance using the lens of creative insubordination (Gutiérrez, 2016) to answer these questions: 1) What challenges do kindergarten teachers discuss about implementing playful math in kindergarten? and 2) How do teachers discuss navigating implementation challenges? We found that teachers used playful resistance as a way to enact “Using the Master’s Tools,” an approach to Creative Insubordination outlined by Gutiérrez (2016). This study corroborates and extends prior work on creative insubordination by focusing on early childhood mathematics and exploring teachers’ strategies to employ playful resistance.

Purpose

This study responds to the widely discussed concern about ‘kindergarten as the new first grade’ (Bassok, Latham, & Rerom, 2016) by positioning kindergarten teachers as professionals with agency to make choices in their classrooms. In this study of early childhood (EC) teachers’ playful resistance, we highlight teachers’ agency as they invoke ‘the master’s tools’ to make developmentally appropriate changes within existing structures, in particular, disrupting a system that is eliminating children’s opportunity to play. Analysis of a weeklong professional development (PD) with four kindergarten teachers revealed what they identified as barriers to curricular interruption and initial steps they imagine in thinking ahead to implementing play in their classrooms. We analyzed teachers’ resistance using a lens of creative insubordination by exploring the strategies teachers imagined to resist and overcome challenges to bringing in play posed by their perceptions of the curriculum, school administration, and district and state testing and evaluation mandates; and to answer the questions:

1. What challenges do kindergarten teachers discuss about implementing playful math in kindergarten?
2. How do teachers discuss navigating implementation challenges?

Framework

Acts of resistance or ‘creative insubordination’ are the ways professionals interrupt rules to provide better services and conditions (Grando & Lopes, 2020, p. 621). Gutiérrez (2016) outlines an approach to resisting the systems operating against teachers using six strategies for being creatively insubordinate: press for explanation, counter with evidence, use the master’s tools, seek allies, turn a rational issue into a moral one, and fly under the radar. Gutiérrez (2016) proposes that these approaches are a stand against the status quo in efforts to change schools to match the best interests of the students. These strategies provided a lens for us to examine how teachers imagined paths of resistance. In our study, we found the teachers enacted on approach in particular, ‘using the master's tools’ to align with the rules and goals while bending the rules to meet the needs of students. Although, using the master's tools is an ineffective strategy to dismantle oppressive powers (Lorde, 1984), we found it effective way to work within the system. We offer the phrase “playful resistance” to capture how teachers used the masters tools to resist constraints (e.g., enforced pacing, administrative control, limited teacher autonomy) by bringing play into mathematics.

Methods

As part of a four-year longitudinal research project to investigate play in early mathematics, we facilitated a week-long PD with four kindergarten teachers designed to support EC teachers to incorporate play into their math classrooms. All discussions and activities during the PD were video and audio recorded. In individual interviews during the PD teachers were asked to describe their teaching experience, philosophical views about play and current teaching environment. All interviews were audio recorded. Using descriptive codes, we analyzed observation notes, video recordings, and audio recordings from the teacher’s interviews to understand how teachers talked about navigating challenges to enacting math curriculum by using the masters’ tools.

Findings

Throughout the PD, teachers discussed various challenges with bringing play into their classrooms including: issues with curriculum, state-wide assessment portfolios/pop-up observations, disjointed communication with administration, lack of autonomy, fears of reprimands, and views of play and academics as separate. Some of these challenges stem from an era of accountability, standardized testing, and an emphasis on academics over play in practice and research (Author 2; Schoenfeld, 2002). The larger social climate can frame play and academics in tension and perpetuate teachers' beliefs and practices that deemphasize play. All these challenges set the larger context of the school, administration, and classroom. However, the analysis for this study focused on the challenges teachers discussed related to the curriculum, lack of teacher autonomy, and administrative control as these were the most prominent in our discussions with the teachers in this study.

In Table 1, we provide a summary of vignettes that illustrate how teachers proposed to navigate the challenges. We found that the teachers had explicit ways of describing and planning for creative insubordination to bring play into mathematics instruction, specifically related to using the master's tools (Gutiérrez, 2016).

Table 1
Summary Vignettes

Navigating the Tension Between Play and Academics	Navigating Limited Time and Autonomy with Playful Resistance
This vignette highlights how the teachers discussed the tension between their mathematics curriculum and play and envisioned navigating this challenge with playful resistance by bringing in games to differentiate mathematics instruction and supplement the official curriculum. In this example, the teachers employed playful resistance as they followed the rules of using the curriculum materials while bending them by imagining how to differentiate activities with games.	This vignette highlights how teachers discussed navigating tensions they faced related to limited time and teacher autonomy for curriculum and scheduling. The teachers in-the-moment decisions without permission to teach with less fidelity to the curriculum and schedule illustrates how they employed playful resistance to administrative control as they discussed interpreting "problem-solving time" as a space to bring in a playful lesson. The teachers used the master's tools by following the dictated school schedule, yet, through their interpretation of "problem-solving time," they created a plan for playful resistance.

Conclusion and implications

We found that the teachers used playful resistance as a way to enact using the master's tools. While the teachers discussed other ways they could resist neoliberal practices (e.g., flying under the radar), we found that explicit connections to play were related to the approach of using the master's tools. Theoretically, this study corroborates and extends prior work on creative insubordination by focusing on early childhood and exploring how teachers invoke strategies to develop playful resistance. From a practical perspective, we see an opportunity to rethink future PD with these (and other) teachers that supports them to develop strategies for creative insubordination. We envision using this data in conjunction with readings from Gutiérrez so they can explore how they came up with their own strategies and how they might develop others. We then would have them practice using strategies in order to defend and support the decisions they make for their classrooms.

Post-Humanist Perspective for Investigating Learning With Representations in Biochemistry

Song Wang, UC San Diego and San Diego State University, sow004@ucsd.edu
Stanley M. Lo, UC San Diego, smlo@ucsd.edu
Thomas J. Bussey, UC San Diego, tbussey@ucsd.edu

Abstract: Research on external representations in biochemistry education has primarily focused on student interpretation of their assumed correct meanings. This orientation is related to the philosophical assumptions of representationalism, metaphysical individualism, and humanism. Engaging with feminist critique of science, this study aims to problematize these philosophical assumptions in research on learning with representations in biochemistry. We propose agential variation theory as a framework that create a new space for exploring the semiotic potential of different representations.

Introduction and background

Since molecular structures and events are not directly visible, biochemists rely on external representations such as diagrams, animations, three-dimensional (3D) models, etc. to explain biochemical phenomenon. In biochemistry teaching and learning, visualization and spatial reasoning have been identified as essential skills for students. The importance of visualization and external representation in biochemistry teaching and learning has directed research efforts towards the development of new external representations for biochemistry classroom instruction.

Treating the referentiality of external representations as a transparent and direct link between sign and meaning, existing research on learning with representations in the context of biochemistry education mainly focus on measuring individual student performance and student preference, with little attention towards how the meanings of external representation are experienced by students. Without critically examining how the experienced meanings of representations emerge, new forms of external representations are often treated as new signs referring to existing biochemistry concepts rather than as a dynamic transformation of the learning environment in which students experience the meaning of biochemistry concepts.

In recent years, augmented reality (AR) technology has received increasing attention in biochemistry educational research. AR technology affords the experience of a computer-generated 3D representation superimposed on top of the real world. Blurring the boundary between representation and reality, AR technology prompts researchers to reflect on the relationship between representation, meaning, knowledge, and reality. This study critically reflects on the implicit philosophical assumptions that underpin normative research on learning with representations, and explore possibilities for research informed by feminist, post-humanist perspectives on science, technology, and education.

Implicit philosophical assumptions in research on representations

Three philosophical assumptions, namely representationalism, metaphysical individualism, and humanism, work together to hold the normative worldview and paradigm of research on learning with representations in place. These philosophical assumptions are commonly associated with classical ontology, which entails a physical reality underpinned by objectively real, counterfactually definite, uniquely spatiotemporally defined, local, dynamical entities with determinately valued properties. Research that operationalizes this ontology seeks to create accurate and authentic representations through measuring the determinately valued properties of bounded entities.

Representationalism

Representationalism is the view that scientific models are best understood as representations of reality. Representationalism separates words (epistemology) from things (ontology) and produces the question of mediation between the two realms that made knowledge possible. Barad criticized this dualist notion for trapping epistemology between two facing mirrors of scientific realism and social constructivism where it “gets bounced back and forth, but nothing more is seen” (Barad, 2007, p. 803). If we commit to the assumption that cognition involves a separated cognitive subject representing the Other, the study of cognition itself would require another degree of separation, i.e., meta-cognition. Yet another degree of separation, i.e., meta-meta-cognition, would then be needed to investigate meta-cognition and gain insight on the processes through which the cognitive subject reflects on its own cognition. Studying cognition under the assumption of representationalism is akin to placing two mirrors against each other. Researchers become trapped in between two reflective surfaces, bouncing back and forth.

Metaphysical individualism

The metaphysics of individually determinate entities with inherent properties is another assumption on which many research practices are hinged. Research on learning with representations commonly puts the individual student at the center of attention. Assuming individual students are determinately bounded entities entails characteristics that can differentiate and describe individuals. However, scholars from a range of disciplines such as neurophysiology, anthropology, physics, feminism, and disability studies have called into question the self-evidentiary nature of bodily boundaries (Haraway, 1985). What it means for a body to be labeled (e.g., expert or novice) is always in a state of becoming with surrounding entities, and these labels cannot be seen as individual characteristics that can be measured to describe some facts about students as bounded entities.

Humanism

Another assumption that is closely related to representationalism and metaphysical individualism is humanism, which assumes a separated position of the human subjectivity to reflect on nonhuman nature at a distance, and attributes agency to only the human side of this separation. With the separation between human and nonhuman taken for granted, current research on learning with representation often focuses on conceptual understanding and identity in mutually exclusive research practice, with learning outcomes often reduced to measurable competencies and identities compartmentalized as different "human factors" in an impersonal process of cognition. The separation of humans as exceptions from the nonhuman nature ironically worked to dehumanize the human subject in cognition.

Agential variation theory

We propose agential variation theory to build a post-humanist account of learning that seeks to do without the assumptions of representationalism, metaphysical individualism, and humanism. Agential variation theory does not assume determinately bounded, pre-existing learning subject and object of learning. Rather, knowledge is thought of as sedimented out of the intra-activities of learning that differentially make learner subjectivity and the object of learning bounded and intelligible to each other. Students are not already bounded individuals entering a pre-existing, fully structured learning environment to engage with material that are external to them. Instead, learning is the always already ongoing (re)configuration of the separation between the learning subject and the learning object. What makes knowledge possible is not our ability to observe from afar but the opposite: we are always already entangled with what we wish to learn, and as the separation between the learning subject and the object of learning continuously (re)configures as an effect of different practices, the subject learns and forgets.

Methodology consideration

It is important to articulate new methodological language and labels along with theoretical perspective. We introduce Haraway's notion of String Figure, or SF as a metaphor to articulate an approach to qualitative inquiry that contest the philosophical assumptions discussed above.

Characterized as "a game of cat's cradle… of giving and receiving patterns…of relaying connections that matter", String Figure was first proposed by Donna Haraway as a methodology for forging partial connections through situated knowledge and local specificities (Haraway, 2016). Instead of retreating to the distant and secure position of an enlightened outsider, the researcher is tracing the ongoing (re)configuration of material and cultural practices as part of the world. Knowing as part of the world requires being accountable for our own involvement in (re)enacting normative boundaries. In this study, String Figure is explored as an approach for understanding learning as a process of giving and receiving patterns to craft conditions for external representations to become meaningful. SF frames the introduction of new forms of external representations (e.g., AR representation) as part of an ongoing transformation of the material and cultural practices of biochemistry education.

Exploring Student Approaches to Science Knowledge Representation With Immersive VR Drawing

James Planey, University of Illinois Urbana-Champaign, planey@illinois.edu

Abstract: Drawing has been shown to be a productive tool in promoting learners to reflect on their knowledge. This pilot investigation seeks to identify the potential affordances of drawing representations of science concepts within a fully immersive virtual reality (VR) drawing environment. Drawing in VR provides new possibilities for exploring spatial arrangement and scale that have the potential to innovate the knowledge representation process. Taking a qualitative approach, this work documents the processes of seven participants as they engaged in drawing sessions constructing a representation of their existing knowledge around the lunar phases. Analysis of the recorded sessions allowed for the identification of a series of VR affordances leveraged by participants, as well as patterns of representation construction that can inform the development of future VR drawing software and activity designs.

Introduction

Drawing as a representation of a learner's progress in science has received increased attention over the last decade (Ainsworth & Scheiter, 2021). As part of this renewed focus, recent attempts have been made to break down the theoretical basis more explicitly for drawing's advantages in learning and create explanatory models for how drawing influences the science learning process (Wu & Rau, 2019). While previous research has found similar benefits to learning from multimedia when compared to the construction of drawings (Schmidgall et al., 2019), a common challenge in astronomy education is the majority of graphical representations found in authoritative sources (often by necessity) have concessions made in the accuracy and scale of the visual-spatial representations presented (Galano et al., 2018; Taylor & Grundstrom, 2011). While there is growing literature around the value of virtual reality as a medium for science learning (Jensen & Konradsen, 2018), the use of virtual reality for more generative applications (such as drawing or 3D modeling) has been largely relegated to fields such as engineering, architecture, and fine arts. The goal of this study is to bring the theoretical advantages of an immersive VR drawing interface into an application of science knowledge representation to explore how the tool is taken up by a learner as they explain their knowledge around the cause of the lunar phases.

Materials & methods

Environment design

The VR drawing platform "Tilt Brush" was utilized for this initial exploration of the potential affordances of VR drawing (tiltbrush.com). Tilt Brush was designed with a focus on general artistic expression via sketching in VR. At its core, Tilt Brush allows users to place drawn strokes anywhere around themselves in 3D space as well as manipulate those strokes to reposition them, change their size or rescale the entire drawing environment.

Participants and study design

The data discussed here was collected from the undergraduate research-participant pool of a midwestern university. While in-person data collection was not possible due to COVID mitigation steps at the time of data collection, an attempt was made to preserve as much as possible the interactions between a drawer and facilitator as the participant engaged in a prompted exploration of their knowledge around the lunar phases.

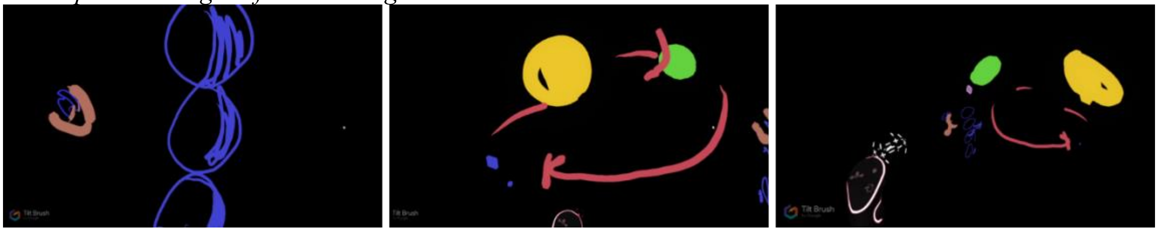
Each session was audio recorded and screen captured from the perspective of the VR user. Participants were first introduced to the VR equipment and Tilt Brush software. Participants were asked to explain the mechanism behind the change in lunar phases while drawing and thinking out loud. The facilitator remained on Zoom with the participant to address any VR technical questions. In addition, the facilitator provided conceptual support or clarifications only after prompting the participant to first attempt to reflect and address their question based on their own knowledge. In total, seven sessions were conducted, with four female and three male participants. The age range of all participants was 19-22, and of the seven, only three had previous experience with VR (two with some, and one a frequent VR user).

Results and discussion

To begin a high-level analysis of the kinds of approaches and potential affordances of the VR drawing system, session recordings were reviewed wholistically in order to generate a collection of observed actions and processes around the construction of a lunar phases knowledge representation. After the initial prompt, participants took multiple approaches to initiate the construction of their lunar phases knowledge representation. A majority of the participants engaged in a process of first creating 2-dimensional sketches within the drawing environment (ex: rings to represent the Sun, Earth, or Moon), often as acts of recall of prior knowledge and "textbook figure" representations of the lunar phases (see left of Figure 1 for example). Participant 2 exemplifies a particularly unique process captured in sequence in Figure 1. Participant 2 first began their session by drawing the progression of the lunar phases stacked vertically in 2D (Figure 2 left). After acknowledging their uncertainty around the mechanism that might produce this progression of phases, they abandon their 2D representation and begin to generate a 3D arrangement of the Earth, Moon, and Sun (Figure 1 center). Here they again express uncertainty about the spatial relationship between the Earth, Sun, and Moon, and as they manipulate their drawing by rotating themselves around it, they realize that their spatialized sketch was only interpretable from the single point of construction (work seated at arm's length) (Figure 1 right). Participant 2 then begins to move and manipulate the elements to align them so that the orbits sketched are no longer dependent on a single perspective.

Figure 1

Participant 2's stages of VR drawing construction.



Conclusion

Overall, given the limitations of the drawing sessions to accommodate non-contact protocols, all drawers were able to engage and leverage some of the affordances provided by the drawing environment to explore their conceptions around the lunar phases. The facilitator's support around the availability of specific VR functions was critical in many instances to their uptake and use by the participants. While the novelty of VR and the Tilt Brush drawing environment to many of the participants is certainly a factor, another limitation may be inherent in the design of Tilt Brush as a sketch-based artistic platform. While it provides all of the necessary tools to engage in the exploration of science ideas via VR drawing, some functions (such as selecting and moving drawn elements) are placed behind multiple menu interfaces. This makes their use "as needed" more cumbersome and also makes these capabilities less visible. These findings have already prompted the creation of a custom streamlined drawing environment for future studies that minimizes interface interactions for critical spatial affordances of VR allowing users to draw, manipulate, resize, and move within their drawings via button and controller motion interactions.

Abstract: This case study analyzed an IVR activity to understand (a) whether immersion reflects a subjective psychological process towards presence and flow or whether these states reflect objective properties of VR, as well as (b) the relation of immersion to learning. Data were collected with questionnaires, post-VR-activity interviews, and screen-recordings of the activity of two higher education students. Our findings supported a subjective nature of immersion as well as a positive relation to students’ learning.

Introduction and theoretical framework

Recently, there is an increasing interest in using Immersive Virtual Reality (IVR) in K-16 education. However, empirical studies have often resulted in contradictory findings when comparing the learning effectiveness of IVR to traditional instruction with low-immersion media (Hamilton, 2021). One main explanation provided so far, is that IVR environments may induce a sense of presence and flow but that they may also detract students from the learning process. We argue that this explanation is not sufficient, and that presence and flow is not a given in IVR, as immersion is an individual and subjective psychological process. Similarly, Agrawal et al. (2020) note an ongoing debate on whether immersion reflects a subjective psychological process or whether it is simply an objective concept reflecting the technical affordances of VR. This work examines this issue by focusing on two higher education students, who participated in a case study structured around an IVR for cultural heritage learning to ask: (a) What was the nature of experienced immersion for each student?, (b) What were the main factors affecting the students’ experienced immersion?, and (c) What was the relation between immersion and learning?

Methodology

Learning intervention

An IVR learning environment was designed to support learning about a cultural heritage site (an early Christian Byzantine church), dated to 5th century A.D. in Cyprus. The IVR environment employs an inquiry-based learning scenario according to which students assume the role of historians who investigate the dating of a church ceiling mosaic through the collection of evidence.

Participants

As a case study approach, we recruited two higher education students who were communication studies juniors at a public university. Susan was 21 years-old while Tom was 23 years-old (both names are pseudonyms). Both students voluntarily participated in this case study. The students had no prior experience with VR environments.

Data collection and analysis

Screen-recording of the VR learning experience: Each student used a head mounted VR display to experience the environment through a single-user mode. As the user’s navigation of the VR environment was projected to an external screen, we were able to screen record the VR experience from a third-person’s point of view. These data were analyzed descriptively, in order to understand each student’s learning performance and experience.

Immersion and conceptual gains questionnaires: Upon completing the VR activity, each student responded to the Virtual Reality Immersion (VRI) questionnaire which was an adapted version of the Augmented Reality Immersion (ARI) questionnaire (Kyza & Georgiou, 2017). The VRI comprises of the Total Immersion scale, which has two subscales: Flow (3 items) and Presence (4 items). All items were evaluated on a Likert-scale from 1-7. In addition, a conceptual understanding test was administered to assess students’ learning about the concepts related to the topics of the VR investigation. The conceptual understanding test included eight multiple-choice items and four open-ended questions, and had a maximum score of 10. The data collected with the immersion and conceptual gains questionnaires were analyzed to create a quantitative indicator for experienced immersion as well as a quantitative indicator for learning for each student, which provided a numeric estimation of students' total immersion and conceptual understanding.

Post-activity interviews: Each student participated in an individual, thirty-minute, semi-structured interview after the intervention. Students were prompted to discuss their feelings of presence and flow, as well as the factors which had positively or negatively affected these feelings. Interviews were qualitatively analyzed using the Critical Incidents Technique (Flanagan, 1954). With this approach we sought to identify and contrast specific incidents which could be conceived as factors shaping students' immersion and learning.

Findings

Learning performance

When examining the students' learning performance, we find that both visited the learning stations within the fixed duration of thirty minutes, and that they viewed all the available multimedia resources. However, only Susan successfully completed the inquiry-based mission and specified the correct era of the wall mosaic. Susan's investigation lasted 28:17 minutes, while Tom's investigation lasted 24:10 minutes; the additional time in Susan's case was invested on the inquiry-based exploration of the church.

Quantitative indicators of learning and immersion

The examination of students' immersion indicators showed that Susan achieved higher levels of immersion, especially in terms of presence. More specifically, Tom's sense of presence was relatively low, while Susan experienced a higher sense of presence. Likewise, the examination of students' learning indicators showed that Susan achieved higher learning gains than Tom, especially in terms of conceptual knowledge.

Qualitative accounts of experienced immersion

Tom's interview suggested that while the VR environment captured his interest, there were three main barriers which negatively affected his sense of presence: (a) usability issues related to his navigation in space, (b) the multimedia learning resources which were perceived as "distractors" compromising the fluid progress of the game play, and (c) the limited sense of embodiment due to the lack of full-body interaction. On the other hand, Susan reported that the VR environment not only captured but also maintained her interest, resulting in a high sense of presence. We identified three main factors which positively affected her sense of presence: (a) the overcoming of usability issues, (b) the multimedia learning resources which served as "focal" points due to their audio-visual properties, and (c) a sense of embodiment due to the realism/authenticity of the environment.

Conclusions and implications

This work contributes empirical substantiation to the subjective nature of immersion as well as to its positive relation to the learning process. The findings are aligned with prior studies which support the claim that immersion is a subjective human experience, which may be mediated by learner characteristics (Georgiou & Kyza, 2017, 2018). For instance, differences in learning styles between the two students could provide a plausible explanation regarding their different perceptions of the VR environment. Likewise, it might be that students' digital skills may explain the persistence or overcoming of usability issues. Put simply, learner characteristics and personality traits may define students' immersion and subsequent learning. Our future work will explore these issues more systematically, given that this case study is part of a broader research effort that includes 50 additional students. Our next steps will focus on the analysis of the collected data for the extraction of more generalizable findings.

GROOVA: A Data Visualization Tool for Elementary School Students Co-Designed by Teachers and Researchers

Golnaz Arastoopour Irgens, Clemson University, garasto@clemson.edu
Danielle Herro, Clemson University, dherro@clemson.edu

Abstract: This paper describes a Research-Practice Partnership in which a data visualization tool, called Groova, was co-designed. The curricula and tool are conceptualized as boundary objects which served to increase the partners collective knowledge on ways to improve students' data science learning. Findings included teachers' beliefs that the tool was developmentally appropriate for elementary students, the tool would encourage student learning, and that their design ideas and voices were heard.

Introduction

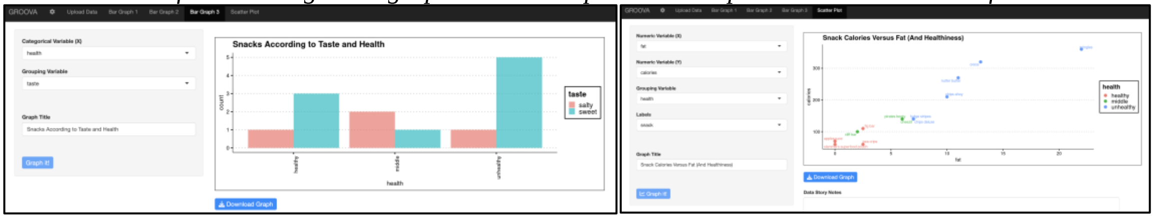
Data science skills and practices assist people of all ages in making informed decisions to better understand risks for individuals and broader larger society (National Science and Technology Council, 2018). For middle-school students, data literacies include *data storytelling*, the presentation of data and statistics coupled with visual and narrative elements to communicate to a broad audience the results and implications of data analyses (Wilkerson et al., 2021). One approach to engage elementary-school teachers in data science is through a research-practice partnership (RPP). In an RPP model, the intended outcomes are jointly determined and cycles of continuous improvement are supported by agreed upon rules, roles, routines and strategies (Coburn & Penuel, 2016). Farrell and colleagues' (2022) RPP conceptual framework outlines mutual learning between researchers and practitioners that involve *shifts in collective knowledge* by interacting with *boundary objects*. Examples of boundary objects in RPPs include co-designing curricula, assessments, or educational tools. In this paper, we describe how researchers and teachers co-designed a data visualization tool for students which served as a boundary object in this RPP.

Methods

Context and participants

This study is a preliminary analysis of GROOVA and is part of a larger RPP project in which researchers and elementary school teachers co-designed and implemented data science curricular units. In year 1 of this project, 7 researchers and 9 teachers participated in summer co-design sessions and implemented 4 data science units. In year 2, the same 7 researchers, 7 educators from year 1, and an additional 9 educators participated in summer co-design sessions and implemented 6 data science units. In year 1, teachers voiced difficulties with using TUVA, the data visualization tool (Arastoopour Irgens et al., 2023). Motivated by their partner teachers' experiences, one researcher developed GROOVA using R Shiny

Figure 1
GROOVA Interface showing a bar graph and scatter plot with sample data about nutrition facts.



Categorical Variable (X): health
Grouping Variable: taste
Graph Title: Snacks According to Taste and Health

Numeric Variable (X): fat
Numeric Variable (Y): calories
Grouping Variable: health
Labels: snack
Graph Title: Snack Calories Versus Fat (And Healthiness)

In this part of a larger descriptive case study, we collected field notes from teacher and researcher summer meetings, teacher's daily journal entries, and transcribed interviews from teacher focus groups. We coded all three data sources and then weaved the codes into three themes (Terry et al., 2017) that described teacher's perceptions and reactions to the data visualization tool that researchers presented at the summer meeting.

Findings

Better usability and more developmentally appropriate than other tools

When the researchers presented GROOVA to the teachers, the teachers' reactions were mainly about the increased usability of the tool compared to TUVA. When teachers explored the tool, they stated that GROOVA was "quicker, easier, and more efficient [than TUVA]" and had "less distractions." One teacher wrote in their journal, "Groova was super friendly and cool… It is very **user friendly** and **accessible for students and teachers**." In their interview, one teacher noted that GROOVA had options for increasing. She stated,

> "Last year… I got to see TUVA and I was like 'whoa, this is rough!' Like even me as an adult and a teacher, I was kind of like, "ummm…I don't really get it."… With GROOVA, they can step their way into, you know, you might have some kids that with that basic bar graph they need to stop right there, and just live in that basic bar graph. But you know your higher kids might use that scatterplot, that might click for them, so I think that's great, that there's options."

An effective learning tool

In addition to being user-friendly and developmentally appropriate, teachers also commented on GROOVA as an effective tool for graphing and telling data stories. For example, one teacher wrote in their journal, "Groova is a fabulous tool! I can see this being a wonderful way for students to create their data tables that **enable them to feel successful and reduce student stress.**" Another teacher wrote, "Groova looks cleaner and **better for students to understand**. If students understand the information better, he/she can explain a data story." This teacher connected the ease of usability of the tool to improved predicted learning outcomes.

Teacher's design ideas: "It's what we want too"

During the summer meeting, teachers were given a demonstration of GROOVA using sample data and then access to test GROOVA with a sample dataset. Then, researchers asked teachers to identify features that they wanted to add to the tool. One teacher explained in their interview that they had "buy-in" for using GROOVA because the researchers were listening to their needs and implementing their requests into the tool. She said,

> "We had a chance to share our ideas and what we felt like Gol [the researcher] needed to add to GROOVA… We said that graphs didn't have titles. So that's when, Gol [the researcher] went back and said, 'Well, I can add it where they can put their very *own* titles,' and because it was so important for them to be able to create their own titles based on the data, she was able to add that. **So, I feel like the buy-in is that it's what we want, you know, it's what we want, too**."

Conclusion and next steps

In this study, GROOVA served as a boundary object for mediating activity and knowledge between teachers and researchers (Farrell et al., 2022). This boundary object emerged from the RPP participants' shared goal (Coburn & Penuel, 2016). Future analyses will include observations of GROOVA in teachers' curricular units, discussions with teachers about improving the design, and discussions with students about their experiences.

Intelligent Tutors, Cultural Blind Spots: Implications of Underrepresentation in Adaptive Learning Research

Juan D. Pinto, University of Illinois Urbana Champaign, jdpinto2@illinois.edu

Abstract: As intelligent tutoring systems (ITS) continue to mature and spread to lower- and middle-income countries (LMICs), it is becoming clear that basing such tools around models of learning overwhelmingly studied in Western countries has left severe blind spots that need to be addressed. This paper aims to raise awareness of the disconnect between the collectivist value systems espoused by many cultures and the Western individualistic mentality of ITS developers and researchers, along with some implications.

Introduction

Artificial intelligence in education (AIED) is an area of research in which the latest technological advances and the learning sciences meet. While this field encompasses multiple goals, one long-standing vision has focused on personalized learning through software that can adapt to the needs of individual students. This paradigm has dominated the design of intelligent tutoring systems (ITS) in the United States and other western, educated, industrialized, rich, and democratic (WEIRD; Henrich et al., 2010) countries. Not surprisingly, lower- and middle-income countries (LMICs) have yet to see much of the payoff from all the research these tools have sparked.

While the current imbalance in representation is not exclusive to academia, it stems largely from AIED research being predominantly undertaken in WEIRD countries. Several meta-analyses have highlighted this issue among published research in AIED and ITS journals and conference proceedings (Blanchard, 2012; Nye, 2015; Roll & Wylie, 2016). This underrepresentation in LMICs can be partly attributed to obvious barriers to AIED adoption, such as hardware access or electrical and internet reliability, but less tangible realities, such as cultural differences, may prove to be more formidable obstacles in the long run. Yet it is difficult to know what these challenging barriers will look like without investing adequately in research within LMIC contexts. In this paper, I aim to raise awareness of some of the practical implications of our current cultural and social blind spots.

Cultural behavioral differences

Much AIED research has focused on using data to capture student behaviors. However, studies in psychology have found that an overreliance on WEIRD populations for research can lead to an overemphasis on psychological constructs and behaviors that are not representative of the general global population (Henrich et al., 2010). One of the significant behavioral differences that researchers have identified across cultural contexts is that of student collaboration (Nye, 2015; Ogan et al., 2015; Ogan & Walker, 2012). These studies have found that students in many LMICs often collaborate extensively while using ITS. This appears to be the case regardless of socioeconomic status, urbanicity, or experience level with ITS (Ogan et al., 2015; Ogan & Walker, 2012). In these contexts, students have been observed providing help to classmates through oral communication or in some cases physically taking control of another student's computer. Practices such as these deviate significantly from the way ITS and other adaptive learning systems are typically designed to be used in WEIRD classrooms.

Implications for research and practice

While increased collaboration is generally considered positive in the learning sciences, this behavior does not align with the intended individualistic practice espoused by much ITS work. The learner models commonly developed in WEIRD countries may not reliably transfer to these different cultures, in part because they function under an assumption of a one-to-one student-to-device ratio, which is the foundation of the personalized learning paradigm at the center of much AIED work. Suggested solutions to this problem have included modifications to the algorithms used for knowledge tracing, which create and update the learner models used by ITS (Ogan & Walker, 2012), though it is difficult to see this as anything more than a band-aid solution. Some promising work has instead been aimed at designing ITS that enable students to share hardware while still being able to use their own input devices—an approach that has the added benefit of lowering hardware costs (Nye, 2015). Still, the majority of research continues to work towards a vision of one-to-one, machine-to-human tutoring.

All of this suggests that the heavy emphasis that AIED research has placed on personalized learning may come in conflict with the more collaborative pedagogies espoused by some cultures (Ogan et al., 2015). There may be a disconnect between collectivist value systems in some cultures and the Western individualistic mentality of AIED developers and researchers. Of course, I'm not claiming here that such values are the shared cultural heritage of all peoples in LMICs—a statement that would be reductionist at best. Instead, I am pointing out that it is problematic to assume that educational tools will always be used as intended.

Despite the difficulty of adequately addressing such a fundamental difference in how ITS are used in different contexts, the good news is that there does seem to be a growing interest on the topic. Roll & Wylie (2016) found that a much larger proportion of IJAIED papers from 2014 featured learner collaboration than a decade earlier, with not a single paper featuring it two decades earlier. To the best of my knowledge, such a systematic review has not been done in the ensuing years. It is important to continue identifying the trajectory of this research as a form of accountability and because awareness of LMIC underrepresentation in ITS research is the first important step towards mitigating the issue. Suggestions on where to go from here include hosting more conferences such as AIED outside of WEIRD countries—which may help researchers in these contexts become engaged in the community—as well as a call for researchers to more consistently describe the relevant contextual factors of their samples (Nye, 2015). The latter suggestion has the added benefit of helping to address some of the algorithmic biases that knowledge tracing and learner behavior models often carry (Paquette et al., 2020)—another issue that may be negatively affecting underrepresented populations such as those in LMICs. However, truly addressing the blind spots highlighted in this paper may ultimately require entirely reimagining what personalized learning will mean in an ever-more-interconnected, information-overloaded world.

Conclusion

This paper has highlighted one of the key implications (and subsequent challenges) of work that aims to expand adaptive learning to populations in LMICs. However, there remain fundamental questions to ask that this paper has not touched on. For starters, it has not called into question the very premise that expanding AIED access to LMICs is desirable. As is true of any large-scale implementation of a new technology, such an effort will undoubtedly bring with it both predictable and unpredictable unintended consequences. One such issue is the potential for neocolonialist outcomes that supplant traditional local practices and paradigms.

One of the principal driving forces behind AIED is the desire to reduce inequalities in education by making learning more personalized to individual students and their needs. Adaptive learning systems present the opportunity to make an especially positive impact in LMICs due to common shortages in these areas of qualified teachers (Zualkernan et al., 2013) and other resources such as textbooks (Nye, 2015). Yet the only way to work toward an equitable future on this front is to carefully reflect on the problems that may be introduced and possible ways to mitigate them. This is precisely what this paper has attempted to do, though only as an entry point into the conversation.

Abstract: This meta-analysis includes 217 empirical studies and investigates the effectiveness of facilitating learners' agency as a strategy to adapt and individualize instructional support to learners' prior knowledge. We conclude that (1) facilitating learners' agency might have different effects on learners with different levels of prior knowledge; (2) allowing learners to control simulation flow enhances effects of simulations.

Introduction

Empirical research provides supportive evidence on the effectiveness of learning with simulations in different domains of higher education (e.g. Cook, 2014, Theelen et al., 2019). Student-centered approaches and adapting instructional support to the competence level and needs of learners enhances knowledge and skills (e.g. Bernard et al., 2019). We assume that facilitating learners' agency (i.e. control) over the flow of own learning is beneficial for developing a whole range of skills in higher education. However, there is a lack in systematic knowledge about designing effective instructional support within simulations in higher education, and in particular allowing support to be adapted based on learners' needs or characteristics.

Theoretical background and research questions

This meta-analysis is grounded in the research on the effectiveness of simulation-based learning in fostering the development of complex skills in different domains (e.g. Chernikova et al, 2020). We adopt the idea of adaptability as one of defining elements of scaffolding (e.g. van de Pol et al., 2010) and emphasize that by adapting the scaffolding, the effects on learning outcomes can be significantly increased (e.g. Belland et al. 2017). To capture adaptability of learning environments we rely on the framework by Plass & Pawar (2020).

As the empirical evidence considering effects of facilitating learners' agency by adapting instructional support is mixed, we expect to collect meta-analytic evidence to clarify those. On the one hand, learners' agency and control over own learning is associated with increased motivation and learning gains (e.g., Al Moteri, 2019). On the other hand, the meta-analysis by Belland et al. (2017) showed better effects for the external decision-making authority (i.e. decisions made by instructors or systems).

The following research questions were addressed in the paper.

RQ1: What strategies aimed at facilitating learners' agency are used in primary studies of simulation-based learning environments in higher education?

RQ2: To what extent can facilitating learners' agency enhance effects of simulation-based learning on learning gains in learners with higher and lower levels of prior knowledge in higher education?

Methods and results

A state of the art meta-analysis procedure (Schmidt & Hunter, 2014) was used. The analysis is based on extending the collection of primary studies in a meta-analysis by Chernikova et al. (2020) by 74 further studies (total N=217) and is focusing on facilitating learners' agency within simulation-based learning environments.

All primary studies were double coded by one of the authors and a student assistant with interrater agreement above .92. The level of prior knowledge was coded as "high" if the simulation context was familiar to the learners on conceptual and procedural levels as mentioned by the authors of primary studies and as "low" if the simulation context was unfamiliar (e.g. new topics). Strategies, which aimed at allowing participants to control learning situation, were coded at the next step. If learners were in control, strategy was coded as "by learner", if decisions were made by instructor or system; strategies were coded as "by instructor/system".

Average effect of simulations on learning was found to be g=.95, SE =.06. This effect was used as reference point for estimating effectiveness of each strategy for adapting instructional support.

The following strategies facilitating learners' agency (RQ1) were found in primary studies: (1) giving participants control over time/amount of support (used in 20 studies); (2) giving participants control over solution steps in simulation (i.e., deciding on activity/task order), identified in 37 studies.

In regard to RQ2 giving participants control over solution steps in simulation was beneficial for all learners, independent from levels of their prior knowledge. Giving participants control over time/amount of support they get had some positive tendency for learners with high level of prior knowledge, but not low level.

Table 1
Effects of facilitating learners' agency

	High prior knowledge Hedge's g (*SE*); *N*		Low prior knowledge Hedge's g (*SE*); *N*
1. Control over scaffolding			
By learner	1.15 (0.32); *N*=10	*	0.51 (0.14); *N*=8
By system/instructor	0.99 (0.10); *N*=61		0.82 (0.13); *N*=62
2. Control over task order			
By learner	1.19 (0.19); *N*=18		0.86 (0.20); *N*=19
By system/instructor	1.00 (0.09); N=52		0.75 (0.13); *N*=58

Discussion

This meta-analysis focuses on simulation-based learning environments in higher education and strategies that can be used within these learning environment to facilitate learners' agency or in other words enhance learners' control over the flow of simulation and own learning.

The findings of the current meta-analysis go in line with the effects reported in a range of more traditional learning environments (see Belland et al., 2017), confirming the claim that learners with lower levels of prior knowledge might have problems with identifying their need for help. Interestingly, the effect is different when learners are given the opportunity to decide on the task/solution steps order. This strategy has similar effects for both levels of prior knowledge; and its implementation is associated with higher effects of simulations on learning outcomes.

A couple of limitations need to be considered: (1) the categorization of strategies to adapt instructional support is relatively coarse-grained and may be confounded with some implicit instructional support used in primary studies; (2) this research only addresses objective measures of learning outcomes, but not attitudes, or motivation, which might be also affected within simulation-based learning environments.

Positivist and Constructivist Orientation Impact on Supervisors' Conceptions of Video Use in Teacher Professionalization

Ricardo R. Monginho, University of Évora – CIEP-UÉ, rrm@uevora.pt
Frank De Jong, Aeres Hogeschool Wageningen, f.de.jong@aeres.nl
Erick Velazquez-Godinez, Computer Research Institute of Montréal, erick.velazquez-godinez@crim.ca
Paulo Costa, University of Évora – CIEP-UÉ, plc@uevora.pt

Abstract: This research aims at getting insight in the supervisors' conception in the use of video to bridge learning of students and the professionalization of teachers. Therefore, we interviewed supervisors why and how video technologies are being used or not in the process of enhancing their professional practices and collaborative learning with the student teachers. The main finding is that supervisors' knowledge orientation probably has an impact on how they perceive the use of video in their teacher professionalization practice. In fact, both groups (positivist *vs.* constructivist) are using video but the first group is prioritizing more objective ways to use video technologies and the latter group focuses more on using video in constructive ways to support the learning process.

Introduction

The Covid-19 pandemic prompted a transformative shift in education nearly two years ago. Teachers deserve commendation for their commendable efforts in ensuring the continuity of education, despite challenges in discipline and motivation arising from the absence of social interactions with peers and teachers. This transition compelled teachers to step out of their comfort zones, often marked by resistance rooted in social, psychological, and professional factors (Savina, 2019). While some teachers embraced the positive possibilities of online learning and sought to enhance their e-didactics, many still struggle to systematically integrate videos into their teaching practices, hindering productive and contemporary learning experiences. Insufficient understanding of how videos can support collaborative learning in teaching contributes to ineffective outcomes, limited engagement, and missed opportunities for technology-enhanced learning.

Our research constitutes the initial phase of a doctoral research project conducted in Évora, Portugal, and aims to investigate the influence of the supervisors' conceptions of knowledge, whether objectivist or constructivist (Fosnot, 1996; Perkins, 1999; Darling-Hammond, 2000), on their reported professional practices and their use of video technologies to facilitate collaborative learning between themselves and their student teachers.

Method

The research employed an exploratory approach, employing semi-structured interviews (in-person [5] and online [6]) with teacher-supervisors. Various analysis methods, including manual NVivo analysis, natural language topic analysis, semantic network analysis, and SPSS (M)anova procedure on KBDex were utilized to examine and interpret the supervisors' reported practices and perspectives. The study involved 11 supervisors from six universities and higher education institutions (HEIs) in Portugal.

Analysis

The analysis employed NVivo to analyze the supervisors' visions of knowledge (positivist or constructivist) as the initial step. The fourth part of the semi-structured interviews was specifically utilized for this purpose. To ensure reliability, three researchers received clear instructions to differentiate between positivist (P) and constructivist (C) visions in the supervisors' discourse. They independently analyzed the interview text corresponding to Part D and provided feedback. Inter-rater agreement was measured using Fleiss' Kappa test, resulting in a high agreement level of 0.876 among the three researchers (Table 1). In the second step, a list of stop words was used to prepare the text for topic analysis. Through topic modeling, the most frequent words from the semi-structured interviews were extracted and combined with a comprehensive word list. This process identified seven noteworthy categories for further analysis. Lastly, KBDex, in conjunction with the previous analysis results, was employed to examine semantic network differences between supervisors with positivist and constructivist knowledge perspectives across the identified categories.

Table 1

Inter-rater level of agreement (Fleiss' Kappa)

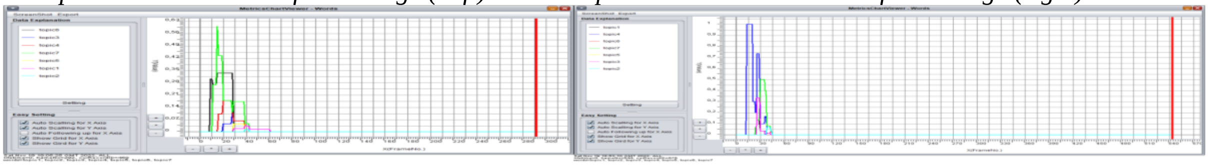
	Kappa	Asymptotic Standard Error	Z	P Value	Lower 95% Asymptotic Cl Bound	Upper 95% Asymptotic Cl Bound
Overall	0,876	0,174	5,032	0,000	0,535	1,217

Findings

The qualitative analysis revealed that there were five supervisors (Group A) with a positivist orientation and six supervisors (Group B) with a constructivist orientation in their perspectives on teaching and learning (Figure 1). Excerpts from the interviews showcased the supervisors' viewpoints on knowledge. Those with a positivist vision described knowledge as a set of research-based assumptions that inform a professional area, while those with a constructivist vision emphasized the incorporation of information into existing knowledge through transformative mental and bodily processes. The topic analysis identified seven categories, supported by frequent words, such as supervision process, video, collaboration, and reflection. A Manova analysis indicated a significant difference between the two groups, with constructivist-oriented supervisors showing stronger scores on the conceptualization of "Video-Teaching-Supervision."

Figure 1

Group A - Positivist view of knowledge (left) and Group B - Constructivist view of knowledge (right)



Discussion and conclusion

Because of the exploratory character of the study we intend to give continuity and update in the future. Looking at the 'Video-Teaching-Supervision' dimension throughout the complete interview data, it is clear that the constructivist-oriented supervisors differ from the positivist oriented by more attention to video and the supervision process, the role of the teacher in the learning process, collaboration supervisor-student-teacher/teacher in practice and training, internship and the supervisor. To summarize, video is being used by supervisors from both groups although they seem to be doing it in a different way and with slightly different goals. For instance, ones prioritizing more practical skills versus others giving attention to the development of reflection skills; more objective ways to use video technologies versus more constructive ways to use videos to support the learning process. Based on the variance analysis it can be concluded that the two groups of supervisors conception of video use is characterized by different foci. Sample size of 11 teacher supervisors may limit the generalizability of the findings. Additionally, the subjective nature of the interview responses and potential interviewer bias could influence the results.

Teachers’ Beliefs and Practices of Technology Integration: A Case Study of Kerala (India) Teachers From an Ecological Perspective

P. A. Nandan, Sahana Murthy
nandan.p.a@iitb.ac.in, sahanamurthy@iitb.ac.in
Indian Institute of Technology Bombay, India

Abstract: Research on teachers’ beliefs and practices of technology integration suggests that contextual factors be given sufficient attention, in addition to cognitive and affective factors. The present study used an ecological perspective to understand how contextual factors situated at three ecosystem scales affect the enactment of teachers’ beliefs and practices of technology integration. We present findings from a multiple-case study of three middle and high school science teachers in Kerala, India.

Introduction

The significance of teachers’ beliefs in classroom practices of technology integration has been established by prior research. While most researchers agree that teachers’ beliefs and practices of technology integration form and change through a dynamic interplay of cognitive, affective and contextual factors, existing studies are predominantly focused more on the individual characteristics of teachers, and are inadequate to account for the complex interactions happening between teachers and the ecosystem of the school (Nadelson et al., 2018) and this creates a crucial gap. In the present study, we use an ecological perspective to address the research question: ‘How do contextual factors contribute to the enactment of teachers’ beliefs and practices of technology integration?’

Theoretical framework

The present study operationalizes teachers’ beliefs about technology integration as related, but independent components of pedagogical beliefs about teaching and learning, self-efficacy beliefs for using technology and beliefs about the value of the use of technology (Park & Ertmer, 2007).

Throughout the study, we used an ecological perspective from research gap identification to findings and interpretation. We have adopted the learning ecosystem conceptual framework proposed by Hecht & Crowley (2020). In the present study, we consider the ecosystems of teachers at three scales i.e. regional, school and classroom ecosystems. We consider the ecosystem as a constellation of inter-twined and entangled elements such as teachers, students, parents, school administrators, teacher educators, community, technology, etc., and their dynamic relationships that we can find within and across the school and out-of-school places. Another aspect is the ecotone, which is a zone of transition between two ecosystems, where one set of environmental conditions merges into another (Ryberg, et al., 2021).

Educational context

The present study is conducted in the rural area of the Thrissur district of Kerala in southwest India, which is known for its high literacy rate. Kerala has implemented various innovative programs to support teaching and learning through technology such as VICTERS (Versatile ICT Enabled Resource for Students) and Samagra eResource Portal. Kerala is exceptional in terms of the degree of society’s participation in public education, particularly at the local level, in the form of various civic collaborations with schools and teachers. All teachers in the selected schools are qualified with minimum BA/BSc and BEd degrees and state eligibility tests (SET). Teachers received induction training on the use of ICT through a platform called KITE's Open Online Learning (KOOL). The majority of parents are daily wage workers and from fishermen communities. However, some parents are also educated and involved in teaching, business, politics, banking, etc. People in this area speak the language of Malayalam.

Method

The present study used a multi-case study research design to develop an in-depth analysis of each teacher. We define our case as a middle or high school science teacher in the state of Kerala, India, who utilizes technology for the teaching and learning process. The goal here is the theoretical replication of similar or contrasting findings we get from each case. A broader study designed for 14 middle and high school science teachers from different types of schools (government and government-aided private) in the Thrissur district of Kerala is ongoing. For the present study, we used a maximum heterogeneity sampling strategy (Patton, 2015), to purposefully select three teachers from the 14 teachers. Data were collected through semi-structured interviews with individual teachers and observation of teachers' continuing professional development (CPD) programs.

The audio-recorded interviews were transcribed into Malayalam text and then translated into English for further analysis. We first identified the instances of transactions reported by the teachers. These include but are not limited to dynamic interactions of teachers with students, families, teacher educators, administrators and the material elements they engage with such as technology. Within those transactions, we classified them as transactions within and across the ecosystems at three scales. Transactions which involved or led to teachers' beliefs and/or practice of technology integration were considered for further analysis. We examined teacher statements which directly or indirectly related to one of the three beliefs (i.e. pedagogical beliefs about teaching and learning, self-efficacy beliefs for using technology and beliefs about the value of the use of technology).

Findings and discussion

This study conducted among middle and high school teachers in the state of Kerala, India has shown different patterns of transactions within and across ecosystems at *the classroom, school and regional scales*. At the classroom scale, we have identified that *immediate feedback, family background of students, availability of resources, the need of students, adaptability of technology, nature of learning content and ability of students* are the contextual factors that affect teachers' technology practices. However, contextual factors such as the family background of students and the availability of resources do not influence teachers' beliefs about technology integration. At the school ecosystem scale, *sharing success stories by colleagues, monitoring and auditing of teacher practice by the head teacher, availability of resources, and administrative decisions or policies* are found to be the contextual factors that affect teachers' technology practice. However, only the contextual factor 'sharing success stories by colleagues' is capable of influencing teachers' beliefs about technology integration. In the regional ecosystem scale, *policies or guidelines, parents' involvement in children's education, and pressure from the teachers' families* are found to be the contextual factors affecting teachers' technology practice.

The study found that contextual factors situated at the regional and school ecosystem scale have equal potential to influence teachers' technology practice at the classroom ecosystem scale. This finding reiterates the observations of Hecht & Crowley (2020), who argued that ecosystems exist at both micro and macro scales in nested, but nonhierarchical, structures. However, we found that contextual factors have diverse effects on teachers' beliefs about technology integration. Not all contextual factors are capable of influencing teachers' beliefs, for example, the contextual factors situated at the regional ecosystem scale did not influence teachers' beliefs about technology integration. At the same time, we also noticed some contradictions in teachers' reported technology practice and their beliefs about technology integration. The contextual factors situated at the regional scale such as monitoring/auditing, availability of resources, and administrative decisions/policy are capable of forcing teachers to use technology in a teacher-centred manner, even if they hold student-centred beliefs. Another important observation is that the *community of practice of teachers* functioned as ecotones and augmented the influence of contextual factors acting across the ecosystems scales and facilitated productive changes both in the beliefs and practices of teachers. For example, the teacher professional development programs provided by the teacher educators at the regional scale are facilitated by continuous and constant support provided by the community of practice of teachers through both physical and virtual teacher subject groups (ecotones). The discussions and sharing of innovative ideas and success stories in these teacher groups made a positive influence on teachers' technology practice and affected their beliefs about technology at the classroom scale. Even if the contextual factors at the regional and school scale could not affect teachers' beliefs about technology integration positively, the community of practice of teachers (ecotones) facilitated this process and made possible productive changes both in the beliefs and practice of teachers.

Examining Demonstrations of Presence in a Multimodal Art Exhibit Created by Latina/x Youth

Catherine Dornfeld Tissenbaum, McKenna Lane, Mónica González Ybarra, Idalia Nuñez
catdoti@illinois.edu, mllane2@illinois.edu, mgonza36@illinois.edu, idalian@illinois.edu
University of Illinois Urbana-Champaign

Abstract: Museums have longstanding issues with reproducing colonial narratives of marginalized communities and/or erasing their perspectives altogether. In response, visitors of color may feel that museums are "not for them." Our team developed a multilingual after-school program aimed at increasing representation of Latina/x youth in museums through co-creation of an art exhibit. We used thematic analysis to examine visitors' written responses to the exhibit and identify how the exhibit allowed the artists to demonstrate presence.

Introduction

Museums have problematic histories regarding the representation of objects, artifacts, and artworks from communities of color. Museums tend to represent colonial perspectives due to a largely homogenous workforce and an unwillingness to broach uncomfortable topics (Dewhurst & Hendrick, 2017; Feinstein & Meshoulam, 2014; Hooper-Greenhill, 2000; Martinez, 2020; Seitz, 2012). In response, visitors of color may find that exhibits diminish and/or erase their perspectives (Martinez, 2020). As an example, mainstream museums may lack multi-layered representation of Latinx artists or fail to accurately contextualize Latinx works (Acevedo & Madara, 2015; Zamora, 2007), thus recreating feelings of exclusion and irrelevance.

In response, we began a multi-year project aimed at supporting the inclusion, representation, and relevance of museums to Latinx youth through co-design of art exhibits. We leveraged community partnerships to develop a multilingual after-school program that scaffolded participants' design of a multimedia exhibit about identity, community, and culture. In turn, we hoped that museum visitors would relate to and reflect on the girls' experiences via a "Response Wall." To examine how the exhibit impacted visitors, we used thematic analysis (Braun & Clarke, 2006) to investigate visitors' responses on the wall: *what themes emerged in visitors' responses to the exhibit, and how did these responses bear witness to the artists' presence in the museum?* This paper illustrates how youth-driven designs can increase museums' capacity to serve marginalized groups as artists and visitors while using a practitioner-friendly approach to analyzing visitor impacts.

Methods

This project was developed with the input of multiple partners, including Latina/x middle-school girls; school staff; a university art museum in the U.S. Midwest; and a nonprofit organization that encourages career exploration for young women. From Sept. – Dec. 2021, up to 10 girls joined 10 after-school sessions, with five girls attending most sessions. Participants identified as Latina/x young women and spoke English, Spanish, and/or Indigenous Guatemalan languages (Q'anjob'al and K'iche'). During the program, the girls engaged with activities that examined their identities, communities, and conflicts in middle-school life. They created a community map of important locations in their daily lives; a "snack-off" video of creative dishes; a music playlist; framed drawings of important words in their lives; and an artists' statement that blended English and Spanish to describe the exhibit intentions. The exhibit was displayed at the university art museum from April - July 2022 with free admission. A digital archive is available at https://catdoti.github.io/latina-community-voices/.

This study draws from a larger data corpus documenting the program. We focused on visitors' responses to the exhibit based on 204 written and/or drawn sticky notes on the Response Wall. The first two authors qualitatively analyzed all notes using thematic analysis (Braun & Clarke, 2006). We read all notes independently, then generated a tentative coding scheme. We met to sort notes and identify themes based on broad categories of notes being "related" or "unrelated" to the exhibit. We finalized all themes, codes, and interpretations when writing our report. The full coding scheme can be found here: http://bit.ly/3Ar3ZOf.

Findings

Visitors left 204 responses on the Response Wall, of which 83 (41%) were related to the exhibit and 121 (59%) were not (or could not be determined). We noted that 153 responses (75%) were written in English, 41 (20%) in Spanish, and 10 (5%) in other languages. We identified six themes within related responses (see Table 1), which include sub-codes not listed here due to space constraints; more detail will be included during the presentation. Five responses were left by the participants themselves after reading other visitors' responses.

Table 1
Emergent Themes in Visitors' Responses

Related to Exhibit	# Codes	Unrelated to Exhibit	# Codes
General exhibit feedback	24	General addition of presence	93
Specific exhibit feedback	19	Provocative statements	18
Feelings of inclusion	12	Languages other than English/Spanish	10
Other Latinx representation	15		
Responses from participants	5		
Responses about the museum	11		

Discussion & conclusion

This project aimed to increase representation of Latina/x youth in museums, and we see the visitors' responses as evidence of progress toward this goal. Related responses indicated that visitors had largely positive experiences with the exhibit, with some alluding to shared identities (e.g., "Feels like home") or directly stating them (e.g., "I'm Puerto Riceña pero I relate con muchas cosas que los estudiantes están diciendo"). Other notes thanked participants for sharing pieces of their identity, highlighting how the exhibit created space for Latina/x cultures (e.g., "I feel so proud to be Latina when I see others embracing our beautiful cultura") and languages, with at least 20% of responses including Spanish. Some praised the inclusion of Latinx perspectives (e.g., "Gracias por crear una exhibición para representación y darnos una voz") while others attempted to co-participate through basic phrases (e.g., "Me gusta tu cultura"), both of which legitimize Spanish in a "mainstream" American art museum.

This initial analysis discusses one element of a multi-year project and thus has several limitations. First, the Response Wall was anonymous, and we lack demographic information about respondents. Second, we cannot assume that the artists' perspectives encompass the varied identities, cultures, and lived experiences of all Latina/x youth. Last, participants did not analyze responses with us. As we continue this project, we intend to integrate our participants into analytical and interpretive research of this project's impacts.

While the exhibit co-design process served as a participatory experience for its artists, it also invited visitors to participate via the Response Wall. Visitors' contributions of responses as sticky notes not only allowed artists and visitors to interact, but also provided tangible artifacts that acknowledged the artists' efforts and presence, further building on the exhibit. Some visitors used this space to encourage, relate, appreciate, and offer feedback, and some took it as an opportunity to express their own identities through creation of images, text, and other personal markers. For all notes, regardless of relevance, adding to the Response Wall was a way to document presence and witness the artists' creations. When the artists visited the exhibit shortly before deinstallation, they left a message of their own: "We loved all the love you guys gave us."

Play-Inspired Organic Differentiation in Early Math

Brittany Caldwell, Jamie Vescio, Anita Wager
Brittany.caldwell@vanderbilt.edu, jamie.l.vescio@vanderbilt.edu, anita.wager@vanderbilt.edu

Abstract: As part of a larger project to explore the possibilities for children to learn mathematics in play, we examined how opening up a pattern block activity provided space for children to differentiate their interactions. The limiting nature of the original task would have stopped children from demonstrating what they could do and might explore. Using Bishop's (1988) fundamental mathematical activities as our codes, analyzed video of eight children engaging in pattern block play revealed how they organically differentiated, pushing learning opportunities beyond the scope of the original lesson.

Situating the problem

Revising a lesson to invite children to play with mathematics and take agency provides them with opportunities to demonstrate mathematical understanding beyond what the lesson goals require. In a spatial reasoning activity modified to be more playful, we found that children's varied engagement that derives from a child's agency, rather than a different activity put forth by the teacher, is what we call 'organic differentiation'. This engagement can range from children participating in ways that align with the expected goals for the task (e.g., placing the pattern blocks on the puzzle) to a demonstration of pushing their participation beyond expectations in a challenging or new way (e.g., using pattern blocks to create a new design). Organic differentiation may allow children agency to approach activities in ways that align with their own experience, interests and expertise. As part of a larger study of designing classrooms that support children's mathematics learning with play, we explored the questions:

1. How do playful pattern block activities support children's engagement in mathematics?
2. How do open-ended play-based activities provide opportunities for organic differentiation?

Conceptual framework

Vygotsky (1978) viewed human development as a socially-mediated process; informed by social experiences/ interactions (including play). When considering learning opportunities, the children operated in their zones of proximal development (ZPD); working in spaces they were familiar but also trying new things. As a lens to examine children's engagement with the mathematical activity, we drew on the work of Bishop (1988) who identified six fundamental activities of mathematics (counting, locating, measuring, designing, playing, and explaining) that he found to be universal and necessary for mathematics. These fundamental activities enable us to see what mathematics is around to be learned, what mathematics children are doing, and how to label those practices as such.

Methods

These data are from video recordings of two small groups of kindergarten children. Analysis focused on a guided play activity: pattern block puzzles where children were provided with a large box of pattern blocks and several templates to create shapes with the pattern blocks. From Bishop's (1999) six fundamental activities, we collectively identified "designing" and "locating" as the primary practices children engaged in. Using video analysis software, we coded each video multiple times, focusing on individual children each time. Descriptive codes that characterize the ways children participated in locating and designing guided the narratives we wrote for each child. We then compared narratives and codes and discussed children's engagement across groups.

Findings

Our analysis shows that the children engaged differently with the pattern blocks even when given similar instructions and materials for the guided play math center. We argue that these children's actions, the mathematical practices they engaged in, and their engagement supports our finding that this playful activity afforded the children the opportunities to self-differentiate in an organic way. To characterize the children's engagement, we identified four common patterns of play: the rotators, the aligners, the designers, and the duplicator. Although some children participated in practices that were used across the groups (e.g., rotating shapes), we identified these groups to showcase the primary ways the children engaged in mathematical practices.

The Rotators (n=2) would look at the puzzle, select the shapes, and then rotate and slide them to fit together. They participated in the math practice of locating as they actively rotated and slid shapes to fit within the puzzle. The different ways the children did this (in the air or on the paper) and the different goals of rotating (to match the shape or to determine the fit within the puzzle), highlight, even within this group, the ways the children differentiated their engagement with the mathematical practice of locating to be successful with this activity. The Aligners (n=3) made sure each shape fit perfectly on the pattern block puzzles or in line with the other shapes. A key characteristic of this group was their attention to the final product which required that pieces were precisely placed. Making sure that each shape fit perfectly within the pattern-block puzzle, the children would look at the puzzle and then find that shape in the box and place it directly on top of the puzzle in the exact placement. They attended to precision in the placement of each shape by touching it on either side with both hands in order to slowly and more accurately adjust it to fit the puzzle. The Creators (n=2) did not follow the pattern puzzle instead, upon recalling that the teacher had told them, “we are making shapes out of other shapes”, decided to create their own. In their designs, the children attended to symmetry and created patterns using tessellations and symmetrical patterns. The Duplicator (n=1), unlike all other children who either stayed on the pattern block template or completely deviated from it, used the pattern block template as a guide and completed his puzzle off of the paper itself. To do so, he first sorted all of his shapes and then using the snake pattern block puzzle as a reference duplicated the puzzle on the desktop next to it. During this process he continued to use rotating and sliding to ensure that the correct sides of each side aligned with one another.

Discussion, conclusion, and implications

Play can afford children opportunities to organically differentiate their engagement with mathematical activities. While differentiation is often thought of as a way that teachers can create various access points for children during lessons (Goddard & Kim, 2018), we saw organic differentiation through the ways the children naturally engaged with the materials differently and participated in different mathematical practices. The children used the same materials, but the ways they engaged were very different. The findings are are purposefully presented, not to suggest linear learning trajectories, but to highlight the complexity and fluidity of children’s engagement during playful activities when they have the autonomy to engage with materials.

The findings have implications for teaching. Playful activities where children can engage with materials with autonomy can be spaces where children can naturally challenge themselves to push their learning further. Rather than providing constrained tasks with explicit standards in mind, by opening up an activity we found that children went well beyond the intended mathematical goal. Rather than a teacher having to intentionally give each child a different task, the autonomy the children experienced contributed to the children differentiating how they engaged while still staying on task. Teachers can increase students' autonomy by providing spaces for organic differentiation.

Tools Dictate the Divide: Entrenched Gendered Practices in the Making of Kinetic Sculptures

Santiago Ojeda-Ramirez, Lora Cawelti, Joey Huang, Kylie Peppler
sojedara@uci.edu, lcawelti@uci.edu, chujenh@uci.edu, kpeppler@uci.edu
University of California, Irvine

Abstract: One of the promises of STEAM-based education is to ameliorate existing gender disparities regarding access to STEM fields. We analyze youth making kinetic sculptures as a novel STEAM-based approach to infusing historically gendered practices into the study of robotics. We found the distribution of labor was based on gender normative practices. This study highlights how STEAM-based education requires an examination of our tools and materials and how they reinscribe existing practices along traditional gendered lines.

Introduction

The potential of STEAM to transform education depends on how it tackles evident gender disparities regarding access to (and invitations to participate in) fields such as science, technology, engineering, and mathematics (STEM). In particular, activities related to electronics engineering and robotics have a particularly male-centered culture that needs to be changed in order to make learning spaces welcoming and nurturing to many gender identities, particularly female youth (Peppler, 2013). Prior work has explored the emergence of new ways of exploring STEM, starting at the tool level, where the introduction of the LilyPad Arduino in a classroom setting produced similar disruptions of gendered participation around electronics and coding as seen in the broader Maker Movement (Buechley & Mako-Hill, 2010). By examining children's use of a wider array of materials during the construction of kinetic sculptures (sculptures in which movement is a paramount element), we aim to identify tacitly accepted practices rooted in gendered stories of materials, examining children's use of artistic media and an Arduino-based robotic kit while learning coding, robotics, electronics, and sculpture making. The questions that guide our study are: (1) What are the practices in making a robotic kinetic sculpture? (2) How do gendered patterns affect the division of labor in a mixed-gender triad while designing and building a kinetic sculpture?

Methods

In the spring of 2022, data were collected during a workshop in a combined 5th and 6th grade class at a charter school in Orange County, California. From a total of over 15 hours for four student groups, we analyzed 75 minutes of video and audio recordings focused on one student trio, a sample composed of two girls and one boy, which served the purpose of identifying how youth divided labor with respect to gender in a group composed with majority girls. Our analysis focuses on the final hour of a kinetic sculpture workshop as students worked to piece their final sculptures together. The excerpt contains complex manipulation of materials with key moments of negotiation in the division of labor, while still being representative of the overall project labor division. We drew from Buchholz et al.'s (2014) methodology, coding *instances* in the video data, and determined the practices that took place. Each time one of the three youth exhibited a mediated action, it was coded and categorized as arts, electronics, or coding practice, using sub-codes within each of these categories. Two authors coded the video data to identify practices and count the frequency of these practices' appearances. We also registered duration (measured in seconds) for each category and subcategories of practices and coded 15 minutes of data; inter-rater reliability of the coding scheme was calculated by Cohen's kappa with k=.82. This coding process led us to determine the frequency and duration of each practice.

Findings

After coding the frequency and duration of each practice, three major groupings for the practices emerged: *Arts Practices*, *Electronic and Robotics Practices*, *and Computing Practices*. Our findings align with notions of art perceived as predominantly feminine, with girls engaging in art practices with more frequency and duration (70%) than their male counterparts (30%). Overall, the boy in the studied trio engaged 85% of the time spent with electronic and robotics practices, with girls collectively at 15%, reflecting a heavily male indexing of historically masculine-perceived practices (Buechley et al., 2010). Of the total time spent coding, the studied boy engaged 66% of the time in the coding activities, and the two girls altogether engaged in coding 33%. Nevertheless, girls held the computer (without coding) for more time (59%) than the boy (41%), which suggests that the computing activities themselves have a gendered division of labor that is worthy of further study. We observed that students from this trio had a very clear division of labor, which largely fell along gendered lines.

Table 1

Percentages of labor division in key practices by gender

Description of Practice	Percentage of Time Girls Engaged in Practices	Percentage of Time Boy Engaged in Practices
Arts (Including touching/hold art materials, balancing materials, drawing, planning the design, selecting and applying color/texture, building/manipulating/cutting materials)	**70%**	30%
Electronic and Robotics (Including touching/holding the Arduino Kit, connecting/disconnecting cables, manipulating/troubleshooting the potentiometer, manipulating/troubleshooting the servo motor)	15%	**85%**
Computing (Including coding/troubleshooting code; touching/holding the computer)	33%	**66%**
Totals	**47%**	**53%**

Figure 1

Kinetic sculpture made by the studied trio: "A bowl that spins and has symbols."

Discussion

Our findings reinforce previous research on how STEAM activities and group practices that integrate the arts into STEM provide opportunities for broader participation in STEM education (Mejias et al., 2019; Peppler, 2013). This is evident in the way girls were engaged and spent more time in artistic practices during the kinetic sculpture project, as well as in the way the boy dominated electronics and robotics elements of the project. Interestingly, the arrangement of a trio of two girls and one boy did not favor girls' use of electronic and robotics, nor computing materials; gendered scripts of materials and practices seemed to have prevailed, with the two girls dominating artistic practices and the boy leading STEM practices. This study highlights how simply high-quality STEAM-based education alone is not enough to eradicate existing gender divides in STEM fields. To truly transform STEM education, it requires a closer examination of our tools and materials and how they implicitly reinscribe existing practices along traditional gendered lines.

Peer Feedback: Exploring What Hurts and What Helps

Robert Jacob Robbins, Texas A&M University, jarobbins93@tamu.edu
Shawna Thomas, Texas A&M University, sthomas@tamu.edu
Mahjabin Chowdhury, Texas A&M University, mahjabin@tamu.edu
Jonan Phillip Donaldson, University of Alabama at Birmingham, jonandonaldson@uab.edu

Abstract: The role of peer feedback in project-based learning is poorly understood in computer science education. Therefore, the current study analyzed 238 student reflections in a design-based computer science course. While lack of experience and poor teamwork presented peer-feedback-related challenges, students' learning experiences benefited from feedback processes that were perceived as interesting and entailed perspective-taking. The relevance of learning theories is also discussed. These findings may inform approaches to future assignments as well as general approaches to peer assessment within project-based learning in computer science.

Introduction

One of the fastest growing education programs, computer science, has enjoyed the successful use of project-based learning (PjBL). Therein, students engage in social learning which benefits artifact construction and students' ability to apply real-world knowledge. Peer assessment consists of students evaluating the performance or achievement of their peers. Ideally, this process should be well-suited to collaborative learning environments such as those afforded by PjBL curricula. However, there exists little research on the use of peer assessment in a PjBL computer science setting. The current study addressed this gap by exploring college students' peer assessment experiences within a PjBL computer science course. Specifically, this study explored what students perceived as working well in the peer assessment process and what they struggled with. This study also evaluated how these experiences aligned with learning theories. The overarching research questions included: *What did students discuss in terms of their struggles with the peer review process? What did they report worked well? How are the strengths and struggles connected with the learning theories?*

Method

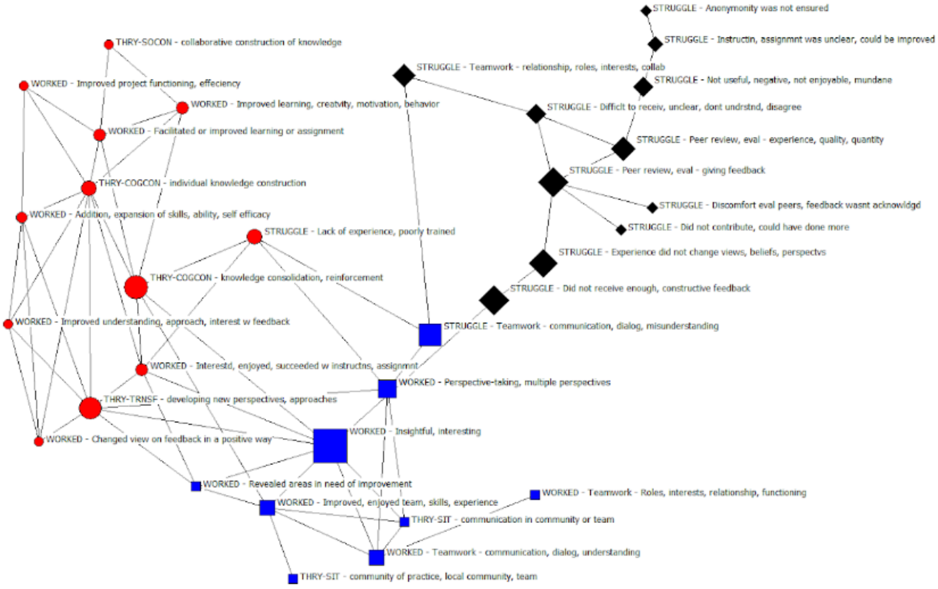
This study included 55 students in an undergraduate computer science course in the Spring of 2022. Students worked on 2-3-month-long, collaborative projects and completed written reflections of their experiences. This study is based on five learning theories including metacognition theory where learners reflect about their learning experience, cognitive constructivist theory where learners are engaged in individual knowledge construction (Piaget, 1956), social constructivist theory as the learners were also involved in collaborative learning through projects (Vygotsky, 1978), situated learning theory as the course included teamwork and communities of practice (Lave and Wenger, 1991) and transformative learning theory where learners develop new perspectives (Mezirow, 1997). We coded students' reflections at the sentence level in the MAXQDA Analytics Pro data analysis software. We used *a priori,* in vivo, and axial coding within categories, including what worked well, student struggles, and learning theories (Thornberg, 2012. We used MAXQDA software to create correlation matrices at the level of $p < .05$, $p < 0.01$, and $p < .001$ levels. We then imported the matrics into the UCINet network analysis software and the NetDraw social network visualization software (Borgatti, 2002) to create semantic network maps using the Girvan-Newman algorithm (Girvan & Newman, 2002). We used betweenness measures of centrality to identify leverage points to indicate the more important nodes in connecting to each other in a semantic map. The resulting network maps were used to identify design moves to improve the peer feedback process for subsequent courses.

Findings

A three-cluster semantic map was generated at $p<0.001$ level (Q=0.44, see Figure 1) using the categories of "student struggles", "aspects of peer feedback that worked well" and "learning theories". In the **red** cluster, the leverage point (biggest node) of the cognitive constructivist principle of *knowledge consolidation*, was connected to the struggle, *lack of experience*, and the "what worked" subcategory of *interested, enjoyed, or succeeded with instructions or assignment*. This indicates that knowledge consolidation may promote interest in the project and positive views towards feedback. To address lack of experience with feedback, future course iterations may benefit from emphasizing students' personal interests in and enjoyment with the feedback process. In the **black** cluster, student experiences consisted exclusively of struggles. These were related to experiences in the blue cluster. Thus, the leverage points of *giving feedback*, *experience did not change views, beliefs, or perspectives*, and *did not receive enough constructive feedback* may be addressed by emphasizing perspective-taking and insight or interest within the peer assessment process. In the **blue** cluster, the leverage point, *insightful or interesting*, was connected to the situational learning principle of *communication in a team* as well as *improved or enjoyed one's team, skills or experience* and *perspective-taking or exploring multiple perspectives.* Thus, the struggle of *teamwork miscommunication, dialog, or misunderstanding* could be addressed in future courses by emphasizing team communication and exploring multiple perspectives.

Figure 1

Semantic Network Analysis of Student Struggles, What Worked, and Theory (p<0.001)



Implications and conclusion

Results of the current study indicate that three learning theories, especially cognitive constructivism, and situational learning, were aligned with the students' perceived struggles and benefits. Results also indicate that a lack of experience and poor teamwork and communication produced challenges for students going through the peer assessment process. On the other hand, when peer assessment was perceived to improve skills, seemed insightful and interesting, and integrated perspective-taking, students reported benefits to their learning experience. While these insights will be used to shape subsequent feedback assignments, they may also inform general approaches to peer assessment within computer science courses that leverage project-based learning. For instance, when creating peer assessment criteria, including students as co-designers may ensure that assessment guidelines and prompts are interesting and insightful.

Probing Mathematical Language in Concreteness Fading Vector Addition Learning

Yilang Zhao, Matthew Berland
yilang.zhao@wisc.edu, mberland@wisc.edu
University of Wisconsin–Madison

Abstract: This study designed an intervention to teach middle schoolers vector addition in two conditions: concreteness fading (CF) and concreteness introduction (CI). All the participants had three learning tasks (in a different order) followed by a storytelling activity. We discovered the CF participants had consistent growth in using math language and were more confident when demonstrating their learning.

Introduction and theoretical framework

Current secondary-level vector addition learning and teaching rely heavily on symbols and abstract concepts, which fails to let students make sense of the notations and concepts (Karnam et al., 2020). In response to this issue, we propose that a concreteness fading intervention can be a potentially effective way to teach middle schoolers vector addition. Fyfe et al. (2014) propose *concreteness fading* (CF)– a three-stage instructional approach that enables students to use concrete learning materials that tie to their previous experiences, gradually decreases the level of concreteness of the learning materials, and eventually provides more abstract and generalizable learning materials. To evaluate mathematical learning, the use of mathematical language can be a good way because students' success in mathematics requires them to use proper mathematical language and vocabulary to communicate (Powell et al., 2019). Thus, our research question is *how mathematical vocabulary changes over the course of a concreteness fading intervention.*

Methods

This study recruited 14 8th graders from a charter school in a large Midwestern city in the U.S. who had no previous knowledge about the topic. We designed a four-stage CF intervention to teach vector addition. This study had two different conditions: *concreteness fading* (CF) and *concreteness introduction* (CI). Each condition included three learning stages (see Table 1) and an extra stage (*Constructionist Problem Design*, Stage 4: CPD) to allow the participants to demonstrate their learning from the intervention (CF task order-EP, ID, AR, CPD; CI task order - AR, ID, EP, and CPD). Four two-hour study sessions were conducted from February to March 2022, which were videotaped and later transcribed. By examining the transcripts, the research team developed a math vocabulary dictionary with scores for each word. A math vocabulary score can reflect their use of language related to the topic of vector addition. We used the python package Pandas and Seaborn to analyze and visualize results.

Table 1
Learning Activities

Stage	Activity	Duration
Enactive Physicality (EP)	The participants played football passing on a tiled floor, using informal vector addition skills.	20 mins
Iconic Depiction (ID)	The participants played a short football passing simulation game.	20 mins
Abstract Representation (AR)	The participants worked on a worksheet on vector addition problems that uses formal math notation and symbols.	20 mins

Results and findings

Figure 1 shows a consistent arc of the participants' math vocabulary scores in the CF condition. In stages 1 (EP) and 2 (ID), their math vocabulary scores are relatively low; there is a spike in stage 3 (AR); then, in stage 4 (CPD), all their math vocabulary scores are greater than their scores in stage 1 and 2. Figure 2 (CI Condition) does not present as clear an arc.

Figure 1
Math Vocabulary Total Score (Σ) by Stage (Concreteness Fading, n=6, CF group)

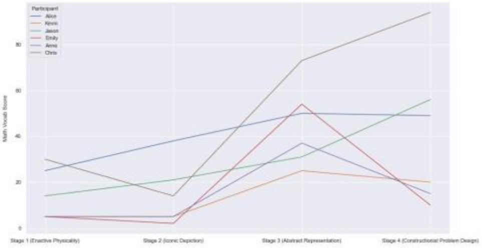

Figure 2
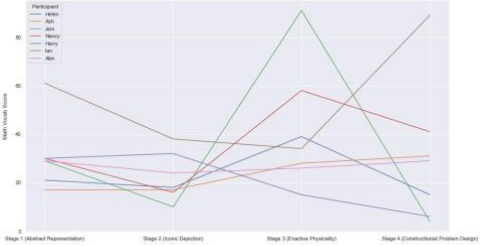
Math Vocabulary Total Score (Σ) by Stage (Concreteness Introduction, n=7, CI group)



The spike that the CF participants have in stage 3 (AR) suggests a change in the use of math vocabulary throughout the intervention. The CF participants seemed more comfortable with the use of math vocabulary in a similar but more abstract context. In contrast, the participants' math vocabulary use in the CI condition showed no clear trend. Those CF participants utilized their previous experience and informal vector addition knowledge to solve problems in stage 1(EP) and tested their knowledge and problem-solving strategies again in stage 2 (ID), during which they further developed their math vocabulary related to vector addition. Another finding is all the CF participants' math vocabulary scores in stage 4 (CPD) are higher than those in the first two stages. In stage 1 (EP), the participants needed to use their own language to figure out an approach to describe their positions on the tiles and the ball flying path, which activated the participants' previous math language to solve a new problem. Stage 2 (ID) provided a similar problem and some math symbols, in which the participants could connect their problem-solving experience in the previous stage with the possible encountered math vocabulary. Tackling similar questions with a progressive increase in math vocabulary may enable the participants to develop their own math vocabulary during the intervention.

As for the contribution of this paper, we provide a new lens to inspect learning in a CF intervention: by examining their mathematical vocabulary, we can quickly estimate their mathematical language change over the course of intervention. Thus, we believe mathematics educators should pay more attention to students' progressive development of mathematical vocabulary and language in class. However, this study also has limitations: this study's small sample size may harm the generalizability of the results. Also, this analysis cannot uncover whether their use of math vocabulary represents their understanding of vector addition. Though we see value in understanding their use of math vocabulary, exploring their understanding of vector addition requires a more nuanced investigation on their conversations.

A Quest for Information—And Data Literacy: Can 6th Graders Make Informed Decisions?

Betty Tärning, Eva-Maria Ternblad, Magnus Haake, Agneta Gulz
betty.tarning@lucs.lu.se, eva-maria.ternblad@lucs.lu.se, magnus.haake@lucs.lu.se, agneta.gulz@lucs.lu.se
Department of Cognitive Science, Lund University

Abstract: Information- and data literacy, the ability to critically examine and evaluate information and arguments in relation to empirical evidence, is increasingly crucial in a world overflowing with data and information from a multitude of sources. Information- and data literacy in younger students being understudied, we investigate these skills in Swedish 6th graders to learn more about the educational challenges. Next, these findings will inform the development of a digital game for data literacy.

Background

Today digital information is easily produced and accessed without being properly reviewed. Thus, misinformation easily spreads and turns into ‘truth’. Many youths are caught up in a tangled mess of facts and opinions and hence need updated skills in how to orient this information (Mihailidis, 2018). The term information- and data literacy (IDL) includes being able to critically examine and evaluate information and arguments in relation to empirical evidence. In turn, the following kinds of abilities are involved: understanding tables, graphs, and diagrams and being able to translate such visual formats into verbal formats, and vice versa; understanding basic statistics and how data can be used to create a narrative; being able to distinguish when data is correctly and fairly used as opposed to when it is not (Vahey et al., 2012). This is also highlighted as one the most prominent challenges of our time and research shows that only about half of the world´s 15- to 16-year-olds understand the difference between facts and opinions (Agence Science-Presse, 2019).

Citizens who can make well-informed decisions for themselves regarding what they read or hear is, furthermore, essential to sustain the fundamental structures of a democratic society. In this, schooling and education have fundamental roles to play, equipping young people with knowledge and skills so that they, as they grow up, can meet their surroundings in a capable way (Biesta, 2017). In this, IDL provides a ticket for participating in society and making well-informed decisions, lowering the risk of being misled or deceived, as well as of one-self creating misunderstandings or spreading misinformation. However, previous research has shown that children as well as young adults struggle when it comes to these issues (Ku et al., 2019). IDL should hence be highlighted in school curricula. Yet, the topic is complex and relates to many subjects and tasks within the natural sciences as well as the social sciences. To be able to work with IDL in a tangible and preventive way we need to know, as a first step, what skills students of different ages actually have. What do they know? What is more and less challenging? Learning more about this is necessary to inform interventions to support both early and later developmental stages of IDL. This study aims at contributing to our knowledge on IDL skills among 6th grade students.

Method and procedure

We enrolled 104 students (54 boys and 50 girls) from three schools and five different classes to fill out a questionnaire, validated by five middle school teachers. The questions (11 in total) were categorized into four subcategories, suggested and agreed upon by the authors. Three questions addressed the subcategory of *representations* targeting the ability to interpret diagrams, such as matching tables with diagrams. Two questions addressed *proportionality* where the students were asked to for example, compare a news headline with a diagram.

Four questions targeted students’ knowledge about *scientific method* and asked questions about when science can be trusted. Finally, two questions asked whether a set of statements in combination with a picture or a diagram represented *facts vs opinions*. The questions were presented in random order and all questions but the two on facts vs opinions were multiple choice questions. When more than one answer could be correct, this was spelled out in the question. The questionnaire took about 15 minutes to complete.

Results and discussion

For the nine multiple choice questions, the number of response alternatives ranged between two to four. To receive a full score all alternatives had to be filled in correctly, that is if two alternatives out of four were correct these two had to be filled in and the two incorrect alternatives were not to be filled in. Questions that were left blank by the student were calculated as incorrect responses. Results were calculated both per question (see Table 1) and averaged over categories (see Figure 1).

Table 1

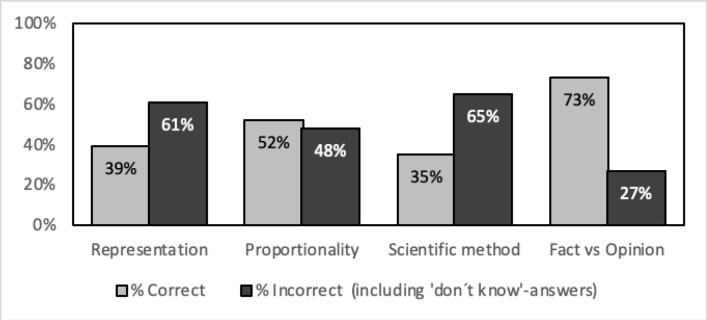
Table showing the number of subjects answering correct or incorrect per question.

	Representation					Proportionality				Scientific method						Fact vs Opinion			
	Q1	**Q6**	**Q7**	**Tot.**	**(%)**	**Q2**	**Q10**	**Tot.**	**(%)**	**Q5**	**Q8a**	**Q8b**	**Q9**	**Tot.**	**(%)**	**Q3**	**Q4**	**Tot.**	**(%)**
Correct answers	41	22	60	123	39%	54	54	108	52%	50	56	30	10	146	35%	70	82	152	73%
Incorrect answers	63	82	44	189	61%	50	50	100	48%	54	48	76	94	272	65%	34	22	56	27%

* 'No of subjects incorrect' includes 'don´t know'-answers

Figure 1

Histogram showing the distribution of precent correct and incorrect answers per category.



These results indicate that questions regarding representations and scientific methods are the hardest for this age group; not even 50% of the 6th graders knew the answers here. The questions on representations require abilities to correctly read and interpret diagrams and detecting misleading formats, such as a truncated diagram – important skills in order not to make misinformed judgements or decisions. The questions on scientific methods tap an understanding of what science is and is not. One questionnaire item addressed ‘false balance’ presenting a scenario with a TV debate featuring two scientists discussing on the same premises and as equals; one communicating what an overwhelming majority of all scientists in the area agree on – the other communicating the opposite.

The questions about proportionality and facts vs opinions seemed less challenging for the students (52% answered the proportionality questions and 73% answered fact vs opinion correctly). Possibly they are more familiar with these types of questions, for example evaluating a graph in relation to its heading. The two questions concerning proportionality, however, had only three alternatives to choose from (while most others had four) with only one alternative being correct, which may have made these questions easier for the students. The fact that facts vs opinions, were by far the easiest for the students to answer might not come as a surprise since these types of questions are commonly discussed in Swedish classrooms under the umbrella of source criticism.

A next step is to look at the questions in more detail and anlyze how and when different categories start to become more difficult. On a more general level, there is evidently room for improvement when it comes to different aspects of IDL and this results contributes to the understanding of youths’ information- and data literacy skills and where we have to put in extra effort. Starting 2023, we intend to develop a digital pedagogical game where students can learn and practice IDL. Before then, we need to investigate how students are best scaffolded.

Sorting Out the Bad but Bringing in Filter Bubbles

Betty Tärning, Eva-Maria Ternblad, Agneta Gulz, Magnus Haake

Abstract: Being information literate, i.e. being able to critically evaluate information and arguments in relation to empirical evidence, is extremely important. Our study combines learning science and drama to explore if 6th grade students can grasp certain aspects of information literacy, such as fake news and filter bubbles. By analyzing free-text responses we concluded that the students are aware of the problems with fake news but have a very vague and naïve view of filter bubbles.

Background

Living in a time often referred to as the information era, it is of utmost importance to educate our youths in how to critically examine and evaluate information and arguments in relation to empirical evidence, something that is often referred to as being information literate. The Association of College & Research Libraries (ACRL) summarizes this skill as having the ability to locate, evaluate and effectively use information needed. The fact that youths today are bombarded with information in all sorts of platforms and media does not automatically make them informed citizens, rather they need to learn how to use information effectively and we need to teach them about the dangers of trusting "fake news" as well as not trusting trusthworthy information.

Previous research has shown that children, as well as grown-ups, struggle when it comes to information literacy. For example, Breakstone et al., (2019) showed that high-school students have a hard time telling

the difference between news stories and advertisements, and that only 4% of them reflected upon why ties between a climate change website and the fossil fuel industry might decrease the websites credibility. Further on, Nygren and Guath (2019) showed that 88% of their participants had difficulties with distinguishing news from ads in digital newspapers. These results togheter with the fact that students often tend to overestimate their information literacy skills (Gross & Latham, 2012), the need to educate our youths in this topic can not be highlighted enough. Being information literate also includes the ability to be open to other views and opinions and being able to reconsider one´s own belief, something that has proven to be difficult (Flynn et al., 2017). The risk of not being open to other thoughts and discussions are that you might end up in a so called "digital echo chamer" where one only confirms one's already established thoughts and ideas and hence does not challenge possible misinformation.

This study is part of a larger project, aiming to map out 6th grade students' understanding and skills in information literacy , exploring if and how these skills best can be taught. In this study we combined learning science and performing arts and storytelling to inform the students about the subject. According to Willingham (ref, årtal) the art of storytelling in classrooms works because we seem to understand and remember stories better than pure lectures.

Method and procedure

In this study we worked together with a local theatre group that wrote a play (in collaboration with a researcher) on different aspects of information literacy. The same group also performed this play on site in classrooms. The performance was accompanied by a pedagogical follow up with discussions and interactions between actors and students. The researchers also met with the students who answered a free-text questionnaire with four questions (about fact resistence, false balance, burden of proof, and fake news/filter bubbles). 145 students (73 boys and 72 girls) from 3 schools in southern Sweden were enrolled in the study. In the experimental group (4 classes) the students saw the play before answering the free-text questions (in this study we only analyze the question about fake news/filter bubbles) while students belonging to the control group (3 classes) saw the play after answering the same questions.

Results and discussion

The students could choose to respond to two questions of their own liking. The most popular question to address was the one about fake news/filter bubbles, which was formulated as follows: "*Why could it be problematic that an app like for example TikTok choses what type of feeds you are shown?*". In sum, the majority of students (74% in the experimental group and 79% in the control group) responded to this question. Many students (33% in the control group and 48% in the experimental group) wrote about the potentional problems with falsely spreading fake news and commercials. *"TikTok can make us see bad things about a country that are not true, and then they may spread it further, and then you have spread a rumor that is not true, and TikTok can also show videos prohibited for children."* (Student, control group). *"Then we don't see what is real but we see what TikTok wants us to see and believ that this is true even if it isn't"* (Student, Experimental group).

However, very few (9% in both groups) discussed these issues further by bringing up the problem with getting filtered information that may narrow your view and understanding of different topics. "*If the app only selects what you like, you may not really get to take part in other news [...] You might not learn much if you only watch videos in the same genre all the time. The information you receive can also be false"* (Student, control group) *"Yes it can be problematic because if you like a video and only are fed such videos, then you wont learn about other things happening"* (Student, experimental group).

Many students (29% in the control group but only 13% in the experimental group) mentioned the risk of being exposed to "risky or bad" material. *"There could be bad things there, some accounts are creepy and dangerous. You can't trust everyone in that app"*. (Student, control group) *"You can be shown unsuitable things because it is an algorithm and it doesn't know what is good or bad"* (Student, experimental group)

Some of the students (17% in the control group and 13% in the experimental group) mentioned the fact that is is a good thing how filtering things can provent them from seeing scary or bad things. *"TikTok selects material according to our liked videos, for example if I like a video with a cute cat, then it appears on a so-called "for you"-page where things you have liked pop up in other videos such as other cute cat videos"* (Student, control group). *"I see no problem because they chose to show us what we like"* (Student, Experimental group)

The topic of fake news and risks with social media is something quite heavily discussed in Swedish schools. This together with the fact that most Swedish youths use TikTok themselves possibly makes them comfortable and confident to discuss this topic. Many students seem aware of the problem with fake news on social media, wich relates to source criticism, something that is part of the Swedish curricula. Even though this is reassuring, their knowledge and discussions about the actual filtering problem are quite shallow and naive. Some students discuss how the filtering may protect them from seeing inappropriate material but they don't see the problem with only receiving a narrow field of "nice" and "good" feeds in their flow (as for example seeing cute cats). The issue with only receiving information that aligns with your previous preferences and opinions is very rarely mentioned.

One might suspect that their replies stem from discussions in school, warnings from parents or other adults and their own habits of use. However, they seem to lack a wider outside perspective, understanding that algorithms in social media may create filter bubbles and how this could narrow their field of view. This could be due to lack of education, but also to our participants' young age. Filter bubbles is also a complex topic in general and many adults don't see the problem with the issue. This makes teaching about information literacy even more important and we cannot expect people to learn about this themselves.

It is also hard to know if students actually apply their knowledge about fake news/filter bubbles when interacting with an app like TikTok. For instance, do they reflect upon whether or not a post in their feed is actually true or not, and do they search for alternative perspectives to possibley contradict what they already believe? This would be interesting to investigate further as well as how keen they are to share information or posts that they suspect to be fake.

Student Staff as Co-Designers in Higher Education

Muelder, Hannah, University of Oslo, hannah.mulder@iped.uio.no
Bergstrom, Nora, University of Oslo, nora.bergstrom@student.jus.uio.no

Abstract: Student-centered learning initiatives in Higher Education rely on the participation of student staff to co-design and facilitate learning. Using an ethnographically inspired approach we investigate their involvement in the empirical setting of colloquium leaders facilitating sessions for first year law students at a Norwegian university. We identify challenges around tensions between individual's agency in designing and renewing teaching-learning and their structural environment. This provides practitioners with additional tools to understand, evaluate, and adapt their practice.

Introduction

Educational initiatives that have the goal of letting students learn from each other and develop more general academic competences are increasing. These initiatives rely on the participation of student staff (i.e. advanced Bachelor and Master students employed by the university) to facilitate student learning and co-creating and co-designing teaching-learning (Healey et al., 2016). Little research is done on how student staff contribute to the pedagogical initiatives at their educational units. We draw on Bovill et al. (2016) who discuss challenges emerging in co-creation and co-design processes, among them the navigation of institutional structures, practices and norms. Often co-creation initiatives start in individual classrooms, redefining norms and practices there. Expanding innovation across institutions requires the establishment of new practices, structures and norms on a higher level.

We put special focus on the student staff´s perceived structural embedding and individual agency using a sociocultural and practice-based approach (Wertsch, 1998). Agency we define as the "temporally constructed engagement by actors of different structural environments – the temporal-relational contexts of action" (Emirbayer & Mische, 1998). The structural environment is assumed to be dynamic and sustained by and changed through human agency. Emirbayer and Mische (1998) differentiate between iterational agency, thus routinely patterns, practical-evaluative agency in emergent situations and a projective element of agency, reconfiguring current structures. Rooted in this theoretical framing, we explore the dynamic between individual and structure in student staff practicing development work. Starting point are individual's perceptions of these structures and their experience of agency within them.

In this study we investigate student staff working as colloquium leaders (CL) for first year law students at a Norwegian university. CL are 3rd to 5th year law students facilitating colloquia. They apply to be CL and are employed by the university based on grades, motivation letter and an interview. Purpose of the colloquia is for the first years to support each other in solving cases and writing texts, to learn to collaborate and learn from collaboration. Within this theoretical embedding and empirical context, we ask: *What agency do CL perceive to have in co-designing colloquia for first year law student?*

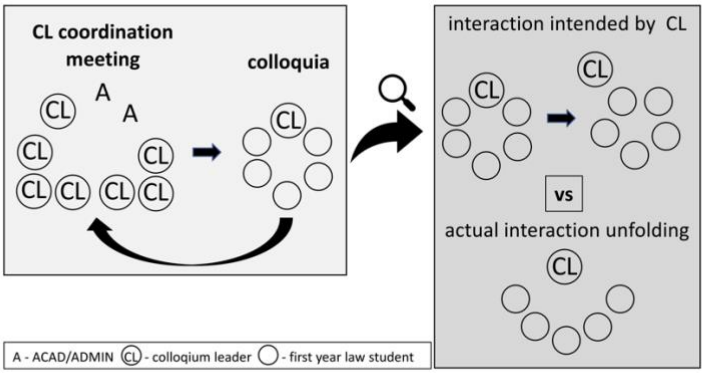
Methods

Using an ethnographically inspired approach our research comprises field observations of a colloquium and CL coordination meetings, a survey among 13 CL with 4 reflective questions addressing their colloquium work and role understanding, and follow-up interviews with 8 CL. The interview guide was developed based on a thematic analysis of the CL's survey replies. The interviews addressed CL's own expectations and experience with colloquia, their work during and surrounding colloquia and their development within it, the role of collaboration, safe spaces and student ownership within colloquium work and their role, responsibilities and embedding within the wider institution.

Preliminary findings

Figure 1 visualizes our preliminary findings. To the left is the timeline of activities for CL: CL participate, co-create and co-design in CL coordination meetings organized by student, administrative (ADMIN) and academic (ACAD) staff. It comprises of input from the organizers – ACAD, ADMIN and student staff and reflective discussions among CL. Then CL proceed with around six of their own 2-hour colloquia, of which they have full responsibility. Within and surrounding the colloquia, CL interact indirectly with ADMIN and ACAD through the provided structures. Further, CL also co-create and co-design with the participating first years in the colloquia and engage in individual design work surrounding these. This pattern is iterated once with a mid-semester CL coordination meeting. Within the two settings CLs' agency differs, also based on their role.

Figure 1
Activities colloquium leaders participate in and interaction patterns they experience.



CL1: "The educational offers by the faculty are mainly lectures and courses, of which the former is *completely passive* and the latter often does *not require active participation from all students*. [...] It is largely based on my experience that students *expect the CL to provide answer* and do not take into account their fellow students in the process. [...] Even if I do *not provide direct answers* or try to initiate a dialogue these often *stay CL focused* [...]."

The excerpt to the right, a survey response by one of the CL describes a recurringly reported pattern within colloquia, visualized in the center of Figure 1: CL intend an interaction pattern, in which they act as facilitators when and where necessary, and move to the background over time, aiming for participating first years to talk to each other. This is also suggested by the organizers in the CL coordination meeting. Instead, what CL report happens is that students mainly communicate with them, expecting input and answers, instead of with each other. This pattern resembles other teaching at the faculty as reported by the CL. Taking the structure-agency perspective, we note that organizers and CL aim to innovate, changing prevailing structures in students taking ownership of their learning and collaborating, by exerting their projective agency. However they are hindered by established institutional cultures of passive learning playing out in students using their iterational agency, an instance of the challenge described by Bovill et al. (2016). Institutionalized norms and practices already play a role here within individual innovative settings, not only when expanding beyond. And the responsibility of redefining these norms in this instance appears to lie with the CL. As the last sentence of CL1's excerpt shows, CL try to use their practical-evaluative agency to address the issue but perceive it difficult to solve.

Implications and questions for discussion

Empirically, we catch a first glimpse of the complexity of the co-design of teaching-learning that CL engage in and its challenges. Conceptually, these preliminary results provide starting points to investigate the interplay between structures and individual agency within changes to one's practice, the structural environment or one's professional development. Practitioners, student staff and those organizing their work can gain a deeper understanding of the tensions and challenges arising and the support student staff members need.

Based on this current state of our study we would like to open the following questions for discussion:

1. Where does co-design begin and end in terms of structural arrangements, who is meeting whom?
2. What differences in co-design work can be identified before and during colloquia and CL coordination meetings?

Weaving in and out of School Experiences to Craft STEM Identities

Carrie D. Allen, University of North Texas, Carrie.Allen@unt.edu
Joanna Weidler-Lewis, KU – Center for Public Partnership and Research, jweidlerlewis@ku.edu

Abstract: Out-of-school time (OST) experiences suggest promise for providing historically marginalized youth with expanded notions of and avenues for becoming in STEM. Yet, OST are often isolated from school experiences and require youth to weave together disparate notions of STEM and positioning with respect to STEM. In this paper, we examine this process for young women of color in STEM as they leveraged identity resources across OST, family, and school during high school and into college.

Purpose

The work described in this paper was motivated by a concern with the persistent underrepresentation of large populations of youth (namely, females and youth of color) in fields of STEM and by the growing body of research that demonstrates the ways K-12 learning environments overwhelmingly reconstitute constrained notions of what it means to participate in and be "good at" STEM. For instance, being "scientific" is often reduced to achieving established answers in uniform ways (Calabrese Barton et al., 2012). Youth, for example, who can work to get the answer quickly and work independently, are more likely to be seen as "scientific" in school (Carlone et al, 2011). Such practices offer limited avenues for expressing and being recognized as a STEM-oriented person, while further marginalizing youth already underrepresented in STEM fields. Out-of-school time (OST) experiences suggest promise for providing youth with expanded notions of and avenues for becoming in STEM (Bell et al., 2009). Yet, these experiences are often isolated from or in conflict with STEM school experiences; and, as such, they require that youth *weave* together STEM identities across these spaces. In this paper, we analyze this weaving by examining the ways in which young women, underrepresented in STEM, leveraged available identity resources across these spaces to craft a STEM identity during high school and into college. Specifically, we asked: *(1) What identity resources are available to youth within and across the social spaces of their lives? (2) How are these resources woven by youth to author STEM identities?*

Conceptual Framework

We draw on Holland and colleagues' scholarship (Holland, et al., 1998), that emphasizes how identity is developed, performed, and contested in local practice and on critical feminist scholarship (Crenshaw, 1989) to consider how identity contestations intersect with broader patriarchal, racialized, and historicized structures. Using Holland et al.'s (1998) development of *figured worlds*, we view STEM as a "socially and culturally constructed realm of interpretation" (p. 52) that has particular actors, actions, and outcomes that are valued over others and has a collective understanding of appropriate actions. How youth talk about STEM, who is good at STEM and why, provides an indicator of their figured worlds of STEM. Further, as youth "author" STEM-oriented selves, they draw on figured worlds to do so (e.g., emphasizing involvement in research or "getting" math). When examining youth's identities in the context of their high school lives, we considered how participation was structured across STEM experiences, access to different forms of participation, and implications such practices had for youth's figured worlds of STEM and the kinds of identity work they engaged in (Holland & Lave, 2001).

Method

This paper draws on student interview, student survey, and parent interview data from a 5-year ethnography that focused on the identity work and college and career trajectories of youth from populations underrepresented in STEM (Allen & Eisenhart, 2017). The ways in which 9 young women authored STEM identities during high school and into college was analyzed using case study methodologies (Yin, 2013). All youth were from the same large city in the West; they were selected for the larger study because of their expressed interest in STEM (as identified by their school counselors) and successful academic record). Focal youth were selected through two primary criteria: (1) they maintained an interest in a STEM career throughout high school and (2) they expressed involvement in some form of out-of-school or extra-curricular that was STEM related. For this second category, "STEM related experiences" was defined broadly to include experiences such as a "career fair" to more involved, longer-term experiences, such as an engineering camp.

Youth were interviewed twice each year from 10th to 12th grade (fall and spring) and then surveyed once each year (in the fall) into their first two years post-secondary. Interviews focused on students' views of STEM, interests, planned majors, and experiences in STEM-related courses. Parent interviews focused on hopes and goals for their child, and their experiences with college and STEM. All interviews were recorded and transcribed. In the initial analysis, interviews were first coded for STEM learning experiences, views of STEM, views of self with regard to STEM, and OST STEM experiences. Next, data displays were created for each youth of (1) salient STEM experiences, organized by year; (2) their conceptions of STEM, their involvement in STEM, and their self-identifications as a "STEM person." For this new analysis, we deductively coded for moments of weaving and the interconnections between how youth participation in STEM activities and their forms of self-authoring.

Findings

OST STEM experiences played a critical role in disrupting dominant notions of STEM and providing identity resources for connecting with STEM disciplines. Furthermore, they supported young women in weaving together multiple identities. Naomi (African-American and culturally Jewish), for example, shared how she discovered engineering as a path that she "could do for the rest of her life" after participating in an engineering camp: "At first, I didn't want to go. I heard the camp was [for nerds]…I mean, I thought an engineer was some white guy with glasses and pants pulled up high." However, once Naomi met friends "like her," participated in robotic challenges, and experienced the "hands on" and social aspects of engineering, she came to see how her "social," "athlete" self and engineering could be interwoven.

Similarly, Shawna's (Vietnamese-American) OST experiences were particularly influential in her continuing to pursue a career in medicine. While she had always had an interest in science and the human body, she found courses she took through her high school and a local university's Pre-Collegiate program to be too devoid of "human interaction," and had come to the conclusion that most science careers would put her "in a lab all day." Shawna, however, valued "helping people" and connecting with others. Once she participated in a summer program that took her abroad to provide medical care to those lacking access to it, she came to see how her interests in science and her passion for helping others could be brought together. OST experiences became the social and material threads that these young women were able to leverage to reject and counter the times they were positioned unfavorably with respect to STEM in the social and discourse contexts of their schools.

Discussion and Conclusion

Our findings give further credence to the role that students' OST experiences have for expanding notions of STEM, self, and possible futures. They also speak to the ways that young women can weave together identities across the social spaces of their lives that are coherent with their multiple selves such as being caring, altruistic, social, and also scientific. The extent to which in school experiences can replicate or complement the identity resources available to youth remains to be seen, but at a minimum these findings motivate additional work regarding the designs of coherent ecosystems (Dierking et al., 2021) that support youth learning and participation in STEM that extend beyond the classroom.

Abstract: Stealth assessment is embedded within technology-rich environments, like games, to measure and support learning. In this paper, we discuss how stealth assessment is being used and where it may be headed. We identified 93 relevant studies consisting of 41 journal articles, 27 conference papers, 14 book chapters, 10 dissertations, and 1 book. These studies included participants ranging from third grade students to adults. We briefly discuss our findings in this paper.

Introduction

Stealth assessment (Shute, 2011) uses methods and technologies to collect and analyze learners' interaction data and make real-time inferences of learning based on the data. Digital learning environments employing stealth assessment can help researchers to accurately assess learners' competencies and adapt the learning environment to fit learners' needs (Shute & Rahimi, 2017). Such adaptivity is closely linked to learning, engagement, and motivation theories (e.g., Csikszentmihalyi, 1990; Deci & Ryan, 2012; Vygotsky, 1978). The backbone of stealth assessment is evidence-centered design (ECD; Mislevy et al., 2003) which provides the requisite models for the system. There are four core models: the Competency Model (CM) defines the set of knowledge and skills of interest, along with their sub-facets (unobservables) and their relationships to each other. When defining the competency model, researchers respond to the question of *what* to assess; the Evidence Model (EM) identifies appropriate indicators (observables) in the game that provide evidence for the CM variables via statistical linkages (i.e., the statistical model). When defining the EM, researchers answer the question of *how* to assess; and the Task Model (TM) involves the creation of various task types that can elicit the evidence needed for the evidence model. After more than a decade of research using this method to assess and support various competencies, across different learners and in various settings, in this in-progress study, reviewed how stealth assessment is being used and where it may be headed. We address the following research questions: (1) What are the publication trends and contexts of research that use stealth assessment? (2) What is the purpose of the stealth assessment research? (3) What types of validity are more common in stealth assessment studies?

Method

To address the research questions, we conducted a systematic review using the updated PRISMA (Page et al., 2021) method. To provide comprehensive coverage of the literature, two search phases were conducted: database and reference search. In the database search, the following search string was created: "stealth assessment" OR "game-based assessment" OR "embedded assessment" OR "evidence-based assessment" OR "computer-based assessment for learning" OR "evidence-centered design" AND ("game" OR "online-learning" OR virtual reality") OR "stealth assessment" AND ("game" OR "online-learning" OR virtual reality"). We searched through the following databases: Web of Science, Scopus, Emerald, Google Scholar, Taylor & Francis, EBSCOhost, IEEE, Elsevier, Springer, and Wiley Online Library. The inclusion criteria were as follows: 1) the studies should be published between 2004-2022; 2) the language of the publication should be in English; 3) stealth assessment should be the focus of the study; 4) the studies should target learning outcomes. Following the PRISMA guidelines, we included 32 studies for review. Finally, through hand searching within various papers' references and conducting additional targeted search (e.g., identifying studies from scholars who we knew were employing stealth assessment methods), we included an additional 61 studies for review, reaching our total number of studies to 93. To extract the data, we created a spreadsheet to collect and summarize focal features per study. At this stage, we entered the information of each included paper in separate columns. In this study, both qualitative and quantitative analyses were used. First, the basic features of our dataset provided a descriptive analysis of the papers. Second, a content analysis method was conducted to obtain an in-depth understanding of each included study to examine our research questions. Two researchers independently extracted the data from each study and met to resolve their disagreements in an iterative process.

Results

Addressing RQ1 (i.e., the publication trends of stealth assessment), we identified 93 studies (41 journal articles; 27 conference papers; 14 book chapters; 10 dissertations; 1 book). These studies included participants ranging from third grade students to adults. The competencies that were assessed in those studies (see a sample of studies in Table 1) included: (a) hard-to-measure competencies such as creativity (e.g., Shute & Rahimi, 2020), persistence, problem solving, computational thinking, risk taking, safety and emergency readiness; and (b) content knowledge and skill acquisition, such as mathematics, physics (e.g., Shute et al., 2020), genetics, geometry, reading and writing, and ratio and proportional reasoning. The studies included in this review came from various fields of study including computer science, educational technology, learning sciences, bioengineering, and applied mathematics. Moreover, 81 studies used or designed a game, while 11 studies used a simulation or an immersive learning environment to assess their competency of interest. Regarding RQ2 (i.e., the purpose of stealth assessments in each study), so far, we were able to categorize 60 studies into three categories: (a) validational studies (*n* = 42); (b) studies that used the stealth assessment estimates for purposes of providing adaptivity or feedback to students (*n* = 4); and studies that only discussed the design phase of a stealth assessment (*n* = 14). This result suggests that most of the current stealth assessment studies are validational. Finally, regarding RQ3 (i.e., the type of validity approaches in stealth assessment studies), from the 60 studies that we coded, most of the studies (*n* = 24) used a *convergent* validity approach (i.e., correlational analysis between the stealth assessment estimates and the external measures); 18 studies used other types of validation methods (i.e., predicting the posttest and classifying accuracy). The remaining studies did not specify any validational measures.

Discussion & conclusion

In this systematic review, we included 93 studies that have used stealth assessment to assess a competency within a digital environment, typically a game. Our findings indicate that studies that have used a stealth assessment methodology focused on a diverse set of competencies, included a range of target audiences, and came from multiple fields of studies. This finding shows that this methodology has been adopted and adapted by researchers in multiple contexts to assess and, in some cases, support learning. Although some studies included uses of the stealth assessment estimates in real time (e.g., for adaptation or providing personalized feedback to the learners), most of the studies are still at the validation stage where they describe the design of a stealth assessment for a particular competency using a validational approach (e.g., convergent validity) to indicate the accuracy of their assessment. After more than a decade of work in this area, it seems that stealth assessment can move to a new phase which is using the stealth assessment estimates to enhance learning (e.g., by adaptivity or personal feedback and support). Finally, our results indicate that most of the studies used a game as the vehicle in which to embed their stealth assessment. However, eleven studies used other learning environments. Despite the common understanding about stealth assessment, it is not only bound to games. We hope to see more studies that use this methodology in advanced, technology-rich learning environments in the future.

Stressors in Online Exams - Same Same but Different?

Anna-Lena Roos, Loris T. Jeitziner, Carmen Zahn
annalena.roos@fhnw.ch, loris.jeitziner@fhnw.ch, carmen.zahn@fhnw.ch
University of Applied Sciences Northwestern Switzerland

Abstract: In order to design optimal online exam environments that are conducive to learning and not too stressful for students, knowledge about potential stressors in these situations is important. In the present study, we investigated a newly developed instrument to assess stressors in online exams regarding its factor structure and its association with digital skills and performance. Analyses revealed an eight-factor structure, with the factor system failures being the most stressful for the students.

Introduction and related work

Exams are perceived as stressful by many students (Bradley et al., 2010), and stress can negatively impact one's performance (Hafeez et al., 2018). Online environments for learning and test-taking from home are becoming increasingly popular and can also impose technological, social, and emotional challenges for students (Loderer et al., 2020). Online exam environments are, obviously, different from traditional on-site exam environments at school or on campus, but to date only little is known about students' subjective experiences in online exam environments and about the stressors they might face in these new settings (Harley et al., 2021). Besides technical problems, social and emotional aspects of writing an online exam from home could also play a contributing role in the perception of stress (Schult & McIntosh, 2004). Other factors that might be stressful for the students include exam proctoring, prominent time indications on the computer screen, or external disturbances (e.g., noise from children playing outside). These differences and challenges can affect students' subjective experience of online exams and thus their perceived stress - and in the long run also their performance. Hence, knowledge about potential stressors is important for the design of optimal exam environments. In this study, we therefore investigated the factor structure of a newly developed instrument to capture these stressors arising in online exam environments.

Method

The present study took place in spring of 2022 and was part of a large multicentred project on the topic of e-assessment. The sample of the present study consisted of N = 367 students from different study programs (299 females, 56 males, 10 not specified, 2 various; M_{age} = 25.88, SD_{age} = 5.43) from the University of Applied Sciences and Art Northwestern Switzerland FHNW and the Bern University of Applied Sciences BFH. After concluding their individual online exams at the end of the spring semester in 2022, participants were asked via email to participate in an online survey that included multiple scales addressing their subjective experiences in online exams (e.g., stressors, emotions, appropriateness of exam format). Along with these scales, demographic data (i.e. age, gender) were collected. The stressors questionnaire was first developed in a previous study (Jeitziner et al., 2022), and it included scales for the context of online exams based on stressors that might occur in these settings. The participants reported on their level of stress (i.e., "*For each of the following statements, please indicate how stressful the situation is for you during an online exam.")* on a scale ranging from 1 – "not stressful at all" to 5 – "extremely stressful". In an exploratory factor analysis, a five-factor structure was found (i.e. System Failures, Social Pressure, Self-inflicted Noises, Time Indications and External Disturbances). For the present study, the 26 items scale was further developed, and additional items were included. The final questionnaire consisted of 31 items. Based on these new items, we expected an eight-factor structure consisting additionally of the factors Physiological Reactions, Proctoring and Difficulty. To test this hypothesized factor structure, we conducted a confirmatory factor analysis in R.

Results

The confirmatory factor analysis was calculated based on the described sample (N = 367). All of the items indicated no multivariate normality ($p < .001$). Moreover, since the Likert-like format of the questionnaire implied ordinal scaling of the data, we chose weighted least squares estimation instead of maximum likelihood. The hypothesized model indicated a good fit (TLI = .99; CFI = .99; RMSEA = .015). Therefore, we did not modify the model or conduct post-hoc analyses. In a next step, we descriptively investigated participants' perceived level of stress separate for each of the identified factors. *System failures* (e.g., "The internet shuts down") were the largest source of stress ($M = 4.33$, $SD = 0.77$), followed by the factor *difficulty* ($M = 3.90$, $SD = 0.80$) of the exam (e.g., "The exam is too difficult") and the factor *social pressure* ($M = 3.00$, $SD = 0.86$) (e.g., "The feeling of being behind compared to other students"). The factors *external disturbances* ($M = 2.35$, $SD = 0.92$; e.g., "Sounds of footsteps in the room"), *time indication* ($M = 2.31$, $SD = 0.84$; e.g., "A visible countdown clock on the screen"), *experience of physiological reactions* ($M = 2.24$, $SD = 0.92$; e.g., "feeling one's own heartbeat") and *experience of proctoring measures* ($M = 2.12$, $SD = 0.83$; e.g., "Feeling observed to avoid cheating") indicated medium levels of stress. The factor *self-inflicted noises* ($M = 1.39$, $SD = 0.60$; e.g., "Noise of own keyboard while typing") indicated low levels of stress.

Discussion

The goal of this study was to investigate potential stressors in online exams using confirmatory factor analysis and to provide insights on how stressful each of these stressors is perceived by students. We found that our hypothesized factor structure fitted the data, and we were able to break down the construct of stress in online exams written from home into eight different factors. In comparing the factors, we found that for our student sample, possible system failures and difficulty of the online exams were associated with the highest levels of stress. This implies that a lot of students fear that the infrastructure, soft- or hardware may cause problems, which concords with previous research on students' subjective experiences in digital educational environments (Bogdandy et al., 2020). Similar to on-site exams, difficulty seems to be a major stressor also in online exams. Unexpectedly, although proctoring has become increasingly important and much discussed recently - especially in the context of higher education due to the introduction of online exams from home during Covid-19 - it was not perceived as very stressful by the students. It should be noted, however, that although this factor was not perceived as a major stressor, it may indirectly cause stress through potential system failures (e.g., when using virtual machines or webcam monitoring as proctoring measures), which is why it is worth considering it in future studies.

This study, evidently, has certain limitations, which provide directions for future work. First, we examined potential stressors in online exams in a predominantly female sample, which implies that our results should be taken with caution and that future studies should consider a more heterogeneous sample. Second, we asked students to self-report their perceived levels of stress in their online exams. For a more complete measurement of exam related stress, future research should not rely only on self-reports, but should also consider other measures such as physiological measurement (e.g., electrodermal activity or heart rate variability; Roos et al., 2022).

In sum, the present study identified that some stressors in online exams are similar to those of on-site exams, but as described, there are also differences. These identified aspects could be helpful for the development and design of future online exam environments.

Global MOOC Learners' COVID Narratives: Pandemic, Purpose, and Core Questions of the Human Experience

Nathaniel W. Cradit, University of Michigan, ncradit@umich.edu
Caitlin Hayward, University of Michigan, cholma@umich.edu

Abstract: The ongoing COVID-19 pandemic caused many to reconsider their life's purpose and contributions. Massive open online courses provide an accessible avenue to explore knowledge safely at home. In this study, 70 learners from 28 nations on six continents were interviewed about their goals and the outcomes of their participation in MOOCs offered by a large US university. Learners shared deeply personal narratives of the ways open learning expanded a sense of possibility, redefined self-purpose, and offered flexible learning opportunities, demonstrating MOOCs' value beyond access, toward expansion of human capability.

Background

Massive open online courses (MOOCs) are a 21st-century development in distance education that expand institutional reach to a global scale (Baggaley, 2013; Diver & Martinez, 2015). Once expected to disrupt the postsecondary status quo, contemporary critiques now include profit, privacy, epistemic hegemony, and postcolonial influence by well-resourced universities (Laryea et al., 2021). Nonetheless, millions worldwide engage in MOOCs annually, with some studies indicating a more than tenfold enrollment gain due to the pandemic (Shah, 2021). We must understand both how learners use these courses and how the pandemic influenced their experiences. Part of a larger study of global learners MOOC experiences, this poster presents data demonstrating how MOOCs satisfied an emergent need for exploring one's goals and sense of purpose. Our inquiry was guided by the research question: How has the COVID-19 pandemic influenced MOOC learners' experiences and outcomes? The human capabilities framework (Sen, 2003) served as an instructive lens for this study. Originating in economics, the framework emphasizes well-being on three interrelated dimensions: functionings (i.e., goals we value), capabilities (i.e., skills and attributes empowering us to pursue goals), and agency (i.e., our ability to apply skills toward our goals). This framework allowed us to analyze whether and how MOOCs enabled expansion of one's goals, purpose, and capacity in the face of the pandemic.

Study design

Participants were recruited from the population of 130,000 learners in MOOCs offered by a United States university who answered a post-course survey. We used stratified random sampling to invite a narrower group of participants who mirrored the nationality proportions in the total learner population. 70 learners from 28 nations on six continents participated in this study. Qualitative inquiry with semi-structured interviews allowed participants to guide the conversation within established research-goal bounds. Data analysis included both deductive and inductive coding strategies, first identifying codes related to our research question and framework, then coding for findings identified in our engagement with the data. Codes were subsumed into themes in accordance with Deterding's and Waters's (2021) flexible coding method for large qualitative interview datasets.

Findings

We identified the following answer to our research question: the pandemic influenced learners' MOOC experiences and outcomes by enabling social contribution, redefining one's sense of purpose, and fostering exploration via flexible modularity. We include brief narrative fragments to illustrate the richly nuanced ways learners conceptualized their pandemic-related course experiences and outcomes. Notably, the experiences detailed were common among our global sample regardless of nationality, indicating the universality of both these core, humanistic needs and the applicability of the MOOC format in addressing them. Joseph (all names pseudonyms), a learner in Mexico in an introductory social work course shared:

> I've been working in the corporate world for over 20 years and I'm in that point of life where you are like, "well, what I'm doing, does it make sense? Do I envision myself doing this for another 20 years?" And the answer was no. I want to do something geared towards helping.

As Joseph used a MOOC to explore contribution, Jonna, a finance undergraduate in India, described the ways a MOOC helped her define a new sense of purpose during a time of pandemic-induced personal crisis:

> I was feeling purposeless at the time, unclear what I was doing with my life, because several family (members) had just died due to COVID, and I wasn't sure why I was living. Online means were all that was available at that time. It gave me a purpose. It helped me in interviews, in college. I use the word "purpose" in my interviews now. I didn't think I was that good in finance. But no, I see that as my purpose now.

The preceding outcomes were enabled in part by the MOOC format's flexible, modular content. Susan, a data scientist at the US Centers for Disease Control and Prevention, was part of a team using a MOOC to gain skills for the agency's pandemic response. She emphasized the importance of these modality characteristics:

> I wouldn't have progressed as fast if I hadn't completed that class. We're using data science skills to look at these longer-term outcomes and disparities around case rates, hospitalizations, vaccinations, testing, mortality, and trying to get a big-picture view. Now we're using surveillance data to tell the stories of health disparities and COVID in a comprehensive narrative. I probably could've gotten this content elsewhere, but not in this format, and the format really mattered. I could go in and watch a video for 15 minutes, then go do something else, then come back when I was able.

While open access is touted as the key benefit of the modality, a plurality of participants in our study named this sense of modularity and temporal agency as the prevailing factor in their successes. We encourage course designers, faculty, and providers to consider that it is not only MOOCs' openness that lends meaningful advancement to postsecondary accessibility, but also what learners encounter after enrolling in a course.

Discussion

Our study demonstrates the value of MOOCs in advancing not only specific skills and knowledge, but also satisfaction of core questions of the human experience, e.g., purpose and contribution. We build upon the work of Veletsianos et al. (2016) who offered a qualitative understanding of MOOC learners' experiences and called for further insights beyond quantitative datasets. Our study gathered one of the largest and most globally-representative collections of qualitative data on MOOC learning to-date. Its timing at the start of year three of an ongoing global pandemic allowed us to analyze the interplay between COVID-19 and open courses in real time. Given the role technologically mediated learning has played throughout the pandemic, we anticipate an expanded role for MOOCs in the coming years. The capabilities framework also lends significance to this study. Employing this lens, our study contributes to a growing understanding of how MOOCs can allow individuals around the world to advance their social participation, personal dignity and fulfillment, and quality of life. Beyond showing MOOCs expand access to postsecondary education, our study shifts the scholarly focus by demonstrating how these courses expand human capability for individual and collective benefit through satisfaction of core questions of the human experience, purpose and sense of contribution, each supported by the format's flexible modularity.

Understanding Emotion-Cognition Interplay When Processing Feedback During the Standardized Patient Debrief Sessions

Vitaliy Popov, University of Michigan, vipopov@umich.edu
Catherine Gabelica, IESEG School of Management, c.gabelica@ieseg.fr
Zhaoyuan Zhang, University of Michigan, zhaoyuan@umich.edu
Yiqun Yao, University of Michigan, yaoyqok@126.com

Abstract: This study examined how medical and social work students perceive and process feedback during a post-simulation debrief session. A novel methodology was employed for multimodal sentiment analysis, which consists of gathering sentiments from videos (n=113) by fusing audio, visual, and textual data features. Results indicate that most students expressed positive or negative deactivating emotions when reflecting on their performance. Evaluating and looking for alternatives were the most frequent reflective behaviors with few occurrences of looking forward behaviors.

Introduction

Simulation-based training augmented with team-level feedback on communication skills during debriefings are widely used in medical schools to improve skills needed for highly reliable clinician-patient interaction. Feedback in post-simulation debriefing settings is defined as the transmission of information to individual team members or the team as a whole regarding actions, events, processes, or behaviors relative to task completion or teamwork. Feedback is widely acknowledged to be central both to motivation (by promoting team efforts) and to learning due to its informational value (Gabelica & Popov, 2020).

In this study, we explored the ways in which medical and social work students perceive and process information cues contained in feedback during Breaking Bad News (BBN) debrief sessions. Constructive uptake of feedback can be "obscured by emotional static" (Chanock, 2000, p. 95), where team members' emotions can hamper cognitive processing of feedback. This study makes two contributions. First, our multimodal sentiment analysis provides unique insights into the ways in which medical and social work students perceive and process information cues contained in feedback during debrief sessions. Feedback on crucial aspects of team interaction needs to be perceived and meaningfully processed to reach the expected benefits of improved communication. Second, we explored a multimodal system for automatic quantification and interpretation of an individual's response when receiving feedback based on verbal and nonverbal behavior markers during the debrief sessions, such as words (speech content), head and body movements, facial expressions, tone of voice, and turn-taking. Specifically, we leveraged machine learning to build a sentiment classifier to reliably predict in near-real time students' cognitive-emotional states when receiving feedback. Specifically, we explore two research questions:

1. How do medical and social work students self-reflect as well as perceive and process information cues contained in feedback during BBN debrief sessions?
2. Can we leverage machine learning to build a sentiment classifier, so we can reliably predict in near-real time students' cognitive-emotional states when receiving feedback?

Method

Our research team transcribed, analyzed, and annotated 113 standardized patient simulation videos. To understand how students perceived and processed their feedback, meaningful units of analysis (i.e., phrases, sentences or series of sentences), were hand-coded using two coding schemes to affective and cognitive dimensions of feedback perception: team reflection coding scheme, and the taxonomy of academic emotions Gabelica et al., 2014; Pekrun, 2006). To code emotions, we adapted the taxonomy of retrospective outcome emotions from Pekrun's (2006) using a combination of categorical (e.g., discrete categories such as anger, happiness), and dimensional (valence: positive or negative; activation: activating or deactivating) approaches to emotion measurement. Each student response was hence coded as: (1) positive activating, (2) negative activating, (3) positive deactivating, (4) negative deactivating. A team reflection coding scheme was adapted from Gabelica et al. (2014) to capture the degree to which team members engaged in three cognitive (reflective) behaviors: evaluating performance or strategies, looking for alternatives, and making decisions ("looking forward").

Results

We found that a large majority of students expressed either positive (e.g., relief) or negative (e.g., disappointment) deactivating emotions when reflecting on their performance (Table 1). We found that 'evaluating' and 'looking for alternatives' were the most frequent reflective behaviors with very few examples of looking ahead reflective behaviors (Table 2). Table 3 shows with what accuracy we can predict student' sentiment using each modality vs. multimodal model.

Table 1
Distribution of emotions across students based on Pekrun's (2006) taxonomy

Sentiment	Positive deactivating	Negative deactivating	Positive activating	Negative activating
Overall	75	344	30	18
Medical student	44	178	10	9
Social work student	31	166	20	9

Table 2
Distribution of reflexivity across students based on Gabelica et al. (2014) scheme

Reflexivity	Evaluating	Looking for alternatives	Making decisions (feed-forward)
Overall	232	202	14
Medical student	124	100	10
Social work student	108	102	4

Table 3
Performance of unimodal and multimodal classification models for negative and positive deactivating sentiments

	F1*-score for negative deactivating	F1-score for positive deactivating
Video features	0.49	0.41
Audio features	0.67	0.52
Text features	0.85	0.60
Combined features	0.88	0.71

*F1-score is from 0 to 9, 9 being the highest in terms of precision and recall.

Discussion and conclusion

In this study, we have identified and captured emotional and cognitive responses to team-level feedback during BBN debrief sessions using audio, visual and textual clues from video data. We have found that most of the expressed emotions were negative deactivating, and that students were mostly engaged in reflective behaviors related to their past team performance. Hence, they seemed to have missed an opportunity for 'feedforward', that is for leveraging insights about themselves for better team performance in the future. Necessary future research should address the extent to which negative deactivating emotions are related to low future-forward team reflection. This study is part of broader research with the objective of optimizing feedback delivery and reception to prepare future medical professionals to provide the best care possible to their patients.

Vernacular Science and Community Mediation: Tracing the Invisible Fabric

Brian Drayton, TERC, brian_drayton@terc.edu

Abstract: There exists within many communities of interest in our society an invisible fabric of vernacular science activity. This fabric may play an important part in the reception, interpretation, and evaluation or filtering of the results of mainstream science. As illuminated in an ethnographic study, this fabric is seen to be both the result, and the enactment, of people's agency as participants in their world as experienced, and as thought about.

Introduction

How does a community of interest mediate the definition, transmission, use, and valuation of science in American culture? A theoretically rich account of science knowledge must take account of social/cultural context and the processes by which science is understood, constructed, and used in everyday settings — the 'vernacular' culture of science (Wagner, 2007). Vernacular science is constructed through conversation, and situated in specific *communities of interest* (Fischer, 2001) or *practice* (Lave and Wenger, 1991) with their specialized knowledge, practices, and discourse. Knowledge is produced through communication and interaction (including disagreement, e.g. Holland and Lave's (2009) "local contentious practice"). The community is an *agent* of education, as well as *context* for it: People engaged in their local communities are part of a “figured world”(Holland et al.,1998). Their knowing and doing, and their sense of themselves in those communities, is largely mediated by language, immersed in discourse processes. Discourse, gossip (Foster 2004), and discussion are *revealing* and *socially constitutive* activities (Bailey et al. 2014, Condor & Antaki 1997, Halliday 1990) that contribute to the development and transformation of social norms.

Data sources and analysis

I conducted ethnographic research in a rural community in New England which presents a rich diversity of active social networks. Data consisting of field notes from observations, community documents, and interviews (recorded and transcribed by permission) were coded in a concept-driven framework (Spencer et. al 2014) with respect to the following: a. The science central to the group's interest; b. The structures and sources of information and authority relevant to their science of interest; c. The processes, customs, or structures that support and frame the discussion or decision-making. As memos and research narratives were constructed, hypotheses were tested against the whole body of data, and member-checked with participants.

Findings

1. The science is often tacit, isolated, and/or atheoretical — but not necessarily unsystematic. The science of central interest to the participants in these communities is often not recognized as science: Child nutrition or vaccination is not science, it's health or parenting. The botany and ecology of gardeners is not thought of in those terms, as a member of a local garden club said: . *We don't usually do anything scientific...Well, actually I guess we do, but it's just not called that.* The science relevant to each community was not related to formal disciplinary knowledge, so consistency with established theory was not an important criterion, while richness of claims was convincing. Thus, if an authority figure makes a claim, there is no external motivation or leverage for critique.

2. A person gains ***authority*** *within the community's discourse primarily through* ***authenticity****.* People were able to identify specific persons within their community whose authority served as a warrant for claims made: *In most cases, you give more credence to what those active farmers are experiencing and understanding about whatever it is, certain varieties of grass, certain land management practices, health issues with animals. Those are very powerful.* An authority with a well-articulated alternative worldview, who performs authenticity, often is appealing because the search for and use of scientific knowledge in a community of interest is connected with members' articulation of identity. The person just quoted had been disillusioned while a student at a major military academy. From field notes: *9/11, the wars in Iraq and Afghanistan shook his confidence in established authorities...It seemed important to seek information that could help him make up his own mind.*

3. Diversity of opinions is valued, but conflict is avoided. In all cases, controversy over science is seen as secondary to the core purpose of the group , and so while differences of opinion are known to exist, many are not discussed or critiqued, in order to preserve the comity of the group whose focus is not the establishment of knowledge. Silence is constructed (Drayton, 2023). As a parent said about the prevalence of "alternative medicine" in the school community, *[My husband and I] lie...The kids are fully vaccinated. We're not going to suffer through,* *we're not going to try to wait out strep. I'm getting the drugs for it, the antibiotics, but I'm definitely not going to say that out loud.*

Discussion and significance

This preliminary work suggests that robust vernacular science cultures are present and active in many communities of interest, and are not to be understood simply by deficit models (where the deficit may lie in the learner, the science teacher, or the scientists). Such science is of daily use for matters of direct relevance, with informal authority structures and methods of transmission. Its atheoretical nature, and isolation from mainstream disciplinary knowledge, reflects a difference in core function from mainstream science, whose aim is to render a coherent and verified accounting for natural phenomena. Vernacular science engages with real phenomena, but its purposes include community solidarity and personal identity, as well as providing the basis for growing expertise in a particular area of practice. A fuller account of the varieties of vernacular science current in a communnity may well provide important insight into barriers to the credibility and uptake of mainstream science as conveyed in schools or the media.

Knowledge in New Pieces: Exploring Modern Youth's Intuitive Knowledge

Paulo Blikstein, Leah F. Rosenbaum
paulob@tc.columbia.edu, leah@tltlab.org
Teachers College, Columbia University

Abstract: Youth's worlds are increasingly large, connected, and inextricably digital and analog. The intuitive knowledge that youth develop in navigating and constructing these worlds may similarly evolve in ways that could inform formal education. We present initial findings of a broader research program that studies what and how youth know about complex systems from their daily experience with them. Findings could guide the design of educational activities and curricula that leverage such knowledge in preparing youth for contemporary life.

Motivation and background

Youth's exposure to complex systems, natural phenomena, and forms of social interaction has increased dramatically. Some systems are technological; networked, internet-enabled, real-time processing devices are an inextricable part of youth's reality, making the gathering, processing, and flow of data as real a consideration as why the seasons change. Other systems arise in discourse; conversations about resource use, climate change, global economics, and systemic inequity and algorithmic bias, to name a few examples, are "in the air" more so now than ever. Youth inhabit and explore increasingly large, detailed, complex, and interconnected worlds.

This project is inspired by Knowledge in Pieces (KiP, diSessa, 1993) and its account of the diversity and contextuality of intuitive knowledge. KiP's *phenomenological primitives (p-prims)* capture small bits of intuitive knowledge about how things work (diSessa, 1993) (e.g., "forces act in balance," and "multiplication makes numbers bigger") that constitute the building blocks of sense making. This pilot is a first step in studying the novel, overlooked intuitive knowledge "pieces" - that is, the **knowledge in new pieces** (KiNP) - generated by youth's modern, techno-social lives. We are guided by the following research question: *what do youth know about complex systems based on their everyday, out-of-school exposure to such topics?*

This work could inform curriculum design and education in a few ways. diSessa's work tells us that learners do not simply "forget" typically unproductive p-prims (Smith III et al., 1994); they may be unaware that they regularly use a p-prim, and a given p-prim may remain productive in certain contexts. KiP also describes how, as learners' conceptual understanding matures, it develops into *coordination classes* (diSessa & Sherin, 1998) that highlight concept-relevant features and inform more consistent reasoning. We also base this work on research of how people think with and about technology (e.g., Danovitch & Severson, 2021; Turkle, 1984). We focus less on documenting youth's technology practices and instead seek to use the intuitive knowledge gained from those practices as a springboard for formal learning. Finally, we draw from *connected learning* in which, through community-supported pursuit of personal interests, youth learn knowledge and skills that can support their academic, civic, or career development (Ito et al., 2013).

Pilot methods

We collected several hours of video data with 5 youth aged 8-15. Using convenience sampling, all participants lived in major metropolitan areas, and 4 of the 5 youth had at least one parent with an advanced degree. Semi-structured interviews lasted 45 minutes and addressed topics drawn from the first author's 10+ years of informally talking with youth about technology (Table 1). Interviews were conducted on Zoom, automatically transcribed, verified by the second author, and collaboratively and thematically coded (Braun & Clarke, 2006).

Table 1
Sample interview topics and prompts

Topic	Interview Prompt(s)
1.Exponential Growth	How long would it take a great meme to get 100 views? 1,000 views? 1 million views?
2.Artificial Intelligence	How do AI assistants understand you and do what you want them to? If you got a different answer from an AI assistant and from an adult, whose answer would you trust?
3.Robotic Workforce	As robots advance, they do jobs that people used to do. People who had those jobs, what do they do now? What would you tell someone worried about being replaced?
4.Industrial Impacts	When you buy a t-shirt, what happened for it to be made and get to you?

Pilot findings

Related to ideas of exponential growth (Q1), participants identified a range of variables that affect content's view rate: number of followers, influence ("famous" or "regular" person), metrics (views or reactions), and timeliness ("in the news" or "just random"). Some participants offered sophisticated mathematical reasoning about exponential growth, characterizing powers of 2 before they were exposed to such concepts in school ("If you send it to 2 people, and those people send it to another 2 people, it keeps getting larger and larger").

About half the participants also offered detailed considerations of the environmental and human impacts of the clothing industry (Q4). They indicated an awareness of complex resource and supply chains as well as of the unintended consequences of industrial workflows: large plantations using land and water to grow cotton, factories using energy to spin thread and fabric and to sew fabric into shirts, stores selling the shirt, trucks using fuel to transport goods at every step. Participants also recognized the social, policial, and economic dynamics that shape those networks. One participant described such work as happening "in places like China, India. …because Americans don't have time for that" and discussed issues of cost of living ("maybe not good work, but it's a work that can provide enough"), wage theft ("there's some places that don't even pay their people"), labor relations ("the people who are actually in control … are less willing to pay [their workers] five times more."), and global economic dependence ("The work then gets shipped off to different countries … The country is completely dependent on that."). Another participant summarized these issues using an intuitive sense of ethical "balance:" "every time you're going to do good, you're also going to do evil." He discussed the impact of t-shirt production as a complex ethical dilemma, between generating jobs and low prices in some countries while destroying the environment in others.

We also found ways in which youth's previous knowledge about socio-technical systems was insufficient to sustain complex sensemaking. Most participants agreed that a social media post would continue to gain views indefinitely. Similarly, most participants expressed an understanding of AI as based on "very delicate coding" composed of endless if-then statements (Q2), likely the type of code they are familiar with from environments such as Scratch. Finally, all but one participant expressed no qualms about expanding robotic workforces (Q4). Participants were confident that replaced human workers could either become robotics technicians ("they could program the robots") or change careers ("there are a bunch of other jobs out there").

Conclusions

Our preliminary data suggest that youth indeed know some advanced knowledge pieces even without formal instruction on them, up to a certain limit. The topics addressed by the interview protocol are typically not yet taught in formal education to children of our participants' ages, suggesting our participants acquired these ideas through first hand experience with online content or through immersion in local or global public conversations. There is also great potential for educational designs and curricula to precisely address the missing pieces that are harder to glean from everyday experiences (e.g. balancing the novelty of technology with the ethics of its human implications). In expanding this pilot work, we aim especially to diversify our participant pool, including internationally, to access a wider range of youth perspectives (Kafai et al., 2010). We believe these preliminary findings justify further study of the "new pieces" of youth's intuitive knowledge. Educational designs and curricula that reflect and honor students' intuitive knowledge could better prepare them for life and civic participation in the 21st century.

“More Than Just Making Stuff Explode”: The Impact of Engagement With Scientific Practice Beyond Disciplinary Content

Engin Bumbacher, University of Teacher Education Vaud, Switzerland, engin.bumbacher@hepl.ch
Leah Rosenbaum, Teachers College, Columbia University, leah@tltlab.org
Paulo Blikstein, Teachers College, Columbia University, paulob@tc.columbia.edu

Abstract: As part of a larger project, this study evaluates middle school students’ learning from a technology-based, evidentiary reasoning unit. Post-unit survey responses indicate students developed a deeper understanding of the nature of scientific work and of productive scientific mindsets. These take-aways beyond content knowledge emphasize the learning opportunities and outcomes that can arise from engaging learners in authentic scientific practices.

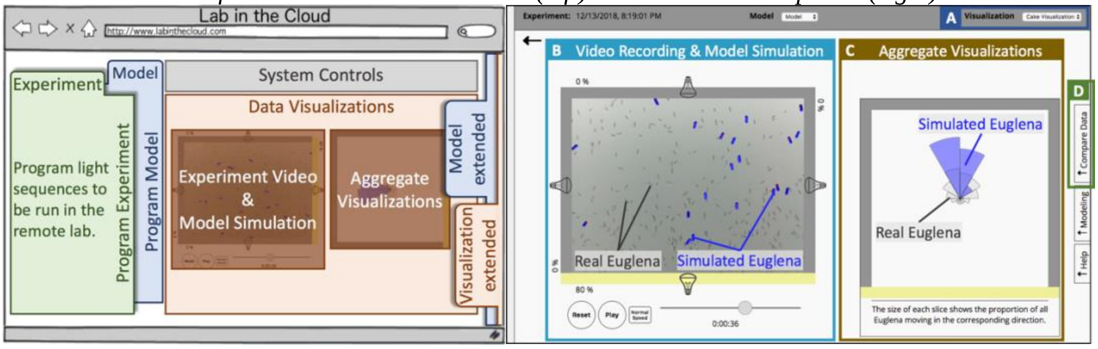
Introduction and background

Recent science education reforms work to shift science learning beyond a mere understanding of scientific content to include knowledge about the function and interplay of the different scientific activities, often referred to as understanding of the nature of science (NOS) (Williams & Rudge, 2016). Research suggests that students’ understanding of NOS be developed alongside their science content and procedural knowledge through practice-based teaching approaches (Duschl & Grandy, 2013). The design of practice-based learning activities that foster content, procedural, and NOS learning remains a persistent challenge (Williams & Rudge, 2016).

Acknowledging the intricate relationship between the design of practice-based science activities, how students engage in scientific practices, and what they learn about science through the activity, this poster addresses the following research question: what do students take away about the nature of science and how scientists work from engaging in a practice-based, technology-driven learning activity? We report on a middle school unit in which students coordinated real data with computational models to reason about the behavior of *Euglena gracilis*. Throughout, students had to make decisions about what kind of data features and patterns to use to evaluate their hypotheses and models. We propose that above-content take-aways emphasize the broader- than-expected learning opportunities and outcomes of engaging learners in authentic scientific practices.

Figure 1

Lab in the Cloud software environment overview (left) and visualization options (right)



The size of each slice shows the proportion of all Euglena moving in the corresponding direction.

Methods

Based on the Bifocal Modeling framework (Blikstein, 2014), which juxtaposes scientific models and real-world data for real-time comparison, we designed Lab in the Cloud (LiC), a web application that integrates a remote laboratory (Hossain et al., 2016) with a modeling and data visualization environment. In the Experiment area (Figure 1, green), students remotely controlled the lab’s lighting to vary conditions for live *E. gracilis*. They also programmed models (Figure 1, blue) to enact their theories of *E. gracilis* phototaxis. Students studied the resulting experimental and model data in the same visualizations (Figure 1, orange), both as an overlay (Figure 1, part B) and in aggregate (Figure 1, part C) (Bumbacher, 2019), to modify and refine their theories about *E. gracilis* phototaxis. The 76 participants (39 F, 37 M) were 7th grade students in a Northern California public school and all had the same life science teacher.We analyzed students’ answers to the nature of science question “Did you learn anything about science and how scientists work that you did not know before? If so, what did you learn?” through their post-unit survey responses. Through multiple rounds of independent and collaborative thematic analysis (Braun & Clarke, 2006), we refined the codebook presented in Table 1 and achieved Cohen's Kappa of at least 0.80 on 25% of the corpus. The remaining responses were coded independently.

Table 1
Codebook for students' reported learning from the E. gracilis phototaxis unit.

Learning Area	Example(s)	Students	# Ideas	
			Mean	St. Dev.
Nature of Scientific Work		**75%**	**1.2**	**0.4**
Experiments & Data Collection	"scientists learn new things and experiment with technology like using computers or microscopes."	29%		
Models & Tools	"I didn't know scientists used robots to mimic the animal or plant."	45%		
Interpretation & Argumentation	"If you don't have good evidence to support your claim, no one will believe what you are saying."	14%		
Scientific Mindset		**42%**	**1.3**	**0.5**
Patience & Perseverance	"you don't always figure things out the first time and that scientists need to be patient when they experiment."	12%		
Attention to detail	"scientists carefully observe different actions or outputs with precision and close observation."	28%		
Other:	"...scientists... could get proven wrong. But that is not a bad thing."	14%		

Findings

Almost all students (91%) reported learning science content (Table 1). Encouragingly, 75% of students reported learning about sophisticated aspects of NOS (or in a students' words, "they study more than just experiments and making stuff explode.") and over 40% reported learning about scientific mindsets. Neither of these areas were overtly discussed by the instructional unit and, thus, represent above-content learning. Students tended to report NOS learning about novel tools - software, computer modeling, and robotics - that go beyond mere experimentation and data collection. "Attention to detail" was the most common idea within reported learning about scientific mindset. Students' reported NOS and mindset learning can potentially transfer beyond the particular study of *E. gracilis* to other scientific reasoning in school and life.

Conclusions

This paper contributes to the small body of work on the impact of practice-based learning on students' understanding of NOS (Rönnebeck et al., 2016). The study was situated in a novel technology-driven activity that combines real data with computational modeling to engage students in evidentiary reasoning in disciplinary meaningful ways. The results indicate that engagement in this activity helped students learn about epistemically rich aspects of scientific work, such as the importance of carefully linking evidence to claims. We believe that these self-formulated insights could be solidified by teachers to help learners becoming participants of scientific conversations who use evidence from real-world data to critically review and evaluate scientific claims.

Situating Evaluation: Theory Driven Evaluation in Practice

Joanna Weidler-Lewis, KU – Center for Public Partnership and Research, jweidlerlewis@ku.edu
Jimmy Frickey, Trent University, jimmyfrickey@trentu.ca
Maxime Goulet-Langlois, McGill University, maxime.goulet-langlois@mail.mcgill.ca

Abstract: Theory driven evaluation is a social practice that contributes to the consequential production of people, knowledge, and resources. Evaluators are overlooked actors supporting the Learning Sciences community. Our poster explores how theory driven evaluation has been taken up in Canada and the United States. Using collective autoethnography, we show how evaluation is implicated in learning as becoming. We conclude with suggestions for how to engage with evaluation to support better designs for learning and becoming.

Introduction

Our prior work argued that evaluators play a consequential role contributing to the design and organization of learning (Weidler-Lewis & Frickey, 2021) when evaluation is understood as social practice (Schwandt, 2018). This conceptualization of evaluation is informed by the view of learning as social practice (Holland & Lave, 2009) and the ways in which learning is contextual, situated in activity, and mediated by cultural tools (Lave & Wenger, 1991). Furthermore, learning is a process of becoming of persons, knowledge, and tools (Packer & Goicoechea, 2000). We showed how boundary judgments enacted by evaluators shape practices by legitimizing some forms of knowledge and validating certain stakeholder's interests over others thereby implicating evaluation in perpetuating or disrupting dominant, logics many in the Learning Sciences intend to dismantle (Esmonde & Booker, 2017). This poster continues our nascent work moving from theory to practice as evaluators in Canada and the United States. We present three autoethnographic narratives detailing how theory driven evaluation was enacted in our work and the resulting implications for the becoming of persons, knowledge, and tools.

Theory driven evaluation

According to theory driven evaluation (TDE), evaluation should not only have scientific credibility but should also have "practical worth" (Chen, 2013). TDE is aligned with Learning Scientists who recognize relevance to practice as a significant criterion for rigor (e.g., Gutiérrez & Penuel, 2014). We argue TDE should also lead to practical action and inform questions such as "how ought we design for learning?" Practical action is facilitated by boundary judgments, judgments dictating what should be included or excluded from a given context (Schwandt, 2018). Boundaries are negotiated through collective sensemaking and require normative judgments (i.e., what is *good* or *right*). TDE helps to answer the question *what should be done* while recognizing that there is not a single or correct answer to what boundaries ought to be in an investigation. Therefore, TDE includes ongoing reflection regarding what decisions were made for and by whom with what consequences and impacts for whom. The work we are presenting in this poster represents this reflective practice.

Collective autoethnography as method

In autoethnography, researchers apply their analytic lens on themselves and their interactions with others to interrogate traditional research relationships and to understand broader cultural meanings through personal experience (Chang, 2016). Autoethnography is generally an individual endeavor yet critical methodologists recognize how collective autoethnography builds shared knowledge, sustains community, and works toward social transformation (Wężniejewska et al., 2020). We, the authors, are currently embarking on this process and are documenting our individual work in order to think collectively. As we make note of the dilemmas of practice we face, we are capturing how our boundary judgments are shaping the practices we are tasked with evaluating.

Autoethnographic narratives of evaluation in practice

Given the early stages of our research, we briefly describe our contexts and a few examples of the consequential boundary judgments we have enacted.

Frickey is evaluating a community organization in Ontario working to support folks living in poverty through means designed to shift attitudes toward poverty sufficient to impact public policy. Previously, the organization received multiple grants to develop and implement their program, including two evaluations, each completed by different evaluators. The data collected from these prior evaluations were to demonstrate impact to support continued funding for the program, however, key features of the program's theory of change were disrupted because of COVID-19. The data collected no longer supports its original purpose. During the lockdown, additional work not captured by the data was required for the program to function. Frickey is faced with the dilemma of how best to use prior data to retain its scientific credibility while maintaining its practical worth. Therefore, he must generate new *knowledge* by either reconfiguring the existing data and/or seeking new types of data.

Goulet-Langlois is evaluating a pilot project aimed at preventing reincarceration and sexual exploitation through the redesign of intervention practices with women transitioning out of prison in Québec. Prior to his involvement with the evaluation, the directors of the agency saw the evaluation as a means to demonstrate only outcomes that secure long-term funding by showing a reduction in recidivism rates correlated with their services. By reducing outcomes measure to only individual metrics like recidivism all the mitigating factors of women's lives were overlooked that could be taken up through evaluation including women's social, economic, and indigeneity status. *Goulet-Langlois* was able to engage stakeholders in sensemaking regarding how such reductions limited the ways in which women were seen and thus how this hindered the development of the pilot programming. Thus, TDE directly informed the production of *persons* (i.e., the women) in this context.

Weidler-Lewis evaluates developmental outcomes for youth. They are currently evaluating programming supporting children ages birth to five years by a state agency in the Midwest United States. The state mandates that evaluation use a "results accountability framework" that measures "how much did we do?" and "how well did we do it?" Prior evaluators used this framework to compare the number of children who had cases marked completely resolved to all others without attending to all the work done to support children who did not meet the completely resolved criterion. Weidler-Lewis's research into the amount of work done by the staff revealed that the data management system used to track children's development could be improved to document staff work at the different trajectories towards resolution and provide new categories to think with regarding what was going "well" and what was not. Thus, Weidler-Lewis's evaluation resulted in new *technology* for their practice.

Discussion and conclusion

Although the presentation of our findings is brief, our narratives demonstrate how our decisions as evaluators led to the production of knowledge, persons, and tools. In this way, we are consequential actors in designs of learning insofar as learning is taken as becoming. We argue that rather than separate evaluation as something outside of the scope of designs for learning, learning designers should seek out evaluators who take up the TDE perspective. Then, together, learning designers and evaluators can engage in joint sensemaking to see how each comes to make judgments that shape the practices we value. Together, we can design and evaluate with the aim of creating intentional opportunities for learning of the type that the Learning Sciences community is known.

Using a Design-Based Research Methodology to Improve Competency-Based Grading

Kelli Adam, Merlyn Joseph, Robert Lightfoot, William Cameron Walker, Jonan Phillip Donaldson
kadam@tamu.edu, joseph@tamu.edu, rob.light@tamu.edu, cwalker@tamu.edu, jonandonaldson@tamu.edu
Texas A&M University

Abstract: Competency-based grading (CBG) was implemented in an introductory computer science and a graduate-level pharmacy course to address the limitations of traditional grading schemas, which do not accurately reflect a student's competency. This study outlines how student perceptions of the CBG schema were collected through reflections, and a design-based methodology was used to identify course-level and universal recommendations for improving the CBG schema. In future iterations of the courses, the identified design moves will be implemented, and students' reflections will be analyzed to identify additional improvements to the CBG schema.

Introduction

Competency-based education (CBE) is a unique perspective on curriculum where the student engages with sources of knowledge, reconstructs knowledge, and takes responsibility for their learning. The instructor becomes a guide in the learning situation instead of the source of knowledge (Claassen, 1998). In this way, CBE emphasizes mastery of outcomes and uses various techniques to evaluate the degree to which students demonstrate competencies.

Real-world application of CBE needs more rigorous research (Pellegrino, 2014). The current study employed design-based research (DBR) to allow educators to integrate research, curriculum design, and practice (Joseph, 2004). The current study evaluated CBE within a computer science course and a pharmacy course taught by study co-investigators. Analyzing these courses with a DBR methodology allowed the instructors to better understand their respective course curricula by identifying real-world design moves.

Assessments are essential to CBE as they allow instructors to measure when a student has mastered a specific outcome or goal (Albanese et al., 2008). However, these assessments must resemble skills, activities, and functions in the real world. Assessments then become a learning experience in which learners apply their knowledge, skills, and values in an integrated manner. As a direct result, CBE assessments allow students to build knowledge rather than acquire it and demonstrate their competence in the activity.

Traditional A–F grading schemas calculate the final letter grade from activities averaged together. However, students may earn an "A" grade despite lacking competence in the core skills of the course. Both courses in this study opted for competency-based grading (CBG) to better evaluate the student's knowledge. Each course coordinator broke down the core competencies and redesigned their grading schema. Both courses used similar CBG structures when implementing a core set of activities requiring students to demonstrate minimal competency to pass the course. Each course started the new CBG schema by identifying the key activities required to demonstrate competency in the course learning objectives. However, both courses allowed students to earn a higher letter grade by providing additional assignments that helped further demonstrate student competency. This allowed each student to choose their path to learn the course material while having a consistent foundation. Any passing grade demonstrated that students had mastered all course objectives.

CBG now requires students to meet all course competencies with a 70% achievement in each category and a student will not pass the course if this requirement is not met. Once the core competencies are mastered, students can accumulate points from additional pathways to earn an “A” grade in the course.

Research questions

With traditional grading schemes, students may earn an “A” grade despite needing to be more competent in the core skills of the course. To address this issue within their respective classes, two courses implemented a CBG schema. Our overarching research questions to improve our CBG schema included: *How did students experience learning in a CBG context*, and *How can these experiences improve the learning experiences?*

Methods

The current study is the second iteration of a more extensive DBR project where we implemented a CBG schema in introductory computer science and graduate-level pharmacy courses (Barab & Squire, 2004). We collected student perceptions of the new grading schema via reflections. We then used network analysis to identify ways to improve CBG in the two courses and develop evidence-based recommendations. We used network analysis because it provides a holistic and expansive method of understanding the complexity of student learning experiences.

At the end of each course, consenting students (n=133) reflected on four open-ended questions that we anonymized. We then coded the responses at the sentence level in the MAXQDA Analytics Pro software by using open coding techniques within predetermined categories, including what worked, student struggles, and suggestions regarding the grading schema. Correlational analysis was used to correlate student's struggles, what worked, and their suggestions for improvement. The matrices were imported into the UCINet network analysis software (Borgatti, Everett, & Freeman, 2002) and the NetDraw network visualization software (Borgatti, 2002) for network analysis. Girvan-Newman cluster analysis was conducted, and resulting network maps were analyzed to identify design moves to improve the CBG schema within the context of each course. Relationships between student struggles and what worked well allowed us to leverage the strengths to address the weaknesses.

Findings

We created a network map of correlations at the $p<0.001$ confidence level that shows positive, significant correlations between student struggles and what worked for them. Girvan-Newman cluster analysis found seven clusters at $Q=0.724$ where cluster sizes represent betweenness. For example, students in the red cluster struggled with their grades being easily demoted, the desire for multiple attempts on core assignments, and a need for more practice. What worked well for these particular students was feedback about their learning, the satisfactory/unsatisfactory grading, and graded attendance. These students' experiences aligned with the self-determination theory principle of intrinsic motivation. The design moves that addressed these students' struggles were to improve the structure of how to achieve the goals of each assignment and potentially incorporate practice assignments or example assignments before the graded assignment. We worked on design moves not reported here for the last five clusters. In the next iteration of this study, the analysis will be completed again to identify further improvements in implementing the CBG schema.

Implications and conclusion

The learning sciences have a long history of designs for learning that explicitly aim for greater learner agency and empowerment. Though grades were assigned in these courses, the instructors were able to implement a system of ownership and empowerment that encouraged learner agency. We found that students identified with the self-determination principle of intrinsic motivation through increased autonomy and self-perception of competence, and we expect that these principles can be applied to other disciplines. Framing this study on motivation theory is beneficial in promoting attention, competence, and autonomy among students.

Using a CBG schema, the instructors have created classes that empower students to take ownership of their learning. This empowerment allows the students to learn in a way that meets their individual needs. CBG allows students to tailor their learning experiences based on how they want to learn. Instructors in both courses ascertained that this CBG schema set higher standards than the traditional points-based schema. When implementing a CBG schema, instructors should consider which skills their students require to be competent when leaving the course. As we continue to work toward a set of principles for CBG, we must maintain constant awareness that factors unique to each context will require significant adaptation of design principles.

Creating Classrooms of Care: Exploring Secondary Mathematics Teachers' Agency in the COVID-19 Pandemic

Elizabeth Metts, Katherine Schneeberger McGugan
elizabeth.c.metts@vanderbilt.edu, k.schneeberger.mcgugan@vanderbilt.edu
Vanderbilt University

Abstract: This interview study explores how the shift to online schooling during the pandemic presented teachers the opportunity to think critically about their grading systems and the scope of mathematical content they addressed. Centering teachers' agency as they responded to the ever-changing and uncertain educational and social environment of pandemic teaching, we investigate how teachers achieved agency as they were driven to better serve their students' needs.

Introduction

It is well documented that there are numerous inequities entangled in institutional structures of U.S. schooling (Milner, 2021). Exacerbated by the pandemic, inequities associated with access to food, shelter, and healthcare as well as income insecurity have amplified opportunity gaps in teaching and learning (García & Weiss, 2020). At the same time, American students' lives during the initial years of the pandemic were marred with injustice as they witnessed multiple public police killings of Black citizens, an uptick in anti-Asian violence, and an insurrection in the seat of the U.S. government. All of these aspects complicated the already uncertain shift to online schooling for teachers to negotiate – they had to create an online learning environment that met the needs of students' personal lives and the broader context of learning during a pandemic. This context presented an opportunity for teachers to exercise agency in ways that aligned with their pedagogical goals. This poster explores secondary mathematics teachers who were explicitly committed to equitable and responsive teaching in ways that centered their students' needs and addresses the research question: How do secondary mathematics teachers agentically recreate practice in ways that align with their pedagogical responsibilities?

Theoretical perspectives

Teachers must negotiate a variety of demands, often requiring them to transform and (re)define their teaching practice according to their pedagogical responsibility – a highly personal aspect of their sensemaking comprised of their sense of obligations and informed by both institutional and moral commitments (Horn & Garner, 2022). This study centers teachers' agency as they responded to the ever-changing and uncertain educational and social environment, driven to better serve their students' needs (Deed et al., 2020). Agency is a dynamic and socially mediated phenomenon – deeply embedded in local contexts, larger social and institutional structures, and relationships (Clarke & Hollingsworth, 2002). We draw on Priestley and colleagues' (2015) temporal model of agency which identifies three dimensions of teacher agency: iterative, practical evaluative, and projective.

Methods

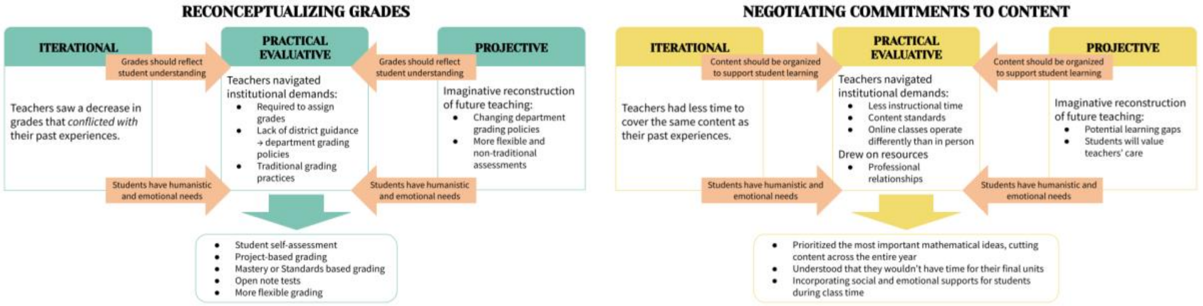
This study extends a four-year ethnographic study of eight experienced secondary mathematics teachers' learning, conducted in partnership with a professional development organization serving teachers in a large urban school district. At the onset of this study, our goal was to better represent the knowledge and questions that arise as we learn from and with teachers. As such, this interview study puts the teacher-as-researcher forward, recognizing them as experts in their experiences. Therefore, we designed an interview method we refer to as *reflexive longitudinal lifeworld interviewing* in which we developed interview protocols akin to those of lifeworld interviews (Brinkmann & Kvale, 2015) alongside of in-process data analysis (Emerson et al., 2011) of responses and content analysis of relevant current events (Altheide & Schneider, 2012) to inform subsequent protocols. Over the course of this analysis, agency emerged as a key phenomenon across participants. We then conducted cross-case, open inductive coding (Saldaña, 2021) to identify specific spaces in which teachers were reconceptualizing their practice followed by theoretical driven coding (Brinkmann & Kvale, 2015) informed by the temporal agency model.

Findings

We found that teachers in this study exercised agency during online teaching in two ways: by reconceptualizing grades and negotiating their commitments to mathematical content (summarized in Figure 1). During our study, teachers responded to decreases in students' grades in ways that aligned with two common pedagogical responsibilities: to reflect students' understanding and to students' wellbeing. They did so by incorporating practices like student self assessment and open note tests. In so doing, teachers also reimagined their grading practices beyond the COVID year to better align with these pedagogical responsibilities including committing to more flexible and non-traditional assessments and challenging department grading policies. Teachers were also forced to make decisions around the depth and breadth of mathematical content. Teachers in our study had fewer instructional days in which to cover the same content in their previous experiences. Teachers in our study prioritized what they considered the most important mathematical ideas to cut content across the entire year while also making space to incorporate social and emotional support for students during class time. These adaptations to their practice were rooted in two pedagogical responsibilities: to support student learning and to students' wellbeing. Teachers also acknowledged lasting effects – they anticipated potential future learning gaps, and they believed that students would value the care that teachers expressed more than covering content.

Figure 1

Agency in two Authoring Spaces: Reconceptualizing Grades and Negotiating Commitments to Content



Discussion

Throughout this study, pedagogical responsibility informed teachers' agency and reconceptualization of practice as they rebalanced their responsibilities to lead with an ethic of care and prioritizing their commitments to equity. We see agency as necessarily connected to teachers' pedagogical responsibilities and commitments. Teachers' reconceptualizations of their practice were anchored in their pedagogical responsibilities, and over time, they worked to set goals, enact their vision, and evaluate themselves against their commitments. Our focus on pedagogical responsibility and teacher agency offers a look into the institutional, ethical, and professional dilemmas or motivators teachers experienced as they taught through the pandemic.

Reframing From Design Fields: Supporting Pre-Service Teachers in Designerly Thinking

Douglas B. Clark, David Scott, Joshua P. DiPasquale, Sandra Becker
douglas.clark@ucalgary.ca, scottd@ucalgary.ca, sandra.becker@ucalgary.ca, joshua.dipasquale1@ucalgary.ca
University of Calgary, Werklund School of Education, Calgary, Canada

Abstract: Guided by contemporary theory and research from design fields, we propose a framework for conceptualizing K-12 educators' stances towards design that focuses on problem framing, information gathering, divergent thinking, and iteration. We use this framework to analyze data drawn from 28 pre-service teachers' conceptualization of design within the context of a design course taken by over 400 pre-service teachers. Our analysis demonstrated that most participants made only moderate progress in refining their thinking about design.

Theoretical framework

Insights from design fields suggest that a designerly stance towards design for K-12 educators focused on supporting second order changes would emphasize four key themes as follows: (a) view of the problem space (e.g., Buchanan, 1992; Norman, 2013; Schön, 1984), (b) approach to stakeholders and inquiry (e.g., Bang & Vossoughi, 2016; Christensen et al., 2016; Krippendorff, 2004), (c) framing and frame creation (e.g., Buchanan, 1992; Dorst, 2011), and (d) conceptualization of the design process (e.g., Norman, 2013; Owen, 2006). These elements overlap and interrelate with one another and share, in many instances, common themes. We developed a detailed rubric based on these four areas that we used to guide this study and data analysis leveraging the structure and ideas that Crismond and Adams (2012) used to in their framework for engineering education. As with Crismond and Adams, we developed pairs of contrasting statements for analyzing pre-service teachers' approaches to design on a scale from beginning to designer to "informed designer" whose "level of competence lies somewhere between that of the novice and expert designer" from the perspective of the design fields (Crismond & Adams, 2012, p. 743). Space precludes including the full rubric here, but we will share the full version at the conference.

Research questions

1. When viewed through the theoretical framing outlined above, how do pre-service teachers' understandings of design evolve in a course that includes an emphasis on design-based thinking from the perspective of the design fields as well as perspectives on design from the field of education?
2. Which aspects of design as defined in the theoretical framing come most naturally to pre-service teachers and which aspects require more support, revisions, or emphasis?

Methods, data sources, and coding schema

We employed case study research (Stake, 2005; Yin, 2014) to consider how, and the extent to which, pre-service teachers engaged in designerly stance towards design within the context of a mandatory five-week course taken by 400 students at a university in western Canada focused on a range of design processes in the field of education including perspectives from design fields (Design Council, 2007; Norman, 2013) as well as design perspectives in education including design thinking (IDEO, 2012). The bracketing of the boundaries for this case involved limiting the focus of the research to data gained from this course. In total, the team analyzed the work of 28 pre-service teachers across the 18 sections of the course who consented to allow their work to be used as data in this study. Data in this regard were drawn from three course pre and post reflections and design projects.

Findings

In the sections that follow, we analyze the data set in relation to our conceptualization of the four proposed themes for a designerly stance to design. Each theme is presented as a continuum from beginning designer through transitional to informed designer (Table 1).

Problem Solving vs. Problem Framing. Findings from this study indicated that conceptualizing the problem space was the most challenging area for participants. Pre-service teachers demonstrated almost no progress from Pre to Post in terms of Problem Solving vs. Problem Framing. Our analysis of the data suggested that most of the pre-service teachers in this study entered and left the course with a largely beginner's view of the problem space, particularly in relation to complexity. The majority of participants continued to view problems as uncomplicated and stable with the goals to be achieved largely fixed and predetermined (Schön, 1984).

Skipping vs. Doing research. One notable area where the participants demonstrated growth from Pre to Post occurred in the area of inquiry and research as shown in the table and figure. In particular, we noticed an uptick in attempts to gain empathy for stakeholders, particularly students. This shift can be most likely attributed to the emphasis that the course placed on design thinking perspectives highlighting the importance of empathizing with the needs of the 'user.' This view additionally aligns with prominent contemporary educational discourses emphasizing the importance of student-centered pedagogies. Thus, there was close alignment between the pre-service teachers' prior understandings and this aspect of design as inquiry.

Idea Scarcity vs. Idea Fluency. Our analysis of the data set suggested the pre-service teachers started at a more transitional stance towards divergent thinking and idea fluency but made little progress beyond that during the course. They overwhelmingly associated design with the creation of more active and engaging learning environments (in alignment with predominant student-centered discourses in their program) involving a shift away from traditional approaches to education rooted in teacher-centric pedagogies, passive learning, and content coverage. These student-centered discourses are heavily emphasized in teacher education programs, and it is therefore not surprising that the pre-service teachers had conceptual access to them. Participants demonstrated minimal progress during the course, however, in considering genuinely new and original frames that went beyond the typical student-centered frames of progressive education.

Haphazard or Linear vs. Managed and Iterative Designing. An area where participants demonstrated substantial growth occurred in relation to process. Pre-service teachers initially displayed a range of beginning designer and early transitional perspectives that shifted towards primarily transitional stances by the end of the course. In particular, participants became much more attuned to the iterative nature of design.

Scholarly significance

The proposed framework for analyzing educators' stance toward design, in line with theory from the design fields, focuses particularly on problem finding, as opposed to solely considering design in terms of a problem-solving mindset as has been the focus traditionally in education. Many approaches to design in education, including typical backward design frameworks, are generally taken up with a narrow focus on the disciplinary content standards and goals dictated by ministries of education. The ongoing presence of this tradition in teacher education programs may partially explain why education as practiced in K-12 classrooms has changed so little in North America over the last century (Payne, 2008; Tyack & Cuban, 1997). Findings from this study highlight the importance of approaching the design process more in line with design fields that focus on problem finding if we wish to better support future teachers in fostering the kinds of second-order changes that could transform schools.

Supporting College Freshmen's Knowledge of Fractions With Serious Video Games

Yan Tian, University at Albany, SUNY, ytian3@albany.edu
Caro Williams-Pierce, University of Maryland, carowp@umd.edu
Reza Feyzi-Behnagh, University at Albany, SUNY, rfeyzibehnagh@albany.edu
Tara Yasenchak, University at Albany, SUNY, tyasenchak@albany.edu

Abstract: This study explores the use of two interactive serious video games, Slice Fractions and Slice Fractions 2, in supporting college educational opportunities program freshmen to develop knowledge and understanding of fractions. With a quasi-experimental design, we collected data from 14 participants, each finishing a pre-game interview, gameplay, and a post-game interview. Preliminary data analyses revealed that the participants scored significantly higher on the post-game assessment intended to measure fractional schemes/operations.

Introduction

Well-designed serious video games (SVGs) have great potential in mathematics education. Yet it is unclear how video games contribute to better learning. From the perspective of situated epistemic cognition (Hammer & Elby, 2002; Hammer et al., 2005), knowledge is emergent and comes from activations of fine-grained resources; stable activations of locally coherent sets of epistemic resources form frames, which are context-specific structures guiding one's interpretations and actions; to learn is to differentiate varying situations and flexibly draw on appropriate resources. The concept of frame is very similar to scheme, which comprises a perceived situation, associated activity, and expected result (von Glasersfeld, 1995). Because of the compatibility, while taking a broad situated epistemic cognition perspective, we draw on existing constructs and findings from the scheme theory to investigate the learning of fractions in gameplay.

Slice Fractions (SF1) and Slice Fractions 2 (SF2) are two SVGs that organically integrate mathematical content and game mechanics, offering a visual and action-based experience of fractions along with rich opportunities for inquiry, exploration, and strategic thinking. Previous empirical studies found SF1 to be helpful for Grade 3 students' learning of fractions, to the same extent as or superior to traditional instructions delivered by teachers or worksheet apps (Cyr et al., 2019; Gresalfi et al. 2017). Yet we still lack understanding of how the gameplay has contributed to students' knowledge and practices. Also, these games are not yet investigated with learners at other ages/levels. This study investigated the use of SF1 and SF2 as remedial tools in supporting undergraduate students who are economically and educationally disadvantaged compared to their other first-year peers, and enrolled in an educational opportunity program (EOP) geared to support them in both finances and learning. For this poster, we ask: How do SF1 and SF2 influence EOP students' fractional schemes/operations?

Methods

This study employed a quasi-experimental design. Each participant finished a pre-game session, gameplay, and a post-game session. Each pre- or post-game session included an assessment and a semi-structured interview focusing on one's knowledge of fractions and views of mathematics. Adapted from Norton, Wilkin and colleagues' (2009, 2018) studies, each assessment contained 24 items eliciting six fractional schemes/operations (4 items on each): the part-whole scheme (PWS), the partitive unit fraction scheme (PUFS), the partitive fraction scheme (PFS), the splitting operation (SO), the iterative fraction scheme (IFS) and the reversible partitive fraction scheme (RPFS). Depending on one's pre-game performance, a participant played the easier Slice Fractions (SF1) and/or the more challenging Slice Fractions 2 (SF2) for a total of 1-1.5 hours during the gameplay session.

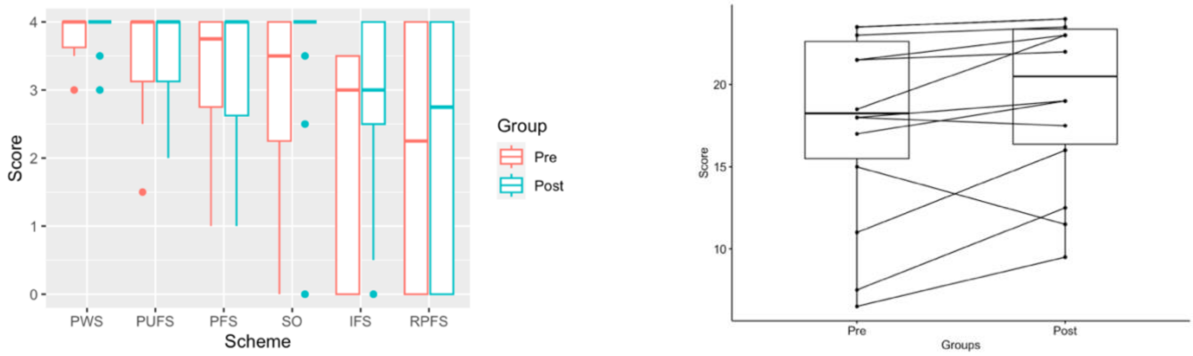
Participants were 14 EOP freshmen from a large public university in the U.S., with an average age of 18 years old. Seven were females, six were males and one was non-binary. Also, seven were African Americans, three were Asians (including South Asians), and four were Hispanic/Latinx (two participants had multiple races/ethnicities). All participants had fractions reviewed in a 5-week pre-college summer program and were taking intensive pre-calculus or calculus. Seven participants played SF1 and seven played SF2. To analyze the pre-and post-game assessments, first, we evaluated each item and assigned 0 (incorrect), .5 (correct with assistance), or 1 (correct without assistance). Then, we calculated the sums, so a participant received a score between 0 and 4 on each scheme/operation and a total score on each assessment.

Preliminary results and next step

Figure 1a displays the participants' pre- and post-game assessment performances on each fractional scheme/operation. The boxplots suggest that the participants as a group primarily made progress on items intended to measure the splitting operation (SO; $M_{pre} = 2.96$, $SD = 1.43$; $M_{post} = 3.57$, $SD = 1.11$), and the iterative fraction scheme (IFS; $M_{pre} = 2.11$, $SD = 1.66$; $M_{post} = 2.79$, $SD = 1.37$). Looking at the participants' overall performance, at pre-game assessment, they had an average score of 17.71 ($SD = 5.82$); at post-game assessment, the average score was 19.18 ($SD = 5.08$). Figure 1b shows the paired plot of the participants' assessment performances, which suggests that playing Slice Fractions (SF1) or Slice Fractions 2 (SF2) helped make an improvement on fractional schemes/operations. To better understand the impact of the gameplay on fractional schemes/operations, we evaluated the assumptions and conducted a paired t-test. Even though our sample size was small (< 30), following a Shapiro-Wilk test, we failed to reject the null hypothesis that the paired differences followed a normal distribution ($w = .91$, $p > .05$). Therefore, we could assume the normality of the data and proceed with a paired t-test. There was a significant difference between the participants' pre- and post-game performances on fractional schemes/operations[$t(13) = 2.36$, $p < .05$] with a moderate effect size (*Cohen's d* = .63).

Figure 1

(a) Boxplots of the Participants' Scores by Scheme/Operation; (b) Paired Plots of the Participants' Total Scores



(a) (b)

Although this is only the first step in a mixed methods analysis, we are nonetheless able to partially answer our research question: How do SF1 and SF2 influence EOP students' fractional schemes/operations? Our analysis here shows that the games helped the students improve their fractional schemes and operations, particularly the splitting operation and the iterative fraction scheme. Next, we will qualitatively examine the gameplay data and the interview data, comparing the participants' explicit knowledge of fractions and views of mathematics learning pre- and post-gameplay, as well as exploring themes in the participants' gameplay experience. Lastly, we will explore the similarities and the differences in knowledge of fractions exhibited in different contexts, from the perspective of situated epistemic cognition, thus triangulating the assessments, the interviews, and the gameplay.

Knowledge Facilitating Epistemic Game Moves

Hillary Swanson, Utah State University, hillary.swanson@usu.edu

Abstract: This paper introduces a new category of knowledge, which integrates ideas from two existing frameworks: *epistemic forms and games* and *knowledge in pieces*. This category features knowledge elements that facilitate the enactment of moves made in epistemic games. Resources for *epistemic game moves* work synergistically with epistemological and conceptual resources during the enactment of epistemic games. The paper introduces the two foundational theoretical frameworks and then introduces the new category of knowledge.

Introduction

The importance of prior knowledge in learning is widely accepted. Constructivist perspectives view students' pre-instructional knowledge as abundant with resources for the construction of more formal knowledge. Research has documented resources for building knowledge of different kinds across a range of domains. This includes resources for developing both *conceptual* and *epistemological knowledge* (Goodhew et al., 2019; Hammer & Elby, 2002). Yet other research has documented resources for productive engagement in *scientific practices*, including argumentation (Hudicourt-Barnes, 2003), inventing and critiquing representations (diSessa et al., 1991), and conducting scientific inquiry (Warren et al., 2001). While this body of work describes a rich terrain of moves students enact during their productive engagement in scientific knowledge-construction practices, it does not model the knowledge underlying these moves. This paper offers a first-iteration description of knowledge underlying and facilitating such moves.

Theoretical foundations

Collins and Ferguson (1993) characterized the knowledge-building work of scientists as epistemic games. Just as the game of tic-tac-toe is constrained by the cross-hatch structure, epistemic games are constrained by corresponding epistemic forms. The forms are templates, which drive the moves scientists use to fill them out. Collins and Ferguson unpack the example of a list game. The list game is played to fill out the list form, which the scientist uses to answer the question: "What is the nature of X?" Playing the list game consists of moves such as adding elements to the list, removing elements, merging elements that are similar, and decomposing elements into more primitive elements. For example, a scientist trying to answer the question: "What is the nature of the Spotted Owl?" might generate a list of known characteristics including the owl's size, shape, color pattern, diet, and behavior.

Knowledge in pieces (KiP) is a theory of knowledge and learning that views knowledge as a complex system of smaller elements, which are drawn together in networks in response to the sense-making demands of a given context (diSessa, 1993). Novice knowledge systems are highly context dependent, meaning knowledge elements are activated inconsistently across contexts for which experts would draw on the same knowledge. The transition from novice to expert (i.e., learning) is characterized as a process of reorganization and refinement of the knowledge system. For this reason, KiP views elements of novice knowledge as *resources* for the construction of more expert knowledge. A goal underlying KiP research is the construction of theoretical machinery for producing computationally explicit models of human knowledge and learning. Towards this, a number of knowledge categories have been defined and populated with elements. This includes categories of conceptual knowledge (e.g., phenomenological primitives; diSessa, 1993) and epistemological knowledge (e.g., epistemological resources; Hammer & Elby, 2002).

A new category of knowledge

This paper introduces a new category of knowledge, which facilitates the enactment of moves made in epistemic games. For simplicity, I call the elements of knowledge in this category *epistemic game moves*. I hypothesize that these knowledge elements can be more precisely described as primitive elements. A number of these elements facilitate reasoning-specific moves and may therefore be described as reasoning primitives.

Epistemic game moves work synergistically with epistemological and conceptual resources to facilitate the play of epistemic games. Imagine the scientist trying to answer the question: "What is the nature of the Spotted Owl?" The scientist must draw on epistemological resources to know that the question can be answered by producing a list, and to know the nature of the list form and the rules for filling it out. The scientist must draw on conceptual resources to know the characteristics of the Spotted Owl. The scientist must draw on knowledge of epistemic game moves to fill out the list form by adding and removing characteristics of the owl, and possibly merging and splitting characteristics. Knowledge facilitating the addition and removal of characteristics involves discerning characteristics that belong to the owl's nature from irrelevant characteristics (e.g., number of owl sightings in a given year). Knowledge facilitating the merging or splitting of characteristics involves recognition of similarity.

There are many epistemic games, including temporal and spatial decomposition games, hierarchical list games, compare and contrast games, cross-product games, agent-based modeling, and analogical modeling. Each of these games can be described in terms of moves played to fill out a corresponding form or template. These moves are facilitated by knowledge belonging to the category introduced in this paper. In the case of temporal and spatial decomposition games, the moves involve knowledge that facilitates dividing a larger entity into smaller components. In the case of hierarchical list games, the moves involve knowledge that facilitates organizing elements according to nested relationships. In the case of the compare and contrast game, the moves involve knowledge that facilitates the identification of meaningful similarities and differences. In the case of the cross-product game, the moves involve knowledge that facilitates the organization of elements along multiple dimensions. In the case of agent-based modeling, the moves involve knowledge that facilitates the identification of system elements and the articulation of the rules governing their behavior and interactions. In the case of analogical modeling, the moves involve knowledge that facilitates mapping between elements common to both the phenomenon of interest and an analog. Considering the knowledge underlying the enactment of moves across epistemic games suggests a general relationship to knowledge involved in processes of analysis and synthesis.

Discussion

This work introduced a new category of knowledge, which facilitates the enactment of moves made in epistemic games. By studying the *epistemic game moves* of novices, we can design classroom experiences that build on students' resources to foster their development of expertise with epistemic games. While students' productive engagement in particular epistemic games has been described in the literature, the present work adds to the discussion by characterizing the knowledge underlying the moves involved in these games. The work is only in its infancy and while the theoretical constructs are inspired by classroom data, more systematic investigation is necessary.

Climate Change Encounters Online: Epistemic Engagement and Emotions on Social Media

Christiana Varda, Eleni A. Kyza
christiana.varda@cut.ac.cy, Eleni.Kyza@cut.ac.cy
Media Cognition and Learning Research Group, Department of Communication and Internet Studies, Cyprus University of Technology

Abstract: This exploratory study sought to understand how adults evaluated a simulated social media post on climate change, relating to meat consumption, by considering the epistemic actions on the post, and participants' subsequent epistemic engagement when prompted to explain their emotions. It extends work on epistemic cognition in information-complex environments and investigates the extent to which prompting reflection on emotions can serve as a means of supporting misinformation resistance. Some preliminary findings are presented and discussed.

Introduction and background

In their day-to-day routines, people turn to the internet to find answers about scientific issues that concern them. Despite the potential that social media platforms hold for raising awareness and increasing engagement with controversial issues such as climate change, information on social media may be misinformative, and purposely designed to elicit an emotional reaction (Zhou et al., 2021). When evaluating controversial information, when the information is novel or contrary to expectation, people can experience epistemic emotions, such as curiosity or surprise, that encourage closer attention to the epistemic qualities of the information, and more specifically to the source and evidence provided (Chevrier et al., 2019). Furthermore, the inherent interactivity of online information means that there is a range of available actions that can enable epistemic engagement with information in order to ascertain the source and the evidence provided. Online, epistemic engagement might manifest via *epistemic actions*, such as clicking on links to evaluate the claims in a post, clicking on the user profile, or even using search engines to retrieve additional information. Such actions can be regarded as epistemic since they are motivated by the need to evaluate the knowledge base for the information claims encountered.

Research examining how emotions influence actions taken during information evaluation has focused on sharing intentions (Bago et al., 2022), which may exacerbate the spread of online misinformation. However, in order to support individuals' resistance to misinformation, we also need to understand what motivates epistemic actions taken online when experiencing emotions. Barzilai and Chinn (2018) state that epistemic engagement varies across a range of situations, including in epistemically unfriendly environments such as social media. The authors theorize that emotions and self-regulation are aspects that should be taken into consideration when designing learning environments that aim to foster epistemic engagement. Emotion regulation is an aspect of self-regulation (Boekaerts & Cascallar, 2006); prompting reflection on emotions can heighten awareness about the emotions experienced and implicitly regulate intense emotional reactions (Torre & Lieberman, 2018). It is unclear how such prompts to reflect on one's emotions while evaluating controversial information bear on epistemic engagement.

In this exploratory study we examined how emotions and epistemic engagement manifest via online actions on a social media post focused on climate change, and the extent to which prompting reflection on emotions can enhance epistemic engagement with information. We therefore asked, during information evaluation of a controversial topic: (1) What epistemic actions are spontaneously taken and why? (2) To what extent does prompting reflection on emotions support epistemic engagement?

Methods

Thirteen undergraduate students participated in the study. Participants were presented with a simulated Twitter post focused on the impact of meat consumption on climate change. The post named a scientist and their academic institution, named a high-impact scientific journal, used argumentation to support the information claim, and included a URL. It also included an image which prominently featured the percentage of all anthropogenic emissions linked to livestock production. The username was blurred out. Participants could click to take any of the actions available on a typical Twitter post. Indicatively, these actions included, but were not limited to: liking, sharing, commenting on, clicking the user profile, bookmarking, or reporting the post, etc. Participants were informed that they could use the internet as they normally would. A manipulation check with 25 participants indicated that the social media used could elicit emotions.

Data were collected using a cognitive semi-structured interview and via screen recording during the evaluation task. Participants were first asked questions about their routine social media habits, were then presented with the social media post and asked to verbalize their thoughts and to take any actions they would normally take. Participants were then asked to explain their actions and were then prompted to reflect on their emotions using a set of emoji cutouts; they were asked to select the emoji(s) that most closely represented the emotions they had experienced, and to put them in order of intensity. This process was repeated with additional posts that used different rhetorical appeals. The average duration of each session was 27 minutes. We coded the data for actions based on the participants' trace data and the emotion(s) explicitly verbalized. Epistemic engagement was examined on the basis of the reasons provided for (a) the action and (b) the emotions experienced, and was coded using the AIR model (Chinn et al. 2014) to capture verbalized epistemic aims, criteria and processes. To answer our research questions, we examined co-occurrences of spontaneous actions and epistemic engagement (RQ1) and verbalized emotions — via prompted reflection —and epistemic engagement (RQ2).

Preliminary findings and discussion

In our first research question we sought to understand what actions were taken on the post and why. Preliminary analyses indicate that participants took a range of epistemic actions on the post including clicking on the URL, searching for additional information on the named scientist and checking the user profile; these actions were motivated by the need to evaluate the source and evidence for the information provided. Additionally, participants also deferred to the opinions of valued others, by stating that they would share information with a more knowledgeable peer, or by clicking on the comments to evaluate how others are responding to the information.

In our second research question, we asked whether our intervention supported epistemic engagement. The actions participants took prior to the intervention were spontaneous and immediate, and the explanations suggest they were motivated by epistemic aims. During the prompt participants paid closer attention to the language used, or the data on the image, while reporting curiosity or surprise. Beyond these emotions, participants also reported feeling sad or worried, and in such instances, they focused on how the information implicated them in contributing to climate change. The latter emotions seemed to turn attention to the topic, rather than the epistemic qualities of the information, but were often experienced alongside epistemic emotions, such as curiosity.

Analyses are ongoing, but preliminary findings suggest that when faced with the controversial topic of reducing meat consumption participants took epistemic actions to evaluate the knowledge claims appearing in the post, particularly by clicking the link. During prompted reflection on emotions participants paid closer attention on the language used in the post and the evidence provided (i.e., the data on the image). Examining how epistemic engagement manifests on social media when emotionally responding to information, can provide insights on how to support epistemic practices that bolster misinformation resilience on social media. Which epistemic actions on social media are driven by epistemic aims, criteria and processes and which emotions can enhance such engagement? Additionally, although the study takes place in a simulated social media environment, which divorces it from the socially inherent nature of the authentic setting, it provides some initial indications as to how emotions can support or constrain epistemic actions. Findings may inform instructional design aimed at bolstering misinformation resilience; moving beyond the cognitive aspects of evaluation and integrating the emotional and behavioral dimensions of evaluating information online may heighten emotional awareness and enacted epistemic engagement during online information evaluation.

Following the Becomings: Intra-Actions in Collaborative Creative Making

Alekh V, Chandan Dasgupta
alekhv@iitb.ac.in, cdasgupta@iitb.ac.in
Indian Institute of Technology, Bombay

Abstract: With this study, we attempt to follow the becomings in collaborative making to understand the intra-actions among the various entities of the situated making context contributing to emergent creativity, by specifically looking at a making context where novice makers collaboratively work on design problem solving**.** Our findings suggest that the collaborative making is sociomaterially entangled, *making together with* human and non-human entities is highly relational and dynamic resulting in emergent creative acts.

Introduction

The new materialist and posthuman frameworks open alternative possibilities to look at learning and creativity with agency conceptualized as emergent manifestations and *becomings* through intra-actions among the entities within the phenomenon, decentering humans from the sole center of actions (Barad, 2003, Pickering, 1993). The notion of matter as being in a constant state of reconfigurations can challenge human-centric approaches in learning and points to rethink learners-non-human encounters (Barad, 2003; Haraway, 1985). The emergent outcomes from the encounters of humans and non-humans thus become unpredictable and cannot be reduced to human actions. Here, we extend the notion of agential cut and intra-activity (Barad, 2003) to *making together with*, to see the intra-actions among the various actors in making contexts that can result in emergent meanings, creativity, and learning. We place *making together with*, as a lens to acknowledge, understand and appreciate the relational and dynamic connections among the human and non-human entities entangled in any making contexts. *Making together with* upholds the idea of flattened ontology which avoids privilege to human entities and considers all material entities as possible actants (Latour, 1996). In this article, we attempt to follow the becomings in collaborative making context to understand the intra-actions among the various entities of the situated making context contributing to emergent creativity (Sawyer & Dezutter, 2009), where novice makers engage in design problem solving.

Methods

Data for this study was collected as part of a Lego Mindstorms-maker workshop where seventh-grade students from an English-Medium school in the city of Mumbai, India engaged in an engineering design problem. Two teams- A and B- were formed randomly and they worked on designing a cleaning robot, where the robot is required to clean at least two of the following trash materials- paper bits, water droplets, eraser dust, and pencil dust. Along with the Lego Mindstorms kit and the supplementary materials (cleaning mop wipes, cardboard, and sponge), each team was also provided with a cost-calculation sheet and a workbook. A facilitator was allocated to each team to take observation notes and provide technical and logistic support. For our analysis, we followed the making activities of Team A, which consisted of two female participants (A1 and A2) and a male participant (A3). We conducted the analysis with data sources as video, photographs, design artifacts and field notes. We followed theories of new materialism and adopted the methodological process of thinking with theory (Jackson & Mazzei, 2012). We plugged the theoretical concept of intra-activity into the data sets in order to gain a deeper understanding of the entanglements in the making process. Instead of coding or categorizing, we looked for ‘‘hot spots,’’ where the data ‘‘glow’’ and ‘‘create a sense of wonder’’ (MacLure, 2013), and the identified hotspots were illuminated through the lens of posthumanism and new materialism.

Findings

We found that the making actions were "messy" and "meshed" with human and non-human elements of the situated making contexts. An instance of *making together with-lego components-makers-facilitator* influencing the flow of creative actions, in making a four-wheeled robot with a cleaning unit attachment is illustrated as below:

A1:	[places the lego EV3 brick over the drive unit].. the brick is falling out.
Facilitator:	Why don’t you use these [points to the slots on lego EV3 brick sides]
A2:	[Checks the lego EV3 brick slots]
A3:	Hey.. plug these [points to lego beams] into the brick holes and then to the drives

Figure 1

Facilitator placing the lego parts in front of the makers (a), Team A visiting Team B's workplace (b), Makers attaching the mop wipe with the sponge using stapler (c), Teams racing with the robots (d)

(a) (b) (c) (d)

Here the makers tried to fix the lego brick onto the vehicle chassis. As the facilitator placed the box of lego frames, beams, and connectors near the makers (see Figure 1(a)), makers and materials engaged in repetitive cycles of adding, connecting, falling, resisting and removing the lego beam and frames to the brick until a stable structure was arrived at. In this instance of becoming of the cleaning robot structure, we see that makers, facilitator, lego kit listening to and responding to each other actions. Also, we see that the *time* intra-acting with the makers, materials, and facilitators as the facilitator gave a sense of the time to complete the making by counting seconds. The leaking time has pushed the team to look for quick and cheap alternatives as the cleaning mop wipe was attached to the sponge combination using a stapler (see Figure 1(c)). Time was always an actor in the entire making process, but this particular instance showed how time shaped the *becoming* of the creative outcome.

Facilitator:	Time is up.. I will count to 10 now
A3:	No,, no.. we need only few seconds.. [looks for bands]
A1:	[Finds stapler] No.. with this [hands over stapler]
A2:	[Attaches sponge with the cleaning mop wipe using stapler]

The designed robot was able to clear out majority of the trash materials from the *test floor*, which made team B to perform the robot task with the same trash materials. As soon as the task was completed, A2 of team A proposed the idea to race with the robots, and both teams engaged in racing with the cleaning robots without changing any design. Thus, *the cleaning robots became racing robots* and *the testing floor became the racing arena* (see Figure 1(d)). This unexpected and unscripted play was short-lived as the facilitators interrupted the racing in between and instructed teams to get back to the work tables.

Discussion and conclusion

In this study, we included human and non-human agencies to understand the *making together with* various entities of the situated making context, leading to emergent creative acts. Makers and materials engaged in repetitive cycles of resistance and accommodation while materializing ideas as in the case of mounting lego EV3 brick (Pickering, 1993). The relational dynamics of the entities involved in the making were evident in situations where the *floor* turned to *test floor* and then into *racing arena*. The making *grew* across space and materials as the makers entangled with sketches, Lego kit, supplementary materials, and visited team B in another room (see Figure 1(b)), to review making. The *actant* time revealed itself towards the end of the making activity. We think about the spontaneous learning which could have emerged via unexpected modes of play, if the *racing* was not stopped.

Pedagogical Practices Associated With Sophisticated Pedagogical Scenarios Using VR Simulations in Science Courses

Bruno Poellhuber, Université de Montréal, bruno.poellhuber@umontreal.ca
Christine Marquis, Cégep de Saint-Jérôme, cmarquis@cstj.qc.ca

Abstract: In the context of the documented decline of student interest in science, ascribed to a high level of concept abstraction, the sheer quantity of science concepts and teacher-centred teaching approaches, we tested the potential of desktop VR (DVR) simulations to engage students. The literature shows that the activities and support built around the simulations themselves are of utmost importance. In this design-based research involving 39 faculty and 5,780 students, the research team and the pedagogical team accompanied teachers in their development of pedagogical scenarios, with tools derived from the NRF/Jeffries (2022) model in nursing simulations. Scenarios were documented through individual teacher interviews. A multilevel regression analysis to predict the students' behavioural engagement showed that the scenario score, associated with high-quality scenarios, is the single and most important level-2 variable associated with the teachers. Pedagogical practices associated with high-scores scenarios were analysed and compared to those associated with low-scores for the prebriefing, briefing, simulation and debriefing phases. Sophisticated scenarios are characterized by more activities in the briefing and debriefing phases, as well as by collaborative activities.

Introduction and theoretical framework

Despite the increasing importance of science and technology and STEM programs in our society and in higher education, we are observing a slow but continuous decline in student interest in science and technology, starting in high school (Potvin & Hasni, 2014). The high level of abstraction of science concepts, the very wide scope of science content (in biology, for example) and teacher-centred approaches have been identified as possible explanatory factors. Active learning and student-centred teaching strategies have been identified as a promising solution (Freeman et al., 2014). VR simulations allow for errors and offer access to rare or inaccessible realities or specialized equipment, while improving the learning and understanding of both theoretical concepts and laboratory techniques and arousing interest (Martinez-Jimenez et al., 2003). In the domain of desktop virtual reality (DVR) simulations, the instructions, activities carried out before and after the simulations seem to be more important than the simulations themselves, particularly when coupled with gaming elements (Merchant et al., 2014). This led us aim at exploring the pedagogical and didactic potential of scenarios that involve virtual reality simulations for postsecondary science learning. In another portion of the project (Wall-Lacelle et al., to be submitted), a multilevel regression with the students' behavioural engagement as dependent variable led to the identification of the scenario's quality score as an important variable associated with the teachers level. This led us to identify practices associated with high-score scenarios, which is the focus of this article. The concept of a pedagogical scenario is present in instructional design literature, but it is also present in health sciences literature, where pedagogical scenarios are constructed to precisely describe the sequence of activities carried out by students before, during and after a simulation. We relied on an adaptation of Jeffries (2020) framework used for nursing simulations, that describes activities that can take place at different moments; pre-briefing and briefing (before the simulation) and debriefing (after the simulation). Because of its simplicity, we relied on Chamberland et al. (1998) typology to classify teaching methods and activities along three axes; 1) teacher-centred vs. student-centred; 2) mediatized or non-mediatized; 3) the group organization: individual, team or class, and coded them along their modality (face to face, remotely synchronous, remotely asynchronous). From the students' perspective, the research is grounded in Pintrich's (2003) expectation/value motivation model and Fredricks's (2004) view of engagement (questionnaire).

Methodology

This design-based research project (Brown, 1992) involved the participation of 39 teachers (8 university teachers and 31 college teachers) and 5,780 students from one university and six colleges in three distinct iterations corresponding to the following semesters: winter 2021, fall 2021 and winter 2022. Courses and labs in the winter 2021 semester in Quebec were taught almost totally remotely. A mixed methodology relying on both individual questionnaires and individual interviews (teachers) was deployed. The participants were volunteer science teachers and their students. The teachers used Labster simulations that are contextualized in real-world problems and are somewhat gamified in some kind of mission. The team of researchers and educational developers assisted them through collaborative scenario design activities in each discipline (biology, chemistry, physics). After living one of these pedagogical scenarios, the students had to answer a motivation and engagement questionnaire. The pedagogical scenarios were analysed and rated based on 11 criteria derived from the NLN/Jeffries model (2020). Each pedagogical practice in the scenario was then classified and we classified scenarios in 3 categories.

Results

The pedagogical practices associated with the high-score scenarios were compared to those associated with low-score scenarios for each phase: prebriefing, briefing, simulation, debriefing. Regarding the prebriefing phase, the high-score scenarios rely more on student-centred activities (blue), as well as on non-mediatized activities (red). These prebriefing activities are also more often carried out in person (grey), while the low-score scenarios did them remotely, either asynchronously or synchronously. Overall, the high-score scenarios have far more briefing activities than the low-score scenarios, relying heavily on teacher-centred activities with the class. Teachers give logistical instructions, present the whole scenario and/or the learning objectives and the simulation itself and point out the most important aspects or key elements. During the simulation phase, the high-score scenarios also rely on teacher-centred activities aimed at providing student support (for ex., circulating around the class to answer the students' questions). While the low-score scenarios rely mainly on individual activities, the high-score scenarios rely mainly on collaborative activities, as well as on non-mediatized activities, in face-to-face settings. For example, many teachers had the students work in teams, with a roadmap containing questions to be answered, or had them work in teams using a whiteboard. Overall, the high-score scenarios have far more debriefing activities than the low-score scenarios, relying on student-centred activities, often along with teacher-centred activities with the whole class. They also rely on non-mediatized activities and in-person activities.

Discussion and conclusion

The results show that high-score scenarios differ from low-score scenarios in multiple ways. The former are richer and more complete, which is not surprising, and rely on far more activities in the briefing and debriefing phases. Furthermore, in the simulation phase, they rely on teamwork and analogue documents to be completed during the simulation by team members. The activities during the simulation in the low-score group tended to be individual and asynchronous, which likely means they were assigned to students as out-of-class assignments with little or no guidance or support. The activities in the high-score group tended to be face-to-face, in class, for all phases. This context offers teachers a better chance to give more complete instructions, to monitor the students' progress, to lead debriefing discussions or teamwork and/or to wrap up with a review of the most important things to remember. The evolution of the context from remote to face to face may also reflect some ot the evolutions of the scenarios with courses gradually moving from remote in winter 2021 to face to face in winter 2022.

The Role of Whole-Class Conversations in Supporting Early Elementary Students' Engineering Design Sense-Making

Kristen Wendell, Tufts University, kristen.wendell@tufts.edu
Chelsea Andrews, Tufts University, chelsea.andrews@tufts.edu
Jessica Watkins, Vanderbilt University, jessica.watkins@vanderbilt.edu

Abstract: We consider how intentionally planned and facilitated whole-class conversations can "make space" for students' sense-making about engineering problems and solutions and position them with epistemic authority to contribute to collective thinking. We conducted a case study on a first-grade engineering lesson that included whole-class Idea Generation and Design Synthesis Talks. We found students sense-making as they refined their design proposals and analyses in light of classmates' contributions to the whole-class conversations.

Introduction

For elementary students, the task of constructing an artifact for an engineering design challenge offers an opportunity to construct knowledge. As they design solutions to problems, students can build knowledge about how designed systems work, how they interact with the natural world, and how they influence people and society. However, for engineering design experiences to be sites of knowledge building, students need support to engage in *sense-making*, both individually and collectively. Sense-making involves developing understandings of the world through generating, using, and refining one's ideas in interaction with other people, representations, tools, and objects (Schwarz et al., 2020). In this paper we consider how Design Talks—intentionally planned and facilitated whole-class conversations that can be incorporated in engineering design lessons—can "make space" for students' sense-making about engineering problems and solutions and position them with epistemic authority to contribute to the class's collective thinking (Engle & Conant, 2002; Haverly et al., 2020).

With a team of elementary teachers and engineering education researchers, we have been exploring five different kinds of Design Talks. Here we focus on a case where a teacher implemented two Design Talks within a lesson—Idea Generation and Design Synthesis Talks. We ask: *How did these Design Talks make space for early elementary students to participate in sense-making about engineering designs?*

Table 1
Design Talks are whole-class conversations that can connect students' engineering design work to NGSS practice standards (talks need not be implemented sequentially)

	Framing Question	Sample Teacher Prompts
Impact	Should we design this? Who and what will be impacted?	If we designed this solution, what might happen?
Problem-Scoping	What do we need to consider to solve this problem?	Whose perspectives should we consider in solving this problem?
Idea Generation	What are multiple possibilities for solving the problem?	What ideas do you have for solving the design problem?
Design-In-Progress	Why did a design perform as it did? What features should we change?	Why do you think this device performs in this way?
Design Synthesis	What are similarities and differences in our designs? What can we learn from these patterns?	What are different categories of solutions?

Data collection and analytical framework

This qualitative descriptive case study comes from a first-grade engineering design lesson on designing a tool to help Kindergarteners more easily use the monkey bars. The lesson took place at a suburban elementary school in the northeastern U.S. during a curriculum unit on plant and animal structure and function. Researchers video recorded all large-group talk among the class of 14 students and all small-group interactions of one focal group of students. We selected this lesson's two Design Talks for further study after we noticed that multiple students were offering contributions and that multiple ideas were at play in the space; we also were interested in these conversations given that they involved the youngest learners in our project.

In conducting this research, we were grounded in the perspective that learning engineering involves increasing participation in its disciplinary practices. To look for evidence of the practice of sense-making, we drew on the notion of epistemic authority (Carlone, Mercier, & Metzger; 2021; Engle & Conant, 2002). We explored when and how students exercised authority to make contributions to the class's collective thinking.

Findings

The lesson opened with an Idea Generation Talk that offered opportunities for students to brainstorm multiple solutions to the problem. The teacher, Ms. M, began the talk by displaying a photo collage of plants and animals that excel at vertical movement and inviting her students to brainstorm: "So we want to design something to help kindergarteners be able to use [the monkey bar] structure. These pictures of some plants and animals might give you some ideas of what we could design. What are you noticing?" In the resulting 10-minute large-group conversation, 12 of the 14 students voiced contributions and connections. Defying the stereotype that first graders fixate on their own ideas, these students worked with a wide range of design ideas, refining both their own and others' ideas as the conversation evolved. The first five students to propose ideas suggested gloves and shoes with special features for jumping, stretching, and sticking. Then, showing epistemic authority to evaluate and refine the community's ideas, a sixth student noticed that if the tool was "too sticky, they can't, what if they can't swing?" Ms. M valued this different way of contributing, pointing out a new problem nested within the solutions proposed so far, and invited more thoughts. Additional students weighed in with new designs that had features to decrease stickiness or detach once the Kindergartener was ready to swing to a new bar. For instance: "when you're about to swing, there's these little slots, that keep out a couple more of those things, so then you can swing a little better."

After students drew individual sketches of their design ideas, the teacher facilitated a Design Synthesis Talk. She asked each student to display their sketch and briefly describe their idea to the group. Then she asked the class how they might summarize the set of ideas into four or five "big ideas" to tell the Kindergarteners. Students pointed out that one group of ideas prioritized sticking to the monkey bars, another group focused on reaching farther, and another group focused on jumping. These categories reflected not just different design parameters but altogether different functions for playing on the monkey bars. Ms. M wrote these categories across the top of the white board, and each student considered the main function of their idea and posted their sketch under what they thought was the best heading. Some students saw that their design had characteristics of several categories, and they asked for advice from classmates. This realization of a difficult choice and request for help from other students showed that they saw their peers as having authority to contribute to the class's work. Thus, in this Talk, we observed that students were positioned with epistemic authority to identify common themes across their solutions and advise each other on how to classify different solutions.

Conclusion

In this case study we found first graders engaging in serious engineering design thinking during two Design Talks where they collaboratively generated and then compared ideas. Initiated by carefully framed open-ended prompts and sustained by Ms. M's responsive facilitation moves, the Design Talks were participation structures that enabled nearly all the students to author themselves as contributors to the class's knowledge about possible structures and functions that might solve the kindergarteners' monkey bar problem. These findings highlight the promise of Design Talks for making space for students' shared sense-making in engineering.

Co-Designing for Environmental Engagement: Moving Inside People Outside and Moving Outside People Outdoors

Heather Killen, Elizabeth Bonsignore
hkillen@umd.edu, ebonsign@umd.edu
University of Maryland, College Park

Abstract: We developed, with youth, a framework categorizing how people interact with nature. Our framework, *inside* versus *outside* versus *outdoors*, was developed using assets-based co-design principles with a small group of young men. Artifact analysis from co-design sessions found that our group readily applied this framework to community park infrastructure, community and individual behaviors observed within parks, and to support conversations involving participants' personal values and sociocultural contexts.

Language to frame how people approach nature

Educators focused on promoting caring environmental attitudes have often emphasized first connecting people with nature. Sobel (2004) talks about how people must have "an opportunity to bond with the natural world to learn to love it before being asked to heal its wounds" (p. 9). But what constitutes the natural world? Sweitzer, Davis, and Thompson (2013) located their place-based climate change educational efforts in National Parks, investigating how the love and care people have for these exemplary natural places might inspire climate change action. Certainly, national parks are part of the natural world, but many people don't have access to these kinds of exemplary natural spaces. Focusing only on this type of nature to foster connection may introduce inequity. Researchers have responded to this limited outlook by exploring how people connect to the nature found within places that are more urban and human constructed – which can also be deeply imbued with human emotion and meaning, and therefore hold power as contexts to support nature-connectedness (Lim & Barton, 2010).

This is not to say that the nature in human constructed places like playgrounds within urban parks is exactly like the nature in large, protected, undeveloped areas like national parks. However, these differences are not easily captured by current language. We might use terms like wild, uncultivated, undeveloped, untouched, or native to describe a national park, but these same terms could also be accurately used to describe the grassy median found between each direction of a large freeway. During work with youth, researchers and participants collectively adopted language that spoke to the different kinds of nature found in a freeway median versus a national park. Further, we found that by using a simple categorizing language of *inside*, *outside*, and *outdoors* we were able to talk more clearly about the different sociocultural values we and our families held in a neutral way, allowing for generative conversations about how different people connect, or do not connect, to nature.

Context, methods, and analysis

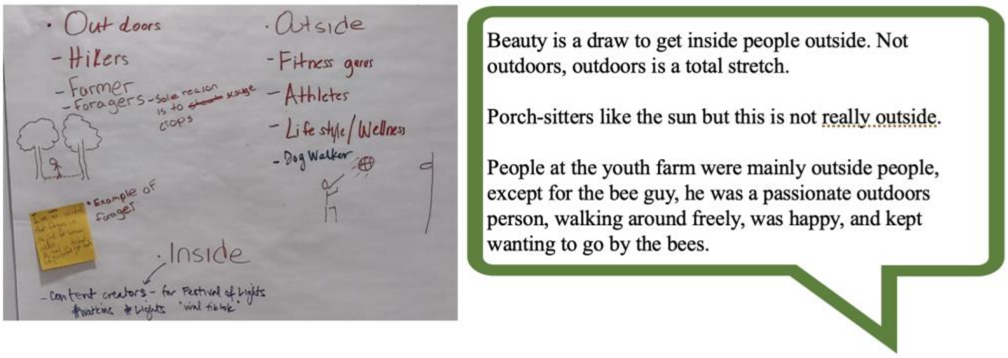
We worked with four youth, ages 16 to 19 and self-identifying as Black men, during a six-week, county-sponsored youth employment program. This program, located in a suburban area adjacent to a major metropolitan city, involved work and mentorship with municipal employees to support park sustainability and plant cultivation efforts. Twenty hours of each 40-hour week were led by the authors. Through assets-based co-design, which highlights naming and using participant's assets and capacities to build community capital (Wong-Villacres et al., 2021), we collectively explored how community members used different local parks and how Wi-Fi connectivity within those parks might support environmental education. As part of information gathering to support our program goal, in an early session we listened together to an interview, conducted by Jen White, of writer Baratunde Thurston (Harven & Remington, 2022). In that interview, Thurston and White discuss how the idea of "going outside" versus "going outdoors" differed for them as children. This struck our group very powerfully. We quickly adopted the categorizing language of *inside*, *outside*, and *outdoors*. In this poster we present our qualitative analysis, using structural and value coding (Saldaña, 2021) of 18 co-design artifacts that captured group reflection and brainstorming and journal entries written by the researchers at the conclusion of every session. We report how we collectively developed *inside*, *outside*, and *outdoors* as a framework to determine ways to promote opportunities to reflect on and situate the park users we observed, ourselves, and our families.

Findings: Three framework applications

Analysis indicated that our group used the framework of *inside*, *outside*, and *outdoors* in three primary ways. First, we used the language to frame a clearer understanding of community park infrastructure and community and individual behaviors observed within parks. In analyzing the design artifacts, we observed that our group readily recognized how park areas fit within the framework in straightforward ways. For example, built installations such as playgrounds and basketball courts were “outside areas,” while unpaved nature trails were “outdoors.” As seen in Figure 1, participants found the framework useful to categorize people and activities that we had observed within various parks. Athletes, “fitness gurus,” people interested in lifestyle and wellness, and dog walkers as outside people, while hikers, farmers, and wild food foragers were outdoors people.

Figure 1

Co-developed ideas of how people might be categorized in the inside/outside/outdoors framework. On the left are captured ideas within a group brainstorming session. On the right are examples of some of the ways youth participants enacted these categorizations within group discussions.



Beauty is a draw to get inside people outside. Not outdoors, outdoors is a total stretch.

Porch-sitters like the sun but this is not really outside.

People at the youth farm were mainly outside people, except for the bee guy, he was a passionate outdoors person, walking around freely, was happy, and kept wanting to go by the bees.

We also observed the framework supported conversations about values. Journal entries recorded conversations in which inside people were discussed positively as content creators that might be enticed to bring their inside activities outside. Discussions about the value of being outside versus inside (fitness, mental health, and more connection to food), what might constitute each context, and what people might fear about being outside, such as being around insects, was also supported (see Figure 1). When discussing the challenges of shifting outside people (which many youths self-identified with) to outdoors people, a discussion of safety issues tied to race was sparked.

Perhaps most powerfully, we found the inside/outside/outdoors framework supported conversations involving participants’ personal sociocultural contexts. Analysis of researcher journals indicated that our group was able to use the framework to place themselves and their family members in the park space, and therefore in nature. For example, a researcher recorded how our youngest participant discussed their father as an inside person that only was outside to bring him to the park when he was young. This was the first time this participant shared anything about his family. As researchers who identify as older, non-black woman (one of us is White and one of us is Asian American) we found this categorizing language, supported through an asset-focused design approach that allowed participants to challenge beliefs about themselves and appreciate their strengths, broadened conversations and opened space to talk about values across socio-cultural backgrounds.

Guide, Safety Net, Project Tester, and More: Investigating the Roles of Facilitators in an AI Summer Camp

Yukyeong Song, University of Florida, y.song1@ufl.edu
Xiaoyi Tian, University of Florida, tianx@ufl.edu
Joanne Barrett, University of Florida, jrbarrett@coe.ufl.edu
Maya Israel, University of Florida, misrael@coe.ufl.edu
Kristy Elizabeth Boyer, University of Florida, keboyer@ufl.edu

Abstract: Summer camps have become popular for introducing K-12 learners to computer science (CS) and artificial intelligence (AI) in informal learning environments. Facilitators play crucial roles in guiding and engaging learners in these contexts, but there is limited research on their roles in informal AI learning. This paper examines facilitators' dialogues with campers in a middle school AI summer camp, identifying eight major facilitator roles. The roles differed depending on group dynamics and project phase. The paper provides empirical grounding to define facilitators' roles in AI learning and guide the design of professional development for camp facilitators.

Introduction

Informal learning settings, such as summer camps, are becoming more popular in AI education due to their less structured nature and lack of school-based performance evaluations (Callanan, Cervantes, & Loomis, 2011). Research has shown that summer camps improve students' learning, build confidence in AI and STEM fields, and encourage interest in pursuing future careers in STEM (Bhattacharyya, Mead, & Nathaniel., 2011; Yi, Gadbury, & Lane, 2021). AI summer camps often introduce innovative technologies such as machine learning and conversational AI and employ hands-on and project-based learning, aligning with the constructionists' view of learning. However, engaging young learners in hands-on activities and project-based learning is often challenging without proper guidance and facilitation (Roque & Jain, 2018).

Facilitators play a critical role in constructivism learning, particularly in informal learning settings, as they often determine the quality of the camp experience (Owens & Browne, 2021). However, there is currently no comprehensive framework for understanding facilitators' roles in AI education. Previous frameworks have focused on specific aspects of facilitation or specific contexts (Wang, 2008; Owens & Browne, 2021), making it challenging to apply them to AI learning. Therefore, this study aims to explore the interaction dynamics between facilitators and learners in an AI summer camp and provide a theoretical ground for defining and systemizing the roles of facilitators in informal AI learning. This research addressed the following research questions (RQs): **RQ1.** What are the roles of camp facilitators in informal AI learning settings? **RQ2.** How do the facilitators' roles vary by facilitators and the project phase?

Methods

A basic interpretive qualitative methodology (Merriam & Grenier, 2019) was used to label the interactions between the facilitators and campers and draw themes from them. Before the study, we obtained approval for this study from the University of Florida's Institutional Review Board.

In the summer of 2021, we conducted an in-person two-week-long AI day-camp to provide middle school learners with a learning opportunity to design and develop conversational AI in the southeast region of the United States. Fourteen campers participated, including two girls and 12 boys, 11 Black/African American, and 3 White/Caucasian students. We recruited seven camp facilitators, including five undergraduate, one graduate student, and one post-doctoral researcher, four women and three men, 2 Black/African American, 2 Asian, and 3 White/Caucasian.

The data was collected over the three days in the second week. On day 6, campers brainstormed the project ideas; on day 7, they engaged in the initial chatbot development, and on day 8, they did final touch-ups and connected the projects to Google Home speakers. Each camper pair was assigned to one facilitator and their interactions were recorded using OBS software on the study laptops. The recordings were later transcribed and anonymized by the research team.

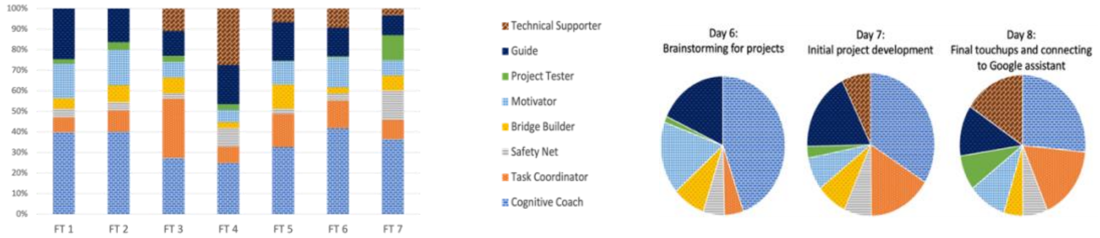
This study framed facilitation into four categories; cognitive, social-emotional, managerial, and technical and defined the interactions in each category (Graesser & Person, 1994; Owens & Browne, 2021; Wang, 2008). Two researchers labeled one full recording together for further refinement of the initial coding scheme. They worked independently to label 20% of the transcription and iteratively reviewed and improved the coding scheme until satisfactory inter-rater reliability was met (Cohen's kappa = 0.85). Then, the rest transcriptions were labeled independently. We grouped the similar interactions yielding eight themes. To increase the credibility of our findings, we conducted a member checking and data triangulation using facilitators' daily reflection notes.

Results

After coding 1,847 interactions between facilitators and campers, we derived eight themes, which we present as eight primary roles of facilitators; Cognitive Coach (624; 33.8%), Guide (288, 15.6%), Task Coordinator (247, 13.4%), Motivator (198, 10.7%), Technical Supporter (168, 9.1%), Bridge Builder (126, 6.8%), Safety Net (117, 6.4%), and Project Tester (79, 4.2%). We are also interested in how the frequency of each role varied among facilitators and by project phases (see Figure 1).

Figure 1

Distributions of facilitators' roles by individual facilitators (left) and different phases of the project (right)



The variation of distribution among individuals was due to the need to adjust their roles depending on the campers. For example, campers in FT 4's group may need more help with technology because of limited digital literacy. In contrast, FT 6 might need to act as a motivator more because campers were easily distracted. Facilitators also adjusted their roles depending on the project phases. For example, "Cognitive Coach" and "Motivator" peaked on day 6 because it was a Monday, and many campers needed a refresher and review on the concepts. "Technical Supporter" emerged from day 7 when campers started developing their projects, and the percentage enlarged to day 8 as they advanced the projects using more complex features in Dialogflow. In contrast, "Bridge Builder" began to decrease on day 8, as campers had already spent enough time building rapport with their partners.

Conclusion

By examining the roles of facilitators in AI summer camp settings, this study provides insights into the competencies required for camp facilitators and designing professional development for them. This study's findings can contribute to the development of a comprehensive framework for understanding facilitators' roles in AI education, ultimately supporting the growth of AI and STEM education.

Programming Time: Exploring Time as a Cultural Construct Across Novice Computational Platforms

Ravi Sinha, Phyllis Kyei Mensah, Breanne K. Litts
ravi.sinha@usu.edu, phyllis.kyeimensah@usu.edu, breanne.litts@usu.edu
Utah State University

Rogelio E. Cardona-Rivera, University of Utah, rogelio@eae.utah.edu
Melissa Tehee, Utah State University, melissa.tehee@usu.edu

Abstract: Public critiques of technologies and the algorithms that power them have pushed designers to critically consider for whom they design and who they include in design processes. In education, similar critiques highlight how computational technologies designed for novice learners commonly privilege certain ways of knowing and being. In response, this poster explores how the cultural construct of time is represented across computational platforms for novices and what this means, particularly for Indigenous learners and designers.

Introduction

Issues of (mis)representation and lack of representation of minoritized groups have shaped the underlying computational models that drive technology "innovation." This has caused profound harm to these groups, particularly Indigenous communities. Given that industry leaders in technology design, such as Apple, Google, and Microsoft, cannot resolve this misrepresentation (Eubanks, 2018; Noble, 2018; O'Neil, 2016), education scholars also find similar issues in education technologies (Litts et al., 2021). The solution requires acknowledging how these technologies and novice computational platforms are themselves instantiations of cultural systems that privilege particular ways of knowing and being in the world.

As an example of how misrepresentation is embedded in novice computational platforms, scholars have found that Indigenous cultures tend to use event-based time intervals that rely on events, seasons, natural cycles and elements, social norms, etc. (Sinha, 2019), rather than the quantified time-based metric interval systems such as clocks, seconds, minutes and hours (Sinha et al., 2011), which many novice computational platforms tend to rely on. In response to this persistent need for novice computational platforms to design for diverse interpretations and representations of time, we investigate the research question: *how do novice computational programming platforms represent the cultural construct of time*? To address this question, we analyzed how time is represented in 45 computational platforms designed for novice learners. Our analysis illustrates how these platforms can privilege particular cultural ways of knowing and being. Findings highlight opportunities to design for accessible forms of programming that align with Indigenous representations of time.

Methods

We curated a list of 45 novice computational platforms that are frequently used in K-12 settings using search terms such as "block-based computational platforms," "digital storytelling platform," and "immersive storytelling platforms." Across platforms, we searched for representations of "time" as either a programming element on the platform or in tutorial blogs on the platform's online community. We identified time features in 29 of the 45 platforms and conducted further analysis to identify the specific ways in which time is represented.

Findings: Representing time

For this poster, we share how time is represented in three platforms: Scratch, Alice, and MIT App Inventor. These serve as illustrative examples of how time is represented across platforms. We found that there are accessible and simple ways to represent time functionality in a game or story. For example, in Scratch, the "current ()" block can be used to report the year, month, date, day of the week, hour, minute, or second in a project. The block displays time in a 24-hr format, and a date based on the device's local time. This affords learners to include a 24-hr clock and a Gregorian calendar date in their projects. However, it becomes more difficult to include date-time in other formats. For example, adding a 12-hour clock requires more complex coding (see Figure 1).

Figure 1

Comparison of 24-hour clock (left) and 12-hour clock (right) in Scratch.

```
when clicked
forever
  set Time to join current hour join : join current minute join : curren
```

In Alice, time is represented in projects using the event-listener option. For example, the event listener "addTimeListener," can execute actions after a certain time has elapsed. In the code snippet below (Figure 2a), after myFirstMethod is executed, the "walking footsteps" audio file plays after a delay of 0.25 seconds. In Figure 2b, to implement an animation where an eagle flies to a log and sits on it, the duration of each move - forward, up, down during flight can be controlled via the "delay-duration" option to further smoothen the visual effect in the scene.

MIT App Inventor also provides learners a range of approaches to integrate time in their games and stories. Objects can be moved or transformed on canvas by setting the time intervals. Timer event is the most general method to define those set time intervals. Objects' properties can also be used to define those intervals. For instance, one can specify the "TimerInverval" property to control the animation effect. When moving the object, the smaller the interval, the faster the object will appear moving. The interval is defined in terms of milliseconds. Additionally, it also allows users to add a specific amount of time (e.g., hours, days, years, etc.).

Discussion

The novice computing platforms we examined provided accessible support to facilitate the representation of time in quantified time-metric intervals (seconds, minutes, hours) and dates using months and years after the Gregorian calendar. However, the platforms we explored do not inherently or explicitly provide structures and blocks that allow users to represent time with events, seasons, life, natural, and cosmic cycles, which are fundamental to Indigenous cultures and stories (Sinha, 2019). We envision a future where these platforms provide accessible structures and representations to easily integrate real-world elements and connections by, for example, drawing on weather or location data. While experienced users may rely on advanced skills to replicate event-based time intervals on these platforms, the existing underlying biases in the structures and representations pose significant limitations for novice users. Insights from our analysis reifies the argument made by scholars (e.g., Litts et al., 2021) to (re)examine the deeper design structures of the computational platforms and the implicit biases in their design toward the goal of designing culturally sustaining/revitalizing computational tools for all.

Exploring Students Interpretations and Values of Documentation in Creative Learning Domains

Yinmiao Li, Northwestern University, YinmiaoLi@u.northwestern.edu

Xiaoyang Zhou, Daniel Klug, Daragh Byrne, Marti Louw
xiaoyanz@andrew.cmu.edu, dklug@andrew.cmu.edu, daraghb@andrew.cmu.edu, mrlouw@andrew.cmu.edu
Carnegie Mellon University

Abstract: Within creative domains, documentation is often central to demonstrating outcomes, process and progress. We deployed a design probe to elicit and externalize conceptions of documentation across the same cohort of 11 students in two semesters. We demonstrate the values of documentation to be coherent across background, time, and experience of the student participants. We also share insights on nine main roles documentation plays for students and discuss how documentation plays an important role in communicating work and building self-confidence and motivation for project-based work.

Introduction and background

Documentation is an important but under-studied aspect of learning within creative domains such as art, architecture, design, and making (Sawyer, 2017; Peppler & Keune, 2019). The act of documenting not only enables students to internally reflect on the process of creative inquiry, but it also makes learner's thinking externally visible (Brown, 2002; Ritchhart & Perkins, 2008), reveals struggles and accomplishments (Barron & Darling-Hammond, 2008; Cross, 2007), affords formative assessment (Braun et al., 2019), and enables feedback on learning process and product with stakeholders (Braun et al., 2019; Keune et al, 2022). In this poster, we characterize how students describe documentation activity and its purposes in higher education project-based course settings. Our guiding research question is: *What are the values of documentation that undergraduate student learners self-report?* We developed a series of design probe activities deployed to the same group of eleven undergraduates in Fall 2020 and Spring 2021. The probe invited students engaged in interdisciplinary creative technology programs to reflect on the perceived values of documentation in their creative process. The contributions of this work are: a set of reflective probe activities designed to externalize student valuing of documentation and a coding scheme to characterize documentation values.

Methodology and results

We opted to use a design probe methodology to elicit student perspectives. Four activities were prepared: a mind map task on the term 'documentation'; an image markup task to annotate objects and tools that support their documentation; a diagramming task to map a recent project and how documentation was involved; and an exercise inviting participants to list reasons why they value documentation. *This last activity is the focus of this analysis.* The activities were deployed over the course of a single week, and each took ~15-20 minutes to complete. The development of our design probe, participants, a preliminary analysis of the Fall 2020 data, and example outputs from probe activities can be found in (Chen et al., 2021). To analyze student reflections, we adopted a grounded theory approach (Corbin & Strauss, 2005) and inductively code participants' responses. Throughout our iterative analysis, two coders presented outcomes to the research team to address ambiguities and to ensure reliability.

Across Fall 2020 and Spring 2021, participants responded with 237 value statements (Fall=110; Spr=127). From this, 9 organizing categories were identified. All categories appeared in both Spring and Fall data. Table 1 shows the categories, their definitions, the total number of statements per category (*Frq*), and the number of participants that identified each category in the activity (*Ps*).

Table 1
A Summary of the Categories for the Values of Documentation.

Category: ***Documentation for…***	**Definition:**	**Frq**	**Ps**
… Reflection	Documentation is used to **self**-reference prior project work, and work in progress.	**59**	10/11
…Communication	Documentation is used to accurately inform or persuade, and receive feedback	54	**11/11**

	from **others**.		
…Demonstration	Documentation is used to demonstrate the project attributes and personal capabilities to **others**.	40	10/11
…Self-Regulation	Documentation helps **individuals** build self-confidence, provide motivation for project making	24	8/11
…Record Keeping	Documentation is used to store, archive and organize records of learning artifacts.	17	7/11
…Project Management	Documentation helps with project management: e.g. organizing, multitasking, time management	11	6/11
… Creative Process	Documentation artifacts help support **individuals** generating, exploring, comparing ideas, and showing iterations.	11	6/11
…Proof	Documentation is used as evidence to track accountability to **others**.	6	5/11
…Requirement	Students complete documentation as an **expected professional output** or **course assignments.**	6	5/11

Discussion, conclusion and future work

Documentation is at the heart of creative dialogue with oneself, one's collaborators, and with the extended creative community that learns from and builds on the precedent work of each other. As a key practice in creative-, project- and studio-based learning, documentation acts as a point of both *inward* reflection — an internal motivation for learning —, as well as, *outward* communication — an external motivation of learning. Our work has aimed to better characterize this from a student-centered perspective and highlights that our student participants value these internal aspects in 4 main categories, documentation: for reflection; for self-regulation; for record keeping; and for sustaining the creative process. For the external aspects, students valued documentation: for communication, for demonstration, as proof, and as a requirement.

Preliminary evidence suggests that some students do experience and value documentations' role in fostering self-regulation and in how it provides intrinsic motivation to advance the quality of project work, encourage iteration, as well as, to seek self-improvement of skills and performance outcomes. A better understanding how, when, and why documentation moves from required educational outcome to a valued personal practice is needed. We believe that our design probe paired and coding framework has utility in increasing understanding of documentation as an intersectional practice in creative learning environments; where there are no right answers, but rather choices to be negotiated around which direction to take.

Educators' Ideas About Dignity and How to Support it in Schools

Ashley Seidel Potvin, University of Colorado Boulder, ashley.potvin@colorado.edu
William R. Penuel, University of Colorado Boulder, william.penuel@colorado.edu

Abstract: Teachers play a central role in creating dignity-affirming environments. We explored educators' shifting conceptualizations of dignity over time and the ways they envisioned creating conditions for dignity in schools. Educators conceptualized dignity as respect, inherent worth, kind treatment, a sense of feeling seen and heard, and something that was characteristic of being human. Educators articulated conditions that enabled dignity-affirming classrooms.

Introduction

Within schools and classrooms, dignity is always at stake (Espinoza & Vossoughi, 2014) and policies, practices, and interactions can either affirm or thwart the dignity of its members (Worline & Dutton, 2017). Dignity is a complex concept that involves both rights and responsibilities (Mevawalla et al., 2021). Espinoza and colleagues (2020) define dignity as "the multifaceted sense of a person's value generated via substantive intra- and inter-personal learning experiences that recognize and cultivate one's mind, humanity, and potential" (p. 326). Dignity is contingent upon the opportunities for meaningful learning experiences and the treatment of others, as well as an ethical "anchor" that guides responsibilities toward others (Mahalingam, 2019).

Relationships are at the heart of teaching and learning, and teachers therefore play a central role in recognizing students' inherent worth and in creating dignity-affirming environments. Teachers design learning experiences that can affirm dignity through offering meaningful opportunities for participation, such as when students see themselves in the curriculum. The affirmation of dignity requires repeated opportunities for meaningful participation, characterized by shared decision-making, being seen and heard by those in power (Espinoza et al., 2020), and awareness of the "invisible labor, invisible identities and invisible sufferings" (Mahalingam, 2019, p. 244) in schools. While dignity can be a transformative lens for the "the ways we design and animate educational environments and ought to be a central tool for educators…" (Espinoza et al., 2020, p. 327), there are few empirical accounts of how educators conceptualize dignity. We add to this literature an account of educators' ideas about dignity as they participated in a course sequence focused on cultivating compassion and dignity in schools. We ask: *What conceptions of dignity do educators hold? How do educators envision creating conditions for dignity within their schools and classrooms?*

Methods

We investigated our research questions using interview data collected from educators pursuing a graduate certificate in education focused on creating more compassionate and dignity-affirming school environments (see Penuel et al., in press). Dignity features prominently as a theme in the courses through instructional materials and contemplative practices that explore self-compassion in relation to dignity, and the idea of common humanity as a basis for extending compassion to all beings (see Jinpa, 2015). The 25 participants were PK-12 educators in the certificate program, principally from rural areas. Analysis relied on interviews conducted over Zoom at three time points during educators' participation in the certificate (start, middle, and end). The first interview asked about current understandings of compassion and dignity. The second and third interviews asked educators about course experiences and how, if at all, their conceptions of compassion and dignity changed. Interviews were transcribed verbatim. We focused on 56 excerpts about dignity and followed a multi-step, open coding analysis process.

Results

The most common word used in educators' definitions of dignity was "respect" (n = 23). For Tania, dignity meant showing respect for who people are, "honoring someone's being." For Sharon, it meant "respecting [students] for who they are." After the conclusion of the certificate, Sharon went further, noting that dignity meant "treating [students] with respect for who they want to be and how they want to be." For some educators, dignity meant showing respect for others across lines of difference (e.g., of beliefs, identities). According to Danielle, "Dignity is creating…for the differences around you and holding them to the same respect that you hold your own facets of your identity." Payton said that dignity meant being "more open-minded about all the different types of people and kids that we have here."

The second most common conception of dignity was that it is something that is characteristic of being human (n = 19). Kayla said, "People should be treated with some dignity just because they're people, right? It's part of being human." After completing the certificate, Justin said that dignity was "honoring people just for being human but realizing also that there's something about them that is really magical, and trying to figure out what that is, in every single person." Another common conception was of dignity as inherent worth (n = 18). Brooke commented that dignity "doesn't change" and is "exactly the same in every person," but at the same time recognized it was contingent upon others' actions. Ellison indicated that the dignity inherent in others calls for a response of the self, to honor the dignity of others: "The dignity inherent in other people calls on the dignity in me for a response. There's like this pinging and we're all pinging off each other and dignity is when I can honor the same spark in them that I know is in me." Two other categories of responses to the question of what dignity means emerged: dignity was about treating people kindly (n = 7) and about feeling heard and seen (n = 5). Both are relational dimensions, with the first focused on responsibilities of the actor conferring dignity on another, and the second a quality that is perceived in terms of how others treat them.

Educators also offered images for how to create conditions for dignity in schools (n=11). Five comments pertained to building relationships of respect toward others. For Danielle, dignity involved "creating space for the differences around you" and showing respect for all facets of others' identities. Dominic said that promoting dignity meant "you create an atmosphere where folks [who] have different experiences can feel valued." Brandi suggested that the best way to create conditions for dignity was to keep an open mind in conversations. One educator explained that it was important for students to recognize their own inherent worth and to speak up for themselves when not being treated well. Six educators spoke about dignity in relation to curriculum. One spoke of highlighting the dignity of figures in history and characters in readings. Another spoke of the need to have texts available that reflect the cultural identities of students. A third emphasized the need for students to see themselves reflected in the curriculum. Two others noted that they brought dignity as a topic directly into the curriculum, through engaging their students in discussions of human rights.

Discussion and conclusion

Educators' conceptualizations of dignity largely aligned with the literature, including that dignity refers to the inherent worth and value of a person and that it is an important aspect of what it means to be human. We identified some important extensions in educators' conceptualizations. First, while some scholars distinguish between dignity and respect in that respect needs to be earned (e.g., Hicks, 2011), educators often connected these two concepts. Students deserved to be respected and treated with kindness because of their inherent worth. Educators also recognized that dignity was about feeling seen and heard, a feature indicative of meaningful participation (Espinoza et al., 2020). We view these conceptualizations as educators' emergent understandings that dignity is socially affirmed and validated (Espinoza et al., 2020). Educators also began to articulate the conditions that enabled dignity-affirming classrooms and schools. These included: a) honoring and validating students' diverse identities and experiences, b) developing systems to address interpersonal conflict, create community, and encourage healing, c) designing curriculum where students could see themselves, d) engaging students directly with the topic of dignity within the curriculum, and e) creating an environment that recognized and elevated student voice. These are important steps toward creating dignity-affirming environments through offering opportunities for meaningful participation. Future research should continue to investigate what meaningful participation looks and feels like within schools, not only from educators' perspectives, but also from students' and their families' perspectives.

Holistic Individualized Coaching: Foregrounding Teachers' Psychological and Affective Attributes to Support Learning

Dionne Cross Francis, Pavneet Kaur Bharaj, Kathryn Habib, Anna Hinden, Anna Gustaveson
dicross@unc.edu, pkbharaj@unc.edu, khabib@unc.edu, annarh@live.unc.edu, annagus@unc.edu
University of North Carolina, Chapel Hill

Abstract: In this study, we sought to explore if and how teachers' participation in the Holistic Individualized Coaching (HIC) model oriented them to observe and respond to students' thinking in meaningful and efficient ways. Results show that while teachers responded in diverse ways to the coaching experience, attending to their underlying psychological and affective attributes (e.g., beliefs, teaching efficacy, emotions) facilitated overt and subtle shifts in knowledge, emotions, efficacy, and perceptions.

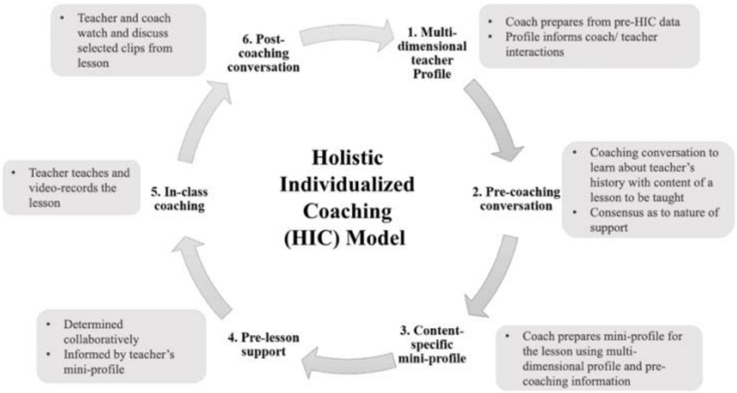
Introduction

Teachers' beliefs (Fives & Gill, 2015) and emotions (Cross Francis et al., 2020) impact their ability to teach mathematics effectively. Empirical findings show that coaching can significantly improve teachers' instruction as well as student mathematics learning (Darling-Hammond et al., 2017; Gibbons & Cobb, 2016). However, existing coaching models tend to overlook the effect teachers' psychological and affective attributes have on their capacities to learn and teach. We examined the impact of a Holistic Individualized Coaching (HIC) approach on the emotions and efficacy beliefs of two elementary mathematics teachers in Ghana.

Methods

HIC takes into account the teacher as an individual by attending to the their emotions, beliefs, identity, knowledge and current instructional practices. HIC not only taps into teacher's content knowledge, but engages teachers in conversations addressing key disciplinary ideas, effective pedagogical approaches, strategies to unpack and understand students' thinking, and psycho-social-emotional attributes that undergird teachers' actions. It involves six steps (Figure 1) that engage teachers' content knowledge, pedagogical approaches, strategies for understanding students' thinking, and psycho-social-emotional attributes.

Figure 1
Holistic Individualized Coaching (HIC) Model



The two participants in this study, Rayna and Dustin, were both elementary teachers who taught at a public and private school in Ghana respectively. **Rayna** initially reported medium levels of enjoyment and low efficacy in relation to her math teaching. She believed math to be primarily about quick and accurate computation while acknowledging a need for critical thinking. Her instruction focused on direct instruction and practice exercises. **Dustin** reported high levels of enjoyment and efficacy related to math. He wanted to make learning more interactive while expressing the firm belief that in math class "students must listen first, as it helps in assimilation". We used multiple data sources including: 60-minute interview transcripts from interviews conducted prior to coaching about previous math experiences; self-efficacy and math emotions surveys; and, transcripts of post-coaching conversations. We used invivo coding to analyze interviews identifying statements about math-related beliefs, teachers' vision for their teaching, emotion and efficacy. Surveys were analyzed and results integrated with qualitative data on the same construct to create a comprehensive picture of the teacher's psycho-social-emotional attributes.

Findings

Rayna: Overt shifts in teacher efficacy and emotions

Rayna engaged in five HIC cycles around number concepts, working with the coach to design lessons that incorporated manipulatives to support students' learning (e.g., base ten blocks). They focused on foregrounding strategies to attend to challenging concepts based on Rayna's prior experience in teaching the topics. As the lessons unfolded, Rayna was able to see how students made mathematical connections and drew meaning from the manipulatives. Rayna consistently reported that students had responded well to the lessons, sharing excitedly in one post-coaching conversation, "*I thought my teaching was good".* The coach worked with Rayna to review students' work, and in doing so supported Rayna in figuring out useful strategies for the range of topics students struggled with. The coach intentionally focused on supporting Rayna in broadening her math knowledge and facilitation skills around topics she found challenging to teach, in efforts to create mastery experiences and strengthen her efficacy. Rayna was able to effectively use some of the strategies the coach shared to support the students' understanding of number concepts. During the post-coaching conversation, Rayna expressed positive emotions, stating, "*I think they fully grasped it. I am so happy about it, extremely happy! Ah, this work has given me more confidence when it comes to teaching math. It has really made me come to like it.*"

Dustin: Subtle shift in instructional beliefs

Dustin's first coached lesson focused on completing number sequences. He encouraged students to apply a procedure to identify missing numbers in the sequence, directing them to "*find the two closest numbers, then subtract them and divide*". In the post-coaching conversation about this clip, Dustin justified his emphasis on the use of this procedure. The coach encouraged him to consider what might happen if the students used any two numbers, as well as what they might have learned from exploring that possibility. These types of conversations frequently occurred, in which the coach encouraged Dustin to allow students to explore, and he pushed back foregrounding the importance of efficiency in timebound contexts (i.e., "the smart way"). Because of Dustin's strong content knowledge, high knowledge and teaching efficacy, and strong identity as a math teacher leader in his school, the coach navigated the conversations responsively by gently nudging Dustin as to not challenge his math identity or threaten his efficacy, while supporting him to see the value of a more student-centered approach. In a later lesson on application of the associative property, the coach suggested that students draw pictures on dot paper to reflect doubling and halving, and work on contextual problems. Dustin agreed to incorporate the pictorial representations but opted to exclude the contextual problems. His openness to only one of the coach's suggestions reflected a subtle shift in Dustin's perspective in transferring more of the intellectual work in lessons to students. We regard this as a subtle shift, as his statement *"I get you; I should have let them do it"* was related to that specific lesson and did not seem to carry over to the next lesson.

Discussion and conclusion

We foreground these examples to show that framing interactions with teachers based on who they are as professionals and learners increases their receptiveness (subtly in some cases) to changing their instructional practices. These shifts may initially be overt or subtle depending on the teacher, the context, and the approaches the coach uses during the interaction. This study has notable theoretical and practical implications. First, we note that the application of HIC (i.e., leveraging comprehensive information) increased teachers' receptiveness to reconsidering their perspectives and practices in both subtle and overt ways. Second, we advocate for an expansion of current approaches to teacher PD to include coaching models that acknowledge the contributing role of psychological and affective attributes to teachers' work. Thus, in addition to the skills currently described as essential for coaching (Gibbons & Cobb, 2016), coaches need deep knowledge of the range of constructs that inform teaching and how to use this information to enhance teachers' instructional practices.

Exploring Computer Science Identity Development Among Undergraduate Computer Science Majors

Xornam S. Apedoe, University of San Francisco, xapedoe@usfca.edu
Wen Li, University of San Francisco, wli74@dons.usfca.edu
Sami Rollins, Northeastern University – Arlington, s.rollins@northeastern.edu

Sophie Engle, Alark Joshi, Matthew Malensek, Chris Brooks
sjengle@cs.usfca.edu, apjoshi@usfca.edu, mmalensek@usfca.edu, cbrooks@usfca.edu
University of San Francisco

Abstract: Disciplinary identity may play a significant role in determining one's persistence in a field. This study documents undergraduate computer science major students' evolving computer science (CS) identity as they participate in the CES|CS program. Drawing on data from two identity measures (CUPID and STEM-PIO) and student interviews, we present a case study of two students' evolving CS identities over two years.

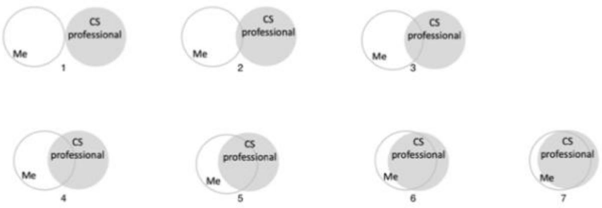
Introduction

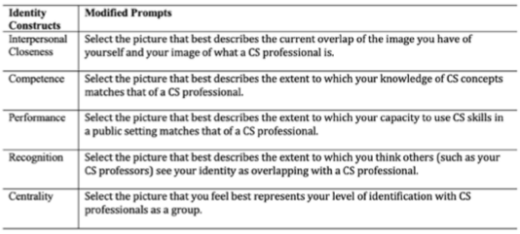
Attrition rates for students in computer science, particularly those from historically underrepresented or minoritized groups, remain high, despite many initiatives to recruit and retain such students (Howles, 2009; Kena et al., 2015; Mahedeo et al., 2020). The Community-Engaged Scholars in Computer Science (CES|CS) program provides diverse, academically talented, low-income computer science (CS) students with scholarships and a comprehensive suite of structured opportunities to learn from and contribute to the computer science community. The program activities are designed to support the development of a strong disciplinary (CS) identity by promoting engagement in the CS community both within and outside the university.

Methods

We draw on prior work on computing identity (e.g., Lunn et al., 2021) to explore CS students' disciplinary identity over time. We use two existing, validated instruments to measure CS identity. A modified version of the Conceptual Understanding & Physics Identity Development (CUPID) (Mahadeo et al., 2020) instrument assessed students' perceived recognition, interest, and performance/competence, with responses based on a 5-point Likert scale (1= not at all; 5 = very much so). Recognition items include: (R1) My family sees me as a computer-savvy person; (R2) My friends/classmates see me as a computer-savvy person; and (R3) My instructors/teachers see me as a computer-savvy person. Interest items include: (I1) Topics in computing excite my curiosity; (I2) I like to peruse forums, social media, or online videos about computer-related topics; and (I3) Computer programming is interesting to me. The Performance/Competence items include: (P/C1) I can do well on computing tasks (e.g., programming and setting up servers); (P/C2) I understand concepts underlying computing processes; and (P/C3) Others ask me for help with software (applications/programs). A modified version of the STEM Professional Identity Overlap (STEM-PIO) (McDonald et al. 2019) instrument, shown in Figure 1, was used to assess perceived recognition, performance, competence, typicality, and centrality. Each instrument was administered to students at the end of their 1st year in the program (Aug 2020); midpoint (December 2020), and end (May 2021) of their 2nd year in the program; and again at the end of their 3rd year in the program (May 2022). Interviews were conducted at the mid-point of their 2nd year in the program (January 2021).

Figure 1
Modified STEM-PIO Pictorial Representations & Prompts





Identity Constructs	**Modified Prompts**
Interpersonal Closeness	Select the picture that best describes the current overlap of the image you have of yourself and your image of what a CS professional is.
Competence	Select the picture that best describes the extent to which your knowledge of CS concepts matches that of a CS professional.
Performance	Select the picture that best describes the extent to which your capacity to use CS skills in a public setting matches that of a CS professional.
Recognition	Select the picture that best describes the extent to which you think others (such as your CS professors) see your identity as overlapping with a CS professional.
Centrality	Select the picture that you feel best represents your level of identification with CS professionals as a group.

Findings

Based on the interview data and students' responses to the CS identity instruments, preliminary findings provide valuable insight into the evolving nature of Greg and Camila's (pseudonyms) CS identity. Figure 3 provides a snapshot of Greg's identity shifts over time. Greg described his experience in *CES|CS*:*"…it's been a lot more… thoughtful about like design and how you want to proceed, what ways you want to improve on certain things and the people you meet. It's been a lot more positive."*

Figure 3

Greg's scores on the CUPID & modified STEM-PIO instruments

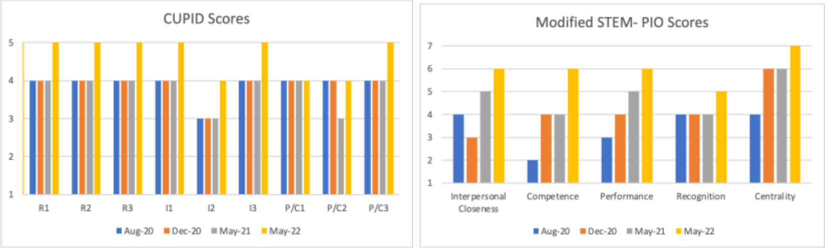


Figure 4 shows Camila's CS identity shifts over time. Camila described her experience in *CES|CS*:*"…it's [CES|CS] definitely made me feel secure, and made me feel like, I'm, gonna be successful as a CS major…."*

Figure 4

Camila's scores on the CUPID and modified STEM-PIO instruments

Designing for Belonging: Partnering With Community-Based Educators to Develop a New App for Creative Expression

Natalie Rusk, MIT Media Lab, nrusk@media.mit.edu
Rupal Jain, MIT Media Lab, rupal@media.mit.edu

Abstract: In this poster, we share an example of designing for belonging in a new app for creative expression, developed in collaboration with community-based educators who are working to expand learning opportunities for children and families from marginalized groups. These partners are not recruited for a single participatory design event, but rather partnerships are emergent, ongoing, and part of a larger shared process to support more expressive, collaborative, and equitable computational experiences. We discuss three core design considerations that prioritize designing for belonging in the app influenced by global partners.

Introduction

Children from marginalized communities have rich cultural resources yet too often are introduced to computing in ways that require learners to respond with a single, predetermined answer rather than inviting young people to express their unique interests and identities (Resnick & Rusk, 2020). In this paper, we describe the central role of community-based educators in the design of OctoStudio, a mobile app for creative expression with computational tools. The project has been motivated and shaped by long-term relationships with educators who organize creative learning opportunities for children, families, and educators in their communities, including in Brazil, Chile, India, Mexico, South Africa, Uganda, and the United States.

The intention for OctoStudio is to enable learners from diverse cultural backgrounds to create interactive projects based on their ideas that reflect the world around them and to seamlessly share their creations with friends and family. The work is grounded in constructionist and creative learning approaches (Resnick, 2017; Roque, 2016) and informed by research on the importance of learners to be able to express their ideas, interests, and identities to broaden participation in computing and motivate deeper learning (National Academies, 2021). In each aspect of the design process, we have drawn on designing for belonging principles (Powell & Menendian, 2016) and foregrounded partner voices in decisions about how best to address needs and interests of their communities and integrate their rich cultural perspectives (Garcia & Lee, 2020).

OctoStudio is designed to make it easy to create with code on mobile devices, addressing the unique constraints and affordances of mobile phones, including the limited screen size, built-in sensors, ease of access to photos and sound recording. Learners can select or create their own characters, backdrops, and sounds, and choose from a palette of coding blocks to design interactive projects. The app is currently in alpha prototype phase. Iterative design cycles engage community-based partners in exchanging ideas relevant to their local context, trying out the app in their communities, and participating in reflection and design discussions with each other and our university-based development team. Data collection to understand this dynamic process includes thematic analysis of sessions with partners to understand perceptions and tracing ways that partner feedback is shaping design decisions.

Key design considerations

In this section we describe three design considerations that prioritize designing for belonging in the app and that have been influenced by and iterated with partners. These design considerations are not simply a list of features, but attention to multiple levels of design, including system infrastructure, available assets, and tools (Table 1).

1. **Welcoming through seamless integration with local technology tools and practices:** Our global partners have expressed strong interest and need for more tools for creative expression that can run on mobile phones and that are not dependent on online connectivity. Thus, we have prioritized designing the app to work on locally available mobile devices and to provide quality experiences with no or intermittent data connectivity. Partners have been instrumental in prioritizing features, balancing trade-offs, and considering how to creatively leverage the existing data infrastructure of different locations globally. The app is designed so that all creating and saving of projects takes place offline, without requiring any internet connectivity. Based on partner feedback, we have also prioritized making projects easy to share with family and friends by enabling learners to screen record their creations without use of data and by leveraging free, cross-platform, messaging platforms.

2. **Inviting learners to recognize themselves and their worlds:** The app is designed to provide learners with a wide range of expressive tools and a diverse media library for creating their projects. Although the images

of people in the standard emoji library provide a choice of six skin colors, they lack racial and cultural representation in important ways. Based on feedback from partners, our team has redesigned images for the app library, making changes to more than 90 emojis of people, including body types, headwear, and hair texture and styles to support broader representation of racial, cultural, and gender identities. Partners have also guided the development of backdrop images and sound clips to make the media library more familiar and relatable for children in their communities Partners have contributed local photos (e.g., a neighborhood scene from Limpopo, South Africa and a pathway with street art murals from São Paulo, Brazil). The app provides examples and tools to highlight ways that learners can create their own characters, backdrops, and sounds.

3. Encouraging contributions through creative tools across physical environments: The app is intentionally designed to facilitate both ease of creating anywhere and integrating personally meaningful images and sounds users encounter on-the-move. Coding blocks support multimodal expression (motion, text, color, sounds, vibration), creative tools for adding your own media (sound, photo, paint, and text editors), and sensing blocks that enable physical interaction (shake, tilt, touch, magnet sensing). These novel tools allow learners to construct interactive projects that enable them to engage with their bodies and physical environment. For example, the "*when I shake*" block starts actions if the learner shakes the phone, which opens up a variety of projects based on dance, music, sports, and other forms of movement and output that extend beyond the device.

Table 1

Examples of app design to address three levels of design considerations

Leveraging Infrastructure	**Diversifying Media Assets**	**Providing Creative Tools**
Sharing with no or intermittent internet connectivity	Revised emojis to support more diverse representation.	Coding blocks that support interactivity with physical world
 Hola 🙌, les comparto mi proyecto, se llama México a través del tiempo 💓 11:45 AM [redacted] ¡Qué bueno! @[redacted] 11:59 AM *Educator in Mexico sharing her project on WhatsApp app*	 *Examples of standard emojis versus revised emojis in app*	 *Example project that plays drum sound when you shake the phone.*

Discussion

Work with partners has illuminated how designing for belonging happens at interconnected levels from macro to micro considerations. Integration of system-level infrastructure and communication practices is coupled with careful attention to designing individual assets and tools that encourage creative expression and agency.

Abstract: We explore how student agency was enacted in small, medium, and large ways that impacted the emergent design of a technology-enhanced science learning environment. Small acts corresponded to students choosing how to participate, medium acts when students' imagination was supported, and large acts when students' ideas changed the curriculum. We analyzed video data from 21 class videos to highlight the design trajectory from the first iteration (one 5th-grade classroom; topic: moths and adaptation) to the second (four 4th-grade classrooms; topic: food webs). Our findings suggest that supporting choice and imagination led us (researchers and teacher co-designers) to make curricular changes to follow students' ideas (e.g., an activity about decomposition to figure out how plants get their energy). Future learning environment designs should be responsive to all three types of student agency.

Motivation and theoretical framework

Agency has been shown not only to enhance student motivation and engagement in STEM, but also to connect social change to disciplinary learning (Goulart & Roth, 2010; Basu, 2008). However, agency has been difficult to operationalize, and even within science education, scholars conceptualize agency differently (Arnold & Clarke, 2014). For Arnold & Clarke, agency was defined as "the discursive practice of positioning oneself or being positioned as responsible" (p. 751). The National Research Council (2009) has reported the temporal aspects of agency that may help teachers identify moments to encourage student agency: "A sense of agency or belonging can be experienced retrospectively when reflecting on past events, it can be experienced in relation to current activities, and it can be projected into the future through imaginative acts regarding what one might become" (p. 74). Agency has also been defined as the capacity to act on one's knowledge of science (Basu, 2008; Barton & Tan, 2010) or "a person's capacity to engage with cultural schemas and mobilize resources in ways that did not exist before, creating new contexts and practices" (Varelas et al., 2015, p. 517). This wide range of definitions (from responsibility based on how one chooses to position oneself, to acting from one's imagination, to the capacity to act) suggests the importance of understanding and conceptualizing sub-types of agency. From this range of definitions, we argue three contexts when agency is relevant for students: moment-to-moment interactions, dreaming about the future, and acting on the dream to realize a desired future or outcome.

In this paper, we propose three different types of agency that build up to students taking social action: choosing (small; Rodriguez, 2015; National Research Council, 2009), dreaming (medium; Carlone et al., 2015), and changing (large; Arnold & Clarke, 2014). We present empirical data from the Generalized Embodied Modeling and Science through Technology Enhanced Play (GEM-STEP) project about learning through embodiment in a mixed reality environment to provide examples of these three types of agency. These examples show how agency impacted children's learning and our iterative co-design process. Specifically, we ask: How does the co-design/co-facilitation process between researchers-teachers-students support student agency?

Methods

The data for this study comes from the GEM-STEP project, where students play within a system that tracks their location and shows them on a shared visualization as an agent within the scientific phenomenon of study (in this case, moth adaptation and terrestrial food webs). Our curricula leveraged embodied modeling technology that enabled students to appear as and control agents within a simulation on screen with their movement (e.g., a moth hiding from an artificial intelligence-controlled controlled hawk, a robin eating and gaining energy from an AI-controlled beetle, and carbon dioxide molecules that meet up with water molecules at an on-screen zoom-in of a plant leaf's chloroplast; See Figure 1).

Authors 1-3 time-indexed and content logged (Derry et al., 2010) 21 days of video (9 days of the moth unit; 3 days x 4 iterations of the food web unit) and iteratively watched these videos as an author team to refine hypotheses (Engle et al., 2007) about moments when students are engaging in small, medium, and large acts of agency. We noted moments when teachers and researchers give students choice as small agency moments (e.g., "Are we ready? Are we all where we want to be [in the tracking space]?"). When children asked creative questions or made observations that required imagination, we noted those moments as medium agency (e.g., “I ate the garden, but I couldn’t eat [another student’s name]”). When students made a suggestion that led to real change in the activity design or curriculum, we noted those as large agency moments. We also tracked overall how our planned design decisions did or did not support all three types of agency, and what unplanned design decisions occurred in response to students’ small, medium, and large acts of agency.

Findings

We identified planned and unplanned design decisions that impacted student agency in the moth and food web iterations. For example, within the moth curriculum, we planned for students to have choice (small acts of agency), but students surprised us and created their own moments of medium agency when they made up narratives about moths facing imminent death and the hawk “birdie” being broken. Because the moth iteration somewhat restricted students’ agency to use their bodies to engage in the activity (i.e., staying still and hiding on a tree from the hawks was a popular strategy), we also intentionally designed the food web activities to require more movement in order for kids to engage (i.e., eat the moving beetles when you are a snake or robin). This design change opened up more opportunities for both small and medium acts of agency.

In the food web unit, we expanded the possibilities of students' imagination by designing the game so that children can take the perspective of multiple animals. Through the food web activities, students began to wonder and worry about the plants: Where do they get their energy from? In response to their concerns, we added a decomposition activity to meet students’ desires to learn more about the connection between producers and decomposers. Although we saw large moments of agency the fewest amount of times than the other two types of agency, we plan to ask children, “Why should we care about food webs?” in order to understand what socio-environmental connections or changes children may suggest.

Future directions

Overall, because this project builds on the tradition of iterative design-based research, we are fortunate to make changes to our curriculum in real-time response to students’ choices, imagination, and sociopolitical agency. We hope this inspires other science learning environments to design curricula and activities in a way that can be responsive to students’ agency.

Designing Teacher Professional Development Using Conjecture Mapping to Support Teachers' Computational Thinking Integration Efforts

Secil Caskurlu, Florida State University, scaskurlu@fsu.edu
David Phelps, Telos Learning, david@teloslearning.net
Rafi Santo, Telos Learning, rafi@teloslearning.net
Aman Yadav, Michigan State University, ayadav@msu.edu

Abstract: This poster presents our efforts to (a) design a scalable competency-based teacher professional development that provides continuous support to increase middle school Social Studies, Arts, and Language Arts teachers' capacity to make sense of computational thinking integration opportunities within their teaching context; and (b) examine how different elements of teacher professional development influence teachers' capacity to make sense of computational thinking integration opportunities in their teaching context.

Introduction

Given the benefits of integrating computational thinking (CT) into the K-12, it is crucial to support teachers in understanding both CT and instructional practices to help students gain CT skills (Ketelhut et al., 2020). Previous efforts focused on teacher professional development (TPD) interventions have largely involved short-term workshops with limited follow-up activities that do not provide substantive support to teachers, especially teachers who do not have a background in CT, to integrate CT into their teaching. Additionally, while existing research has begun to establish CT's relationship to the disciplines of math and science (Weintrop et al., 2016), fewer efforts have looked at how humanities teachers (e.g., Language Arts, Social Studies, and Arts) make connections between CT and their subject area (Yadav et al., 2017). There are also TPD efforts that are focused on coaching, co-designing, and/or co-teaching with scalability concerns due to the amount of time and resources needed to support teachers and coaches (Margolis et al., 2017). Finally, only a few studies (e.g., Margolis et al., 2017) have investigated how specific characteristics of TPDs influence teachers' knowledge, skills, and attitudes toward CT integration in K-12. Therefore, this study aims to (a) design a scalable competency-based TPD that provides continuous support to increase middle school Social Studies, Arts, and Language Arts teachers' capacity to make sense of CT integration opportunities within their teaching context; and (b) examine how different elements of TPD influence teachers' capacity to make sense of CT integration opportunities in their teaching context.

Methods

This study utilized design-based research, particularly, conjecture mapping to design TPD (Sandoval, 2014). The initial conjecture map was created based on the high-level conjecture that teachers require scaffolds and TPD opportunities to engage in enhanced disciplinary teaching via CT and to make sense of CT integration opportunities within their teaching context.

Phase 1: Co-design with CT experts

We worked with expert teachers and experts in computer science and CT education, to ideate CT-integrated learning experiences. Based on the ideated lessons, we identified and categorized an initial set of design principles for each discipline.

Phase 2: First implementation of teacher professional development

Eight teachers participated in the first iteration of the TPD during Summer 2021. The TPD consisted of seven days of professional learning that included knowledge-building sessions, designing CT-integrated lesson plans, and mock instruction with associated peer observation and feedback. After professional learning, each teacher received one-to-one support to design CT-integrated lesson progressions and discuss implementation plans related to this planned instruction. Those individual sessions were planned based on individual teachers' pedagogical and content needs. Finally, teachers participated in a whole group meeting to discuss the potential challenges they might face during implementation and whether they need any additional support from the team. Finally, to support the TPD efforts, we identified CT integration pathways in Social Studies, Arts, and Language Arts and associated practices with high-level examples (Caskurlu et al., 2022). We also developed self-paced online building blocks that include (a) three general building blocks (i.e., abstraction, algorithms, and patterns and data practices) to build an understanding of CT and (b) subject area-specific building blocks that focus on CT integration pathways with concrete examples and scaffolded activities.

The following data sources were used to examine how different elements of TPD would influence teachers' capacity to make sense of CT integration opportunities in their teaching context: semi-structured interviews after design fellowship, one-on-one check-in meeting video recordings, teacher lesson progression design documents, and TPD video recordings. Data were analyzed using thematic synthesis.

The review of the first implementation data showed that TPD supported teachers to conceptualize CT and make connections between CT and their subject area. The initial high-level conjecture remained the same. However, the results also revealed a need for including (a) more collaborative activities where teachers design lesson plans together and provide feedback to each other; (b) additional resources related to computational tools; and (c) more concrete examples of applications of CT integration practices in the classroom. Accordingly, we made the following revision on the existing embodiments and added new ones:

- Professional learning: Additional collaborative activities were added to create a community of inquiry among teachers.
- Design fellowship: In addition to teacher professional learning sessions, the second iteration included a design fellowship where teachers designed CT-integrated lesson progression with support from the research team and presented their design and provided feedback to each other.
- CT integration pathways and associated practices: In addition to revising CT integration pathways and their practices, additional resources including a description of each pathway and how it looks like in practice aimed to clarify the content and make them accessible to teachers.
- Remixable unit concepts: We created remixable unit concepts that can be used to remix content by customizing it and/or to make adaptations to design CT-integrated unit progressions to provide more concrete examples of how CT integration pathways can be implemented in classrooms.
- Inspiration library: We created a repository of resources that address CT, CT tools, CT integration ideas, and/or curricular resources.

Phase 3: Second implementation of teacher professional development

Eleven teachers participated in the second iteration of TPD, and six continued working closely with us into the Fall semester as design fellows. The following data were collected: (a) a pre-survey asking teachers about their previous CT experiences and their perceptions of CT integration pathways; (b) TPD video recordings; (c) a post-survey asking teachers about their experiences in the TPD and their perceptions of CT integration pathways after TPD; (d) design fellowship video recordings; (e) implementation reflections; and (f) semi-structured interviews.

Data analysis is still in progress, but the preliminary results showed that the design iterations of the TPD provided unique affordances that helped teachers conceptualize CT, envision concrete applications of CT practices to their teaching, and design CT-integrated units. Teachers also noted that they established future collaborations with other teachers to co-design CT-integrated units. The conjecture map resulting from this process advances our understanding of TPD around CT integration in terms of the teaching and learning approaches used in TPD.

A Teacher Community in the Making: Contradictions as Uniting and Driving Forces for the Creation of Culture

Yeliz Günal-Aggül, Boğaziçi University, yeliz.gunal@boun.edu.tr

Abstract: This participatory design research study supports a group of mathematics teachers teaching at different schools in Turkey as they design their community within a non-profit organization. The method of formative interventions is used to support teachers' expansive learning while creating their community and its unique culture. The study examines how teachers identified their common contradiction as an initial step of community building.

Objectives and context

Teacher communities have long been acknowledged as mediums in which teachers can sustain their professional development and produce solutions to their problems of practice, and these communities have been promoted as a part of educational reform processes (Horn et al., 2017). On the other hand, when trying to design these communities and make them operative among teachers, researchers have mostly overlooked the fact that the development of teacher communities is a matter of cultural creation and change (Engestrom, 2016; Stigler & Hiebert, 1999). This ongoing study addresses this gap by employing the method of formative interventions, a type of participatory design research approach in the learning sciences, to support a group of mathematics teachers in designing their community with its novel cultural practices and artifacts (Engeström, 2016; Gutiérrez et al., 2016).

Participant teachers in this study teach in different schools and at various levels, and, all of whom are engaged in a non-profit organization called Teachers Network, which promotes teacher empowerment by supporting teacher solidarity in communities. After some unsuccessful attempts to establish a community among mathematics teachers in the network, one of which I participated in as an observer, I consulted with facilitators from the network, and we made a call to network mathematics teachers to design a community. Unlike typical formative interventions, in which practitioners from the same organization transform their work practices, this method has been implemented to create a community by a group of teachers who do not share the same workplace but are all part of the generalized mathematics teaching activity system of Turkey, which is centralized with a Ministry of Education, a common curriculum, and high-stakes testing for school enrollments.

Theoretical framework, research questions, and method

In formative interventions, based on Engeström's (2016) theory of expansive learning, practitioners are supported in a way that specific epistemic or learning actions that characterize the expansive learning process (questioning, analyzing, modeling, examining, implementing, reflecting, consolidating and generalizing) would emerge. Drawing on the methodological tools that Vygotsky (1997) employed in his double-stimulation experiments, expansive learning is mediated by two types of tools: the "first stimulus," which helps practitioners face the contradictions in their activity system that gave rise to persistent dilemmas in their practices that they couldn't solve alone, and the "second stimulus," which is put into action to design a novel solution (Engeström, 2016).

The completed first of three phases of this project included mediated tools and activities that supported questioning and analyzing actions. The overarching research question of this study is "How does a group of teachers who teach at different schools design their professional community during a participatory design process?" This paper answers the following sub-research questions: How did teachers exercise questioning and analyzing learning actions, and how did the mediating tools support these actions? What kind of common contradiction did teachers identify, and how did it function in designing the community?

To answer the research questions, focusing on the practitioners' conversations and written artifacts, I primarily drew on video recordings of eight online or hybrid community meetings that lasted between 129 and 172 minutes and artifacts. The expansive learning actions from the transcripts were coded deductively utilizing Maxqda software, which was followed by the inductive analysis of the context specific sub-types of them.

Findings

The book *The Teaching Gap* (Stigler & Hiebert, 1999), which compares mathematics teaching practices in three countries (Germany, Japan, and the USA) and conducts a critical evaluation of the cultural and structural factors that affect these practices in the U.S. and Japan, constituted the backbone of the activities during the first phase. The community read the book part by part, wrote reflection papers, and discussed it with my questions, which invited them to reflect on their experiences as mathematics teachers in Turkey. The book was selected since it had a strong potential to trigger teachers into questioning taken-for-granted aspects of their practice, which they could not find opportunities to reflect on during the rush of their regular practice. Questioning action has emerged in three interconnected aspects of mathematics teaching in Turkey: the cultural codes (e.g., whether children are provided with space to control their learning), the curriculum (e.g., the scientific rationale behind it), and the teacher learning systems (e.g., professional development opportunities, collegial interaction).

According to Engeström (2000), contradictions "manifest themselves through disturbances, ruptures and small innovations in practitioners' everyday work actions" (p. 153). The tools and activities helped make these disturbances explicit to teachers. These problem areas mentioned above have been manifestations of an overarching contradiction that emerged in the community meetings as a repeating discussion topic: The lack of a robust, common-orienting "framework" or "structure" in the country that mathematics educators share and work toward achieving, that teachers follow to collaborate, and that introduce "alternative codes" to the dominant cultural codes of teaching that limit the possibilities of equitable and meaningful student learning. Teachers were experiencing this as a contradiction since, despite the lack of a shared orientation, teachers had been introduced to various approaches through professional development activities and curricular materials that the Ministry of Education disseminated, which could not go beyond being a "haphazard collage of experience and workshops, pasted together with little connection," preventing teachers from achieving a sustainable improvement in their classrooms (Ball & Cohen, 1999, p. 27). As teachers found space and time to delve into these problems in community, they started to interpret these supposedly arbitrary and unrelated problems in the light of this contradiction (Engeström, 2000). Demet (a pseudonym), one of the participants, elaborated on the contradiction that manifested as repeating disturbances in her practice, which she expressed in her reflection paper as *experiencing a vortex of trial and error that was getting bigger and faster every day*.

Teachers in the community did similar critiques, referring to their own teaching experiences, in different sessions or in the different sub-groups that we created for group activities, sometimes using different terminologies. After six sessions, I put the teachers' comments and critiques about this issue together and prepared short video clips. We watched and discussed these clips along with the questions that invited teachers to clarify what they meant there, whether they referred to the same problem in their sayings, and whether they agreed with each other. In this way, *teachers' individual questioning action turned into a collective one, and they naturally started a collective analysis* on whether curricular materials actually provided the "structure" that they needed. The remaining parts of the intervention were built on the energy of this contradiction (Engeström, 2016); the community planned various activities to further their analysis (e.g. contacting curriculum makers) and developed long-term goals toward modeling their community (e.g. designing the community's orienting framework for teaching mathematics by reading scientific resources). During these discussions, "mathematics teaching" has been identified as the object to expand through the community's activity, and it turned into a motive (Engeström, 2016).

Significance

This analysis has shown that through the use of participatory design research methods, researchers can facilitate the development of a teacher community as a cultural creation process. Furthermore, it illustrates how formative interventions help practitioners from diverse workplaces identify common contradictions as the initial step toward designing a novel professional community as a solution to these contradictions.

Connect: A Tool for Collaborative Interview Data Analysis

Hazel Vega, Golnaz Arastoopour Irgens, Tolulope Famaye, Ibrahim Adisa, Caitlin Lancaster,

Abstract: A growing scholarly interest around participatory approaches has acknowledged that interaction between researchers and participants is still constrained. However, little is known about methodological tools that allow researcher-participant collaboration that defy these strict roles. Thus, we are designing Connect, a tool to support researcher-participant co-interpretation of discourse data from interviews. In this paper, we synthesize previous work leading to our design, describe Connect, and expound goals and principles guiding our design.

Introduction

In the learning sciences, research has demonstrated how the values and perspectives of participants shape the goals of research projects and interventions (e.g., Bang & Vossoughi, 2016). A growing scholarly interest around participatory approaches has acknowledged that interaction between researchers and participants is still constrained, and improvement in this area is needed to open avenues for epistemic diversity (Philip et al., 2018). However, little is known about tools that allow researcher-participant collaboration in which roles are de-settled to generate more democratic knowledge construction (Bang & Vossoughi, 2016; Philip et al., 2018). Thus, in this paper, we describe a tool to aid in *collaborative data analysis between "researchers" and "the researched*." This tool is situated within quantitative ethnography (QE) methodology (Shaffer, 2017).

Prior work

The research leading to the design of *Connect* is based on previous studies of the professional identity of English teachers in Costa Rica. Vega and Arastoopour Irgens (2021) explored the identity tensions and negotiations of pre-service and in-service teachers during their teacher education program and in their transition to teaching. In a pilot study, Vega used on-the-fly annotations of ENA discourse networks (Shaffer, 2017) based on the teachers' interpretations (Vega & Arastoopour Irgens, 2021). The network creates node-link representations of relationships between coded data. In interviews, Vega (2022) added annotations that teachers suggested or that they deemed necessary. This pilot study inspired a tool prototype, which adapted ENA features, such as creating node-link representations of discourse, such that teachers could participate in the data analysis process without the background knowledge needed to use ENA. This prototype was created on Google Slides with a drag-and-drop option for users to create visual representations of their interpretations. Altogether, this research has shown how 1) data visualizations provide a space for joint cognition, 2) co-constructed interpretations build a fuller picture of the research phenomenon, and 3) joint sense-making enhances new interpretations in research., a tool to augment researcher and participant collaboration.

Connect: Goals, description, and design principles

Inspired by our findings, we propose *Connect*. The following are the main goals guiding our design:

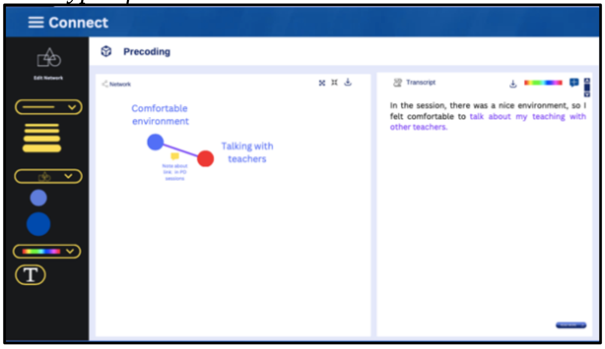
1. Engaging research participants in QE data analysis: *Connect* integrates QE participants' voices in a research stage in which they have traditionally had limited participation. Acknowledging barriers in terms of time commitment and expertise, *Connect* provides a space for participants to shape knowledge construction.
2. Expanding existing tools: QE scholars have developed a range of researcher tools. ENA, in particular, is focused on meaning-making and facilitates multiple data interpretations (Buckingham Shum et al., 2021). These functionalities can be expanded towards collaborative ends. *Connect* reworks these functionalities to leverage researchers and participants' expertise and bridge theory and practice.
3. Involving participants in tool co-designing: A human-centered approach to design requires roles, interaction, functions, and attributes of tools to be determined by researchers and all stakeholders (Buckingham Shum et al., 2019). *Connect* involves participants' perspectives to design and improve the tool.

Connect is designed for researchers and participants to analyze interview data in a collaborative space by logging in and working simultaneously. An initial screen allows the users to upload transcripts with spreadsheet or text file extensions and start using features to annotate transcripts and create and annotate data visualizations.

The collaborative space includes two sections: (a) the transcript (right hand-side of Figure 1) and (b) the network (left hand-side of Figure 1). On the transcript side, the users view the interview transcript. From left to right in the upper left corner, they have the following tools: (1) a downloading button, (2) a color bar to color-code data segments, (3) a comment button to annotate the transcript, (4) arrows to navigate the transcript. The design principles underlying our decisions for this segment of the tool are based on the fundamental principle of QE of grounding interpretation in the discourse. Codes and broader interpretations stem from the data and are verified in relation to evidence in the discourse. Therefore, the transcript is visible in the tool and users interact with the text by providing additional information not captured in previous interviews and co-constructing preliminary codes. These features will enhance co-interpretations that are fully grounded in the data.

On the network portion of the tool, users create networks representing important themes or codes identified in the transcript. The left menu includes the following elements for network construction: (1) a drop-down feature to insert lines with different levels of thickness, (2) a drop-down button to insert nodes of varied sizes, (3) drop-down feature to customize colors for dots and lines, (4) a text tool to add text to the network. The design principles for this segment of the tool are inspired by node-link representations in ENA inch which larger nodes represent more frequent occurrences of the codes and thicker links represent more frequent co-occurrences between codes. However, in ENA, the networks are constructed via sophisticated statistical tools, which require coded data and expert knowledge. Coding and modeling the data is typically a time-consuming and specialized process, which may not be realistic for participant engagement. Thus, we have adapted features of ENA, which that are helpful in data analysis conversations and would not require time-intensive tasks. From our previous research (Vega, 2022), we determined that these features will be accessible for participants. Next steps will be to develop a web-based version of *Connect* using R Shiny and Javascript and conducting user testing.

Figure 1
Prototype of Connect



In the session, there was a nice environment, so I felt comfortable to talk about my teaching with other teachers.

Abstract: We suggest that tinkering is implicit in movement and changes to movement while exploring embodied models, as students must interpret and react in real time to the system outcomes. Using movement analysis, we explore the ways that physical movement fosters and reflects computational tinkering across episodes in two embodied science models. We argue that patterns and shifts in movement may be a window into the computational growth that takes place as learners participate in the modeling environment.

Introduction

Embodied cognition asserts that cognition is deeply rooted in the human body and its interactions with the real world (Barsalou, 2008). Studies show that leveraging students' physical movements to explore scientific and computational models can support sensemaking and foster new science learning (Planey & Lindgren, 2020; Zhou et al., 2022). However, the impact of embodied experiences on students' computational practices has yet to be explored. Research has shown that cycles of exploration and tinkering, or playful experimentation, support learners' sensemaking as they learn scientific phenomena and gain computational fluency with models (Wagh et al, 2016). Tinkering enables learners to engage computationally and conceptually as they pursue questions of interest and then notice and explain the resulting outcomes of their tinkering (Martinez & Stager, 2013). We suggest that tinkering can emerge in new ways, via movement, within computational embodied models due to the physical nature of the modeling experience. We extend and explore the concept of tinkering within the physical world by examining activities built on the Generalized Embodied Modeling: Science through Technology Enhanced Play (GEM-STEP) platform (Danish et al., 2022), an embodied science modeling environment.

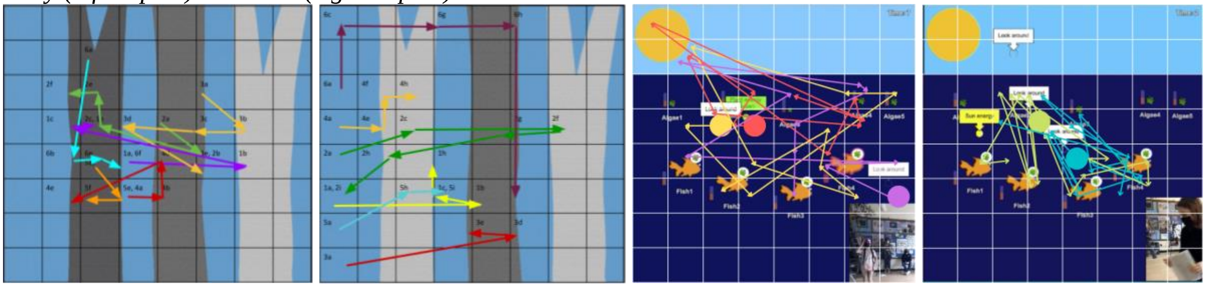
Methods

We explore two cases of embodied science models in the GEM-STEP mixed reality platform, that allows learners to control agents in a model with their movement by wearing tracking tags. Two classes of students (5th, 6th) explored either a moth camouflage model or an aquatic ecosystem embodied model. In the moth camouflage model, students embody moths with hidden wing colors and must use a system level match meter to find a tree on which to safely camouflage. In the aquatic ecosystem model, learners bring agents (algae, fish) energy from the right source (sun, algae) to keep the system alive and stable. We use video and screen recordings to conduct movement analysis (Gudmundsson et al., 2011) on an early and later round of each model, comparing movement in three categories of tinkering: *success rate* (quantitative measure of success), student *initial positioning* (where students stood at the start of the model), and *strategy & movement* (patterns of movement and coordination at the group level).

Findings

In the early round of the moth camouflage model, learners started by positioning themselves in a slightly distanced cluster in the center of the model (*initial position*) then moved independently of each other (*strategy & movement*), resulting in unintentional matches. Due to this independent movement, the number of matches fluctuated over the round of the model (*success rate*). Based on initial explorations, students deliberately started the round off of trees to ensure the round started with zero matches. They implemented a strategy where only one learner at a time walks forward until the match meter identifies a safe tree, resulting in decreased speed but greater accuracy (*success rate*). In the early round of the aquatic ecosystem model, students started in a cluster in the center of the model (*initial position*) then each made scattered movements across the model to interact with all agents in the system (*strategy & movement*), resulting in a less stable system (*success rate*; 196 seconds, 2 of 4 fish alive, low energy). In the later round, students devised a strategy to make energy transfer more efficient by distributing energy transfer tasks (*strategy & movement*) and started the model between agents that they were tasked with supporting (*starting position*). They further adapted their previously discussed strategy after observing that fish were at risk of dying, communicating and employing a new strategy in the moment. This resulted in a longer period of stability and healthier agents (*success rate*; 221 seconds, 2/4 fish alive, high energy).

Figure 1
The moth camouflage model (left pair) and aquatic ecosystem model (right pair) with movement tracked for in early (left in pair) and later (right in pair) rounds.



Discussion and future directions

Across both models, students used initial movement based explorations to construct and revise strategies that resulted in greater success in later rounds. The moth model case captures tinkering across rounds while the aquatic model case additionally captures tinkering within a round. We suggest that movement can be understood as a window into learners' computational tinkering that emerges during computational embodied contexts. Within this space, students' cycles of engagement with models are synchronous, meaning that they can change the rules of their characters as they assess system level outcomes while actively using models. The synchronous nature of the embodied models gave students opportunities to tinker with the model rules, test theories in real time, and adapt as their understanding of the computational and scientific system evolved. This synchronicity can be challenging and complex for students, as it requires negotiation and coordination of strategies and goals with peers, and additionally requires learners to observe and make sense of the potential system level impacts of others in the embodied model.

Uncovering Factors That Generate Relatedness to Place and People During In-Person Field Trips (FTs) to Inform the Design of Virtual FTs

Ana Saavedra, Daniel L. Schwartz, Doris Chin
anamar@stanford.edu, daniel.schwartz@stanford.edu, dbchin@stanford.edu
Stanford University

Abstract: Virtual learning experiences are on the rise, but those experiences are far-off from offering similar experiences to in-person field trips. Students reported on their experiences during a field trip to illuminate factors that may contribute to the benefits of field trips. Among the findings, students reported that gaining expository information about a place was the main contributor to feeling connected to that place. Results provide initial design guidance when building virtual field trips.

Introduction

This research examines the qualities of a successful school field trip to inform the design of Virtual Field Trips (VFTs). In-person field trips can generate lasting memories and meaningful connections between participants. Research shows that field trips provide benefits in place awareness and science learning (e.g., Ardoin et al., 2018). Digital tools might also build a sense of connectedness, but there has been less development on how to foster this type of non-academic learning in the digital arena (Reich & Ito, 2017). Technologies for creating VFTs have become increasingly available (e.g., Pano2VR) and some are simple enough that students can create their own VFTs (e.g., Thinglink). In the best of worlds, VFTs can bring every student to places and people that would otherwise be infeasible, while also supporting some of the otherwise unique in-person learning experiences.

To design VFTs that generate similar effects to in-person experiences, we need to understand the factors that promote beneficial in-person experiences so they can later be designed into VFTs. We refer to the outcomes of field trips as benefits because in the literature they are usually reported as benefits. We identified two benefits from existing research about field trips 1) **Connection to place**: After attending a field trip, students report higher connection with a place. For instance, students report a higher commitment towards ecological behaviors (e.g., recycling) when they feel connected to nature (Otto & Pensini, 2017). 2) **Connection to people**: During a field trip, participants build connections to others that seem to last or that they feel deeply about (Richmond et al., 2018). In this study we begin to explore factors that contribute to those benefits by measuring students experience after the field trip.

Methods

Participants and procedures

Fifty-seven students from a school located in Bogota (Colombia) participated in the study. The study was approved by the Stanford Institutional Review Board. Two weeks after returning from a field trip organized by the school students completed a survey using a *Google Forms* link. The school's wellness coordinator administered the survey based on the instructions we provided. Students did not receive a time limit to answer each question.

Measures

We designed a survey with open-ended questions targeting the two main benefits: 1) connection to place and 2) connection to people on the field trip. The first question of each section asked students to name which activity achieved the two main benefits. Additional questions in each specific section asked students about why and how the activity contributed to a particular outcome. Research shows that not only the context but also the people who are present in that place may contribute to creating a connection to place (Ardoin, 2018).

Coding

Two procedures were implemented for coding students' surveys. The first procedure coded the activities that the students listed in response to the first question of each section (e.g., rafting; town race; art workshop). For the questions that asked students why and how in relation to the activity, we coded responses based on grounded theory analysis. The coding protocol was updated in an iterative review-revise process informed by conversations and analysis rounds among the researchers.

Results

Table 1 shows the percentages of reasons for each of the selected benefits. For instance, if an activity generated connection to place what were the reasons provided by the students? One thing that stands out in the descriptive results of Table 1 is that there are different factors that produce the selected benefits. Also, the social factor plays a different role when producing connection to place in comparison to connection to others.

When asking students why the chosen activity made them feel connected to the place, their responses suggest that what contributed most was learning about the place during the activity. For example, finding a clue and learning about an historical event of the town. In relation to how people (friends or guides) helped students feel connected to the place, on average students mentioned as influencing factors receiving an instruction or experiencing an emotion. When looking at connections to others, the question probed for qualities or emotions that made students feel this connection. For qualities, students mainly focused on the social component.

Table 1
Reasons for Connection: Codes and Percentages of Student Responses for the Two Selected Benefits

	Social	**Location**	**Fun**	**Happiness**	**Felt supported**	**Other emotions**	**Instruction**	**Learning**	**New/novel**
Connection to Place									
Activity	8%	***42%***	0%	0%	0%	9%	7%	***29%***	4%
People	14%	3%	10%	6%	12%	***22%***	***30%***	3%	0%
Connection to Others	***27%***	0%	9%	***22%***	8%	***30%***	2%	1%	0%

Discussion and scholarly significance

The current exploratory study tried to identify some of the factors that lead to the reported benefits of in-person field trips. In this sample we found that different features affect different outcomes. The social factor plays a different role in the two elected benefits. Another finding is that activities where students can learn about the place, often through expository instruction, generate a connection to place. While field trips may be associated with direct experience, direct explanation can also happen during a field trip and seems to support connection to place. Finally, emotions play a key role in generating the selected benefits. Concurrently, a good next step is to engage in design experiments to figure out how to design for the identified factors that, by hypothesis, would improve the benefits of VFTs.

Abstract: This study proposes "proactive-accentuated nodding (PAN)" to enhance active listening in presentation education. PAN means to nod saliently without missing the relevant point of nodding. The evaluation in a university class showed that PAN reduced subjective distance between the listeners and the speaker as well as the listeners and other listeners, and to facilitate listeners' awareness of flaws in the presentation. On the other hand, the speakers rated their satisfaction with their own presentation lower when listeners conducted PAN.

Introduction: Proactive-accentuated nodding

Presentation education has focused on becoming a good speaker. However, as ethnomethodology (Sacks 1992) and the collaborative communication model (Clark 2008) indicate, talk is not a one-way act of information transmission from the speaker, but is a collaborative act that is established through interaction between the speaker and listener. If this is the case, education for "good talk" will require learning to develop not only good speakers but also good listeners. In this study, "nodding" is taken up as a basic research for fostering "good listeners" and examine how encouraging listeners to engage in "proactive-accentuated nodding (PAN)" affects both listeners and speakers. Here, "proactive" means nodding actively without missing the relevant point of nodding. “Accentuated" means nodding with large movements. The former encourages cognitive effort of intentional listening, while the latter encourages the conscious expression of understanding and agreement as a physical expression that is salient for the speaker. This combination is the essence of the active listening, which is actively involved in the collaborative organization of talk, and hence PAN is well suited for training as a listener.

Experiment

The effectiveness of PAN was piloted in a university presentation class for 58 Freshers. Students were divided into groups of five and gave an oral presentation of their arguments to the other students in the group using slides they had prepared (they had approximately 7 minutes). Presentations were made on MS-Teams (the facial image of each was displayed on their screens). No special instructions were given for the first two presentations (henceforth N-PAN condition), and after the two presentations were completed, they were instructed to perform PAN for the next three presentations (henceforth PAN condition).

To measure the effect of PAN, a questionnaire survey was administered to listeners and speakers after each presentation. The first is the IOS scale (Aaron et al. 1992). In the IOS, Listeners rated the subjective overlap between themselves and the speaker as well as the distance between the self and the other listeners on a scale of 7 (7 being the most overlapped and 1 being no overlap at all). The speaker rated the overlap between himself and the audience. The audience then responded to 11 items (5-point method) related to their understanding of the presentation, their relationship with the presenter, and their relationship with other audience members, while the presenter responded to 11 items (5-point method) related to their self-evaluation and satisfaction with the presentation and their relationship with the audience. After the class, the participants reported their impressions of the presentation activities incorporating PAN in an open format.

Results

First, the impact of PAN on the audience is shown. First, it was found that <u>the subjective distance between themselves and the presenter was originally close, but PAN brought them even closer</u> (mean IOS rating of 5.53 (SD= 2.00) for N-PAN condition and 5.09 (SD=1.90)) for PAN condition. This difference was significant (t=2.14 (186), p<.05*). Second, <u>the subjective distance between themselves and the rest of the audience was originally close, but PAN brought them even closer</u> (mean IOS rating of 5.66 (SD=2.36) in the N-PAN condition and 5.20 (SD=2.51)) in the PAN condition, and this difference was significant (t=2.00 (186) , p<.05 *). Third, <u>PAN had</u>

the effect of making the audience aware of the shortcomings of the talk. The score for the item "I can explain the bad parts of the presentation to others" was 2.84 (SD=1.16) in the N-PAN condition, but 3.15 (SD=1.03) in the PAN condition, and this difference had a significant trend (t=-1.89 (186), .1>p>.05 +).

Next, we show the impact of the PAN on the speakers. First, it was shown that the subjective distance between the presenter and the audience was originally far and was not changed by PAN (mean IOS rating of 2.57 (SD=1.80) for N-PAN condition and 2.38 (SD=1.66) for PAN condition). Second, we found that PAN lowered presenters' satisfaction with and evaluation of their own presentations. The score for the item "satisfied with my presentation" was on the positive side in the N-PAN condition (3.74 (SD=0.775), but shifted to the neutral side in the PAN condition (3.03 (SD=1.13). This difference was significant (t=2.63 (186) , p>.01 **). The score for "I am sure the audience enjoyed listening to my talk" also decreased from 4.04 (SD=0.58) in the N-PAN condition to 3.59 (SD=0.57) in the PAN condition (t=2.16 (186) , p<.05 **).

Discussion

The act of nodding indicates affirmation, understanding, and empathy (Hewes 1989), and the PAN asked the learners to listen to the presentation so as not to miss the places where such nodding was relevant. In their post-activity reflections, learners stated, "I was able to listen to the presentation with an awareness of where I could relate." and "For I was able to listen carefully to the presentation, it was easy to empathize with the presenter." Such comments suggest that PAN was effective in promoting active empathy with the speaker. In addition, large movements may have made it easier to see nods from other audience members even in the online presentation. These may have reduced the subjective distance between the listener, the speaker, and the other audience members by the IOS scale.

On the other hand, PAN had the effect of making the audience aware of the shortcomings of the talk. This is a side effect of actively searching and listening for points to nod. In other words, by listening to the presentation while looking for points to nod, it is possible that the audience also became aware of the weakness and insufficiency of the talk. The comment such as "I was able to pay attention to detailed information." suggests that PAN made the audience pay attention to parts of the presentation that they would normally ignore, thereby making them aware of the inadequacies of the presentation instead of overlooking them.

The effect of PAN on the speaker was severe: PAN did not reduce the subjective distance between the listener and audience. Furthermore, it lowered their evaluation of and satisfaction with their own presentation. This result is in sync with the study of Pertaub et al. (2002), who found that it is the neutral audience that raises the self-evaluation of a talk, while the positive audience gives only the same level of self-evaluation as the hostile audience. Furthermore, in the present practice, everyone in the class knew about the PAN, and the speakers were aware that the nodding of the listeners was, in a sense, exaggerated and excessive. For this reason, the simple positive effect of nodding could not be achieved. In addition, it can be pointed out that the PAN may have reorganized the activity of the classroom presentation. The true audience of the class presentation is actually the instructor who conducts the evaluation, and the other students as listeners have no agency for the presenter. In this sense, students do not have to worry about the evaluations of other students. However, with the introduction of PAN, other students become active listeners and evaluators who listen while looking for the appropriate place to nod. This may have placed a psychological burden on the presenter to be evaluated.

Conclusion

In this study, proactive-accentuated nodding was proposed. Evaluation of PAN in the college class showed that PAN had a generally positive impact on listeners while having a negative impact on speakers. We also noticed that the introduction of PAN may have reorganized the in-class presentation activities themselves. In the future, we intend to examine the causes of these results through more detailed analysis and to identify ways to design learning methods for better listening.

Examining Preservice Mathematics Teachers' Instructional Moves in Promoting Student Agency

Martin Ako, Marta Kobiela
martin.ako@mail.mcgill.ca, marta.kobiela@mcgill.ca
McGill University

Abstract: This study investigated how elementary math novice teachers (NTs) promoted student agency as they practiced enacting a lesson to engage students in the mathematical practice of defining. We conducted an interaction analysis of video recordings of two NTs' rehearsals to understand how NTs' instructional moves promoted or truncated students' agency. The results highlight ways in which NTs enacted contradictory moves as they attempted to promote students' agency and suggest where NTs might need support.

Introduction

Researchers and educators have sought to encourage students' engagement in mathematical practice (Lehrer et al., 1999). A key aspect of fostering disciplinary practice is promoting student agency, where students contribute and defend their ideas and comment on their peer's ideas (Clarke et al., 2016). Despite its value, promoting student agency can be challenging (Clarke et al., 2016). Research provides some images of more experienced teachers promoting student agency (e.g., Priestley et al., 2012). However, less is known about the teaching moves that preservice novice teachers (NTs) enact when attempting to promote agency in mathematical practice. In this study, we examined the ways that two elementary NTs promoted or truncated (took away) agency as they engaged students in the practice of mathematical defining during a rehearsal. In a *rehearsal*, an NT practices teaching a lesson to their peers, who act as students or observers, while a teacher educator provides feedback (Lampert et al., 2013). We focused on defining because it can be an accessible entry point for children to engage in mathematical practice (Lehrer et al., 1999). We asked: How do NTs promote or truncate student agency to engage in defining?

Theoretical perspectives and methods

We conceptualize *disciplinary practices*, such as defining, to consist of socially-negotiated and historically-situated forms of activity of the disciplinary community (Ford & Forman, 2006). In classrooms, students can engage in defining through activities in which they contrast examples and non-examples of a mathematical object to collectively author a definition (e.g., Lehrer et al., 1999). Because we are interested in how NTs distribute agency while engaging students in defining, we drew upon the sociological perspective of agency which examines agency as a function of the surrounding social structure (Clarke et al., 2016). This perspective involves examining opportunities for teachers to support students to take responsibility for and exert some level of control over their learning. We are therefore interested in how NTs' interactional moves (e.g., eliciting students' thinking) position students as authors of definitions. We thus drew on positioning theory, which provides a lens to understand how social interactions are enacted based on social attributes of the participants (Davies & Harré, 1990).

This study was conducted within a math teaching methods course for future elementary teachers within a teacher education program in Eastern Canada. NTs in the course learned about promoting student agency in defining through analysis of classroom videos, discussion of a reading, reflecting on their experiences when defining, and co-planning a definitions lesson. In addition, within their math and science teaching methods courses, NTs also worked to develop a set of core teaching principles (e.g., children are sensemakers) and practices (e.g., positioning students competently) (Lampert et al., 2013) intended to promote student agency by centering students' voices during instruction. Data came from one class. A subset of NTs participated in a rehearsal to support authorship of geometric definitions. Of the 20 NTs who conducted definitions rehearsals, 11 agreed to participate in this study. NTs conducted the rehearsals in groups of 2-3, with each NT teaching part of the lesson (~7-10 minutes). NTs were provided with two different definition lesson plan templates that they could use. To allow for a fine-grained analysis, we selected two NTs (Sam and Liz (pseudonyms)) who taught different lessons. We conjectured this might present a greater variety of ways in which student agency was promoted or truncated. Sam had taught a grade 2 lesson to define triangles. She started by asking students to discuss whether a shape was a triangle and then had them construct triangles and justify their constructions. Throughout their discussion, they collectively wrote rules for triangles. Liz taught a grade 4 lesson. She asked students to compare within and across groups of shapes, pre-sorted into types of quadrilaterals, to construct definition rules for different quadrilaterals.

To understand the nature of the NTs' moves when teaching, we drew upon Erickson's (1992) approach to interaction analysis. First, we delineated the rehearsal videos into episodes that began when the NT started teaching and ended when the NT stopped teaching (Lampert et al., 2013). We then transcribed the episodes, focusing on both verbal utterances and actions, and used conventions to capture emphasis, overlapping/latched talk, and pauses. We identified aspects of organizational structure by noting shifts in the topic or focus of discussion. We then identified participation structures to determine where agency was distributed by asking: Who is the primary speaker(s)? How are others participating (e.g., Agreeing?). Finally, to characterize the interactional moves that NTs used to promote or truncate agency, we asked a set of analytic questions about each turn of talk.

Results and discussion

Our results indicate that while the NTs made efforts to promote students' agency in defining, they nonetheless struggled in how they sustained students' agency. We provide two illustrative examples. First, the NTs sometimes *framed defining as a collective activity* for students to contribute rules and properties by using words such as "we" and "us". For example, Liz introduced the discussion by stating, "Ok, so we are gonna write some rules about how group A is different from any other quadrilateral that we sorted." Yet, at other times, Liz used language that *framed defining as individual activity* in which she was the sole author. For example, Liz asked students about the name of the "angle" of a square shown. After a student said, "a right angle," Liz responded, "A right angle. So in (group) A, I am noticing that…the squares have right angles-yeah," hence adding a new rule to the definition of square by herself. Even when another student drew attention to other shapes with the same property, Liz did not open the proposal for discussion but instead wrote it down as a rule for the shape. By fluctuating between the use of "I" and "we," she sent mixed messages about the distribution of agency. Second, both Sam and Liz *extended students' agency for participation to new students by asking for additional rules or properties*. They did this by recruiting more ideas on the same topic. For example, after Sam had already asked students to comment on why the example she had presented was a triangle, she asked, "What's something else that can tell us it's a triangle by looking at the picture?" In both rehearsals, this move allowed multiple students to participate in authoring definitional rules. However, NTs also *did not encourage discussion about students' proposed rules*. Instead, as seen in the example with Liz, when students introduced correct ideas, the NTs labeled the proposals as "rules" and wrote them on the board as rules. By shifting the authority to themselves, the NTs truncated students' agency.

Our study makes a contribution by characterizing novice teacher practice in promoting student agency when supporting mathematical practice. Our results highlight the complexities involved when NTs attempt to promote student agency. Given that the rehearsals were organized around core practices (Lampert et al., 2013), one would expect NTs to enact these practices with fewer difficulties. These core practices served as starting points for NTs to promote student agency (e.g., by inviting collective participation for students to contribute rules and properties). However, NTs also enacted these practices in ways that truncated students' agency (e.g., by revoicing too soon). Our results may help teacher educators anticipate ways that NTs may truncate agency.

Pragmatic Imagination: A Tool for Seeding Participatory Design

Bregje van Geffen, Mary Lou Fulton Teachers College, Arizona State University, bvangeff@asu.edu
Steven Zuiker, Mary Lou Fulton Teachers College, Arizona State University
Ruth Wylie, Mary Lou Fulton Teachers College, Arizona State University

Abstract: This study explores the design and use of activities that seed and support district-wide teacher participation in developing a garden-based learning program. Participants envisioned and shared preferred futures for school gardens by fostering pragmatic imagination in a process of thought and action. Thematic analysis of artifacts establish five preferred futures that can serve as a foundation for ongoing participatory design framed in relation to future possibilities as well as past and present circumstances.

Introduction

Garden-based learning in the US is a century-long participatory design agenda within school communities, among schools and their local neighborhoods, and, most recently, across a national network of support organizations (i.e., sgsonetwork.org). As part of a researcher-practitioner partnership, this study positions school gardens as everyday project sites for integrating STEM opportunities and, by the same token, integrating student garden experiences across subject areas. This study aims to contribute to scholarly discussion on the role that possible and preferred future scenarios play in co-designing and continuously improving education programs. To this extent we employ the idea of pragmatic imagination (Pendleton-Julian & Brown, 2018) as theoretical inspiration for seeding the co-development of curricular activities and projects using an existing garden-based learning framework (Zuiker & Wright, 2015). In particular, the study examines the enactment of activities that challenge teachers to envision preferred future possibilities for a garden-based learning agenda over the next 10 years. Our design intention is to engage participants in exploring what is and what can be by grounding participatory design in creating possible future scenarios This preliminary effort interrogates emergent, future-oriented qualities of the outcomes generated through these activities.

Theoretical framework

Grounded in pragmatic philosophy, the idea of pragmatic imagination assumes that thought and action are irreducible aspects of experience (Alexander, 1990). Moreover, thought and action in educational and participatory design processes alike depend not only on how judgments situated in the present moment relate to habits developed through past experience but also how they relate to imagined possibilities projected into the future (Pendleton-Julian & Brown, 2018). Therefore, imagination from a pragmatic perspective is a critical partner in reasoning; it is a gap-filling process (Pelaprat & Cole, 2011) utilized to frame problems and envision possible resolutions (Steen, 2013). While the idea of pragmatic imagination is theoretically rich, embodying it in the design of participatory design agendas the learning sciences (e.g., Zuiker et al., 2017) remains limited. To seed interplay among past, present, and future as resources for participatory design, the following design study addresses this gap by fostering pragmatic imagination around possible future scenarios for garden programs.

Design

Two activities embody pragmatic imagination by challenging teachers to push the boundaries of the present toward possible futures. First, groups co-constructed a map of their school and local communities in order to identify allies and prospective partners. Second, groups discussed the future of garden-based learning in their schools in order to co-construct a newspaper frontpage from the future, including a headline and short lede about programmatic successes in the year 2032 (cf. Finlev et al., 2018). Underlying these activities, engaging with an extended timespan, like future headlines, can invite optimistic goals and increase empathy while potentially also reducing blind spots (McGonigal, 2022). Headlines, therefore, constitute a single written artifact grounded in both the relational task of partnering and the aspirational task of envisioning preferred futures.

Methods

A total of eleven teachers enacted our designed activities for 30 minutes during a monthly district-wide development meeting in the US southwest. Four pairs and one triad completed both activities, generating five future newspaper headlines and ledes. Thematic analysis (Preiser et al., 2022) organized inductive coding of the headlines in conjunction with their ledes, allies, and prospective partners.

Findings

Our thematic analysis resolved five themes: formal learning initiatives, expanding garden initiatives to home, expanding garden initiatives to the community, connecting gardens to in-school facilities, and within-garden initiatives. For example "Growing Minds and Gardens in the district community" aligns with the theme *within garden initiatives* because the group imagined a pollinator, vegetable, and indigenous plants garden; and with *expanding garden initiatives to the community* because the lede links the garden to a community farmers market. In this section we describe each theme in order to arrive at judicious interpretations of the future-oriented qualities of the activity outcomes. Four of the five groups imagined different ways to use the garden for *formal learning*, including ways to integrate the garden (partly) with the academic curriculum (e.g., using the garden as a habitat for science lessons), incorporating nutrition into the program (e.g., by working with a chef), implementing environmental education, and providing outdoor experiences for students (e.g., creating an outdoor classroom). Two groups had ideas on how to *expand gardening learning to home*. One group imagined allowing students to take food from the garden home, and another group suggested the garden project could connect with existing initiatives such as ones that provide farm fresh food bags. While all groups were interested in connecting to their local community, one group imagined *expanding school facilities for community use*. Their idea was to start using school spaces for neighborhood support by using the garden as a community garden, organizing farmers markets with cultural activities, giving access to a ‘food forest’, and building relationships with alumni. In addition, two groups imagined *connecting the garden with other school facilities* by using the harvest from the garden for meals in the school cafeteria. Finally, two groups imagined *possibilities within their garden*. One group imagined creating a pollinator and vegetable garden and growing indigenous plants, while the other group imagined a thriving ‘clean’ garden with edible plants. The 5 thematic descriptions above illustrate how participants projected and explicated current efforts to develop curricular activities and projects onto preferred futures for their shared agenda. At the same time, the themes also expansively frame participatory design by seeding aspirational goals in the immediate present purpose of curriculum development. Discussion considers affordances of future-oriented qualities for participatory design processes.

Discussion

We conjecture that the idea of pragmatic imagination can be a powerful tool for seeding participatory design. Findings demonstrate aspirational goals that amplify a present moment design agenda by projecting future possibilities associated with thinking about and acting through a district-wide, garden-based curriculum development agenda. The positive and opportunity-based qualities underlying these headlines can serve as a robust foundation for ongoing participatory design at the intersection of the past, present, and future of this agenda. In the upcoming months, we will be using the data we gathered during the activity to explore how teachers imagined embedding their future school garden within social networks as well as how teachers showed agency during the activity needed to put their ideas into action. In addition, we will use the results of this paper to make a video of the ideas the teachers imagined for their future garden and present that to them so we can use their feedback to reflect on our results. As we think this pilot study showed the potential of its ability, we think it is important to conduct additional research that provides insight into the working mechanism of how knowing, making, and playing are bound together by the imagination (i.e., Pendleton-Jullian & Brown, 2018).

Toward a “Queering” of Mathematics: Understanding the LGBTQ+ Experience and Designing to Disrupt Normative Learning Practices

Nickolina Yankova, University of California, Irvine, nyankova@uci.edu

Abstract: The experience of LGBTQ+ students in mathematics has been underexplored despite mounting evidence of discrimination, hostility, and retention in higher education and the workforce. This poster presents a qualitative pilot study which draws on semi-structured interviews to understand how one’s queer identity informs their experience in mathematics. Grounded in sociocultural learning theory and queer theory, it further aims to distill emergent design principles for a “queering” of mathematics that deconstructs and disrupts normative learning practices.

Introduction

With the sociopolitical turn in mathematics education, issues of power, identity, and equity have become especially important, undermining previously held perceptions of mathematics as culture-free and unbiased (e.g., Gutiérrez, 2013). Despite mounting evidence of discrimination, hostility, and retention in higher education and the workforce (e.g., Freeman, 2020), LGBTQ+ students have largely been left out of the discourse around minoritized populations in STEM, and mathematics in particular. Only relatively recently has such work started to emerge with visibility studies centering the experiences of LGBTQ+ students (e.g., Forbes, 2022) and curriculum design studies focusing on more inclusive pedagogy and content (e.g., Rands, 2009). Though advocating for inclusivity and representation in course design is important, what is needed is a more consolidated push toward a “queering” of mathematics in learning design at large that calls for a rupturing of existing norms and practices and a deeper rethinking of who and what gets privileged in mathematics spaces, with implications for the design of more equitable learning environments in mathematics (Dubbs, 2016). In this poster, I present preliminary findings from semi-structured interviews with graduate students who identify as queer to address the following research questions, guided by sociocultural learning theory: *How does one’s queer identity inform their perceptions of and experience in mathematics? How do we design for a queering of mathematics which deconstructs and disrupts normative learning practices?*

Toward a queering of mathematics

Once a slur, the term “queer” has been reclaimed in recent decades, in part as a transgressive act and in part as affirming identity. Definitionally, queer can be understood one of two ways: as pertaining to a minoritized gender or sexual identity (i.e., signifying an LGBTQ+ identity) or as pertaining to queer theory, a critical theoretical lens that challenges, deconstructs, and disrupts what’s normative, with an orientation toward action for social justice (Rands, 2009). The act of “queering” in the latter case then represents a subversion of norms toward equity. Applying queer theory in the learning sciences has been a relatively recent endeavor, with some disciplines and contexts emerging as more “queerable” than others, namely those in the humanities and social sciences (Rands, 2009; Dubbs, 2016), for their centering of social issues, with math not intuitively subject to be queered. Rands’ foundational work on “queering the unqueerable” identifies two approaches to a queering of mathematics, an “add-queers-and-stir” approach toward representation and inclusivity and “mathematical inqu[ee]ry,” an inquiry-based approach beyond inclusivity toward social justice.

Methods

In this exploratory pilot study, situated in the context of a 4-year minority-serving public institution in Southern California, with an HSI and an AANAPISI designation, I interview queer graduate students (n=4, ongoing) to understand how one’s queer identity informs their perceptions of and experience in mathematics, toward distilling emergent design principles for more equitable spaces for mathematics learning. Interviews are being conducted in person, or over Zoom, and are audio recorded, including questions around one’s experience as a queer person in mathematics, with other topics touching upon the tools, materials, and spaces of mathematics learning. In my analysis, I engage in iterative thematic analysis to surface emergent themes around queer students’ experience in mathematics, informing subsequent design goals.

Findings

In my preliminary analysis, the following themes around current curricular practices emerged as salient in informing identity and perpetuating an idea of mathematics as a space for dominant groups in the field (i.e., white, male, straight): *reinforcing the binary; math as impersonal; math as stagnant; math as gendered; importance of intersectionality*. Table 1 below presents a brief description of each theme and a corresponding data excerpt. In reflecting on their experiences, participants further painted a line of contrast between mathematics and the humanities or social sciences, where aspects of identity are made visible and more welcome, which is in line with extant work (Rands, 2009).

Table 1
Emergent themes

Theme	Description	Data excerpt
Reinforcing the binary	Math reinforces binary stereotypes.	*“Math is supposed to be this simple, sequential, binary thing… it always has a specific outcome.”*
Math as impersonal	No space for one’s identity in math.	*“You are not supposed to bring anything of you or from your background.”*
Math as stagnant	Math hardly changes over time.	*“What you’re learning has already been known, and there's only for you to now learn that.”*
Math as gendered	Math is perpetuating gender norms.	*“Most of the classes I took were very like male-dominated.”*
Intersectionality	Aspects of identity as intersecting and tightly connected.	*“I can't isolate my queerness from everything else that I am.”*

These five themes further presented opportunities for points of disruption of current norms and practices toward more equitable spaces for mathematics learning, configuring design goals to aim for (i.e., designing to disrupt the prevalence of the themes above). As such, a queering of mathematics should aim to dissipate binary divides and the focus on discrete outcomes and weave in considerations of math on a continuum (e.g., by considering different problem-solving approaches and the plurality of what counts as mathematics). It should further present opportunities for bringing one’s intersectional identity to the classroom (e.g., by leveraging applied mathematics in context and integrating personally-relevant, mathematics-integrated projects and products) and consider ways of challenging the notion that math is stagnant by shifting class structures and teaching practices (e.g., by shifting focus to collaboration as opposed to individual work or by drawing on different materials in the teaching and learning of mathematics).

Discussion

This exploratory pilot study sheds light on the experience of queer students in mathematics and contributes to a pressing call for a queering of mathematics toward more equitable learning opportunities for LGBTQ+ students (Dubbs, 2016). It lays the groundwork for further work to expand upon the design recommendations above and concretize them with a design implementation. With no consolidated approach on how to queer mathematics, a promising starting point, for instance, would be calling into question the dominant tools and materials that are in use in mathematics spaces.

Scientific Practices in Professional Coffee Roasting

Bradley Davey, Reed Stevens
bdavey@u.northwestern.edu, reed-stevens@northwestern.edu
Northwestern University

Abstract: This poster expands imagery about who and what counts as "scientific" through examinations of non-laboratory, scientific workplaces. Using participant observation and microethnographic analyses of professional coffee roasters, we demonstrate that their senses are (1) used as scientific instruments, (2) coordinated with more normatively recognized instruments, and (3) prioritized over those instruments in moments of conflict. This analysis offers ways to recover the body in scientific work—a growing concern in the era of the Next Generation Science Standards.

Introduction and methods

American K-12 science education is modeled after the practices of professional scientists (NRC, 2012). These practices convey science as a disembodied, objective, and value-neutral enterprise—an image of science some call the "Legend" (for an extensive review, see Miedema, 2022). Recent scholarship calls for the body, along with its embodied practitioners, to be recovered and recentered in scientific activity (Latour, 2004; Maslen & Hayes, 2022) and science education (Hardahl et al., 2019; Stevens, 2012; Varelas et al., 2022). This poster responds to such calls and expands both who and what we count as scientific through close-up examinations of *non-laboratory, scientific workplaces*. Systematic investigation of these workplaces stands to reshape and expand our images of science, which in turn, shape the ways that science education is conducted in schools. In this poster we present an image of science developed from one of these everyday scientific contexts, that of professional coffee roasters among whom we have conducted ethnographic fieldwork. The work represented here builds upon prior attempts to expand understandings of what should count as science and mathematics (e.g., Bang et al., 2012; McDermott & Webber 1998; Stevens, 2000; Stevens, 2013) by locating the body as irreducibly central to roasters' workplace practices.

We began participant observation (Becker & Geer, 1957) at coffee roasteries in a large Midwestern American city in May 2022. We have since participated alongside and observed roasters in their workplaces, at professional conferences, company-wide trainings, and coffee courses. This poster draws from a broader corpus that consists of audiovisual data (Erickson, 2006), semi-structured and photo-/video-elicitation interviews (Harper, 2002), as well as field notes, jottings, memos, and annotated photographs (Emerson et al., 2011). In total (and ongoing), these sources represent roughly 200 hours and 250 pages of data.

Through interaction/microethnographic analysis (Streeck & Mehus, 2005; Stevens & Hall, 1998) we developed three claims about the scientific work of coffee roasting. The senses are (1) *used as scientific instruments*, (2) *the senses are coordinated (Hutchins, 1995) with more commonly understood scientific instruments*, and (3) *the senses, as scientific instruments, are prioritized over other instruments when they provide conflicting information*.

Findings: The senses as scientific instruments

Interaction analyses showed that coffee roasters' senses act as instruments to generate evidence and warrant claims. This evidence takes the form of evaluative statements like, "that smells great" or "that smells burnt, and we should try again." Roasters also generate evidence in the form of specific flavor and aroma experiences like "strawberry," "chocolate," and so on, and warrant claims about the quality of coffees with such statements.

Roasters coordinate their senses with more normatively recognized scientific instruments. For example, a roasting team in our study used an instrument known as a ColorTrack. This is a $7,000 device that analyzes the color of raw and roasted coffee and resembles spectrophotometers found in laboratory science. Roasters used their senses of smell and sight in coordination with the ColorTrack to determine the roast level (i.e., light, medium, dark) of coffees and to iterate on successive roasts of experimental coffee products.

What the senses 'said' often conflicted with different instruments (such as the ColorTrack), a situation Stevens and Hall (1998) term a "breakdown." These moments are when we learn that the body is a roaster's *most important* scientific instrument. Stevens and Hall write, "Breakdowns occur when routine ways of working are disrupted. And disruptions can appear at different places in a system of activity" (p. 140). When a roaster's senses conflict with their various representational media (e.g., ColorTrack, time, and temperature values), the senses are given priority. We have not observed a single instance of the instruments overruling the senses.

Discussion

In this poster we argued that coffee roasting not only involves scientific work and practices, but that the body is its key scientific instrument. Data showed that much of this sensing is coordinated (Hutchins, 1995; Stevens & Hall, 1998) across members of the roasting team and between internal representational states (the senses) and external representational media (data and material artifacts). Moreover, roasting involves highly disciplined ways (Stevens & Hall, 1998) of perceiving the world which in our fieldwork we can see through breakdowns in roasters' activity. As roasters resolved these breakdowns, we found our argument: that the body is *the* most important instrument—rather than an auxiliary instrument—as roasters prioritize their senses over conflicting forms of instrument-generated data. In advancing this argument we aim to contribute to ongoing conversations within science (e.g., Latour, 2004; Maslen & Hayes, 2022) and science education (e.g., Hardahl, 2019; Varelas et al., 2021) that challenge the erasure of the sensing, agentive body in images of science (Stevens, 2012).

Ongoing conversations about the body's role in science education are needed, as they influence how we teach and learn science. In our broader research program, we seek to also question the who and where of scientific practice, where the laboratory remains the default standard of what counts as science. Our examination of coffee roasting, the first of many planned sites for the investigation of *everyday scientific practice*, stepped outside of the lab into the wider world of how science is used. The roasters in our study inspire us to imagine potential transformations of science education; in the future we hope that this line of research will inform reconstructions of disciplinary education in science and beyond (Stevens et al., in preparation).

Mathematics Learning Supported by App: An Experience With Students From a Public School in Maceió (Brazil) in a Learning Sciences Project Identifying the Arithmetic Discourse Profile

Claudia de Oliveira Lozada, Federal University of Alagoas, clalloz@yahoo.com.br

Abstract: This work brings a qualitative research is being carried out by the Federal University of Alagoas and is based on an intervention in a public school in Maceió, Brazil. Using the Arithmetic Discourse Profile analysis tool and its criteria, we were able to assess the level of students' mastery of mathematical operations by integrating the use of applications with concrete material. The results showed that in relation to the criteria of focus on goal or on procedure and bondedness, students still have difficulties hesitating when talking about procedures, expressing uncertainty. Regarding the objectified/syntactic mediation, flexibility, agency/external authority criteria, there was an improvement, demonstrating that the use of integrated applications with concrete material for learning mathematical operations is effective.

Introduction

Nathan, Walkington and Swart (2022) explain that "mathematical cognition emerges from the interaction of symbolic, verbal and sensorimotor knowledge and processes; symbol systems are important disciplinary representations that encode formal knowledge, but their arbitrary, abstract, and amodal (i.e., ungrounded) nature presents challenges for learners". Thus, mathematical cognition is a complex process that also implies the subject's interaction with the environment, with the object and with the other in the construction of knowledge as a social practice.

On the other hand, it is necessary to analyse what discourse the students construct about arithmetic and the learning of mathematical operations and, therefore, is essencial observe and collect information about the participation processes, procedures used and identity in the narratives produced along the learning path, examining students' verbal interactions and writing by doing a procedural assessment. Therefore, the analysis through the Profile of Arithmetic Discourse proposed by Heyd-Metzuyanim, Tabach and Elbaum-Cohen (2022) using the criteria of Objectified/syntactic mediation, Flexibility, Agency/External authority, Focus on goal or on procedure, Bondedness will enable assess the extent to which a student masters arithmetic discourse by showing signs of understanding of basic arithmetic operations. In this sense, we present the initial results of a research involving the use of Apps integrated with concrete material to improve the learning of basic arithmetic operations, considering the use of technologies in the teaching-learning process, as recommended by the National Common Curricular Base, educational document Brazilian.

Pedagogical intervention using apps integrated with concrete materials

The experience reported in this work is an initiative that originates from the Academic Actions Committee of the Community of Learning Sciences Brazil (Ca.Br) from one of its functions, which is to articulate actions with Universities. The project started in August 2022 with 5 meetings in the workshop for teachers and 2 days of intervention at school, in classes from 1st to 5th grade of Elementary School.

Thus, in this work, we present the initial results of the intervention with two students who have difficulties in basic arithmetic operations and, for that, we use an App integrated with concrete materials to improve mathematical learning. To carry out the pedagogical intervention, we designed a map, with the methodological route in 3 steps, called Map of the learning process supported by App integrated with concrete materials: 1. Embodiment: use of App involving basic mathematical operations integrated with concrete material, in this case, golden material and open abacus. 2. Mediated Process: individual follow-up of the student while using the App, observing how student perform the operations (using mental calculation, verbalization, finger counting, use of paper and pencil), what difficulties student have (at that moment, the teacher intervenes with questions integrating the use of concrete materials to support the learning process with the use of the App, asking the student to explain his reasoning and if the doubt persists, the teacher explains demonstrating with the two resources – the App and the concrete material). It is a phase of learning monitoring, intervention and explanation for students. 3. Outcomes: triple collaborative process: between the student – integrated didactic resources (App and concrete material) – teacher mediation. It is expected an improvement in learning and the development of mathematical skills and competences such as understanding the algorithm of operations, agility in mental calculation, diversity of ways of performing mental calculation (by grouping and decomposition) and justification of mathematical procedures used to resolve operations. For this intervention, the App was used "Funny Mathematics" available on PlayStore, two kits with golden material and two abacus. The App features the four basic arithmetic operations: addition, subtraction, multiplication and division. It has an attractive layout with characters.

Findings and discussion

We will describe the results of 2 students who are in the 2nd year of Elementary School, aged 7 and 8 years old. The intervention was mediated by two monitors from the Matedtec team of the Federal University of Alagoas (Brazil). The first action of the intervention was the presentation of the App and how it works. The students knew about the golden material and the abacus because they participated in another intervention carried out the week before. At the beginning with smaller numerals, they were able to carry out the operations, although with greater slowness and in subtraction, they had the help of the golden material. As the numerals introduced consisted of tens, there was greater difficulty and mediation with the golden material was intensified, at the same time that they counted using their fingers. They do not master addition and subtraction operations that require regrouping and several times when asked about the meaning of 1 or 2 tens, they had difficulty to answer. So, it was necessary to use the abacus and show the orders and classes and then, as they were able to understand the orders and classes of numerals up to tens and the Matedtec team intensified the integration of operations with the App and golden material, the students were able to perceive that the noun 1 ten, 2 tens mean numbers/quantities (Objectified/syntactic mediation). With the use of the golden material and the abacus, the students realized that there is more than one way to carry out calculation procedures and in the different rounds they started to vary the procedures (Flexibility), as well as they started to pay more attention to the monitors' speeches during the mediation by examining verbs and pronouns related to the operations, which helped to perform the calculations, that is, they improved attention to look for verbal clues to solve the operations (Agency/External authority). But, regarding the Focus on goal or on procedure, in the subtraction operation with regrouping they could not explain the procedure and when the team explained it, they could not relate the procedure to the result, that is, they had difficulty in examining the procedure even with the aid of the golden material, presenting difficulties in relation to Bondedness. Regarding the division, they had difficulties and the use of the golden material was essential for them to understand the division based on the distribution of equal amounts. Regarding multiplication, in some operations performed with the 6, 7, 8, 9, the students had difficulties and again the use of the golden material was essential for them to understand what it means to multiply one factor by the other, that is, grouping with equal amounts . Thus, the students had greater difficulty in the multiplicative conceptual field that encompasses division and multiplication operations.

With intervention, there was a significant advance in the understanding of addition and subtraction operations when the App was associated with concrete material. It was found that this integration of didactic resources contributed to improving mental calculation, and it is important that the subtraction algorithm with regrouping is worked first with concrete material so that the students understand the role of orders and classes and quantities that exceed, so it is necessary to regroup and relocate in another order, for example, in the tens. These results also confirmed what Andin, Fransson, Rönnberg and Rudner (2015) found in a research: parietal activation patterns demonstrated greater involvement of the visual and quantitative systems for calculation than language. Hence, the layout of the App (visual aspect) and pieces of concrete material (quantitative aspect) when integrated, substantially improved the understanding of mathematical operations by the students, that is, there is a sensorimotor integration (touch on the smartphone screen and manipulation of the pieces of the golden material). The authors also identified that in exact operations the verbal system is more activated than in approximate mathematical operations and this we noticed when the students had to do the subtraction with regrouping, because in the case of an operation of passing the quantity to the other order, the students had difficulties in regrouping and explaining orally what should be done, that is, the retrieval of arithmetic facts in the cognitive structure is more agile in operations without regrouping, the language-calculation network is easily mobilized because they find more specific activation patterns and more similar ones that have already been assimilated.

Preparing Preservice Resident Teachers for Equity-Centered Computational Thinking in STEM (STEMeCT) Education

Jesse Ha, Wei Wei, Kimberley Gomez
jesseha@ucla.edu, weiwei17@ucla.edu, kimgomez@ucla.edu
University of California, Los Angeles

Abstract: While computational thinking (CT) in science, technology, engineering, and mathematics (STEM) education has been gaining momentum, there is a shortage of qualified teachers, especially in low-income schools that primarily serve minority students. STEM+C3 seeks to ameliorate the problem by establishing an urban teaching residency program that prepares teaching candidates to integrate CT and equity-centered practices. The project aims to understand the impact of the program on teaching residents and their students' perceptions of equity and CT.

Introduction

The integration of computational thinking (CT) in science, technology, engineering, and mathematics (STEM) education has been gaining momentum over the last 15 years (Tang et al., 2020; Weintrop et al., 2016; Wing, 2006). However, there is a shortage of qualified teachers, especially within schools that serve students in high poverty urban or rural and/or in high minority communities (Barth et al., 2016). Moreover, these same students have been marginalized in STEM fields, only making up 13% of the STEM workforce while comprising approximately 38% of the US population (Aish et al., 2018; Anderson, 2015). Nationwide, access to CS education is inequitably distributed with Black, Latino, and Native American students and students eligible for the National School Lunch program having the lowest access (Simoni et al., 2016).

STEM+C3 is an urban teacher residency program at University of California, Los Angeles (UCLA) that seeks to respond to these problems by taking an equity-centered approach in preparing pre-service resident teachers (TR) to integrate CT within their STEM classes in underserved communities. STEM+C3 integrates three critical C's: 1) computational thinking practices; b) computer science principles; and c) community of practice to foster a sustainable and systemic approach for developing equity-centered STEM teachers who understand and leverage CT in their teaching practices. STEM+C3 seeks to integrate these C's through a two-year cohort model. The program supports TRs by integrating CT and CS into their teacher preparation coursework at UCLA and pairing TRs with experienced partner teachers (PT) within a local partner school district who mentor the TRs following a gradual release of responsibility model (Fisher & Frey, 2013). Thus far, the program has recruited three sets of cohorts totaling 39 TRs, including 16 math and 23 science teachers. The TRs participate in a summer professional development (PD) workshop that introduces a framework for embedding CT and equity into STEM, 90 hours of partners in practice PDs that deepen TR understanding of CT by engaging them in cycles of reflection and revision, and a community of practice forum that engages TRs and their respective PTs in sharing knowledge.

STEM+C3 draws on asset-based pedagogies that are culturally relevant (Ladson-Billings, 1995), responsive (Gay, 2002), and sustaining (Paris, 2012) and their application to computational thinking (Kafai et al., 2020). Our program also conceptualizes CT as a tool for underrepresented students to resist marginalization and oppression in and outside of STEM classrooms (Kafai & Proctor, 2022). In brief, our program's approach involves mentoring and training teachers to design lessons and curricula that integrate CT practices and which explicitly value their culturally-relevant ways of knowing and being (Gay, 2002). Figure 1 provides a depiction of the integration of equity and CT within STEM+C3.

Research on the impact of the STEM+C3 is guided by questions at three levels that seek to ascertain: a) the program's impact on supporting TRs becoming equity-centered CT-integrated STEM (STEMeCT) educators; b) what specifically was involved in the development of TRs perceptions, conceptions, and understanding of becoming STEMeCT educators; and c) the impact and extent as well as the ways in which students have responded to TRs STEMeCT instruction. Our data sources include individual, partnered (TR & PT), focus group, and artifact-based interviews, surveys, equitable assessments of CT knowledge, classroom observations, artifacts from professional developments and classrooms, and learning management system data for TR coursework at UCLA.

Figure 1
Computational Thinking for Equity

<table>
<tr><th colspan="2">Computational Thinking for Equity
CT for Equity seeks to empower students to use problem-solving and design skills that are informed by computing to explore, express, critique, and create artifacts about the world around them.</th></tr>
<tr><td>Develop and Use Abstraction
Consider and focus on key components and filter out unnecessary details to make problems easier to solve and includes acknowledging the benefits and consequences of generalizations and or lost details.
Decomposition
Break down a problem of interest into smaller, more manageable components, and the ability to describe this process in detail in order to make decisions, obtain help or find solutions.
Exploring Equity Issues through Computational Thinking and Data
Encourage alternative ways of solving problems. Promote inclusivity and provide universal access to all students, particularly those from underserved and intersectional populations.</td><td>Algorithmic Thinking
Recognize when a solution to a problem can be broken into step-by-step instructions. This set of instructions considers the audience, the purpose, and can be used by someone else or a computer.
Debugging and Evaluating
The ability to identify and correct errors within an algorithm, and ensuring your solution is effective, feasible, and considers the impacts on various identities.
Collaborate Around Computing and Data
Work with others to understand, develop, and design computational artifacts or data visualizations to explore and explain phenomena, solve problems, or develop solutions that matter to students.
Communicating with and About Computing and Data
Describe, explain, and justify observations, patterns, and predictions around computational artifacts and data within the context of the problem as well as communicate applicable ethical considerations.</td></tr>
</table>

Abstract: We report on a program designed to sustain undergraduate and graduate geosciences students' critical identity work in and around geosciences disciplines *and* the prospects of changing them for more equitable futures. We analyze students' culminating narrative artifacts to theorize broader processes of identity development and learning.

Introduction and theoretical framework

Among the natural sciences, the geosciences have suffered from a particularly persistent lack of diversity stemming from issues of access to programs and resources and, crucially, from deep historical and cultural practices within the field's various disciplines (Ormand et al., 2022). To address these issues, a university-based program ("The Program") was specifically designed to engage undergraduate and graduate students in a set of activities that sustain their identity work (Tan et al., 2013) in and around geosciences disciplines *and* prospects of changing them for more equitable and just futures. Here, we analyze students' culminating narrative artifacts to theorize about broader processes of identity development and learning in the sciences.

We draw from sociocultural and sociopolitical theories of learning and frame identities as lenses through which a person positions themself and their actions and through which others position such a person relative to socially and culturally available categories (Varelas et al., 2012). Identity *work* can thus be observed two prominent ways: in (1) in ongoing social interactions, as individuals negotiate, contest, and reify their multiple identities within communities of practice; and (2) in one's own narrative self-elaborations relative to practices and communities (Tan et al., 2013). We also draw from narrative perspectives on sensemaking and changemaking, recognizing that stories told about the geosciences reflect ways of finding meaning and value in the world, and mediate organizing processes for social and cultural change in the discipline. Examining student narratives thus gives us insight into their *experience of becoming* geoscientists, the meaning they see in this process, and what they feel is important for others to know.

Empirical context and method

The Program engages students over the course of two semesters in the authoring of personal narratives that are designed to change people's perceptions of what the geosciences are and who can become a geoscientist. The goal of the program is to show students how their own personal experience affords them a unique perspective to influence the discipline. Students are taught that narratives are "compelling" to an audience due to the way that storytellers establish and resolve conceptual, emotional and values-based tensions, and that narrative sensemaking within the contexts of a story can also pattern and compel certain ways of making sense of the world more broadly. Further, they are taught that counternarratives are a particular kind of narrative where storytellers draw from their own particular experiences to craft stories that stand in tension with status quo interpretations of the world, and which rationalize and compel change for better, more just and equitable futures. Students then set to work developing their own "changemaking (pathway) stories" to be crystallized in a short web-based video (~ 5 minutes) and a written personal profile, a process which involves personal reflection, interviewing (home) community members to better understand their audience and message, and participation in biweekly meetups where iterative drafts of stories are shared for peer feedback. To date, three cohorts of Program participants produced 28 video-based "pathway stories" and associated text-based personal profiles on a public website. These constituted the data corpus for this study and are treated as embedded cases for descriptive and comparative analysis. We took a narrative approach to the data (Czarniawska, 2004), treating stories as artifacts of student sensemaking that may reveal, pattern and contest the way meaning in experience is found and made. Members of the research team initially viewed cases independently, open coding videos and the text of the profile pages and writing short analytic memos. Codes were then compared and refined, a process that revealed that many students told their stories in the general form of a counternarrative, but constructed their narratives from very different kinds of experiences and for very different ends. We then analyzed, discussed and contrasted cases using a shared scheme for coding narrative elements: context, tension, resolution, change project, counternarrative, and lesson.

Analysis and results

For brevity, we present a single case—that of David (pseudonym)—to illustrate our main findings. David was a second-year geology student interested in studying paleontology. He rooted his "pathway" narrative chronologically in a childhood fascination with dinosaurs and youth-oriented science books. In his story, he identifies himself as Hispanic and a Catholic, and says he grew up in Texas where he did all his education and "found" his faith (profile). A dualism between "intellectual" and "faith" was thus established as the central emotional and epistemic tension driving his narrative. While he began to "fall in love" with his faith in middle school, the school "questioned" him about his belief in science. The school believed in a literal interpretation of the bible, and forced him to pit "science and faith against each other" in his own mind (video). Dealing with this was a "struggle" (video). David traces this struggle forward in the context of his schooling, saying that he experienced "the opposite problem" when he entered an "intellectual" culture in high school that "challenged" and "questioned" how he could "believe" in a thing that "doesn't have proof" (video). It wasn't until after a great deal of thinking, research and praying that he found a way to "resolve" the "schism" inside himself dividing faith and science (profile). He realized that belief without proof is "the definition of faith" (video). Not only did he not need to choose between science and faith, but "they rely on each other" and are both necessary to "answer each other's biggest questions" (video). Science and faith both "define" him, and they do different things. "Without a creator," the "mysteries" and "coincidences" in science would never be explained. Faith also instills in him an "appreciation" for nature and a "responsibility" to "learn" about and "take better care" of it (profile). Now he feels his scientific path in paleontology has been "set before" him by God (profile), and he studies geology not just to "discover new dinosaurs," but also to "enact social justice" and apply his learning about the past "to take care of" the present and future planet (change project; video). David draws a key lesson from his experience: While it may at the time have seemed easier "to simply choose a side" in the "struggle between two choices," he needed to have the courage to "swim in the gray" long enough to see that the choice was not "as simple as it seems."

In this narrative, we see David positioning himself as a child fascinated with dinosaurs, a Texan, a Catholic and a serious student. He articulated a formative tension he experienced navigating schooling environments that challenged and pressured him to make a stark choice: faith or science. It was his resistance to this normalizing pressure that caused him discomfort, but ultimately enabled him to understand religious and scientific worldviews as complementary and see how they could make him a more socially and ecologically conscientious scientist. David was not alone in presenting counternarratives built around tensions that were resolved through an eventual realization that one did not need to respect categories or choices received from authorities. Other student narratives drew a similar lesson that younger people could and should take time to hold complexity long enough to understand how to approach academic and professional disciplines in a different way. Having the courage to "swim in the gray" and maintain a critical stance toward received worldviews is directly linked to student's identity and future visions of changemaking.

Looking across student narratives, our analysis reveals the following about the relationship between identity and learning: (i) Developing an identity as a geosciences professional required reconciling past experiences that seemed to "split the self;" (ii) This process required reasoning about the past while also projecting a future identity as a geosciences professional and changemaker, and student narratives reflected both a move towards central participation in geosciences disciplines and towards changemaking in the field; (iii) The process engaged students' multiple identities (e.g., as members of various communities made to intersect through the fashioning of "pathway" narratives) and their articulation around their personal disciplinary interests.

An Investigation of Feedback in Engineering Design Workshop for Teachers

Minyoung Gil, Pennsylvania State University, mgil@psu.edu
Matthew M. Johnson, Pennsylvania State University, mmj125@psu.edu

Abstract: In this study, we found the nature of teacher educators' feedback used in an engineering design workshop. The findings showed that teacher educators frequently focused their feedback on the participants’ process, and none of them focused on personal evaluation or simple praise, which is common feedback in classrooms. This study suggests the importance of teacher educators reflecting on their feedback during engineering design activities for effective engineering education.

Learning engineering through a teacher workshop

In the United States, the Next Generation Science Standards and several state standards require that elementary students be taught engineering content and practices (National Research Council [NRC], 2013). However, this creates significant challenges for teachers with no experience with learning or teaching engineering. Professional development (PD) can help teachers acquire new knowledge. Especially by alternately wearing a student's and teacher's hat during PD, teachers can better understand how to apply their own learning experiences to their classroom teaching. Additionally, teachers can identify potential difficulties and obstacles that students may encounter, which can help teachers anticipate the type of support their students will need (Sargianis et al., 2012). To support teachers' learning, teacher educators are required to guide teachers on how to implement engineering design instructions in their classrooms and provide productive feedback to their students. By observing teacher educators' feedback, teachers can transfer their learning to their students. Considering the importance of teacher educators' feedback during PD, we developed the following research question: What is the nature of the feedback given by teacher educators during an engineering design workshop?

Methods

This study analyzed video recordings and work products from an engineering design workshop for teachers in rural, low-income elementary schools. The eight participating teachers had an average educational career of 12.75 years, but none of them had experience teaching engineering. Four teacher educators with an average of 13.5 years in teacher education and 10 years in engineering teaching provided the workshops. In the study, teachers were engaged in the engineering design activity named “Save the Penguins” (Schnittka et al., 2010), which asks participants to design a container to keep a penguin-shaped ice cube from melting. Since the workshops were conducted remotely, the videos were recorded and divided into main sessions and breakout room sessions.

The data collected from the workshop were organized and analyzed in three stages. The first step was making event maps (Kelly & Crawford, 1997). Second, transcripts were created by selecting the part where the interaction involved feedback. Last, we extracted the emergent types of feedback based on transcript analysis based on Hattie and Timperley (2007)’s four levels of feedback: task (FT), process (FP), self-regulation (FR), and self (FS). FT focuses on immediate task accomplishment, FP on extending thoughts, FR on self-control and commitment, and FS on simple praise. The study's feedback data was initially coded based on emergent types, and both authors met to discuss and reach a consensus in cases of disagreement. After finalizing feedback types, the data were analyzed using the constant comparative method (Glaser, 1965).

Findings

In the workshop, feedback from teacher educators was presented in various types, from simple status checks to active scaffolding. First, FP was the most frequently observed type of feedback (see Table 1). Teacher educators encouraged teachers to come up with the next plan, suggested some ideas for further exploration, and asked about the expected pitfalls when they applied this activity to their classrooms. This feedback led teachers to come up with strategies to comprehend the tasks and expand their thoughts, which is more effective than at the task level for enhancing deeper learning (Hattie & Timperley, 2007). We also found a connection between teaching experience and the frequency of FP. Walter and Ellen, who have extensive experience in teaching engineering, used the FP much more than other teacher educators. Here, we do not intend to generalize the results, but we infer that more experience as engineering teacher educators might have taught them to use process level of feedback to facilitate teachers' comprehensive learning.

Table 1

The Frequency of Teacher Educators' All Levels of Feedback

	Walter (18*)	Ellen (26*)	Teddy (2*)	Linda (8*)	Total
Task level (FT)	8	4	6	6	24 (34%)
Process level (FP)	21	12	9	3	45 (63%)
Self-regulation level (FR)	1	0	0	1	2 (3%)
Self level (FS)	0	0	0	0	0 (-)
Total	30	16	15	10	71 (100%)

* Years of teaching experience

In addition to FP, FT was also frequently observed, with teacher educators reaffirming information related to the task or pointing out mistakes that teachers were making to prevent misunderstandings about the task. Finally, although infrequently used, teacher educators also addressed teachers' contributions and efforts, mentioning their achievements based on evidence or criteria of engineering design activities, which can be linked to the self-regulation level of feedback. For example, when teachers figured out the way to make the container cheaper, Linda said, "Great, you found a cheap and effective idea!" One of the most important tasks in engineering design activities is making a model in a cost-effective manner. Thus, this type of feedback can be linked to self-regulation level, not self-level, in terms of being distinguished from simple praise. Finally, FS was not provided during workshops, which is uninformative and has a negative effect on learning (Hattie & Marsh, 1995; Hattie & Timperley, 2007).

Conclusion and implications

Even though engineering education has been emphasized in elementary education, most elementary school teachers have little understanding of engineering (NASEM, 2022). Teachers in rural areas often face challenges in accessing high-quality professional development opportunities, including those related to teaching engineering design activities. This study found that teacher educators frequently provide process and task-level feedback to teachers, which can help teachers implement effective engineering design instruction. In it, we also found that the teacher educators with comparatively long experience in teacher education and teaching engineering frequently used the process level of feedback. Task level of feedback was the next frequent type of feedback, and none of the teacher educators used the self level of feedback. Learning and doing engineering through teacher workshops is essential for them to develop their teaching expertise in engineering. Furthermore, teachers' engineering experience during teacher workshops can be connected to classroom practices (Johnson & Gil, 2022; Sargianis et al., 2012), so it is important for them to experience meaningful and effective feedback during engineering workshops. Furthermore, feedback during engineering design activities has a positive effect on the classroom environment as well as relationships between teachers and learners (Burnett, 2010). Therefore, this study suggests that investigating feedback experiences that teachers received in engineering design workshops become a cornerstone for future studies on feedback in engineering education for teachers.

Designing for Teacher Noticing in College Mathematics

Rossella Santagata, Christina Kimmerling, Patricia Cristina Fuentes Acevedo, Alessandra Pantano, Roberto Pelayo

Abstract: We report on the first phase of a design-based research project aimed at investigating the efficacy of a video-annotation curriculum for college mathematics instructional teams centered on teacher noticing and aimed at supporting the teaching of proof-writing. Teacher noticing involves attending to student thinking and classroom interactions to guide teaching decisions. We discuss our design efforts and share the evolution of the design conjectures that resulted from an interdisciplinary collaboration between mathematics and education scholars.

Introduction and theoretical framing

The transition to upper division proof-intensive math courses can be challenging for college students, with many switching majors within three years (Leu, 2017). Additionally, math classrooms can be marginalizing spaces, particularly for women and students of color (Leyva et al., 2021). Research suggests that student-centered instructional practices can lead to higher learning gains and benefit all students and particularly minoritized students. Noticing in Mathematics for Student Success (NIMS²) is an NSF-funded research project aimed at investigating the efficacy of a video-annotation curriculum for college math instructional teams centered on teacher noticing. Noticing involves attending to and making sense of student mathematical thinking and interactions to inform teaching decisions (Jacobs et al., 2010). This includes ways teachers attend to issues of equity, culture, and power (van Es et al., 2022). While noticing has been examined extensively in K-12 settings, very limited research exists in higher-education contexts. This poster focuses on the project's first design phase and explores the design conjectures and considerations that drove the adaptation of noticing learning activities to the higher education context.

Mode of inquiry

The project is a partnership between the Mathematics Department and the School of Education at a public Hispanic-serving institution on the West coast of the United States. The interdisciplinary team, consisting of both faculty and PhD students, met weekly over the course of the first phase of the project to design the curriculum for instructional teams (including mathematics faculty, teaching assistants, and undergraduate learning assistants) teaching an introduction to proof-writing course. Data sources for the project included field notes from weekly meetings and relevant artifacts, such as conjecture maps outlining the working theory guiding the curriculum design. Artifacts were analyzed to document the design process and decisions.

Findings

Four considerations emerged from the project meetings that guided the design of the 10-hour video-annotation curriculum:

- The need for a proof-writing framework. In meeting discussions, it became clear that a central challenge of the noticing curriculum was to elevate the skills of proof writing (e.g., generating examples to make sense of the statement to be proved, or making use of a definition) from general mathematics content. While an assigned task may focus on functions (mathematics content), students must also access skills that proficient proof writers possess. Thus, we realized we needed a framework for proof writing to unveil potentially hidden aspects of the introduction to proof course.
- Supporting the development of a vision of high-quality mathematics instruction. The curriculum aimed to shift the vision of mathematics instruction at the college level by centering student thinking and participation. However, unlike K-12 teachers, college instructors lack pedagogical training and may feel pressure to cover material rapidly in large lecture courses. To support the enactment of noticing, parameters for high-quality mathematics instruction within the constraints of the college setting were made explicit, considering both lecture-based and group-work contexts. For example, we conjectured that the noticing curriculum would need to make explicit how interactions can be shaped to create opportunities to notice student thinking and responding in ways that support understanding in settings that are typically dominated by teacher-directed instruction. We also decided to make explicit norms for

discursive participation in noticing sessions to support an inquiry stance to student thinking and instructional practice.

- Centering equity. Drawing from research (Leyva et al, 2021) and our personal experiences with university mathematics departments, we recognized from the beginning that we needed to center issues of equity in the design of the noticing curriculum. Through project meetings, we continuously grappled with where and how to elevate this issue. Equitable, quality teaching is multidimensional, addressing student identity and authority as well as reimagining instructional practices (Aguirre et al., 2013; Schoenfeld et al., 2020). We determined that our equity and responsive teaching framework needed to explicitly attend to recognizing students' assets (instead of deficit perspectives) and discuss how implicit bias may impact what instructors attend to and how they interpret student responses. We thus included in the design opportunities for participants to consider how sociocultural and political factors might inform one's noticing. Finally, we decided to prioritize opportunities for instructional team members who have varied expertise and perspectives to collaborate and learn from each other.
- Practical constraints. The final set of design considerations stem from the practical constraints of developing a curriculum for college instructional teams. These included: acquiring video clips that would generate the type of thinking and conversation desired for our noticing tasks and coordinating participant schedules. To meet scheduling demands, the curriculum modules needed to have both face-to-face and online asynchronous components, with asynchronous tasks including opportunities to enact and reflect on learnings in practice.

Discussion and Next Steps

The main aim of the NIMS² project is to adapt a body of work that has been very generative for understanding and improving the competencies of K-12 mathematics teachers to the context of mathematics college teaching and instructors at various levels of their teaching careers. The first exploratory phase of the project was productive in that the interdisciplinary collaboration between education and mathematics scholars was able to surface specific needs and goals that can be integrated into the design of the video-annotation curriculum. A tension that remains is to design tasks and activities that are responsive to and engage productively mathematics department instructional teams while also preserving the complexity of theoretical understandings of high-quality teaching and equitable practices that we draw on from educational research. Ultimately the multiple opportunities to test and iterate the curriculum and revise it based on learning evidence and participant feedback will allow us to adjust and optimize the design.

Centering Culture in the Clinic: How Healthcare Professionals Learn Through a Trauma-Informed Cultural Competence Training

Abstract: Inequities in the healthcare system are a persistent issue and disproportionately harm minoritized groups. There are movements in the healthcare community toward providing culturally centered care where healthcare professionals are cognizant of their own and the patients' personal cultures. Our team of university researchers and healthcare professionals co-developed a trauma-informed cultural competence training (TICCT) and investigated how this training shifted the healthcare professionals' interactions with colleagues, care for patients, and self-perceptions.

Introduction

The healthcare community is beginning to address historical inequities in care practices by finding ways to incorporate patients' cultures while recognizing that the healthcare professionals' culture is also present in the relationship (Hammel, 2013). In pursuit of this goal, we, a team of university researchers and healthcare professionals, formed a research practice partnership to co-develop a Trauma Informed Cultural Competence Training (TICCT). We implemented the TICCT with all medical professionals at the Intensive Outpatient Clinic (IOC) over six months using online modules, a mid-course team discussion, and an in-person workshop. The course included modules on developing self-awareness and awareness of others as cultural beings, understanding healthcare inequities, trauma-informed approaches to care, and applied skills. Situated in constructivism, cultural competence, and trauma-informed care, we draw on a range of qualitative data to investigate the research question: How does a TICCT shift healthcare professionals' interactions with colleagues, care for their patients, and self-perceptions? We found key shifts which revealed an interdependence across relations to self, colleagues, and patients in the form of a holistic commitment to TICCT within the context.

Overview of the literature

Cultural competence and trauma-informed care are approaches to healthcare that recognize the history of the healthcare system and the positionality of the healthcare provider. A culturally centered approach to healthcare focuses on insight and intentionality of how a healthcare professional's social location and worldview may differ from others, particularly patients and colleagues, toward the overall goal of learning and applying more culturally responsive care (Hammel, 2013). The core components of cultural competence include awareness of your own and others' culture as well as developing knowledge and skills for effective and respectful cross-cultural interactions (Tehee et al., 2020). Trauma-informed care is an approach rooted in the belief that an individual's current and future decision-making is influenced by their past traumas (Schimmels & Cunningham, 2021). Trauma-informed care considers trauma experienced by both patients and healthcare professionals that might influence their relationship and care.

Research design

Our team of university researchers and healthcare professionals designed the TICCT over Summer 2021 and implemented the first training module at the end of 2021. Over roughly six months, all IOC healthcare professionals (n = 9) completed the online modules, mid-course team discussion, and in-person workshop. All nine members of the IOC team consented to participate in the research, and six members consented to participate in a one-on-one in-depth interview and a follow-up meeting. Here, we focus on the six team members who consented to participating in all aspects of data collection, which included: fieldnotes and recordings of team discussions, course participation data, six interviews approximately one hour in length, and five member-check meetings approximately 30-minutes in length – one participant left their position at the clinic during data collection. Pseudonyms are used for all participants. We developed themes inductively with a grounded open-coding process (Saldaña, 2009) and deductively used three literature-informed areas as thematic categories:

personal, patient, and colleague. In addition to triangulating themes across data, we shared insights and adapted as appropriate to achieve resonance across participants. We then employed an intrinsic case study approach (Stake, 1995) by developing data from each participant as a case, specifically tracing engagement across personal, patient, and colleague categories.

Findings

Through individual and collective engagement with the TICCT, participants reported shifts in practice, which we traced across three spheres: interactions with colleagues, care for their patients, and self-perceptions. First, participants shared extensively that interactions with colleagues shifted through developing deeper understandings of self and others, critical self-inquiry, vulnerability, and discussions of challenging issues at the intersection of health and social wellbeing. Many aspects of the TICCT, such as online discussion posts and in-person activities, generated a shift in work toward becoming a "better team member" (Summer, Interview, 03/29/2022). Second, participants also shared how the TICCT supported their empathy with patients. For example, Angela reflected on how she noticed she was able to "examine from different directions" and had more "openness in going into things with [patients]" (Angela, Interview, 04/14/2022). Lastly, in addition to shifts in interactions with colleagues and care for patients, participants reflected on how they applied their growth in understanding their own personal history and culture, which led to "a different way of orienting to people and the world" (Inez, Interview, 03/23/2022). Tamara further reflected on this personal shift, "it's good to look back on how you were thinking when it first started, and how that has changed, y'know, with learning more" (Interview, 03/28/2022). Finally, participants across the IOC shared different ways in which they internalized the movement toward centering culture beyond their work setting and into their personal lives. Our findings show how group engagement with a trauma-informed cultural competence training guided shifts in practice with their patients and colleagues at work as well as across their personal lives. Moreover, prior to implementing the TICCT, participants shared how the IOC embodied a practice of working as a collective team toward holistic wellbeing, which makes this clinic setting unique compared to individualism and siloed approaches often observed in other healthcare settings.

Discussion: The importance of cultural training & holistic commitments

Though massive health inequities persist across the healthcare system in the United States, there continues to be minimal support for and available training in cultural development, competence, and humility for healthcare workers (Browne et al., 2018; Schimmels & Cunningham, 2021). Our study offers important insights into how healthcare professionals used the tenets of cultural competence and trauma-informed care to develop a deeper understanding and empathy for their colleagues, their patients, and in their personal lives. Participants shared instances of applying the awareness and skills gained from the TICCT across all spheres of their life, which often yielded holistic commitments to feeling more, listening more, and interacting differently. As scholars invite us to center culture in clinical contexts (e.g., Browne et al., 2021; Lekas et al., 2020), this study contributes empirical insights into how healthcare professionals engage with and learn through cultural trainings. The perspectives and stories of the healthcare professionals we shared in this poster demonstrate the potentially transformative nature of centering culture in healthcare contexts, particularly in humanizing not only patients but also the professionals themselves as whole beings with rich cultural identities.

Using Hierarchical Time Series Clustering to Capture the Trajectories of Epistemic Emotions: The Case of Confusion

Byunghoon (Tony) Ahn, McGill University, byung.h.ahn@mail.mcgill.ca
Clarissa Hin-Hei Lau, McGill University, University of Toronto, clarissa.lau@utoronto.ca
Jason M. Harley, McGill University, Research Institute of the McGill University Health Centre (RI-MUHC),
jason.harley@mcgill.ca

Abstract: This study explored the use of hierarchical time series cluster analysis to group learners based on their epistemic emotional trajectories while rating true or fake news articles. We analyzed one epistemic emotion, confusion, while accounting for the dendrogram shape and cluster validity. Our analysis highlights the dynamic nature of emotions by taking account of the temporal fluctuations of how an emotion is experienced. Such analysis can aid further research on how learners digest complex information.

Introduction

Evaluating the legitimacy of health-related news involves deciphering complex information, and hence can often involve epistemic emotions: emotions elicited when appraising whether new information aligns with one's existing beliefs (Vogl et al., 2021). Such emotions have particular functions. For example, confusion can potentially foster learning as it requires active engagement and cognitive effort for learners to resolve the aversive state (Vogl et al., 2021). To help support individuals to more effectively and reliably navigate the current media landscape filled with information that varies widely in quality, it is crucial to understand the roles of epistemic emotions in health news literacy contexts.

We used a hierarchical time series cluster analysis to explore the types of epistemic emotion trajectories students can experience when evaluating health-related news articles. While prior work that employs cluster analysis to explore learners' emotional profiles exists (Poitras et al., 2019), research accounting for emotions' dynamic nature is scarce, especially in an epistemic context. Our primary research question for this short report was: what are the emotional profile clusters formed for the epistemic emotion confusion?

Methods

Participants and study procedure

The current study used data from 71 undergraduate students (58 female; $M_{\text{age}} = 20.0$; $SD_{\text{age}} = 1.49$) at a North American University. Students participated and data was collected online. $25 electronic gift cards were given as compensation for participants who completed the study. Our participants were from a larger RCT study featuring three conditions: 1) video-based learning group (n=23); 2) text-based learning group (n=24); and 3) control learning group (n=24). The first two groups' learning focused on emotion regulation and media literacy, while the control group focused on space and blackholes.

Post learning, all learners rated the credibility of 12 media vignettes (100-120 words). Six vignettes were factual and from mainstream news sources while six were fake and from non-mainstream sources. After each rating, learners completed the Epistemic Emotions Survey (EES; Pekrun et al., 2017). We hence had 12 time points for each learner. The aim of our larger study required counterbalancing the vignettes. Therefore, the 12 vignettes were presented in a different order for vignette group A (n = 37) than group B (n = 34). This report focuses only on vignette group A.

Hierarchical time series cluster analysis

We used R, with the dtwclust package (v5.5.11; Sarda-Espinosa, 2022), and chose hierarchical clustering due to our small sample size (Meyers et al., 2017). Datapoints were first standardized. Data screening revealed that no data was missing and therefore no participants needed to be dropped. Our analysis produced seven cluster validity indices (CVI): the Silhouette index (SIL), Score Function (SF), Calinski-Harabasz index (CH), Dunn index (D), Davies-Bouldin index (DB), Modified Davies-Bouldin index (DBstar), and COP index. High values for the first four, and low values for the last three supported a better model (Sarda-Espinosa, 2022).

Interpretation of dendrograms

Hierarchical clustering produces dendrograms, which shows how data points merge into clusters. While the CVI can suggest optimal number of clusters, the nature of cluster analyses being exploratory allows researchers to develop their own interpretations based on their expertise (Meyers et al., 2017). We interpreted our dendrograms by first identifying a consensus amongst the CVI. Often the consensus would be two clusters, but in cases where: 1) one cluster was disproportionately small (e.g., 2 vs. 35 members) and 2) CVI showed support for a higher cluster count, we explored results with higher cluster counts. We aimed to identify varied emotional profiles, and hence avoided results with a single cluster containing the vast majority of the participants.

We opted for a six-cluster result (SIL = .21; SF = 8.49e-06; CH = 9.31; DB = .60; DBstar = .72; D = .25; COP = .26) based on improved DB and Dbstar indices from five clusters to six (DB = .80; Dbstar = .85 for five cluster result). Doing so helped us avoid having two clusters where one would only have a single member. While choosing a higher number of clusters can be valid, we opted for the more parsimonious cluster count.

Findings

We identified a dominant cluster (n = 24), which revealed that participants generally experienced low levels of confusion throughout the media rating activity, with the exception of small peaks at the very beginning and in the middle. Our second cluster (n = 9) grouped participants who seemed to steadily experience moderate to high levels of confusion. Lastly, we identified four “clusters” with just one membership that were outliers relative to participants clustered into the first two groups. These participants seemed to exhibit higher levels of confusion than the first two clusters, characterized by rapid fluctuations of self-reported confusion.

We believe our approach can reveal “conventional” trajectories of emotions learners may experience in specific contexts. For example, our analysis shows that 24 learners out of 37 (i.e., 64.86%) tended to experience low levels of confusion with moderate ‘spikes’ or ‘bumps’. A typical learner therefore may find most of the 12 media vignettes not too confusing but may encounter an article occasionally that elicits confusion. Our second cluster suggests that some learners, on the other hand, may experience moderate to high levels of confusion throughout media message rating, though this is less common. Our analysis also revealed outliers, highlighting unique emotional experience trajectories.

Time series analysis from D’Mello & Graesser (2012) suggest that new information that contradicts existing information can lead to confusion and disequilibrium. A state of engagement may be achieved by resolving confusion—if unresolved, frustration, or even boredom may occur. Identifying patterns we can discern from other cluster analyses (for other emotions and both vignette groups) as well as exploring the feasibility of running an analysis that accounts for more than one emotion at a time stand to expand our understanding of how learners assess and understand media messages. Lastly, our time points were not continuous intervals (e.g., emotions measured every second). Therefore, conducting a time-series analysis with a continuous data channel, such as skin conductance or automatic facial expression recognition software, represents another future direction.

Abstract: We report on the curation of data sets and design of a tool that allows students to investigate questions using COVID-19 data. Student work from iteration one informed redesign and curation of new data sets to support deeper student thinking. Iteration two resulted in more complex, yet unanswerable, questions. Results reveal opportunities to address the scope of data sets and the tool's limitations, highlighting the importance of iterative design to support students working with data.

Introduction

Engaging with large, publicly available data sets present opportunities for students to explore issues relevant to their lives (Lee et al., 2021). Creating meaning from data sets calls on students to create questions that can be answered with the data available, create and test hypotheses, construct data visualizations, and analyze visualizations to come to a coherent understanding of the data. Curating the right data for students to explore is one challenge in this process (Cherrstrom & Boden, 2020) and involves balancing scope, messiness, and other characteristics of the data (Kjelvik & Schultheis, 2019). Our objective in this study is to explore how the iterative design of a data tool and curation of data sets supported students' meaningful investigations of how different communities were impacted by COVID-19.

Methods

We used a design-based research method (Bell, 2004) to refine the curation of data sets and a data tool (called the Data Explorer, or DE) students used to investigate the data sets. The DE lives within a curricular unit, *Covid-19: Data Science, and Equity.* It was created using an open-source web-based inquiry science environment which is informed by Knowledge Integration pedagogy (Linn, 2011). Students created questions after exploring available data sets and selected a single data set for further investigation. After reviewing their data set, students selected one X and up to three Y variables. The DE then automatically displayed variables in a bar or line graph with labeled axes. Two rounds of iterative refinement of data sets and DE were completed. In the first iteration of the DE (I1) students could explore state or county COVID-19 data sets. Data sets contained COVID-19 cases and population percentages for different racial/ethnic categories across four states or counties. I1 data sets were nine by eight cells. In iteration two (I2) students could choose between four larger data sets on vaccination, job-loss, essential workers, and pre-existing conditions[1]. Data sets also included demographic information such as age, gender, poverty levels and race/ethnicity. The first and second authors created these expanded data sets based on student interest and increased availability of published data. New data sets ranged from 14 by 16 cells (essential workers) to 59 by 16 cells (vaccination).

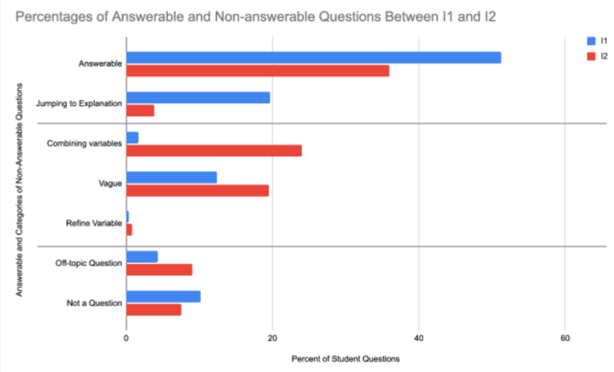
I1 was used in two schools with three teachers (two 8th-grade teachers and one 9th-grade teacher) and their students (N = 403) in fall 2021. I2 was used in fall 2022 by the original ninth-grade teacher and two additional ninth-grade teachers at a different school (N = 227). All schools were located in the same metropolitan area. To assess the effectiveness of curated data sets and the DE the first and second authors analyzed student questions. Questions were categorized as "answerable" or "non-answerable" based on the students' chosen data set. Non-answerable questions were further categorized into the reasons they could not be answered (Figure 1).

Results

Iteration 1 results: In I1, 51.2% of the 234 student generated questions were answerable. Of the remaining non-answerable questions (48.8%), questions that jumped to explaining why trends in the data existed (19.7%) were most common (Figure 1). These questions were unanswerable with the data available. Results suggest that, while a valuable exercise, the data sets used in I1 were too simplistic for students to deeply investigate how different communities were impacted by COVID-19. For I2, the first and second authors sought to broaden the topics of data sets and curate more complex data sets to support students to ask and investigate more complex questions.

Figure 1

Percentages and examples of answerable and non-answerable question types in iterations 1 and 2.



Answerable I1: What is the relationship between the percent of the population and percent of covid cases by race?

Answerable I2: What the difference between covid cases between Latinos in Alameda county and San Francisco?

Jump I1: Why is there so many cases with Hispanic and Latino people in Los Angeles county?

Jump I2: Why does Butte have a high social vulnerability index?

Combine I1: Why is there more cases of Latino people than African Americans in San Francisco county and Santa Clara county?

Combine I2: What's the vaccination rate for the people in poverty?

Vague I1: How do all the races relate to each other?

Vague I2 What is the impact on the economy?

Iteration 2 results: Fewer answerable questions were constructed in I2 (36% out of 133 total questions). However, many non-answerable questions were a result of students attempting to combine two variables together in a data set (24%), something infrequently seen in I1. For example, students attempted to explore how certain risk factors, such as poverty (Figure 1) or having health insurance, affect vaccination or COVID-19 outcomes. A higher percentage of students wrote vague, on-topic questions (19.5%) for data sets they were investigating but did not specify variables. This suggests students had difficulty identifying relevant variables within larger, more complex data sets in I2.

Conclusion

We iteratively curated data sets and designed the DE to support students to investigate large, publicly available, COVID-19 data sets. Results show promise in students' ability to pose complex, relevant questions, but also highlights the need to provide students with additional support to create answerable questions using available data. Results indicate the scope of data sets must be somewhere between the simplistic data sets in I1 and overwhelming data sets in I2. Balancing the complexity, scope, and size of data sets proved challenging (Kjelvik & Schultheis, 2019) and iterating on these data sets to address these issues will be important to better support students. The results also suggest possible improvements to the DE. 24% of students attempted to combine variables in ways the DE could not support. This indicates the DE must be updated to allow for these complex comparisons. We hope that future iterations of the DE (including this new feature and refined data sets) will support students to create meaningful, answerable questions.

Endnotes

(1) Data sets for I1 and I2 were curated from county public health websites, the Center for Disease Control, US Census, U.S. Bureau of Labor Statistics, and the Economic Policy Institute.

Abstract: Machine Learning (ML) may be a promising tool for predicting student success. Our research aims to predict student performance in specific STEM courses using ML. Self-reported scores on learning strategies, metacognitive awareness, mindset, and misconceptions about the brain were evaluated along with learning analytics to predict grades. The model demonstrated a high correlation between learning attributes and performance with an initial classifier accuracy of 78%. This approach is promising for tailoring our learning strategies for specific courses.

Introduction

Learning is known to be challenging and stressful for incoming undergraduate STEM students especially given the sheer volume of content to be mastered and the limited capacity of the human brain (Wieman, 2007) . The McGill Office of Science Education created the SciLearn program to support incoming undergraduate STEM students with their transition to university-level learning. The program includes a series of workshops, peer collaboration sessions, and special events. The program has been integrated in two large introductory science courses. This study aims to use machine learning to predict student success (Shahiri & Wahidah, 2015; Guleria et al., 2015) in first-year STEM courses. The research question guiding our work is: *How can we leverage attributes that are highly correlated with students' academic success to help early undergraduates become self-regulated learners?*

Machine Learning Methodology

Our methodology involved the normalization of data, correlation of study features, and generation of predictive models (classification and time series) with predicted grades. The system model is divided into three phases *Data Acquisition*, *Modeling*, and *Evaluation.*

Data Acquisition

This phase involves collection of data from various sources (Table 2) for the cohort Fall 2021 & Winter 2021.

Table 2:
Data Attributes and Source (count 400 students)

Data Category	Attributes Collected	Data Source
Demographics (Background)	Background data: Educational background, gender, first-generation, disability etc.	Survey
Learning Inventory Data	Learning Strategies Inventory (LSI), Metacognitive Awareness Inventory (MAI), Mindset and Neuromyths score.	Survey
Progression Data	SciLearn Peer collaboration and lab attendance, grades on assignments(assesments), learning analytics progression data	McGill Learning Management System (LMS)
Atomic Habits Adopted	Atomic Habits (evidence-based strategies: napping, scheduling, notes taking, avoid multitasking and peer learning)	Feedback text McGill LMS

Modeling & Evaluation

Modeling involved data cleaning, normalization, one-hot encoding, feature engineering, analysis, and model training. Four metrics were used to evaluate the performance of our model included 1) *Accuracy*: How many times the ML model was correct overall (Ben-David, 2007; Huang & Ling, 2005) 2) *Recall*: Model's ability to detect positive samples (Baeza-Yates & Ribeiro-Neto, 1999) 3) *Precision*: How good the model is at predicting a specific category (Baeza-Yates & Ribeiro-Neto, 1999) 4) F1-Score: model's balanced ability to both capture positive cases (recall) and be accurate with the cases it does capture (precision).

Results and Key Observations

Correlation Analysis

Pearson correlation coefficient scores were used to understand the relationship between input features and the target category (grades). The analysis have shown a positive correlations of five main attributes; Scilearn lab attendance, internal assesment (recent grades), background, learning profile, and the adoption of atomic habits. While learning profile (LSI, Mindset and MAI attributes), and progression data (assesments and SciLearn lab attendance) have shown the strongest correlation with grades as shown below (see Table 5).

Table 5
High impacting features with the grades

Data Category	Features	Correlation score with Grade
Learning Inventory	LSI	0.81
	Mindset	0.85
	MCAI Knowledge	0.76
	MCAI Regulation	0.72
Progression Data	Assesments	0.89
	Scilearn Lab attendance	0.72

Performance Analysis

Five classification models have been created and tested using five ML techniques, MLR, RF, SVM, EC and DT. Results (Table 4) demonstrate the accuracy and performance measures for each model.

Table 4
Model Comparison

Model	Accuracy	Recall	Precision	F1 Score
Support Vector Classifier	78%	0.73	0.75	0.74
Decision Tree	68%	0.62	0.59	0.60
Random Forest	65.5%	0.60	0.54	0.56
Elastic-net Classifier(EC)	61%	0.45	0.60	0.51
Multinomial Logistic Regression	58.2%	0.41	0.46	0.43

Conclusion and Future Work

This pilot study has limitations, including a small sample size and reliance on self-reported data. Participants in the SciLearn program were self-selected and may not be fully representative of McGill's first-year cohort. Additionally, the courses in which data were collected were taught by instructors known to be excellent teachers, which could affect the machine learning modeling process. However, this research has shown promising initial results, with a high correlation between early learning attributes and grades, and an initial classifier accuracy of 78%. Future research will focus on increasing the sample size, including more time-based features and exploring time-series modeling to improve the accuracy, identifying early markers of success and provide timely guidance.

Heterogenous Sensemaking: How Multilingual Girls and a Teacher Engaged in Joint Learning

Shakhnoza Kayumova, Esma Nur Kahveci
skayumova@umassd.edu, ekahveci@umassd.edu
University of Massachusetts Dartmouth

Abstract: The study explores how heterogeneous sensemaking, student accounts of different ways of encountering, noticing, and wondering about a phenomenon, emerged during joint sensemaking interactions between science teachers and multilingual students, and the diverse resources and repertoires of practices supported by such interactions.

Introduction

In science education, there is an increasing emphasis on promoting robust sensemaking practices among all students and positioning them as active agents in the process of knowledge construction (Berland et al., 2015). Sensemaking arises as students grapple with ideas in order to make sense of a phenomenon or unravel the workings of a design (Odden & Russ, 2019). However, it is also important to recognize that sensemaking is a heterogeneous and culturally embedded practice (Warren et al., 2001) rooted in the ongoing every day and disciplinary activity systems in which youth participate and interact (Kayumova & Sengupta, 2022).

Theoretical framework

We conceptualize science learning environments as activity systems that combine heterogeneous discursive and embodied communication and coordination efforts of teachers and multilingual students as they engage in joint sense- making and problem-solving (Kayumova & Dou, 2022). However, spaces of joint participation can also exacerbate status differences and existing inequities among students, particularly from nondominant backgrounds (Barron, 2000). To this end, teacher-moves play a critical role in supporting or foreclosing heterogeneity that emerges. In this study, we focus on joint sensemaking created by teachers and multilingual students, "the indeterminate processes of learning as a context for deep intellectual activity" as an opportunity to identify heterogeneity inherent within science learning and design work (Vossoughi et al., 2021, p. 18). The study is grounded in longitudinal research aimed at examining how positioning multilingual youth in asset-based terms supports more equitable opportunities to learn (Kayumova & Tippins, 2021).

Methods

The project took place in the Northeastern United States with multilingual youth whose home and community languages are other than the dominant English language. The data was selected from video and audio data, student interviews, documented observations by staff and teachers, extensive field notes, and artifacts collected during the summer 2021 implementation of this program. The program participants were multilingual young people from local middle schools. We coded the selected video footage for students' verbal and nonverbal accounts of noticing, encountering, and wondering about a phenomenon (Rosebery et al., 2010) and teacher moves that supported these diverse instances of joint sense-making, including coordination and communication. Here we present a representative case of a science teacher, Andrew, and three multilingual (Merriam, 1988) girls engaging in joint sensemaking about a water cycle and the formation of vapor.

Findings

Our findings showed that students used multiple resources such as their language, gestures, and everyday experiences to engage in sensemaking. The key repertoires of practice included the way they oriented attention to the process, extended the activity to everyday situations, and tacitly and flexibly coordinated the joint sensemaking communication. To illustrate, here we provide an example of one such moment from an extended collective sensemaking interaction. In this interaction, Andrew, the science teacher, and three multilingual girls are engaging in sensemaking about vapor formation that they notice on a black can. Girls utilized their hand gestures and a combination of English and Brazilian Portuguese to explain how light was absorbed by matter. When girls expressed their understanding verbally using translanguaging between English and Brazilian, Andrew attentively listened and nodded his head in agreement without interrupting. They also used body gestures to explain in further detail how sunlight hits the surface of the can, reflecting or absorbing as necessary. The girls used to point as means to direct Andrew's attention towards the black can and the outside where liquid drops had formed.

Andrew coordinated the communication by inviting all three girls into the conversation by posing a question related to their personal experience, using gestures to communicate his ideas. Thesetypes of communication and coordination support girls' diverse sensemaking repertoires and provide them with opportunities to share their experiences as evidence to support the inquiry. Girls contributed to the sensemaking by sharing examples from their daily lives, adding to the heterogeneous yet collective sensemaking repertoires that emerged among the students and teacher.

Discussion and scholarly significance

This research provides a perspective on the importance of joint sensemaking in creating meaning in science classrooms within teacher-student interactions. Our findings indicated that such interactions not only support disciplinary sensemaking but also allow the emergence of diverse resources and repertoires of practice among students. Such experiences are especially critical for supporting heterogeneous sensemaking repertoires of multilingual youth and transforming the discipline across various activity systems.

Professional Development for Contextualizing Science Teaching and Learning: A Case From Ethiopia

Engida H. Gebre, Simon Fraser University, egebre@sfu.ca
Dawit Asrat Getahun, Bahir Dar University, dawit.getahun@mail.mcgill.ca

Abstract: In this study we present the results of a two-day professional development workshop on contextualizing science teaching and learning. We worked with 19 science teachers, discussing the purposes of science education, learning expectations in their classes, and data-supported low performance of students in national exams. We then asked teachers to work on discipline-based groups and outline the structure of a typical class in their teaching. Finally, they developed learner-centered projects to foster better contextualization of learning. Results show that teachers developed lessons to challenge learners' traditional conceptions about topics.

Introduction

Using context-based approaches in science teaching and making science learning relevant to everyday life of students has received increasing attention in recent decades (de Putter-Smits et al., 2013; Silseth, 2018). The rationale for contextualization relates to addressing a problem of information overload in science education (Gilbert, 2006), motivating students (Bennett et al, 2007) and increasing learner agency. One of the challenges and requirements in contextualizing science education is professional development of teachers. Teachers often teach the way they learned and not many teachers have the competence to make science learning relevant for students' everyday life in a meaningful way. In this paper, we discuss preliminary findings related to how teachers contextualized their lesson plan and developed engaging learning environments following a two-day professional development workshop on the subject. Our research question is "How do teachers contextualize their lesson planning and teaching following professional development for the purpose?"

Contextualizing science teaching and learning

Contextualization of science education could be teacher-centered or learner-centered. In teacher-centered contextualization, teachers often use examples that are familiar to students expecting that such familiar examples will facilitate learners understanding of the topic. Learner-centered activities in contextualization gives students the agency to choose topics, frame contextualization processes, and determine learning and problem-solving strategies (Taylor, 2017). In other words, the role of the educator is to facilitate student-led projects and challenge them progressively based on learners' level of competence and stages of dealing with their learning activity.

Context and methods

In spring 2022, we worked with 19 teachers (9 biology, 5 chemistry and 5 physics teachers) from six secondary schools in Ethiopia and conducted a two-day professional development workshop that focused on discussing the meaning, purposes and ways of contextualizing science education. We started with grouping teachers by subject and asking them to discuss and outline what their typical lesson for a given day looks like. Teachers prepared a list of activities they typically do in a given 50-minute class. We then asked teachers to discuss 1) the purpose of teaching science from their perspective, the extent to which they use their science knowledge in their everyday life, and how much they think students are using their knowledge to address everyday problems. Following the discussions, teachers developed lessons that is relevant for their students to contextualize their learning.

Contextualization for challenging traditional views

Teachers, working in groups, developed lessons that can be applied in their classes. Teachers chose to use issues that are familiar to students and develop learning activities for students to work on. One of the groups on biology teaching chose "traditional medical plants" and their use by the community. Their rationale was that there is considerable use of traditional medicine and medical plants in the community where the school is located. Similarly, physics teachers chose the "rainbow and its formation" for their lesson based on the explanation that students and occasionally members in their community have misconceptions about rainbow where it is considered as "Saint Mary's belt". The teachers want their students to examine how rainbow colors are created and experiment with glasses and paper to create the colors. The following exchange between the three teachers who worked on the rainbow lesson and one of the researchers represents the teachers' reasoning.

> *Researcher: Tell me what your project is about and why you chose "rainbow" for students to work on?*

Teacher A: *The goal of this project is for students to describe and examine the formation of rainbow. Project activities include answering questions such as what is rainbow, what causes rainbow, why rainbow appears with rain and how does a rainbow get its color.*

Teacher B: *Rainbow is a natural phenomenon that students know about. Students and community members don't know much about the concept of diffraction and refraction of light, they have misconceptions. In physics, it is related to single-slit diffraction, properties of wave interference and even ways of creating dim-lights that students use in their house.*

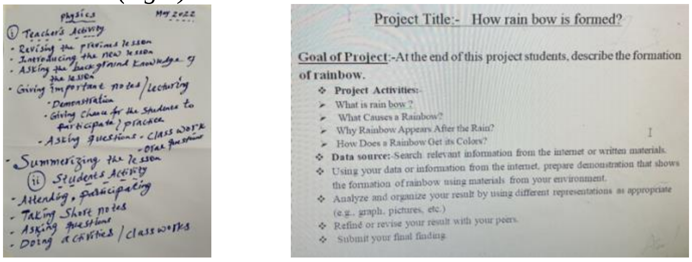
Teacher C: *Rainbow-related misconception is common around churches where it is often related to a promise from supernatural force or St. Mary's belt. Starting from what students know and getting them to experiment the process of creating colors will help them question their views.*

Shifting activity structures

Our second observation from the workshop was that teachers started thinking in terms of ways of engaging students actively in the learning process. Figure 1a presents a typical lesson that teachers reported using in their classes at the beginning of the workshop. Figure 1b is the nature of activities teachers developed for the rainbow project mentioned above. Figure 1a and b represent the shift in the nature of the activities from direct instruction to a more student-focused project where the role of the teacher is not even properly specified.

Figure 1

(a) Typical Activities in Physics Classes (left) and (b) Project Activities on Rainbow Formation (right)



Physics May 2022

(i) Teacher's Activity
- Revising the previous lesson
- Introducing the new lesson
- Asking the background knowledge of the lesson
- Giving important notes/Lecturing
  - Demonstration
  - Giving chance for the students to participate/practice
  - Asking questions - class work
    - oral question
- Summerizing the lesson

(ii) Students Activity
- Attending, participating
- Taking short notes
- Asking questions
- Doing activities/classworks

Project Title:- How rain bow is formed?

Goal of Project:-At the end of this project students, describe the formation of rainbow.

- Project Activities:-
  - What is rain bow ?
  - What Causes a Rainbow?
  - Why Rainbow Appears After the Rain?
  - How Does a Rainbow Get its Colors?
- Data source:-Search relevant information from the internet or written materials.
- Using your data or information from the internet, prepare demonstration that shows the formation of rainbow using materials from your environment.
- Analyze and organize your result by using different representations as appropriate (e.g., graph, pictures, etc.)
- Refine or revise your result with your peers.
- Submit your final finding

Discussions

Contexts can be the foreground that constitute or "animate" the action in that they make the action (e.g., learning) thinkable, possible, desirable, relevant and necessary (Clarke, 2013). The fact that our participating teachers started from topics that students know about (rainbow) and use the phenomenon to challenge learners' understanding in practical ways through experimentation and to teach about discipline related concepts such as "single-slit diffraction" implies contextualization also serves as a way of challenging traditional views. The teachers could have simply lectured about "single-slit diffraction" and give dim lights and rainbow as examples.

Abstract: The study focuses on understanding the discourse, interaction, and problem-solving relating to pedagogical content knowledge (PCK) demonstrated by teachers in one professional training workshop on Computational Thinking (CT) and its implementations in classrooms.

Introduction and theoretical framework

While the application of Computational Thinking (CT) to both student's educational experiences and teacher's professional development has been wide (Liu et al., 2022), the discussion on how best to support professional development the process and outcome of such professional development have been scarce (Sengupta et al., 2018). The present study focuses on a single training workshop for teachers in a longitudinal CT professional development project to understand:

1. How did the teachers engage in a professional development workshop featuring design thinking?
2. How did the interactions between teachers and the workshop facilitator shape teachers' pedagogical content knowledge?

Introduction and theoretical framework

Context

The workshop that the present study focused on had two stages: 1. Conceptualizing with teachers the implementation of CT in classrooms through discussion; and 2. Engaging teachers in CT-embedded group projects to experience CT in practice. A facilitator was present throughout, but the teacher participants remained actively engaged. The workshop lasted approximately two hours.

Data sources and analysis

Qualitative observational data was videotaped. One dyad (two teachers) was selected based on their high willingness to implement CT yet both experiencing challenges in doing so. Their self- and other-directed behaviors in workshop were coded, with emergent codes of teacher's engagement pattern presented in Table 1.

Table 1
Code Scheme for Teachers' Engagement Pattern to Instruction

	Positive Engagement	Negative Engagement	Disengagement
Immediate	Eye-Contact or Nodding Answering Questions	Engage in distractions Engage in actions/interactions that are discouraged by the facilitator	Disengaged from the facilitation Ignoring additional instructions
Delayed	Providing additional examples Paraphrasing key concepts	Using key concepts for slight sarcasm	Disengaged from the facilitation

Results

RQ 1. Three levels of engagement patterns in the workshop were identified (i.e., positive engagement, negative engagement, and disengagement) that are either immediate or delayed (Table 1), providing six distinct types. When engaged, the participants showed a moderate level of positive engagement toward the instructions, which aligned with the intention of the facilitator's instructions. However, instances of negative engagement and disengagement were also present, indicating times when the teachers' responses mismatched the instructor's intention or expectation. A notable distinction can be drawn between the two stages of the workshop. In the conceptualizing stage, participants showed mostly positive engagement or disengagement, but both at a mild level, indicating boredom, instead of intense satisfaction or dissatisfaction toward the content. However, during the practical ideation stage where participants were given a CT-embedded group task to complete, the level of engagement drastically increased. Specifically, both immediate and delayed positive engagement were demonstrated up-prompted by the participants, showing an active effort both to communicate and reflect on the CT concepts introduced.

RQ 2. A few features from the teachers' interaction stood out to challenge the effectiveness of the workshop on shaping teachers' knowledge. First, although teachers mentioned key concepts naturally during their group project ("we are *empathizing*", "What type of learning is this? *Kinesthetic* where you would have to touch things?"), these comments were made as social tools to lighten up the mood through humor and sarcasm, instead of for learning and conceptualization means. This speaks to both the challenges for the teachers to internalize new concepts, as well as their misunderstanding of the key points. Second, teachers held near exclusively pessimistic views about their students when providing anecdotal classroom experiences as examples ("my kids would cry". This again shows that teachers found implementing CT in the classroom to be challenging and were reluctant to change. Third, at no point in the workshop did any of the teachers asked follow-up questions or mentioned potential hesitation they may have toward the facilitation, despite them clearly having faced challenges in implementing CT in classrooms in the past. Any question that was raised was about the in-the-moment technical or logistical problems that they have for the workshop, instead of conceptual ones that speak to the core intention of the workshop. This shows that, even if shown positive engagement, the teachers rarely engaged with the concepts at a deep level.

Discussion and scholarly significance

Overall, the findings from the present study support that: 1. Teachers generally positively engaged in the professional development workshop, while 2. Their depth of engagement where relatively shallow. In other words, the discourse, interaction, and problem-solving demonstrated by the teachers showed that the workshop may not have fully prepared them to develop CT-related PCK and implement them in classrooms.

The challenge of integrating CT has long been present, with past research pointing to the technical difficulty of the computing tools as a key factor (Ketelhut et al., 2020). The present study, though, provides an additional layer to this challenge by indicating how the type and depth of engagement from the teacher participants are also critical. This becomes especially poignant given the rapidly changing and ever more diverse world that the teachers today teach in, where computationally literacy and accessibility must coincide.

While the present study was able to identify engagement as a key factor in effective CT professional development projects, future work can be done related to how best to design a project that supports positive and deep engagement from teachers and translates to a successful implementation of CT in classrooms.

Materiality, Diversity and Inclusive STE(A)m:
A Comparative Exploration of Design Affordances on Youth Making

Gabriela T. Richard, Penn State University, grichard@psu.edu
Lillyanna Faimon, Penn State University, lkf5240@psu.edu

Abstract: This study examines how designs and material affordances shape diverse participation, engagement and learning. We conduct an exploratory, comparative analysis that seeks to better understand the implicit affordances and (dis)affordances of digital and physical tools and activities in youth STEM+Arts participation and learner agency. Quantitative and qualitative findings illustrate important nuances in how participants engaged in and expressed computational thinking, collaboration, creativity and self-efficacy. We discuss these findings in light of increasing calls for social justice-oriented and transformative research and practice.

Introduction

While scholarship continues to demonstrate the benefits of diverse making and informal STE(A)M activities for learning, research is increasingly calling into question the implicit biases in the design of technologies, systems and activities, which can have an impact on equitable STEM participation, interest and persistence. Studies have found systemic patterns of inequity (e.g., Scott, Sheridan & Clark, 2015), with critical scholarship increasingly calling for social justice-oriented research and practice (e.g., Gutiérrez, et al, 2019). This study seeks to further address how tools and their material affordances shape diverse learning, engagement and shared meaning making. Our research questions are: How do diverse digital and physical content creation tools shape youth learning and participation? How do these technologies and activities affect learners' self-efficacy and computational thinking?

Methods

We applied multimodal methods (qualitative and quantitative) to conduct an exploratory comparative analysis on two iterations of a workshop designed to support inclusive youth learning of making and integrated design. The 2018 curriculum updated the original bidirectionally responsive curriculum, which focused on three primary content creation tools (Lilypad Arduino, Scratch, and MakeyMakey), while the 2019 curriculum used a newer e-textile microcontroller - the CircuitPlayground Express (CPE) - in place of the Lilypad and MakeyMakey (Richard, Giri & Faimon, 2022). The 2018 participants were aged 14-18, and the 2019 participants were aged 13-15. The 2018 workshop pair is Ebony (Black, female, aged 16) and Priscilla (Latinx and Black, female, aged 14). The 2019 workshop pair is Julio (Latinx, male, aged 13) and Eddie (Latinx, male, aged 14). All are pseudonyms.

The quantitative analysis used pre- and post-survey measures derived from Robinson's computational thinking questionnaire (2015), which established criterion validity (r=.572, n=37, p<.01) and used 5 subscales. Data were analyzed using Wilcoxon matched pairs, given the small sample size and nonnormal distribution (e.g., Wiedermann & von Eye. 2013). The qualitative microanalysis (Derry, et al., 2010) of the video data compared two sets of focal case study student pairs to provide insight into learners' actions and engagement.

Quantitative findings

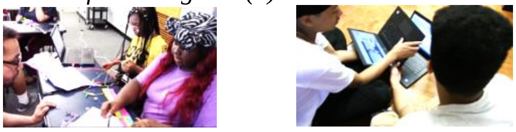
For the 2018 workshop, collaborating, $z = -2.03$, $p = .04$, $r = .59$, abstracting, $z = -1.99$, $p = .046$, $r = .58$, and developing computational artifacts, $z = -2.23$, $p = .026$, $r = .64$, were statistically significant with large effect sizes ($r > .5$). For the 2019 workshop, abstracting, $z = -3.19$, $p < .001$, $r = .58$, and developing computational artifacts, $z = -2.78$, $p < .01$, $r = .51$, were also significant; however, instead of collaborating, connecting computing was highly significant, $z = -2.77$, $p < .01$, $r = .51$. Collaboration items underscore self-efficacy beliefs about working with others to convey ideas, whereas connecting computing emphasizes using technology to shape others' experiences.

Qualitative vignettes

For the 2018 curriculum we focus on how Priscilla and Ebony engaged with Collaboration and Analyzing Problems and Artifacts. This vignette took place about halfway through the creation of their final integrated design project, which is a versatile headband or belt that lights up with the Lilypad Arduino and controls a Scratch catch game, connected by the MakeyMakey. During their creation process Priscilla and Ebony work together to create and troubleshoot their project, describing to the facilitators that "[Priscilla] does the coding" and "[Ebony] does the sewing", but they are "going to work on the Makey Makey together" (*Collaboration*). The process of troubleshooting their connections and the plan for their design took up much of their shared discussions (*Analyzing Problems and Artifacts*), as they talk back and forth with facilitators about including several LEDs along with a tricolor LED. They are purposeful about dividing responsibilities while also working together toward their shared idea and detailed plan. As shown in the background of figure 1a, Priscilla engages in troubleshooting their code via the alligator clip connections between the Lilypad Arduino and the LEDs, as well as writing code for the tricolor LED so it creates the colors they want to use. Meanwhile, because of the complexity of their design, Ebony plans out where she is going to sew the connections (*Collaboration*). Using the tricolor LED added many complexities; while it does not require a ground connection, the other LEDs do, and Ebony and Priscilla had to remember multiple ways of connecting the different material components and work together to finish their project.

Figure 1

Priscilla and Ebony sewing and coding (a); Julio and Eddie recording sounds for their game (b)



(a) (b)

For the 2019 curriculum we focus on how Julio and Eddie engaged in Collaboration and Connecting Computing. Their final project was a negotiated design inspired by the Marvel movies and comics. It used two gloves and the CPE to control the same Scratch fighting game—the Iron Man gauntlet from Avengers *Endgame* and the Infinity Gauntlet from *Infinity Wars*. Because of the affordances in the CPE and because they were intentional in creating two gloves that could control one game, Eddie and Julio engaged in similar parts of the design process though the process itself was not as interdependent, making collaboration more of a concerted effort. While Eddie focused on coding – including creating code to test if they could use two CPEs for one Scratch game (*Analyzing Problems and Artifacts*), Julio focused on the more intricate artistic elements of their glove controllers. Making their projects authentic to and incorporating aspects of the Marvel movies seemed to drive Julio and Eddie's collaboration. They were both intent on collaboratively picking realistic Avengers-themed sounds for their game, choosing to record them (fig. 1b) from the movies through YouTube clips instead of using any built-in Scratch sounds *(Collaboration)*. Later in the workshop they both reflected on what they learned and created, demonstrating awareness of their ability to use computing and design technologies that can affect others *(Connecting Computing)*. When asked if they had ever worked with microcontrollers before, Eddie immediately shook his head and responded: "No… It was easier than I expected. It was really simple." Julio sat in thought for a few moments, then responded emphatically: "I never knew that… I could make a controller out of tape and cloth….[*gestures to the CPE*] I never knew it could grab like something and program it into the computer."

Discussion

The findings help illustrate how diverse tools and activities can scaffold and make different kinds of collaborative, critical and creative possibilities salient for learners. We argue that the findings in this study help to illustrate key nuances for equity and inclusion. For instance, robust understanding of the design of systems and their impact on the world, the ability to articulate ideas and correct complex problems, and effective collaboration are all crucial for critical design literacy and social justice. We plan to investigate this further in future work.

Connect Two: A Duoethnography Exploring Reconnecting Teacher and Student Relationships After Covid-19

Mary Lamothe, The University of North Texas, mary.lamothe@my.unt.edu
Carrie Allen, The University of North Texas, carrie.allen@unt.edu

Abstract: This paper explores experiences of two practitioners returning to their work contexts after COVID shutdowns through a duoethnography methodology. Drawing on the notion of entanglements, this analysis considers themes of disconnection and connection through parallel storytelling. In particular, both researcher-practitioners explore their experiences in the context of social emotional learning (SEL) and noticings of shifts in student and teacher actions post-COVID. Findings suggest themes of disconnection.

Framework

Storytelling has served as the embodiment for not just human connection, but generational connection, for millennia. Storytelling has taken many forms, including cave drawings, cultural dances, chants, music lyrics, but verbal communication provides precision to a basic human need to explain, educate, and enlighten (Anderson, 2010). Recently, Keifert (under review) has proposed storytelling to share lived experiences and reimagine shared futures using the metaphor of entanglements to purposefully understand connection through storytelling and finding commonalities between our stories. When considering individual and collective experiences of disconnection amidst COVID, entanglements may help bring stories together in ways that surface the meaning-making and impacts of COVID on those working within and occupying educational spaces. For the purposes of this paper, entanglements is used as a framework to highlight commonalities and differences between two researcher-practitioners after returning to their school and district roles after COVID shutdowns.

Method

Researchers of the current study implemented a duoethnography method to explore common themes among two social emotional learning practitioner's experiences after returning to school, post-COVID-19 shutdowns. The tenets of duoethnography as described by Breault (2016) include viewing one's life as a curriculum. Through this lens we first examined our lived histories that helped shape our current understanding of and beliefs about SEL.

To facilitate dialogue we engaged in five, 30-minute Zoom sessions and created audio recordings of our conversation. The researchers had dialogue on subjects such as "possible stressors that exacerbate behaviors with students and teachers" and "how SEL can bridge the gap between all stakeholders." These topics were used to drive the conversation. Both participants shared stories from different perspectives. Participant one is a district level coordinator in a large urban school system sharing a view from a systemic lens. Participant two is a campus educator for a mid-sized suburban school system sharing a view from a local, school-level lens. As researchers engaged in dialogue, the themes of teacher and student disconnections began to emerge, and thus were used as guiding questions for further analysis. We utilized the approach of parallel storytelling (Benegas & Gerlach, 2020) in a collaborative Google Document, in which each researcher contributed ideas, stories, and experiences related to guiding questions that supported dialogue. Low inference coding was used to identify common themes in conversation between participants in the transcripts of multiple conversations. By configuring data in a table, themes emerged, and patterns noticed on the topic of teacher and student disconnection being evidenced through differing aspects of the participants' work environments.

Findings

The duoethnography surfaced two primary themes: (1) students struggling with regulating their emotions after COVID shutdown (see Table 1); and (2) teachers experiencing burnout (see Table 2).

Table 1
Students struggling with regulating their emotions after COVID shutdown

Participant 2: Student behavior is probably more difficult right now than it has been since I've been in education. They [students] are struggling to cope with even small things, much less the big things that many of them are dealing with.

Participant 1: I have some campuses that are in the most extravagant neighborhoods, but their students are suffering from depression and having suicidal ideations at an alarming rate. It has quadrupled from what it was prior to the pandemic.

Participant 2: It all is just like, it's like a toxic soup that's been simmering for a while with this pandemic stress which leads to…compounds into this cycle of negativity and stress, and outbursts, behavior outbursts.

Table 2
Teachers experiencing burnout

Participant 1: Teachers are showing increased anxiety and being burned out early in the year as opposed to a time where teacher burnout was closer to STAAR testing time. Their classrooms aren't being managed properly. We have teachers who are so on edge. They are taking all of their days before Thanksgiving, as far as sick days and personal days, just trying to get a handle on their own mental health.

Participant 2: What can we do to decrease the stress and burnout for our teachers? Teachers are struggling to cope with even the small behaviors from students. Typically, things that you would think could be handled in the classroom. It's just too much because so many are just at the end of their coping ability. We're seeing the exact same thing, too... with high teacher absences. They're often quick to anger, assume the worst.

Practitioners noticed that students experienced behavioral outbursts and had increased mental health needs after returning back to school from Covid shutdown. Practitioners noticed that students did not display capacity to self-regulate. Researchers noticed that many teachers experienced emotional dysregulation due to pandemic stresses and currently are struggling when the slightest discomfort happens. Teachers' inability to cope with minute student behaviors emphasizes disconnection with students' needs. Teachers' coping skills have diminished after the Covid-19 shutdown. With both teachers and students in an emotionally dysregulated state, there appears to be a need for an emotional support between them for co-regulation.

Discussion/conclusion

Parallel storytelling revealed practitioner-researcher noticing of students' emotional dysregulation with fewer strategies for managing emotions, and teachers experiencing secondary trauma and burnout. Sharing lived experiences through entanglements and SEL strategies can be methods used for re-imagining a new normal. A shared devastation such as the Covid-19 isolation could serve as a catalyst for reconnection through sharing lived experiences. A structured design, such as those informed by entanglements or SEL instruction, assists those in education to positively make those connections. Students who learn explicit SEL skills through conversation starters or community circles establish valuing their position of belonging to a community of learners. Teachers who have an opportunity to be taught self-reflection and social awareness have safe spaces for students to engage in instruction. Storytelling, as a method of sharing lived experiences, can begin to repair disconnection between teachers and students.

Exploring Extended Reality for Scaffolding Psychomotor-Intensive Tasks in Complex Real-World Settings

Nicholas C. Wilson, Harvard University, nicholas_wilson@harvard.edu

Mehmet Kosa, Casper Harteveld, Mohsen Moghaddam, Kemi Jona
m.kosa@northeastern.edu, c.harteveld@northeastern.edu, m.moghaddam@northeastern.edu,
k.jona@northeastern.edu
Northeastern University

Abstract: Extended reality (XR) has the potential to leverage newly available multimodal streams of data (e.g., gaze, hand tracking) to accelerate the progression from novice to expert in many fields. By providing adaptive and personalized learning interventions, these advances in XR technology enable a new category of intelligent tutoring systems, which can scaffold psychomotor-intensive tasks in complex real-world settings. We present the preliminary results of two prototypes of XR-based intelligent tutoring systems in the context of advanced manufacturing, primarily focused on demonstrating their ability to scaffold complex tasks. We outline key research questions to move toward adaptive and personalized XR scaffolding.

Introduction

This project seeks to design and understand the affordances of extended reality (XR) technologies for providing intelligent, adaptive, and personalized scaffolding for psychomotor-intensive tasks *in complex real-world settings*, such as advanced manufacturing, with an eye toward supporting novice and differently-abled learners. Skilled performance in these industrial settings is psychomotor in nature, requiring acute spatial perception, reasoning, and coordination of motor skills. Advanced manufacturing is a valuable application area for exploring XR technologies for supporting the learning of novices in psychomotor-intensive tasks such as assembly, maintenance, and inspection that involve careful hand-eye coordination (Moghaddam et al., 2021).

Supporting novice-to-expert skill progression

Advanced manufacturing tasks, such as the operation of a semi-automated metal additive manufacturing process, a computer numerical control machine, or a robotic station, often require operators to engage in psychomotor tasks requiring sophisticated spatial reasoning while carefully and precisely following complex procedures. Operators of these machines must apply a thorough understanding of advanced manufacturing equipment, material properties, and upstream and downstream processes, in addition to developing an awareness of how each of these elements interact together. Leveraging the robust accumulated evidence on the novice-expert gap for complex systems (Hmelo-Silver & Pfeffer, 2004), the goal of the current research is to develop interventions mediated by XR technologies to more inclusively and scalably support the progression of novice-to-expert skill and knowledge development in psychomotor-intensive tasks through just-in-time provision of spatially contextualized learning scaffolding, dynamically tailored to the expertise of individual learners and the real-time setting in which they are acting.

Preliminary results

As part of our iterative, design-based research process, we developed and studied two prototypes, each providing incrementally more sophisticated scaffolding. The first explored the affordances of a simple static (i.e., non-adaptive) AR guide for scaffolding an authentic electromechanical assembly task compared to "business-as-usual" paper instructions. The task involves assembling fuel cell modules of custom-made marine engines, which require following different procedures for each engine model. Seventeen Mechanical and Industrial Engineering students were recruited as participants (6 females, 11 undergrads) and divided into two groups: AR and paper. A questionnaire was used to collect their demographics and related prior experiences to counterbalance the groups. All participants received initial online training on the AR app and hardware (HoloLens 2). Each participant performed three assembly cycles on separate dates using their designated mode of instruction and returned after a few days to perform a final assembly using the opposite mode of instruction. At the end of each session: (1) the experimenters recorded time to completion, number of errors, frequency of help-seeking behavior, and the types of errors and questions, and (2) the participants reported their cognitive load (NASA-TLX), self-efficacy, experience with HoloLens/AR app, and general feedback through structured and open-ended questions.

We found that the number of errors in the AR condition was reduced by 31-84% with negligible reductions in the paper condition (Moghaddam et al., 2021). The task completion times of the two groups are about the same; however, that was partly due to the unfamiliarity of participants with AR and some technical issues. Further, most participants reported absolute independence from AR after two/three cycles, which points to the effectiveness of AR in improving task competency, but also to its decreasing utility as an "assistive tool" for routine tasks once expertise is developed. Further, several participants suggested devising interactive help and voice command systems.

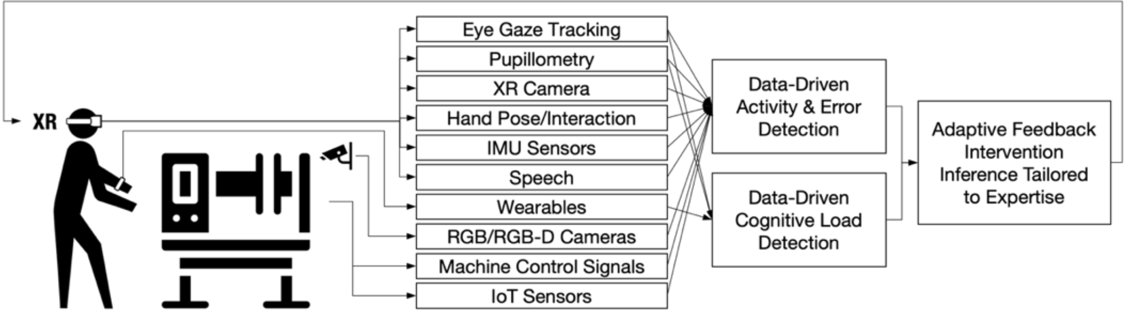
Informed by these results, a second prototype was developed to scaffold the task of setting up and operating an additive manufacturing machine. This version added spatiotemporal alignment of training instructions with the physical equipment and environment in the form of text, 3D animations, videos, and audio cues as well as on-demand access to operations manuals and demo videos via hand gestures and voice commands that allow the user to interact with the app through natural language. Results suggest that users find the spatiotemporal alignment and in particular the 3D animations useful for understanding what they are required to do. While the prototype is modularized—that is, the training modules can be taken in any order—the prototype still follows a step-by-step approach for each module and thus does not adapt to the learner. This would be an important next iteration to consider as some users found it more challenging than others.

Key questions and research agenda

Figure 1 shows a conceptual view of the flow of possible data streams and their combination in formulating adaptive feedback and guidance in real-time to a learner operating in a complex setting such as a manufacturing facility. Our efforts have only just begun to access and integrate the full set of potential inputs available.

Figure 1

Conceptual overview of the possible input to consider for adaptive feedback integrated with XR.



We are now exploring a challenging set of research questions surfaced by the development and application of intelligent XR tutors: (1) *What are the effects of adaptive and personalized XR scaffolding on different dimensions of expertise and the speed of the novice-to-expert development process?* (2) Given the explorations in the previous research question on how to best scaffold psychomotor-intensive, human-machine interaction tasks, *how can we characterize the progression of development from novice to expert for a particular task to advance our theoretical understanding of expertise development and build more robust, generalizable knowledge on what indicators can be used to guide tutoring interventions across a range of tasks and settings?* (3) *How can different streams of user and machine/task data be synthesized to create a context-aware XR system capable of providing just-in-time interventions tailored to the expertise and task context of learners?* Only by accurately detecting the state of work context (e.g., current activity/step, potential errors) and the required human information processing resources can an XR system adapt learning scaffolds to the needs of a learner in real time. New sources of multimodal data captured by XR devices, cameras and sensors, wearables, and machines provide new opportunities to interpret, predict, and guide the behavior of learners through the adaptive scaffolding of XR instructions and feedback.

Implementing Higher Education Micro-Credentials: Uncovering Challenges to Improve Professional Practice

Anne Reed, Samuel Abramovich
annereed@buffalo.edu, samuelab@buffalo.edu
State University of New York at Buffalo

Abstract: This study employed a survey to identify challenges faced by professionals who implemented higher education micro-credentials. Inferential statistics were used to determine if amount of experience predicts the challenges of professionals involved in this work. The results of this study have implications for the development of both formal and informal support systems for this growing population of higher education professionals who are tasked with creating micro-credentials.

Introduction

Micro-credentials (MCs) widen the scope of postsecondary learning opportunities; with more options for learners, they are often considered a viable way for institutions to offset declining enrollment and bring new learning opportunities, providing recognition (e.g., assessment, credentials) for learning that is traditionally under recognized (Oliver, 2019). Consequently, there has been an increase of higher education organizations designing MC programs, targeting smaller amounts of curriculum, and avoiding the levels of oversight applied to traditional credentials. However, the increase in micro-credentials offered in higher education is very likely ahead of established good practices for ensuring quality and positive results (Pollard & Vincent, 2022). Importantly, there is not yet basic knowledge about who is implementing MCs in higher education, nor the challenges they identify in this work. Without this knowledge it is not possible to align resources and support (e.g., training, sample curricula) with needs, which is crucial for maximizing the efficacy of professional practice (Caffarella & Zinn, 1999), and for sustaining MC programs long-term (Ahmat, et. al., 2021).

Methods

We employed a quantitative, non-experimental survey design to investigate the identity and perceptions of higher education professionals who have experience working with MCs. We specifically sought to measure time working with MCs because we hypothesized that experience predicts this population’s challenges of working with MCs. Because MCs are different from other credentials (e.g., different curricular design, awarding methods), they entail different processes and procedures, which presents a learning curve for Novice professionals. Therefore, we hypothesized differences between professionals with less than one year experience, and those with one year or more experience. We based these categories on studies of other educational technologies that indicate educators’ attitudes toward the technology changes after a year of practice (Valtonen, et al., 2015).

Data collection

We developed and implemented a survey instrument to better understand the population of professionals with experience working with MCs (e.g., designing, administering, teaching) and to elicit their perceptions in relationship to our hypothesis, $H_0 1$: *There is no significant difference between Novice and Experienced professionals on perceived challenges of working with MCs*. Two items from our survey were used to directly answer the question: *How long have you been working with MCs in higher education?* (Multiple choice); and *What key challenges have you experienced working with MCs? (*Multiple response set). The response options for the multiple response question acted as our dependent variables (DVs): DV1 Financial resources; DV2 Effort/time required for implementing; DV3 Faculty buy-in DV4 Employer buy-in; DV5 Buy-in by leadership; DV6 Student buy-in; DV7 Uncertainty regarding how to design MCs; DV8 Equity of opportunity; DV9 Keeping MCs different than traditional credentials. We received 148 valid survey responses. Participants were categorized into two groups- Novice (less than 1 year experience) (n = 74) and Experienced (1 year or more experience) (n= 68).

Data analysis

The data was analyzed using inferential statistics. Each response option for the question *What challenges have you experienced working with MCs?* was treated as a binary variable (i.e., yes/no) and coded either 1 or 0. Then, we conducted an Independent Samples Test of Proportions to obtain the inferential statistics needed to test our hypothesis.

Results

A test of proportions was conducted for each of the nine variables in the response set- “Challenges of MCs.” Results indicated a significant difference in the proportion of the groups on – DV7: Uncertainty regarding how to design MCs (z= 3.49 p < .001); 39% of Novice and 13% of Experienced practitioners perceived DV7 as a challenge, 95% CI [.12, .40]. Results indicated no significant differences on any of the other variables.

We were not surprised that novice professionals were more frequently uncertain about how to design MCs than experienced professionals; research on other educational technologies (e.g., online courses, games) has shown that amount of experience working with a technology is positively correlated with design-confidence (Northcote, et al., 2015). This finding has implications for the quality MCs, since design of an educational technology influences learning outcomes, including learner satisfaction and persistence (Rienties & Toetenel 2016). If a professional is uncertain about design (e.g., quality principles, processes), they will likely design MCs that are sub-optimal. Although our study does not confirm which specific aspects of designing MCs produce uncertainty for Novice’s, a reasonable solution would be for beginners to learn design principles and strategies from their more experienced counterparts.

While we recognize that a lack of a statistically significant finding is not a finding itself, it should be emphasized that we found no other differences between the two groups regarding their challenges of developing and implementing micro-credentials; eight of the nine challenges investigated in this study were perceived by professionals regardless of amount of experience. This indicates that there are likely several problems of practice (i.e., complex challenges that are common across an occupation) (Norton & Hathaway, 2015), for professionals who develop and implement micro-credentials.

Discussion and conclusion

The needs of implementers of MCs in higher education are critical to the success of these new credentials. Institutional leadership can provide support by properly allocating resources, such as financial resources (e.g., marketing to address stakeholder buy-in), human resources to support the effort and time required to conduct this work, and professional development (PD). Besides institutional support, there is also a clear need for more research in this area. Specifically, further research is needed to determine why some challenges do not cease with increased experience, and what is needed to overcome challenges that could, if not addressed, impact the quality and effectiveness of MCs in higher education.

Lastly, our results indicated there are likely several general problems of practice that apply to all implementers of MCs in higher education, regardless of experience. This is noteworthy, since problems of practice are often the catalyst for the formation of Communities of Practice (CoPs), a type of informal, peer-to-peer support network comprised of individuals who share similar work roles and a common context. Through sharing experiences, members of a CoP use their collective knowledge to generate new ways to address recurring problems (Li, et al., 2009). We recommend that implementers of MCs come together to form CoPs. If effective, CoPs would provide space for these professionals to further develop their expertise and improve professional practice, which, as a result, would lead to large-scale improvements on the quality of higher education MCs.

Situating Here-And-Now Decisions in More Just Imaginings for Teaching Writing

Erin Lane, University of Washington, erinlane@uw.edu

Abstract: Drawing on translingual ideologies (Horner et al., 2011) and participatory design-based research (Bang & Vossoughi, 2016), I partnered with a teacher to co-design elementary writing from 2020 to 2022. The teacher's discourses of writing shifted from centering competition and competence to relationships and identities. Further, attending to daily teaching demands *and* translingualism emerged as a mediational tool in our work. These findings have implications for researchers co-designing with teachers to navigate daily dilemmas while imagining futures.

Introduction

With waves of recent 'learning loss' outcries brought on by covid-19, the current moment requires learning designs that resist neoliberal reforms and deficit framings of young people (Philip et al., 2022). Specifically, we need forms of learning that attune to the dailiness of teaching *while* working toward more just pedagogies. Participatory design-based research (PDR) offers generative frameworks for "being-with" teachers while remaining oriented toward aspirational ideologies; PDR names "consequential learning in the here-and-now" as a priority alongside imagining possible futures (Bang & Vossoughi, 2016, p. 174). Writing classrooms can be ripe for the reproduction of deficit ideologies as discourses of appropriateness (Flores & Rosa, 2015) and linguistic competence (Flores & Rosa, 2022) dominate the framing of writing practice (Lane et al., 2021). However, teachers often have little time or mediational resources to distance themselves from school-based dailiness and "see anew" (Gutiérrez & Vossoughi, 2010) to generate novel forms of teaching and learning. For these reasons, I conducted a collaborative design-based research study with a sixth-grade teacher (Mr. Riley, pseudonym) from 2020-2022. We sought to reshape writing activity, focusing on translingual ideologies and resisting deficit frames. In this analysis, I ask: How can a PDR study support shifts in a teacher's writing discourses and build toward more just school writing environments?

Theoretical framework

This work draws on participatory design-based research (Bang & Vossoughi, 2016), which promotes collaborative studies that resist top-down implementations and center deeper participant learning. Our learning focused on translingual language ideologies: these posit that languages, instead of being bound, fixed entities, are always in flux, emerge in hybridity, and are sociocultural phenomena (Horner et al., 2011).

Methods & data sources

Mr. Riley and I met 2-4 times per month for two academic years. I conducted teacher interviews at the beginning, middle, and end of the study. In the second year, I conducted 29 audio-recorded classroom observations. All interviews, meetings, and observations were audio-recorded and transcribed. For the present analysis, I wrote analytic and thematic memos of the three interviews while developing a codebook to identify recurrent themes. This led me to zoom in on salient design meetings that Mr. Riley identified as impactful. I then engaged in inductive and deductive coding of design meetings and the three interviews.

Participants & positionalities

Participants included Mr. Riley, a White male teacher, his sixth-grade class, and myself, a White, female former English teacher. The school's student demographics are reported as 23.6% Asian, 15.5% Black/African-American, 40.5% Hispanic/Latinx, 2.7%, Native Hawaiian/other Pacific Islander, 5.6%, two or more races, 12.1% White, with 73.5% low-income, and 38.1% receiving EL services. I met Mr. Riley through the director of his teacher preparation program, for whom I worked as a teacher coach. We initially spoke about my interests in translingualism, and he shared his desire to improve his writing instruction. Considering our subject positions (Daniels & Varghese, 2020), I aimed to disrupt the linguistic "white listening subject" (Flores & Rosa, 2015) which frames racially and linguistically minoritized young people as linguistically deficient in the name of "competence" (Flores & Rosa, 2022).

Findings

From November 2020 to June 2022, Mr. Riley's reasons for teaching writing evolved from competition and competence to seeing writing as a relational act rooted in students' identities. First, in November 2020, Mr. Riley described learning to write as important in order to be a "communicator" in the world. He emphasized that people get "judged" on how they write when seeking jobs. He also talked about wanting his students to be able to write essays for seventh grade. These goals reflect discourses of competition (to seek jobs) and competence (grade-level preparedness). Later, in September 2021, when asked about goals for his students, he referred to an experience of his class writing outside in a courtyard at the end of the prior year: "there is just like this *vibe* that we had…letting kids experience the joy of writing and being able to identify as writers and not just as students who are checking off a box." He described a "magic in the air," when all students were working on writing as a community. In June 2022, he said, "I think something really strong, powerful happens when you ask kids to write about their lives and then you actually…talk to them about it…kids really open up." He described his experience with teaching writing in 2021-2022 as "the exact opposite" of what it had been before, when he felt "very pressured to teach kids to do a certain thing." Later he added, "I want them to be able to share with the world what they think…what they need for who they are, where they're from…" In this way, Mr. Riley's discourses about reasons for teaching writing shifted from focusing on an academic- and job-centered context to discourses centering community and identity.

Second, situating here-and-now decision making against a backdrop of translingual ideologies allowed for micro-shifts in daily decision-making and set the stage to support shifts in his discourses of teaching writing. In January 2021, we navigated tensions during a design meeting where Mr. Riley expressed concern about sentence structure, and I emphasized flexibility in language use. I alternated between referring to translingual language ideologies ("it matters that they can play with language and be flexible," and "there's multiple opinions around asking kids how it sounds…that can be very…biased…" and "students [should] come away with…agency [to] play with sentence structure") and resisting a stable idea of "competence" (Flores & Rosa, 2022), and providing specific examples of how Mr. Riley might build a lesson around sentence combining (such as how to choose examples and how to plan a remote lesson). Eventually, we co-designed an assessment asking students to use Flipgrid to record themselves talking *about* varieties of sentence combining choices as a way of supporting flexibility and foregrounding student thinking, framing young people as adept language users. Several other design meetings reflected similar tensions and negotiations between immediate concerns and overarching ideologies.

Significance

Decisions in education often get framed as being pragmatic or idealistic, both obscuring what we can imagine and positioning educational actors against each other. However, seeing these perspectives as a kind of epistemic heterogeneity (Rosebery et al., 2010) and designing specifically for it (Taylor, 2020), researchers and teachers can co-design and co-learn in ways that shift both the classroom and research practice.

Rule Formation in Simulation-Based Discovery Learning

Teeba Obaid, Simon Fraser University, teeba_obaid@sfu.ca
Philip H. Winne, Simon Fraser University, winne@sfu.ca
Tenzin Doleck, Simon Fraser University, tdoleck@sfu.ca
Hosein Aghajani, husein.aghajani@gmail.com

Abstract: We gave learners a cognitive tool to formulate rules during simulation-based discovery learning about Ohm's law. We selected four cases from a larger sample based on posttest Knowledge Integration scores and used microgenetic analysis to examine different phases of the learning process. Our analysis identified the steps involved in forming distinct rules and tracked shifts in thinking at each stage, including predictions, selective searches, and reasoning processes when interpreting simulation results.

Introduction

This research investigated learners' engineering approaches and regulation of scientific discovery processes as they used a web-based simulation to explore electric circuits and learn Ohm's law. We tracked learners' selective searches among variables, rules they formulated, experimental tests they designed, and ideas they generated about their experiments. Making visible these aspects of inquiry learning allowed characterizing patterns of discovery learning in science. We use microgenetic analysis to dive beneath the surface of scientific discovery to expose detailed operational definitions of different engineering approaches learners use in simulation-based discovery learning.

Theoretical framework

Discovery learning is a self-directed and constructive approach to learning. Prior research has shown that learners do not experiment sufficiently with variations offered by simulations (Chambers et al., 1994). de Jong et al. (1988) identified several challenges associated with simulation-based discovery learning, including the ability to test hypotheses, design experiments, interpret data, and regulate the learning process. Strand-Cary and Klahr (2008) found that explicit instructional approaches were more effective than exploration-based methods in teaching control of variable strategies. These findings suggest that while simulation-based learning can be a valuable tool, specific strategies may be necessary to ensure effective learning outcomes. Bruner et al. (1956) identified different strategies for discovery learning: confirmation redundancy, simultaneous scanning, successive scanning, focus gambling, and conservative focusing. In confirmation redundancy, learners test alterations of the same instance. In simultaneous scanning, learners simultaneously considered all attributes. In successive scanning, participants attended to one attribute at a time. In conservative focusing, learners changed only one attribute on each trial to investigate a single hypothesis. Finally, in focus gambling, learners changed all but one attribute in each trial. This study was our model for investigating learners' strategies for inducing a rule by manipulating variables in a simulation. Wiese and Linn (2021) found that while 99% of 7th grade learners were able to identify at least one underlying rule governing the three computer models provided, only 14% could identify all the underlying rules. This highlights a gap in research concerning rule formation in simulation-based discovery learning. Thus, the present study asks: *How do students' engineering approaches and searching strategies in rule formation impact Knowledge Integration?*

Methods

Undergraduates participated in a 2-hour Zoom session to develop their understanding of Ohm's law through a simulation. Pretests and posttests were conducted to assess their understanding, and their open responses to posttest items were scored using a knowledge integration (KI) rubric. The KI rubric uses the following scores: 0 (blank), 1 (off task), 2 (invalid scientific idea), 3 (partial link), 4 (one valid link), and 5 (multiple valid links). The rubric scores were used to assess how students linked concepts and formed rules during the session. The study used the WISE domain to develop a unit of instruction on electric circuits. The students used a PhET electric circuit simulation to construct circuits and read measurements needed to discover relations involving current, resistance, and voltage. During the investigation phase, students used a rule formation tool to form IF-THEN rules. Sections of the tool labeled IF and THEN allowed learners to specify a hypothesis in terms of a prediction and findings. The prediction and finding areas provided drop-down menus from which students could select values for current and voltage drop. A section of the tool labeled FOR ALL CONSTANT VARIABLES specified control conditions. The study analyzed data from four participants who attained the same very low score on pretest items and tested the same relationships in the exploration phase. These participants displayed particular combinations of KI levels in the posttest for current and for voltage drop. The KI score patterns indicate possible variations in (a) engineering approaches, which we describe as students' comparative selections of variables, and (b) searching strategies for forming rules during simulation learning.

Findings

Case study 1. Student A's posttest showed scientifically invalid ideas (KI level 2) for both voltage drop and current. They used a limited range of variables in their comparative trials, which were restricted to changes in resistance and battery voltage value. Their predictions and findings for voltage drop and current were based on the same rules from previous trials, with no identification of problems. Student A used confirming redundancy in their rule generation, but did not deduce which attributes should be eliminated, resulting in redundant results and no distinct findings.

Case study 2. Student B demonstrated a scientifically invalid idea (KI level 2) and a partial link (KI level 3) in their posttest. They made discoveries about voltage drop by changing the number of bulbs in their trials, but did not test other variables. Their predictions were mostly based on previous rules. They verified more predictions and falsified others for voltage drop, but did not falsify any for current. They did not identify any problems in formulating their rules, but used successive scanning to test a single hypothesis about voltage drop. Their engineering approaches and searching strategy limited them to make a partial link about voltage drop and an invalid idea about current.

Case study 3. Student C had a partial link (KI level 3) and 1 valid link (KI level 4) in their posttest. They tested multiple variables to measure current and voltage drop. Their trials show changes in bulbs, resistance, and ammeter placement. Their predictions were either based solely on prior rules or aimed at filling any gaps within those rules. They verified some predictions and falsified others for current, but did not falsify any for voltage drop. They used successive scanning and focus gambling strategies equally. Their engineering approaches, predictions, and utilization of focus gambling resulted in a higher KI level for current (KI level 4) compared to voltage drop. They needed more trials to confirm findings generated by a focus ambling strategy.

Case study 4. Student D demonstrated a high level of knowledge integration (KI) in their posttest, providing multiple valid links (KI level 5) and one valid link (KI level 4). They conducted extensive trials to measure current and voltage drop, testing the most variables compared to their peers. Their searching strategies show they filled more gaps in their predictions and falsified more experiments. Unlike their peers, Student D identified problems in their experiments and used both successive scanning and conservative focusing to make discoveries. Student D employed conservative focusing when identifying a problem in a circuit and systematically tested the most crucial variables by altering only one attribute at a time. By honing in on voltage drop, Student D effectively avoided getting lost in extraneous details and remained focused on the fundamental principles underlying the circuit.

Conclusion

Describing how learners engaged in discovery learning with scaffolded rule formation helps identify searching strategies (i.e., focus gambling, etc.) that can be used to identify engineering approaches (i.e., planning and carrying out investigations). This will help intervene more effectively to guide students during simulation-based discovery learning. Clarifying the specific operations related to rule formation and concept attainment from simulation-based discovery learning will aid in developing a classification system of cognitive engineering approaches.

From Every Angle: Group In/Equity Behaviors

Ann Katharine Kolodzik, Grinnell College, kolodzik@grinnell.edu
Paul Hutchison, Grinnell College, hutchiso@grinnell.edu

Abstract: We set out to develop a reliable coding scheme for relatively quick (compared to some qualitative coding schemes) analysis of equity in collaborative small groups by modifying a previous coding system (Slattery & Hutchison, 2018). In this poster, we describe the coding scheme and argue it can generate useful across-group comparisons, identify which group members have fair access to learning resources and positive positional identities, and show how group members affect peers' fair access.

Introduction

Many science educators and researchers consider group work a key element of an effective STEM learning environment (Esmonde, 2009; O'Donnell & Hmelo-Silver, 2013), but inequitable group dynamics can undercut the benefits of collaboration and reduce fair access to learning opportunities for some students. Describing the dynamics of inequity in groups is a necessary step toward understanding how to mitigate it. There are numerous methodologies for characterizing and analyzing group in/equity (i.e. Esmonde, 2009; Engle et al, 2014, Langer-Osuna, 2016). These coding schemes are labor intensive and limit the amount of data that can be analyzed. We are interested in schemes that would take less time and allow for analyzing larger amounts of data.

Theoretically, we begin from Esmonde's (2009) definition of equity. She argues a small group is equitable when all students in it have fair access to learning resources and positional identities as "knowers and doers" of STEM. Thus, an effective coding system for researching group in/equity must reflect who has access to resources and positional identities and the factors that affect an individual's access. Shah and Lewis (2019), building on Esmonde's definition, identify two important facets of an equitable group: participatory equity and relational equity. Participatory equity describes when the classroom has a "fair distribution of both participation opportunities and participation itself" (p. 249). It is by participating in the group's discourse that students access both learning resources and positive identities. The second facet, relational equity, occurs when students care about their peers' learning and respect the contributions all students put forth (Boaler, 2008).

Group in/equity behaviors

We started with a previously developed system (Slattery and Huchison, 2018) that codes discourse behaviors as attenuating or amplifying inequity. We felt two important revisions were necessary. First, the existing scheme fails to capture the positive impact off-task behavior can have on participatory equity (Langer-Osuna et al, 2018). Then, it does not track who behaviors were directed toward. So we added a code to note the potential inequity attenuating impact of social interactions, and we tracked the participants who engaged in the behavior and to whom the behavior is directed.

Group in/equity behavior coding then consists of two components: behavior/function and direction. These indicate the significance of a student's behavior and the student or students the behavior impacts. To assign behavior/function, the researcher examines each utterance or action, and labels it using one or more of the nine behavior coding categories (see Table 1 on the next page). To code direction, the researcher identifies the participant(s) at whom a behavior is directed. For example, whose idea was ignored or encouraged.

Discussion

To both refine and test our coding scheme, we analyzed a series of roughly 30-minute video segments of three collaborative small groups. A research team had collected the video during small group activities where college-aged students learned about climate change in an inquiry learning format. (Franklin et al, 2018)

Because in/equity is not a binary designation, groups are not simply equitable or inequitable, but rather one episode is more or less equitable than another episode. Behavior code counts provide a way to make relative, across group comparisons and could also identify differences within a single group's episodes on different days. Further, the direction code can provide insight into the dynamics of a single group by identifying repeated patterns of behaviors between group members that attenuate or amplify inequity and pinpoint who repeatedly initiates and receives in/equity behaviors.

While our intent in this poster is describing the coding scheme, it bears noting we found it reasonably straightforward to use consistently across trained coders. Our percent agreement among three coders was 88% before reconciling. We believe this coding scheme has the potential to provide insight into understanding the in/equity impact of things like activity type, group composition, teacher intervention, and other factors that might impact participatory and relational equity in collaborative small groups.

Table 1
Group In/Equity Behaviors and their impact on equity

Behavior	Description	Effect
Social Bonding	Any socially related statement or action that elicits a positive response from another member or members of the group	Attenuates Inequity
Encouraging/ Energizing	Statements or actions that promote the ideas or statements of another student	Attenuates Inequity
Orienting/ Clarifying	Statements or questions that attempt to clarify/understand an idea or action in the group	Attenuates Inequity
Gatekeeping	Attempts to get any/all members of the group to participate in the discussion or activity	Attenuates Inequity
Forwarding	Taking a leadership role in moving the group towards completion of the task at hand	Attenuates Inequity
Ignoring	Not verbally engaging or acknowledging the ideas or attempts to contribute of another member of the group	Amplifies Inequity
Overtalking/ Aggressing	Talking louder while another student is talking, making harsh comments or tone of voice toward another student	Amplifies Inequity
Individual Blocking	Any action or statement that prevents another student from contributing their ideas to the group	Amplifies Inequity
Derailing/ Group Blocking	Statements or actions that cause the group to become off task or lose focus on the task	Amplifies Inequity

Friends or Feedback? – Computer Science Students' Goals and Their Intention to Use a Feedback-Tool

Tugce Özbek, Tobias Mömke, Aida Roshany, Ingo Kollar
tugce.oezbek@uni-a.de, tobias.moemke@uni-a.de, aida.roshany.tabrizi@uni-a.de, ingo.kollar@uni-a.de
Augsburg University

Abstract: A lack of technology acceptance might hinder students from using educational technology. The UTAUT-model specifies performance expectancy, effort expectancy and facilitating conditions as relevant factors that influence the intention to use (ITU) a technology. Little is known about learner characteristics that influence ITU. We investigated the effects of different achievement goals of *N*=155 computer science students on their ITU of a feedback tool and learning outcome.

Aims and theoretical background

Digital technologies offer great promise for student learning. Students are more likely to engage in higher-order activities when technologies are implemented in class compared to when no technology is used, and such activities are also associated with a higher learning outcome (Wekerle et al., 2022). A key factor influencing the use of digital tools is students' technology acceptance (Venkatesh et al., 2003). A well-established model that focuses on the acceptance and use of digital tools is the Unified Theory of Acceptance and Use of Technology (UTAUT; Venkatesh et al., 2003). According to this model, *performance expectancy* (PE) and *effort expectancy* (EE) are decisive for the *intention to use* (ITU) digital tools, which in turn predicts the actual use of the tool. PE describes the user's perception that using the tool will help him or her achieve performance benefits. For students, for instance, this might refer to the belief that the use of a tool will promote his or her learning. EE, in contrast, describes the perception of how much easiness is associated with the use of the tool. For example, this might be a student's perception of whether the tool has an intuitive user interface. Further, facilitating conditions (FC) describe the user's perception of the extent to which there is a supportive infrastructure for the use of the tool (Venkatesh et al., 2003), which is also assumed to impact ITU. While these relationships have been supported empirically in many studies, it is still unclear what influence learner characteristics have on the use of tools and how these relate to student performance, particularly when it comes to educational technology. In this realm, we focus on achievement goals as a motivational construct that might influence the ITU (Hullemann et al., 2010).

There are many types of achievement goals that might influence learners' behavior (Daumiller, 2019). For the ITU of a peer feedback tool, especially the following three kinds of achievement goals seem to be relevant: learning approach goals (LAG, i.e., the goal of students to learn as much as possible), appearance approach goals (AAG, i.e., the goal of being perceived as competent by others) and relational goals (RG, i.e., the individual's striving to build close relationships with other students). Research suggests that learning-related goals, such as LAG, are particularly beneficial for learning and positively associated with learning outcomes. However, for AAG, studies often show positive, negative, or null effects on learning outcomes (Hackel et al., 2016). Positive effects on the behavioral level may also be assumed for RG and are associated with positive outcomes (Daumiller et al., 2019). The aim of this study was therefore to investigate the effects of different goals on ITU of a digital peer feedback tool of computer science students.

Based on UTAUT, the core connections that PE, EE and FC predict the ITU of the feedback tool were first assumed. In addition, since feedback tools provide learning opportunities that also involve interactions with peers, we assumed that LAG, AAG and RG positively predict the ITU of the digital peer feedback tool. Furthermore, we assumed that ITU of the tool also predicts students' performance.

Method

A total of *N*=155 computer science students took part in the study. They were first introduced to a digital feedback tool called "getFeedback!" in a lecture and then carried out a test task. After that, they answered items to measure PE (3 items, e.g., "Using getFeedback! increased my productivity", Cronbach's α=.81), EE (4 items, "I found getFeedback! easy to use", Cronbach's α=.90), FC (4 items, "I have the resources necessary to use getFeedback!", Cronbach's α=.52), ITU (4 items, "I think I will use getFeedback! this semester", Cronbach's α=.91; Venkatesh et al., 2003) and LAG (4 Items, "[When using the tool getFeedback!] …I want to constantly improve my competences", Cronbach's α=.93), AAG (4 items, "...I want to be perceived as competent", Cronbach's α=.80) and RG (4 items, "...my main concern is to have a friendly relationship with students" Cronbach's α=.93; Daumiller et al., 2019). One week later, the students worked on their tasks and then gave each other feedback. In order to examine the connection between feedback performance and ITU, students evaluated the feedback messages of each other. Due to the small sample size, the mean values of the scales were treated as manifest variables and a manifest path model was calculated.

Findings and conclusions

A manifest path model showed a good fit to the data, df = 13, $\chi 2$ = 7.85, p = .25, RMSEA = .005, CFI = .980, TLI = .96, SRMR = .033. PE (β=.46), FC (β=.23) and LAG (β=.29) significantly predicted students' ITU the feedback tool (p<.05). There was no significant effect for EE (β=–.08) and AAG (β=.08) on ITU. Surprisingly, however, there was a significant negative effect of RG (β=–.28) on ITU (p<.001). In addition, performance was significantly predicted by ITU (β=.24) Thus, the assumptions of the UTAUT for the prediction of intention by PE and FC could be confirmed. When interpreting the effects of FC, the insufficient reliability should be considered. In addition, ITU was significantly predicted by LAG. For AAG, in contrast, no significant associations with ITU were found. This might indicate that learning goals may also have effects on the use of digital peer feedback tools probably because students with learning goals regard working with the peer feedback tool as a learning opportunity. An explanation for the missing effect of appearance goals might be that, on the one hand, students with this primary goal might not want to help other students in order to perform best themselves. On the other hand, they might want to demonstrate their competencies. Hence, the two effects may cancel each other out (Daumiller et al., 2019). The negative effect of relational goals might indicate that digital interactions are associated with the fear of negatively influencing social relationships. Investigating the link between goals and technology acceptance further might therefore be a promising avenue for future research.

Abstract: This qualitative design-based research-practice partnership studies justice-centered practices towards consequential informal STEM learning and program design, focusing on authority sharing to understand how to reimagine and restructure power dynamics in nature-based field trip programming. Findings offer a lens for disrupting injustice in informal learning.

Introduction

We explore what supporting justice in ISL looks like in daily practice and design with educational leadership teams. Centering justice in on-the-ground enactment, we seek to contribute to emerging understandings of daily justice-centered design and enactment, insights on strategies for building institutional capacity to advance justice in ISL. We focus on three interconnected components of *authority sharing*: a) offering youth opportunities to be an expert/authority, b) decentering adults, and b) supporting new and hybrid forms of expertise. Working in justice requires integrative, cross-cutting, and critically connected actions across multiple areas and scales of activity (Ayers et al., 2008). In ISL, programs can be shifted in-the-moment, over time, at individual scales, and at institution scales (Penuel, 2017). In learning from and participating in the concrete and consequential efforts that particular institutions are engaging, we seek to strategize together towards more multidimensionally impactful transformation, generating knowledge for the field grounded in a research-practice partnership.

Justice-centered informal STEM learning

Informal STEM learning (ISL) settings can help disrupt systemic underrepresentation in science, technology, engineering and mathematics (STEM) (Philip & Azevedo, 2017). However, while informal STEM programs and practices may be made accessible to a wide range of audiences, the learning experiences themselves may welcome some participants while excluding others. Models that position educators as sole decision makers for learners carry implicit assumptions that center information-and-skill delivery and absorption, even within inquiry and practice-based models. STEM programs are called to leverage the experiences and practices youth and their families and communities offer towards more meaningful learning (Dawson, 2014; Feinstein, 2017). Informal learning leaders play an important role in this shift. We seek to offer lenses to guide informal learning structures towards justice outcomes of rethinking what counts as STEM, what it means to participate in STEM, and who gets to lead in STEM.

A focus on daily informal educator practice and design

Informal education leaders' daily "practices" refer to (a) the process of designing structures, programs, and activities and (b) pedagogical approaches to interactions with youth in-the-moment. Core Equitable Practices are pedagogical practices that support learning in empowering ways. When educators engage in these practices, they position themselves with youth as co-learners, co-disruptors, and co-creators in STEM. As a part of educator daily practice, we argue that Core Equitable Practices can a) welcome and legitimize youth's lives, b) disrupt power relations that marginalized low-income youth, youth of Color, and girls, and c) support new individual and collective participation forms, agency and identity (yestem.org; Greenberg et al., 2023). We seek approaches that directly address issues of justice at the individual and collective level through disrupting/transforming power, valuing youth along with their communities, and supporting STEM-agentic lives (supporting the ability of youth to use STEM as a tool for greater agency in whatever they desire to focus on in life). These patterns of practices can form an integral part of informal learning leaders' and designers' everyday practices (Peercy et al., 2022).

A centering of justice necessitates an ethical and political choice as educators. Our term "core equitable practices," draws from prior work in "core practices," a practice-based framework of teaching emphasizing daily action shaped by context (Kloser, 2014). Such practice happens in relation to systems of power (Peercy et al., 2022). To build capacity for justice-oriented informal learning, core equitable practices need to be studied further to understand how they can make visible, disrupt, and transform daily injustices in informal spaces.

Area of focus: Authority sharing

In exploring the core equitable practice of *authority sharing*, we seek to enhance understandings about implementation of a justice lens through daily practice in informal STEM education (including any tensions/challenges and possibilities for follow-up research questions). Typically, in learning environments, the educator is seen as an expert authority (Wrong, 2002) who decides what knowledge is important and how youth can demonstrate competency in taking up that knowledge. Adults hold expertise, but youth also bring valuable experiences to learning spaces. When we move beyond a binary of adult versus youth-centered learning, authority is shared. This helps to position youth knowledge and practice as valuable. It can also help de-center White, Western, masculine-lens epistemologies. When new, more egalitarian authority structures are created, whose knowledge and experiences matter (and how and why) is expanded. Adults can restructure authority in informal learning spaces through assigning roles (both implicitly and directly), valuing input/participation, and acknowledging expertise and effort. Authority Sharing involves supporting youth in using their expertise to educate others, drawing from the stance that youth have powerful ideas and experiences that matter in learning and doing STEM. Beyond giving youth the opportunity to be authorities, adults can embrace new forms of authority that bridge/merge and/or challenge traditional forms.

Context, methodology, & methods

Across more than 5 years of iterative and interdisciplinary research, we generated a set of 9 core equitable practices, including the practice we study here, *authority sharing* (Greenberg et al., 2023). We are now partnering with leadership in critical participatory design-based research (Getenet, 2019) using Summer 2022 data from 32 graduate student educators' actions and perspectives, informed by 3 institutional leaders and 4 university research partners. Data include interviews, researcher notes, focus groups, informal dialogue with educators, photos of teaching, and participant-observation. Our process of co-analyzing that data is described in our poster.

Abstract: Empirical evidence on what predicts students’ perceived collaborative interdisciplinary problem solving (CIPS) is limited. This study responded to this gap by building a multiple linear regression model to predict CIPS using 375 surveys collected from 71 undergraduates over eight weeks in an interdisciplinary digital literacy course. Motivating goal-directed affect positively predicted students’ CIPS, while anxiety was a negative predictor, indicating the importance of optimizing students’ motivation and emotions to facilitate their interdisciplinary learning.

Introduction

Addressing real-world problems requires technical skills and competencies to collaborate with others and navigate diverse knowledge landscapes. A promising way to cultivate these skills and competencies is by incorporating real-life, workplace, and societal issues into classrooms via interdisciplinary learning (Hains-Wesson & Ji, 2020). Accumulating evidence suggests the benefits of interdisciplinary learning, such as promoting learners’ organization of knowledge; facilitating critical thinking, metacognitive skills, and collaboration; and supporting the application of knowledge and skills to real-world issues or problems (Ivanitskaya et al., 2002).

Dealing with multiple disciplines simultaneously and communicating with group members from other disciplines may make interdisciplinary tasks difficult (Abbonizio & Ho, 2020). Cognitive theories typically view learning as an active goal-oriented process (Schuell, 1986), suggesting the importance of motivating goal-direct affect in learning. Growing research recognizes that epistemic emotions influence and are influenced by students’ motivations, social interactions, and cognitive processes (Pekrun et al., 2017). This study examined how these constructs contribute to students’ collaborative interdisciplinary problem-solving (CIPS).

Methods

This study was conducted in a digital literacy course that covered eight topics, such as Computational Thinking and Quantitative Reasoning. The participants were 71 undergraduate students (33 females, $Mean_{age}$=20.33 years old) from a public university in Asia. They came from ten different schools across Business, Sciences, Engineering, Humanities and Social Sciences. Four to six students from different schools were placed into a group to facilitate their interdisciplinary learning. A flipped classroom learning approach was employed: each week before the class, students were instructed to watch an hour-long video and take a short test; in class, they had 90 minutes to participate in CIPS activities, present their work, and fill in a weekly survey on their perceived difficulty of the activities, motivating goal-directed affect (five items adapted from the Positive and Negative Affect Scale, Cronbach’s alpha=0.94, Watson et al., 2018), epistemic emotions (seven items to measure discrete emotions adapted from the Epistemically Related Emotions Scale, Pekrun et al., 2017), and CIPS (adapted from the Integration subscale in Cole et al., 2018, Cronbach’s alpha=0.94). We conducted multiple linear regressions using all the other independent variables to predict CIPS.

Results

Table 1 shows how the key variables predict students’ CIPS. Among these variables, one unit increase in motivating goal-directed affect contributes to a 0.49 increase in CIPS, while one increase in anxiety leads to a 0.15 decrease in CIPS. Students’ perceived task difficulty, motivating goal-directed affect and various epistemic emotions explained 31.0% of their CIPS.

Table 1
Regression results using collaborative interdisciplinary problem-solving as the dependent variable

Predictor	*b*	*b* 95% CI	sr^2	sr^2 95% CI	Fit

		[LL, UL]		[LL, UL]

					R^2 = .310** 95% CI[.22,.37]

Note. * indicates $p < .05$. ** indicates $p < .01$.

Discussion and conclusion

This exploratory study found that a significant amount of variance in collaborative interdisciplinary problem-solving can be explained by (1) motivating goal-directed affect and (2) anxiety. We posit two possible reasons for this pattern of results. First, motivating goal-directed affect and anxiety might be influential variables that buffer the effects of conditions, perceived difficulty and epistemic emotions. This result implies that external conditions (e.g., nature of activity or difficulties encountered) may be less significant than the internal motivating state in learning. Indeed, Gill and colleagues (2021) found that the task was of secondary importance compared to the quality of interaction between motivated students in interdisciplinary learning. Anxiety was negatively predictive of collaborative interdisciplinary problem-solving. This result corroborates Saito and colleagues (2018), where greater learner anxiety predicts worse performance and limits the learner's opportunities to engage actively in the classroom (Yashima et al., 2016). Second, another possible reason is the self-selection bias of the current participant pool, which represented only approximately 35% of the classes sampled. The voluntary participants may be more motivated than the typical student population, resulting in a greater contribution of motivating goal-directed affect in the regression model than expected.

Some limitations of the current study should be noted. Firstly, we collected multiple observations from a single student, resulting in a nested data structure that was not accounted for in the regression analysis. Second, we used a single item to measure perceived difficulty and discrete epistemic emotions. Although research (e.g., Fisher et al., 2016) suggests robust psychometric properties of single-item measurements may replace multi-item counterparts, future studies could be strengthened with multiple-item measurements of these constructs.

Can AI Help Teachers Write Higher Quality Feedback? Lessons Learned From Using the GPT-3 Engine in a Makerspace Course

Gahyun Sung, Harvard University, gsung@g.harvard.edu
Léonore Guillain, Taskbase, leonore.guillain@gmail.com
Bertrand Schneider, Harvard University, bertrand_schneider@gse.harvard.edu

Abstract: We explore how a cutting-edge language model, GPT-3, can be used to augment and assist periodic feedback writing in a makerspace course. Personalized messages were generated using student data then edited and combined with human instructor feedback. We discuss the lessons learned: namely, AI did well in summarizing work and positive encouragements, yet could write off-target feedback for struggling students. An initial interview with an instructor revealed that future iterations must consider ways to formalize and manage human expert roles.

Introduction and setting

Could AI technologies augment periodic feedback, a standard practice in many learning environments? We study how this might be done in one context less explored but ripe for automated data-based feedback systems: a makerspace, a physical project-based learning environment where students monitoring can be a challenging task. Our context is a semester-long course on digital fabrication at a graduate school of education in the U.S., where students (n = 19) applied standard makerspace tools for a personal project. For many, the course is not only a chance to learn a new skillset, but to revisit their identities and perspectives on learning. Yet, we also saw students who quietly struggle to keep up. While instructors reaching out could help these students, this requires keeping tabs on multiple data sources and writing time-consuming feedback. Our study tests whether AI could assist this instructor responsibility, with the current paper focusing on results of our explorations on what tasks AI could and could not do well in an educational context, as well as lessons learned on supporting AI-human partnership.

A platform for developing a human-AI partnership: Preliminary findings

Our platform used GPT-3, a cutting-edge generative AI model that can generate humanlike speech with a high level of sophistication and naturalness. During an exploratory phase, we fed various blog posts written by students to GPT-3 to identify when and how the system might be used in a project-based environment. Our explorations led us to believe GPT-3 may provide the starting point of a helpful feedback: it was able to 1) use supportive language to appreciate projects (e.g., imaginative, impressed); 2) recognize the work put in (e.g., I appreciate the effort, I'm impressed); and 3) value students' strategies (e.g., you did a great job of staying organized throughout the process). Based on our explorations, we developed a writing platform seen in Figure 1. The system is shown on left, while on right is the structure of the periodic feedback sent out.

Figure 1

How can GPT-3 be used in project-based learning contexts?

Our platform used GPT-3 for two tasks: generating encouraging messages for students and summarizing student blog posts on their weekly projects. Again, GPT-3 showed clear value in summarizing student reflections of their own work. The machine-generated summaries were concise and accurate, giving instructors overviews on how student work was progressing. They were also close enough to natural speech to directly add to emails, making it easier to encourage peer engagement. GPT-3 also performed acceptably in writing congratulatory messages. However, we noticed that feedback was often insensitive for struggling students. One prompt (“Write a supportive message to a student with {*stress* (*high)} and {*enjoyment* (*low)}.”) may result in messages of varying quality:

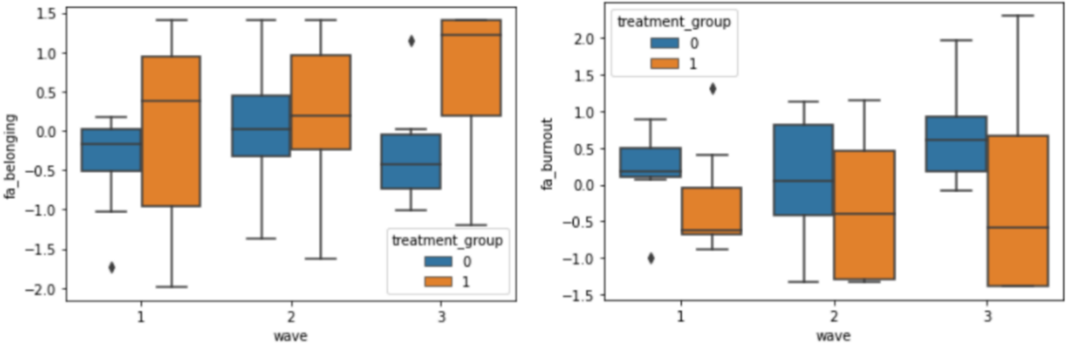
> **Message 1**: We're sorry to hear that you're not enjoying the class and that you're feeling so stressed. Can you tell us more about what's making you feel this way? We want to make sure we're doing everything we can to support you. Are there any specific things we can do to help you feel more comfortable and successful in the class?
> **Message 2**: We think that you're not enjoying the class and that you're feeling slightly stressed. I encourage you to reach out to the teaching team for help.

While the first message is not perfect, the second message is too short to reasonably expect any effect, and the term “slightly” depreciates the level of reported stress. While further tinkering with the prompt could result in better feedback, this may defeat the purpose of making the process easier for human instructors.

Below, we show a descriptive graph of self-reported levels of belonging and burnout for students who did and did not receive the AI-augmented areas of the feedback (i.e., yellow boxes in figure 1). Students who received augmented feedback (orange) seem to report higher belonging and lower burnout, but further analyses on the final data will test these differences statistically and explore the effects with student interviews.

Figure 2

Descriptive trend of student belonging and burnout with and without the AI-augmented feedback



There were also two lessons learned from involving instructors with the platform. One, we quickly realized that human input was an indispensable, limited resource. The makerspace facilitator we interviewed noted that this seemed to add a layer of complexity to writing feedback. While the learning curve may be justifiable for a larger class - for instance, this may make feedback possible in a course with 100+ students -, we acknowledge that these concerns hit a pain point for future iterations. Second, the facilitator noted that for instructors to put trust in these messages, a basic understanding of how AI worked and where it failed was necessary. Conversely, our interviewee also pointed out that other facilitators might be too trusting of the output, and neglect to thoughtfully edit AI feedback. This is a central tension: how do we prompt users to think deeply about the quality of their feedback, but at the same time lessen workload? These questions will be guiding our next iteration efforts.

Conclusion

To sum up, the design and implementation of an AI-augmented feedback system revealed that GPT-3 is helpful in summarizing written products and writing words of encouragement, yet can write off-target feedback for struggling learners. An instructor interview also revealed that we need to consider resource constraints and ways to build trust in AI. In future work, we hope to build system-side quality safeguards, e.g., automatically ‘flag’ sub-par or repetitive messages. We also hope to include existing richer data sources in the input, such as open-ended student feedback, and in particular the camera-based location data from the makerspace, an objective measure of work patterns inside the space. These additional inputs are hoped to increase the accuracy and relevance of AI-generated feedback. On the other end of the pipeline, we also hope to seek advice from students and instructors about effective feedback in different scenarios, to create better prompts for GPT-3. Throughout these improvements, we aim to continuously engage instructors and learners in an iterative co-design process.

Abstract: Understanding the roles of agency in learning can be expanded by taking up a posthumanist stance and examining material conversations in creative spaces—such as in this participant observation study set in a university textile technology art class. Using video/audio records, artifacts, and field notes, we categorize being, doing, and becoming agency of materials and the learning opportunities they offer in ecoprinting and computer/machine embroidery. Learning with becoming materials may depend more heavily on iteration.

Introduction and purpose

Materials hold energy from their pasts that speak to how we can—or should—use them to create artifacts and learn in the process. We consider the agency of materials as members of a university course on textile technology and examine traversals across materials, exploring artefact creation as joint projects involving shared agency, guided by a research question: How might we learn from and with materials through negotiations of agency?

Theoretical framework

Our work is guided by theory on agency and its role in learning. To this, we bring a posthumanist stance that positions materials as learning partners. Agency has long been treated unproblematically as making decisions, constrained by structures (Giddens, 1984). We take a situative approach to agency (Svihla et al., 2021) in which decisions unfold interactionally and vary in their consequentiality. We also take up a posthumanist view of material, extending classic descriptions of design as a conversation *with* materials (Schön, 1992). By treating materials as living and having the capacity to engage in joint projects, we center "withness" (Shotter, 2006) in which materials are worthy of respect. *Being* materials exert covert and potentially coercive influence or implicit background structure on the design landscape. *Doing* materials are ones that are selected specifically for a particular role and meet a specific need that is negotiated between designer and material. *Becoming* materials are those that are agentively repurposed by the designer as part of an interactional relationship between maker and material (Gravel & Svihla, 2020). We conjecture that becoming material conversations offer fertile grounds for both negotiating agency and learning.

Methodology

We used participant observation to investigate materials as partners in learning, alongside students as co-investigators (DeWalt & DeWalt, 2010). Students engaged in an ecoprinting process (Ratnayaka & Haar, 2022) and used Snap-based TurtleStitch to produce machine-embroidered designs (Wolz et al., 2019). The course, at a large southwestern US university, centers on textile art. The study team includes the course instructor, two learning scientists-as-observers, three graduate students, and two undergraduate students. We collected data through video/audio recording, artifacts, and field notes. We used discourse and interaction analysis to attend to ways members negotiated agency with materials.

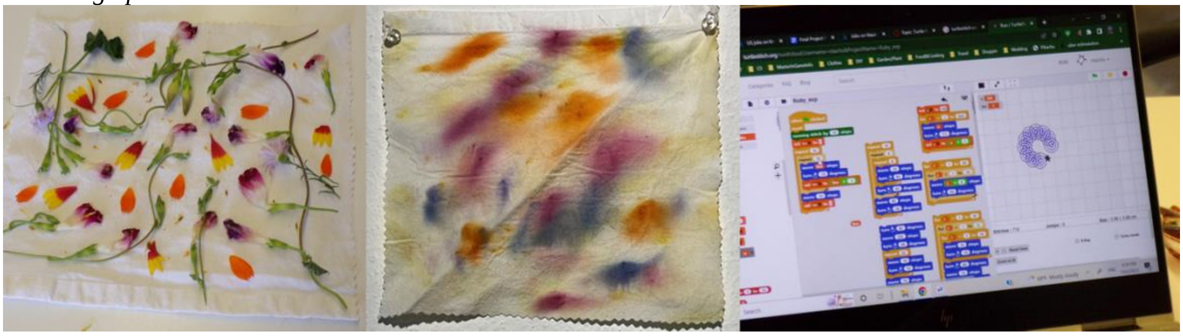
Results and discussion

In ecoprinting, the dowel around which we wrapped the fabric and the steamer pot were being materials; their absence would be noticeable, but their presence was little remarked upon. The fabric and plastic were doing materials, selected for their dependable behaviors. We negotiated agency with the plants, as a becoming material, willing to contribute, yet surprising us. For instance, eucalyptus, a plant we sought for its ability to make distinct orange or brown prints, produced pale yellows. Plants withheld their capacities from us, requiring us to interact with them to discover what they could become. The water held more consequential agency than we anticipated. It seemed like a being material, present as damp, as steam, a backdrop. Yet through our material explorations, we were surprised by its roles in shaping the final print (Figure 1).

In TurtleStitch, the computer itself, browser window, and program were being materials. The individual code blocks, embroidery machine, and thread were doing materials. Created code blocks and the editable values of existing blocks were becoming materials, producing unexpected results for us as inexperienced programmers. Although the preview on screen provided feedback, its translation to fabric was slow. Here, the embroidery machine held more consequential agency than expected, as a computer-drawn line running over itself hundreds of times is acceptable, but doing so even a few times with thread can break thread, needle, or tear fabric.

Across both, we experienced surprise in the transition between working with materials and the product that resulted. The time between code and rendered preview was shorter than the steambath of ecoprinting, but in both, the materials offered little ongoing feedback about how they would behave in final form. In lieu of ongoing feedback in ecoprinting, members gathered to review one another's designs both during designing and when unrolling final designs, sometimes making edits to their own yet-to-be-steamed design. In reflecting on their process, work, and material agency, members noted that they had plans or had implemented additional designs, at least partially in response to the unexpected ways certain materials behaved.

Figure 1
Examples of student work, left to right: preparation for ecoprinting; the completed ecoprint; TurtleStitch code and design preview



Implications

Our analysis foregrounds the negotiated nature of agency between designer and materials, providing insight into roles different materials play in designing and learning. Though the materials differed across ecoprinting and computer embroidery, both included *becoming* materials that had consequential agency, manifested as surprise. Our status as newcomers with the particular materials positioned some as becoming materials, but in the hands of an expert, the same materials might be being materials. Thus, as we learn, our relationship to the materials changes. Our ongoing research builds on this to consider ways we can support learner agency, such as anticipating deliberate, iterative work and reflecting on varied negotiations with different forms of material agency.

Joint Media Engagement as a Resource for Family Learning: Catalysts and Transmedia Connections

Flora Troy, Brigid Barron, Maria Romero
ftroy@stanford.edu, barronbj@stanford.edu, romeromr@stanford.edu
Stanford University

Abstract: With an abundance of information sources available, families are learning in novel ways. To understand how family-based collaborative learning moments emerge in everyday life we collected and analyzed caregiver narratives of a recent knowledge-building occasion. Learning stories were analyzed to understand their origins, affective qualities, technologies used, and forms of joint media engagement. We find digital tools are leveraged to address immediate needs for information and problem-solving as well as support established interests, connections, and bonding.

Background

In the U.S., young children's time spent on mobile devices tripled between 2013 and 2017, from an average of 15 to 48 minutes daily. During the pandemic, screen time increased dramatically when children spent more time at home, with a recent international meta-analysis estimating an average increase of an additional 84 minutes daily (Madigan et al., 2022). As conversations around digital media and young children evolve from quantifying "screen time" to considerations of content and context, learning sciences research has an important role in providing insights about everyday learning relevant to caregivers, educators, and designers. In this project, we explore how digital media resources can serve as powerful learning tools when adults and children use them as catalysts for collaborative exchanges around personally meaningful content. Digitally anchored activities shared with parents, siblings, grandparents, and extended family can generate questions, explanations, and extended conversations that build connections to real-world experiences and support the development of language and literacy. Digital tools also allow for the co-creation of artifacts that offer opportunities to reflect on original content. Ethnographic studies have shown that these forms of joint media engagement (JME) can be a powerful mechanism for fostering cultural knowledge, coordinating activities between home and school, and co-developing interests that evolve over time (Barron & Levinson, 2017; Takeuchi & Stevens, 2011). In addition to these benefits, learning together can be a source of bonding and shared enjoyment. Given the potential of leveraging technology for learning, it is essential to understand the conditions that catalyze generative moments in the context of daily life. We contribute to this agenda by sharing findings from a study of parents and children learning together. We report qualitative analysis of collaborative learning narratives reported by caregivers. Two questions organized this analysis. (1) What motivates learning together (origins, purpose, content)? (2) What sources of enjoyment and challenge do caregivers articulate?

Methods

This project uses a remote research tool, dscout, as an experimental method to conduct qualitative research with remote participants. We captured instances of parents and children learning together from 50 diverse families in the service of better conceptualizing child-driven contemporary learning ecologies. Families each had at least one child between the ages of 7-10. The gender balance is approximately 55% male. In our sample, 50% of families reported household incomes below the national median for families in the United States ($75,000). Participants answered a series of questions using short videos, photographs, responses to multiple/choice and rating queries. This poster focuses on caregivers' reports of using technology to learn with their child. Data for each entry included a 2-minute video (and transcription) of the caregiver describing and reflecting on the learning moment.

Findings

Our coding system includes seven primary dimensions: learning catalysts; focal content; mode of joint engagement; learning partner roles as guides and learners; media resources; affect; and sources of enjoyment/challenge. Examples of learning together ranged in content and form. Each transcribed caregiver video-response was coded for the primary four themes below (see Table 1). Learning together promoted bonding and collective positive affect across the sample. Due to space limitations, Table 1 highlights one subcode and example for four major themes.

Table 1
Selected Codes for Family Learning

Topic	Code	Example
Affect	**Joint positive affect**: Caregiver and child share positive emotions from an activity	Gardening is my passion and it was fun to share it with them and see the delight on their faces when I told them in a few years we will have a tree and may even get apples.
JME	**Conversational anchoring**: Digital artifacts support joint understanding of a concept, activity, or place	We went on NASA's website and we were learning about the different layers of Earth's atmosphere. So we got to learn all about the various layers of the atmosphere as it went through.
Media resources	**Video sharing platforms:** Use of platforms like YouTube or TikTok	So we did the counting, then I put it on a TV because we have a smart TV, so it does YouTube. We sat there and we did all the dances.
Catalyst	**Life Challenge:** Joint learning is motivated by an immediate or possible future challenge related to health, well-being, repairs, communication, or finances	So my kids were fighting again and freaking out. I was telling them that they needed to figure out some coping mechanisms to help them deal with their emotions so that you don't take them out on each other. He was like, “Whoa! Like what?” So, I said, Hey, let's Google it. And so we went to the Internet to find coping mechanisms for him.

Here is one learning moment example from a mother, Brianna and her nine-year-old child learning together.

> We actually found a book on Epic about owls, and we learned the different things about how owls are, the difference between the owls and how they live, how they eat, how they expand, how they travel. We worked together to do some more research and looking at pictures and videos and listening to the different sounds these owls make. We learned together, and it was just about bonding, building, and learning together.

In this case, the parent and child collaborated to search the online Epic reading database for a book to learn about a topic of interest, owls. The form of joint media engagement, collaborative interest-driven search, leveraged the internet to find videos, photos, and audio to enrich their understanding of how owls live. Holistic learning occurs here through reading, visualizing, listening, and discussing the topic. By building knowledge together, Brianna and her daughter bonded, and she appreciated her daughter’s research skills, setting the stage for expanding this practice elsewhere.

Implications and future directions

With countless ways to interact with information today, how can we best support families? This project analyzes instances of child-caregiver driven collaborative learning to understand catalysts of inquiry, productive JME co-learning practices, preferred media resources, and to conceptualize affective and epistemic benefits. Future design work can leverage these insights for co-designing family reflection tools that surface productive JME and shared joy, as a metacognitive and meta-emotional resource for making choices about how to spend valuable time together.

Dialogic Coaching Routines to Develop Teachers' Adaptive Expertise in Video-Based Coaching

Marguerite E. Walsh, Lindsay Clare Matsumura, Dena Zook-Howell, Richard Correnti
m.walsh@pitt.edu, lclare@pitt.edu, dkz5@pitt.edu, rcorrent@pitt.edu
University of Pittsburgh

Abstract: Instructional coaching that builds teachers' integrated knowledge of dialogic teaching concepts and practices is essential for achieving ambitious education reform goals. An enduring challenge, however, is that relatively little research has focused in-depth on the processes that facilitate teacher learning in coaching contexts. Here, we illustrate a 'dialogic coaching' approach that connects the learning processes needed to develop teachers' adaptive expertise for dialogic teaching to an interactional framework for coach-teacher joint reflection.

Introduction

Instructional coaching is a widely used form of teacher professional development to advance dialogic teaching approaches. Historically, however, coaching as it normally occurs is often misaligned with learning theory that emphasizes joint participation in the core processes that underlie a complex task (e.g., facilitating a classroom discussion). Our presentation illustrates a 'dialogic coaching' approach that emphasizes eliciting and scaffolding teachers' pedagogical inquiry and reasoning processes to connect dialogic teaching concepts to their own practice.

Theoretical framework

Effective professional development requires integrating professional learning activities in robust, theory-driven frameworks of teacher learning and change processes. Here, we draw on an adaptive expertise research (Hatano & Inagaki, 1986) to identify three interrelated pedagogical thinking and reasoning processes needed to support teachers' learning of dialogic teaching: *problematizing* teaching-learning situations to negotiate a shared problem space; *weighing* alternative scenarios to resolve problems; and iterative linking between teaching specifics and abstractions (i.e., *instantiating* and *generalizing*). (Walsh, 2021). We highlight these pedagogical reasoning processes in specific because they closely align with the nature and demands of dialogic teaching. Specifically, as an approach that fundamentally hinges on responding to students' developing thinking and ideas, teachers must learn to flexibly reason through alternative ways of interpreting and responding to pedagogical scenarios and dilemmas (i.e., *problematizing* and *weighing*) and build integrated knoweldge by iteratively connecting specific lesson interactions to broader pedagogical concepts and aims (i.e., *instantiating* and *generalizing).* Together, these processes can destabilize routine ways of thinking and acting in the classroom and enable more productive decision-making.

Illustrative exemplar

In this section, we draw on excerpts of coach-teacher dialogue from a larger study of a successful video-based coaching program (Correnti et al., 2021). In the following, the coach and teacher discuss a video clip where the teacher had asked students to explain the meaning of the idiom "You can't feed hope with food," with the goal of having students infer the larger meaning using text details. Our aim is to highlight how coaching interactions can elicit and scaffold the pedagogical reasoning processes needed for adaptive teaching expertise described above.

Problematizing: Developing a clarified conception of the problem space

Table 1
Excerpt 1

Turn	Quote (coach= C; teacher=T)
1	C: You began by asking: "What is the author talking about?" *What is the pattern of the conversation and how did this impact your learning goal for students?*
2	T: My goal was for the students to make the connection that there wasn't any food, water, or schools—the things Salva hoped for—so there wasn't anything to 'feed hope.' *The pattern I noticed was students guessing and then I would try to explain why it wasn't quite right.* **[instantiating]**
3	C: I thought we could look again and *see if you think that at any point the balance of talk is not in the students' court.* **[generalizing]** […video plays…]

4	T: I probably shouldn't have started the conversation with 'you can't feed hope with food,' *because the students spent so much time trying to figure out what that meant…I think I beat the dead horse for so long that…the meaning got lost…*
5	C: What did you notice the students saying?
6	T: Keyla said there wasn't enough to eat. The government didn't have money to give to the camp…*so, they were saying all the things about the camp that made it unrealistic or made it difficult to hope.* **[instantiating]**
7	C: Let's look at a couple of talk moves that might be useful *when kids are throwing out a lot of details, but they are not getting that big message in the text.* **[generalizing]**

The coach begins by inviting the teacher's thinking about the link between her pedagogy and student learning (T1), prompting the teacher to offer an initial formulation of the problem space (i.e., that students were 'guessing' and she was 'explaining') (T2). The coach then suggests a slight reframe focused on student participation linked to a broader aim (T3). After viewing the clip, the teacher offers a new framing of the problem space (T4) to which the coach responds by orienting the teacher to student's expressed thinking in that moment to draw attention to the fact that students were providing many important details (T5). The teacher then offers a strong inference based on specific evidence (T6), providing the basis for a more sophisticated formulation of the problem space, i.e., that the pedagogical problem was not that the interaction had 'gone on too long', but that teacher facilitation was needed to help students infer larger meanings from multiple text details (T7).

Generating and weighing alternatives: Refining and resolving the problem space

Table 2
Excerpt 2

Turn	Quote (coach= C; teacher=T)
10	C: If students are throwing out these various details, how might you use talk moves *to help pull these details together so that they could start to see them as a unified piece?* **[instantiating + weighing]**
11	T: Well maybe, "What is the basis for that conclusion?" Or, "I hear you saying… "What do you think…?" Or even, something like, *"Okay. Given what Keyla and Vanessa just said and what we just read about, what do you think the author is trying to tell us?"* **[instantiating]**
12	C: I think that this would help them get to *the 'so what' of that portion of the text so that they can collaboratively build toward the big ideas. It is important for students to know details, but it is also important for them to help each other put those details together to interpret the larger message.* **[generalizing + weighing]**

Once the problem space is identified, the coach invites the teacher to propose specific talk moves that might be useful for similar future situations. The teacher offers several specific alternatives given students' expressed thinking, ending with *'what is the author trying to tell us'* (T11). The coach affirms this alternative and connects her explanation to a general principle of dialogic teaching (T10). This connecting of specifics to general principles is critical for developing more integrated knowledge and transfer insights to future lessons. As such, it is central to adaptive teaching expertise—the ability to choose talk moves to achieve dialogic teaching goals in practice.

Discussion and implications

This poster provides insight into how dialogic coaching interactions can support teachers' development of adaptive teaching expertise through problematizing and iterative linking of teaching specifics and abstractions, contributing insight into the 'black box' of teachers' professional learning conversations.

Can AI Disrupt Disinformation? Assisting Learners in Identifying Fake News Through an AI-Powered Platform Informed by Inoculation Theory

Eury Hong, Brett I. Schechter, Inara B. F. de Sousa, Mutiara S. Prasetyo, Renato Russo, Paulo Blikstein
eh3011@tc.columbia.edu, bs3407@tc.columbia.edu, ib2510@tc.columbia.edu, mp4155@tc.columbia.edu,
rfr2126@tc.columbia.edu, paulob@tc.columbia.edu
Transformative Learning Technologies Lab, Teachers College, Columbia University

Abstract: The recent increase in the spread of disinformation poses dangerous implications for society. This project draws on inoculation theory to design and test an interactive platform based on Large Language Models – Aide – that uses language modeling to educate users on common textual strategies employed in pieces of disinformation. Preliminary user experiences with Aide suggest an influence on learners' disinformation sense-making processes.

Introduction and theoretical framework

Disinformation is a central concern in today's world. While the origin and definition of disinformation are widely debated, we draw upon the definition of disinformation as any information whose primary function is to mislead individuals (Fallis, 2015). This study is inspired by the epidemiological theory of inoculation as a response to disinformation, and builds on research proposing that preemptive exposure to controlled doses of disinformation can offer "cognitive resistance" against future disinformation (van der Linden, 2022). The platform developed to "inoculate" learners in this study, Aide, utilizes artificial intelligence (AI) to help users identify misleading tactics employed in pieces of disinformation. Previously, AI models that identify different textual features present in disinformation have been developed for social media moderation (Zhuk et al., 2018). However, there is still a gap in the application of AI and Large Language Models in teaching and learning about disinformation. Through a progression of interactions with Aide, users observe how the platform detects these textual features, namely unwarranted correlations, overgeneralizations, and emotional triggers. The team chose this set of strategies following related work (e.g., Roozenbeek & van der Linden, 2019). Aide emphasizes the methods and processes for determining the validity of information, rather than solely confirming or denying a learner's preconception of it. This study builds on previous work by the researchers (Russo, Blikstein & Penalva, 2021; Russo & Blikstein, 2022) to investigate how Aide's use bolsters learners' ability to identify common strategies in disinformation campaigns and assists in developing critical mental models that can be applied to daily information consumption. We present preliminary findings related to learners' ability to identify textual features of disinformation, and their stated tendency to apply similar strategies in real life.

Methods

Aide has been designed as a mobile app implementing a JavaScript-based interface in connection with OpenAI's API for GPT-3, "a third-generation, autoregressive language model that uses deep learning to produce human-like text" (Floridi & Chiriatti, 2020). We hypothesized that an AI agent's linguistic analysis would allow learners to critically reflect upon disinformation by serving as a resource outside of learners' social bubbles. A convenience sample of 4 international graduate students in the US majoring in education (22-26 years of age) was recruited to test the application. They were individually interviewed and recorded for approximately one hour on Zoom, and had their screen recorded for observation of their interaction with the app. We examined how interaction with the prototype was associated with verbal expressions that denoted reflection and/or learning, such as when users' manifest analytical approach to identifying disinformation tactics mirrored that of Aide. Prior to user testing, participants received a brief explanation of Aide's functionality. Researchers then asked about participants' media consumption and sensemaking processes when encountering news articles. For the majority of the interview, participants interacted with the prototype utilizing think-aloud strategies. Finally, participants shared their impressions and ideas on how to improve Aide for future use. Researchers took notes during the interviews and watched the recordings to identify evidence of learning as they interacted with Aide.

Results

We found preliminary evidence of learning and effectiveness of the prototype during the user testing. Prior to interacting with Aide, only one out of four participants could define disinformation. Although we understand that a memorized definition is not the most appropriate way to assess one's learning, that provides us with a point of reference for familiarity with the topic. After approximately 20 minutes of interaction with Aide, 3 out of 4 participants seemed to recognize general patterns of disinformation explored in the prototype, such as "unwarranted correlations" and "overgeneralizations." It is intriguing to notice that by minute 20, participants had already (1) briefly discussed forms that disinformation could take, (2) seen Aide's evaluation for a news headline, and (3) were evaluating a news story by themselves, following Aide's heuristics. Also, the participant who spent most of the test interacting with Aide (53% of total interaction time) came up with concrete pattern recognition such as "conspiracy theory" and "emotional trigger."

We also noticed a tendency to assimilate patterns. Learners stated that the strategies evidenced by Aide could help them read the news more critically in the future. More specifically, one participant said that Aide "tells me what to do with disinformation." Another participant stated that she wanted "to imitate what Aide does. Because Aide provided two strategies of disinformation, I want to do something similar." Although this insight is encouraging to develop further the prototype, it also signals the need for attention to excessive reliability on a Large Language Model-based system: although one participant alerted against the embedded biases that the prototype itself has, other participants were enthusiastic about the idea of "outsourcing" criticality in consuming the news. For example, one learner said that she wants "Aide to decide for me whether the news is trustworthy or not." Despite the preliminary nature of this data, this also serves as a warning as to how much further we can go in relying on AI systems to make decisions on our behalf.

Discussion and future directions

Although the tests conducted in the current research are limited, they show Aide's potential as an effective implementation of the inoculation strategy against disinformation. Participants showed engagement and enthusiasm in using Aide as a tool to identify disinformation patterns on a day-to-day basis. The study hereafter needs more explicit instruction and design elements that make the overall journey more explicit, as well as the tasks expected from the user at all stages. Data collected so far leads the team to conjecture that visibility of those steps tends to promote effective learning and enhanced engagement.

In conclusion, the initial research phase indicated that interaction with Aide inspires users to adopt critical sense-making processes toward disinformation. In particular, preliminary results suggest that Aide influences learners to express disposition in detecting textual features commonly employed in disinformation. Following this, we will focus on testing that enables further insight into how Aide serves as a scaffolding tool. In the next phase of data collection, we will analyze how learners approach news prior to, during, and post their interaction with Aide, identifying evidence of learning associated with interaction with the platform. We understand that one particularly important aspect of Aide needs further consideration from the research team: its reliance on a commercial API to access an AI linguistic model. As most AI solutions, OpenAI's API has biases and its algorithms are not accessible to researchers and end-users.

Despite the limitations, we conjecture that this research can lead to insight into novel ways to employ technology in the learning process and teaching approach towards disinformation in the K-12 context, ultimately leading to the reduction of disinformation spread. In contrast to the harm brought about by AI, we expect to contribute to harnessing its potential to impact positive change in education and society.

Envisioning a Sociopolical Framework for Care Within Teacher Education

Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu
Paul Sutton, Pacific Lutheran University, suttonps@plu.edu
Rebecca Smith, University of Portland, smithre@up.edu

Abstract: The purpose of this qualitative study was to envision a framework for how to authentically care for students, particularly within a COVID sociopolitical context. Our research question examined: What could a framework of sociopolitical care look like? This research utilized Noddings' (1998, 2012) care theory, critical theories, and indigenous pedagogy to envision care that centers the student within a broader relational community.

Major issues addressed

Noddings' (1988) care framework has provided meaningful guidance for educators seeking to care for their students. In it, she argues for a reframing of the aims of education around care, modeling, dialogue, practice, and confirmation. However, for reasons surfaced by the twin pandemics of the COVID-19 and systemic and institutionalized racism, the limits of Noddings' ethic of care has come into full relief. While Noddings is careful to create some space for student agency in how she conceptualizes care, the process of caring is initiated by the teacher and is focused on a unidirectional relationship whereby the teacher cares for the student.

In this paper, we explore the construct of care within Teacher Education, focusing on the role of care in the early months learning during the early months of the COVID-19 Pandemic. Previous work examined how the context of the COVID-19 pandemic impacted how we consider and define the elements of care (Smith, Sutton, & Tierney, 2022). Through our examination of literature and our data, we identified the need to adopt a framework for sociopolitical care that centers issues of equity, power, positionality, and the cultures, relationships, and communities often marginalized in normative frameworks of care. Doing so, we also identified the need to disrupt conventional views of who is acting and who is being acted upon in relationships of care. Our research question, "What could a framework of sociopolitical care look like?", is an initial attempt to explore these issues.

Potential significance

This study highlights the need for teachers to listen to the expressed needs of their students, particularly as those needs relate to the sociopolitical context of the time. Demonstrating care for students should not be a simple show of values, which could be detrimental in promoting imbalanced power dynamics (Noddings, 2012) or deficit models of students, perpetuating racist thinking (Matias & Zembylas, 2014). Rather, care entails co-construction of learning between the teacher and the student, revisioning Noddings' (1988) framework to be more inclusive and racially conscious.

Theoretical perspectives

Research studies that focus on critical care for students utilize a variety of terminology in their understanding of care and advocacy for students. Rector-Aranda (2018) calls for teacher education programs to integrate *critically compassionate intellectualism* (CCI), which combines critical pedagogy, authentic caring, and social justice curriculum. Roberts (2010) calls for *culturally relevant critical teacher care* (CRCTC), which integrates tenets of culturally sustaining pedagogy (Paris & Alim, 2017) and critical race theory. This framework entails a focus on students' voices, counternarratives, and student futures, in addition to a consideration of political and ideological thinking, especially related to race and power (Roberts, 2010). In addition, we consider the relationship between indigenous pedagogy and culturally sustaining pedagogy (McCarthy & Lee, 2014). Hanson et al. (2000) recognize that responsible teaching needs to be recognized as both cultural and political, specifically recognizing histories of colonial violence. These critical perspectives related to care can contribute to a revisioning of Noddings' (1988) framework to be more inclusive and racially conscious.

Methodological approaches & data sources

The research question was addressed in 10 virtual working meetings with the researchers. Researchers in this study recognized gaps in the data related to the sociopolitical context of care needed to authentically teach and learn in teacher education. Thus, we have developed the proposed theoretical revision to relational pedagogies to help guide our own practice and to encourage like-minded educators in their own practice. Our positionality within this work is as three white-identifying researchers. In this work, we do not presume to be embodying indigenous pedagogy. Instead, the framework presented is influenced by indigenous perspectives, as well as sociopolitical and sociocultural perspectives, theories of power, and our own lived experiences as teacher educators.

Major findings: Revisioned practice of care framework

Drawing from indigenous perspectives and pedagogies (Castagno & Brayboy, 2008; Holmes & Gonzalez, 2017; Sabzalian, 2019) to rethink care, we propose an extension of Noddings' care framework that centers students within a larger ecosystem of community. We argue that acts of care are more than the actions of an individual teacher to an individual student; authentic caring involves a collaborative process between students, students and teachers, students and the community, and teachers and the community. We propose that care results from co-constructed structures of support, built by students, community members, and educators so that care becomes a fundamentally de-settled and de-colonized process that reflects the values, norms, traditions, and epistemologies of students' communities.

Indigenous theories of co-constructed, de-settled, and decolonized practice, both with and by a community, emerge most powerfully in the work of Indigenous scholars, many of whom are cited above. Underlying Indigenous ways of approaching education are several interconnected and overlapping shifts that we believe should be used to rethink an ethic of care in classrooms and schools. The first includes a shift from an individualistic ethos, which tacitly asserts that care is an act of an individual teacher to an individual student, to an ethos that sees students as part of larger communities who may instill different norms, values, and epistemologies than those espoused by the White, middle class school system. The second includes a shift from thinking of schools and the process of educating children as separate from communities; instead, education is nested within communities and thus accountable to them. The third, and perhaps most important shift, argues that an ethic of care should only be defined as care if it has been co-constructed by teachers, students, and the community. When schools are repositioned as places that are part of a larger ecosystem of families, cultures, and communities, it also demands educators to think of care as a co-constructed, collaborative process embarked upon by the ecosystem of support the student and school is situated within. In particular, the teacher education classroom can draw from the same principles of co-constructed, de-settled, and decolonized community by co-constructing a caring teacher education classroom space with students and making space for them to bring in their myriad identities and lived experiences. In this revisioned *Practice of Care*, we flatten the hierarchy typically present between teacher candidates and teacher educators in part by de-centering the teacher educator and centering student experience, identities, local community strengths, and the sociopolitical context.

Exploratory Case Study of Collaborative Practices in Flexible Learning Spaces

Pauline M. John, Priya Sharma
pmj5179@psu.edu, psharma@psu.edu
Pennsylvania State University

Abstract: Flexible learning spaces are considered to support active learning pedagogies with flexible furniture, plenty of writeable surfaces, multiple projectors or display screens and other technology. This study uses a case study methodology to investigate collaborative practices in two flexible learning spaces in a higher education institution. Findings suggest that flexible learning spaces allow participants to share mediating artifacts and provide a horizon of observation that can support students' shared understanding and work.

Introduction

Higher education is being called upon to adopt contemporary technologies and pedagogies to address 21st century skills like innovation and collaboration. One response is the increased focus on designing and integrating flexible learning spaces with flexible furniture, writeable surfaces, and enhanced technology aids to support student centered learning. Flexible learning spaces have been studied for their impact on academic performance, instructor and student behavior, focusing mostly on utility functions and perceptions of space regarding teaching, learning and technology (Gordy et al, 2020). Much of the empirical research around learning spaces has focused on data related to feedback, students' perceptions, and satisfaction surveys. However, research that focuses on students' in-class collaborative actions and their interrelations to space and its elements is underreported in the literature. This study uses a case study methodology to focus on the collaborative practices within a flexible classroom. Our research questions engage specifically with physical artifacts in the classroom, which we narrowed via ongoing analyses to one element, a portable whiteboard, and its affordances for collaboration. Our main research questions are: (1) How do students interact with physical artifacts in the classroom to support collaboration? and, (2) What triggers students to engage with the physical artifacts in the classroom?

Theoretical framework

To frame this study we primarily draw upon Distributed Cognition, where cognitive processes are distributed across members, distributed across time and help to coordinate between humans and resources and systems in the environment (Hollan et al., 2000). The DiCoT (Distributed Cognition for Teamwork) framework (Blandford & Furniss, 2006) is used as the framework for describing the collaborative activity of the small groups in this study. Of the three themes in the DiCoT framework (physical layout, information layout, and design and use of artifacts), we focused on the physical layout and artifact themes and chose two principles from each of the two themes- Situation Awareness, Horizon of Observation, Mediating Artifacts and Scaffolding.

Context and methods

This research was conducted in two flexible learning spaces on a university campus within the northeastern United States. Data from one space was selected for presentation. The space has movable and adjustable chairs and tables, multiple projectors, and whiteboards–both portable and wall-mounted. The class analyzed was a 200 level undergraduate Physics course with 21 students where most class time was spent solving worksheets in groups.

We used an exploratory case study methodology and collected video and audio recordings and field notes. Initially whole classroom recordings were used and over time these recordings became more group focused. The video recordings and field notes were reviewed together to identify three episodes described in the findings. Verbal (speech, hums) and non-verbal (gestures, movement, use of artifacts) interactions in each of these episodes were transcribed using guidance of interaction analysis (Jordan & Henderson, 1995). Each turn of verbal or non-verbal participation is coded into active social (discussion), passive social (explaining, nonverbal participation), and physical (interaction with artifacts) (Vujovic et al, 2021).

Findings

Three episodes of collaborative activity using a physical element of the classroom as a shared artifact, i.e., a portable whiteboard, will be illustrated in the poster using figures and tables. One of the episodes is illustrated here as an example (Figure 1). At the start of this episode four students are seated around two square tables working together on the problems in their worksheet and request help from the TA. The TA asks one of the students to write out the solution on the portable whiteboard as they solve the problem again. As seen in the script, students gesture to the whiteboard and engage in active and passive social talk as they reason through the problem.

Figure 1
Left: Screenshot of classroom, Right: Interaction between students and TA in with codes

Actor	Verbal	Nonverbal	Code
G1.TA	And this one is the	Gestures to shared artifact	Active social
G1.S3	Yeah, fifteen minus zero and fifteen minus (unclear). Ahaa! I get it, I get it"		Active social
G1.S1	They're not even		Active social
G1.S3	No because they have to (unclear)	Gestures to shared artifact	Active social
G1.S2	Oh		Passive social
G1.TA	There you go		Passive social

Discussion

The episodes were chosen for illustrating the use of the whiteboard in performing the task and three key themes emerged: whiteboard as mediating artifact, horizon of observation, and triggers for whiteboard use. In all three episodes the whiteboard was brought into coordination to help solve worksheet problems. Based on episode data we found that the mediating artifact could support shared work such as in episodes 1 and 3 where the shared whiteboard artifact allowed students to engage both actively (by writing or gesturing toward the whiteboard) or more passively by looking at the whiteboard content as part of the activity. The whiteboard also helped make student cognitive work visible, by providing a reference point and a clear representation of the group thinking. A key affordance of the flexible space specially the whiteboard was that all students could see and hear each other's talk and gestures and view the progress of the problem solution on the whiteboard. We noted that in all selected episodes, whiteboard use was triggered by either the instructor or TA and was aimed specifically at encouraging students to make their thinking visible. The instructor and TA themselves used the whiteboard to explicate their thinking. In another episode with little student interaction, we noted that the professor answered student questions by turning draw and explain answers on the whiteboard. Such modeling reinforced the mediating nature of the artifact and its role in coordinating multiple perspectives over a horizon of observation.

Conclusion and limitations

We used this exploratory case study to examine how flexible learning spaces and the whiteboard as an artifact impacted students' engagement in collaborative activity. Our initial findings suggest that flexible classrooms and artifacts can support coordination of collaborative work by making by visible students' cognitive process and affording a joint horizon of observation. Such arrangements allow for active cognitive engagement by students which is supportive of learning and suggests that cognition is affected by how individuals adapt to their environment and the artifacts. Data and interpretations are limited by the focus on the whiteboard in this study; a deeper analysis of collaborative work would include a broader range of artifacts and actions. Multimodal approaches that examine different forms of media and artifacts would provide additional nuanced insights.

Ubiratan D'ambrosio and Ethnomathematics: Contributions to the Learning Sciences

Claudia de Oliveira Lozada, Federal University of Alagoas, clalloz@yahoo.com.br

Abstract: In this work, we bring an overview of research on the life and work of Ubiratan D'Ambrosio and Ethnomathematics as a research program and as a reference for valuing the culture of peoples and their ways of conceiving mathematical knowledge, overcoming the Eurocentric view predominant to decolonize knowledge. Starting from an exposition on the main aspects of Ethnomathematics, we propose a reflection for the field of Learning Sciences in the world with the purpose of giving visibility to the production of knowledge in different sociocultural contexts.

Introduction

In this work, we bring a brief report on the life of Ubiratan D'ambrosio (brazilian researcher and Ethnomathematics, a research area permeated by crucial issues such as Critical Mathematics Education and Social Justice, for that, we will use D'Ambrosio's works on the subject, and in this way , we seek to preserve our identity as Brazilian researchers, valuing our context, our culture and our way of conceiving knowledge mathematical. Although Mathematics has been built by different peoples throughout the history of mankind, with the process of formalizing its language, the Eurocentric view of operating with Mathematics prevailed, and the ways in which different peoples deal with mathematical knowledge, suffered a process of denial, rejection and acculturation, promoting a process of mischaracterization of the corpus of the various mathematics that circulated around the world. These different mathematics gradually disappeared, becoming invisible and treated as something out of use, a process that is a legacy of colonization and forms of oppression of the native peoples of the territories. The different forms of knowledge were erased and gained a “unique” version, somewhat depersonalized, but which serves the structures of power and domination policy, economic, social and mainly cultural. The different mathematics could coexist and integrate, which is what is expected when one thinks of human diversity on the planet, but what was seen was a movement to eliminate knowledge, impoverishing the collection of knowledge in the history of Humanity. And why is one mathematics useful and the others not, if the logical mechanisms of reasoning involved in the social practices in which Mathematics circulates follow a line with different forms? To propose a “unique” Mathematics, with rules, symbologies, theorems, notations, would be to crush the spontaneous and creative manifestations of human thought, to belittle Mathematics itself as a corpus constructed throughout history by different ethnicities. Thus, starting from these initial notes, we bring the trajectory of Ubiratan D'Ambrosio and Ethnomathematics in the sense of bringing reflections to the field of Learning Sciences worldwide in order to give visibility to the production of knowledge in different contexts sociocultural and decolonize knowlegdes.

Ubiratan d´ambrosio and ethnomathematics: A citizen of the world understanding the different mathematics of the world

Ubiratan D'Ambrosio was born on December 8, 1932 in the city of São Paulo, Brazil. He was of Italian descent and in 1951 went to study Mathematics at the University of São Paulo, one of the main Brazilian universities. He taught in basic education and after completing his graduation in Mathematics he became a professor in higher education. When he was a student he loved to read books in the library of the University of São Paulo and through them he got to know other cultures and other knowledge. In 1964, Ubiratan moved to the United States and became a research associate in the Department of Mathematics at Brown University, in Providence, Rhode Island. He then landed a tenured teaching position at the State University of New York at Buffalo. He served as a professor in undergraduate and graduate courses in mathematics. In 1970, he went to work on a project of the United Nations Educational, Scientific and Cultural Organization (UNESCO) that was being implemented in the Republic of Mali, in Africa, to train doctors in mathematics. There, he goes on to observe how African people deal with Mathematics in their social practices and how they conceive mathematical knowledge. Ubiratan observes a richness in the construction of Mathematics of these peoples and begins to reflect that there is no only one Mathematics, but there are several Mathematics and several ways of dealing with Mathematics that exist in the world and that still resist.

Thus, at this time, questions and criticisms began about the teaching of Mathematics, which had a perspective that disregarded different cultures, did not focus on the student's protagonism or on their prior knowledge and on different contexts, nor on the reality and experiences of students.The technicist teaching, based on training, repetition of procedures, which was an inheritance of the modern mathematics movement, began to be questioned. Ubiratan returns to Brazil in 1972 and goes to work at UNICAMP (State University of Campinas). From his readings, experiences and research, he conceives Ethnomathematics as a program, explaining that: “The Ethnomathematics Program is conceptually designed as a program of broad investigation of the evolution of ideas, practices and knowledge of the human species in different cultural environments. Essentially, it implies an analysis of how groups of human beings generated forms, styles, arts and techniques of doing and knowing, of learning and explaining, how they deal with situations and solve the problems of their daily lives, of their natural and sociocultural environment.” (Ubiratan, 2018, p. 191-192)

The word ethnomathematics was created by D'Ambrósio from the adaptation of three Greek radicals: ethno, mathema and tica. The radical “ethno” refers to culture, people; “mathema” is related to the act of understanding, way of doing; and the term “tica” means technique. D'Ambrosio explains that Ethnomathematics is transdisciplinary, transcultural and recognizes specific cognitive strategies of a culture to deal with reality and build knowledge in the context of that culture. Thus, Brazilian Indians and Quilombolas, among other groups, build their mathematical knowledge considering their social practices and cultural elements. An example is the construction of ocas (houses of Brazilian Indians). The construction of ocas by the Guarani Tambeopé Indians, fo example, is sustainable, made with elements taken from nature and the dimensions are not standardized, but determined by the number and height of the people who will live in the space, that is, the material to be built, the way of measure space, the construction technique does not follow conventional architectural techniques or traditional geometry. The geometry used by the Brazilian Indians to building ocas is linked to space, context, culture, indians and their characteristics and is not related to the formal geometric conception. The geometry of the Brazilian Indians is a set of knowledge that emerged from living with nature and the forest. In this way, the different mathematics that are born with these groups and constitute the corpus of Ethnomathematics have peculiar logics, symbologies and languages, which are different from the predominant Eurocentric mathematics in the school, that is, Ethnomathematics implies "a study of the cultural evolution of humanity in its broad sense, based on the cultural dynamics that can be seen in mathematical manifestations” (D'Ambrosio, 2005, p. 102). This way, ethnomathematics seeks to understand the production of knowledge as a collective construction, developed through dialogical relations between individuals and the socio-cultural context, giving new meaning to mathematics from the point of view of a social practice and as such it has peculiarities that do not may restrict themselves to standardizing ways of dealing with mathematical knowledge, which stifle the learning process because students see only one way of working with mathematics in the school. In 2021, Ubiratan D'Ambrosio passed away leaving a legacy for World Mathematics Education with his studies on transdisciplinarity, history of mathematics, ethnomathematics, mathematical modeling and teacher training. He won several international awards such as the Felix Klein Medal and formed several Brazilian researchers, having as a greater meaning of existence, respect for human beings and their diversity of thinking.

Future reflections on ethnomathematics for the field of learning sciences

Ethnomathematics gives voices to different peoples, gives citizens of the world the opportunity to express their ways of reasoning, of building knowledge, of giving protagonism to everyone so that they manifest their creativity in the way they conceive mathematics and its understanding. Ethnomathematics is the place of respect and sharing in which everyone is important with their uniqueness: “I think, I exist. I am a human being in the world. I understand Mathematics in a different way than you, but we can learn from each other. I'm Brazilian, I'm Latino, I speak Portuguese, I'm indigenous, I live in a tribe, I'm black, I live in a quilombo, my way of doing math with mathematics is different from yours, but it's also right. I build an Oca, a home for Brazilian indigenous peoples, using my geometry, it's different from yours, but my architecture is just as beautiful as yours. I'm a child from the periphery, I learned to count by selling candy in traffic. My way of counting is different from what the teacher teaches at school, but it’s also right.” Thus, with these words, it is hoped that the Learning Sciences will open space for the different peoples that are part of this great research community to express their knowledge and transform the classrooms of their countries, allowing children of different ethnicities to express how they conceive mathematical knowledge and other knowledge and create their own ways of doing mathematics, restoring the cultural dignity of peoples, breaking down the walls of oppression and domination, decolonizing knowledge and opening up space for dialogue.

Theorizing and Modeling Teachers’ Knowledge of Noticing

Melissa J. Luna, West Virginia University, melissa.luna@mail.wvu.edu

Abstract: Efforts to improve science education offer a vision of science teaching requiring teachers to notice the productive resources in students’ thinking and allow these resources to drive learning. However, we do not yet understand the complex teacher knowledge involved in the practice of teacher noticing. This research reports on in-progress theory-building work and presents a conceptual model of teachers’ *knowledge of noticing*—a special kind of teacher knowledge that matters for science teaching.

Overview

Efforts to improve science education emphasize that an important shift needs to take place in what teachers attend to in the science classroom—shifting attention away from content as a body of correct information and towards content as disciplinary ideas and reasoning (Coffey et al., 2011). Teachers “need to understand what initial ideas students bring to school and how they best may develop an understanding” (p. 256) of phenomena in the world (NRC, 2012). This requires teachers to continuously notice the substance in students’ thinking and allow this substance to drive students’ learning. However, while the field supports this shift in what teachers attend to, it does not yet understand the complex teacher knowledge involved in the practice of teacher noticing, and therefore it does not know the true extent of making this practice learnable (Grossman et al., 2009; Sherin et al., 2011). As such, this research decomposes the practice of noticing by unpacking the knowledge pieces elementary teachers draw on when noticing students’ thinking across the work of teaching science (in lesson planning, in teaching, and in assessing learning). Specifically, this research reports on in-progress theory-building work and offers up for scholarly discussion a conceptual model of teachers’ *knowledge of noticing*.

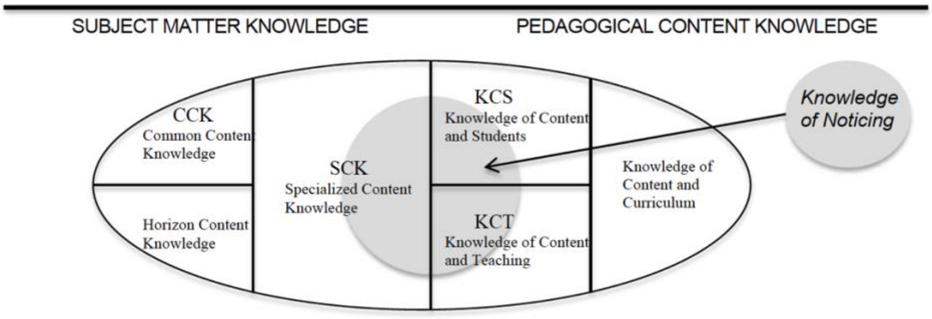
Motivation for theorizing teachers’ *knowledge of noticing*

There has been limited research examining what within students’ thinking teachers notice (i.e., the productive pieces within a students’ idea) and the teacher knowledge base noticing draws on. It seems this is an important missing piece in research on teacher noticing, one that requires us to unpack the knowledge involved in this practice. Discussing teacher noticing as a process absent its knowledge base limits its usefulness as a construct in understanding teacher practice. As such, we need a practice-based theory (Ball & Bass, 2003) of teachers’ *knowledge of noticing* for the purposes of making the practice of noticing the disciplinary substance in students’ thinking both learnable (Grossman et al., 2009; Sherin et al., 2011) and useful to teachers in ways that support authentic disciplinary learning for their students.

Building a conceptual model of teachers’ *knowledge of noticing*

Figure 1

Conceptual model showing where teachers’ knowledge of noticing lies on Ball, Thames, and Phelp’s (2008) map of teacher content knowledge



An investigation of elementary teachers’ noticing practice across the work of teaching science provides the empirical basis for developing a conceptual model of teachers’ *knowledge of noticing*. I have identified the teacher knowledge pieces evident in the empirical data and have mapped those pieces onto Ball and colleagues’ (2008) model of content knowledge for teaching (Figure 1). As a result of this mapping, a *knowledge of noticing* model has begun to emerge. For example, the shaded area on Figure 1 shows where the knowledge pieces identified from the empirical investigation mostly populated on the map of teacher content knowledge. From this initial representation, a picture of teachers' *knowledge of noticing* presents itself as an amalgamation of Ball and colleagues' specialized content knowledge (SCK), knowledge of content and students (KCS), and knowledge of content and teaching (KCT). (Table 1 lists and briefly describes these three categories of knowledge applied to the domain of science teaching.) Also emerging from this representation is the idea that teachers' knowledge in use while engaged in noticing is more than a grouping of these three types of knowledge. It seems to involve a special category of teacher knowledge active at the junctures of these domains—what I have named teachers' *knowledge of noticing*. This theory building work is on-going and further analysis of teacher noticing data will test whether this new category of teacher knowledge is indeed unique.

Table 1

Three domains of content knowledge for teaching (Ball et al., 2008) adapted to reflect science teacher knowledge

SCK: scientific knowledge and skill unique to teaching; disciplinary knowledge "not typically needed for purposes other than teaching" and "in its decompressed or unpacked form" (p. 400).
KCS: knowledge that combines knowing about students and knowing about science; knowledge that involves "specific [disciplinary] understanding" interacting with "familiarity with students and their disciplinary thinking" (p. 401).
KCT: knowledge that combines knowing about teaching and knowing about science; knowledge that involves "specific [disciplinary] understanding" interacting with "an understanding of pedagogical issues that affect student learning" (p. 401).

Potential contribution

Two reasons further motivate the model building work of this research, one theoretical and the other practical. First theoretically, as Schulman (1986), Schoenfeld (2008) and other scholars have argued, a model of teaching has explanatory power for understanding what drives teaching practice. Second, a model of teachers' knowledge can be leveraged in teachers' learning. This model building work is in service to both contributing to our theoretical understanding of teachers' knowledge in use surrounding their noticing practice and to informing teacher learning and knowledge construction around this practice. The research presented will report on the progress of this theory-building work and offer up for scholarly discussion a conceptual model of elementary teachers' *knowledge of noticing* the disciplinary substance in students' thinking.

How do Good Practices Emerge in Vocational High Schools? Lessons From Eleven Cases

Viviana Hojman, Universidad del Desarrollo, vhojman@udd.cl
Rodrigo Jara, Universidad del Desarrollo, rodjarab@udd.cl
Fabiola Melo, Université de Montréal, fabiola.melo@umontreal.ca

Abstract: Good educational practices are those that are valued by communities. With the intention of understanding them and knowing the elements they have in common, 11 cases were analyzed from the theoretical perspective of the Activity Theory, finding 10 common characteristics. The aim is to provide knowledge for educational improvement in secondary vocational education, while sharing the results to inspire the emergence of such practices in other institutions.

Introduction

Chilean secondary education is divided into two cycles. The first cycle is common to all students and the second cycle is differentiated. In the second cycle, students can choose between two educational paths: scientific-humanistic or vocational (Agencia de Calidad de la Educación, 2016). The vocational path is popular among students from the most vulnerable socio-economic sectors of society (Larrañaga, Cabezas & Dussaillant, 2013), as it aims to provide comprehensive training in a specialization that facilitates the transition from school to work and integration into the labor market (Servat, 2017; Sevilla, 2010). This type of education is crucial for improving productivity and the economic and social development of the country (Ministerio de Educación & UNESCO, 2018), as well as facilitating the social mobility of the students who follow it (Servat, 2017). However, one of the main challenges is the adequacy of the training, which requires the adaptation of the training to the needs of each institution (MINEDUC, 2018).

In order to understand how school leaders address these challenges, good educational practices developed in their organizations have been examined from an AT theoretical perspective. From AT, it is understood that activity is composed of a set of essential elements: subjects, objects, mediators, rules, community and work organization, elements that constitute what is called an activity system (Engeström, 2015). A set of actions then constitutes an activity, while an activity sustained over time constitutes a practice. A practice is not an isolated and individual phenomenon, but a systemic activity that takes place in collective and relational contexts that have been developed over time (Engeström, 2015). A practice is created by a community, with a set of rules and an organization, where there are subjects who have a shared sense of purpose (an object) that they approach collectively with the help of mediators. Each practice is understood as a set of relations between subjects and their purposes in their specific social situation (Hojman et al., 2022).

Based on the above, we can understand a good practice as an initiative that develops something that the educational community considers valuable, while good leadership practices seek to improve the management and/or organization of schools, have an impact on student learning and the overall results of the institution, and have continuity over time (Hojman et al., 2022). It is then possible to understand good practice as complex, historically and culturally situated, and to understand how it is created, sustained, and transformed over time.

Methodology

The study conducted is qualitative, exploratory and located in a dialectical epistemology to capture the richness, depth and quality of what is produced (Creswell and Creswell, 2018). To this end, paradigmatic cases were selected through purposive sampling, which is a common selection for studies that seek to analyze values, rituals or meanings (Creswell and Creswell, 2018).

The first step was an open call, in which institutions belonging to the network of the Center for Innovation for Educational Leadership (CILED) of the Universidad del Desarrollo were formally invited to participate in a project that would allow them to share their practices with other institutions through the publication of a book. Schools interested in participating filled out a Google Forms form in which a member of the institution described the good leadership practice they wished to share. Once the call for entries was closed, a blind evaluation process was conducted in which a committee reviewed each case and prepared a report that was then reviewed by the project director, who formalized the selection of eleven practices. Some of the inclusion criteria were: to be vocational high schools, to have a consolidated practice for more than one year, and to have some method to evaluate the practice.

For the data collection, the researchers were supported by a guide with the main thematic categories to be explored, as well as guiding questions for each category. This guide was organized to understand each of the relevant elements of the activity according to AT, so that, for example, the category of subjects sought to understand how the subjects who were part of this practice were organized. At the end of the information gathering process, an integrative analysis of all the cases was carried out, which allowed to have a guiding vision of the relevant elements for the continuous improvement of leadership in TVET.

The members of the institution were selected based on whether they were employees of the selected institution, whether they were over 18 years of age, and whether they had a relationship with the practice. Informed consent was obtained from both the institution and the participants at the beginning of the fieldwork process.

The main objective was to understand the good practices of leadership in secondary vocational education, together with their emergence and history. The specific objectives were to understand the relationships in each practice based on activity theory; to describe the protagonists (subjects) of the good leadership practices by understanding their relationships in practice; to understand the meaning (object) that the actors of the good leadership practices attribute to their practices; to describe the mediators involved in the good leadership practices; and to describe the trajectories (including the conformation of the communities, their rules and their social organization) of the good leadership practices.

Findings and analysis

The practices were studied in depth using the case study methodology, which aims to achieve a complex and deep understanding by studying the experiences of individuals, groups or contexts, also taking into account less concrete elements such as relationships or projects (Creswell and Creswell, 2018). This analysis was made from the AT, exploring how the theory allowed the understanding of each element of the practice and, based on this, what were the common elements that emerged between them.

Considering the above, after the analysis process, it was possible to find the following common elements between practices: (1) students are at the center of the practice, since they not only participate, but also have a leading role in its development; (2) Community collaboration and participation are key aspects. They allow for the development of the activity and its stability over time; (3) because the practice arises in response to a shared need among members of the community, there are clear and shared meanings for all participants; (4) There are different types of leadership involved, depending on the institution, the level of development of the practice, and the skills of the institution's team; (5) networks are created with the community, providing greater opportunities for support, resources, and external observers; (6) It is a practice that develops gradually over time, and as it is established, it generates cultural changes; (7) It allows for the translation of theoretical learning into practice through the development of learning activities that contribute to students' learning and development of competencies; (8) it emerges from the school community itself, based on the needs identified by them; (9) although there are resources that are fundamental to the development, they are seen as tools that support the shared value of the practice; (10) All practices systematically improve from year to year by having a system that records and evaluates experience and learning.

Abstract: We investigate how high-school engineering teachers anticipate and deal with disruptive and productive failures in students' design challenges. This study involved a six-week participatory design process with two teachers, revealing that teachers often make design challenges too prescriptive in order to prevent disruptive failures, which can hinder opportunities for productive failures. We discuss the implications of failure mitigation and suggest opportunities to better support teachers, including the design of an intelligent system.

Introduction

High school engineering courses provide students with hands-on, open-ended design challenges that require the application of various learning objectives such as practicing the Engineering Design Process (EDP) and iterating on their prototypes, which can lead to both productive and disruptive failures. *Productive failures* (Kapur 2008) force students to revisit their documentation and engineering knowledge to engage more deeply with the problem, and though they may cause deviations from the original curriculum plan, they are beneficial to the overall learning. On the other hand, some deviations from the teacher's plan may not have pedagogical value, such as students ignoring the tasks at hand. We refer to those deviations as *disruptive failures*. These dimensions lead to a significant cognitive and pedagogical load for teachers in planning and executing design challenges. This paper aims to investigate the following questions: (1) What disruptive and productive failures are high-school engineering teachers anticipating that students will face in solving design challenges? (2) How are they actively trying to prevent and help students recover from disruptive failures, specifically?

As part of a larger endeavor geared towards designing intelligent educational supports for high-school engineering teachers, we conducted a six-week participatory design (PD) process with two teachers with diverse backgrounds and teaching experiences. For this paper, we focus on two research activities from the PD process focused on student failures, and teachers' prevention and recovery strategies. Our findings suggest that teachers dedicate significant efforts to preventing disruptive failures by constricting design challenges that limit or eliminate the opportunity for students to learn from productive failures, and highlight the need for technological tools for teachers to effectively plan for and prevent disruptive failures while supporting productive ones.

Design challenges and productive failures

Engineering education faces challenges in designing authentic and open-ended design challenges that provide hands-on opportunities for students to apply engineering practices and grapple with real-life situations. Moore et al. (2022) found that, in practice, design challenges are often formulated in ways that restrict the possible solution space, reduce creativity and inventiveness, and undermine students' engineering identity. Promoting ill-structured problem-solving is crucial to prepare students for engineering professions and their challenges (Trueman, 2014). More importantly, Kapur's (2008) productive failure theory contends that problem-solving activities should be designed for students to reach an impasse and generate opportunities for students to explore the affordances and constraints of the problem before consolidating their learning through comparisons and organization of student-generated solutions into canonical solutions (here, analogous to the *evaluation* and *presentation* phases of the EDP). Kapur explains that this structure leads to better performance on both ill- and well-structured problems and increased creativity and transfer of learning. While previous studies focus on implementing productive failure in problem-solving and corroborating its benefits, we use productive failure theory as a pedagogical lens to understand current design challenge formulations focusing on whether those formulations offer opportunities for students to productively fail.

Methods

This study took place in summer 2022 as part of a teacher professional development internship program hosted at a major university in the Southeastern U.S. We selected two teacher interns with different backgrounds and experiences, Macie and Stanley (pseudonyms), to co-design a task model of their students' activities and challenges to serve as the basis for prototype development of an artificial intelligence-enabled system. Over the six weeks of the program, the teachers participated in eleven participatory design *research blocks*, sessions ranging from two to four consecutive hours dedicated to research activities designed to elicit teachers' tacit knowledge (Moreno et al., 2021) of engineering education and the practical constraints they face. Audio recordings and photos were taken, and all artifacts, including written reflections, curricula designs, presentation slides, flow charts, and task models were collected. For the purposes of this analysis, we focus on two activities, spanning three research blocks: (1) one synchronous research block consisting of a discussion of design challenges, focused on eliciting teachers' practices and priorities when creating and/or choosing design challenges, including the breakdown of the components and properties they consider, and (2) two asynchronous research blocks consisting of a Miro board-based flow chart design activity, asking teachers to document the anticipated obstacles and recovery strategies when students start building the physical prototype – a challenging step according to previous discussions with the teachers. We used Braun and Clarke's (2006) theoretical thematic analysis to qualitatively code the design challenge discussion transcript and the flow charts for mentions of student failures (disruptive or productive) and the strategies teachers use to prevent or repair them.

Findings and discussion

In the design challenge discussion, the total number of failure references is not important since the discussion was free-flowing. However, from the Miro flow chart activity, we extracted a total of 31 digital sticky notes referencing failures. All failures were inductively categorized into three classes: (1) failures related to classroom practices (i.e., students' behavior problems in the classroom such as not following classroom rules or being off-task), (2) failures in engaging with the EDP (i.e., students trying to circumvent completing the steps and/or substeps of the process, such as documentation, reflection, sketching, and planning), and (3) failures tied to design challenges (e.g. failures around the design requirements, materials, tools, and prototype construction such as inadequate materials, improper use of tools, etc.). Within these groupings, failures related to the EDP were documented most frequently (n = 14), with lack of student planning as the most common failure (n = 9).

Across all categories, we found that most failures were disruptive in some way, such as students challenging classroom authority, actively trying to circumvent using the EDP or playing around with materials without learning from the activity. Only three failures were identified by the research team as potential productive failures. Two were categorized as EDP failures: (1) teams not having a plan to handle failed prototypes, and (2) students' building process not going as planned. One was a design challenge failure: student's prototype not working according to the design challenge requirements.

Both teachers described common strategies for mitigating, preventing, or safeguarding against the above failures. We arranged Macie and Stanley's strategies into four categories: (1) adding rules and restrictions to the design challenge (e.g., requiring the use of all EDP steps, limiting materials usage) (2) reflecting and making changes along the process, (3) using extrinsic and intrinsic motivational approaches (e.g., including students' interests in the design brief, giving prizes for documentation), and (4) using outside resources for help (e.g., other teachers' materials posted online, outside curricula such as Project Lead the Way).

Our research surfaced that, in anticipation of failures which are mostly disruptive, teachers constrain the design challenges to become even more prescriptive. These restrictions could preclude productive failures (Kapur, 2008) from happening, which, our research found, are rarely occurring as is. Such a narrow and evident set of solutions could even eliminate the need for and utility of the EDP, ultimately resulting in a lack of understanding of its actual value, and of opportunities for students to apply their inventiveness and cultivate their engineering identities. In their development and implementation of design challenges, teachers need to balance open-endedness, open exploration, and opportunities for productive failures while ensuring that their students achieve the various learning outcomes that will lead to success in the engineering pathway. We need to find ways to support teachers in preventing disruptive failures in order to redirect scaffolding and restrictions towards the appropriate aspects (e.g., supporting students in applying analytical skills and the EDP steps).

Situated Networks of Learning and Development: Shared Attention in Student Co-Design of Learning Environments

Gavin Tierney, California State University, Fullerton, gtierney@fullerton.edu
Theresa Horstman, University of Washington Bothell, thorst@uw.edu

Abstract: This paper reports on student co-design of Situated Networks of Learning and Development. Situated Networks of Learning and Development are systems of nodes that represent the subject matter and experiences required to meaningfully engage in a situated learning environment and a particular content domain. This study examines data from student co-design of Situated Networks of three university courses connected to a single-subject credential program in a teacher education program in the United States. Results indicate that the co-designed Situated Networks increased the intentionality of the design, captured activities and markers of success, and served as an organizational mechanic, allowing for highly tailored and customized learning experience for the community that creates it.

Major issues addressed

Student co-design is the process in which students participate as an integral part of the design of learning programs and curriculum in order to integrate student perspectives and experiences. The process of co-design creates an opportunity to accurately reflect and be responsive to the needs, identities, and histories of learners and the uniqueness of the community being designed in and for and, at the same time, co-design has the possibility to challenge implicit hierarchical structures and inequities embedded in curriculum design and products, redistributing power, and supporting the agency of learners (Bang & Vossoughi, 2016; Iversen, Smith, & Dindler, 2017; Tierney, Horstman, & Tzou, 2021). This paper reports on student co-design of digital technology using Situated Networks of Learning and Development. In our work we define Situated Networks of Learning and Development as systems of nodes that represent the subject matter and experiences required to meaningfully engage in a situated learning environment and a particular content domain (Horstman, Tierney, & Tzou, 2020). One promise of representations of situated networks is how they mark the combined social, emotional, and academic achievements that learners accomplish (Horstman, Tierney, & Tzou, 2020) and create visible trajectories for learners to follow (Pinkard, Barron, & Martin, 2008). Taken together, individual learning objectives can create a pathway that, when followed, indicate what participants have learned, but also indicating membership of a learning community, having achieved valued practices and rites of passage.

Potential significance

In our study, the specialized use of digital tools for designing a technology captured the thinking of the design group, creating narratives of thinking over time. The Situated Networks used in our research on co-design captured co-design activity, forcing specific moments of design space to be recognized. As representations of learning and development, the design team reflected on their next steps, specifically on how to emphasize elements that support equity within the learning environment. As such, the co-designed Situated Network: 1) Acted as conceptual maps of learning and development for shared reflection and redirection - increasing the intentionality of the design by the community that has created it; 2) Captured activities and markers of successful completion but within the larger context of a learning trajectory; and 3) Served as an organizational mechanic, allowing for highly tailored and customized learning experience for the community that creates it. This study broadens and reframes understandings of student co-design, specifically attuning to tools aimed to processes of shared attention amongst designers. Emerging findings indicate how shared attention guide the value of the co-design as a metacognitive process for learners, an assessment tool of learning for instructors, and an evaluation tool for programs.

Theoretical perspectives

Our approach focused on the co-design of a digital technology as a construct for organizing and sequencing a learning program. We leverage technology as a mechanism to involve students in the design process as collaborators, creating representations of the thinking of the design group over time. In this way, technological tools, and the design practices for creating them, have the potential to make visible and prioritizes the needs of the community (Horstman, Tierney, & Tzou, 2020). Co-design of situated networks creates a unique opportunity that reflects values associated with sociocultural models of program design - being responsive to the uniqueness of the community the technology serves, and redistributing power and promoting equitable participation, enabling the agency of learners (Collins & Bilge, 2016; National Research Council, 2000).

Methodological approaches & data sources

This study examines data from student co-design of Situated Networks of three university courses connected to a single-subject credential program in a teacher education program in the United States. Data includes video recordings of virtual design sessions for the co-design revision of three university education courses (19 sessions total). The three design teams (21 students total, plus 2 facilitators) created Situated Networks of Learning and Development, then iterated on that design to center equity within course frameworks. In addition, student co-design participants were interviewed following their participation in the design process. First, we examined Situated Networks as a design tool for mapping developmental trajectories and, second, the co-design of the Situated Networks with students in the credential program in order to identify learning and engagement in and across courses. The videos were analyzed and coded for using a previously developed coding scheme (Tierney, Horstman, & Tzou, 2021) that focused on negotiation of design content, as well as identified learning and development. We then analyzed interviews for perspectives on the design process and individual learning that occurred through co-design. Memos and associated vignettes of data were generated around emerging themes.

Major findings

Co-design teams were asked to design Situated Networks of Learning and Development of courses they had previously taken. The Situated Networks that were designed were made up of individual Learning Objectives: Authentic requirements of a situated learning environment. Specific goals, expertise, and subject matter is defined within the community. The Learning Objectives were then purposefully clustered into Nodes that embody groups of learning objectives with defined relationships in and among those learning objectives and can embody granular to broad sets of experiences and criteria to be met.

By involving students to be an integral part of designing the digital badge systems, they introduced concepts more directly linked to their experiences and development in and across the university courses. One key element of this process was how student participants drew links between existing course content and issues of race, equity, and inclusivity. This suggests the value of combining co-design and digital badges as a design tool to integrate development and engagement more deeply into learning environments. The sequence of topics identified by the group represented not only the agreed-upon priorities of the community, but also shows how the group views and interprets the relationship between topics. For participants, the artifact of the Situated Network created a vantage point from which both the learners and educators can reflect on how they've represented the hierarchy and relationships of the content itself. The Situated Networks demonstrate how the participants interpreted and prioritized learning content and activities. In this way, the Situated Networks provided a tool for design participants to reflect, individually and as a group, on what they learned. Further, the Situated Networks helped reify the design process across time.

A Case Study: Design Cycle for a Meaningful Maker-Based Learning Approach

Charles Soares Pimentel, Jarrett Dunbar
pimentelufrj@gmail.com, dunbar.jarrett@gmail.com
American School of Rio de Janeiro

Abstract: Carrying out activities involving maker-based education has been implemented in educational institutions that aim to propose a student-centered teaching and learning process. This work presents an approach for teaching Design concepts to K-12 students, during the development of ergonomic design projects. The methodology used is the Design Cycle of the International Baccalaureate Middle Years Programme, which underlines the importance of identifying an opportunity to solve a real world problem through the use of design thinking.

Introduction

Different studies show the importance of the teaching and learning process being active and meaningful. A research carried out by Michael (2006) presents evidence from learning sciences, cognitive science and educational psychology supporting student-led learning. In his work, the author points out some elements that underline the value of active construction of meaning for the student, the difference between learning facts (*"what" - as declarative knowledge*) and learning to do something *("how" - as procedural knowledge*), as well as the voice of an educational process that is facilitated by the articulation of coordination, whether for oneself, colleagues and teachers.

Hands-on activities, mediated by New Information and Communication Technologies (NICTs) have the potential to help students achieve goals for active learning, which can be stimulated by their involvement in interdisciplinary projects (Halverson; Sheridan, 2014). This approach allows students to lead their academic training and develop important skills for professionals in this millennium, as it enables the connection between areas of knowledge to solve real problems, based on the development of artifacts that positively impact the world around him/her.

To collaborate with this discussion, this article presents the work developed in the Design subject of the Middle Years Program (MYP), in American School of Rio de Janeiro, a Brazilian international school. The institution has an International Baccalaureate (IB) curriculum, a child-centered educational approach that teaches life skills. Within the eight subject groups currently offered in the MYP - *Language acquisition, Language & literature, Individuals & societies, Sciences, Mathematics, Arts, Physical & health education and Design* - there is not only an emphasis on the acquisition of knowledge by the student, but also on "understanding concepts, mastering skills and developing attitudes that can lead to thoughtful and appropriate action" (Daly et al. 2012).

Theoretical foundation

The inclusion of the Design subject in basic education has been increasingly explored in educational institutions worldwide. When a design-based learning approach is used in the classroom, students develop skills related to problem solving, decision making and collaborative work (Hsu, Purzer & Cardella, 2011).

In the MYP, for example, Design is a subject that provides students with the opportunity to learn about a multidisciplinary learning strategy, enabling the integration of different areas of knowledge. It provides an educational path in which the student is a co-author of their educational process, and not just a receiver of information. The importance of teaching and learning by disruptive methodologies has been discussed over the last few years by educators, school managers and authors of educational public policies, concerned with the connection between school education and the real world.

This approach is also highlighted by the learning theory of Seymour Papert, Constructionism. Based on Piaget's Constructivism as a reference, Papert (1996) states that the teacher's role is to provide conditions for invention, instead of providing already consolidated knowledge. The emphasis on stimulating creativity and the search for innovative solutions is a counterpoint to exercises with standardized answers, which lead students to reproduce something they memorized during an expository class.

Thus, in the MYP Design subject, the development of projects is guided by the Design Cycle.

The Cycle is a variation of the *design thinking process* and consists of four criterion (with four strands each): Criterion A - Inquiring and Analyzing, Criterion B - Developing Ideas, Criterion C - Creating the Solution, and Criterion D - Testing and Evaluation. The four criterions don't necessarily need to be completed in order, and in fact it's recommended to backtrack and skip when necessary.

Methods

This work is supported by an experience with twenty (20) 7th-grade students, who developed design projects with a focus on Ergonomics. They were presented with the task of identifying the needs of a client in their household and developing an ergonomic, sustainable design invention for them.

For the **provocation step**, students began the unit with a provocation. In this challenge, they were divided into groups of 3-4 and presented with five (5) story cards with client prompts; an elderly man, a baby, an astronaut, an athlete, and a high school student. Groups were tasked with designing a chair for each of the clients based upon the physical needs presented in the prompt.

During **inquiring and analysis step (Criterion A)**, the MYP takes an inquiry-based approach to learning. Students began this project with a presented statement of inquiry: “Through scientific and technical innovation, humans can adapt their everyday environment by developing solutions utilizing ergonomics and invention”. The statement of inquiry serves as the central idea of the unit from which students develop conceptual, factual, and debatable lines of inquiry to help guide their learning. Students concluded their Inquiry and Analysis with the development of a design brief.

The **developing ideas step (Criterion B)**, once students generated their *“How might we…?”* questions, they were then tasked with establishing design specifications using the relevant research provided in their design brief. Students applied this information to “Building a Box” which aids students in visually understanding the constraints and limitations of their solution, as well as taking into consideration elements of the design.

Once the “box” was established, students began their brainstorming process. Lessons on visual brainstorming and ideation were presented in class addressing sketching for industrial design and the SCAMPER (1) technique for idea generation. In industrial design sketching, creative thinking and the visual communication of ideas encourage students to create multiple iterations of a design, as well as communicate the various functions that the designs may have.

Then, during **creating the solution step (Criterion C)**, they began prototyping their solution. Students learned the difference between low-fidelity and high-fidelity prototypes, their intent, and the materials used to create both. As this project only required a low-fidelity prototype, students continued to develop their skills with hand tools and Dremels to create their solutions. Although low-fidelity, each prototype was required to function as intended and must have met the success criteria established in the design specifications.

Finally for **testing, evaluating and feedback step (Criterion D)**, completion of the prototype, as well as general creation, presented opportunities for testing, feedback, and improvement of the design. Students assessed the success of their designs using the success criteria established in their design specifications.

Conclusions

The aim of the IB programme is to develop globally-minded people who recognize their common humanity and shared responsibility for the planet. But this is a worldwide necessity. In the same way, education has the role of developing individuals who are questioners, researchers, who communicate and have principles, with an open mind, risk-takers, but are balanced and careful with others.

When a student develops a project for another person, be it their family, school or neighborhood environment, they begin to develop an outward look, which will impact the world in which they live.

The next step of this study is to expand the use of the Design Cycle through the implementation of interdisciplinary design units and projects that are directly connected with other subjects such as social studies, sciences, or mathematics, for example, to promote interdisciplinary teaching and learning scholarly activities. The results of this new research will be published in the future.

Endnotes

(1) SCAMPER technique: SCAMPER is the acronym for: (S) Substitute, (C) Combine, (A) Adapt, (M) Modify, (P) Put to another use, (E) Eliminate and (R) Reverse

Co-Designing Without Content Knowledge: How Teachers Navigate Co-Design of an Artificial Intelligence Curriculum

Andy Stoiber, YJ Kim, Gyeongri Kim
acstoiber@wisc.edu, yj.kim@wisc.edu, gyeongrikim3037@gmail.com
University of Wisconsin-Madison

Abstract: Currently, co-design is gaining traction as a transformative process to develop AI curriculum for k12 classrooms that simultaneously addresses teachers' lack of AI content knowledge by doubling as professional development. This study details how teachers navigate co-designing a robust AI curriculum when they do not possess the AI content knowledge. Our findings suggest features of co-design may disengage teachers from content knowledge to focus on pedagogy and their own learning goals for students. This work seeks to better understand middle school teachers' assets and knowledge gaps in the context of co-design to help inform the evolving efforts to integrate AI content across the k12 curriculum.

Introduction and background

Co-design, as a form of participatory design, is increasingly valued and adopted by the learning sciences' community as a powerful tool to create educational innovations in real contexts while increasing teachers' agency (Roschelle et al., 2006; Severance et al., 2016) and the likelihood of teachers implementing innovations in their contexts. This poster examines how teachers' content, pedagogical, and technological knowledge (TPACK; Koehler & Mishra, 2009) informs their engagement in co-designing an AI curriculum for middle school students–in other words, a curriculum in which teachers have little to no content knowledge. Due to space constraints, we narrow our focus to teacher orientation toward AI content knowledge.

The importance of this work emerges in relation to an educational landscape under pressure to integrate AI content across the k12 curriculum. As AI's impact on the micro and macro scales become impossible to ignore, education researchers are sounding the alarm: students need to be taught the skills and knowledge necessary to understand the technical and social dimensions of AI to navigate our AI-powered world (Zhang & Aslan, 2021). Currently, co-design is gaining traction as a transformative process to develop AI curriculum for k12 classrooms that simultaneously addresses teachers' lack of AI content knowledge by doubling as professional development (Voogt et al., 2016). This study aims to fill the substantial gap in understanding how teachers navigate co-designing a robust AI curriculum when they do not possess the AI content knowledge.

Methods

We present findings from the first design-implementation-iteration cycle of a larger design-based research study developing responsible AI curricula for Middle Schoolers. In particular, this paper examines the co-design process between researchers and middle school CS and technology teachers who will implement the co-designed curriculum in their classrooms. We investigate the overarching research question: How do teachers navigate co-design of an AI curriculum? Given the unique nature of AI as a nascent subject matter that our partner teachers, like the general public, lacked expertise in, our question may be broadened: How do teachers navigate co-design of nascent subject areas where they are not content experts?

Co-design: Participants and process

We recruited two middle school teachers, Lily and Willow, each responsible for teaching Middle School technology courses involving coding and app development. We organized a total of 6 co-design sessions on Zoom over 3 months–the end of January through the end of April. Sessions lasted two hours on weekdays after school. The core focus of the co-design sessions was to develop a four-week-long socio-technical AI literacy unit organized around the machine learning pipeline and its sources of bias (Suresh & Guttag, 2021), with a concerted focus on image classification and computer vision technology. Each session contained 3 activities, each typically focusing on one of two tasks: activity building–developing individual lesson plans–or curriculum building–tending to the sequence, structure, and flow of activities across time. Co-design activities were structured to: 1) begin with an introduction of the activity's purpose and review of relevant AI concepts and/or pedagogical reasoning, 2) walk through the research team's preliminary iteration of the activity or curriculum flow, and 3) elicit teachers' ideas and questions through whole group discussions.

Data sources and analytic approach

To investigate how teachers navigated co-designing an AI curriculum, we center our attention on data generated specifically during co-design activities. All six co-design sessions over Zoom were recorded and later transcribed. In order to answer our research question, we used the TPACK framework (Koehler & Mishra, 2009) to guide analysis of how Lily and Willow navigated activities laden with AI content. Results demonstrate how teachers negotiated and expressed their content, pedagogical, and technological knowledge while co-designing in an unfamiliar content domain. We view our findings in light of co-design being a process that empowers and supports teachers' agency (Roschelle et al., 2006; Severance et al., 2016). That is to say, the special kind of agency afforded teachers through codesign may help explain how: a) these teachers oriented themselves to the curriculum and the goals they had in mind for themselves and their students that informed their choices navigating co-design.

Key finding & conclusion

Our participating teachers were not AI experts; even Willow, who recently graduated with a computer science degree, claimed no special expertise in AI. During our first session, we asked our participants what they thought their students knew about AI. After Lily explained why she thought her students didn't know much at all, she proceeded to focus on the knowledge gap for teachers: "[Teachers are] familiar with apps in the sense of they know that an app is different than a web page. They understand algorithms. They understand that you're telling a machine, the computer, what to do. But I don't think they've done the next steps. They haven't put those together to AI. They've heard of AI. They just don't understand what it is."

After reviewing AI content and walking through activities or curriculum flow, our participants consistently never had questions about the AI concepts. As co-designers without expertise in AI, teachers' reluctance to discuss the content may signal an understanding of their role like a consultant, contributing where they have the most expertise: matters of pedagogy and classroom culture. As co-design is intended to support teacher agency, it's reasonable to expect teachers to opt to position themselves in a role that empowers them to navigate the co-design process comfortably and confidently.

Willow's navigational choices appeared to parallel Lily. After being presented with a plethora of AI concepts during the first co-design activity in Session 2 , Willow's remarks revolved around the "visual aspect" of using the ML pipeline and the structure and flow of the curriculum, navigating around questions or comments about the content itself. Lily reiterated Willow's key points: "I think I'm kind of mirroring the same thing that Willow had said. The model really worked for me. I could see it flow maybe in my visual head here. But I think the students really need visual, along with everything else." Throughout the sessions, Willow and Lily appear to be in alignment in terms of their role: scrutinizing and highlighting pedagogical elements which are untethered from the AI content.

As efforts to bring AI content into schools evolve and multiply, better understanding middle school CS and technology teachers' assets and knowledge gaps and their relationship to co-design seems crucial to successfully integrate AI content into the k12 curriculum. We hope this work sparks vigorous discussion of the essential role teachers play as schools, institutions, and nations rush to support students' AI literacy in the classroom.

Proposing the Multimodal Learning Analytics Platform for Social Emotional Learning

Gahyun Sung, Harvard University, gsung@g.harvard.edu
Bertrand Schneider, Harvard University, bertrand_schneider@gse.harvard.edu

Abstract: We present an ongoing effort to create an integrated data to knowledge platform that focuses on multimodal learning analytics for social emotional learning research. A key feature of the platform is the ability to extract and analyze multimodal data from video streams with various computer vision algorithms, curated to be applicable to a range of learning scenarios including individual or dyadic work, and co-located learning in an open learning environment.

Introduction

Social-emotional learning (SEL) continues to receive high political and scholarly interest, bolstered by a rising recognition that there are reverberating personal and social implications to helping students develop social emotional competence, or "the capacity to integrate cognition, affect, and behaviors, to achieve specified social tasks and positive developmental outcomes" (Elias, Kress, & Neft, 2003, p. 1023). Emerging approaches of using fine-grained multimodal sensor data (e.g., joint location, facial expressions) for measuring social emotional aspects bring real-time SEL support for teachers and learners into the realm of possibility. However, in past computational SEL research, the methods for data processing and feature engineering have tended to vary, even for similar data and features (Di Mitri et al., 2018). There is a need in the field to build towards a shared set of methods in the data to knowledge pipeline - the set of choices to make to collect data, create metrics, measure constructs, and connect metrics with constructs.

The platform introduced in the current paper attempts to meet this need. The goal of the Multimodal Learning Analytics Platform for Social Emotional Learning (MMLA-SEL) is to provide accessible ways for researchers to create multimodal proxies of social-emotional learning from videos, a common data source in education research. In addition to making multimodal analytics more financially and technically accessible, focusing on videos as a common data source makes it significantly easier to create comparable metrics across settings. In the present paper, we argue for the necessity of this toolkit and discuss current and upcoming features.

Tools and cumulative science

Despite heightened interest, several issues slow down the take-up of multimodal SEL research. Research-grade sensors can be expensive, and collecting and cleaning multimodal data require high technical expertise. As multimodal data is collected with different sensors, the processing steps needed to separate signal from noise also tend to vary, with different groups "reinventing the wheel" in different ways. When post-processed data looks different, metrics created using this data naturally become non-comparable. For instance, a recent meta-review by Horvers and colleagues (2021) finds that one metric, "mean electrodermal activity," had in fact been calculated on data at different stages of the processing pipeline (e.g., raw, denoised, decomposed). Finally, the field of SEL itself also suffers from what some call "conceptual clutter" (Jones et al., 2016), where constructs overlap, are measured in different ways, and terms fall in and out of favor. Partly due to this, the field has measured complex constructs with varying or researcher-designed tools.

Why is this an issue? First, the high financial and technical burden of existing approaches inhibit the participation of content experts and practitioners that could contribute to theory and practice relevance. Second, having to continuously re-invent the wheel for data processing results in a net loss of resources that may have been devoted to next-step analyses and research. Third, knowledge cumulation in the computational social sciences tends to rely on replication studies or quantitative meta-reviews that report the effectiveness of certain feature sets or methodologies in explaining a construct. When both metrics and constructs with similar terms vary on what they mean, it becomes difficult to create accurate summaries that subsequent work could launch off of. The field has expanded rapidly, and now seems to have reached a stage where converging upon a common set of tools for all steps of the data to construct pipeline – data collection, processing, featurization, construct operationalization – is necessary to yield cumulative, robust, and replicable findings.

Features of MMLA-SEL

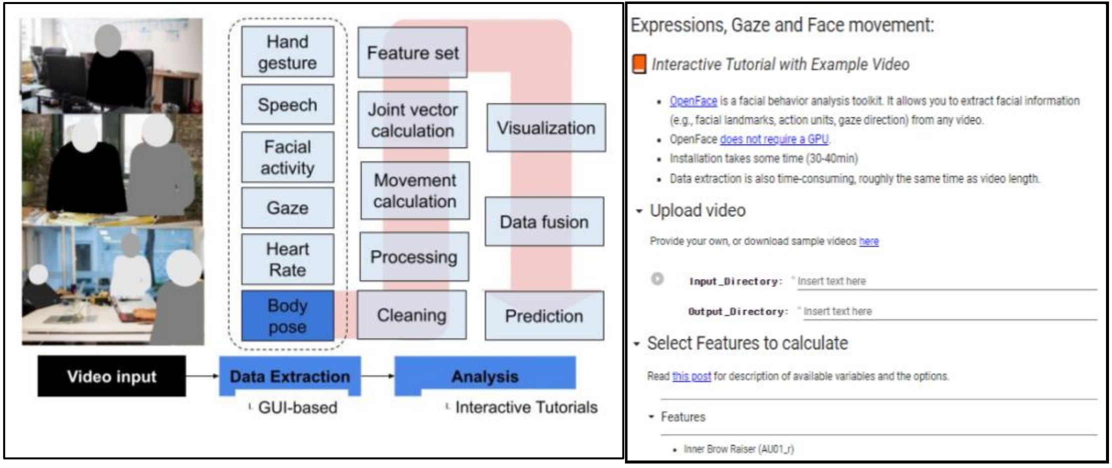
Given this need in the field, our proposed platform focuses on the area of SEL to curate a set of tools that could be used to collect, process, and featurize data in an integrated pipeline. Additional features like forums, data repositories, and interactive meta-review visualizations are hoped to encourage users to be a part of the cumulative knowledge-building process.

The platform expands upon an existing toolkit that can extract data such as heart rate, gaze, facial expressions, hand pose, and body pose from videos collected with typical laptop webcams (see https://mmla.gse.harvard.edu/, Schneider, Hassan, & Sung, 2022). Data extraction is done through a graphic user interface and requires no programming experience, and as calculations happen on the browser, sensitive video data does not leave the user's PC. Current development focuses on expanding the toolkit so that it can collect new types of data (e.g., speech to text), and data on different scenarios: front-facing single learner, collaborating dyads, and multi-angle video streams for 3D tracking in an open learning space.

The data extracted through the GUI interface can then be processed and featurized with interactive computing notebooks. Users can input data and change settings with drop-down menus to create metrics drawn from prior research. For instance, following one particular pipeline, a user can create metrics such as kinetic energy, bounding volume (i.e., openness of pose), prevalence of certain poses (e.g., hand crossed, hand raised), similarity of movement, and head proximity from videos of dyads, as shown in the lefthand diagram in figure 1. An example of a notebook tutorial is shown on the right.

Figure 1

On left, a data extraction and analysis pipeline; on right, a sample notebook tutorial



Expressions, Gaze and Face movement:

Interactive Tutorial with Example Video

- OpenFace is a facial behavior analysis toolkit. It allows you to extract facial information (e.g., facial landmarks, action units, gaze direction) from any video.
- OpenFace does not require a GPU.
- Installation takes some time (30-40min)
- Data extraction is also time-consuming, roughly the same time as video length.

Upload video

Output_Directory: " Insert text here

Select Features to calculate

Read this post for description of available variables and the options.

Features

- Inner Brow Raiser (AU01_r)

Finally, users can consult documentation, forums, and dynamic meta-review visualizations on the platform to guide their research design. Current work focuses on expanding an existing visualization focusing on collaboration to cover a representative set of constructs in SEL. At the same time, we plan to add a functionality to allow researchers to propose an update to the graph with their own research results. Another goal is to foster a forum for multimodal SEL research, and host data repositories where researchers can upload anonymized data and be cited when others conduct new or replication studies. Using iterative prototypes, we hope to engage the research community to gain insight on the needs, conditions, concerns, and goals that potential users may have at all stages of the development process.

Comparing the Pedagogical Strategies of Teachers Who Co-Designed Units to Support Students' Theory Building

AlLisia Dawkins, Utah State University, allisia.dawkins@usu.edu
LuEttaMae Lawrence, Utah State University, lu.lawrence@usu.edu
Hillary Swanson, Utah State University, hillary.swanson@usu.edu

Abstract: Co-design is a collaborative approach intertwining individuals' unique perspectives resulting in a product that holds creative stakes for all parties. In this paper, we focus on two teachers who co-designed a unit to engage students in theory-building practices and explore similarities and differences in strategies. Through preliminary analysis of classroom video data, we identified six pedagogical strategies teachers enacted including *technology use, lesson introduction, whole-class discussion facilitation, monitoring, addressing questions,* and *wrapping up the lesson*.

Introduction

Co-design is an approach to collaboratively creating innovative interventions with researchers and teachers that addresses both practical and theoretical aspects of learning (Roschelle et al., 2006). The value of co-design in these cases is the recognition of the classroom context and teachers' needs while creating interventions, as research shows that teachers' contexts and practices are highly influential in the adoption of learning innovations (Penuel et al., 2007). Yet, how these designs are taken up in context may vary from teacher to teacher, as they have different pedagogical strategies and classroom norms that affect how they teach collaborative lessons (Kaendler et al., 2015). In this study, we describe two teachers' pedagogical strategies during a lesson they created together. We argue that units co-designed with the teachers who implement them are often operationalized differently in practice. We explore teachers' pedagogical strategies to understand how teachers enact innovative units and identify potential strategies that we can intentionally build on in future design iterations.

Theoretical and empirical foundations

Pedagogical strategies are the moves that teachers enact to support learning in their classrooms (Leat & Higgins, 2002). Teachers take up different strategies to support interactions during collaborative activities that differ based on their experiences, beliefs, and goals (Kaendler et al., 2015). Pedagogical strategies, such as monitoring or intervening, are important for collaborative learning because the quality of these strategies can impact groups' interactions (Hoffman & Mercer, 2016). However, research shows that pedagogical strategies that support productive collaborative learning require intentionality and training (Kaendler et al., 2015). This becomes more challenging when teachers are implementing interventions that are new to them. The focus of our co-design was to create a unit that incorporated students' ideas within the teachers' existing curricula, therefore, there was no explicit emphasis on how they might use different pedagogical strategies to support groups' collaboration. Therefore, we ask the research question, *how do teachers who co-design a series of classroom units together enact different pedagogical strategies in their implementations of those units?*

Methods

This study focuses on data from the implementation of a one week-long lesson, implemented by two 8th grade science teachers, Katie and Rebecca. In the lesson, "can crush," students dropped a bottle filled with variable amounts of water (mass) from varying heights, watching as it crushed an empty aluminum pop can on the floor. They recorded the height of the can, post-crush, and compared the amount of can-crush with the initial drop height and amount of water in the bottle. Following each investigation, students responded to questions asking them to make sense of and model the relationships between the initial height/mass of the dropped objects, and the outcomes they resulted in. A total of 60 students consented and participated in the study across both classrooms. We collected video data of the groups and the teachers' interactions during the lesson. To analyze the data, the video data was reviewed and described through content logging (Mayring, 2014). Content logs were compartmentalized into time intervals of two minutes; we then conducted thematic analysis and identified six pedagogical strategies (Braun & Clarke, 2012).

Findings

Although six pedagogical strategies were identified in both classrooms, Katie and Rebecca operationalized them differently during the lesson. For instance, *technology use* in Katie's class was limited and students only used their Chromebooks to take a quiz at the beginning of class and used paper-and-pencil to document progress for the remainder of class; *technology use* in Rebecca's class differed drastically as students used their Chromebooks to work on and document their progress for the entire class period. We summarized the similarities and differences of the six pedagogical strategies used by Katie and Rebecca during the "can crush" activity (see Table 1).

Table 1
Pedagogical strategies by teacher.

Strategies	Strategy Definition	Katie's Strategy Examples	Rebecca's Strategy Examples
Technology Use	How teachers used technology	Students used paper-and-pencil worksheets	Students used Chromebooks to fill out worksheets imported from Canvas and Google Docs
Lesson introduction	How the teachers introduced the lesson	Less direct instruction, but scaffolded with information from past lessons	Gave highly structured instructions in the beginning
Whole-Class Discussions	Class discussion before and after lesson	Students raised their hands to answer questions	Called on students randomly, but with some hand raising
Monitoring strategies	How teachers observed students' progress	Silently observed student progress	Monitored student progress, gave reminders about documenting experiment
Addressing questions	How teachers responded to students questions	Provided direct clarifying responses to questions	Prompted students to ask group members about their answers
Wrap strategies	How teachers concluded their class	Structured wrap-up with lesson goal and clean-up	Left the class with questions to think about the next day

Discussion

In this study, we explore how two teachers who co-designed a unit together implemented that unit using different pedagogical practices. Six themes were identified that we classified as pedagogical strategies including how Rebecca and Katie *used technology*, *introduced the lesson*, *engaged in whole class discussions*, *monitored*, *addressed questions*, and *wrapped up the lesson*. While Katie and Rebecca co-designed the unit together, they both have their unique classroom norms and teaching strategies, which informed how they supported students' collaborative theory building, mirroring findings in the literature (Kaendler et al., 2015). We emphasize that there is no right or wrong way to enact these pedagogical strategies, rather we are exploring the range of strategies to inform how we might iterate on this unit in the future. As a design-based research project engaging in co-design, we will leverage Katie and Rebecca's pedagogical strategies that emerged in the unit, as well as their post-implementation interviews to iterate on them and create new strategies to support groups in the classroom.

Beyond Disinformation: An Agent-Based Modeling and Curriculum for the Post-Truth World

Renato Russo, Paulo Blikstein
rfr2126@tc.columbia.edu, paulob@tc.columbia.edu
Transformative Learning Technologies Lab, Teachers College, Columbia University

Abstract: We propose an Agent-Based modeling approach to research and instruction on disinformation that can both reproduce the interplay between individuals' actions and effects at a larger scale and visualize complex systems at work. Our design is composed of a curriculum framework and four research-informed NetLogo models, the latter being the focus of this poster. Implications include design heuristics for instruction to combat disinformation.

Introduction and related work

Education takes a central role in the debate on disinformation—false information created and spread with the intention to cause harm (Wardle & Derakhshan, 2017). We use a series of computational models in NetLogo (Wilensky, 1999), a constructionism-inspired, agent-based modeling (ABM) environment, to address the learning needs of our audience and guide further research. By manipulating the behavior of agents, learners can generate hypotheses and test them. This approach also allows the visualization of the cumulative effects of small changes over time, or non-linear changes. In contrast to direct instruction, working with NetLogo allows learners to see changes in the models' behavior as they try out what-if scenarios by exploring the model's parameters.

This paper is part of a larger research project that investigates learning and cognitive processes in operation at both individual and system-level (e.g., Russo & Blikstein, 2022). Here, we report on the design of a curriculum unit that employs ABM for the instruction about disinformation, its causes, and implications for society. The set of models in our design affords the visualization of effects caused by *different types of agents* who are interconnected through *different types of networks* and are exposed to messages that are themselves subject to different *types of treatment*. From unit 1 on, each model and set of activities incorporate concepts gradually, making abstract concepts concrete and interconnected. In the past, only a few other Agent-Based models address related topics (e.g., Sobkowicz & Sobkowicz, 2021; Johnson, 2021), and the approach is employed with relative infrequency for educational purposes when it comes to disinformation. We propose that our design addresses a gap in current educational interventions for disinformation: many educational interventions and research up to now adopt a media literacy lens, whereas we propose an ABM approach.

Design

Disinformation Spread is a software-embedded curriculum designed to encourage reflection on the factors that affect belief in and the spread of disinformation and is based on two existing NetLogo models (Rand & Wilensky, 2008; Stonedahl & Wilensky, 2008). The curriculum includes 4-units through which learners experiment with computational models and discuss the factors underlying the phenomenon they depict. During class/workshop meetings, learners are presented with different factors at play in disinformation, especially those with political motivations, represented by variables in the software interface. This paper focuses on the set of NetLogo models that are part of the curriculum.

The models build on one another, from the most simplistic one (unit 1) to the most complex (unit 4). In addition to the standard "setup," "go," and "go-once" buttons, all 4 models have a few common interface and code components. Those components include:

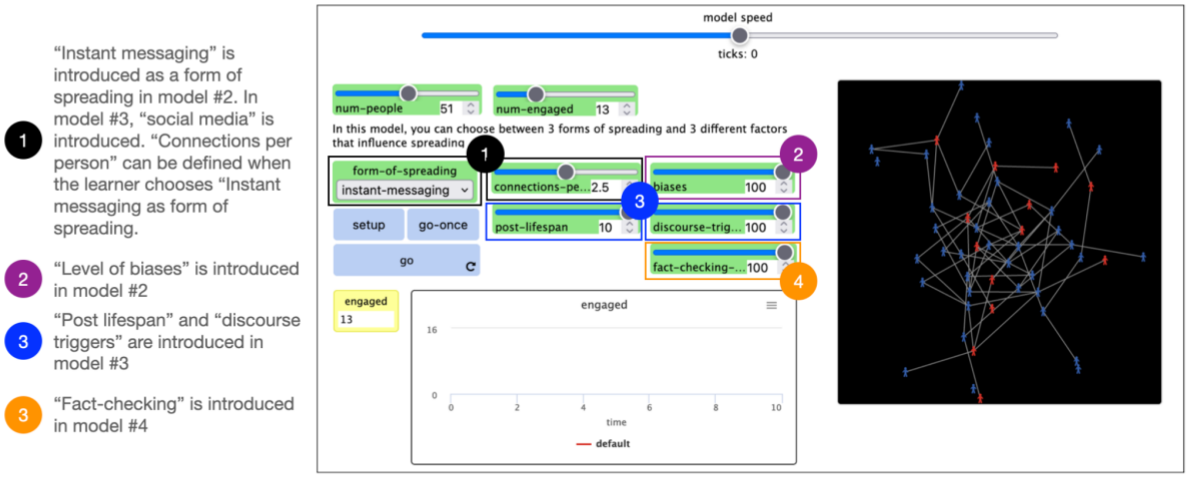
- Variable '*number of people'* (num-people:) represents the number of people in the system;
- Variable '*number of engaged people'* (num-engaged:) represents the number of people who believe in a piece of disinformation and can, therefore, communicate that to other people in the system. These agents appear in red (Table 1);
- An "Engagement vs. Time" a line chart represents the total number of people engaged across time;
- An "Engaged" monitor displays the number of people engaged as the model runs.

Disinformation Spread is designed as a facilitated activity that requires an educator to guide learners in a workshop-like setting. Participating students can experiment with the models and define values for variables in ways that potentially represent their understandings of disinformation. By the end of the unit, it is expected that students will have developed a deeper comprehension of how disinformation spreads and what strategies can be employed at a personal level to address the issue, as well as an awareness of systemic components of the problem.

Disinformation Spread relies on a constructionist approach by inviting the learners to express and debug their mental models using a computational interface, specifically by creating models that express their views on the topic. For preliminary testing data, see Russo, Lei and Blikstein (in press).

Figure 1

Features highlighted in model #4, showing which feature is introduced in each of the previous models



① "Instant messaging" is introduced as a form of spreading in model #2. In model #3, "social media" is introduced. "Connections per person" can be defined when the learner chooses "Instant messaging as form of spreading.

② "Level of biases" is introduced in model #2

③ "Post lifespan" and "discourse triggers" are introduced in model #3

③ "Fact-checking" is introduced in model #4

In this model, you can choose between 3 forms of spreading and 3 different factors that influence spreading

Design critique, conclusion, and discussion

This project proposes an under-explored approach to researching and addressing disinformation through a curriculum based on a series of agent-based models. Existing research in this space tends to focus on media literacy and critical thinking skills (focus on individuals) or on the broader, societal-level understanding of disinformation (see NAMLE, 2019). We understand that this project addresses the interaction between those two dimensions—the individual (micro level) and the society (macro level), an affordance that is typical of ABM. With that in mind, we attempt to explore three characteristics of that approach: offering the learner the opportunity to (i) grasp the effects of individual agents in the system; (ii) make sense of phenomena through visualizations that represent interactions over time; and (iii) to adopt a perspective that brings them closer to scientific epistemology through hypothesis generation, observation, and experimentation. We plan to fine-tune the parameters in the models and add new ones, which will likely afford deeper conversation about their representations and implications. We expect that this work can contribute to the current discussion about disinformation and to our understanding of its causes and implications, both at an individual and at a systems-level.

“The Focus Came in Handy for Me Too”: Exploring Accessibility Learning and Identity Formation in a Web Development Course

Victoria C. Chávez, Northwestern University, vcchavez@u.northwestern.edu

Abstract: In this paper, we explore learners’ knowledge acquisition as it relates to accessibility-related identity formation. Utilizing Nasir’s work on learning, identity, and goals as our conceptual framework, we analyze students’ reflective responses to describe how learning about accessibility through implementation goals helps them foster identities as accessibility users, and how cultivating these identities helps further their understanding of web accessibility.

Introduction

Imagining themselves as the typical users of their sites, students center their own experience navigating a site and “if the design works for them, they conclude that it will work for everyone” (Rosmaita, 2006, p. 278). Thus, what happens when students are asked to implement accessibility that improve their own experience navigating the site?

Conceptual framework

Nasir (2002) explains how learning, identity, and goals are intertwined such that one creates the other and vice versa. She writes: “As members of communities of practice experience changing (more engaged) identities, they come to learn new skills and bodies of knowledge, facilitating new ways of participating, which in turn, helps to create new identities relative to their community” (p. 239). Through this relationship, while “new skills support the construction of [a] more engaged identity” (p. 240), a stronger identification encourages further learning by “prompting [community of] practice participants to seek out and gain the new skills they need to participate in their practice more effectively” (p. 240). Just as learning and identity help create each other, goals help create learning and identity, and vice versa (Nasir, 2002, p. 240).

Data and analytical approach

The responses for our content analysis were selected from a broader corpus (N=28) and are representative of students’ described experiences implementing and testing accessibility features for their website. Namely, students were asked to implement three main accessibility features or behaviours: 1) ensuring their site was navigable using a keyboard only, 2) ensuring toggling behavior was screen-reader friendly, and 3) ensuring their site properly implemented the change of focus required for a modal box. Students also had the option to implement an extra credit feature that allowed the ‘Escape’ key to trigger the closing of a modal while preserving the appropriate keyboard focus and were asked to state in their written responses if they had implemented the extra credit option. In addition, students wrote responses to the following prompts: “Reflect on the work that went into making your website accessible. Was it a lot of additional work? What was the most challenging part? Do you think that designing for accessibility also improves the usability of the site for all users? Why or why not?”

Accessibility learning and identity formation

As students learn about accessibility through related implementation goals, they are enabled to recognize how *they* are beneficiaries of accessibility. In recognizing themselves as users of accessibility, students are motivated to learn the skills necessary to achieve more advanced accessibility goals and thus benefit from accessibility even further. Using the term *accessibility user* to describe any user who uses accessibility features or otherwise benefits from web accessibility, we present the analysis of two student responses to describe how students develop and cultivate ‘accessibility user’ identities, and how that cultivation helps further their understanding of the topic. We chose the responses of these students because they incorporated examples from their personal experiences navigating their sites, while also providing the most in-depth responses to the reflection prompts.

Student A

As they work towards achieving the goal of implementing “press Enter to submit a post”, Student A learns that this common website behaviour they have come to *expect* is indeed an accessibility feature, and they recognize the importance of the assignment’s goal in their learning: “if not for the accessibility requirements I wouldn't have gone through the pain of implementing it.” In this process, the student begins to develop their own identity as an accessibility user noting “[i]t would be pretty annoying” to not be able to take advantage of the conveniences afforded by accessibility features. This identity formation helps them develop a deeper understanding of why accessibility matters: because it "improves the experience for users in general." With this understanding, the student is motivated to gain the skills necessary and "read *many* [emphasis in original] StackOverflow posts" to accomplish the accessibility goal of having a keyboard navigable site.

Student B

As Student B works toward the goal of testing their site's keyboard navigation, they recognize the convenience of being able to navigate a site using one's keyboard and *chose* to continue making use of the feature, thus cultivating their identity as an accessibility user: "in the end, I was using my keyboard to move around the page a lot anyway! The focus came in handy for me too." Their use of "anyway!" suggests that they felt the work put into the task paid off immediately and surprisingly, as they found their own navigation of the site to be improved with the accessibility feature. Like Student A, Student B's progress toward the implementation goal served as a motivator to further their learning about web accessibility as they "had a few strange bugs come up for a while" and had to work on debugging. They argue that despite their difficulty in resolving the bugs and the additional time spent doing so, the task itself was doable: "These definitely did take some additional thought and work to figure out, but overall, it absolutely was achievable, as demonstrated by my final product." By highlighting the evidence of their successful implementation, Student B demonstrates a sense of pride in their accomplishment.

Student C

Like Student B, Student C develops their identity as an accessibility user through the implementing and in particular, the testing, of their site since they *choose* to continue using keyboard navigation to "work with" their site because they found doing so "easier". Rather than be discouraged by the difficulty of implementing the task, Student C is optimistic about it becoming less difficult with more practice: "I'm sure if I developed that as a habit it'd be easier, but it did take some effort this time around." In fact, despite "quite a bit of additional work to get keyboard navigation to work properly," the student pursued a more advanced goal of implementing the extra credit feature, deepening their learning of accessibility. Furthermore, when they describe how another accessibility feature can benefit users in a non-disability related context: "I think all users can benefit from things like alt text (i.e., your browser might be slow one day and images don't load properly)", they plant the seed for deepening their own identity as an accessibility user the next time they find themselves relying on alt text due to something like a slow Internet connection.

Discussion

Finding ways to engage and deepen students' identity as users and beneficiaries of accessibility is crucial for helping students to sustain and improve their accessibility practices. In learning about web accessibility, students are enabled to foment their identities as users of accessibility, and as a result, are encouraged to continue their acquisition of knowledge and skills that will allow them to engage more deeply with this identity. As students acquire the skills necessary to pursue additional and more advanced accessibility goals, they deepen their learning and 'accessibility user' identities. While student identities as accessibility users are not a replacement for learning from and working with disabled users, our goal is to initiate a conversation on accessibility learning and identity formation. It is our hope that this early exploration motivates further work on these topics as a means of improving how accessibility is talked about, taught/learned, and implemented.

Leveraging Intuitive Resources to Reason About the Coriolis Force

Jared Arnell, Utah State University, jared.arnell@usu.edu
Hillary Swanson, Utah State University, hillary.swanson@usu.edu
Boyd Edwards, Utah State University, boyd.edwards@usu.edu

Abstract: Traditional approaches to teaching the Coriolis force have been largely unsuccessful. Our team examined the intuitive knowledge students engaged when reasoning about the topic to design a purely conceptual intervention. In this paper, we discuss knowledge elements that are productive in the context of Coriolis phenomena.

Introduction

The Coriolis force is a challenge for physics instructors as traditional approaches involve demanding coordinate transformations with little conceptual explanation (Taylor, 2005). These instructional methods may be responsible for the numerous myths and misunderstandings that permeate the topic (Stommel & Moore, 1989). Our team set out to build a conceptual approach to the Coriolis force to address this deficiency. To this end, we investigated the intuitive knowledge used by physics students during discussions of the Coriolis force. Students have been engaging with natural phenomena for their entire lives. Through situated experiences, they develop a complex understanding of reality and its mechanisms long before they encounter their first physics class (McCloskey, 1983). We aim to describe how this intuitive knowledge could be leveraged during Coriolis force instruction.

Theoretical framework

The constructivist theory of Knowledge in Pieces (KiP) describes knowledge as a complex system composed of interconnected, discrete knowledge elements (diSessa, 1993). One type of knowledge element that is particularly relevant to physics education is the phenomenological primitive, or “p-prim.” P-prims are intuitive explanations of causal mechanisms and are developed by interacting with the physical world. They describe the causality of common events and young learners treat p-prims as “how the world works,” with no deeper explanation required. The p-prims which are activated (or not activated) will drastically influence the way naive learners perceive the causal mechanisms in unfamiliar circumstances. Through “cueing,” naive learners can be guided to activate productive p-prims. By identifying relevant p-prims which apply to a particular topic, instructors can adjust their lessons, activities, discussions, or experiments to intentionally direct students toward desirable p-prim activations.

Methodology

Our conceptual approach consists of a set of thought experiments that incrementally explain the origin of the Coriolis force for objects moving across the surface of the earth. Students first imagine a puck sliding across a frictionless, stationary, spherical earth to establish the shape of a straight line along the surface (called a “great circle”). Then, the students are challenged to transfer these conceptions to a rotating, spherical earth, followed by a rotating, oblate earth. In doing so, the students are guided to consider the connection between the earth’s rotation and its oblate shape, and subsequently how this mechanism deflects objects moving across the surface.

Eleven undergraduate physics students at a large university in the Intermountain West region of the US participated in 1-on-1 interviews. The researcher used a semi-structured think aloud protocol to introduce the thought experiments sequentially and ask the students to predict the motion of the puck in each circumstance. The interview transcripts were coded according to a knowledge analysis framework, which focuses on identifying the structure, origin, and development of knowledge (diSessa et al., 2015). The students’ responses were grouped by physics concept (such as “reference frames,” “friction,” “equilibrium,” and “gravity”) and reviewed to identify patterns within the students’ explanations, questions, difficulties, and predictions when engaging with each topic. The patterns were compared to lists of previously documented knowledge elements for identification.

Results

The p-prims which students use to understand balance and equilibrium have been well-studied and documented (diSessa, 1993). These p-prims are activated when students identify two agents attempting to achieve results which are mutually exclusive. These battles have two possible outcomes: the opposing agents will negate each other entirely, *cancelling out* any result (leading to a state of *dynamic balance*), or one agent will *overcome* the other (leading to *dynamic imbalance*). The conceptual approach offered several opportunities for the students to represent the phenomena as a pair of agents battling each other, thus activating this rich p-prim cluster. First, when switching from a stationary to a rotating earth, the students saw that the particles of the earth would have a desire to cross over the equator as they attempt to travel along their great circle. The symmetry of the particles across the equator helped the participants activate *cancelling* to predict that neither hemisphere would win out in the conflict. Upon arriving at this *dynamic balance*, all eleven students easily concluded that the opposing particles would pile up and create an equatorial bulge, which is consistent with the reasoning of physicists.

Next, the students were asked to consider a single particle on this rotating earth. Previously, the particle's motion had been driven by the inertial tendency to follow a great circle, resulting in an apparent slide toward the equator. However, as soon as the spherical earth was allowed to bulge outward at the equator, a new agent was introduced: the bulging equator would now act as an antagonist and push objects "downhill" toward the poles. The students displayed a strong intuition that one of these tendencies would *overcome* the other; several proposed a *dynamic imbalance* where the equatorial drift would continue if the effects of the bulge were minimal. Most students were able to foresee that this imbalance could not exist indefinitely: the students correctly associated the strength of the bulge's deflection with the size of the bulge and gathered that there must come a time when the bulge had grown enough to be on par with the equatorial drift. This is a timely activation of another p-prim called *Ohm's p-prim*, which describes how a greater action should achieve greater results. At that point, the students reactivated *dynamic balance* as the oblate shape of the earth *cancelled* the equatorial drift. This new equilibrium explained the causal mechanism behind the stability of the earth's oblate shape.

Finally, this equilibrium was perturbed when the students were asked to consider a puck moving east across the surface. As the bulge of the earth is fixed, its effect is constant. In contrast, the rotation rate of the puck was now faster than the earth beneath it. The students activated *Ohm's p-prim* again, this time connecting the strength of the equatorial drift to the rotational speed of the puck. This allowed them to infer that the equatorial drift of the east-moving puck would *overcome* the earth's oblate shape, deflecting the puck toward the equator. These intuitions were mirrored for a puck moving west across the surface (which would still be moving east, just slower than the ground beneath it). In this case, they reversed *Ohm's p-prim*, predicting that the puck's slower rotation speed would decrease the strength of the equatorial drift, allowing the bulge to *overcome* in this case.

Within these thought experiments, the students were asked to imagine a system that starts in imbalance, becomes balanced, and then is disturbed once again to arrive at a new, distinct imbalance. The students were remarkably adept at alternating between these complimentary p-prim clusters when prompted. This plasticity may have been enhanced by the relatively direct guidance of the semi-structured protocol. If so, it would support the predictions made by KiP researchers who emphasize the importance of cueing to reinforce helpful activations and the importance of contextual connections with prior knowledge (diSessa, 1993).

Discussion

The balance p-prim cluster forms a rich foundation for intermediate physics students to access when navigating the conceptual terrain of the Coriolis force. Though these resources may seem individually simplistic, their cooperation and synergy showcase the complexity and interconnectivity of intermediate learner's knowledge systems. As the students encountered unfamiliar, higher-order physics concepts, they activated these fundamental heuristics that have proven themselves through experience to reliably explain the natural world. This study highlights the potential of interventions which intentionally utilize students' intuitive knowledge. By cataloging knowledge activations, we confirm that intermediate physics students have the cognitive tools necessary to comprehend the Coriolis force on a fundamental level. As evidenced by the findings, guidance from instructors can significantly influence the manner in which students make use of their intuitive reasoning. Our hope is that these findings will inform instructional design for upper-division classroom curricula and enable physics educators to create Coriolis force interventions that will more effectively harness students' productive intuition.

Centering Safety at Community Centers: Making Space for Youth Interest

Sydney Simmons, Northwestern University, sydney.simmons@northwester.edu
Vishesh Kumar, Northwestern University, vishesh.kumar@northwestern.edu

Abstract: Community centers hold powerful potential for interest development within marginalized youth. In order to effectively retain the presence and support the interests of such youth, fostering and maintaining a sense of safety is critical. In this work, we present preliminary findings from an activity system perspective (spanning rules, community, and division of roles) of analyzing a city-run community center. We use the Healing is Rhizomatic conceptual framework to develop an initial conceptualization of how different actors and behaviors support youth safety and interest, and the tensions that emerge in these processes.

Introduction

Woodland (2008) analyzed and envisions community centers as carrying potential to be the much needed reimagining of the traditional school day that enables rich interest development for minoritized youth, specifically Black boys. He highlights the need for a wide variety of factors including cultural relevance in programming and activities, and the need for safety. This is a particularly critical need in response to the constant and rising criminalization and victimization of Black and Brown youth (Parker, 2017).

In response to these concerns, we present pilot work at a community center run by a small midwestern city aimed at centering safety for youth from local low income non dominant communities. Specifically, we are interested in understanding the setup of the unstructured program as created and run by the YYA (Young and Young Adult) division of the city, the participation of the youth at the space, and how different interactions between youth and facilitators shape youth's sense of safety and interest.

Context & methods

In exploring youth safety here, we center the processes, tools, and relationships that offer a stable and contained space in which youth experience shifts with interpreting, feeling, and engaging with notions of vulnerability, awareness, and comfortability? We draw from Lopez's (2020) Rhizomatic framework for this investigation which describes felt sense, relationship, and place "nodes" ("anchors of being and experience"), and their relationship with experiences of "blockage" and "connection" as collectively forming a "bud". Lopez determines that focusing on the relations that form this "bud" is useful to "identify sites through which [youth] can access and channel healing".

Complementing this with Engeström's work on formative interventions (2011), we use activity theory to understand how different aspects of YYA enable (and also create tensions in) youth's experience of safety. We center youth as the Subject, and experience of safety and agency in this space as the Object of the activity system. The work is built on field notes collected over a period of 3 months by us (the primary author on this paper) who acted as a co-facilitator alongside prior YYA staff while collecting notes for potential design interventions to improve youth experiences. We start with presenting select vignettes from our notes that surfaces a mixture of tensions around safety and examine this vignette and other observations through activity theory's components: the broad themes of *Rules* practiced in the space; the varying ways that youth maintain their *Community*; and the *Division of Roles*, especially through lenses of social power that youth engagements.

Findings: Safety and interest

A particular youth who's cemented an interest in basketball enters the community center every day asking the same question, "the court's open today?" In one particular instance however, upon the youth's arrival, a YYA staff member attempted to engage him about his disruptive actions from an earlier event. Through the conversation, the youth kept evading answering any questions in the form of jokes and not responding to questions, to which the staff member firmly responded with "You can go downstairs until you're ready to have a conversation". Consequently, this decision made the youth upset as he spoke with another YYA staff member in a more intense manner. This staff member attempted to use a calmer tone with the youth to explain why the conversation was necessary. Eventually, the youth was allowed to rejoin the YYA space, but was told that the courts would not be open for him until later that evening.

The first staff member emphasized the adult vs. youth hierarchy (a *division of roles)* through his conversation style ending with the decision to initially exclude him from activities. It can also be used in tandem with Tools to describe the types of conversations both staff members had with youth. Not only do the staff members take on different roles in this conversation (stern vs empathetic, which we've observed are their respective roles in other conversations as well), they also had two different conversations, the first being punitive and the second being explanatory. This demonstrates the tension around youth safety through the reciprocity of safety for the community/activity system and safety for the individual.

Analyzing the "bud" that is nodes of felt sense, relationship, and place and their interaction with the blockage experience, it becomes clear that YYA centered safety in this interaction to make space for the youth's interest. Although the youth excitedly came in to play basketball, he was greeted with an unwanted conversation about his previous behavior. This initial felt sense (attacked, leading to humor as defense) paired with the emphasized adult-youth relationship he has with the first YYA staff member he spoke to, prompted a "blockage" to his initial interest, signaled by his tone after the first conversation ended. However, the second conversation was with a staff member he had a better relationship with, signaled by the conversational and explanatory tone. This allowed the youth to end the conversation feeling a sense of safety about being welcome in the space, dissolving the "blockage" and making a "connection" to access the place where he can explore his interests. The tool of conversation and relationships he had with the YYA staff members in the stable space of the Community Center allowed the youth to be able to experience shifts in his interpretation and engagement with feelings of awareness and comfortability regarding his previous behavior to feel safe pursuing his interest in staying in the YYA community and pursuing his interest in basketball.

Implications

We believe that this investigation offers a novel and deeper lens into different ways that safety for (minoritized) youth can be conceptualized and designed to support interest development. Our preliminary notes highlight: 1) the role of institutional *rules* and adult imposition in maintaining group safety – inviting us to explore what kinds of rules can enable such conversations and disciplinary actions to be productive while maintaining individual youth's senses of safety; and 2) the process of engaging in specific roles to affirm one's safety and comfort which might also limit the extent to which youth experiment their own potential interest in different activities – provoking us to recognize how to encourage youth to explore different activities and roles and challenge inequitable norms while staying as safe as they find comfortable (Lewis et al., 2018).

The Utility of Alderfer’s ERG Theory of Motivation for Measuring Adult Learner Motivations in Informal Learning Environments

Adam G. Pilipshen, Stony Brook University, adam.pilipshen@stonybrook.edu
Samuel Abramovich, University at Buffalo - SUNY, samuelab@buffalo.edu

Abstract: This study examines the utility of Alderfer’s Existence, Relatedness, and Growth (ERG) theory as a framework for understanding student motivations in informal learning environments. Data from 1038 students were evaluated to determine the ranking of motivations for studying Aikido; a Japanese martial art. Findings suggest that ERG theory is useful for the creation and interpretation of survey response data but requires additional methodological tools to assess the validity and reliability of its inferences.

Introduction

Alderfer (1972) found that Maslow’s hierarchy of needs (1943) (i.e., physiological, safety, belongingness, esteem, and self-actualization) can be best explained by three groupings: existence, relatedness, and growth (ERG). In ERG theory, the *existence* dimension is concerned with basic material existence requirements and is associated with Maslow’s psychological and safety needs. The *relatedness* dimension refers to social factors such as relationships with friends, family, and significant others and parallels Maslow’s belongingness needs and the extrinsic elements of the esteem category. The *growth* dimension is associated with one’s desire for personal development and is akin to the intrinsic components of Maslow’s esteem category as well as elements that reflect self-actualization. ERG theory also refines Maslow’s hierarchy by suggesting that the satisfaction of *relatedness* needs, or *growth* needs, are not always contingent on the satisfaction of *existence* needs. Whereas Maslow’s theory states basic needs must be satisfied before higher needs can be pursued, Alderfer’s ERG theory suggests needs can have different levels of priority for different individuals. The result of these revisions has allowed ERG theory to be applied to a wide range of studies on motivation, especially research traditionally outside the Learning Sciences.

Unfortunately, even if ERG theory could be useful for education research, it is susceptible to the criticisms associated with Maslow’s theory; that there are few empirically based findings to support its scientific use. Therefore, we argue that special attention must be placed on determining ERG theory’s methodological application and psychometric validity. To that goal, we conducted this study to determine if Alderfer’s ERG theory can be used as a psychometrically valid framework to guide the evaluation of motivations in informal learning environments. More specifically, we sought to determine if an instrument based on ERG theory could reveal different levels of priority of needs among learners. If so, this would both demonstrate how ERG theory can be validly applied to education research, and that criticism of the theory based on its association with Maslow’s hierarchy of needs should not preclude its use.

Methods

One of the researchers for this study is an instructor for the martial art of Aikido, giving us access to a national population of students. Since Aikido has over one million practitioners worldwide and is associated with many physiological and psychological benefits (Szabolcs, Köteles, & Szabo, 2017), we felt confident in hypothesizing that Aikido students could function as a sample population for a large group of learners motivated to pursue a goal. Therefore, by demonstrating how an instrument based on ERG theory can be applied to Aikido students, we can reasonably assume it is possible to do so for other student populations.

An item pool was generated by rewording a survey used by Ko, Kim, and Valacich (2010) to investigate motivations to study multiple martial arts. While Ko et al. (2010) also used ERG theory to guide the development of their instrument, they did not evaluate the validity of their findings. In total, our customized instrument operationalized 10 factors that were categorized and interpreted using the three dimensions of Alderfer’s ERG theory as follows: Our *existence* dimension included the factors of health, self-defense, mental wellbeing, skill mastery, and fun. Our *relatedness* dimension referred to the factors of social facilitation (i.e., comradery with fellow students), and affiliation (i.e., sense of belonging to a school or community). Our *growth* dimension was associated with the personal development factors of philosophy, value development, and cultural learning. To assess if the items in our pool were being operationalized in a way consistent with these dimensions, three teachers and three students were asked to categorize each question in our pool. Reaching full agreement, we arrived at a total of 30 items (3 items for each of the 10 motivational factors). We used a six-point Likert scale with one item from each motivational factor being negatively worded to solicit conscientious responses.

After the instrument was pilot tested, it was sent to subscribers of *Aikido Journal* – the leading Aikido publication in the United States. After which, the instrument was distributed to the popular Aikido Facebook group, that had over 30,000 members at the time of this study, and the Aikido subreddit, a discussion forum on the website Reddit, that had over 7,000 members at the time of the instrument's distribution. The instrument was also distributed by numerous teachers to their respective students. The breadth of which the instrument was distributed allowed us to minimize nonresponse bias and reach a diverse section of respondents not easily obtained in more controlled settings.

Data analysis and results

In total, data from 1038 students were included in this study. Two hundred and twenty-five respondents missed the presence of one or more of the reverse worded items, so we dropped these items from further analysis. Confirmatory factor analysis was then conducted on the remaining data using ERG theory as guidance. This resulted in the combination of the social facilitation and affiliation factors due to their conceptual similarity and because two affiliation items were removed due to low factor loadings. The resulting model had excellent fit (CFI = .994, SRMR = .038, RMSEA = .044) (Hu and Bentler, 1999). Multiple-group confirmatory factor analysis was also used to assess whether motivational differences between males and females were due to true differences or if they were artifacts related to differences in item interpretation. Using the configural, metric, scalar, and residual measurement invariance tests, we found our instrument was similarly interpreted by males and females.

Analysis of latent means revealed skill mastery was the main motivation for all students. When taking gender into consideration, there were some noticeable variations. For example, females appeared to be more motivated by *existence* related motivations (i.e., mental wellbeing, health) which are akin to Maslow's psychological and safety needs, whereas males were more motivated by *growth* related motivations (i.e., philosophy, value development). These findings do not necessarily contradict Maslow as his theory implies individuals address their physical and psychological safety needs before higher order needs are addressed. However, considering more than 80% of females in our study reported to have over three years of Aikido experience, Maslow's theory would also suggest that they would be less motivated by these lower order needs, which was not the case in our findings.

Discussion and implications

Although Alderfer's ERG theory is derived from Maslow's hierarchy of needs, this study serves as evidence that ERG theory has merit as a useful framework that can guide the operationalization and interpretation of motivations. The ease of which motivations can be mapped to, and interpreted by, the three dimensions of *existence*, *relatedness*, and *growth* suggests this theory is useful for research investigating the motivations to engage in learning environments. However, while we were able to successfully use Alderfer's ERG theory to account for and demonstrate the motivational variability between male and female students, additional methodological tools and assessments are needed to ascertain the true validity and reliability of the inferences the theory can generate. For example, a subsequent study should consider the use of path analysis to further evaluate the linkages between the dimensions of *existence*, *relatedness*, and *growth* or between the motivations themselves. Doing so may help uncover any casual relationships among the motivations and could help determine why students prioritize certain motivations over others.

Exploring Changes Within a Cross-Context Community

Sun Jung Choi, Azadeh Javaherpour, Marta Kobiela
sun.j.choi@mail.mcgill.ca, azadeh.javaherpour@mail.mcgill.ca, marta.kobiela@mcgill.ca
McGill University

Abstract: Cross-context communities can benefit teachers by learning from different practices across schools, but such communities may be challenging to establish. This study examined how one cross-context mathematics teacher community consisting of elementary and secondary teachers evolved over two years. Preliminary findings suggested three changes in teacher interactions in the cross-context community: 1) with whom teachers interacted, 2) how they interacted with one another, and 3) what topics they discussed.

Introduction

Teacher communities provide opportunities for teachers to reflect on their practices, examine their strategies, and share experiences with their colleagues (Grossman et al., 2001). Within communities, teacher interactions help teachers learn how to interpret problems in practice and plan future teaching (Horn & Kane, 2015). Much of this research on teacher communities has been conducted within singular contexts (e.g., schools, grade levels, disciplines). However, schools often face challenges that are hard to address in one school alone (Stoll, 2009). Accordingly, educators have looked to expand teacher communities by connecting different contexts (Prenger et al., 2021), what we refer to as cross-context communities. *Cross-context communities* bring together members of different contexts, such as teachers from different levels, schools, or districts. These communities provide members with opportunities to share a broader range of experiences and perspectives (Stoll, 2009). Despite the benefits of cross-context communities, they can face barriers, such as a lack of interactions and shared goals (Prenger et al., 2021). It is less clear how interactions in cross-context communities evolve over time. Thus, this study examined changes in interactions over two years in one type of cross-context community: spanning elementary and secondary levels and connecting different schools. We asked: How did teachers' interactions change in a cross-context community?

Research design

We drew upon situated learning theory which emphasizes the impact of context on learning through members' social interactions within a community of practice (CoP) (Lave & Wenger, 1991). A CoP is a group of practitioners who have common interests and values in a specific domain (Lave & Wenger, 1991). They interact regularly to share information and learn from others' experiences to produce new knowledge (Lave & Wenger, 1991). A CoP includes three aspects: mutual engagement (collective activity), shared repertoire (shared tools, norms, and routines), and joint enterprise (shared goals). Bannister (2015) found that teachers developed a CoP through their shared repertoire (e.g., daily meetings), mutual engagement (e.g., curricular and pedagogical reforms), and joint enterprise (e.g., common goal to support all students). The community was beneficial when members had commonalities and interacted toward their goals. However, Grossman et al. (2001) found that teacher communities risk becoming pseudo-communities when members pretend to agree on values and lack authentic interactions. Thus, to benefit teachers' learning, it is important to understand how CoPs develop.

This study is part of a design-based research project (Bakker, 2018) aiming to support student transitions from elementary to secondary mathematics. The project involved a 3-year partnership with one school board in Canada, serving a large rural community. Elementary and secondary math teachers came together for regular meetings (5-6 meetings with 6-8 teachers per year). In this paper, we focus on the first two years to examine how the community developed. Our overarching goal was to support cross-context coherence in pedagogical practices. To do so, a central task of the community was to develop, implement, and refine versions of one instructional routine (a short lesson with a defined structure that can be adapted to different content and grade levels) (Lampert & Graziani, 2009). Meetings were led by a math coach, in three parts: a) check-in about implementing the routine, b) discussion of instructional strategies, and c) co-planning new routines.

For this paper, we drew upon videos of the check-in portions (occurring in 9 of the 11 meetings). Check-in allowed us to identify a) changes in interactions and b) whether meetings followed a consistent activity structure. First, we transcribed the check-ins to capture verbal and non-verbal discourse (e.g., gestures, gaze). Next, guided by our research question, we created initial themes to characterize interactions by answering analytic questions related to the components of CoPs (mutual engagement, shared repertoire, joint enterprise). We then looked across meetings within and across years to identify commonalities, exceptions, and changes in interaction patterns.

Preliminary findings and conclusions

Our preliminary findings revealed three changes specific to the cross-context aspects of the community. First, we observed changes in whom teachers interacted with. The interactions that happened during the first year were mostly between individual teachers and the math coach. For example, when a teacher shared her struggles in implementing the new routine in her classroom, the coach alone responded. The few interactions that did occur among teachers only occurred between those from the same school. Conversely, in year 2, we observed more teacher interactions across schools and grade levels. For example, when one elementary teacher shared student misconceptions, two secondary teachers respectively shared how they supported students in similar situations.

Second, as teachers developed a shared repertoire that spanned school contexts, their interactions shifted from passive participation to active exchanges of ideas. For example, in the first three meetings, they interacted by nodding, smiling, or saying “okay” or “absolutely.” In contrast, at a meeting in year 2, when one of the elementary teachers shared her teaching materials and student responses, a secondary teacher asked for more details about the materials. She then connected them to her classroom activities. Teachers from different contexts increasingly interacted when they found commonalities in learning activities across school levels over time.

Finally, interactions shifted in the focus of discussions: from discussing how to tackle challenges with students in their individual schools to developing joint enterprise across contexts. In year 1, teachers focused more on dealing with student struggles with new routines and lack of confidence rather than sharing common goals. They sought strategies to boost student confidence and support student struggles. However, in year 2, teachers started to connect their goals to instructional routines. For example, one elementary teacher told a secondary teacher, “Actually, next year, you will have some students who remember this routine because when I was with them, I did the same routine.” The secondary teacher responded, “Yes, it will be interesting.”

The preliminary findings of this study indicated three major changes in teacher interactions within the cross-context community. We interpret that these changes provide evidence of community development by establishing joint enterprise and shared repertoire through mutual engagement (Lave & Wenger, 1991). These findings contribute to expanding our understanding of cross-context community development by illustrating changes in interactions specific to cross-context communities. For example, like Bannister (2015), we found that teacher-to-teacher interactions were initially limited. However, our results also highlighted that *who* teachers interacted with changed and was related to context membership. Moreover, our findings are a first step towards the development of a framework characterizing cross-context community changes in interactions. Such a framework can be used by community facilitators to learn to anticipate possible changes in interactions and to plan structures to support similar community growth. Moving forward, we will further investigate how the design elements and other factors contributed to changes in teachers’ interactions.

Ethical Complexity in Youth-Led Computer Science Curriculum Writing: Emergent Ethical Deliberation in Curricular Co-Design

Shai Moore, Bradley Davey, Sepehr Vakil
ShaiMoore@u.northwestern.edu, BDavey@u.northwestern.edu, Sepehr.Vakil@northwestern.edu
Northwestern University

Abstract: Questions of ethics and politics are typically missing in computer science education (Vakil, 2018). Amid growing concerns about the intersections of ethics, race, and technology (Benjamin, 2019), youth voices are seldom centered. This study explores the emergent practices from youth who interrogated themes of ethics and technology in an OST community learning space as a part of our research practice partnership (RPP). We follow two vignettes where participants collective debates of morality; which we term ethical deliberations.

Research design, data collection, and methods

In our exploration we ask: (1) what pedagogical moves and framing did facilitators use to support sensemaking about ethics of tech and (2) what was the nature of student ethical thinking and discourse, and what shifts were observed over the course of the program? This program is centered around a design-based RPP project which focuses on the interests and perspectives of youth. Using a grounded theory (Corbin & Strauss, 1990) approach to identify trends in youths' negotiation of ethics and technology, a team of educators and researchers analyzed 10 hours of recordings and field notes to develop codes to identify patterns in participants' speech and interactions (Saldaña, 2015). We used a constant comparative method (Charmaz, 2014) involving iteratively working between codes and transcripts to identify the patterns and generated codes We describe as contributing to a collective deliberation of morality; which we term ethical deliberations (see Table 1 below).

Table 1
Counts of the codes for elements of ethical deliberation across vignettes

Code	Definition	Vignette 1 Counts	Vignette 2 Counts
Legitimacy	What is it?	17	6
Ownership	Who gets to?	0	2
Rules	How does it work?	1	0
Infraction	What was violated?	3	3
Consequence	What happened next?	0	3
Other		27	11
Total no. of turns		48	25

Findings: Elements of ethical deliberation

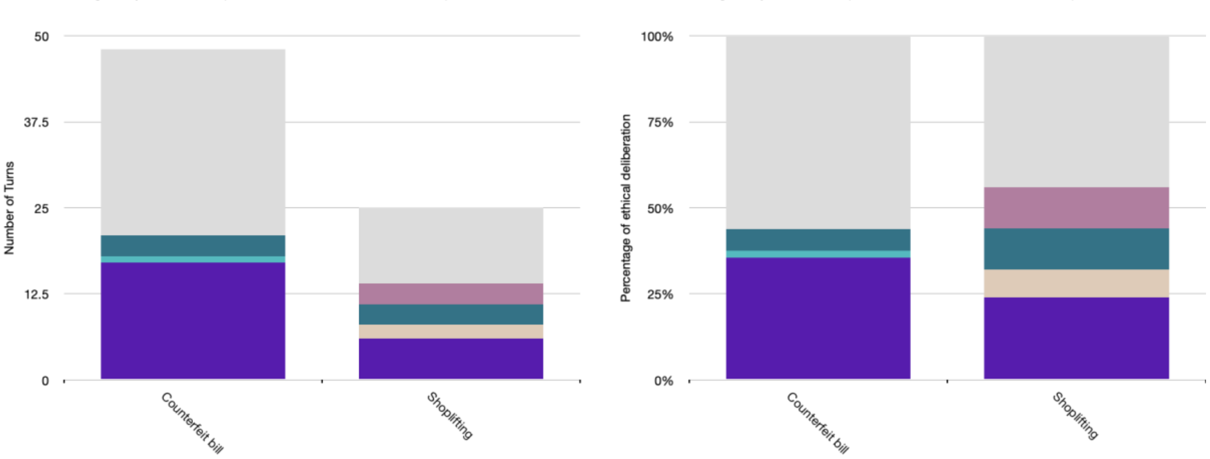
This poster presents data from two vignettes representing early shifts in ethical deliberations during our study. These conversations illustrate how participants took up a practice of using discussions as a way of interrogating and evaluating ethics both within and outside the realm of technology. In both cases, the data presented represents a zoomed in section to a larger conversation presented to participants as an ethical concept.

In the first vignette, we highlight a segment of a conversation that takes place on the first day of the program about the murder of George Floyd and the technologies present. Drawing on Winner's (1980) expansive framing of technology and ethics, Facilitator Moore presents the counterfeit bill as central technology to the case and prompts participants to consider how the clerk might have assessed the legitimacy of the bill; a determination that ultimately led to Floyd's death and the world-wide recognition in the weeks that followed. While racialized violence was quickly identified as a salient ethical issue by participants, there was little uptake on the role of technology or artifacts despite multiple attempts by facilitators. However, even in this introductory conversation, participants were able to use the discussion to interrogate how a counterfeit bill might differ from a federally minted bill (coded as rules) and how a counterfeit bill might be created (coded as infraction).

The second vignette highlights a discussion that takes place about halfway through the program on the ethics of shoplifting. We see collective and complex ethical sensemaking through participant-led cross talk through deliberating the ethics of shoplifting in a luxury retailer. In these quick turns, there is a judgment made of the luxury retailer by the collective that there are places where shoplifting might be considered appropriate due to need. In contrast with society's laws around shoplifting, this deliberation illustrates how participants were engaging in serious deliberation rooted in their lived experiences. Noticing the way participants responded to a luxury retailer, Facilitator Ian considered posing the same question based on human necessities and reframed his prompt to question how their stance may shift if someone was shoplifting food. We see an implicit uptake of justice and power in discourse by the participants that shows significant movement between the two vignettes.

Figure 1

Distribution of ethical deliberation across vignettes: total counts (a); proportion to the whole conversation (b)



(a) (b)

While the conversation in Vignette 1 was nearly twice as long as Vignette 2, there was significantly more concentrated ethical deliberation in the latter conversation. Additionally, participants have created a quasi "court" structure where they become the arbiters of what is deemed legal. In these vignettes, participants exhibited a practice of creating legal structures for societies. Critical race theorists have advocated for returning to the legal origins of modern policy (Ladson-Billings and Tate, 1995). We see this return as a natural way of engaging in ethical deliberation and a counter-narrative to normative ethics as they are defined in CS education.

Significance and implications

Our findings have implications for the design of computer science education that seek to center youth as equal partners in the complex work of ethical sense-making of emergent technologies. Deliberative discussions can serve as a powerful vehicle for rich engagement with the ethics in technology and should become a part of standard in computer science and technology education. While youth are ready to engage in deep, rich discussions, facilitators must create room for questioning and engage expansive views of tech ethics. We argue for standard practice in regular conversations in group discussion to increase complexity in ethical deliberations. Our future work will look at additional conversations to determine deeper relationality between the elements of ethical deliberations identified here.

Abstract: This poster presents findings on middle school students' understanding of core Computer Science (CS) concepts, such as variables and control structures, using cognitive think-aloud interviews with eight students. Each student worked on 16-22 formative assessment tasks designed to assess understanding on the 'Algorithms and Programming' middle school CS standards. Our study describes students' interpretations of the CS concepts and discusses potential factors influencing student interpretations. Significance and next steps are described.

Introduction and research questions

Education researchers and policy makers have emphasized introducing CS as early as possible to prepare K-12 students for future careers and life in a computationally intensive society. Many CS curricula, particularly for middle school levels, have been developed to help students understand key introductory CS concepts such as variables and control structures. These curricula predominantly employ a block-based programming representation which helps students learn core CS concepts without having to deal with complex syntax. However, some studies have explored and found that young students still encounter challenges in understanding the concepts of variables and control structures, even when using block-based code. For example, Mladenović and colleagues (2018) compared elementary students' misconceptions of loops in block-based and text-based programming languages and found that young students had misconceptions about simple and nested loops, even in block-based languages. Although some such studies have started to explore students' challenges with key CS concepts, there is still a need for research on middle school students' understanding of key CS concepts, such as variables and control structures, using a variety of programming representations, both block-based and text-based. Here, we report on a pilot study leveraging a cognitive think-aloud approach to uncover middle school students' challenges with the concepts of variables and control structures and identify the contributing factors. Our research questions are as follows: (1) What do middle school students' responses to various short assessment tasks reveal about their understanding of the concepts of variables and control structures?; and (2) What are the potential factors influencing middle school students' responses to CS assessment tasks?

Methods

Context

We employed an evidence-centered design approach (Mislevy & Riconscente, 2006) to design 75 formative assessment tasks aligned with fine-grained learning targets associated with middle school 'Algorithms and Programming' standards. Tasks used a JavaScript programming representation and a combination of block- and text-based formats for these tasks to align with the representation used in the CS Discoveries (CSD) curriculum that was familiar to all participating students (Basu et al., 2022). We present data collected from eight hour-long interviews with seven 8th-grade students and one 7th-grade student who worked on 16-22 tasks each. About half the students reported having taken CS courses in their previous grade levels. All students were instructed to independently think-aloud through each task during the one-hour interviews. All the interviews were audio recorded and transcribed.

Data analysis

Based on the cognitive interview recordings and notes, we developed a memo for each student by listing their final answers for each assessment task, how they described their problem-solving processes, challenges they faced, time taken to finish the task, and feedback on the tasks. The analytical approach comprised reviewing students' responses and their thinking processes and grouping their responses into five categories: 1) provided correct answers and correct reasoning; 2) provided correct answers but partially correct reasoning; 3) provided incorrect answers but a partially correct reasoning; 4) provided incorrect answers and inaccurate/irrelevant explanations; and 5) decided to skip due to lack of understanding of the task and/or the underlying concept.

Preliminary findings

Students' understanding of variables

Students demonstrated an understanding of how to *name variables* appropriately on half of the tasks (2 students each responded to 2 tasks on this aspect). There was only 1 task aligned with *variable initialization*, and the only student who responded to this task was able to provide the correct answer. In contrast, students struggled with *manipulating values of variables*, whether it be numeric variables, string variables, or variables representing compound datatypes such as lists. For instance, some students did not understand what a string variable is, so they had challenges parsing string variables. Some students did not understand when two numeric variables are linked by assignment such as "count = start + 1." Moreover, students struggled with using variables alongside loops and conditionals.

Students' understanding of control structures

Students answered most tasks on *nested loops* and *nested conditionals* partially or fully correctly (6 students each worked on 1-2 tasks on each of these two aspects). In comparison, students demonstrated difficulty understanding code that includes a compound conditional statement using Boolean operators as part of the condition. Students could neither accurately identify needed Boolean expressions for representing a condition nor predict the correct output of a program with a conditional including Boolean operators. For *repeated conditionals*, only 2 students worked on aligned tasks, and only one student answered correctly, albeit with partially correct reasoning. *Procedures inside control structures* was also difficult for students; 4 students each worked on an aligned task and only two students answered correctly with partially correct explanations.

Potential factors influencing students' reasoning

We found that some factors may influence students' reasoning, such as their prior programming experience and familiarity with JavaScript block-based and text-based representations. We noticed that most students reasoning process leveraged their prior programming experience. Students familiar with other block-based programming languages such as Scratch often tried to tie their reasoning back to that representation, even when not appropriate. Regarding code representations, we found that students generally preferred a visual block-based representation, especially some students who had never seen text-based code, even though the CSD curriculum programming environment allows them to toggle between block-based and text-based representations.

Discussion and future directions

This work is part of a pilot study for a larger project that aims to deepen middle school teachers' understanding of five Algorithms and Programming standards by implementing standard-aligned formative assessments. Our findings suggest that programming representation plays a significant role in formative assessment tasks and the types of student understanding and challenges that tasks can elicit. To forge deep conceptual learning, students should be exposed to different programming representations so that their learning is not limited to the affordances and constraints of one programming representation. Regarding the next steps, we are revising some of our formative assessment tasks to better capture student challenges and understanding of the underlying concepts.

Social Context Challenges in Administering Authentic Assessments of Citizenship Competency

Paula Waatainen, Vancouver Island University, paula.waatainen@viu.ca

Abstract: The authentic assessment framework from Gulikers et al. (2004), its research situated in an adult vocational nursing program, called for the use of an authentic social context. This dimension is not typically included in authentic assessment models that focus on K-12 education but is closely aligned with citizenship education. This poster identifies moments in earlier phases of a design-based research study when classroom social context complicated teacher assessment of student citizenship competency and proposes to study how to mitigate for it.

Introduction

Social contexts in classrooms can be quite different than the social contexts associated with real-world processes that teachers engage students with or simulate in citizenship education. In designing more authentic assessments of citizenship competencies that students may develop via engaging with complex problems with real-world value, the social context of the classroom may interfere with student abilities to fully demonstrate their competency. This poster aims to prompt conversations that will support the researcher in designing the third phase of a design-based research study that appears to have identified this concern in the first two stages of design.

Theoretical framework

Wiggins (1989) wrote of *authentic tests* that were contextualized, complex intellectual problems, representative to a discipline or profession. They required self-assessment, a public performance, and a multi-pronged view of student learning. Authentic assessments have realistic value of task and context (Herrington & Herrington, 1998), a fidelity of the task to real world conditions and a realistic social context (Gulikers et al., 2004) and are also authentic in value to students (Gulikers et al., 2008). Koh and Luke (2009) developed criteria for intellectual quality including knowledge manipulation, knowledge criticism and the value of using supportive task framing.

Purpose

The research proposed in this poster will be the third design phase in a design-based research (DBR) study. The purpose of Phase 1 was to collaborate with two Grades 6 and 7 teachers to design an authentic assessment of citizenship competencies that their students developed when participating in a real city planning public engagement process. Students generated individual ideas and were prompted to deliberate to prioritize which ideas would be submitted to the city process. The purpose of Phase 2 was to apply findings from Phase 1 in collaboration with a Grade 12 Political Studies teacher to design an authentic assessment of her students' competencies associated with deliberative dialogue, including prioritization, in rich simulations such as Model United Nations. The purpose of Phase 3 will be to collaborate with another teacher to design and administer an authentic assessment of deliberative dialogue requiring prioritization, but to focus design decisions and data collection on the influence of the social context of the classroom and how teachers can mitigate for it in designing and administering the assessment. I propose to write an exemplar of practice for teacher education as practical output.

Methods

The DBR process is structured on McKenney and Reeves (2018) model for educational design research, with practical and theoretical lines of inquiry, and an iterative process. Clinical partnerships were formed in each phase, with the researcher engaging in design with two Grades 6 and 7 teachers in Phase 1, and one Grade 12 teacher in Phase 2. Data collection involved design-process notes, annotated shared digital planning documents, observation notes, semi-structured interviews with teachers and student participants, and an examination of artifacts. Thematic analysis identified themes in what could be learned about the nature of citizenship competency and practical lessons for teachers in designing assessments of competency, resulting in the creation of exemplars of practice for each phase and a graphic organizer. I propose to use a similar methodology in Phase 3 but am seeking suggestions.

Selected findings phases 1 and 2

Phase 1

The Phase 1 findings that first raised questions about the impact of social context came from observing Grades 6 and 7 students deliberating in one of the classes. Their teacher had placed them into small groups based on the topic area of the individual ideas each student had generated for the city (e.g., transportation, recreation, and social planning), only pausing to separate two students with a history of conflict. Of five groups, two successfully navigated our deliberation process to determine which of their ideas to prioritize to develop further and submit to the city process. The teacher directly supported a third group, and I observed two groups, offering only a few nudges and reminders of the process described in scaffolding we provided. One group squabbled loudly and in good humour, teasing each other as they each wrote their own idea into a shared slide presentation, refusing to give priority to any of them. One student expressed his frustration to me as I passed, lamenting that his idea to fix a dangerous intersection should be more important than other transportation issues, but nobody was listening to him. The last group sat, in what two students later described as painful silence, before politely combining all their ideas into an unwieldy "dog park with food trucks and recycling centre" proposal. I did not collect any data to shed light on the transportation group's dynamic, but two student participants in the dog park group noted that they hardly knew each other and were used to working in friend groups, so were slow to start.

Initial analysis of student interviews, self-assessments, and observation notes in Phase 2 indicates that Grade 12 students may also have found deliberation to prioritize more difficult because of the social context of the classroom. Students engaged in five deliberations over five weeks, with regular formative feedback and self-assessment. In early deliberations, we noticed some students struggling to deliberate to prioritize when it involved eliminating other students' ideas or wishes. For example, when directed to generate just three priorities for their new mayor and council, half the groups submitted lists of ideas from all students in their group. In post-interviews, two students noted that deliberation seemed to get easier as everyone got to know each other better in the class.

Significance of study

When students in phases 1 and 2 were struggling to deliberate to prioritize, their teachers had to judge if this indicated less competency, lack of engagement, social pressures, or commitment to putting forth the best idea. Real socials contexts they emulated or simulated – strangers in a town hall meeting or world leaders negotiating at the United Nations – were not the only social contexts that appeared to be influencing students. That the social context in the classroom can initially impact competency to deliberate is aligned with work by Hauver et al. (2017), who interviewed Grade 4 students about how they navigated the social context when deliberating on an issue of authentic importance to them – how to spend playground equipment money at their school. The Hauver study did not include classroom assessment, but their interview process could offer guidance to Phase 3, in hopes that the next exemplar of practice generated from this study can offer some guidance in navigating simulated vs. classroom social contexts in designing and administering authentic assessments of citizenship competencies.

Agile Design Research to Close Gaps: The Design of the Mentu Learning Platform

Fernando Díaz del Castillo H., Shaia Foundation (Mentu), nando@mentu.co

Abstract: The Mentu Learning Platform is being designed to support high-quality learning in Latin America, focusing specifically on the needs of public schools that serve disadvantaged populations. With very promising results, we report on the design and implementation of the tool and highlight gaps from the actual product to the vision that is still under construction.

The Mentu learning platform

The percentage of students who are in learning poverty in Latin America is around 80%, an increase of 30% from pre-pandemic estimates (Saavedra et al., 2022). Mentu is a web-based tool that seeks to close educational gaps in Latin America, by offering high quality resources to both teachers and students, that are grounded in the Learning Sciences and in Learning Engineering (Goodell & Kolodner, 2023). We report on the design and results of a prototype of the platform used by over 4,000 students in 2022. Our vision is to expand the content to a full K-12 curriculum for Math and Language Arts.

Key elements of the design

The prototype was a replacement curricular unit on the topic of Fractions targeted to the 5th grade. The key elements are:

- **Gamification**: an animated narrative provides context and relevance for the learning activities; badges and points awarded for achieving learning objectives and desired behaviors (Kapp, 2012). *Vision: badges, medals, narrative and embedded games.*
- **Instructional sequence:** Grounded in the Teaching for Understanding model (Blythe, 1998; Wiske, 1999).
- **Pre and post tests:** standardized test administered using Concerto Platform (Oppl et al., 2017) at the start and end of the learning unit. *Vision: adaptive test that is used to personalize the upcoming content.*
- **Messing-about activities:** open and closed ended questions that introduce students to the topic, connect new ideas with what they already know and start engaging with the learning goals. *Vision: open-ended activities, digital and offline manipulatives, discussion, AI conversational agents, and student-directed planning of learning.*
- **Direct instruction and practice activities (*learning challenges*):**
- **Videos** 3-6 minutes of direct instruction. *Vision: interactive videos with embedded activities; on-demand video library.*
- **Infographics**: texts and images with explanations and multiple-choice questions. *Vision: embedded interactive manipulatives within the text; collaboration and discussion.*
- **Training**: closed-ended exercises ranging from operational fluency to word problems, with immediate feedback. *Vision: adaptive feedback and sequence of activities; collaborative activities.*
- **Reinforcement**: additional training and instruction for students who need it.
- **Formal Assessments**: series of word problems connected to the storyline. *Vision: adaptive test that gives access to badges for each standard.*
- **Synthesis activities:** seeks autonomous, self-directed application of learning in novel contexts. Synthesis activities use closed-ended and multiple-choice templates and thus share the challenges of assessing understanding with such questions (Wolf et al., 1991). *Vision: open-ended, hybrid, project-based activities that replace the current version of the synthesis.*
- **Social-emotional learning:** learning resources focused on learning how to learn, embedded throughout the learning journey on topics such as growth mindset, self-efficacy, note-taking and learning from videos.
- **Teacher dashboards:** Three types of dashboards were prototyped for teachers, providing both aggregate information at the class level and individual student data. *Vision: multiple dashboards and a range of available analytics coupled with interpretation support materials for both teachers and learners.*

Settings where implemented

3,500 students from 17 schools in Colombia in Fifth to Eighth grade, ages 10-16 for periods of 4-10 weeks. A survey was conducted before each implementation to understand users: used in computers and tablets; most schools have a computer lab –few use mobile devices; mobile devices are underused due to lack of wireless connectivity; devices shared by several classrooms; quality of connections and infrastructures vary greatly.

Description of each version

Version 1: 1,800 learners. Changes to the user interface, responding to feedback: interviews, focal groups, surveys and observation of user interaction recordings. Tweaks: added visual indicators of completed activities, added direct instruction on how to learn online, and improved data capture.

Version 2: 1,700 additional learners: standardized number of questions in the training exercises to 15; added support materials for those who did not demonstrate understanding; redesigned story and characters; implementation process in closer contact with schools and teachers, and an improved teacher training program.

Version 3: tested in 2023. New formats for instructional videos with improved motion graphics, and higher quality post-production; gamification: points for completion of activities and correction of responses.

Outcomes

In version 1, the standardized difference between post and pretest was 0.17, encouraging yet small. Additionally, students reported that they enjoyed using the platform (75%) and that they would like to use it every week (90%). For version 2, we found that the iterative improvements were fruitful: the standardized difference was 0.70. We are currently analyzing data to better understand the impact of each design change and continue improving.

Conclusions and next steps

Educational interventions that seek to improve the quality of learning tend to be complex and take very long times to design, implement, test and finally scale. Most never reach this last step. After decades of introducing computers in schools, technology in education has fallen short of its promise (Cuban, 2001; Reich, 2020). Yet, millions of children around the world are currently attending school and not learning. Agile software and business development methodologies, combined with Design Research focused on learning impacts, has the potential to create solutions where we have failed before.

Figure 1
Learning Journey

The learning journey includes animated storyline videos, instructional videos, infographics, practice exercises with feedback and assessments.

Examining Active Learning Teacher Education Classroom Activities Using the ICAP Framework and Suggestions for Future Enhancements of ICAP

Garrick Burron, Jim Slotta, Leslie Stewart-Rose
garrick.burron@mail.utoronto.ca, jim.slotta@utoronto.ca, leslie.stewartrose@utoronto.ca
Ontario Institute for Studies in Education, University of Toronto

Abstract: Active learning currently lacks a model to describe classroom activity design and sequencing. Chi et al. (2018) has offered the ICAP Framework to describe active learning. To test ICAP, we applied the framework to the observations of two teacher educators teaching. Analysis found that ICAP lacks descriptive capacity when different engagement levels occur simultaneously and that ICAP lacked prescriptive capacity to guide class sequencing.

Introduction

Provincial and state education systems have recently pivoted to 21 Century Competencies as important curricular outcomes. However, meeting these competencies while also meeting content-focused learning objectives is challenge for K-12 teachers who receive little guidance regarding how to integrate the 21 Century Competencies. Active learning may be a means to meet this challenge while also supporting pro-social components of schooling such as cultural responsiveness, inclusiveness, and social justice (Haak et al., 2011; Segarra et al., 2018). One possible site for integrating active learning into education is investigating how teacher educators (TEs) induct teacher candidates (TCs) into active learning under the assumption that this induction will encourage TC to use active learning in their careers.

Chi et al. (2018) has offered the ICAP Framework to define "active learning", which includes four levels of activity (interactive, constructive, active, and passive). *Passive* represents students listening without manipulating the information; *active* is where students work with information only using the information within the current lesson; *constructive* is where students are manipulating information and connecting that information to other knowledge outside the lesson; and *interactive* is where students are engaging in constructive thinking with others. Chi argues that these various levels can be assessed by observing student work and behaviors (e.g., worksheets, mind maps, debates, conversations, etc.) to determine if students are making interconnections between knowledge. In ICAP these interconnections are thought to avoid encapsulation of new knowledge. This allows the new knowledge to be applied more broadly and retrieved more easily.

This paper examines if ICAP's present form can serve as this set of guiding principles for active learning. Thus, we apply the ICAP Framework to two case studies of teacher education classrooms.

Methodology

The Teacher Educators (TEs) in this case study, Emma and Anna (pseudonyms), were selected because they described themselves as "active learning educators." Both were teaching discipline-specific educational praxis classes (Music and Science pedagogy, respectively) in a Central Canadian two-year masters-level teacher certification program. Their students were in their final year. We conducted three classroom observations totaling of 9 hours of observation per TE. This represented a quarter of the TEs' total class time for the semester. The observational data was analyzed according to the ICAP Framework.

Addressing difficulties in using ICAP to assess classroom behaviors

While the ICAP Framework appeared superficially clear, it became apparent in observations that it was common for multiple levels of ICAP behavior to exist simultaneously. For the purposes of reporting findings of class behaviors (next section) the highest behavior level seen was reported.

Findings

Case 1: Emma

Background: Emma was a teacher in grade 9-12 Music, Drama, and English for fourteen years, and a TE in music pedagogy for more than ten years. She is a tenured faculty member within her university department.

Observations: It was common for Emma to move across the ICAP Framework continuum and for her class to have many discussion-focused activities or individual-thinking activities. For example, one of the observed classes showed the instructional sequence of: 40 minutes in interactive level, 20 minutes in the constructive level, 10 minutes in the active level, 10 minutes in the constructive level, and finally 25 minutes in the active level. When the nine hours of observed class time were evaluated against the ICAP Framework, Emma spent: 24% of her classes in interactive; 27% in constructive; 46% in active; and 3% in passive.

Case 2: Anna

Background: Anna taught junior and intermediate English, Science, and Math for three years. As a TE she has been educating TCs for four years in Junior/Intermediate Science Pedagogy classes.

Observations: The classes observed for Anna were design-based learning focused. Anna also moved through various ICAP levels. For example, one of the observed classes showed the instructional sequence of: 40 minutes in the constructivist level, 5 minutes in the passive level, 35 minutes in the interactive level, 10 minutes in the active level, 10 minutes in the passive level, and 70 minutes in the interactive level. When the nine hours of observed class time were evaluated against the ICAP Framework, Anna spent: 46% of her class in interactive; 33% in constructive; 10% in active; and 11% in passive.

Discussion

Our observations support ICAP as a helpful, if incomplete, descriptive tool for determining if active learning is occurring. However, the ICAP Framework cannot account for variation of activity between students during some activities. For example, in situations where the TC students are engaged in different levels of activity at the same time, as with a TC student presenting to a class, the presenting student is operating at a different ICAP level than students who are listening. The same can be said for interactive-level (group) activities where TC students are engaging at different ICAP levels within the group. Less engaged students may be operating at an ICAP level of *active* while students who are more engaged may be operating at the *interactive* level. During group activities, this type of behavioral difference was observed within and across groups. In situations where different engagement levels are occurring simultaneously, it is unclear what the granularity of an ICAP-level rating should be (e.g., class level, activity level, student level, or highest level observed).

Another problem in ICAP is that there is no guidance regarding how much of each ICAP level is considered ideal. In Chi et al (2018), the authors clearly favor interactive- and constructive-level learning while being dismissive of the effectiveness of passive and active learning levels. This implies that ICAP sees little value in the passive and active levels of student activity. However, our TEs used activities that elicited all levels of student activity at various points of their teaching, and it is hard to imagine a class that entirely avoids any active- or passive-level instruction. Chi does argue that higher levels of ICAP subsume lower levels, however that is not what was observed within our study as the TEs had clear divisions between their instructional usage of each level. Thus, the question of what amount of each ICAP level is ideal is left open. Due to this, the prescriptive element of ICAP for class instructional design appears limited because the framework cannot provide an expression of what instruction *ought to be*, but rather can only provide an assessment framework for what the instruction *is*.

Conclusion and recommendations

While ICAP is a useful descriptive framework for determining the active learning behaviors elicited in a class, it cannot currently explain what ratio of the ICAP levels is ideal, or adequately express how to represent situations where multiple ICAP levels are occurring simultaneously. Further, our case studies show that exclusively operating at high levels of ICAP is not the behavior of our observed TEs, and it may not be achievable. Elaboration of these issues presents a rich target for the expansion of ICAP and could allow it to move from its present descriptive framework to a more useful prescriptive framework.

Addressing Challenges in Creating a Community of Practice for Youth Advisors to Co-Design Health Research

Sara Wardak, Rebecca Raeside, Mariam Mandoh, Stephanie R Partridge

Abstract: Establishing domain, community and practice in a health-related community of practice consisting of youth advisors present challenges. Addressing challenges of involving young people in co-design makes it possible to combine online and in-person interactions to form a community of practice of knowledge-sharing benefiting both youth and researchers. A youth health community of practice facilitates connections and exemplifies an effective way of engaging youth as active partners and learners in the research and development process.

Background and aims

In global chronic disease discourse, most adolescents feel their voices are tokenistic (World Health Organization, 2017). Subsequently, health research has increasingly involved co-design including consumers throughout the research cycle (NHMRC, 2016). Youth must be 'engaged and empowered' to improve their health (UNICEF, 2020), doubling as a learning experience for them. However, establishing a youth health research community of practice poses challenges.

We led the Health Advisory Panel for Youth at the University of Sydney (HAPYUS) (Valanju et al., 2022). HAPYUS, consisting of sixteen youth advisors aged 13-18 years inclusive, was established in 2021 to advise research teams on adolescent chronic disease prevention. The first author was the first youth advisor in 2019-2020 and is now an undergraduate student and research assistant in the last author's research team. The last author is HAPYUS' assembler and leader. HAPYUS collaborated online through the application Slack during Australia's coronavirus lockdown, with online platforms being the most accessible interaction method for members living in regional areas. Nevertheless, youth advisors wished to interact in-person, which became possible with funding and a relaxation in coronavirus restrictions. In July 2022, we ran an in-person youth health research workshop for HAPYUS with Charles Perkins Centre. We aimed to co-design adolescent health projects, while introducing youth to research. Our research question was – how can we address challenges in coordinating the youth health research workshop within the community of practice framework? In this poster, we will diagrammatically answer this, featuring "a process of collective learning in a shared domain of human endeavor" (Wenger, 2009) with the community of practice framework's three elements - domain, community and practice.

Method - addressing challenges using the community of practice framework

1: The domain

The first element of a community of practice is having an identity defined by a shared domain of interest. While youth advisors were selected based upon their youth health interest, this does not in itself establish a community of practice. We addressed the challenge of establishing the requisite shared nature of the youth chronic disease prevention research domain through Slack. While online engagement is often seen as sub-par (Tice et al., 2021), it meant the shared domain of youth health issues was already established in a comfortable environment before the workshop - particularly helpful for youth who may lack the confidence to immediately engage face-to-face.

Figure 1

Diagram Representation of Youth Advisor Community of Practice Challenges and Solutions

2: The community

The second element of a community of practice involves shared interaction and learning together. HAPYUS had challenges in establishing community as youth advisors have inherent characteristics to consider – most are minors, geographically scattered due to the community's distributed nature, and have competing secondary school commitments. Additionally, building upon the domain established online to create a community is more effective in person, as learning community decreases online (Nubani & Lee, 2022). Since youth advisors were minors, they had to be financially supported by Charles Perkins Centre to potentially come with a parent/guardian, especially from regional areas. Moreover, the workshop was held in school holidays, away from standardized testing periods to avoid interfering with formal education. Furthermore, communities reproduce themselves with new members that subsequently become future community leaders (Barab & Duffy, 2000). We are evaluating how to sustain this community, with youth moving onto employment or further study. However, given that the first author was a youth advisor before HAPYUS and subsequently co-ran the workshop, community reproduction has potential.

3: The practice

The third element of a community of practice is shared practice and resources, requiring sustained interaction and time (Wenger, 2009). In the workshop, youth advisors co-created a community-based text message intervention for improving adolescent physical and mental health – 'HEALTH4ME'. Youth advisors created a message bank in groups based upon priority areas and determined the intervention's scheduling. Establishing shared practice and resources with young people can be challenging. Youth have unique insight into their own lived experience but are not research experts. Furthermore, engagement is required for sustained interaction - difficult in a day-long workshop. Hence, youth advisors were accompanied by two external researchers per group who did not participate in co-design but guided them, providing research expertise necessary in practice for youth to learn and contribute. For motivation, we conducted a scavenger hunt led by the first author around the university campus of the workshop with prizes as a break, and a networking lunch to meet researchers in a casual format - much more effectively conducted in-person than online. Youth advisors were thus motivated and guided in practice.

Conclusion and future directions

After the workshop, HAPYUS created a private Slack channel by themselves without researchers, but included the first author who was only a year older than some of the youth advisors. This suggests there may be value bridging the gap with young people as researchers in an intermediary role alongside established academics. This facilitates knowledge-sharing more effectively than if the student and teacher of research were strictly separated.

HAPYUS was a pilot study. We received a Medical Research Future Fund Consumer-led grant to recruit many more adolescents for future iterations – researchers in partnership with youth will continue to shape this community of practice. We welcome insights into how we can improve this community of practice through a poster link for anonymous feedback or contact details for asynchronous communication.

Acknowledgments

We acknowledge the sixteen members of 2021-2022 HAPYUS for their invaluable insights, Charles Perkins Centre for supporting the July 2022 workshop, and researchers who volunteered to facilitate HAPYUS' learning. HAPYUS is funded by a Medical Research Future Fund Grant.

Characterizing Problem Solving Discourse During Middle School Students Rubik's Cube Play

Jesslyn Valerie, University of Minnesota, valer066@umn.edu
Keisha Varma, University of Minnesota, keisha@umn.edu

Abstract: This study characterizes problem-solving discourse of middle school students as they worked collaboratively to solve the Rubik's Cube. In our analysis, we developed 12 categories to characterize students' problem-solving discourse. Results indicate the dyads approached the problem-solving task very differently, a reflection of the problem task's complexity and the diversity of students' organic approaches to collaboration and discourse.

Introduction

Next Generation Science Standards (2013) emphasize the importance of training scientific problem solvers and providing a curriculum that teaches science and engineering problem solving practices. Effective science and engineering education practices are those that provide foundational theoretical knowledge while providing opportunity for utilization of skills to develop authentic learning practices (Wang et al., 2013). Overall, this combination leads to a more meaningful learning experience. Over the years, learning through problem solving has become a widely used pedagogical approach to help students extend their knowledge and understanding by providing them with the opportunity to apply it in a real-world context (Wang et al., 2013). However, experience and knowledge alone are not sufficient in creating expertise. A study on expertise development suggests that one would need to be able to contextualize and create the mental processes involved in the actual problem-solving practice to develop expertise (Ericsson, 2008). Our study would like to give an opportunity to students to be critical and creative problem solvers. We are doing so by allowing students to choose their own partner (working in a dyad) to try and solve the Rubik's Cube without any guidance. Our study focuses on examining students' problem-solving discourse as they are engaged in the Rubik's Cube play.

Theoretical background

In problem solving literature, a problem is defined as a goal-oriented task where multi-step action is needed to reach a desired goal (Duncker, 1945; Newell & Simon, 1972). These multi-step actions are elaborated more by Goel and Pirolli's (1992) framework by describing that problem solving activity involves four different sub-steps. These steps are as follows: first, problem exploration and decompositions, second, identification and interconnections among the components, third, finding a solution to the sub-problem, and fourth, synthesizing the partial solution into the problem solution. We chose this definition because the problem space of a Rubik's Cube is complex. It encompasses various parts of the cube and requires multiple steps of sub-goal completion. While the goal of the Rubik's Cube solved pattern is having each of the sides being a single color, the solution is not immediately apparent. There are many configurations that can be utilized in solving a Rubik's Cube (Korf, 1997). Due to the problem-solving complexity that is embedded within the cube, we thought Rubik's Cube would be the right platform to explore middle school students' problem-solving discourse. Hence, this study is interested in investigating and characterizing the types of problem-solving discourse that middle school students engage in as they are solving a complex puzzle such as the Rubik's Cube. In this study, students work collaboratively in dyads on solving the Rubik's Cube without any guidance from the classroom teacher and/or the researchers.

Methods

We recruited 40 middle school students from a diverse, urban middle school in the United States. Students picked their own partner where they sat side by side. Each of the tables in the classroom was equipped with two action cameras where students were video-taped and audio-recorded. Each of the students were then given a Rubik's Cube that had been scrambled in the same exact configuration. The study was conducted in 45 minutes (one class period) during the students' science class. The set-up of the cameras, picking a partner, and distribution of the Rubik's Cube took about 20 minutes. The students were then given a total of 25 minutes to think-out-loud and work collaboratively with their partner to solve the Rubik's Cube. The audio data was transcribed verbatim. The video data is analyzed to examine the students' gestures and the manipulation of the Rubik's Cube. For this paper, we selected three illustrative cases of dyads chosen based on the amount of productivity, task related discourse, and conversational turn taking. Through an emergent coding process and iterative cycles of reliability check-ins, we created a coding scheme and developed 12 categories that characterize students' problem-solving discourse during the Rubik's Cube activity.

Results

Our research question is: What types of problem-solving discourse do students engage in as they solve a complex puzzle such as the Rubik's Cube? To address this question, we developed 12 categories and calculated the percentages of each of the dyad's discourse (see Table 1). Table 1 shows the three dyads engaged in goal setting/planning roughly the same amount. However, there is a difference in students' reflection. We found dyad 1 utilized the most spatial language to describe the orientation of their Rubik's Cubes' pieces and colors. However, dyad 1 has the lowest percentage of observation (status update), meaning they did not inform one another regarding their individual progress as often as others. Dyad 2 had the lowest rate of observation (spatial consideration), but the highest in observation (status update). This means they did not utilize spatial language to describe their observations but were the most engaged in informing one another regarding their progress. While all dyads were engaged in strategy sharing conversation, dyad 3 spent more of their time engaged in this category. Dyad 3 decided to turn their cubes in the same way, ensuring both cubes were always kept in the same configuration, thus resulting in more strategy sharing. All dyads discussed the difficulties and complexities of solving the Rubik's Cube. However dyad 2 exhibited the highest percentage of engagement in the categories of intentional teaching and requests for assistance compared to others. This is because one of the students in dyad 2 solved one side of the cube within the first three minutes of being handed the cube while their partner struggled. Hence, the struggling partner requested assistance many times resulting in higher engagement in these categories.

Table 1
Percentages of each category of discourse from three dyads

	Code title	Dyad 1	Dyad 2	Dyad 3
1	Goal setting/planning	10.07%	7.32%	9.55%
2	Reflection (prior knowledge)	13.18%	0%	0%
3	Reflection (prior strategies)	2.33%	1.22%	3.37%
4	Observation (spatial consideration)	17.83%	2.44%	12.34%
5	Observation (status update)	3.88%	17.07%	15.17%
6	Strategy sharing conversation	13.18%	9.76%	19.10%
7	Intentional teaching	5.43%	9.76%	1.12%
8	Request for assistance	0%	10.98%	1.69%
9	Articulation of challenges	13.95%	8.54%	10.67%
10	Behavior/discourse clarification	8.53%	12.20%	8.43%
11	General conversation	5.43%	12.20%	15.73%
12	Conversation with researchers	6.20%	8.54%	2.81%

Discussion

Our study found the three dyads in our study took a very different approach to solve the complex problem. Dyad 1 used a lot of their prior experience and knowledge. One of the partners in dyad 2 relied heavily on their partner for help. Dyad 3 decided to execute every move in exactly the same way. These three different approaches provide unique insight into understanding how students engage in a complex problem-solving process. While our students showed that they took on the problem-solving steps described by Goel and Pirolli (1992), this study allowed for the examination of these processes at a more micro level. We were able to witness the goal setting process take place, including how often students modified their goals throughout the task based on their observations of the cube. Students articulated challenges, discussed, and developed new strategies to solve the cube, as they were moving through the different stages of problem-solving discourse. These findings provide insight to the importance of student discourse and collaboration when presented with a complex problem-solving task.

The Presence of African Voices in Building and Sustaining the Learning Sciences Knowledge Community

Tutaleni I. Asino, Oklahoma State University, tutaleni.asino@okstate.edu
Rebecca Y. Bayeck, Utah State University, rebecca.bayeck@usu.edu

Abstract: This paper critically examines the building of knowledge and sustaining of community in the learning science. We explore the presence of Afrikan voices in the Learning Science and question whether the ISLS community is engaged in epistemological violence. Our findings indicate that the Afrikan voice is present in the ISLS community but there are imbalances in terms of which journal these voices are heard.

Introduction

The world is diverse, composed of different life forms – of which humans are one. As human beings, we can have different epistemologies, axiologies, and ontological perspectives. Does our ISLS community reflect this richness of diversity? This question can be asked, especially regarding the ISLS conference. The theme for the 2023 year's annual meeting, "Building knowledge and sustaining our community," demands the ISLS community to engage in "strengthening the theoretical basis for social and computer-mediated practices for teaching and learning,", especially in light of "growing opportunities for digital and social media for knowledge building among teachers, researchers, and learners."

Our paper focuses on the building and sustaining, which anchors the call. We aim to critically explore the 'who' in building knowledge and the "what" in sustaining the community. This critical examination is essential because it calls for the community to reflect on the richness of our world. Moreover, it is through such examinations that we can answer the concerns about whether our work "could be labeled epistemological racism" (Scheurich & Young, 1997, p.4) or reflect what Spivak (2015) termed epistemological violence whereby some exist only in shadows unable to speak.

One of the spaces in which the building and sustaining of community occur is in our journals. At the 2016 ICLS Conference, Ludvigsen et al. (2016) argued that the vision for the future of the field must include ensuring that "the journal receives a high number of research papers that can challenge the frontiers within the field of … the learning sciences" (p.17). We argue that although the high number is great, the diversity of voices is equally important. Although the learning sciences is a global community, there are regions in the world, such as the Afrikan continent, that are still not well represented. Therefore, long-term efforts should include promoting the field and creating targets for the near future (Ludvigsen et al., 2016) to increase contributions and advance the field.

In the six years since Ludvigsen et al.'s observation, we have noticed increased work related to social justice and representation. Many members of the community build on the rich traditions of equity-oriented scholarship across many disciplines to explore how social stratifications, racial and cultural backgrounds infiltrate classrooms; hinder learning, and recreate inequities (Uttamchandani, 2018); thus, expanding the learning sciences community.

Building on this move toward equity and on the desire to expand and strengthen the presence of other regions in the learning sciences community, we examined in this paper the presence of Afrikan voices in the field. We used the term Afrikan voices to refer to research conducted in any Afrikan country and published in any of the major journals in the field. This review, therefore, explores the question of Afrikan presence in the learning science scholarship by examining the number of research conducted in Afrika that make it to the learning sciences journals.

Methods

Drawing on Ludvigsen et al. (2016) argument about the need to increase the number of research papers, we contend that publications in some of the prominent journals in the field are a good measure of Afrikan presence in the field. For this reason, we focused on four journals: Information and Learning Sciences, Journal of the Learning Sciences; Instructional Science; and International Journal of Computer-Supported Collaborative Learning. These journals were selected because they either have Learning Sciences in the title or were endorsed by the learning sciences international society on their website.

To address our main research question, we performed a literature search in the four journals using terms such as Africa, and/or African. Articles published between 2016 and 2022 were searched. This period was selected because it corresponds to Ludvigsen et al. 's (2016) call for a greater presence of other regions worldwide.

Inclusion and exclusion criteria

Articles were included if a) the study was conducted on the African continent; and b) the publication year fell between 2016 and 2022. Papers were excluded if the research was conducted outside of the African continent and did not fall within the timeframe selected in this paper. The search yielded 39 articles, and our findings are discussed below.

Findings

Our results show that 39 papers were published in the four journals included in our review. The details are presented in table 1 below.

Table 1
LS articles focusing on Afrika

Journals	Number of Articles
Information and Learning Sciences 1	37
Journal of the Learning Sciences	1
Instructional Science	1
International Journal of Computer-Supported Collaborative Learning	0

The findings convey that African voices are present in the learning sciences but are not evenly distributed across the different journals. Based on our research, the Information and Learning Sciences journal has published the highest number of articles, accounting for 95% of the articles we reviewed.

Conclusion and future research

Returning to our earlier premise, the conference theme provides us with an opportunity to ask what knowledge is being built and what community is being maintained in the learning sciences community. In this paper, we focused on the Afrikan region and explored if the voices of Afrikan scholars, which we refer to as the Afrikan voice, is present. We conclude that Afrikan voices are present in the learning science, but there is a heavy tilt on where these can be heard.

Our aim in this paper was not to compare the quality of the journals in which Afrikan-related articles are published. However, it is worth stating that the two journals most promoted by the ISLS community have the least publication from or about the continent. Building on Spivak (2015), though we do not have enough data to present causation, we argue that the data reveal a form of epistemological violence whereby the "subaltern" although "can speak and know their conditions," (p. 78) have voices in one journal and appear ominously mute in others.

In this submission, we present a brief accounting of the Afrikan voice in the learning sciences while at the same time contributing to the call for a more diverse building of knowledge that we can then sustain. This building and maintaining, if it is to be equitable, must include a critical examination of why some are in the shadow and the margins. While the paper focuses on Afrika, we are aware that this is not the only voice in the shadow. Hence our future research will expand this research to see which voices are dominant in the learning sciences and which voices are silent. We also intend to examine the articles we found focusing on Afrika to discern the methodological and theoretical stances informing the research.

Deadline Extensions as Public Pedagogy: Envisioning the Ethics of Care in Academic Conferences

Peter J. Woods, University of Nottingham, peter.woods@nottingham.ac.uk
Colin Hennessy Elliot, Drexel University, ch3457@drexel.edu

Abstract: Research into the role care plays within processes of learning has largely overlooked the pedagogical implications of this work within academic conferences. In response, we present emerging findings from a duoethnographic study of our responses to the final deadline extension to this conference. Our findings indicate that extending the deadline of conference proposals represents a compassionate public pedagogy, albeit one with contested ends.

Introduction

Care refers to and defines the behaviors and relationships between individuals in learning contexts (and otherwise) that emerge from a concern for the feelings and needs of others (Noddings, 2012). Within extant literature into the work of academic researchers, scholars largely position care as either a research framework to work towards (Shefer, 2020; Vasudevan et al., 2022) or a tool that defines the socioemotional aspects of professional development (Bozalek & Winberg, 2018). Building on this foundation, we turn towards the public pedagogies of academic conferences as another space to explore the education praxes of an ethics of care. Here we draw on Giroux's (2004) definition of public pedagogy, or the process of informal and incidental learning that potentially presents a subversive response to dominant narratives perpetuated within public media. The circulation of public messaging by academic conferences, for instance, potentially represents a form of public pedagogy because of its ability to undermine the overwhelming narrative of academia being a cutthroat institution where intellectual laborers need to constantly produce new knowledge, allowing conference attendees to develop a new understanding of academic identity through this incidental process.

Drawing on these complementary bodies of literature, we respond to the following research question: how do conferences deadline extensions contribute to the ethics of care within public pedagogy? And what learning opportunities emerge in response? To address this question, we conducted a duoethnography in response to the final deadline extension for this conference by exploring our own reaction to the announcement. Our findings reveal that the announcement acted as a means to extend an ethics of care, one that embodied a public pedagogy through the production of spaces for further knowledge construction and identity development.

Methods

For this study, we rely on a duoethnographic research design (Norris & Sawyer, 2012). Duoethnography positions researchers themselves as the research site through autobiographical writing and other forms of self-reflective data collection but expand the scope of research beyond an individual experience through a comparison across researchers (Rose & Montakantiwong, 2018). Drawing on an embedded challenge to post-positivistic framings of qualitative research (e.g. limiting researcher bias, establishing validity), this study "portray[s] knowledge in transition" (Norris & Sawyer, 2012) related to our shifting understanding of the pedagogical possibilities of deadline extensions that emerged through analysis. The two researchers (Peter J. Woods and Colin Hennessy Elliott, both early career scholars who have attended the conference 3 and 4 times respectively) created personal narratives in response to the final extension announcement that shifted the deadline by 24 hours. We then shared these narratives, asking questions and challenging perceptions of each other, before drawing out three themes (relational core, pedagogical space, and disciplinary identity development, with each described in detail in the findings and discussion section) from moments of overlap and juxtaposition via an open and emic approach. Again drawing on duoethnography, we center on the depth of understanding that emerges through a critical and thorough exploration of these two rich narratives rather than searching for validity through a broad data set (Norris & Sawyer, 2012). We therefore provide insight into an emergent framing of the role of care within the public pedagogies of academic conferences and their organizational praxes.

Narratives

In response to the extension announcement, we produced the following narratives. They are presented here with minimal editing due to limits on the length of submission.

Narrative from Woods

The extension came as a huge relief. I caught it after working on a symposium that was being a giant pain. Having the extra space to work was great, and not just from a logistics perspective but from an intellectual perspective as well. The extra time, on a certain level, feels like an invitation to dig deeper into ideas, to create new pathways to explore, and develop new ways of engaging with what has already been engaged. In this sense, it also feels like an invitation to identify the work I want to do with the field I am slowly engraining myself in and speaks to the ethics of the organization. The fact that it was framed as a response to the hardship of completing things on time speaks to the commitments of the organization, one that goes against the hyperproduction inherent to modern academia and makes me appreciate/identify with the organization even more.

Narrative from Hennessy Elliott

I first heard about the extension of the deadline from a message from a collaborator. I was not able to spend the amount of time working on our paper that I had wanted the past weekend. I felt relief with the realization that I could spend the next morning making changes and spending time with our argument. The extension meant I could sleep on it, instead of working through the later evening and early morning up to the deadline. Getting to sleep after getting my children to sleep was a gift that this extension gave me. The gesture of the extension felt like an invitation to spend a little bit more time on our submission to make it even better. As others may pose, that little bit of extra time could have been spent if planned for differently. Yet, this extension and previous extensions offer a view of deadline flexibility which opens more intellectual space to consider our relationship with the society and the conference itself.

Findings and discussion

Through our emergent analysis, we produced three themes related to an ethics of care within public pedagogy. First, the narratives position the extension within the *relational core* of an ethics of care (Noddings, 2012). While Woods names this explicitly, stating that the extension "speaks to the ethics of the organization," Hennessy Elliott embeds this notion when he states, "getting to… wake up the next morning to do the final edits was a gift that this extension personally gave me," highlighting the relational nature of this decision. Second, this ethics of care created *pedagogical space* to construct new knowledge. As Woods says, the extension allowed them to "create new pathways to explore and develop new ways of engaging with what has already been engaged." Hennessy Elliott related this theme to an ethics of care when he claims that "finding this out meant I could sleep on it, instead of working through the later evening," aligning the pedagogical nature of this work with public pedagogy's inherent challenge to the domineering nature of institutions (Giroux, 2004). Third, the narratives align with Shefer (2020) by framing the ethical and pedagogical impetus of the extension with *disciplinary identity development*: Woods claims that "it also feels like an invitation to identify the work I want to do with the field" while Hennessy Elliot states the extension provided "more intellectual space to consider our relationship with the society and the conference." In turn, the conference extension, a choice positioned within an ethics of care, produced a pedagogical space intertwined with these ethics. These emergent findings therefore illuminate the public pedagogies of academic conferences, revealing how messaging and organizational choices contribute to the ongoing learning processes of academic communities.

Disinformation as an Emergent Phenomenon: An Agent-Based Modeling Curriculum to Address Fake News

Renato Russo, Yuruo Lei, Paulo Blikstein
rfr2126@tc.columbia.edu, ll3589@tc.columbia.edu, paulob@tc.columbia.edu
Transformative Learning Technologies Lab, Teachers College, Columbia University

Abstract: To help youth develop the ability to identify disinformation and impede its spread, we constructed a curriculum unit composed of Agent-Based models that simulate the spread of disinformation in both in-person and online environments. Preliminary evidence shows that learners reflect on cognitive biases upon guided interactions with the models, and that participants seemed to connect the skills addressed in the models to real-life situations.

Introduction and theoretical background

We developed an agent-based computational modeling (ABM) unit to support learners in reflecting on the cognitive processes and systemic phenomena associated with disinformation. The spread of disinformation is well-suited for ABM: it is challenging to conduct experiments in the real world, some of its effects are non-linear, and it involves several actors and relationships (Starbird et al., 2019). Russo and Blikstein (in press) describe the models and their design specifications. Our tool leverages the affordances of ABM and visualization to examine the effect of cognitive biases, social connections, and fact-checking behaviors on disinformation spread. Those factors have been associated with media literacy, and research has recommended their development as part of the efforts to confront digital extremism (Rea, 2022). This poster is part of a larger research project (Russo, Blikstein & Penalva, 2021; Russo & Blikstein, 2022) that aims to investigate causes and approaches to deal with the impacts of disinformation fueled by contemporary media practices. In this poster, we focus on ways in which the models promote reflection about (1) cognitive biases at play when we consume media and (2) phenomena experienced by participants in real life.

Methods

We extend Rand and Wilensky's (2008) computational models to reproduce the spread of disinformation. We designed and tested a sequence of 4 new NetLogo models that allow for exploration of causes and implications of disinformation spread. In this poster, we focus on cognitive biases, fact-checking behavior, information channel, and average number of connections within the population. We interviewed 4 US undergraduate and graduate students (22 to 24 years of age). One-hour Zoom interviews began with general questions regarding participants' media consumption habits, their understanding of disinformation, and their understanding of bias in information spread. Participants then opened and explored the models in sequence. The interviews were audio- and video-recorded. Researchers took notes during the interviews and while rewatching the recordings, and defined emerging themes (Charmaz, 2006). Those notes were then analyzed for interaction with the NetLogo models and potential learning outcomes.

Preliminary findings

Intuitive conclusion as part of an insightful discussion

Among the models' features, cognitive biases were the most frequently discussed by participants. Remarkably, before interacting with the models, only one participant (Xue, pseudonym) stated that bias assessment was one of the standards that she uses to detect "fake news." All 4 participants manipulated the "bias" slider to verify its effects on the model's behavior. One participant (Yeong, pseudonym) concluded that, predictably, when bias goes down, the spread of disinformation is "much, much lower." That conclusion, albeit intuitive, was embedded in a broader discussion about the nature and implications of biases, which highlights the essence of instruction supported by agent-based modeling: the interaction enriched a conversation that potentially led to the type of insight that the models aim to instill in the learners. This is illustrated by the following dialogue:

> **Researcher:** Do you want to adjust the level of biases to check your idea [about biases]?
> **Yeong:** I can test the bias first. So now that the bias is lower. [...] the information is not spreading as fast [...] I'm thinking about the reason. Is it because people have already set their way of thinking? Wait, they're not that set in the way of thinking as there is less bias. So they're more able to analyze the situation in a more logical manner, and not just believe, like, information that they think is likely to be correct.

As we see, upon the researcher's cue, Yeong starts to experiment with the bias control and notices how it changes the model behavior. While he observes the model, he starts to draw conclusions about biases and their effects on people's disposition toward new information. Here, the model does not explicitly tell what biases are. Instead, it provided a visualization of the phenomenon and generated reflection by the learner.

Association between interacting with models and understanding real-life phenomena

Some participants engaged with the potential of the models to explain lived experiences. Upon interaction with the models, Eliot asked for further explanation about cognitive bias in news reporting. During that part of the dialogue with the researcher, he connected the model's results with prior real-life experience, namely linking bias with his grandmother's understanding of COVID-19-related news. In his concluding reflection, Eliot expressed increased awareness about how powerful biases can be and how some media outlets might exploit them. He provided an example of connecting with his family members through social media and instant messaging platforms, and the need to verify the news they read on those channels. He said: "It makes me feel how differently I would feel if I couldn't directly talk to my family or my family [couldn't] directly communicate with me to see what's *actually* going on." This tendency demonstrates the potential of the models as learning tools, and a similar tendency has been found in other testing situations. For example, another participant reflected that she didn't expect that "things would spread so much faster in social media and instant messaging than in in-person communication." A third participant was surprised by the effectiveness of fact-checking in controlling the spread of disinformation. Although those conclusions do not represent the *only* possible scenario – which was emphasized by the researcher – they reinforce the well-documented ability of agent-based modeling to instill reflection about phenomena in a way that would be less likely to happen otherwise (Tseng & Son, 2020).

Discussion and future directions for research

In this project, we employ ABM to develop a learning experience about disinformation. We explore the affordances of ABM to simulate scenarios containing networked communication and emergent phenomena. Interaction with the models potentially affords the emergence of understanding that can be much harder to achieve using direct instruction. By testing the unit, we gained insight into its potential: we verified that the models facilitated discussion and reflection on cognitive biases and their implications in real life. Learners also reflected on the effects of fact-checking. In advancing this research project, we understand that improvement is needed on the demographics of the sample so that it reflects audiences beyond post-secondary students in the US. We also plan to refine the design of the models in a way that emphasizes non-linear effects associated with different factors and develop a research design that allows learners to conduct more sophisticated experiments with the models.

Understanding the Influence of Stereotypical Perceptions of Scientists on Middle School Students' Science Achievement

Samuel J. Bullard, Keisha Varma
bulla049@umn.edu, keisha@umn.edu
University of Minnesota

Abstract: Stereotypical perceptions of scientists are often thought as important influences on learners' future pursuit of science careers, but less research has focused on more proximal learning outcomes, such as middle school science achievement. In this study, we used the Draw-A-Scientist Test to identify commonly held stereotypes among middle school students about scientists. We then examine the potential relationships between these stereotypes and student performance in their science class.

Background

Research in the learning sciences aims to understand how attitudes, beliefs, and stereotypes about scientists and science impact learners, particularly in STEM fields (Potvin & Hasni, 2014; Osborne et al., 2003). Stereotypical imagery of scientists and scientific knowledge generation, internalized by learners, may explain why American universities struggle to retain STEM students, especially those from underrepresented minority groups (Whalen, 2016). The Draw-A-Scientist Test (DAST), a visual data tool, is used to elicit learners' beliefs about science (Chambers, 1983). The DAST checklist, comprising 16 indicators, is used to analyze student drawings of scientists (Finson et al., 1995). Despite numerous studies showing persistent stereotypes of scientists as men in lab coats working in laboratories (Ates et al., 2021; Ferguson & Lezotte, 2020; Meyer et al., 2019; Thomson et al., 2019; Miller et al., 2018), less attention has been given to the role of these perceptions in learning outcomes, such as academic achievement in science class. Researchers in this study sought to address how stereotypical representations of scientists held by science learners influence their academic achievement in middle school science classes.

Method

Study context

This study is part of a larger research project funded by the National Science Foundation, which aims to expand the understanding of culturally responsive teaching and technology integration on middle school students' engagement, attitudes, and achievement in science. The project included multiple schools in the Midwest, but this study focuses on data collected from students at one urban middle school in the region.

Participants

Participants in this study consisted of 42 students taught by two middle school science teachers. Of the 37 participants for whom demographic data was available, about a third (29.7%, n = 11) identified as male and two-thirds (64.9%, n = 24) as female, with two students (5.7%) responding with "Prefer not to say". In terms of race/ethnicity, about half of these individuals self-described themselves as White (56.9%, n = 21), with the remaining participants (43.2%, n = 16) describing themselves as another race/ethnicity (e.g. Asian, Black/African American, etc.).

Data sources

We used the DAST-C checklist, adapted from Finson et al. (1995), to measure middle school participants' stereotypical perceptions of scientists. The checklist includes indicators such as lab coats, eyeglasses, and symbols of research. Coders evaluate students' drawings by indicating whether each indicator is present or absent. The DAST-C typically calculates scores based on the quantity of indicators present, but we grouped the 16 indicators into three categories: *Scientist Appearance*, *Scientific Context*, and the *Nature of Science*, based on thematic similarities.

We collected gradebook data for student participants of this study with assistance from our middle school science teacher collaborators. Students at this school were graded quarterly based on the percentage of total points earned on assignments, quizzes, etc. Seeking to generalize our measure of academic achievement across the entire academic year, we calculated the average value of students' percent grade between the four grading periods. These values were used in the linear regression analysis described in the following sections.

Results and discussion

Following these descriptive analyses, we then fitted a linear regression model to predict students' yearly grade based on their scores on the three primary categories of DAST indicators (i.e., *Scientist Appearance*, *Scientific Context*, *Nature of Science* scores). The model was fit using Ordinary Least Squares estimation methods. Although we did observe a few potential outliers, there was little substantive reason to remove these 4 observations from our data, and the assumptions of OLS regression appeared to be reasonably met regardless. Thus, the model was fitted using all 42 responses. See Table 4 for coefficient- and model-level summaries.

Table 4
Coefficient Estimates and 95% Confidence Intervals for a Model Predicting Middle School Students' Cumulative Science Grade by Categories of Indicators Contained in the Draw-A-Scientist Test Checklist

Predictors	*Estimates*	*CI*
(Intercept)	81.97***	70.08 – 93.87
Scientist Appearance	-7.05*	-14.02 – -0.07
Scientific Context	7.02*	1.19 – 12.84
Nature of Science	-19.39**	-32.73 – -6.05
Observations	42	
R^2 / R^2 adjusted	0.387 / 0.339	

* $p < .05$; ** $p < .01$; *** $p < .001$.

Previous DAST research primarily focuses on students' desire to pursue science careers and neglects how stereotypes may influence learning outcomes (Meyer et al., 2019; Cundiff et al., 2013; Mason et al., 1991; Finson et al., 2002). This study addresses this gap by examining how conventional representations of scientists relate to middle schoolers' science grades. Findings indicate that stereotypical appearances of scientists and danger-related indicators are associated with lower science grades, while knowledge-related symbols are associated with higher grades. However, the sample size is limited, and future research should consider using multiple DAST measures for students. Overall, this study provides context into middle school students' perceptions of science and extends the DAST research by categorizing indicators into thematic structures, revealing distinct relationships between stereotypes and science learning outcomes. In future work, we hope to both utilize larger sample sizes and examine how these stereotypical perceptions might change over time.

Creating an Assessment for Research Collaborations

Rachel Bonnette, University at Buffalo, rnbonnet@buffalo.edu
Samuel Abramovich, University at Buffalo, samuelab@buffalo.edu

Abstract: Achieving transdisciplinary knowledge integration can be challenging. It calls for crossing both disciplines and practices to build new knowledge. By assessing collaborations, we could provide feedback to help guide the process of integrating knowledge. The development of such a tool begins with understanding what aspects of collaborations are important for successful knowledge integration. This poster presents examples from four interviews to make recommendations for adaptation of research frameworks towards assessment.

Introduction

Common complex challenges in Education, like literacy or systemic inequality, call for the ongoing research efforts across disciplines (Rittel & Webber, 1973). Collaborative, cross-disciplinary approaches inherent to the Learning Sciences are vital to making an impact. But, while collaboration across disciplines can be effective for innovating, the form collaborations take changes the expected output of a research project. Additionally, difficulties fully integrating knowledge across groups (e.g., research practice partnerships or participatory design studies) can hinder the level of innovation and inclusivity these approaches can offer. Thus, tools designed to measure these impacts are critical for helping us to better understand and improve the collaborations within the Learning Sciences.

Assessing collaborations in the learning sciences

To design an effective tool for examining and guiding the collaboration process within Learning Sciences research, we explored existing frameworks and research on multiple disciplinary collaboration, focusing on those that distinguished between different levels of knowledge integration. These were few, and none provided a framework for assessing Learning Sciences collaborations. We focused on the MIT-D framework, which proposed a comprehensive general framework for studying elements of multi-, inter-, and transdisciplinary collaborations on research projects in any field (De Oliveira et al., 2019). Although often referred to generally as “interdisciplinarity” in the Learning Sciences (Sawyer, 2005), Choi and Pak (2006) identified different forms of knowledge integration occurring in collaborations across domains, each of which are used in Learning Sciences research. Multidisciplinarity, interdisciplinarity, and transdisciplinarity denote different levels of collaboration, with ease of collaboration decreasing as potential for innovation increases (see Figure 1, below). Transdisciplinarity builds on individual (multidisciplinary) and researcher-only (interdisciplinary) collaborations to holistically incorporate the scientific abilities of researchers with stakeholders’ inherent expertise (Bernstein, 2015), but is the most difficult to implement effectively. Students, teachers, and other stakeholders typically do not share the same type of education or training as researchers, which can complicate knowledge integration and create power imbalances in collaborations (e.g., Maynard et al., 2020). Using the MIT-D framework, researchers could study units (e.g., scientists or research projects) on a combination of four dimensions (Individual Abilities, Content, Collaboration, Outputs and Outcomes). We used this framework instead as the starting point for an inquiry into the relevant categories of assessment in Learning Sciences collaborations. However, this framework presents two significant limitations to its use as the foundation of a collaboration assessment in the Learning Sciences. First, as the Learning Sciences often targets complex educational problems situated within multiple levels of social context (Nathan & Wagner, 2010), an effective framework should include variables at multiple scale levels, as well as considering inputs and outputs impacting the same research project. Second, the framework is too general to be used directly as an assessment instrument, instead intended as a foundation for additional inquiry. In this case, we sought to tailor examples and framework attributes to examining problems within education research (e.g., “facilities and equipment’s suitability to research” suggests physical sciences). “Access to data” might be a more relevant component of successful education research collaborations. Bearing these limitations in mind, we sought to identify the core aspects of Learning Sciences collaborations that should be assessed to support innovative research outcomes.

Methods

We conducted semi-structured interviews with four Learning Scientists in the United States. Our interview protocol was based on the MIT-D Framework and additional collaboration and Learning Sciences literature (e.g., Alvargonzález, 2011; Choi & Pak, 2006; Pea & Linn, 2020; Peffer & Renken, 2016). Interviews were 30 minutes long, conducted via Zoom, and transcribed for analysis. We used provisional coding, an exploratory method that uses a "'start list' set of codes prior to fieldwork" (Miles & Huberman, 1994, p. 58) and evolves as researchers analyze the data, based on our literature review. We discussed the coding scheme and applied it independently to interviews in multiple passes to achieve agreement about the final, two-level coding scheme (Saldaña, 2015). This poster presents the final coding scheme displayed in a matrix, with first level codes presented as nested within second level codes.

Preliminary findings

Themes explored in this analysis revealed opportunities for utilizing and adapting the MIT-D Framework for the creation of a knowledge integration assessment tool (see Table 2, below). Themes are discussed fully in this poster. Within each category of input (research team or organization), the four themes on the left speak to significant considerations that impact both ability to collaborate and integrate knowledge within transdisciplinary research teams. Outputs resulting from these factors include both scientific production as an endpoint (e.g., the publication of research findings) and input for future collaborations (e.g., building networks for future research or the individual skill and expertise development of researchers).

Table 2

Proposed foundations of collaborative, integrative transdisciplinary research.

	INPUT TYPE		**OUTPUT**
	Research Teams	**Organizations**	**Impacts**
Problem Space	*Research Problems*	*Priorities*	*Production*
Relationships	*Cooperating*	*Collaborative Culture*	*Networks*
Knowledge	*Representing*	*Scientific Production Resources*	*Growth*
Research Activities	*Conducting*	*Integrative Resources*	*Domain Integration*

Conclusion

This revised framework could form the foundation for future Learning Sciences collaboration tools or assessments. Research teams would benefit from ways to gauge their level of knowledge integration and build intentionality into collaborative practices. Notably, not all variables in a project are within collaborators' control, but nevertheless suggest consequences for the effectiveness of collaborations. Next steps for this research include the incorporation of interview data on non-scientist Learning Sciences research collaborators to further align the framework and design assessments to support collaboration.

Navigating Tensions: Dominant Traditions and Culturally Sustaining Practices in Music Learning

Lora Cawelti, University of California, Irvine, lcawelti@uci.edu
Kylie Peppler, University of California, Irvine, kpeppler@uci.edu

Abstract: Culturally sustaining pedagogies offer a complex way of thinking about arts learning. In this single case study, I analyzed an interview with a young musician, exploring his experiences with both dominant and culturally sustaining learning. I found that teachers create culturally sustaining environments and ensembles, and young artists can cross boundaries to author their own culturally sustaining learning practices. Implications for supporting young artists to articulate, navigate, and confront their own cultural and scholarly influences.

Introduction

As young artists engage in learning and making music, they experience tensions in the ways arts practices are prioritized or marginalized in across learning settings. Culturally sustaining pedagogies (CSP), (Paris & Alim, 2014), offer a complex way of thinking about arts learning (Dahn et al., 2022). This asset framework helps us understand current conflicts and tensions in academic contexts, and encourages centering nondominant perspectives in teaching artistic theories, artistry, and histories (Peppler et al., 2022). One way adolescent artists learn is through engagement in identity processes (Halverson & Sheridan, 2022), seeing aspects of their cultural identities respected and reflected in their academic arts classes is legitimizing. Culturally sustaining arts practices can be particularly meaningful for those from non-dominant backgrounds who may not feel represented in mainstream academic settings (Pepper et al., 2022), however arts curriculum in academic contexts and cultural institutions is largely rooted in patriarchal, Eurocentric traditions (e.g., Charland, 2010).

The theoretical foundation driving my inquiry for this poster is CSP, specifically through connected arts learning (Peppler et al., 2022). Connected arts learning offers “a framework for how to support learner-centered and equity-oriented creative educational experiences” (Peppler et al., 2022, p. 265), positioning interests, relationships, and opportunities as key to culturally sustained learning. By better understanding how artists learn across contexts, learning scientists and educators might better design and evaluate programs and spaces toward inclusive, CSP. I consider how artists engage in music learning by asking the following questions: *How do young artists experience both dominant arts practices and culturally sustaining arts practices in academic settings? How do they create opportunities for self-driven culturally sustaining arts learning, making, and performing?*

Methods

This poster is based on a pilot study conducted in preparation for my dissertation in which I interviewed five young adults. Four had just graduated from college and one was in his final year; all were either music or theatre majors. For this single case study (Cresswell & Poth, 2018), I focus on one representative case, Miles, a 22 year old Black, male, saxophonist who grew up in a middle class Black neighborhood in greater Los Angeles and attended college in Orange County, California. The interview questions were based on culturally sustaining frameworks (Paris & Alim, 2014) and connected arts learning (Peppler et al., 2022). I analyzed the interview by creating an event history timeline with specific quotations to support each connected arts learning experience. I then interpreted the timeline, looking for learning experiences where Miles identified either culturally sustaining or dominant arts practices, then memoed to interpret each moment (Cresswell & Poth, 2018).

Findings: In school, out of school, and authoring CSP

Miles described a range of experiences across in-school and out of school contexts. Similar to prior research (e.g., Charland, 2010), Miles characterizes foundational courses and ensemble experiences in music, in both high school and college, as rooted in western practice. These in-school courses are considered the fundamentals and core to continuing an academic music pathway. In his high school music theory courses, they learned what he calls, “the ‘rules’ or the music theory associated with classical European music, in the common practice era, which is basically about 1600-1900.” This continued into college where he learned musicianship, theory, and history from “almost strictly classical, European” perspectives. When Miles reflected on his academic foundations, he emphasized that he did enjoy learning and playing classical music even though he only engaged with it when at school. He explained that, “as far as seeing myself with the music or relating to the context in which the music was made, I wasn't really aware of that stuff until late high school.” In his earlier learning experiences he was just happy to learn and play. It wasn’t until around his junior year that he began to question the disconnect between cultural music (heritage/ethnic, pop/youth) and classical music that followed the “rules.”

Not everything happening at school was rooted in western tradition. Miles did encounter learning that came from a culturally sustaining place. The first example of CSP that Miles shares, came from an engaged teacher who moved beyond the traditional curriculum to make learning meaningful for his students. Miles describes an encouraging learning environment, “giving all the props to my band director, because he wasn't a jazz major. He's a classical oboe player who just busted his butt to be able to give us the resources to be able to learn for ourselves.” This teacher moved beyond his own experience to make sure his students had access to music and genres to which they could connect. This was meaningful for Miles, and he identified the extra work it took, “to this day I’m baffled about how he did [it].” Additionally, Miles explained that while most ensembles, band and orchestra, at schools play traditional western repertoire, in jazz band, “I was able to play other music because jazz [band] just ends up being ‘not classical.’ They end up playing a lot of pop tunes, funk tunes, basically it just becomes an outlet.” The jazz band became a special context for CSP in school, allowing students to explore a range of repertoire and perform music that they were excited about and related to.

Through his school years, Miles emphasized the ways he and his peers created self-driven opportunities for CSP through organizing their own band, practicing and performing music of their own choice, from jazz to rock and roll. “A couple of cats and I made a band, and that was our vehicle for playing for those three years. We had people in different grades in the band; played in those festivals in different places, driving to Venice and playing at different restaurants and things of that sort.” This band became a space to bring individuals’ culture and pop-culture into one context, where students were self organized and created music together.

When Miles reached college and took his foundational courses, he started to question what he saw as missing cultural contexts. Though a few professors were thinking about CSP, like one who taught a course on only female composers, most were still deeply entrenched in western musical traditions. Miles realized he could make choices about the musicology and history that he learned, that he could value diverse cultural perspectives in his academics. He took an independent study where “The purpose was our curriculum, as is taught in the states, for music. Through that process I read papers and became really really aware of how bound these things are. Then I started noticing how it affects students in the way that they think.” Here Miles made a change from being a consumer of his academic learning, to becoming an author, or what he calls being a “proactive learner.” As an author, he made an intentional effort to decenter dominant, Eurocentric practices, incorporating critical readings and diverse culturally connected perspectives.

In the past, Miles had taken his cultural interests to out of school contexts, like performing with his band. Now, Miles realized that he could compose music, from within his own program, and present it legitimately within the academy. “It was an intermediate composition class where we worked with dancers, and the theme was climate change. So basically, I made a piece that depicted humanity losing their battle to climate change.” Here Miles described how he was able to incorporate an aspect of his generational and political culture into the music that he composed in class, for other students.

Conclusion

This case highlights the ways dominant practices are taught as foundational to learning music theory, history, and through repertoire. While Eurocentric perspectives still dictate the “rules” of music, CSP occupies a special place in schools, especially in high school contexts before students have interrogated their prior learning. As young artists enter adulthood, they are able to reflect on how their learning affected their artistic, academic, and professional choices. Applying culturally sustaining frameworks will help us understand the ways social and scholarly knowledge constructs affect artistic thinking and arts making, so young artists better understand how to articulate, navigate, and confront their own cultural and scholarly influences.

“Sparking” Math Talk in a Fraction Ball Classroom Lesson

Ethan S. Lin, University of California Irvine, eslin1@uci.edu

Andres S. Bustamante,University of California Irvine, asbustam@uci.edu

Abstract: The Fraction Ball has demonstrated positive impacts on rational number learning. fractions and decimals through basketball. We explored activity features that sparked math talk discussions. We found that 6th graders engaged in minimal math discussions that were mostly preceded by teacher prompting. Future designs might leverage student prior knowledge by incorporating increasingly difficult questions to support peer-led discussions.

Introduction and background

The current study explores how a game-based math lesson supports math talk in a 6th grade math classroom. Fraction Ball is a basketball game where arcs and colors are added to the design of the court to support fraction and decimal learning. Fractions are a notoriously difficult content area (Braithewaite & Siegler, 2018), Fraction Ball is a way for students to stay engaged with difficult content through play-based interactions. Previous research on Fraction Ball has shown significant improvements on rational number reasoning (Bustamante et al., 2022) and the math language environment (Alvarez-Vargas et al., under review). This study investigates how the activities support student math dialogue.

Fraction Ball classroom lessons were guided by the learning science principles that students learn best when they are engaged in meaningful, socially interactive, iterative, and playful activities (Hirsh-Pasek, et al., 2015). We contribute to research on developing active learning opportunities enriched by conversation as dialogue math vocabulary connects students' understanding of abstract concepts to improve understanding (Purpura et al., 2019). Though, Fraction Ball helps students learn abstract rational number concepts and groups’ gameplay increases the rational number language (Alvarez-Vargas et al., under review), open questions remain regarding the extent of the math talk episodes between students and what activity routines spark dialogue. We identify what preceded the students’ math talk to form design conjectures that elicit mathematical classroom discussions. We engaged in participatory design to understand Fraction Ball activity design influences math discussions in a 6th grade classroom, and ask (1) *How do groups engage in math discussions during the classroom activity?* and (2) *What events precede and encourage group math discussion?*

Figure 1
Right: A group engaged in the Fraction Ball Sparks Activity. Right: The students worksheet sample.

Methods

As part of a larger design-based research project focused on Fraction Ball, we collected video data during a 16-minute lesson involving students watching a WNBA game and hypothesizing the shot locations (Figure 1). We analyzed video and audio data, transcribing interactions of two student groups who provided consent. We utilized a validated coding scheme (Alvarez-Vargas et al., under review) to quantify math talk occurrences and their sequence within each group. Additionally, we identified the events preceding math discussions using the Levels of Math Talk Community Framework (Hufferd-Ackles, Fuson, & Sherin, 2004).

Findings

Table 1 presents the total math talk utterances and what precedes them by group. In group one, four students engaged in 19 math talk episodes, which included an average of 4 math talk utterances per student. Of the 16 talk episodes, 12 were preceded by the teachers' active classroom facilitation including asking questions, directing group discussions, probing for student thinking, and clarifying student's explanations. In group two, the four students engaged in 14 math talk episodes, which included an average of 5 per student. Of the 14 talk episodes, 11 were preceded by the teachers' active classroom facilitation including asking questions, directing group discussions, probing for student thinking, and clarifying students' explanations.

Table 1
Events that preceded math talk episodes by group.

Preceded math talk?	**Definition**	**Example**	**Group 1**	**Group 2**
Teacher prompts	Teacher prompts tasks or asks group targeted questions.	Teacher: "Talk to your group and get your final score."	12	11
Sparks video	Actions in video elicit student explanation or questioning.	Student: "That's two whole points right there."	4	0
Student directed questions	Students ask questions to clarify features of the activity. [not explicitly encouraged by activity]	Student: "Oh this [court section]. Which one are we talking about?"	1	2
Worksheet	Worksheet task elicits student explanation or questioning.	Student: "Wait, how did you get this?" Gesturing toward worksheet	1	0
Student Prior Knowledge	Students reference experiences relevant to court or math not explicitly taught in this class session.	Open discussion among students about what the basketball court looks like	1	1
		Total Math Talk Utterances	19	14

Discussion

Our study reveals that teacher prompting primarily instigated student discussions, with secondary contributions from worksheet comparisons and student-directed questions when calculating different total scores. This preliminary analysis paves the way for further exploration of math talk across all Fraction Ball lessons, potentially informing future designs to encourage peer-led discussions.

Exploring Teacher Beliefs Around Critical Action Curriculum: Outcomes From a Learning Exchange

Nisumba Soodhani K, Indian Institute of Technology Bombay, nisumba@gmail.com
Preeti Raman, Massachusetts Institute of Technology, preetirm@mit.edu
Renato Carvalho, University of Toronto, renato.carvalho@utoronto.ca

Jim Slotta, University of Toronto, jim.slotta@utoronto.ca

Abstract: This paper reports on a co-located critical action curriculum design workshop held in India, as part of a two-year learning exchange with teachers. The workshop drew on prior work with teachers on local issues. The research found that teachers believed the local context was important to critical action curriculum design, and that such curricula could motivate students with low interest. The paper contributes to understanding teachers' self-efficacy in designing critical action curricula.

Introduction

The CALE (Critical Action Learning Exchange) professional learning community supports teachers in developing culturally responsive and empowering pedagogies for K-12 pupils confronted with economic, health, and sociopolitical challenges (Carvalho et al., 2021). This paper examines the lesson plans and attitudes toward critical action curricula from a two-day workshop conducted on September 2022 for secondary school teachers in Bengaluru, India. Teachers created lesson plans addressing socio-environmental issues affecting their students during the workshop, which included a session on TinkerCAD and Scratch. The study addresses the need for culturally responsive pedagogies that encourage students' local purpose in authentic cultural contexts and belief systems. The following research questions guided our work: *(a) What are some attributes that teachers perceive as central to an effective critical action curriculum? (b) How did such curriculum co-design influence teachers' perceived instructional self-efficacy?* Critical pedagogy is the guiding framework for the CALE curriculum, which empowers students to contribute to the resolution of critical issues and overcome their sense of powerlessness (Freire, 1970). Through critical consciousness, students challenge oppressive structures and ask questions while teachers guide them with necessary resources and support. Teachers' attitudes and beliefs are crucial in integrating critical action into the curriculum, and understanding their self-efficacy beliefs can contribute to the success of innovative projects like CALE. Self-efficacy refers to belief in one's capability to organize and execute courses of action (Bandura, 1997). Critical action integration is a new concept for Indian teachers hence teachers' self-efficacy can help us understand their instructional goals and aspirations toward critical action in the classroom.

Method

In partnership with a teacher-leader from a secondary school in Bengaluru, India, a workshop was conducted to help teachers design lesson plans. The workshop was designed based on the school's priorities and utilized the six components of the CALE framework to develop open-ended prompts. Fourteen female teachers with varying levels of teaching experience participated in the two-day workshop, which was led by two researchers for 2.5 hours per day. Six science teachers attended on the first day, and seven mathematics teachers attended on the second day. The workshop included icebreaker activities, critical making and critical action discussions, and hands-on activities using TinkerCAD and Scratch. Additionally, a storytelling approach was used for critical action. After the workshop, teachers discussed socio-environmental and economic issues with their students and submitted lesson plans based on common themes. Five teams (2 per team) submitted their lesson plans, which served as primary data sources for the study. The teachers' self-efficacy, beliefs, and attitudes were assessed using a survey questionnaire adapted from Bandura's teachers' self-efficacy scale (Bandura, 2006). Participants were asked to indicate their agreement on 11 items (e.g., critical action can enhance students' motivation to learn) on a five-point Likert scale ranging from strongly disagree to strongly agree.

Analysis & findings

The five lesson plans submitted by teachers were analyzed using content analysis (Mayring, 2015). Individual researchers analyzed the lesson plans and came up with codes that were grouped into broad categories after conflicts were resolved. Thematic analysis was conducted, and themes emerged, including context-specific problem identification, curriculum integration, criticality & action orientation, suitability of activities, and inclusion of 21st-century competencies (Clarke et al., 2015). The results of the teacher attitude and belief survey questionnaire were compared with the lesson designs to gain more insight into the teachers' views on critical action. Our analysis focused on answering the first research question, exploring themes that arose in relation to effective CALE curriculum design. The theme of 'context-specific problem identification' emphasized the importance of selecting a problem statement specific to the local context. For instance, teams 1 and 2 focused on wastewater management through critical making and rainwater harvesting; teams 3 and 4 addressed economic disparity; and team 5 tackled global warming. This theme is particularly important for Bengaluru, a city recently affected by floods and characterized by financial inequality. 'Curriculum integration' emerged as an essential theme, emphasizing the integration of school subjects and critical action. Three teams explicitly connected curricular concepts. The theme of 'criticality and action orientation' emphasized an actionable plan by teachers to encourage students to take a critical perspective on the issue. For instance, an excerpt from team 1:

> *"Students should visit and collect information from the people who are affected. Conduct water quality tests. Develop and test a model for an innovative and efficient water filtration system and recover resources."* - Team 1

The above quote reflects teachers' understanding of critical action and their belief in enacting it with an actionable plan. However, in one of the cases (team 5), their approach was generic and the lesson plan was devoid of actionable items related to the curriculum.

> *"Projects that reduce the global temperature. Avoid products with a lot of packaging. Drive less, recycle more, plant a tree, etc. Make your voice heard by those in power, respect & protect green spaces, cut consumption & waste, and reduce your energy use."* - Team 5

For Research Question Two, we used both quantitative and qualitative analyses to examine participants' attitudes and beliefs toward CALE. Survey responses and lesson plan designs were used for this purpose. Our findings showed that participants had a strong interest in CALE approaches (M= 4.0, SD = 0.0), and felt more confident using them in the classroom (M= 4.14, SD= 0.37), indicating a level of self-efficacy in critical action. However, despite this positive perception, participants reported feeling uncomfortable using CALE approaches in the classroom (M= 3.71, SD = 0.75), which was further confirmed through qualitative data. 80% of participants reported a 'fear of change' or 'lack of time' as reasons for this discomfort. Nevertheless, participants believed that a CALE-based curriculum would help in motivating students (M= 4.57, SD= 0.78) and promoting collaboration (M= 4.57, SD= 0.53) between students. They also felt that CALE approaches would instill 21st-century competencies in children (M= 4.14, SD= 0.37). Our analysis also revealed that team 1 had a better understanding of critical action, while team 4 was less flexible in integrating it into the curriculum. The suitability of activities also differed among teams based on their chosen problem statement.

Conclusion

The study aimed to prepare Indian high school teachers to integrate critical action in classroom teaching. Results showed teachers were interested in integrating it, believed it could develop students' skills, and were confident in implementation, but not comfortable due to a lack of time and fear of change. Acknowledging fear of change is a positive step. Understanding teachers' views is important as they are forerunners of the CALE community. The study helps understand the relationship between teachers' self-efficacy and critical action understanding. The limited participants and contextual nature of the study must be considered. The longitudinal study is part of a larger project involving science and math teachers in southern India, with plans to expand globally. The teachers' lesson plans being implemented soon.

Understanding Higher Education Teachers' Re-design process and Design Principles: Two Cases from Mainland China

Kun Liu, The University of Hong Kong, u3513487@connect.hku.hk
Nancy Law, Faculty of Education, The University of Hong Kong, nlaw@hku.hk
Jianhua Zhao, Southern University of Science and Technology, zhaojh@sustech.edu.cn

Abstract: Enhancing teachers' learning design capacity is increasingly recognized as important in helping teachers create effective learning environments and experiences. However, there is limited understanding of university teachers' existing design practices and motivations for course improvement. This study examines the course re-design process of two teachers at a Mainland Chinese university. The findings reveal different design processes, driving motivations, and challenges encountered, and the need for a common language to communicate LD concepts and pedagogical decisions.

Introduction

The increasing emphasis on technology-enhanced learning and student-centered approaches in higher education necessitates significant changes in teachers' practices, skills, and beliefs (Goodyear, 2015). Learning Design (LD) aims to involve teachers, learning sciences researchers, and instructional designers in creating pedagogically aligned learning environments and learning experiences (Mor, Craft & Maina, 2015). Despite efforts to develop frameworks and tools to enhance teachers' LD capacity and competence (Laurillard et al., 2013), there is a paucity of research on how teachers go about the design process in their everyday professional practice (Bennett, Agostinho & Lockyer, 2017). Understanding these processes is crucial for effective intervention programs supporting professional learning and technology-enhanced pedagogical innovations (TEPIs). This study investigates higher education teachers' design decisions when revising previously taught courses, differentiating between novice teachers adapting existing designs and experienced teachers revising their own courses. It addresses the following research questions: 1. What guiding principles do teachers use when redesigning a course for the first time, and how do they go about the redesign process? 2. What motivates teachers to redesign their courses, and what approaches do they take in the redesign process? 3. What challenges emerge during the redesign process, and what support do teachers need?

As the design process is multi-layered and complex, decisions must be made at various levels, from course level to individual learning tasks (Law et al., 2017). Teachers play a crucial role in transforming pedagogical innovations into practice, with the success of curriculum innovations largely dependent on their understanding and engagement. By examining teachers' design processes and decisions in authentic design practices, this study aims to inform the development of effective support programs for successful TEPIs.

Methodology

This study is part of a larger design-based project that aims to understand authentic design practices of higher education (HE) teachers. Insights from the study will inform professional learning programs and the design of LD supporting tools to enhance teachers' LD practices and capacities. Conducted at a Science and Technology university in Mainland China, the study purposively recruited in-service teachers with experience in course redesign. Consent was obtained from the 16 teachers who participated in the study. Face-to-face interviews were used as the main data collection method, content analysis was employed for data analysis. This paper discusses and compares two of the teachers' course redesign process. Teacher A, a less experienced teacher, took over the first-time teaching of a major elective course for Biology undergraduate/master students with existing course materials. Teacher B is an experienced teacher with overseas teaching experiences before joining this university several years prior to the study.

Results

This study explored how teachers redesigned their courses and what motivated them to make subsequent revisions. Results of the analysis for Teachers A and B are summarized below.

Teacher A's first round of redesign was guided by three principles: integrating theory with practice, linking research and industrial applications to teaching, and using authentic contexts and materials. Guided by these design principles, his first round of redesign followed a top-down, broad to specific process, and mainly focused on preparing PowerPoint slides, planning for how to conduct the lectures and lab sessions. Changes in the second round were mostly to the course structure and learning activities, including new content, re-sequencing topics, and integrating ICT tools. Challenges emerged in designing effective learning tasks and applying educational theory to practice. Teacher A expressed a need for effective design templates of successful practices and a tool to facilitate the representation of the learning activities and support design process.

Teacher B had taught the course he redesigned three times before, adhering to two principles: situating students' learning in a social context and engaging them in authentic disciplinary practice. Based on these design principles, the course was divided into blocks, each with a sequence of learning activities (lectures to illuminate theory, lab work, and group projects), and underpinned by the same pedagogical strategy. The group projects require students to engage in disciplinary practices such as problem formulation /problem solving and play an important role in helping students to achieve the targeted learning objectives. Teachers B's three cycles of redesign were driven by various factors such as observed/reported difficulties experienced by students and increases in student numbers. The first redesign involved splitting the class into two groups and adding a discussion component to address students' difficulties in conducting labs and projects. In the second redesign, co-teaching, cross-course collaboration as well as university-enterprise collaboration were introduced. The third addressed students' difficulties by providing supplementary instruction in Chinese (English was the official medium of instruction for the course) and simplifying group projects.

Discussion

This paper presents two cases of course redesign with notable differences. Teacher A's redesign was more content-focused, loosely guided by some pedagogical design principles, which is similar to previous reported studies (Stark 2000; Bennett et al., 2017). Teacher B's cycles of iterative redesign were underpinned by the same set of consistent design principles, demonstrating clear design granularities, and providing clear rationale that drove the redesign decisions. Teacher B's redesign practices were systematic operationalizations that paid attention to the coherence and alignment of the underpinning pedagogical design principles, which is rare in literature reporting on authentic teacher practices.

These findings suggest that pedagogical considerations and design decisions are interconnected. A focus on coherence and aligned pedagogical considerations at different design granularities may promote constructive alignment in learning design (Nguyen & Bower, 2018). This paper also contributes to the literature on why and how university teachers redesign a course. There are a variety of reasons that drive the redesign of a course, including students' feedback and their diverse learning needs, contextual factors such as the learning spaces and human resources, and faculty teaching and learning policies etc. The study also identifies challenges and similarities in teachers' needs, highlighting the importance of a common language for effective design articulation, communication, adoption, and reuse. This supports the call for a unified way of documenting and describing teaching practice, guiding teachers to better communicate design ideas for professional learning. This will in turn serve as a stimulus to improve teaching and learning quality (Law et al., 2017; Law & Liang, 2020) and foster professional learning communities around learning design across institutions and disciplines.

A Dystopian Game for Change: Building Asynchronous Learning Network Through Co-Design Partnerships Across Disciplines

Kathy H. Zhou, James D. Slotta,
kh.zhou@mail.utoronto.ca, jim.slotta@utoronto.ca
OISE, University of Toronto,

Abstract: This paper is a design-based study of a collective inquiry-based game set in a dystopian world that engages high school students to reflect critically and build media literacy within various disciplinary contexts. We report on the preliminary design activities for an educational game undertaken closely with technology consultants and three high school teachers (Arts, English, and STEM). This paper reports on our first phase of design-based research (Brown, 1992), in which we work closely with teachers, game design experts, and technology consultants to develop an understanding of learning goals, gameplay dynamics, and learning environments (Gee,2005; Squire, 2006; Djaouti,2011), that would be suitable for students to collaboratively building an embodied game-based learning experiences.

Theoretical perspective

How can we help students thrive in a world of disinformation, convoluted and messy social dynamics, and the fluid identities that characterize their lives and flavor their learning? 21st-century education must provide future citizens with learning that empowers them against an uncertain or inequitable future (Freire, 2020). Student resilience to fear and anxiety must grow organically through self-direction, self-organization, and self-regulation (Garrison, 1998; Hayes, 2006; Peters & Slotta, 2010; Papacharissi, 2011). Our work is guided by the notions of critical pedagogy (Freire, 2020; Giroux, 2020), learning communities (Brown & Campione,1996), and collective inquiry (Peters & Slotta, 2010). Our approach is to develop an asynchronous learning network for collective inquiry in hybrid high school classrooms in a dystopian universe. *The Fall of Artica: A Way Back Home (FoA)* aims to facilitate students' critical thinking and collaboration with various contexts, engaging critical actions in embodied synchronous and asynchronous game-based learning environments. The dystopian settings can support meaningful narratives and interaction modes, enabling community building through collaboration, communication, design, and critical making (Carvalho et al., 2022). FoA aims to connect students' identities with critical conversations around dystopian literature, empowering them with meaning and purpose for the different subjects they learn. This poster presents our progress in developing the FoA game concept, including theoretical perspectives, game elements, and a co-design method for developing gameplay.

suburb area of Nuovartica city first, but soon realized they needed to get further away. Thats why they moved here 18 years ago. There are hundreds of people in Crescent Garden, many people died in the recent years from accident and disease. The biggest problems in Crescent garden are lack of clean water and need for good medical care. The residents in Crescent Gardem are afraid that the community won't last too many more years, because they think the water is going to run out completely.

i heard that you guys are in trouble

Yes, we're having a lot of trouble lately. Our biggest problem is that we're running out of clean water. We've been trying to find a new source of water, but it's been difficult.

do you have enough to eat

We have enough to eat, but it's not always the best quality. We're trying to grow our own food, but it's hard to do without clean water.

Research questions

(1) How do game elements vary with curricular context? (i.e., English, Arts, and Science?) (2) How can technology support the face-to-face collective inquiry-based gameplays in critical pedagogy and disciplinary learning afforded by the narrative, conceptual, physical, and interactive game elements?

Methods and data collection

We adopted a five-stage co-design method to create the first playable prototype: Understanding design goals by meeting with three teachers (Arts, English, and STEM) to understand their learning goals and required resources. Through three co-design meetings with each teacher, develop shared understandings with teachers about G4C, critical pedagogy, and learning communities; understand teachers' courses and curriculum; develop broad ideas about what *FoA* could look like. This study collects and analyzes different forms of data: (1) Interview video and audio recordings, transcripts with three teachers, and a new media expert. (2) create material: backstories, transcript of the chat between students and an A.I. empowered learning assistant (3) collect student feedback and artifacts (game concept art such as characters, environment, and props) throughout the gameplay (4) share student artifacts online to students outside of visual art class (5) narratives and quests that create by other classes or from another school.

Findings and discussions

Co-designing with three teachers, we articulated the learning goals, curricular elements (quests, cards, characters, etc.), and gameplay experience that addresses their course requirements. One art teacher anticipated that students would be excited about designing quests and creating game assets for fellows. The gameplay is a generative model in which students engage with the existing plotlines and interact with characters to develop game elements based on their own or collective understanding of the plotlines. Students choose quests from the character that match their personal or collective interests. They allocate, combine, and create game elements and level up their skills in designing and creating. Progress within the game is measured by their level of engagement and the connection they create between the game elements and the wider community. Gameplay is concerned with supporting the collective inquiry of students, collecting game assets guided by the plotline. Students take on "quests" and resolve challenges or solve mysteries within a community of peers by interacting with objects, characters, and other game artifacts. This way, they collectively uncover hidden plotlines and critically evaluate their co-constructed dystopian fiction (e.g., identifying misconceptions or contradictions). Engagement in a game narrative creates the need to find information, allocate resources, collaborate with others, practice communication skills, cross-compare evidence, make critical decisions, think systematically, etc. Although the project is in its early stage, it has opened many conversations about designing learning experiences in specific contexts. This work moves us toward an accessible and inclusive game-based learning environment, which may open further research opportunities relating to learner engagements, tangible and embodied interactions, blended learning, empathy, social justice, cultural inclusiveness, critical making, and more.

Supporting Focus on the Process of Learning, Rather Than the Product, in a STEAM Activity

Blakely K. Tsurusaki, University of Washington Bothell, btsuru@uw.edu

Abstract: This study explores how the design and facilitation of a STEAM activity during a professional development workshop supports a focus on learning through the process. How the activity was introduced and the whole group reflections – both mid-activity and at the conclusion of the activity - supported participants in making observations and focusing on the process, rather than the end product.

Introduction

Learners are often focused on the outcome or product of an activity, rather than the process of learning. The end goal is to get a correct answer or result on a lab or exam or to replicate an example artifact. A focus on the product or outcome is reinforced when learning is assessed through final answers and products. Focusing solely on products has been found to stifle learning, as it does not value learning that occurs during the process of working through an activity (LeJevic, 2013; Perignat & Katz-Buonincontro, 2019). However, many recognize that value should be placed on learning that occurs during the process of completing an activity, experiment, or project. For example, the *Next Generation Science Standards*, a set of standards used by many states in the United States, emphasize the development of science and engineering practices as an important aspect of learning science and engineering (National Research Council, 2013) and the *National Core Arts Standards* include a focus on creating art through processes such as conceptualizing, developing, and refining (National Core Arts Standards State Education Agency Directors of Arts Education, 2014). In this study, we begin to explore: How can the design and facilitation of an activity provide opportunities for learners to focus on the process, rather than the product?

Framework and methods

To address this question, we draw on the Tinkering Design Principles framework developed by Petrick et al. (2013), which positions tinkering and making as forms of legitimate peripheral participation in STEM and STEAM communities of practice. This framework emphasizes, among other aspects, facilitation through modeling STEAM practices, inviting learners to participate via multiple pathways, and prioritizing reflection. The present study uses this framework as a basis to investigate the ways in which such facilitation can support a focus on process, rather than product.

The context for this study is a two day, in-person STEAM (Science, Technology, Engineering, Art, Mathematics) professional development workshop. This study focuses on one of the activities that emphasizes science and art called Suminagashi, a process of paper marbling developed in Japan. Suminagashi inks are dropped into a bin of water, where they float, spread, or sink depending on the density of the ink, the application technique, and the surface tension of the water. The participants use the ink bottles, brushes of various sizes, and other objects to apply and manipulate the ink and create designs (Figure 1) which are then transferred from the surface of the water to various types of paper.

The data for this study consisted of video recordings of the Suminagashi activity from five different in-person workshop groups that were held in geographic locations across the United States. The participants included educators from a variety of institutions, including public library systems, science centers, art museums, and K-12 schools. We focused analysis of the data on the whole group reflection discussions of the activity. A facilitator introduced the activity by demonstrating the process of Suminagashi and then the participants had time to create Suminagashi prints. The facilitator led two whole group discussions – one in the middle of the activity and one at the end. The participants were paused during the middle of the activity to look at each others' prints, ask questions about techniques, discoveries, and choices, and encouraged to think about what they had tried out and observed while creating their prints. A similar discussion was held at the end of the activity to reflect on their learning during the activity. We transcribed the video and analyzed the transcripts using emergent coding (Strauss & Corbin, 1998), looking specifically at how participants talked about how the facilitation and design helped them focus on the process of doing the activity.

Findings and discussion

Overall, many participants noted the ways that both the design and the facilitation of the activity opened up opportunities to focus on the process. Specifically, participants noticed that activity was designed to focus on open-ended exploration, with the facilitator emphasizing that there was “no right way” to approach the activity and using language to position the activity as an “investigation” that relied on observation and other science and art practices. For example, one participant said, “I like that it started out more open ended though, just exploring, because it made me more, feel more free to just dive in” and another added that it “took the pressure off.” One interpretation of these comments is that learners sometimes feel pressure to produce a particular kind of product, and the actions of the facilitator in removing the pressure off of focusing on a final product allowed participants to focus on exploring the process of Suminagashi. Another participant provided more detail about how the facilitation allowed her to focus on the process, saying:

> I think how she [facilitator] started with close observation. And giving us an opportunity to observe and ask questions. Which when we came to our tables, we continued to act in that way. Where if she’d set it up and said, okay, this is what Suminagashi is, you put some drops, and then you put your paper in and it makes a design. We would have come back and just done that. We wouldn’t have come back and like, what’s happening?

Here, the participants discuss the importance of how the activity was introduced and how they were encouraged to make observations and explore using different materials, rather than being told a specific way to do the activity. This encouraged them to try different approaches, make observations, and try again. How the activity was structured and facilitated supported participants’ explorations in an open-ended way, rather than focusing on a specific end product.

This study reiterates the importance of the ways in which STEAM activities are facilitated. Calls for participating in authentically integrated STEAM involve drawing on a number of overlapping art and STEM practices. As legitimate peripheral participants, apprentices in STEAM learn the ways of being in practice through facilitator modeling, invitation, and guided reflection. Our study illustrates the importance of these facilitation strategies in opening up ways to focus on making and tinkering processes rather than products. Our results imply that facilitators should explicitly state norms, especially when they may be different than the norms of many learning spaces, and reinforce these norms throughout the activity. Group reflections, where participants have opportunities to observe and discuss what others have done, and then continue their own inquiry with broader insight from the group, are also useful for putting focus on the process, rather than the product.

Modernizing the ADDIE Instructional Design Framework for 21st-Century Instructional Designers

Saida Harpi, The University of Pennsylvania, Saida.Harpi@gmail.com

Abstract: This conceptual paper examines three main characteristics that support adult learning in workplace training: autonomy, motivation, and meaningfulness. To better support adult learners within workplace training, this paper proposes The Extended ADDIE model by modernizing arguably the most popular workplace training framework, ADDIE, through an intentional and explicit design process. The Extended ADDIE Model is a collaborative, engaging, and inclusive instructional design framework incorporating adult learning theory, collaborative learning theory, and inclusive learning environments.

"Until recently, there has been relatively little thinking, investigating, and writing about adult learning. This is a curious fact considering that the education of adults has been a concern of the human race for such a long time. Yet for many years, the adult learner was indeed a neglected species" (Knowles et al., 2020, p. 18).

Introduction

"It is, first and foremost, a matter of viewing learning from the perspective of the learner, because adults are not very inclined to learn something of which they cannot see the point on the basis of their own life situation." (Illeris, 2003, p. 1) Workplace training and instructional design are part of an increasingly popular industry that focuses on a group of learners that has not been researched as effectively as K-12 learning or higher education. The ADDIE model is the foundational instructional design model that is arguably still the most popular instructional design tool today. ADDIE is an acronym for Analyze, Design, Develop, Implement, and Evaluate, a highly conceptual and generalized concept that is foundational in its approach. Branch (2014) describes the ADDIE model as one of the most effective design tools, as it's a guiding framework that is active, multifunctional, situated, and inspirational. Although this model is a good basis for training, it is missing the important factors that draw connections from the content to the learner. When workplace training is designed like this, there is less emphasis on the learner's needs which risks decreasing engagement and being less effective.

Modernizing ADDIE

The Extended ADDIE framework seeks to address the learner's needs by recognizing the individualistic and cognitive process of learning and connecting it to the collaborative and social nature of knowledge building. To ensure that the learner is interested, motivated, and engaged, the designer must understand how adult learners learn and how to support their learning best. The instructional designer should intentionally design a learning environment that is cognizant of the varying needs of diverse learners. To support adult learning is to support learner autonomy, motivation, and meaningfulness. In an effort to foster independence and motivation, the designer should provide scaffolds that support the learners' autonomy through extrinsic motivations using the self-determination theory. The designer facilitates meaningfulness by first incorporating communities of practice by situating the learner in an authentic context and, secondly, by being inclusive of culturally affirming practice that affirms and creates a sense of belonging for the learners. Situating these theories into practice is further developed below, explicating the interconnectedness of these concepts within the framework.

Andragogy affirms that learners have the capacity to be self-regulated and intrinsically motivated, but to what extent? To address this, I look at the self-determination theory introduced by Ryan and Deci. Ryan and Deci confirm that while humans have naturally intrinsic motivational tendencies, it is equally as important to cultivate and support these tendencies – for it is easily disrupted by conditions that are unsupportive (Ryan & Deci, 1985). Therefore, it is not important to find how to instill intrinsic motivation; instead, it is to encourage it. It is important to lead the learner towards self-regulation through internalization and integration – which are processes that have the learner absorb a value or regulation, *internalize*, and acknowledge the regulation as their own and incorporate it as a sense of self, *integration* (Ryan & Deci, 1985). Beyond one's personal stake in professional development, a learner is situated within a socio-cultural context that the learner interacts with daily. Lave and Wenger challenge the notions of traditional learning with the concept of communities of practice. They argue that learning is not only individualistic but a social process that is historically and culturally situated. They further explain that working groups are continuously working towards a joint goal that is mutually beneficial and social by nature. Wenger writes, "Communities of practice differ from other kinds of groups found in organizations in the way they define their enterprise, exist over time, and set their boundaries" (Wenger 1998, p. 4), on top of the autonomy given to the participants as they develop their identities within the group over time. Designing the educational environment around a "community" encourages interaction between individual participants as well as interactions within an authentic context. Learners will be able to use prior knowledge to make connections to the current content; they are able to situate themselves within the greater community and the job; and, lastly, build social capital. These factors are important for the learner to fill the psychological need for competence, autonomy, and relatedness, which increases learner motivation, interest, and engagement for more efficacious workplace training.

The Extended ADDIE model

I examine and propose a modernized approach to workplace training that bridges the gap between corporate efficiency and meeting learners' needs. To do this, The Extended ADDIE Framework (Figure 1) and corresponding guidelines (Table 1) integrates adult learning theory, collaborative learning, inclusion, and intrinsic motivation into the individual and interdependent components of the ADDIE model (Analyze, Design, Develop, Implement, and Evaluate).

Figure 1
(a) The Extended ADDIE Framework (left) and (b) Guideline for the extended ADDIE Framework

	Collaborate *Communities of Practice	Motivate *Self-Determination Theory	Culturally Affirm *Culturally Affirming Practices
Engage	**Encourage** learners to share knowledge among their colleagues and work towards a mutual goal by collaborating to complete an assigned task	**Account for...** • How much autonomy the learner has • If the motivation is supported personally and with choice	**Be** *Culturally Responsive create an environment that encourages open discourse and knowledge sharing*
Experience	**Use** *authentic* activities rather than activities that are curated and structured within a specific context that is not applicable to the learner	**Account for...** • Is the motivation in accordance with an external directive • To what degree is the motivation autonomous versus controlled	**Use** Culture as a Tool *help facilitate meaningful learning that is important and relevant to the learner and their community*
Enable	**Create** lessons that encourage participation, increase social capital, and support competency	**Encourage** the learner to take an extrinsic factor and internalize and integrate it in a way that is meaningful tothem	**Provide** *Choice present culture as a tool that students choose to use*

Conclusion

The proposed extended framework addresses the learner's needs by recognizing the individualistic and cognitive learning process and connecting it to the collaborative and social nature of knowledge building. To ensure that the learner is interested, motivated, and engaged, the designer must understand how adult learners learn and how to support their learning best. The Extended ADDIE framework's guidelines delineate the learner's needs and give explicit direction on engaging the learner, enhancing the learner's experience, and enabling the learner to connect to the content. This improves the efficacy of workplace training by facilitating competency, agency, and relatability through the intentional use of andragogical principles, communities of practice, and culturally relevant pedagogy. Modernizing this framework provides the opportunity to research and enhance adult learning theory and engage a once-neglected population.

Supporting Collaborative Learning and Development of Students' Science Identities in a Biology Classroom

Elena Boldyreva, University of Toronto, elena.boldyreva@mail.utoronto.ca
Maria Niño-Soto, University of Toronto Schools, maria.nino@utschools.ca
James D. Slotta, University of Toronto, jim.slotta@utoronto.ca

Abstract: An important part of our study conducted in a Grade 11 Biology classroom was supporting students' development of science identities. This study included 55 students who participated as a learning community, co-constructing a collective knowledge base, supported by technology environments. Through the Career Exploration activity, students learned about their peers' interests and became more knowledgeable about various careers; through their subsequent discussions, students were motivated to further explore their science identities.

Objectives

A learning community approach, such as developing and advancing a shared collective knowledge base (Bereiter & Scardamalia, 2014) and supporting inquiry-oriented discourse (Fong & Slotta, 2018; Slotta & Najafi, 2013) was applied and described in this paper. In a science classroom, students are engaged with their peers in a model of a scientific community (Bielaczyc & Collins, 1999). This study examines the context of a scientific classroom learning community, and how students' interactions with peers, materials and activities can foster the development of career identity. Our research question: "How does learning in a collaborative environment supported by the KCI Model and technology contributes to the development of students' career identities?"

Theoretical foundation

Identity can be regulated by culture and context (Leary & Tangney, 2012). It has also been shown that social context can improve an individual's motivation -- by providing support and by contributing to an individual's interests (Thoman et al., 2007). Besides, if a student feels that other classmates are interested in a science subject, they may also express a higher interest (Nazari et al., 2017). The role of conversations has also been studied as a means of gaining value about topics, where students can socially verify and build their perception of an activity as interesting and valued (Nolen, 2001). In collaborative activities, students develop their understanding of the topic and achieve shared representations of it (Clark, 1996). Talking with others about one's educational interests and receiving social recognition during these conversations have been shown to increase interest in science careers (Jackson et al., 2018), where interest is a primary driver of science identity (Maltese & Tai, 2010).

Method

For the development of this year-long curriculum, design-based research methodology was applied and guided by a theoretical model of Knowledge Community and Inquiry (KCI). The curriculum was co-designed with a teacher of a Grade 11 Biology class consisting of three cohorts, totaling 55 students. Throughout the semester, students in all cohorts contributed their ideas to the emergent collective knowledge base and built on their previous ideas. A series of inquiry activities was designed, using a variety of technology environments and materials to support students' collaborative work, along with a Career Exploration activity where students collectively built knowledge about and connections amongst a wide range of science-related professions. Exploration of science careers was a focus of at least one lesson in each unit, in which students contributed to the community Career Folder (on Google Drive), collaboratively editing Google Docs and adding details to the careers posted by other students. Up to six students from three cohorts could contribute to each career page. Students researched and added to the career description, made connections to other professions, explored university/college programs that would support the career, researched the level of demand for each career and the starting salary, and added interesting videos and articles. They also discussed how various careers related to each curricular unit. This growing collective knowledge base served as a platform for further discussions and exploration of potential science careers.

Data sources

Data included tables, documents and personal journals created by students individually, in groups and as a class. Co-constructed tables and documents to which students contributed their responses represent a collective knowledge base built during the school year. Students' answers to science identity questionnaires were collected and coded. Three central questions were asked: 1. What are some interesting career directions that were connected to this course, which you may not have considered before? 2.What is your current thinking about a career? Was it influenced by anything you encountered in this course, and if so, how? 3. Should teachers make a stronger emphasis on career connections within their courses? How can we help students keep thinking about their career?

Findings

Through exploring different careers and contributing to the class Career Knowledge Base, students built their understandings of various careers in science and of their own science identities. In their Career Pages (23 documents created), students identified connections to almost 100 different professions. The top three careers of interest were Neurologist (7 students contributed), Oral Surgeon (6 students), and Forensic Scientist and DNA Analyst/ Pharmaceutical Chemist (5 students per each). The maximum number of words describing a career in a collaboratively created document was 1432 (the career of Neurologist). Students connected their careers of interest to many other careers (e.g., the career of Epidemiologist was connected to 19 other careers). Also, 60 links to various resources related to future careers were added by students. The Career Exploration activity helped students gain insights into specific career interests or discover careers of which they had not been previously aware. They also became informed about qualifications required to pursue certain careers. The Career Exploration activity, including collective knowledge work and discussions about careers, was emphasized by students as helping them see connections between different science fields, industry and other fields, such as business or law, and become interested in exploring various careers. Students indicated in their questionnaires that the exploration of the college and university pathways of each science career was valuable. Collaborating with each other as a classroom learning community, through the exploration and recognition of their peers' interests, social verification and building their perception of the activity as valued allowed students to develop their interest in the topics.

Scientific and scholarly significance

This study demonstrates the potential of a learning community approach achieved through a collaborative student work by progressively adding to and making use of a collective knowledge base, through discussions in groups and as a class, in helping students to start developing interest to and knowledge of many science careers, and contributing to the formation of their science identities. This study contributes to the literature on the factors influencing the development of science identities and will be of interest to a broader educational community.

Peer Relationships in Hybrid Learning During COVID-19: Inferences From One Online Class

Tianyi Feng, Harvard University, dianafeng@g.harvard.edu
Wei Zhang, Harvard Graduate School of Education, weizhang@gse.harvard.edu

Abstract: The COVID-19 pandemic popularized remote interactions in higher education, necessitating examination of their effectiveness in supporting peer relationships. Our qualitative study of one online class in a hybrid graduate program found varying levels of meaningful peer connections, with students relying significantly more on teachers to create interaction opportunities. Group work, course content, and pedagogical approaches emerged as crucial factors in fostering connections, while asynchrony due to lack of collocation and technology failures posed barriers.

Introduction

Higher education institutions have increasingly adopted online classes and programs over recent years. Even for in-person programs, experience with the technology during the COVID-19 pandemic promoted higher adoption of remote interactions like Zoom team meetings and office hours. As such, it is crucial to examine how interpersonal connections in education have been affected by these remote learning setups and whether students can form meaningful relationships. Through semi-structured interviews, the current study investigates peer relationships in a graduate-level online class offered during Fall 2021, when COVID restrictions had largely loosened. As an online class in a mostly in-person program, the class provides a unique window into a potential future where in-person instruction is supplemented by increased online interactions.

Peer relationships in education have been described using various terms. To simplify the concept for participants, we use a basic, all-encompassing definition: relationships among student peers. We rely on two primary theoretical frameworks to situate our study. The Community of Inquiry framework posits that social presence as mediated through teaching presence facilitates the main goal of cognitive presence (Garrison et al., 2000). Considering the class's extensive use of group work and Slack, we also examine virtual group dynamics (McKenna & Green, 2002). Some of its features, including a lack of physicality and the translation of virtual identities into real identities, can well be translated into online learning communities.

Considering the literature review and the course nature, we form the following research questions:

1. How are peer relationships formed in an online class compared to a traditional in-person class?
2. What factors promote or limit peer relationships in an online class?

Methodology

The studied course was a graduate-level Master of Education program at a Northeastern U.S. graduate school. Although the program was mostly in-person, this specific class remained online due to COVID's lingering impact, with course content delivered through Zoom and Canvas. The class focused on teaching novice students to use specialized software to collect and analyze learning data. A previous iteration of the class had been studied to examine how students consume asynchronous video lectures (Schneider et al., 2022).

Out of the 30 students in the class, 12 students (7 female, 11 Asian, 11 local) participated in the semi-structured interviews. We did not collect information on the participants' prior acquaintance before the class, but it is reasonable to assume that students might be acquainted without deep connections since the class occurred during the program's first semester. The interview protocol covered three main topics: past experience; experience in the class; ideas for an ideal tool to build community in the class. Using ATLAS.ti, the authors adopted a flexible, thematic coding procedure to code the interviews (Deterding & Waters, 2021). Given the small size of the data, both coders coded all transcripts and discussed discrepancies to reach consensus on the codes. Inter-coder reliability was not calculated.

Results

RQ1: Different levels of peer relationships can be meaningful to different students.

Even though all the students were in the same class, they reported a wide range of peer relationships that they considered meaningful, from friendships to collaborators in group assignment and to mere conversation partners. Interestingly, some self-reported meaningful connections were not necessarily reciprocal. The reasons for these differences are hard to pinpoint, but students' varying expectations and circumstances, such as family commitments or time constraints, may contribute. However, it is crucial to note that all these students mentioned a general lack of connection in the class. Feelings of loneliness and missed potential career opportunities were among the issues they faced due to insufficient peer connections.

RQ1: Students relied on pedagogical practices to make personal connections.

When asked how they initially connected with peers they eventually formed relationships with, half of the students mentioned connecting through group projects, either during weekly pair/group assignments or the final project. A few students also reported initial connections through conversations in Zoom breakout rooms. All of these bonding opportunities were created intentionally by the teaching team to encourage collaboration among the students. Four out of the remaining six students formed bonds through a social media messaging service that members of a specific shared demographic already used. All four students expressed that they found a sense of connection through the class. Beyond this group, only one student initiated spontaneous communication with peers in addition to the existing pedagogical structure. This contrasts with peer connections formed in in-person settings, where students described naturally forming connections through affinity groups related to hobbies and identities, sometimes outside the classroom.

RQ2: Failure to connect was mostly attributed to the online format itself.

When asked about factors negatively impacting peer relationships in the class, students initially struggled to find an answer. When asked about *other* classes in the program that helped students feel a strong connection with their peers, students frequently cited classes that dealt with subject matters conducive to more personal topics. Students also mentioned that given the technical nature of the class in question, the difficulty of the course could induce stress for the students. When pressed, a few students attributed the problems of the class merely to the fact that it was offered online. In fact, all five students who expressed frustration of lacking connection in the class attributed the failure to the online format in some way. Notably, the only student who was not located locally expressed frustration that they missed out on all opportunities to connect because they could not be on campus. However, a review of the remaining interviews showed that only a small number of students made efforts to meet in person despite being collocated. Finally, technical challenges, like network issues, also created barriers to connect.

Discussion

The current study's findings align with the CoI framework and empirical research (e.g., Kaufmann & Vallade, 2020), emphasizing pedagogical design's role in forming peer relationships in online higher education. However, since our study focused on an online class within a hybrid program with many local students, we have additional insights. First, despite numerous opportunities, students had minimal in-person interactions and relied on teachers to establish communication. Second, even within a small class, students had varying levels of meaningful peer connections, potentially influenced by their enrollment expectations. Lastly, students emphasized the importance of course content in forming peer connections alongside pedagogy.

Our findings prompt further research into the reasons for students' lack of initiative in forming relationships in such scenarios. Additionally, our findings imply that incorporating course concepts tied to personal experiences in online classes with impersonal subject matters may encourage peer connections. The study's main limitation is the self-selection bias of interviewees, who generally attributed the class's problems to the online setting. Future work should connect these qualitative findings with quantitative and qualitative data from the class to better understand peer relationships in online higher education.

PhoneIoT for Teaching 'Internet of Things': Smartphones to Promote Accessible, Engaging, and Authentic Experiences

Devin Jean, Vanderbilt University, devin.c.jean@vanderbilt.edu
Shuchi Grover, Looking Glass Ventures, shuchigrover@acm.org
Akos Ledeczi, Vanderbilt University, akos.ledeczi@vanderbilt.edu
Brian Broll, Vanderbilt University, brian.broll@vanderbilt.edu

Abstract: We rely on a vast network of devices that communicate autonomously to provide many of the services we use every day. However, the enabling technologies behind the Internet of Things (IoT) are often not taught in K-12 classrooms, in part due to the need for hardware. But most teens in the United States have smartphones. Thus, we introduce *PhoneIoT*, a mobile app that allows students to access their smartphones programmatically over the Internet. *PhoneIoT* supports access to live sensor data from the device and controlling a customizable display on the phone's screen. *PhoneIoT* allows students to learn the fundamental concepts of distributed computing and networked sensing using NetsBlox, a simple but powerful extension of the Snap*!* block-based programming environment. Because both *PhoneIoT* and NetsBlox are free and open-source, instructors are able to teach these advanced computer science topics even remotely without extra hardware.

Introduction

More and more, the programs and tools we use every day rely heavily on Internet connectivity to provide complex services. For example, Google Maps uses the location of connected smartphones (even if the app is not open) to approximate traffic statistics by keeping track of the number of phones in a given area. This is an example of distributed sensor networks, which are becoming increasingly important in our daily lives. Such sensor networks are the *Internet of Things (IoT)*, an umbrella term to describe a network of internet-connected sensors and devices that can be used to gather data or perform actions remotely, and potentially on a large scale. Despite being such a ubiquitous reality in modern computing, there are few opportunities for K-12 students to have hands-on experience with these topics. There are existing curricular activities as well as out-of-school clubs and makerspaces that engage students with tangible computing technologies like Raspberry Pi and Micro:bit, which can both act as or interface with simple sensors and actuators over USB or Bluetooth. However, they rely on local connectivity and are disconnected from the ubiquitous internet and IoT. Lastly, due to the cost of hardware and the logistics of keeping track of it, as well as a lack of teachers familiar with these technologies, few schools offer IoT experiences in schools.

A concurrent reality is that close to 90% of teenagers in the US already own a personal smartphone, and this number is only expected to grow (Sandler, 2022). Mobile devices such as these come with a wide variety of sensors including an accelerometer, gyroscope, microphone, camera, and GPS location service. Additionally, they are fully Internet-capable out of the box, allowing external software to easily communicate with them. Because of this, smartphones present a cost-effective opportunity for introducing students to distributed computing ideas such as the Internet of Things by using their own devices. By using everyday devices instead of relying on expensive or specialized hardware, students are able to engineer and examine the world around them through more practical, authentic, and engaging hands-on projects.

In this paper, we describe *PhoneIoT*, our free smartphone technology innovation and associated curricular activities for high school computer science (CS) students, designed to allow students to connect to and interact with their smartphone over the internet. *PhoneIoT* leverages NetsBlox, an extension of the block-based programming environment Snap*!* (Harvey et al, 2013) that makes networked communication and web data easily accessible (Broll et al., 2017).

Design principles & related work

***Easy entry point to hitherto-inaccessible, advanced networking ideas*:** The list of existing tools which allow students to create their own standalone mobile apps from a block-based programming environment is small but growing. This includes programming tools such as Thunkable (Siegle, 2020), App Inventor (Wolber, Abelson, & Spertus, 2011), and Pocket Code (Wolfgang, 2014). Some of these tools (Thunkable, for instance) are similar to *PhoneIoT* in that they provide access to some Internet-based resources (similar to NetsBlox services) and live sensor data from the phone. However, these are all strictly app development tools supporting projects local to the device, unlike *PhoneIoT* which exposes the device to the internet for students to manipulate in a distributed environment, thus making distributed computing and networked sensing accessible to students. For instance, with *PhoneIoT*, students could easily create a single server-like project that runs in the browser and connects to several phones to implement a distributed chat app. This feature is significant, given recent findings of a meta-analysis of (only 12 existing) K-12 IoT curricula, which concluded that K-12 physical computing/IoT experiences are restricted to the IoT ‘sensor layer’ and few-to-none expose students to the crucial underlying ‘networking layer’ due to its complexity and lack of tools (Abichandani et al., 2022).

Accessible & engaging experiences: *PhoneIoT* is designed to be quick to set up and simple to use. “Low floor, high ceiling” has been a crucial guiding principle for the creation of novice programming environments for K-12 learners dating back to Papert's (1980) work on children and LOGO. A low floor entry point is suitable for all students and a high ceiling supports the curiosity of all learners. Block-based programming in general, and in particular, Snap! (a Scratch derivative), have been designed for providing gentle introductory programming experiences to K-12 learners, and have especially benefited minoritized students and those with less preparatory privilege and prior programming knowledge (Goldenberg et al., 2018; Weintrop et al., 2019). Even students who have never used NetsBlox before can learn the basics and build their first distributed app in one class period.

Interactive & Customizable**:** Unlike other tools like Sensor Fusion and Cumulocity (Hendeby et al., 2017; Srirama et al., 2017) which allow for reading sensor values remotely in real time but restrict users to only using the device as a sensor hub, *PhoneIoT* promotes interactivity through a customizable phone display which affords engagement in event-based graphical inputs and remote controllers (see below). Additionally, tools such as Cumulocity are complex and expensive due to running in fee-based, specialized cloud environments.

Promoting creativity, authentic engagement**:** Since the phone is a personal, easily accessible device, *PhoneIoT* provides excellent opportunities for developing projects that promote creative, authentic engagement. For example, the phone’s dedicated step counter sensor opens up a world of possibilities for ‘quantified self’ data science activities that promote personally and culturally relevant projects and artifacts (Lee et al., 2021).

Broadening participation through physical computing and interdisciplinary connections**:** Recent research highlights several benefits associated with physical computing, including increased motivation for students (especially from diverse backgrounds) because working with sensors is tangible and affords interdisciplinary projects (Sentence & Childs, 2020). We ensure broad accessibility through making the *PhoneIoT* app freely available on both Android and iOS, and designed to cover as many phone models and versions as possible.

Protecting Student Privacy**:** To address justifiable student privacy concerns related to providing convenient access to sensors, such as the camera, microphone, and location, *PhoneIoT* proactively (a) prohibits any network communication when the screen is turned off or the app is put into the background, (b) limits the functionality of some sensors, such as the microphone so that *PhoneIoT* cannot be used for eavesdropping (c) prevents direct access to the camera; users must explicitly click an image display (with appropriate optional settings) to take an image from the camera and store it in the display after confirmation, and (d) password-protects each request to the device and passwords automatically expire after 24 hours.

PhoneIoT design: NetsBlox, access to sensor data, & custom interactivity

NetsBlox enables two key features: 1) accessing web-based services, which reach out into the Internet to effect changes or collect and return information, and 2) message passing, which allows two NetsBlox projects running anywhere on the internet to communicate and exchange data. Using these simple networking primitives, students can design powerful applications such as a live weather map or chat server, or remotely control virtual or physical robots (Brady et al., 2022). *PhoneIoT* taps into these existing concepts to provide two core features to students’ projects: 1) the ability to access live sensor data from the device, and (2) the ability to configure and control an interactive custom display on the phone. When the app is opened, simply pressing the “Connect” button connects the device to the NetsBlox server. Also shown on the screen are the device ID and password, which are needed for a user’s NetsBlox project to connect to the device through the server (Figure 1a).

Students can access **sensor data** from *PhoneIoT* in one of two ways. The first (somewhat simpler to introduce to students), is by sending an explicit request to the device through the *PhoneIoT* service in NetsBlox. For example, Figure 1b shows how this can be used to instantly tell the current device location. Explicit requests are convenient if sensor values are only occasionally needed: for instance, when the project is first started. However, it is often the case in practice, both in the classroom and in industry, that live sensor values are needed continuously; *PhoneIoT*’s second sensor access mode does exactly this. The *listenToSensors* function in the *PhoneIoT* service can be provided a list of sensor and update period pairs; it then requests the mobile device to send a message to the student’s NetsBlox project with the specified sensor data every time the update period elapses. Figure 2 shows how to request and receive location updates every two seconds. Note that this *streaming* technique has the added benefit of automatically breaking the values up into separate variables like “latitude” and "longitude" rather than receiving a list as in Figure 1b. With these two simple techniques, students can immediately begin accessing all of *PhoneIoT*'s supported sensors including the accelerometer, location sensor, and microphone, the magnetic field sensor, gyroscope, orientation sensor, or step counter, in their programs.

The second main feature of *PhoneIoT* is the **custom interactive display**. This lets students display information from NetsBlox graphically on the phone screen with labels, text fields, image displays, etc., as well as receive information from the user such as button presses, text entry, and joystick manipulation. The *PhoneIoT* block provides *addButton*, *addImageDisplay*, and *addJoystick*—functions that add a widget/element to the screen. These all typically take as input the location and the size of the new widget as well as an optional input which is a list of other values to set; these can control the orientation, font size, text color, background color, and other properties of the widget. Figure 3 shows an example of two widget-adding functions and the resulting phone screen; the image display has been filled with an image taken by the user's camera.

Importantly, one of the optional settings for a widget is an "event" (message type) to send to the student's project whenever the user interacts with the widget, such as pushing a button, moving a joystick, altering the textbox text, or updating the image. This allows instructors to cover important CS topics such as graphical interface design and event-based programming. This feature allows students to implement custom remote controllers for their NetsBlox projects. The example in Figure 3 is all the code needed to send images and text from a student's phone and display them on the NetsBlox stage running in the browser.

Figure 1

Preliminary evidence from pilot summer camp

Summer camp description:

PhoneIoT was used in a recent online summer camp to introduce students to distributed computing (DC) and IoT. After a brief introduction to NetsBlox and its DC features through a Weather app and MovieDB app, our project-based, hands-on curriculum advanced to multiple interesting *IoT* applications first involving robots, and then *PhoneIoT* apps such as: (1) streaming and plotting 3-axis acceleration data in real time; this project concept was eventually expanded from gathering raw data into a more engaging app where students recreated the classic labyrinth game with a twist: they could tilt their phone to control the ball on the NetsBlox stage; (2) creating graphical controls such as virtual buttons and touchpads, some of which were later used to implement remote controllers for games such as pong. All projects were done as iterative exercises: the instructors showed the *PhoneIoT* or NetsBlox feature and then students had to complete partially complete code. The capstone project was to turn their phone into a remote controller to command virtual robots (which had been previously introduced in the camp's robotics component) with custom controller layouts and behaviors. Students were free to use any

PhoneIoT features, resulting in creative original projects such as slider-based throttles for each wheel, single joystick-based steering/driving, and button-based controls for discrete commands (e.g., "turn left 10 degrees"). As the final challenge, students used their custom controllers to compete and drive their robot around an obstacle course in as short a time as possible. All students completed all tasks.

Feedback and results:

Nine students of color participated in the pilot camp (6 male, 3 female; 6 Asian, 2 Black, 1 Hispanic) from 9, 10, and 11th grades. Student engagement in the camp was very high. In the post-survey, students ranked rank the 2 distributed computing, 3 robot navigation, and 2 *PhoneIoT* projects from 1 (highest) to 7 (lowest). The *PhoneIoT* projects ranked the highest with average score of 2.2 for the tilting game and 3.2 for the remote controller app. There were significant average pre-to-post gains registered on 4-point likert scale survey questions on confidence, ability, and interest in CS. On the question on knowledge of how to build IoT applications, there was a significant gain on the mean score: 1.4 (pre) to 2.9 (post). Open-ended responses on students' camp experience suggests that their perceptions of computer science became more positive and the camp expanded their understanding of this vast and growing discipline. Sample responses were: a) "*Before, I did not have a lot of experience in "Internet of Things," but this camp provided an excellent introduction. It allowed me to understand how hardware (robots, phones, sensors, etc.) interact with code. Overall, it gave me a good understanding of the field and allowed me to think about it as a potential career option*." b*) I learned a lot about how hardware interacts with the software we make over the course of this camp*." c) "*Programming in general is very broad and we can expand it to many things in computer science.*" d) *I saw ways we use coding in real life, before I thought they couldn't go beyond a computer screen."* These positive findings from our pilot are encouraging and validate our approach and the design principles behind the *PhoneIoT* innovation to make the growing Internet of Things topic accessible and engaging to K-12 students. Our ongoing work involves expanding *PhoneIoT* activities to include more personal apps such as mapping one's walking or running route and overlaying points of cultural and community interest.

Abstract: This technological innovation is an outcome based on a call for action to develop a more holistic understanding of computational thinking during problem-solving. Given that the potential to facilitate the transfer of computational thinking skills to more complex and novel problems is critical in higher education, the goal of this innovation was to design an assessment that captures the latter. Through a design-based process with computer science students as co-inquirers, an existing transfer tool was optimized by combining formative-iterative and data-mining assessments at various difficulty levels. Potential outcomes of the design process are discussed considering future educational interventions with computational thinking.

Inspiration for the innovation

This learning and development (L&D) project is based on a need for a combined assessment to unblur *computational thinking (CT)* in educational research. Fostering CT to optimize learning is imperative to solve problems, critically analyze information, communicate, and think creatively and to succeed in an ever-changing digitally powered workforce. For example, we know that students with pedagogical experiences in programming or robotics and personal experiences such as solving puzzles and playing board or card games have mobilized their CT skills in various contexts. Consequently, determining a combined form of assessment that would contribute to a more holistic and complete understanding of CT would seem necessary, especially when assessing its potential to facilitate the transfer of CT skills to more complex and novel problems.

According to Wing (2006), CT implies the ability to engage in five *cognitive processes* to solve problems efficiently and creatively. These include: (1) Taking a large and complex problem, and breaking it down into smaller, more manageable problems or steps, (2) Looking for patterns among the problems, (3) Removing unnecessary detail from the problem, (4) Formatting a general solution, and (5) Coming up with new insights based on the solutions to the problem. Over the last decade, several forms of *assessment* tools have been developed and deployed with varying degrees of adequacy to measure three CT dimensions stated by Brennan and Resnick's (2012) framework: "computational concepts" (e.g., sequences, conditionals, operators); "computational practices" (experimenting and iterating, testing and debugging, abstracting); and "computational perspectives" (expressing, connecting, and questioning). This leads to the affirmation of the need for complementary and unbiased CT assessment tools in educational interventions (Grover, 2015; Román-Gonzáles et al., 2019). It also raises the need to properly combine and provide a more balanced and comprehensive "systems of assessments" at different phases of CT educational interventions and evaluations.

Goal for the technological innovation

A scoping review of CT assessment tools (Cutumisu et al., 2019) revealed that out of 39 studies, $n = 9$ combined multiple measures, such as programming artifacts, surveys, and tangible tasks, to assess different facets of CT (Grover et al. 2015). Moreover, Román-González et al. (2019) provided insights into how to combine assessment tools for a comprehensive evaluation of CT interventions in educational settings and classified them according to their evaluative approach: diagnostic tools (e.g., the Computational Thinking Test by Román-González (2015)), summative tools (e.g., Meerbaum-Salant et al. (2013) in the Scratch context), formative-iterative tools (e.g., Dr. Scratch from Moreno-León et al. (2015)), data-mining tools (e.g., Grover et al. (2017) from the Blockly environment), transfer tools (e.g., Bebras Tasks measuring CT skills' transfer to real-life problems by Dagiene & Futschek (2008)), perceptions-attitudes scales (e.g., Computational Thinking Scales by Korkmaz et al. (2017)), and vocabulary assessment (e.g., verbal expressions of CT language by Grover (2011)). Whereas the diagnostic and summative tools are beneficial to collect quantitative data during pre-post evaluations, they are based on student responses to predefined CT items and provide snapshot images of computational concepts (Brennan & Resnick, 2012), without considering computational practices and perspectives. On the other hand, skills transfer tools provide more authentic assessments that are contextualized in "real-life" problems and assess the extent to which students transfer their CT skills onto different kinds of problems, contexts, and situations; these tools are ideal for educational interventions. Finally, the formative–iterative and the data-mining tools are mainly used during the learning process, in specific programming environments. Data generated from the latter tools are more aligned with learning analytics and thus informative of students' cognitive processes, and, especially useful at analyzing the source code of the programming projects and recording the learner activity in real-time.

From a pedagogical point of view, the potential use of multiple assessments raises concerns regarding the adequacy of capturing CT dimensions at different moments (i.e., before, along, and after) of an educational CT intervention (see example with educational robotics from Chichekian et al. (2022) & Chichekian et al. (under review)). Given that longitudinal research designs that examine CT learning paths are valuable in educational intervention studies that extend beyond the end of the intervention, formative–iterative, data-mining, and skill transfer tools should be included. Additionally, it was pointed out that although different types of CT assessment tools have been developed for grade levels ranging from kindergarten to university students, most of them (84.6%) applied to K-12 settings (Yadav et al., 2016). This is consistent with the growing emphasis on CT curricula for primary to high school students. Considering the most common research designs in educational settings, assessments for different CT dimensions, and the range of the student population age, the goal of the current technological innovation was to *optimize* an existing transfer tool that focused on the learning process during a "real-life" problem-solving task by (1) integrating formative-iterative and data-mining assessments and (2) developing incrementally challenging versions of the tool (i.e., easy, medium, difficult).

Design principles

In the first phase of the design process, a literature review was conducted regarding the relationship between CT and knowledge transfer in higher education. This was accomplished by a summer (2021) intern who had applied to a project we had submitted through MITACS Globalink research. The latter provides funds to undergraduate students all over the world who have applied and been selected through a competitive process to work with a professor on a research project for 8-12 weeks during a summer semester. First, a list of tools measuring the application of CT was extracted from the readings that resulted from the literature review search. Second, the type of tool was defined (e.g., survey, multiple choice, problem-solving task, logic game). Third, because CT concepts have been a popular target for research and curricula development, generalized computer science principles, such as algorithmic thinking, abstraction, and problem decomposition were used as categories to classify the problem-solving tasks found in each tool. A second rater (a computer science instructor) validated 25% of the categorization and a 90% agreement was reached (the remaining was resolved through discussion until full consensus). Fourth, a difficulty level (easy, medium, difficult) was assigned for each task based on the time it took to solve the problem and the length of the word problem. Fifth, the 135 problem-solving tasks that were extracted from all the tools were randomly selected and distributed equally to 9 evaluators (university professors, graduate students, and industry partners) to receive feedback on (1) the agreement of the categorization, as well as a suggestion of another category in case of disagreement and (2) suggestions on how to increase the level of difficulty for each problem.

In the second phase of the design process, a 12-week internship was organized the following summer (2022), but this time with three first-year students (2M, 1F) in a computer science technology program and with the collaboration of a computer science instructor. The overall purpose of the internship was to provide novice students in a career-oriented program an opportunity to learn how to design an interactive web version from a pen-and-paper version of a task and implement it into a web component. This implied understanding complex structures and technical details regarding problem-solving and programming logic skills. During the internship, students worked online through a shared collaborative platform. Funding for the internship was provided by Social Sciences and Humanities Research Council of Canada. Before the internship, the computer science instructor and the researcher met to select a handful of problem-solving tasks out of the 135 that were identified in phase 1. The selection criteria were based on the task's potential to be modified and become more interactive, as well as the possibility to be rewritten in different versions based on a difficulty level. Given that the goal of the current technological innovation was to optimize an existing tool by combining formative-iterative and data-mining assessments in a context where a potential transfer of CT skills would be possible, we opted to limit our selection of problem-solving tasks to the Bebras tasks (https://www.bebras.org/). These tasks consisted of a set of activities requiring the students to transfer and project their CT skills to solve "real-life" problems. As such, the Bebras Tasks were classified as a CT skill transfer assessment tool and because they did not require any prior knowledge of any software or hardware, they could be administered to individuals without any prior programming experience. These tasks also easily catered to the implementation of learning analytics. For example, programming for click counts from the beginning to the end of task completion was embedded as a form of data-mining assessment and a playground was added before the actual problem-solving task as a form of formative-iterative assessment. Automated feedback was also incorporated into the actual task completion by providing students with two occasions to solve a problem wherein an animation of their wrong solution would be available for viewing before a second attempt.

At first, the students worked in a team on one problem-solving task that they collectively opted for and wrote a program collaboratively. Next, they each selected three different problem-solving tasks to work on and continued autonomously but with weekly meetings with the computer science instructor to share their progress and receive feedback. Once an initial version of the prototype comprising 10 problem-solving tasks was ready, a brainstorming session took place with the three students, the instructor, and the researcher to propose ideas on how to add incremental complexity in each task based on the suggestions provided regarding the difficulty levels in Phase 1 and revisit the wording, formatting, and visual representation of each task while considering principles of EDI. A first pilot was then tested with close friends and colleagues to ask for feedback and refine the prototype. Feedback questions focused on the user experience, namely ease of understanding regarding the description and goal of the task, text and response field formatting, and picture quality. Suggestions on how to improve user experience were also part of the feedback that was sought. The latter resulted in (1) modifying task descriptions to clarify the expected outcome and the role of the playground, (2) revisiting the levels of difficulty for each task, and (3) refining the visual representation (i.e., colors and sizes of images). In the next phases, a pilot is anticipated to be launched with a larger population from an online crowdsourcing platform to validate the tasks with other forms of combined assessment (e.g., surveys on CT skills), and in Winter 2023 testing the tasks with a sample of elementary preservice teachers in math education classes. See Figure 1 for an example of the task Plant Life (an interactive version will be available during the presentation).

> The Beaver loves flowers and has invented a simple programming language for visual design based on the idea of plant life. Each plant starts with a square called “a”. A visual object can perform three operations: Grow(), Split(), Die(). The following program (not shown here) explains these operations. Once you have understood how the plant functions, try to replicate the plant represented next to the list by placing in order the correct sequence of commands.

Potential outcomes of the design process

Providing evidence of how CT is generalizable and how it can transfer to different and novel problems (Barr & Stephenson, 2011) can shed light on the underlying factors that contribute to the development of competence in CT. On an *educational level*, CT is a good predictor of academic performance (Haddad & Kalaani, 2015), suggesting that it could be used as an early intervention indicator to increase students’ retention and progression in all disciplines. It can also inform the design of learning experiences that calls upon knowledge transfer in novel situations and that embeds incremental levels of complexity regarding the application of CT in a problem-solving process. Further efforts could also focus on exploring the validity or the pedagogical usefulness of the current tool during educational interventions. Ultimately, interactive tools that provide insights about learning analytics can be assessed alongside cognitive ability tests not only to create appropriate CT interventions to improve students’ CT skills and attitudes, but also potentially contribute to other testing services such as PISA or admission tests.

Similar to co-op opportunities that combine academics with practical paid work experience for undergraduate and graduate students, paid internships for novice college students at the beginning of career-oriented or technical programs proved to be beneficial to initiate collaborative work among peers and with experts from the field. Encouraging student interactions (amongst each other and with the technology being developed) in the design process of technological innovation is optimal for positive learning experiences, especially in the early years of a career program to maintain a certain level of motivation and engagement. While the involvement of students during the design of this technological innovation focused more on the development of skills and knowledge for college and career readiness, the need to integrate more recent framings such as situated CT (identity, participation, creative expression) and critical CT (political and ethical impacts of computing, justice) (Kafai et al., 2019) are warranted for the advancement of a pedagogical perspective in line with learning theories.

Using a Visual-Based Coding Platform to Assess Computational Thinking Skills in Introductory Physics

Derrick Hylton, Spelman College, dhylton@spelman.edu
Shannon Sung, Institute for Future Intelligence, shannon@intofuture.org
Xiaotong Ding, Institute for Future Intelligence, xiaotong@intofuture.org

Abstract: Developing assessment tools for computational thinking (CT) in STEM education is a precursor for science teachers to effectively integrate intervention strategies for CT practices. One problem to assessing CT skills is students' varying familiarity with different programming languages and platforms. A text-neutral, open-source platform called iFlow, is capable of addressing this issue. Specifically, this innovative technology has been adopted to elicit underrepresented undergraduate students' debugging skills. We present how the visual-based coding platform can be applied to bypass programming language bias in assessing CT. In this preliminary study, we discuss design principles of a visual-based platform to effectively assess debugging practices – identification, isolation, and iteration – with the use of iFlow assignments. Our findings suggest how the ability of iFlow to test parts of a program independently, dataflow connectivity, and equity in removing biases from students' various backgrounds are advantageous over text-based platforms.

Introduction

In STEM education, computational thinking (CT) has become a critical component in preparing students for the technical workforce (NSF, 2020). Practitioners are, however, facing problems integrating and assessing CT in the STEM curriculum (Wang et al., 2021). CT presents an additional stumbling block for underrepresented groups in building the pipeline for computational-related careers (Thomas et al., 2018). Our central proposed intervention strategy is for students to create computational solutions to science problems without, at first, requiring them to master intimidating syntax and semantics. This can be accomplished with the aid of a visual-based programming tool, so that we can make students' computational thinking visible while they are shaping it (Ainsworth et al., 2011). We collaborated with the developers of one such tool, called iFlow, where we can create a beta version suitable for our needs. The goal is to design assessment tools for evaluating the effectiveness of visual-based programming in facilitating students' CT skills. We report on one of the assignment questions for eliciting CT skills of debugging, which students self-identified as a barrier in our preliminary study (Hylton et al., 2021).

Innovative visual-based programming platform – iFlow

Visual-based programming was implemented by the application of iFlow. Inspired by the Unified Modeling Language and dataflow programming paradigm, this constructionist environment (Papert, 1991), named iFlow, models a program as an executable directed graph depicting the structure of a computational solution and the interactions among its constituents. The results emerge as data flow through these interconnected elements (see Figure 1 as an example). While there exist successful dataflow programming products such as Grasshopper, LabVIEW, and Simulink, most of them are tailor-made for specific applications that may not be appropriate for introductory courses. For example, Grasshopper only works within the Rhinoceros 3D computer-aided design software, LabVIEW is mostly used in data acquisition and instrument control, and Simulink focuses on modeling multi-domain dynamic systems. By comparison, iFlow is a general-purpose, Web-based, and integrated computational environment designed for students to solve common problems encountered in the science curriculum, with an objective to meet diverse educational needs of students with various backgrounds and interests in science. To clarify, although it bears some resemblance to system dynamics software such as Stella and Vensim, iFlow is not a system dynamics modeler. In iFlow, the representational blocks are directly manipulable (e.g., pulling a slider changes the variable it represents). Their changes can be immediately transmitted across the connector networks, updating the linked nodes on their way and making the entire diagram interactive

iFlow debugging assignment

We describe an assignment intended to elicit and assess users' debugging skills. The assignment prompt is:

> Your lab partner devised a method to test whether the function shown in the *Multivariate Function block* (the green block in Figure 1) is a good fit to the data. S/he decided to subtract the data values from the function values (using an *Arithmetic block* [see Figure 1]) to see how

close they are as a test of goodness of fit. S/he also decided to average the difference of each data point (using the *Mean block*), and since the average is 0 as shown in the *Output block*, s/he decided that the fit is very good. Your job is to decide whether you agree or disagree with your lab partner's work, and if you disagree to improve on the work.

The assignment in Figure 1 illustrates some of the blocks where we can store arrays, define functions, assign variables, do arithmetic computations and statistics, and display outputs. The assignment program was constructed by dragging appropriate blocks from the left "Blocks" palette to the working canvas. The function of each block was described to the student via a manual and training exercise. The blocks are connected via the nodes on the left and/or right sides of the blocks, which represent the input(s) to and output(s) from the blocks. Each block has properties that are listed in table form (by right clicking on the block) that can control each block. The assignment was given to 13 STEM majors in an Introductory Physics lab. A post-activity survey was implemented to collect students' reflection and feedback.

We hypothesize that this visual-based programming can enhance students' cognitive processing of data flow, which would lead to a stronger performance in more traditional computing tools, such as text-based Python and visual-based LabView. This question can be used to assess debugging skills, because it purposefully introduces an error in testing the goodness of fit, which is an essential part of common data analysis in introductory physics courses. The error introduced is averaging the deviations to gauge goodness of fit. This will not work since some deviations are positive and some are negative. Students with more advanced debugging skills should be able to graph the data and fit function with iFlow (see Figure 2) to realize that the fit is not good.

Assessing cognitive processes of debugging in iFlow

iFlow program makes the assessment of debugging practices easier, because it could not only help assess the processes involved in fixing errors, but also resurface the cognitive processes of completely understanding the errors. Such affordance could mitigate the problem, where errors are often fixed without systematically investigating them, and thus, learners are prone to repeat the errors (Li et al., 2019).

We classify the debugging practices dealing with errors into three cognitive processes—identification, isolation, and iteration – adapted from the work of Weintrop and his colleagues (2016). *Identification* focuses on how one makes sense of the solution, *isolation* focuses on one's systematic investigation of the issue, and *iteration* focuses on how one reproduces and fixes the error. To illustrate each cognitive process, we prompted the students with the following questions as a protocol in eliciting thought processes: 1) *Do you AGREE with the given solution? 2) If Yes, explain your reasoning in the space below. 3) If No, you should improve on your solution. 4) Record ALL the things you did to justify your decision and to improve the solution. These things should include anything you did to acquire information needed to understand ALL the issues you identified. For example, if you tried to understand the properties of a block outside of the computational problem, then it should be included in the list of things done.*

For numbers 1-3, we expect students to spot some issues in the solution shown in Figure 1. For example, the deviation (computed by the arithmetic block) can average to 0 as shown in the output block, but with further investigation, a graph generated by an exemplar student (see the Space2D block in Figure 2) reveal that the solution proposed in Figure 1 is inadequate. For number 4, students are prompted to list their actions, so that we can evaluate whether they engaged in the investigative processes. For instance, students should research the error enough to eliminate the canceling of the deviations by comparing the data values (shown as the blue points in Figure 2) to the line fitted to the data (shown as B in the legend of Space2D block in Figure 2). Another issue is the type of function, and students should realize by the practices involved in *isolation* and *iteration* that the linear function is not the best solution.

Design principles of iFlow in assessing debugging

Assessing cognitive processes of debugging can be done in common text-based programming, but visual-based programming has some advantages over text-based programming (Navarro-prieto & Cañas, 2001; Saito et al., 2017; Weintrop & Wilensky, 2017) and assessment. First, iFlow helps its users to investigate blocks independent of the rest of the program, which usually cannot be readily done in text-based programming (e.g., usually, one has to disable the rest of the program in order to check one part). For assessment purposes, iFlow makes it easier for students to isolate and trace back the steps without breaking the entirety of the programming solution (e.g., Figure 2). For researchers, iFlow is advantageous over text-based programming, because we can evaluate what the tendencies of users are when they engage in debugging, such as: 1) identifying an issue based on the visual computational solution, 2) deciding which part of the visual-based computational solution is a reasonable cause of the error, and 3) systematically studying how the cause of error. Therefore, iFlow better helps the practitioners and researchers evaluate investigative processes pertaining to how students isolate errors and fix them.

Second, we believe that iFlow encourages debugging because it visually shows connectivity and relationship among different components on the same page. The hierarchical linearity or non-connectivity involved in the text-based programming usually overwhelms novice students, preventing them from even attempting to identify the issue (Mosemann & Wiedenbeck, 2001), which deters any assessment endeavor. In visual-based programming, students can trace the source of error and test various ideas in a more systematic manner. Correspondingly, the inputs of text-based codes could be assigned hundreds of lines back in the program before being called into computing. Such a gap and lack of connectivity may demotivate students in science classes to engage in the practices of debugging. As a result, iFlow is more suitable than text-based platforms in assessing debugging, since the interface is more welcoming for users to engage in debugging practices.

Third, all of the students can be provided with an equal background in iFlow, which may not be possible if the same platform, such as Python or Excel, is used in the science courses for assessment purposes as well as coursework. The coursework platform for assessment may impose bias since students would have varying backgrounds and familiarity. For instance, we may not be able to assess the cognitive processes in *isolation* correctly if some of the students already know how to deal with the purposeful errors. These students can bypass some of the debugging sub-practices, which makes their prior knowledge interfere with the assessment. Thus, the validity of the assessment is jeopardized.

Discussions and implications

In this technology innovation paper, we only presented the application of iFlow to the assessment of debugging skills. Based on students' positive feedback, such as "*The biggest thing is that iFlow is the most straightforward [compared with Python]. If there's anything that you're not understanding, you are able to just see it.*" we conclude that visual-based programming would be efficient in assessing debugging skills, such as the ability to see the various connections shown on iFlow interface. A few of the advantages are: ability to test parts of a program independently, dataflow connectivity, and equity in removing biases from underrepresented students' various backgrounds. Visual-based programming, such as iFlow (Hylton et al., 2021), is an innovative technology to teach computational thinking in STEM courses. It is a powerful platform not only for students to be able to solve computational problems in science, but also for researchers to assess pupils' learning in various aspects.

The assignment developed for assessing debugging skills can be applied to both text-based and visual-based programming. In our future studies, we plan on building debugging skills of students in STEM courses by an appropriate intervention whose effectiveness can be assessed and refined using appropriate debugging rubrics.

Nevertheless, with the promising affordance in assessing CT in STEM education, there are some limitations to this innovative technology. For instance, iFlow requires more development, as is planned, so it is more responsive to the various needs and provides a smoother interface, such as comparing similar computational solutions side by side without the need to open multiple cloud files. In addition, because the interface is different from conventional text-based programming, it requires constant customization of different manuals and user training materials that are tailored for instructional use.

Designing a Student Progress Panel for Formative Practice: A Learning Engineering Process

Rachel Van Campenhout, Michelle Selinger, Bill Jerome
rachel.vancampenhout@vitalsource.com, michelle.selinger@vitalsource.com, bill.jerome@vitalsource.com
VitalSource

Abstract: Providing students with research-based learning tools is a necessary part of developing learning environments, and additionally, the design of those learning features is critical for their success. It is well established that doing practice questions while reading is better for learning—yet how how students monitor and navigate to this formative practice in the learning platform can impact the success of this study tool. In this paper, we address the learning science and design considerations of a student-facing progress panel using the learning engineering process model as the development framework. Student data and survey feedback is interpreted from the first class of university students to complete the formative practice using the progress panel in the textbook e-reader platform. Directions for future iterative improvements and research are also discussed.

Introduction

The shift to digital textbooks provided an opportunity to transform passive texts into interactive, learn-by-doing resources. Formative practice is well known to be beneficial for students, but the research on the learning science principle, the doer effect, established that doing formative practice while reading was not only effective for learning, but causal (Koedinger et al., 2016; Van Campenhout et al., 2023). To bring this active learning approach to more students, artificial intelligence was used to generate formative practice for thousands of digital textbooks to provide students with a free learn-by-doing study tool. Yet the existence of the practice questions themselves was not sufficient to fully support students. Students needed a way to monitor their progress and navigate to the questions. In this paper, we discuss the design process of a student-facing data dashboard and the first data and feedback gathered from students using it in a Public Relations course at a major public university.

The learning engineering process (LEP) model (Kessler et al., 2022) is used as a framework to describe the design process, the first implementation of this student progress panel in natural learning contexts, and the initial data collected that will inform future iterations. While learning engineering as a practice applies engineering design methods with human-centered design and data-driven decision making to support learners (Goodell et al., 2022), the LEP is a model that provides structure for solving educational challenges (Kessler et al., 2022). This design example serves as a case study for applying learning engineering for student-centered design and development at large. The LEP is grounded in context: who are the learners, who is on the team, and what is the central challenge? The central challenge for this project was to design a data dashboard that would provide students with basic information about the practice available and completed while also providing navigation functionality. This feature needed to be a seamless component of the e-reader and accessed by all learners in all learning contexts in any textbook for which the questions were available. A team of learning scientists, designers, engineers, and product managers worked together to create the final solution presented here.

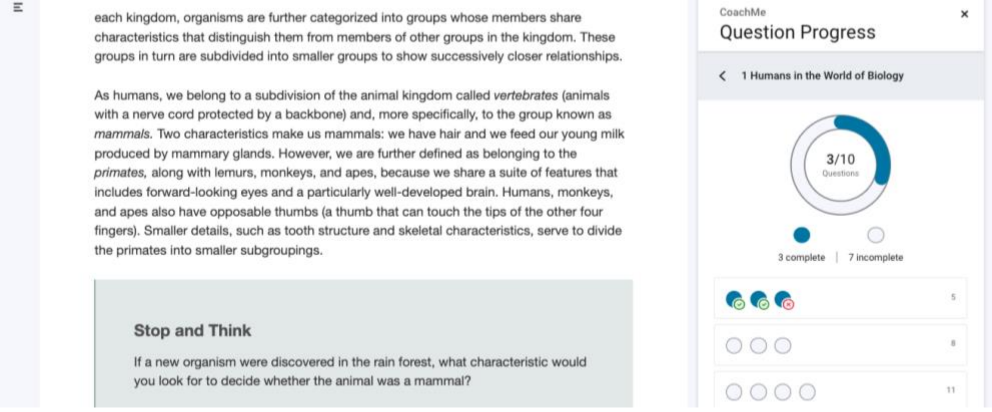
Design

The LEP creation phase includes design, development, instrumentation, and implementation planning (Kessler et al., 2022)—all of which was necessary to create the progress panel, and each step was occurring concurrently. Instrumentation (the data gathering) would be done through both platform clickstream data as well as student surveys, all of which would occur during the research project. Additionally, the design stage itself went through iterations until the final design was completed. Three primary objectives guided the design of the progress panel: ease of navigation between progress and questions, user recognition of question progress and completion status, organization of question progress to increase motivation. Within each design iteration, we considered learning science research, usability heuristics, accessibility guidelines, and common trends across our platforms and others. After iterative cycles and feedback from the learning engineering team, each of the guiding objectives were tested during usability sessions, which confirmed there was no task delay and the experience was intuitive for the user.

The first goal was to create an easy mode of navigation between the progress panel and questions. The challenge was that students must be able to easily discover, navigate, and understand the connection between the questions, the text, and the progress panel. Nielsen's usability heuristics (1994) of user control and freedom, and consistency and standards were used to guide the design. Using a progress panel was consistent with other features in the platform and provided enough screen real estate to accomplish all of the objectives, and make additions or changes in the future. To provide students with control and agency, multiple navigation touchpoints were added so students could access the panel from multiple locations depending on their current course of actions.

Figure 1

The progress panel open next to the corresponding chapter of text.



each kingdom, organisms are further categorized into groups whose members share characteristics that distinguish them from members of other groups in the kingdom. These groups in turn are subdivided into smaller groups to show successively closer relationships.

As humans, we belong to a subdivision of the animal kingdom called *vertebrates* (animals with a nerve cord protected by a backbone) and, more specifically, to the group known as *mammals*. Two characteristics make us mammals: we have hair and we feed our young milk produced by mammary glands. However, we are further defined as belonging to the *primates*, along with lemurs, monkeys, and apes, because we share a suite of features that includes forward-looking eyes and a particularly well-developed brain. Humans, monkeys, and apes also have opposable thumbs (a thumb that can touch the tips of the other four fingers). Smaller details, such as tooth structure and skeletal characteristics, serve to divide the primates into smaller subgroupings.

Stop and Think

If a new organism were discovered in the rain forest, what characteristic would you look for to decide whether the animal was a mammal?

The second goal was to maintain clarity on question progress and status. One of the biggest challenges was on how to balance informing the student of their progress in terms of question completion while also surfacing accuracy information. The primary goal of the questions as formative practice is to give students a no-stakes opportunity to check their understanding of the content, allowing them to continue to answer the practice until correct. Given this central objective from the learning science perspective, question completion needed to be the primary status. However, when answering questions, students receive correctness information which should be clearly surfaced. Adding the red *x* and green *check* to the progress completion circles created a consistent and recognizable connection between the question answering experience and the progress bar, utilizing the recognition over recall heuristic (Nielsen, 1994) to help students better understand what the question markers represent.

The third goal was to show question progress in a manner that motivated students to complete questions. The organization of questions in the progress panel presented a challenge, as listing individual questions could take significant screen real estate while also overwhelm students when seeing hundreds of incomplete questions. The aesthetics and minimal design heuristic was considered when determining how to group and organize questions. The solution was to limit visible questions to the chapter level, and then group questions by activity enrichment. This question organization was also intended to help facilitate motivation in the chapter-level progress circle and question completion markers. The hope was to motivate students without relying too heavily on gamification features, which has mixed research results (Zainuddin et al., 2020).

Accessibility is always considered during the design process to ensure the solution will be functional and meaningful for all students. The W3C standards provide success criterion that are useful guides to check during the design process. For example, W3C success criterion states that the use of color should not be the only means for conveying information to students, as not everyone can visualize color (W3C, n.d.). To solve for this accessibility challenge, completeness became the contrast between a dark solid and a light gray to convey "filling in" without relying on specific colors. For correctness information, the *x* and *check* were included with the red and green color standards for correctness so those with a color impairment would have the symbol cues to follow.

Implementation

The implementation phase of the learning engineering process is when the solution is put into practice—in this case, used by students in natural learning contexts. As a feature of the e-reader, the progress panel could be released as part of a platform update and was targeted for August of 2022 to be available to a higher education institution who was engaging in a research study on the practice feature. Initial feedback on the progress panel feature was provided by students using a Public Relations textbook between August and October, 2022. The instructor created a point scale with a maximum of five points per chapter for completing a minimum of 80% of the available practice questions. As students worked through the textbook chapters, their use of the practice was recorded by the platform and the instructor was provided with data reports that showed how often students were using the textbook, as well as the percentage of practice students were completing per chapter. Given the formative nature of the questions, first attempt accuracy was not a component of instructor reporting or student grades—

only completion. After students had completed the textbook chapters required for the course, they completed a short survey to identify their perceptions of the questions as a study tool. This survey also included three items on the progress panel to identify how students interacted with this new feature. The survey link was distributed by the instructor during class, students were not required to complete the survey, and all results were anonymous.

Results

Data analysis is crucial to the investigation phase of the LEP (Kessler et al., 2022), and both completion data and student surveys were used to evaluate the progress panel. Table 1 shows the final completion data from the instructor's data report (only 10 of 31 students shown for brevity). Each student's total percentage of practice completed is calculated for each chapter. On its own, this data reveals some interesting insights into student behavior. Many students did 100% of the practice for all assigned chapters, even in chapters with 40+ questions where they could have stopped at 80% of the practice and still received full points. This was particularly surprising to us, given that years of internal data analysis revealed that only about 5% of students will voluntarily complete practice when not required. This can also be seen in Step (chapter) 8; 9 of 31 students did practice in this chapter when it was not assigned. This high completion of practice—above what was strictly required—caused us to wonder if the progress panel could be partially responsible for this behavior. Lastly, several students (5, 6, and 9) repeatedly stopped doing practice at the low 80% range—exactly the minimum amount of practice needed to full points. This indicated to the team that students were using the progress panel to monitor the amount of practice they had completed in order to ensure they had done enough to receive full credit.

Table 1
Sample data report showing days used and percentage of practice complete for each chapter and the entire book

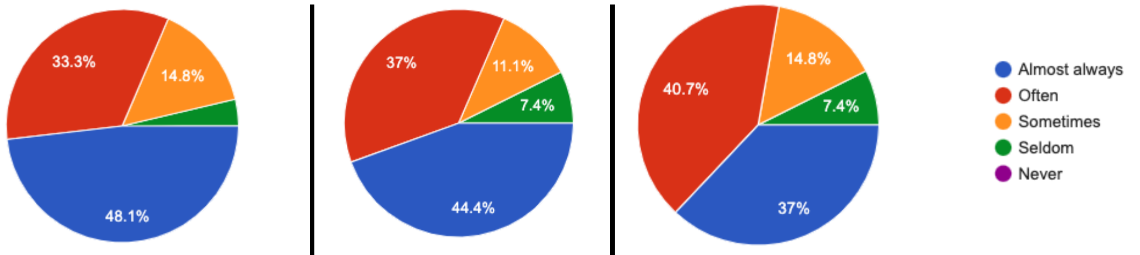
Student 9	12	100	100	100	100	100	100	100	0	100	94.5
Student 10	12	100	100	100	100	80.6	81.2	83.7	0	100	83.2

Figure 2
The results of the three student survey items on the progress panel.



How often did you use the progress panel to monitor how much practice you completed?

How often did you use the progress panel to navigate to the practice questions?

How often did seeing the percentage of practice you completed for a chapter in the progress panel motivate you to complete more/all of the available practice?

The survey included three questions about how students used the progress panel and the results from the 27 students who participated are shown in Figure 2. The first question on how often students used the panel to monitor the amount of practice completed was a pleasant surprise, with nearly half of students responding "almost always," and another third choosing "often." Only one student selected "seldom," and this could potentially align with the small fraction of students were minimally engaged (student 6 of Table 1, for example). This question

confirmed that the progress panel was a helpful feature for students to know how much practice they had completed, even helping students to ensure they had done the minimal threshold of practice required to receive full points as observed in Table 1. While the exact percentage of students in each category shifted slightly, most students also used the progress panel to navigate to questions often or almost always. Given the importance of navigation as a feature during the design process, student responses to this question confirmed that the navigation feature was being used as part of the students' learning process and therefore was a valuable addition.

The third question asked how often seeing the amount of practice completed in the progress panel motivated you to complete more or all of the practice, and 37% of students chose "almost always" and another 40% chose "often." These responses help to confirm that the design of the progress panel was having an influence on how students were engaging with the practice—in many cases, motivating students to complete more than the minimum threshold of 80% of the practice. While Table 1 is only a representative sample, the student responses to this question on motivation can be proportionally mapped to the completion data seen for students.

Discussion: Iterative improvement

In this learning engineering process, the central challenge was to design a solution that showed students their progress and accuracy on the formative practice while also serving as a navigation tool to get to questions and the corresponding textbook content. The final solution was developed with input from a learning engineering team using established design heuristics and research from the learning sciences. In partnership with an instructor, the questions were assigned as part of students' course grade, providing the first opportunity to gather feedback on how this new progress panel was used. The data revealed that students were using it to monitor their progress, and sometimes even to stop at the minimum required percentage—a practical and necessary function of the progress panel. For the high percentage of students completing 100% of practice for chapters when only 80% was required, the student survey revealed that the progress feature helped motivate students to continue answering practice beyond that minimum threshold. The completion data and student surveys both confirmed the progress panel design was successful for each of the three original design objectives.

In this design challenge, the LEP facilitated team collaboration for the design, implementation, and analysis of the progress panel solution. While this initial investigation indicates that the progress panel is functioning as intended for students, it is also part of the LEP to continue to iterate and improve. For example, future design iterations may investigate if adding a static visual indicator of the progress panel on the e-reader interface could increase student engagement. Iterative improvements may also include other components of the LEP such as data instrumentation. Adding data events for interactions within the progress panel itself would help to study how students interact with the panel in the context of the rest of the experience. Continued research will further advance what is known about student motivation, formative practice, and effective design features.

A Conceptual System Design for Teacher Education: Role-Play Simulations to Train Communicative Action With AI Agents

Julia Fecke, Erum Afzal, Edith Braun
julia.fecke@zfl.uni-giessen.de, erum.afzal@erziehung.uni-giessen.de, edith.braun@erziehung.uni-giessen.de
Justus-Liebig-University Gießen

Abstract: This research project focuses on enhancing student teachers communication skills, particularly for prospective teachers, using digital learning tools and framing communication accordingly to Habermas` differentiation of strategic and understanding-oriented communicative action. Specifically, we conducted an experimental study to compare the effectiveness of avatar-based versus video-camera-based interactions in training communication skills. Our findings suggest that the avatar-based approach may be more effective in some aspects than the other. Building up on these results, we are planning to develop an AI agent as a facilitator. This agent will provide feedback and guidance to prospective teachers to support the development of their communication skills. Overall, this research project aims to contribute to the field of teacher education by exploring the potential of digital learning tools to enhance communication skills training.

Theoretical background

For prospective teachers, in order to perform effectively in their professions, not only subject specific competencies are necessarily helpful but generic competencies are also equally important. It is also observed that subject-specific competencies are sufficiently available, prospective teachers often report a lack of generic competencies (e.g. communication competence). Communication skills are mentioned as a key learning outcome of higher education in national and international research papers (germany: Kultusministerkonferenz, 2019; international: OECD, 2013). In order, for prospective teachers to be able to cope with their everyday professional life, they use communication (Braun et al., 2016). Communication is not only needed in the classroom with pupils (e.g. teaching, classroom disruptions), but also among colleagues, school manager, and parents. Even if it is taught in study program, often, students feel insecure to transfer from teacher education to classroom and studies show that teachers feel inadequately prepared to apply generic skills. Especially in the teaching profession, they have difficulties with practicing (Dicke et al., 2016) and are confronted with the so-called “practice shock” (Stokking et al., 2003).

Communication competences represent an essential aspect of performance in social interactions. We define communicative competences as a person's ability to achieve goals in a socially appropriate manner (Habermas, 1984; Braun et al., 2018). Our theoretical framework is based on Habermas’ (1984) theory of communicative action. He differs between two type of communicative action, which are strategic and understanding-oriented communication. Communication can be used to directly reach a hidden conversation goal or remain open for argumentation (Habermas, 1984) - depending on the context, the choice of communication type is essential for achieving the goal.

To train prospective teachers on communicative skills, simulations are well suited (Chernikova et al., 2020). Simulation methods are a pedagogical tool with which learners can interact to mimic real life almost authentically (Cook et al., 2013). Role-playing represents one form of simulations and is considered an effective teaching method and their potential for teacher education has also been demonstrated (Braun et al., 2016; Crow & Nelson, 2015; Gartmeier et al., 2012). But there is also seen potential of role-play simulations in virtual learning environments in German higher education (e.g. Fecke & Müller, 2022; Kunze, Mohr & Ittel, 2016). To enable students of teacher education in developing their communication skills in a safe learning setting, we are developing a virtual learning environment (3D avatar; agent -based interaction) in which the learners can practice their conversation skills with an AI agent. The AI bot represented by an agent that take forward the conversation about a typical situation in the context of school with the learners. Such typical situations may include a conversation with a colleague (teacher-teacher interaction) in which, for example, one colleague confronts the other about a missed deadline, or a teacher-pupil interaction in which the student complains about his or her grade. They will be able to react intelligently to user’s interactions and can suggest various constructive alternatives of interacting (e.g. making counterexamples). The use of 3D AI agent in teacher education to train communicative action enhances teachers' interpersonal skills. The 3D AI simulations were effective in providing teachers with opportunities to practice and improve their communication skills, including active listening, empathy, and verbal and nonverbal communication. Moreover, the use of 3D AI agents allowed for personalized and adaptive training, as well as real-time feedback on the teachers' performance (Chen et al., 2020). These findings suggest that AI 3D chatbots have the potential to be an effective tool for training teachers in communicative action and improving their effectiveness in their profession. Habermas' theoretical distinction between communicative action and strategic action was used as a framework for designing our AI chatbot that can facilitate communication and collaboration in educational settings (Kanwar, 2021).

Research questions

Given this theoretical framing, this paper has two main objectives:

1. What are the specific advantages and disadvantages of the two different digital learning environments - videocamera-based interaction versus avatar-based interaction?
2. Building on the findings of the preliminary project: how can we develop an avatar-based AI agent? This question will be explored by presenting the initial results of our ongoing research in this area.

Procedure

In Summer 2021 (April to July) – in an experimental design – the performance-based simulations were conducted with professional trained actors and students of teacher education (n=61) in two different virtual learning environments (avatar-based and video-camera-based interactions). Before the simulations the participants were randomly assigned into avatar-based (n=29) and video-camera-based (n=32) interaction groups. Avatar-based interaction means, that the one's own person is represented by an avatar in a 3D-virtual environment. The participants and the trained actor were represented by an avatar and were able to interact with each other. The video-camera-based interaction took place in a conventional videoconference tool; where the trained actor had a role-play with students of teacher education on oral communication skills. In each learning environment, the students performed simulations to test their communicative competencies with professional trained actors in a two-way conversation. Here, the trained actors were simulated in several social roles, such as an equal colleague, a pupil, or a supervisor. In doing so, the students of teacher education remained in their role as future teachers. Also, the simulations were recorded by video. We collected quantitative and qualitative data from this experimental study conducted during a semester session of regular teaching course.

An external assessment was used to measure the communicative competencies: During the simulation, the overall assessment of the performance of communicative competencies was evaluated by means of standardized observation sheets by two silent raters based on 4 items rating, capturing the behaviour of students in the simulation.

In addition, self-ratings of communication skills were also used twice: the students filled in the questionnaire once before and once after the role-playing. With a total of 29 items and six subscales, students filled out a questionnaire of self-rated competencies of knowledge processing, systematic, presentation, communication, cooperation, and personal competencies (Braun & Leidner, 2009).

Also, focus groups (moderated group discussion) were conducted: here, the students of teacher education were asked to assess, among other questions about advantages and disadvantages regarding communication in the specific learning environment and the role of the tool used (avatar-based vs. video-camera-based) for the study. The analysis was done by summarizing qualitative content analysis (Mayring, 2015).

Results

Regarding the first aim, we compared the video-camera-based interaction with an avatar-based interaction. Following we presented an overview of the main results:

The quantitative analysis shows that in the avatar-based interaction, self-assessment correlates moderately with external assessment of communicative competence (correlations between self-assessment and external assessment is r=.618, p=.001), while this is not the case for the video-camera-based interaction (correlations between self-assessment and external assessment r=-.116, p=.549).

The focus groups provide a possible interpretation: while in the avatar-based interaction it is clear from the beginning that non-verbal communication is omitted and students can focus on the spoken word, the video-camera based interaction requires attention on non-verbal communication (Fecke & Müller, 2022). This makes it more challenging and leads to possible irritation. In the video-camera-based interaction, even the person is seen on the screen, but facial expression and other gestures are hard to understand via this transmitted social interaction. The participants in the avatar-based interaction also pointed out, that hiding behind the avatar made them feel more secure and it was easy to have the communication within simulated environment (Fecke & Müller, 2022). The results suggest that avatar-based interaction is more appropriate as an initial introduction to practice.

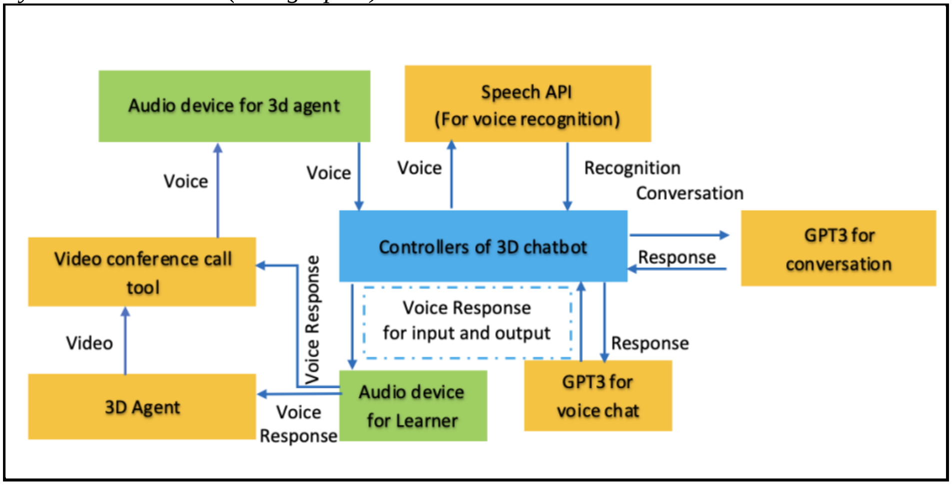
Based on the findings of the first research project aim, we are developing an avatar-based 3D AI bot to provide a rich and engaging training experience that can improve teachers' communication skills in a cost-effective and accessible way. To achieve this goal, we provide a brief overview of the technical implementation of the system below.

Technical procedure

The system architecture, as illustrated in Figure 1, comprises several key components that together create a platform designed to train students of teacher education in oral communication.

Figure 1

System Architecture (own graphic)



These components include video and audio routing, speech recognition and text-to-speech and speech-to-text APIs, GPT-3 as a generative AI model, a 3D AI avatar agent, and a controller for the agent:

- Video and audio routing: This involves using Loopback to redirect audio from the video conference tool to a virtual microphone. There are two audio routings required for this platform - one for learners and another for the 3D agent.
- Speech recognition and Text to Speech and speech to Text API: Google Speech API is used to convert audio into text, which is then processed using the GPT3 model to generate a contextual response. The response is then converted back into text as a response to the conversation.
- GPT3 as Generative AI model: The GPT3 model is a generative model used to generate a large volume of data with the input of small data sequences. It is widely used to train chatbots for business models and conversational chatbots for educational purposes.
- 3D AI avatar agent: This is a 3D animated agent that is a third-party plugin embedded with the model to mimic the auto-generated responses through the GPT3 model.
- Controller of the Agent: After training all of the individual modules, the chatbot controller plays the role of combining all modules by providing a centralized environment where the 3D avatar responds to all communication within due time. It ensures social communication skills in the native language German.

Overall, this platform aims to provide an effective and efficient way for students to improve their oral communication skills using advanced technology.

Discussion

The simulation of typical situations based on theoretical features in the professional life of a teacher has direct relevance for teachers who have already entered the profession.

Based on our findings in response to the first research question, it can be inferred that the use of avatar-based interactions in role-play simulations can be highly effective for providing initial practical experiences in higher education. Both environments (avatar-based vs. video-camera-based) provide more security, as these can be implemented in the protected setting at home (Fecke & Müller, 2022). It is worth noting that in the avatar-based learning environment, there may be limitations when it comes to the expression of gestures and facial expressions as these were not captured by the used avatar. In the video-camera-based learning environment, there is a great uncertainty about the appropriate use of gestures and facial expressions, as well as how they are perceived and interpreted by the others. Simulations in avatar-based learning environments can be used as a learning format in the sense of an introduction to practice and facilitate communicative competencies. Thus, the focus can first be on the spoken word before the adequate application of non-verbal communication follows, e.g. in a next step.

With the further development of this research project (research aim 2), a virtual learning environment can be created in which the participants can develop their communication competencies with a trained AI agent (3D avatar-based). The AI bot is represented by an agent that conducts the conversation on a typical situation in the context of the teacher interaction in schools with pupils, colleagues, supervisors or parents. In order to accomplish our research goals, we have outlined a technical overview of various tools and technologies that can be utilized to create an authentic human-centric learning environment using Artificial Intelligence to practice communication competencies.

Abstract: In this work we present PlayData, a web-based tool designed for young learners to create diverse representational forms for data, taking advantage of the flexibility offered by programming tools. PlayData was designed as a modified version of Scratch 3.0, presenting new specialized blocks for importing, analyzing, and representing data, and a table functionality embedded into the environment. Our design was guided by the premise that the tool should not require extensive instruction to get started with and encourage users to tinker with their data, trying out many ideas iteratively. In this paper, we describe PlayData's functionalities, and how they relate to the design principles that guided its development. We conclude by sharing lessons learned in pilot studies.

Introduction

Data literacy is rapidly gaining more relevance as bigger amounts of data are being generated and different types of data are becoming more accessible to wider audiences. As increasingly more diverse and larger datasets are publicly shared and used for decision-making, new educational approaches for data science education are needed to support the development of data-literate citizens (Finzer, 2013; Wise, 2020). From an educational perspective, it is essential to prepare students for a thoughtful use of data to make informed decisions, participate in the debates of society, and deal with questions from their daily lives. Working with data is also crucial in almost any discipline today. In science learning, for example, data is used as evidence for constructing arguments, supporting claims, and making sense of the world (McNeill et al., 2017). However, even if recent science and math standards require students to deal with data analysis by interpreting and representing data, most exercises in curriculum materials ask students to read visualizations created by others, and not to construct them by themselves (Börner et al., 2019). Along this line, recent studies show that most people cannot fully interpret standard data visualizations (Börner et al., 2016; Maltese et al., 2015), suggesting a need to incorporate more activities into k-12 classrooms to prepare students to be able to interpret and create multiple types of graphical displays.

Computational tools are useful to analyze large datasets and offer many representational possibilities. Furthermore, the use of computers can help make the work with data more authentic to students and afford new forms of representations that are more diverse and interactive than non-computer-based ones (diSessa 2004). However, middle and high school students often lack opportunities to work with data in ways that privilege exploration and meaningful engagement. Existing tools that combine data analysis and visualization with programming often fail to meet the needs of k-12 students, since they were not designed for educational purposes and have steep learning curves. In this work, we describe a new web tool for data visualization based on the Scratch programming language, called PlayData, along with the core principles that guided its development, and lessons learned from early pilot studies.

Background and related work

While most of the data science tools currently available are designed for the undergraduate level, many others have also been developed in the past decades to allow novices to engage with data analysis and visualization. Tinkerplots is an early data visualization and modeling educational tool developed for statistical data analysis (Rubin, 2002). The Common Online Data Analysis Platform, a more recent tool designed for young learners, is based on drag-and-drop features and allows users to create visualizations for data and to perform transformations on the data under analysis (CODAP, 2014). Although these tools were designed for school-aged learners, the kind of visualization afforded is limited to the templates available in the environment. A more flexible approach to working with data is to use block-based programming environments. DataSnap is an extended version of Snap! that provides an interface to import, process, and visualize big data (Hellmann, 2015). In the context of the Scratch environment, Dasgupta & Hill (2017) developed new blocks for personal and social media analytics, called Scratch community blocks, that allow users to access, analyze, and visualize data about their participation in the Scratch online community. While this variety of existing tools supports students in data analysis and visualization tasks, PlayData provides new expressive possibilities to engage with data. The tool was shaped to support both sensemaking and personal expression and draws on existing efforts to connect data literacy to the personal and social context of learners (Lee et al., 2021; Matuk et al., 2021; Wilkerson & Polman, 2020). In the next session, we describe the design process and principles that guided its development, differentiating it from other tools.

PlayData overview

PlayData was developed as a new Scratch 3.0 extension, targeted at middle and high school students. PlayData seeks to support learners in making sense of data through the creation of personal representations, taking advantage of the power and flexibility offered by the Scratch programming language. The tool comprises (1) new programming blocks to import, analyze, and visualize data, (2) a table embedded into the environment that allows users to see the dataset imported, which is opened through the table icon (3), and (4) new custom sprites and backgrounds that can be used in data visualization projects. These components are illustrated in (Figure 1).

Design principles and their translation into blocks

The design of the PlayData tool was refined over several iterations and informed by insights gained through workshops with children and through our own experience while using it. We decided to build the tool as a modification of Scratch, given that Scratch has been widely used in schools for introductory programming activities and its design principles are aligned with our vision around computing education. Our design was guided by a desire to scaffold a "messing about" attitude towards data (Hawkins, 1965), based on the premises that: (1) the tool should be intuitive enough so it doesn't require extensive instruction to get familiar with (low floors), (2) it should afford that many ideas can be tried out in a brief period of time – so one can create, test and refine visualizations iteratively to convey an idea, while the idea itself can change over time as the result of the multiple iterations (tinkerability). The translation of these principles into PlayData's custom blocks is described below.

Design principle 1: Lower the floor for working with data

Although Scratch was designed to facilitate the tinkering process (Resnick & Rosenbaum, 2013), the floors for working with data are often too high to allow fluid experimentation and open exploration. Mastering some of the concepts required to read datasets in Scratch can be complex for young audiences, and thus, creating an effective visualization can be challenging with the available blocks in the environment.

Design principle 2: Encourage open exploration

Another core aspect considered when designing the tool was that it should afford the creation of a variety of representational forms for the same dataset without users having to change large amounts of code. Our goal was to encourage exploratory approaches for working with data, making users feel comfortable to change the code and test new representational possibilities as their ideas evolve. Thus, PlayData allows the creation of diverse outcomes either by changing a few parameters inside the blocks or by making small rearrangements in the code.

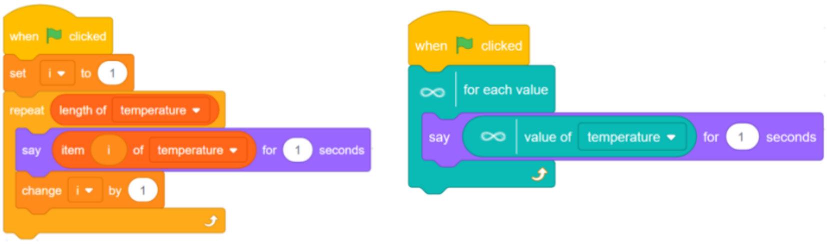
Translation of principles into tool's features

Adding data to the environment: In Scratch, users can add values into lists in three ways: (i) by manually adding values one by one, (ii) by using loop blocks with functions that return calculated values, or (iii) by importing .csv files from their computers. In either case, the process can be time-consuming, non-intuitive, or not flexible. Thus, we designed two new blocks to allow users to import data from multiple sources. The first block imports data from shared online files, such as Google Spreadsheets or .csv datasets available on the web. The second block can be used by directly pasting values copied from tables or spreadsheets. Once data is imported, new lists are automatically created, and can thus be selected from the dropdown menus in the PlayData blocks.

Iterating over the values: To read data in Scratch, users need to iterate over a list of values. To do so, it is necessary to start by creating both a variable and a list; the variable then needs to be initialized and increased by 1 in steps inside a loop block - a procedure to be repeated until the length of the items in the list is covered (Figure 2, left side). This process may seem intuitive to experienced programmers but can be quite complex for novices, requiring knowledge about lists that are usually not familiar to them (Aivaloglou & Hermans, 2016). In PlayData, all these steps are embedded into one single block, presented in Figure 2 (right side). This approach is similar to the one of Scratch community blocks (Dasgupta & Hill, 2017), which is restricted to data about participation in Scratch, while the PlayData block can be used with any type of data imported into the environment.

Figure 2

Code that iterates over the values of a list with traditional Scratch blocks (left) and with PlayData blocks (right)



```
when ⚑ clicked
set i ▾ to 1
repeat length of temperature ▾
    say item i of temperature ▾ for 1 seconds
    change i ▾ by 1
```

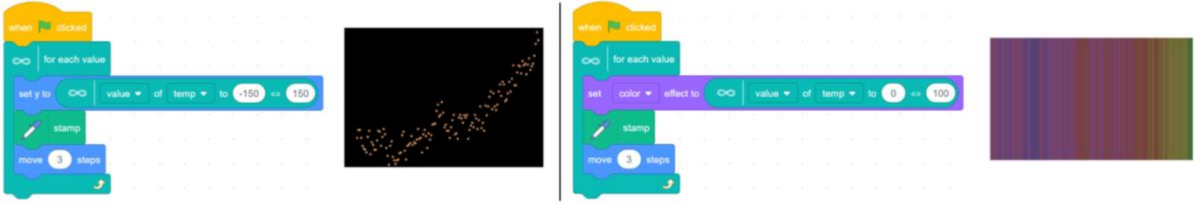
```
when ⚑ clicked
∞ for each value
    say ∞ value of temperature ▾ for 1 seconds
```

Looking at the dataset inside the environment: The table embedded into the PlayData environment allows users to quickly look at their datasets in a spreadsheet-like format, as shown in Figure 1. This is a central feature for an iterative process since users do not need to leave the environment to check their data and compare it with the visualizations created (Zhang et al., 1993).

Changing the scale of the values: One of the challenges of working with data visualization in Scratch is to adequate the original range of values to the range of parameters suited for the environment. For example, if one wants to plot the data in the X-Y axis, there is a need to change the lower and upper values to fit in the screen (which goes from -180 to 180 for the Y-axis, and from -240 to 240 for the X-axis). If one wants to map data to colors, the range of values goes from 0-200. To convert the original values to these new ranges, users need to perform calculations that can be unintuitive for beginners. To solve this issue, we developed a block that automatically converts the original values of a list into any desired range, encouraging users to explore multiple visualizations for their data in faster and easier ways. In Figure 3, in which we present an example that illustrates this idea of offering many representational possibilities using these blocks (two similar scripts producing distinct outputs).

Figure 3

Examples of visualizations created for the same dataset (global temperature anomaly since 1880)



```
when ⚑ clicked
∞ for each value
    set y to ∞ value ▾ of temp ▾ to -150 ⇔ 150
    stamp
    move 3 steps
```

```
when ⚑ clicked
∞ for each value
    set color ▾ effect to ∞ value ▾ of temp ▾ to 0 ⇔ 100
    stamp
    move 3 steps
```

Lessons from pilot studies

During the development of the tool, we ran several workshops (with middle and high school students, graduate students, and teachers), in different phases of its design. The duration of these workshops ranged from 1:30 hours to 10 hours. We collected data from these workshops through video recordings, log data and fieldnotes, and the insights gained in these experiences guided the design decisions described here and allowed us to understand how learners use the tool. Although we won't attempt to describe these results here in detail, they showed us promising pathways for developing activities aligned with the pedagogical goals of the tool.

By using PlayData, students engaged in authentic data visualization and design practices. These practices included translating ideas into programs, selecting parameters (such as the color scheme or the space between data points), inspecting the output and contrasting it to previous expectations, and adding annotations to provide context and better communicate the desired information.

However, there are also some open questions regarding the balance between procedural actions and engagement in sensemaking processes. Sometimes we saw learners creating aesthetically interesting visualizations without a clear understanding regarding the information that was conveyed through the representation - especially in small-duration activities that were not scaffolded to include elements such as asking a question before proceeding to the programming task. The study of if and how the sensemaking process around data evolves through interacting with PlayData is one of the things we are curious to explore in our next rounds of analysis.

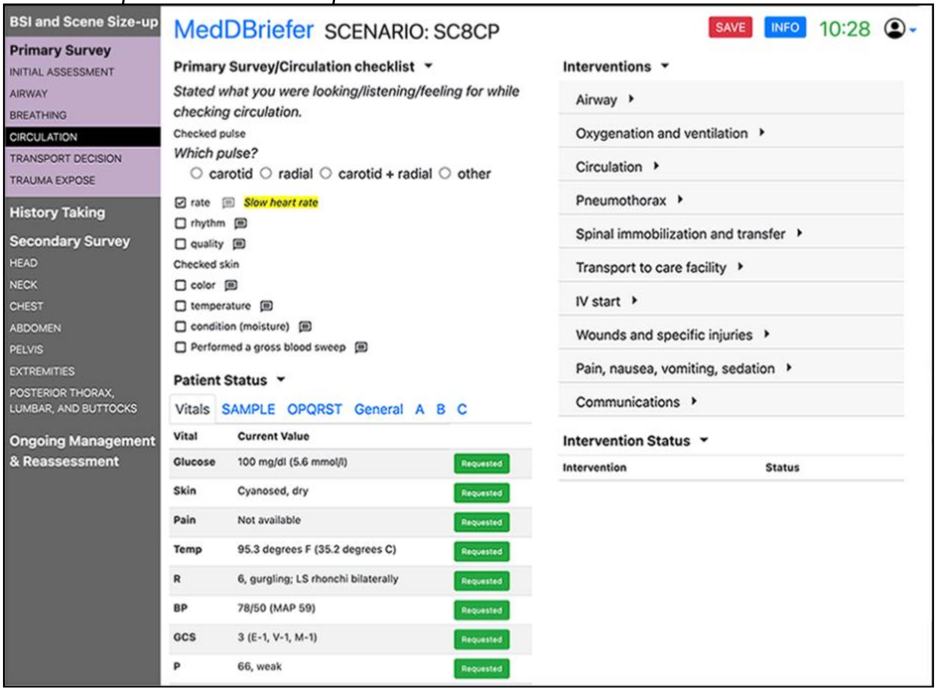
Abstract: MedDbriefer allows paramedic students to engage in simulated prehospital emergency care scenarios and receive an automated debriefing on their performance. It is a web-based tool that runs on a tablet. Although debriefing is purported to be one of simulation-based training's most critical components, there is little empirical research to guide human and automated debriefing. We implemented two approaches to debriefing in MedDbriefer and are conducting a randomized controlled trial to compare their effectiveness.

Introduction

Across the healthcare professions, students who struggle to acquire clinical reasoning and psychomotor skills rarely get enough simulation-based training (SBT) practice during course labs. Experienced SBT facilitators are in short supply. Many are themselves active practitioners (physicians, nurses, paramedics, etc.), which limits the time that they can devote to teaching. To address this problem, we are developing MedDbriefer, a web-based simulation tool that runs on a tablet. When fully implemented, it will allow one or more paramedic students to practice realistic prehospital emergency care scenarios and receive a debriefing on their performance (Katz et al., 2022). While one student treats a simulated patient as the leader of an emergency medical service (EMS) team, a peer uses the tablet's checklists to record the team leader's actions. (See Figure 1.) The system then analyzes the event log and generates a debriefing. If successful, MedDbriefer could help to reduce the shortage of EMS providers (e.g., Amiry & Maguire, 2021) and, ultimately, support training across the healthcare professions.

Figure 1
MedDbriefer's Observer Interface



SCENARIO: SC8CP

Primary Survey/Circulation checklist

Stated what you were looking/listening/feeling for while checking circulation.

Checked pulse

Which pulse?

○ carotid ○ radial ○ carotid + radial ○ other

☑ rate *Slow heart rate*
☐ rhythm
☐ quality

Checked skin

☐ color
☐ temperature
☐ condition (moisture)
☐ Performed a gross blood sweep

Patient Status

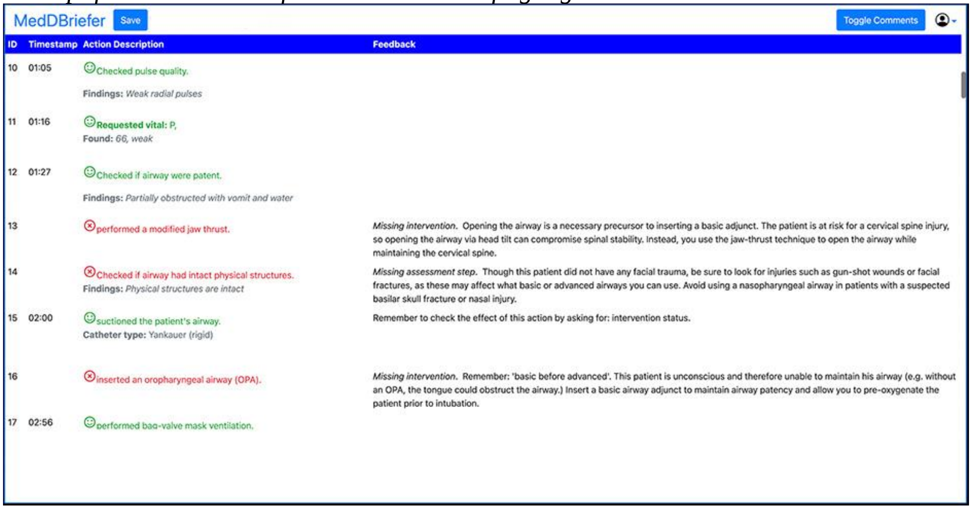
Vitals SAMPLE OPQRST General A B C

Vital	Current Value	
Glucose	100 mg/dl (5.6 mmol/l)	Requested
Skin	Cyanosed, dry	Requested
Pain	Not available	Requested
Temp	95.3 degrees F (35.2 degrees C)	Requested
R	6, gurgling; LS rhonchi bilaterally	Requested
BP	78/50 (MAP 59)	Requested
GCS	3 (E-1, V-1, M-1)	Requested
P	66, weak	Requested

Although debriefing is often deemed to be SBT's most critical component, little is known about how to guide human instructors and automated tutors in conducting an effective debriefing (e.g., Cheng et al., 2017). In addition to enabling students to practice scenarios, MedDbriefer provides a research platform to extend the field's knowledge about SBT, with a focus on debriefing. Toward that end, we implemented two approaches to debriefing in MedDbriefer. One approach reflects that taken in state-of-the-art tutoring systems for healthcare providers, such as vSim for Nursing (Laerdal Medical, 2020): a step-by-step textual recount of students' actions during a training scenario, with color-coded (green/yellow/red) feedback. (See Figure 2.) The other approach adapts one of several debriefing protocols that have been proposed to enable SBT instructors to conduct effective debriefings—namely, DEBRIEF (Sawyer & Deering, 2016). (See Figure 3.) Although several simulation researchers and practitioners have advocated the use of debriefing protocols, there is little empirical evidence to support this practice (Cheng et al., 2017; Sawyer et al, 2016).

Figure 2

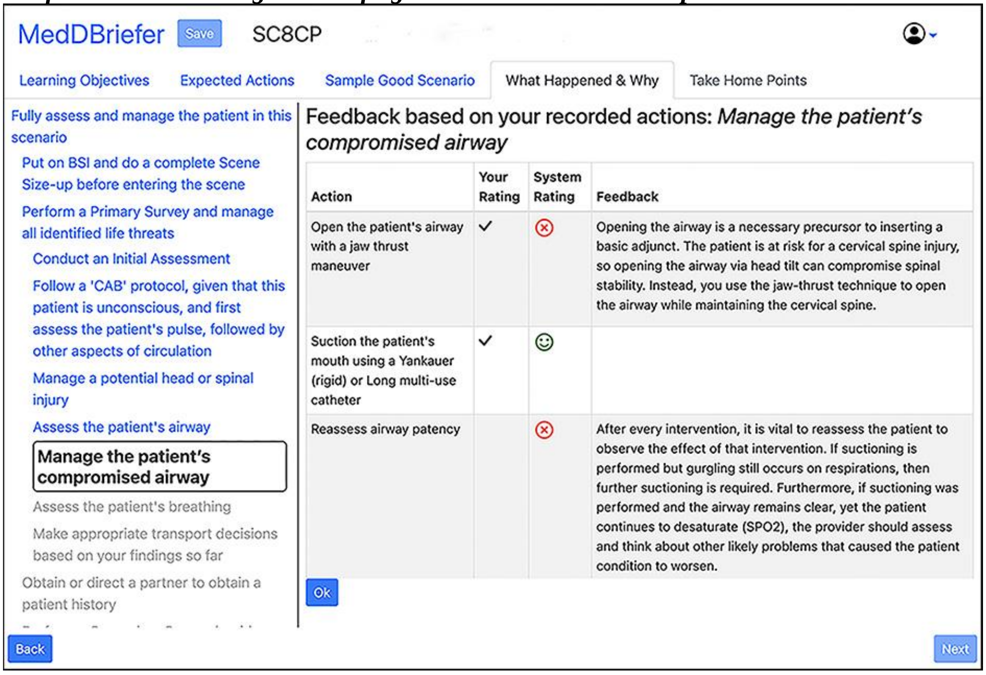
Excerpt from a MedDbriefer narrative debriefing log



ID	Timestamp	Action Description	Feedback
10	01:05	☺Checked pulse quality. **Findings:** *Weak radial pulses*	
11	01:16	☺**Requested vital:** P, **Found:** *66, weak*	
12	01:27	☺Checked if airway were patent. **Findings:** *Partially obstructed with vomit and water*	
13		⊗performed a modified jaw thrust.	*Missing intervention.* Opening the airway is a necessary precursor to inserting a basic adjunct. The patient is at risk for a cervical spine injury, so opening the airway via head tilt can compromise spinal stability. Instead, you use the jaw-thrust technique to open the airway while maintaining the cervical spine.
14		⊗Checked if airway had intact physical structures. **Findings:** *Physical structures are intact*	*Missing assessment step.* Though this patient did not have any facial trauma, be sure to look for injuries such as gun-shot wounds or facial fractures, as these may affect what basic or advanced airways you can use. Avoid using a nasopharyngeal airway in patients with a suspected basilar skull fracture or nasal injury.
15	02:00	☺suctioned the patient's airway. **Catheter type:** Yankauer (rigid)	Remember to check the effect of this action by asking for: intervention status.
16		⊗inserted an oropharyngeal airway (OPA).	*Missing intervention.* Remember: 'basic before advanced'. This patient is unconscious and therefore unable to maintain his airway (e.g. without an OPA, the tongue could obstruct the airway.) Insert a basic airway adjunct to maintain airway patency and allow you to pre-oxygenate the patient prior to intubation.
17	02:56	☺performed bag-valve mask ventilation.	

Figure 3

Self-assessment during a debriefing based on the DEBRIEF protocol



Fully assess and manage the patient in this scenario
- Put on BSI and do a complete Scene Size-up before entering the scene
- Perform a Primary Survey and manage all identified life threats
  - Conduct an Initial Assessment
  - Follow a 'CAB' protocol, given that this patient is unconscious, and first assess the patient's pulse, followed by other aspects of circulation
  - Manage a potential head or spinal injury
  - Assess the patient's airway
  - **Manage the patient's compromised airway**
  - Assess the patient's breathing
  - Make appropriate transport decisions based on your findings so far
- Obtain or direct a partner to obtain a patient history

Feedback based on your recorded actions: *Manage the patient's compromised airway*

Action	Your Rating	System Rating	Feedback
Open the patient's airway with a jaw thrust maneuver	✓	⊗	Opening the airway is a necessary precursor to inserting a basic adjunct. The patient is at risk for a cervical spine injury, so opening the airway via head tilt can compromise spinal stability. Instead, you use the jaw-thrust technique to open the airway while maintaining the cervical spine.
Suction the patient's mouth using a Yankauer (rigid) or Long multi-use catheter	✓	☺	
Reassess airway patency		⊗	After every intervention, it is vital to reassess the patient to observe the effect of that intervention. If suctioning is performed but gurgling still occurs on respirations, then further suctioning is required. Furthermore, if suctioning was performed and the airway remains clear, yet the patient continues to desaturate (SPO2), the provider should assess and think about other likely problems that caused the patient condition to worsen.

As a step towards addressing this gap in SBT research, we are conducting a randomized controlled trial (RCT) to compare the effectiveness of these two approaches to debriefing in MedDbriefer. This paper describes MedDbriefer and an initial field trial that we conducted to prepare for this comparative study.

MedDbriefer

MedDbriefer supports a "voice treating" approach to developing students' clinical reasoning skills. Voice treating entails verbalizing the assessment and treatment actions the healthcare provider would perform, how he would perform them, which actions he would delegate to a team member, etc. Although students often mime actions and use readily available equipment (e.g., a stethoscope) while voice treating, they can focus on identifying clinical problems and deciding how to manage them because they don't need to fully execute procedures.

Since MedDbriefer runs on a tablet, students will ultimately be able to use it to do practice scenarios just about anywhere—in a small meeting room, dorm room, etc.—without needing simulation equipment or a human instructor. A peer who is neither the EMS team leader nor a team member plays the role of "session observer", by using MedDbriefer's checklists to record the team leader's verbalized actions. As shown in Figure 1, MedDbriefer's *Observer Interface* (OI) provides two main checklists. The *assessment checklist* (Figure 1, left) is patterned after one of the "scorecards" used to evaluate EMS candidates during the National Registry of Emergency Medical Technicians' (NREMT) certification exam (NREMT, 2020). The *intervention checklist* (Figure 1, right) includes treatments and other actions that EMS providers commonly perform (e.g., transferring the patient to the ambulance). Interspersed throughout the checklist menus are prompts for the observer to issue to the team leader if he fails to provide sufficient detail while voice treating. For example, the Circulation menu displays a prompt for the team leader to specify which pulse(s) he is checking. (See Figure 1.) The system also provides feedback on the team leader's actions. For example, MedDbriefer displays a callout for the observer to issue when the team leader checks the "patient's" pulse (e.g., *Slow heart rate*, highlighted in yellow in Figure 1).

The chief difference between the two debriefing approaches that MedDbriefer implements is the extent to which they engage students in active reflection on their performance. In the narrative approach, the automated agent critiques each step of the team leader's solution (e.g., Laerdal Medical, 2020). Figure 2 illustrates MedDbriefer's implementation of this approach. In contrast, protocol-based debriefings encourage students to play a more active role in assessing their performance. This approach is illustrated by Sawyer & Deering's (2016) proposed adaptation of the US military's DEBRIEF protocol for simulation-based training in healthcare. DEBRIEF stands for **D**efine the debriefing rules; **E**xplain the learning objectives; specify the performance **B**enchmarks; **R**eview what was supposed to happen; **I**dentify what actually happened and **E**xamine why; and **F**ormalize the "take home" points. During a post-scenario discussion structured according to DEBRIEF, instructors prompt students to assess whether their solution met a set of performance standards ("benchmarks") and consider why it fell short of meeting particular standards.

In MedDbriefer's adaptation of DEBRIEF, the tutor summarizes the "Expected Actions" (Benchmarks) early in the debriefing session. During the "What Happened and Why" (Identify and Examine) phase, students are prompted to check off the actions they believe they performed and then compare their self-ratings with the system's ratings. (See Figure 3.). Feedback on incorrect actions is identical to that presented in the narrative version of MedDbriefer. (See Figures 2 and 3.). Abundant research demonstrates the superiority of active approaches to learning over more passive approaches (Chi & Wiley, 2014). Self-assessment is one form of active learning that consistently shows a positive association with knowledge and skill development (Andrade, 2019). Hence, prior research suggests that the DEBRIEF protocol-based version of MedDbriefer will predict higher learning gains than the narrative version.

Initial testing

At this writing, an RCT to examine this hypothesis is in progress. Approximately 40 students enrolled in EMS training programs are being randomly assigned to a debriefing condition (narrative versus DEBRIEF protocol-based; Figures 2 and 3). First, each student completes an online pretest. This test includes similar questions to those on the NREMT-Paramedic cognitive exam, which targets the clinical knowledge and reasoning skills needed for EMS practice. Next, students do eight scenarios that involve traumatic injury (e.g., due to a lawnmower rollover accident). The first two scenarios serve as a pretest; they are not followed by a debriefing. The intervention is comprised of the next four scenarios, which engage the student in debriefings. Students then do two posttest scenarios without a debriefing. The posttest scenarios exercise the same clinical knowledge and reasoning skills as the pretest scenarios. Students then take on online posttest that is isomorphic to the online pretest. Finally, they complete a brief survey with open-ended questions about what they learned, whether they think that MedDbriefer would be useful for EMS training and why, and how it could be improved.

To prepare for this trial, we conducted a small field test that followed the same procedure and used the same scenarios and instruments as those described in the preceding paragraph. Four recently certified paramedics (seniors in the university's EMS program) participated as team leaders during the scenarios. Peers trained to use the Observer Interface logged the team leaders' actions. All four participants received narrative debriefings after the intervention scenarios. Analysis of debriefing logs, feedback surveys, and screen recordings of observers' interaction with the OI revealed several changes that we needed to make before the RCT, for example: refinements to the algorithms that analyze session logs to generate a debriefing (Katz et al., 2022); clarifications to several feedback messages; and filling in some gaps in the OI's checklists—for example, to add cardiac monitoring by electrocardiogram to the intervention menus.

Table 1

Performance on pretest and posttest scenarios

	Multi-system trauma		**Difficulty breathing**	
Participant	**Pretest scenario**	**Posttest scenario**	**Pretest scenario**	**Posttest scenario**
P1	.76	.95	.80	1.0
P2	.62	.86	.50	.93
P3	.69	.83	.72	.90
P4	.86	.95	.79	.93

Although underpowered, this field trial suggests that MedDbriefer holds the potential to support learning. The fifth author performed a detailed analysis of each participant's data. For example, using the NREMT's trauma assessment checklist (NREMT, 2020) she scored students' performance on the pretest and posttest scenarios (#points earned/42 maximum). As Table 1 shows, all participants' scores increased from pretest to posttest—both on the scenarios that involve managing multi-system trauma and those that involve managing compromised breathing. Scores on the cognitive pre- and post-tests were mixed: Two students' scores increased from pretest to posttest, one student's scores stayed about the same, and one student's scores decreased. However, a closer analysis indicated that debriefing feedback contributed to gains on several test items. For example, one item targeted students' understanding that positive pressure ventilation should be avoided if a patient has a pneumothorax. Participants 1-3 missed this question on the pretest but answered it correctly on the posttest. They all received feedback that addressed this topic during debriefings. In contrast, Participant 4 answered this question incorrectly on both tests. She was the only student who did not receive feedback on this topic during debriefings.

Participants' feedback on the system, as expressed on the post-session survey, was highly positive. In addition to stating that the debriefing feedback was helpful (3 comments), the four participants agreed that, when fully developed, MedDbriefer will provide a useful tool for EMS training; for example, "When I was studying it was very difficult to find resources/scenarios that I could use for psychomotor testing by myself and with other students. This will be an amazing resource!" The data from the RCT will allow us to measure the extent to which MedDbriefer meets students' expectations and predicts gains in clinical knowledge and reasoning skills.

Aide: A Conversational Agent Based on Inoculation Theory and Large Language Models to Empower Learners to Recognize Disinformation

Renato Russo, Paulo Blikstein

Transformative Learning Technologies Lab, Teachers College, Columbia University

Abstract: Disinformation has been fueled in recent years, and inoculation theory offers an approach to supply the tools that will enable citizens to identify disinformation. It proposes that interventions can act like "vaccines" by exposing individuals to controlled doses of false or misleading information. This project draws on that theory to design a conversational agent that uses language modeling to surface strategies commonly used in disinformation. This paper lays out the motivation for the work, points to referential literature and related work, presents core design elements, and delineates future design directions based on testing data.

Introduction

The polyphony of online media and messages abetted a multitude of controversial—and, oftentimes, harmful—agendas, with deep implications for contemporary society (Marwick & Lewis, 2017). Educational researchers acknowledge the need to address the challenges posed by disinformation (Barzilai & Chinn, 2020), defined as the creation and distribution of false information with the intention to cause harm (Wardle & Derakhshan, 2017). This project seeks an answer to a part of that question: Aide is an attempt to support learners in recognizing features of disinformation. It uses large language models (LLM) to improve learners' ability to evaluate cognitive processes at play when we consume and distribute disinformation.

Aide is designed as a polyadic conversational agent (Zheng et al., 2022) to be used as part of a facilitated activity that guides the learner through analyses of strategies used in disinformation identified by previous research (e.g., Roozenbeek & van der Linden, 2019). This work builds on research that investigates disinformation through the lens of learning (Russo & Blikstein, 2022; Russo, Blikstein & Penalva, 2021): although it is a tempting solution to simply advocate for more efficient communication of facts, the present line of research proposes that there are intricate learning and cognitive mechanisms at play when we consume misleading or plainly false information.

Literature review and related work

Contemporary explanations of disinformation and educational interventions to address the issue rely on analogies between the forms of the spread of false information and viruses (van der Linden, 2022). Researchers base that analogy on the networked nature of contemporary communication systems, which would present themselves as pathways for the proliferation of messages that explore both political motivation and a lack of attention from media consumers. That line of research motivates the expansion of interventions based on the "inoculation theory" applied to disinformation, that is, exposing learners to reduced doses of false information in a controlled "therapy" whose functioning is akin to that of vaccines. This type of intervention, researchers argue, would lead to the development of "cognitive antibodies" that promotes inoculation.

That "epidemiological" approach supports the development of interventions that (1) expose the learner to strategies used in the creation (rather than to specific examples) of fake news; and (2) engage learners in actively creating hypothetical examples of misinformation, instead of its passive consumption (Roozenbeek & van der Linden, 2018). Some of those interventions take the form of serious games, like Lamboozled! (Chang et al., 2020) and Bad News (Roozenbeek & van der Linden, 2019), whose approach has been found to be effective in learning about misinformation. Strategies highlighted in Bad News—e.g., conspiracy and emotion – have inspired the design of Aide. This app exposes the learner to disinformation in controlled doses, with the expectation that those work in accordance with the inoculation theory, that is, we expect that our intervention helps learners develop immunity against false information they encounter in the future.

Work on Computer-Supported Collaborative Learning (CSCL) includes evidence of interaction between the use of a conversational agent and students' conversational behavior improvement (Ai et al., 2010). Researchers observed enhanced learning outcomes with the use of direct support in tandem with conversational agents (Dyke, 2013). However, research connecting conversational agents and education seems to focus on the natural sciences. In this project, we propose an investigation into the use of conversational agents in the instruction of an essentially multidisciplinary topic with a deep connection to the social sciences.

Table 1
Selected screens of the prototype

Onboarding screen	Evaluation shown to the learner	AI-created story shown to learner
 **I'm Aide, nice to meet you.** I am an application based on artificial intelligence and I use it/its pronouns. I'll try to help you understand a few mechanisms used in disinformation, you know, those messages that are everywhere and that are misleading or plain false. We can do a few things together, but I like to start with a trick: I can evaluate a headline or news story that may have made the news recently. Press "go" when you're ready.	 Here's what I think of that news story: The chances that this news story is a piece of disinformation are quite high. The news story claims that book bans increase literacy rates and cites a study as source. However, the study does not prove that book bans are the cause of increased literacy rates. In addition, the study only looked at a small number of children in one school district. The story is also emotional because it invoke fear by suggesting that book bans will lead to a decline in literacy rates. Watch out for: Unwarranted correlation Emotional trigger	 HERE'S A NEWS STORY FOR YOU: *There's a new bagel shop in New York that's serving up more than just breakfast. They're serving up a conspiracy! The shop, which is conveniently located near several major government buildings, is owned by a known member of the Illuminati. The shop's menu features several suspicious items, including a bagel with a hidden all-seeing eye symbol. The owner has been spotted meeting with high-ranking government officials, and there's evidence that the shop is being used as a front for Illuminati operations. If you're in New York, be on the lookout for this bagel shop. It might just be the key to uncovering the Illuminati's secrets!* That is an intriguing one 🤔 Now, type your evaluation in the text field below.

Design components

The current iteration of this conversational agent is based on the findings reported in the literature above, on user testing with graduate students, and on feedback from supporting faculty. Although the sample does not reflect the intended population for the final solution, the data allowed for a preliminary assessment of usability design of a learner journey. Three main design decisions derived from preliminary testing are delineated below:

- **Disinformation strategies foregrounded.** Reflecting literature review, Aide exposes learners to techniques employed in creating disinformation, instead of training individuals to "detect" specific instances of fake news. This decision has been made in accordance with "prebunking" as a "prophylactic approach" to treat susceptibility to disinformation (van der Linden, 2022).
- **Mix of learner- and AI-generated news stories.** Active participation in the creation of "news stories" has been shown to be more effective in inoculating individuals than passive consumption (Roozenbeek and van der Linden, 2018). However, preliminary user studies demonstrated that learners need some level of scaffolding before they start creating their own stories. This justifies the use of a mix of sources for stories. The choice for AI-generated stories is justified by four main conjectures derived from previous prototype testing: (1) It affords scaffolding for the task of creating fictitious content *quickly*, (2) it helps surface hand-picked *mental processes* that might or might not be present in our judgment of new information; (3) it scaffolds heuristics for judging new information; (4) the ability to start debates from a perspective that is more likely to be from outside the learners' echo chambers.
- **Conversational tone.** Feedback on previous versions also pointed to the need for colloquial, less rigid language. A similar tone is found in previous work mentioned above. For this reason, the current iteration incorporates word choice that attempts to mimic natural conversations. It also employs emojis to complement the meaning of the written text.

Technical specifications

Aide is a react.js application that makes use of OpenAI's node.js package. User inputs are stored as variables that are passed as part of custom-made prompts. These prompts are then sent as requests to Open AI's API (see "${answerx}" in prompts shown in Table 2), which uses GPT-3 models to generate human-like text. GPT-3 is a pre-trained large language model (LLM) built upon 499 billion tokens extracted from the web (Dale, 2021). Table 1 shows screenshots of the interface and Table 2 describes the prompts in relation to each round of the conversation, their expected learning outcomes, and actions at the learner's and the interface's end.

Table 1

Distribution of actions by the learner and the system, expected learning outcome and prompts across stages

Round	Learner action	Aide's action	Expected learning outcome	Prompt sent to the API
1	Choose news story	Evaluate	Initial contact with disinformation strategies and general method of analysis	"How likely do you think that the following news story "${answer1}" is a piece of disinformation? Justify your answer by stating whether and why it uses rhetorical devices such as unwarranted correlations, conspiracy theories, overgeneralization, cognitive biases, and emotional triggers."
2	Evaluate a news story	Show a news story	Initial contact with disinformation strategies and general method of analysis	"Create a sensationalist short news story that an influencer would share. Use the words New York and bagels, and use an unwarranted correlation or a conspiracy theory:"
3	Choose keywords and evaluate news story	Create story	Visualize connections of a random word made possible through rhetorical strategies	"Create a sensationalist, slightly ironic, optimistic short news story using the word "${answer4}" Use overgeneralizations and unwarranted correlations."
4	Evaluate news story	Create news story (or pick one from the news)	Practice evaluation of information	"Create a sensationalist, optimistic, fake short news story that could be published by a newspaper. Use the words vaccines and rollercoasters. Use discredit towards science as a rhetorical strategy:"
5	Self-assessment	Show previous evaluations	Reflection on learning	NA

Initial learner testing

Testing data presented in this paper focus on learner experience and learner interface, reflecting the nature of a tech innovation paper. The team is conducting other types of evaluation. Testers were female undergraduate and graduate students (22 to 26 years of age), recruited via personal networks of members of the team. No financial compensation was offered for their participation. The team used a local implementation of Aide to conduct 1-hour interviews over Zoom. Participants were granted access to remotely control Aide's interface. Prior to interaction, researchers briefly assessed participants' knowledge about mis- and disinformation. During and after the interviews, the research team took notes; after the interviews, researchers watched the recordings and drew upon Zheng et al.'s (2022) meta-review to identify themes related to interaction and experience with AI-based conversational agents.

All 4 participants could navigate the interface without instructions. Nonetheless, they had difficulties finding the relationship between each page and what phase of the app they were at. This problem possibly occurred due to the lack of information on the landing page and the absence of guiding UI elements that made explicit the tasks that were expected from the learner. For example, one of the participants stated that "the first page says it will only present news, so I thought it would only focus on that. But it now asks me to evaluate and make a story." That reaction illustrates how design decisions on Aide might impact the visibility of the learning journey, engagement of the user, and, ultimately, learning outcomes. We address these issues in next iterations.

Another striking point about the interface and experience was that some participants felt that the app itself should offer explanations about concepts in the topic, rather than an instructor. Three out of four participants stated that it would have been helpful if the interface had made it clearer what “cognitive biases,” “overgeneralization,” or “unwarranted correlations” are. Since the app was designed as a facilitated experience, it was originally thought that a facilitator could guide discussions on those topics. However, possibly because the interface resembled “stand-alone” applications with which subjects were familiar, they expected explanations to be available as they navigate Aide. As a result, after these initial studies, we implemented a new feature to address it (see “highlighting feature” in Table 1).

Future design directions and conclusion

Testing shows that further research is needed on the social aspects of learning about disinformation, and how we could be incorporate those into Aide. Previous versions of this prototype attempted to address those aspects by including an interaction between more than one learner at a time. However, that component has not yet been fully realized in the design. Future testing should reconsider ways to include more human-human interactions, in addition to human-computer ones. Besides facilitation by an instructor, we conjecture that, through conversations with peers, learners can relate their lived experience with concepts presented by the application. Learner data has also shown that it is crucial to implement highlighting strategies (see Table 2) as a support for learning, which will make learning more visible. Finally, we also consider alternatives to GPT-3 and OpenAI to avoid dependence on a framework whose development and continued accessibility are out of our reach.

This paper presented Aide, a conversational agent designed to help learners develop their ability to identify disinformation strategies. Through this work, we expect to contribute to the inoculative approach against disinformation by proposing a solution that explores the affordances of AI based on large language models. We hope to enhance our understanding of how mental models influence our judgment of misleading or plain false messages. In the future, we hope that this understanding is used to devise interventions that help us act against disinformation at individual and systemic levels.

Practice-Oriented Papers

Redesigning the MOOC “Learning How to Learn”

Nana Ariel, Faculty of Humanities, Tel Aviv University, daphnaar@tauex.tau.ac.il
Maaian Millikovsky-Ayalon, The Center of Innovation in Teaching and Learning, Tel Aviv University, maayanayalon@tauex.tau.ac.il
Omri Kimchi-Feldhorn, Sagol School of Neuroscience, Tel Aviv University, omrik1@mail.tau.ac.il

Abstract: In this study we present the redesign process that produced a new academic version (in Hebrew, translated into Arabic) of the popular MOOC *Learning How to Learn*. During the design-based research we explored practices that implement evidence-based principles in the learning sciences in real-life digital learning, and created a course that not only teaches about learning but also practices what it preaches in its learning experience. Our practices address neural, cognitive-emotional, meta-cognitive and behavioral aspects of learning, and they include designing the course as a modular network, creating a local community of lifelong learners, and increasing embodiment in the media design. We present a model for a localized MOOC with maximal adequacy between the theoretical concepts that it teaches and its design, applicable to digital learning in other areas.

Redesigning a MOOC

Digital learning, and MOOCs specifically, increasingly benefit from learning-science-based design. Addressing the need to distribute knowledge on learning to students and other lifelong learners, we redesigned the popular MOOC L*earning How to Learn* and created a new, official academic version in Hebrew with full translation into Arabic, launched in December 2021. Our design-based research (Ariel, Millikovsky-Ayalon & Kimchi Felhorn, 2022) included a productive collaboration between practitioners (lecturer, teaching assistant and learning experience designer) who are also scholars in three different fields – Humanities, Neuroscience and Psychology.

Learning How to Learn (LHTL), developed by Prof. Barbara Oakley and Prof. Terrence Sejnowski, and available in the Coursera platform since 2014, was a central landmark in the attempts of educators and learning scientists worldwide to make the learning sciences accessible and applicable to the masses. It has become one of the most popular MOOCs in the world, with various translations (French, Spanish, Portuguese, Hungarian, Arabic, Korean) and new versions (Russian and Chinese – see Chen and Oakley, 2020 on the redesign of the Chinese version). Following Oakley’s approach, and with her support, our new version of the MOOC presents an academic adaptation which significantly deviates from the original in scope and design.

Our central premise was that a MOOC – particularly one on the subject of learning – should be designed according to the mechanisms of the learning mind and rely on evidence-based practices in the learning sciences (see also Najafi, et al., 2017; Gordon & Willtrout, 2021). Therefore, our aim was not only to present ideas *about* learning but also to implement them in the structure, the pedagogical methods and the overall learning technologies of the course. The original LHTL had already taken steps in this direction, and we expanded it to the overall course design and created an online learning experience that addresses an array of learning mechanisms. The process of redesigning LHTL, which lasted a year, entailed reverse engineering of the original course and iterations that prompted the course development (see figure 1). Our practices addressed neural, cognitive-emotional, meta-cognitive and behavioral aspects of learning, and they include designing the course as a modular network, presenting varied models of learners, increasing embodiment in the media design, and creating a section of active reading of academic articles. The redesign also addressed pressing issues in online learning, such as international versus culturally sensitive teaching, high MOOC drop-out rates, “transactional distance” and online versus blended formats. We will now briefly address three central landmarks in the MOOC redesign.

Redesigning the linear course as a network

While the original LHTL was linear, we decided to turn it into a network, in which the learning experience is modular and self-regulated. The transformation from a linear course to a network required us to treat the original LHTL as a flexible set of materials, reorganized in six central topics that we identified as central issues and concepts in everyday learning – time, attention, memory, emotions, language and body. Each topic comprises a lesson that can be learned in any order and pace, and connected to the other topics through an array of concepts that intercross them, so that the learners reencounter them throughout the course (for example, the term “meta-cognition” appears in each and every lesson; the term “spacing” appears in discussions on time, memory and attention). A course map and an interactive glossary facilitate learners’ orientation in the network. The modular course design resonates with the networked structure of the learning mind: it increases the connectivity between concepts throughout the course and enables learners to encounter them in different contexts and from various disciplinary perspectives, in a way that mirrors the mechanism of neural networks.

The networked design also presents an updated approach to the well-known problem of high attrition and drop-out rate in MOOCs. In recent years there is a growing consensus that the completion of a MOOC is not the best criterion for its assessment (Hayes, 2015; Lackner et al., 2015), and various alternatives are being considered, such as rewards for completion of small sections (Leach & Hadi, 2017). In our course, even if learners take only a few units they do not drop out "in the middle", as there is no "middle" in a network, and learning a single unit grants one a foothold in all the other units connected to it. Accordingly, instead of basing our assessment of the MOOC on the number of learners who complete it, the more important questions we asked concern learners' patterns of behavior in the course, the individual routes they choose, and the self-assessment of their own learning experience. In other words, the networked course design shifts the assessment from quantitative questions such as "how many" to qualitative questions such as "in what way". In a survey among approximately 150 students in 2022, we discovered that many of them can justify their personal modular route, and that the networked structure potentially enables them to develop awareness of their own learning motivations and helps them practice self-regulated learning. When the course is modular rather than linear, every element that the students wander through is the product of their choice, and the actual order of learning is led by an intrinsic rationale, which also potentially increases learners' intrinsic motivation and emotional engagement, which has crucial roles in online learning (Cleveland-Innes & Campbell, 2012; Dillon et al., 2016; Asikainen et al., 2018).

Localizing the course using diverse models of learners

The networked course design enables a flexible learning experience based on conceptual connectivity; however, online learning also relies on human connectivity – between learners and instructors, and between learners and their peers. Moore and Kearsley (2012 [1996]) developed the "transactional distance" theory according to which "distance is not simply a matter of geographic distance, but is a pedagogical phenomenon" (209). Thus, the geographical distance between instructors and learners can cause alienation, but can also function as an opportunity for pedagogical design that promotes a sense of community. Followers of the transactional distance theory demonstrate that it is a central issue in examining MOOCs, as these are usually based exclusively on distance learning (Weidlich & Bastiaens, 2018), risking blindness to the specific identities of the learners. As Chen and Oakley (2020, 5) note, sensitivity to cultural differences in MOOCs is essential: "We realized that, when it comes to MOOCs, simply providing translated video captions and Web pages were far from meeting non-English speakers' learning needs."

Therefore, in the Hebrew-Arabic LHTL we avoided using merely translated versions of the original American LHTL materials, rather creating a "glocal" learning experience – one that addresses global issues and universal learning paradigms, while also fostering local learning cultures. Creating a fair representation of Israeli culture is an impossible task, as it includes various – and often conflicting – voices and identities. This complexity, however, may also be seen as an advantage: from ultraorthodox ascetic religious learners to bilingual Hebrew-Arabic speakers and inspiring autodidacts, local learners present rich and diverse learning models. This resulted in our decision to include, throughout the course, encounters with different types of learners:

- *Fictional characters of learners* (such as Sherlock Holmes, Karate Kid, Charles Chaplin and Alice in Wonderland), presented at the beginning of each lesson according to its topic, and drawing the learners into a world in which their entire environment – including international popular culture – is immersed in learning.
- *Diverse local lifelong learners,* from elementary school pupils, through university students of various ages and sectors, to established scientists such as Nobel laureate Prof. Ada Yonath – are all interviewed in the course about their conceptions of learning and their learning habits. This mosaic of local learners creates the sense of a community that shares personal experience with the course learners, and allows for a more concrete understanding of abstract concepts in each lesson.
- *The course team,* authors of this paper. During the design process we, the academic team, documented our own real-life learning processes and included them as part of the course, becoming part of its community of learners *de facto*. For example, the course teacher presented a video blog of learning bass guitar from scratch for 10 weeks, while reflecting on concepts such as procedural memory, attention and motivation. Thus, our own position as learners did not remain backstage; it became transparent and visible to our learners, showcasing real-life learning dynamics and encouraging the learners to actively share their own, either online or in special blended sessions.

Designing videos using ‘embodied typography’

Following Oakley and Sejnowski (2019), and Clark and Mayer’s (2016) multimedia learning approach, which emphasize the principle of embodiment that eases the assimilation of complex information, we used a technique we call “embodied typography” in our media design. Embodied typography uses kinetic design that dynamically intertwines with the instructor, to visually demonstrate abstract concepts. Our premise was that a MOOC differs fundamentally from frontal teaching; it should not try to imitate a lecture and it should use alternative means suitable to the medium of short videos. Our solution, however, was to almost completely waive the power of visual images, instead choosing to utilize the elasticity of typography – instead of using illustrative images, we used illustrative letters, words, and abstract shapes. For example, when we mention the contribution of spacing to the learning process, the word “spacing” splits; when the concept “retrieval” (from long-term memory) appears, one letter as is ‘retrieved’ from the word. While not challenging the assumption that visual images help learners anchor and remember abstract ideas, or dismissing them as ineffective pedagogical devices, we claim that images often fixate memories on specific objects and are often too culturally specific. Typography enables the creation of abstract, clean yet accessible visual metaphors without committing to context-dependent images.

Throughout the course we use typography and abstract graphic metaphors repeatedly and consistently, to strengthen the networked course structure. In each appearance of a concept, we use the same design to represent it: for example, at each mention of a difficulty in learning (concepts such as stress, anxiety and procrastination) we use the same illustration of intertwined black lines that create a disturbing sense of entanglement. The word “motivation” is always followed by flying lines that illustrate a sense of action and energy. Thus, concepts throughout the course become mental models that create the expectation of consistency and strengthen long-term memory.

The redesign conclusion and its contribution

All the aforementioned practices, and many more that we implemented in the course, ensure that the theory of learning is reflected in every aspect of the course design. As one of our students commented in the assessment, “studying the course is like watching the backstage of your mind”. This tour into one's mind is not created by passively receiving theoretical concepts, but by a meta-cognitive learning experience, stimulated by the course structure and features, as well as by constant participation in interactive questions, discussions, and active reading.

The reverse engineering of the original course, together with various iterations we have implemented following conversations with experts and students, reading relevant literature, and experimenting with technologies, enabled us to constantly revise our premises and increased the course effectiveness and its value as a local version addressing a specific community. Iterations in MOOC design are not an easy task, as shooting the course units may fixate it and not allow flexibility, therefore the iterations started before the course launch. One example was the reading section design. While our far-reaching plan was designing a fully embodied reading that includes interactive guiding comments in the article along the reading, technological restrictions sent us to back to design a different reading experience. After the course launch, learners’ feedback helped us adjust and finetune specific areas in the learning experience: for example, we discovered that group meetings on Zoom between strangers do not promote their learning as expected, and we designed the blended sessions in different techniques and found alternative ways to create personal connections between learners, to address the issue of “transactional distance”.

We have learned about the possibilities and the limitations of MOOC technologies, and some of our wildest ideas had to be adapted creatively to more feasible practices. Thus, the process of *creating* the course became a learning experience in its own right and echoed the theoretical principles taught in the course. The result of our learning process is a MOOC format characterized by maximal adequacy between contents and design, open for the use of new international versions of *Learning How to Learn*. Our claim that learning-science based MOOC design significantly enhances it, also makes this model relevant to MOOC researchers and designers in other areas.

#DryLabsRealScience: Redefining Practical Pedagogy Post-Pandemic

Nigel Francis, Cardiff University, francisn10@cardiff.ac.uk
David Smith, Sheffield Hallam University, d.p.smith@shu.ac.uk
Ian Turner, University of Derby, i.turner@derby.ac.uk

Abstract: The COVID-19 pandemic posed specific challenges for STEM educators, namely the provision of meaningful laboratory experiences when access to equipment and facilities were restricted. #DryLabsRealScience is a community of practice that was formed to address these challenges, providing a free, open platform for sharing innovative, practical approaches to support the life sciences. The network identified datasets, augmented/virtual reality, simulations, and videos as the central and most effective approaches to delivering laboratory-focused teaching and learning. While all these approaches had been used pre-lockdown, the pandemic forced the adaption of these techniques to online delivery. In this paper, we describe the novel utilisation of these approaches to support student laboratory learning in response to the challenges faced by remote and blended teaching.

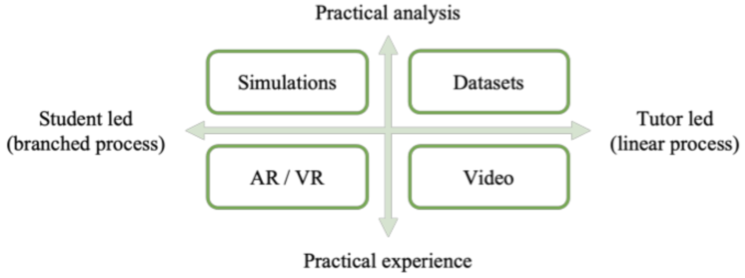
Introduction

When COVID-19 forced the closure of laboratory facilities, higher education (HE) had to rapidly re-evaluate their approaches to delivering practical-based degrees, with the main challenge being the replacement of sessions that developed kinematic psychomotor skills essential to STEM practitioners (Wilkinson et al., 2021). #DryLabsRealScience (#DLRS), a practitioner-driven community of practice, was established to address this issue, providing a free and open network for life science educators to share their innovative approaches to overcoming the challenges of pandemic-impacted teaching. What has resulted is a rich community of practice that enhances the delivery of practical laboratory and field classes in a much broader sense (Francis et al., 2020). Over 90% of participants in the network, which has an international reach of over 200 educators spanning higher, further and school education, as well as commercial education providers, highlighted that attending network events had allowed them to influence departmental policy for dry lab provision (Cramman et al., 2021). The evolving pedagogic approaches developed by the network have had a lasting impact on the practical class provision through the development of a blended educational model.

Approaches

Thematic analysis of the topics presented during #DLRS meetings has revealed four principal approaches: videos, simulations, augmented/virtual reality (AR/VR) and datasets. There is a clear overlap between these methodologies and combined approaches have become embedded as practitioners have embraced blended learning strategies. Each approach has a sound pedagogic underpinning as well as individual strengths and weaknesses that are presented as a conceptual framework (Figure 1). The four main areas of practice can be split along two axes. The horizontal axis describes the pathway for interaction with content: tutor-led (linear process), where a defined outcome is pre-set, and student-led (branched process), where the outcomes depend on the individual's actions. The vertical axis describes delivery as either a physical experience to replicate or enhance psychomotor components or as an environment to experience practical analysis through generating or manipulating practical outcomes.

Figure 1
A new conceptual framework for practical delivery



Videos

Educational videos have been integral to many HE courses, whether for traditional delivery, a flipped approach or as a mechanism for conveying information in blended/online courses. Videos have been shown to be an effective educational tool in various educational contexts (Woolfitt, 2015; Smith & Francis, 2022), including the supplementation of practical pedagogies through video exemplars and guides to practical techniques (Croker, 2010).

The COVID-19 pandemic placed an intense focus on the use of videos to help support the delivery of practical classes, initially remotely and subsequently in the blended learning model as facilities opened again. #DLRS identified three key stages of video usage in practical delivery (i) pre-lab (e.g., health and safety briefings, equipment demonstrations); (ii) replacement labs (e.g., live streaming a lab class, pre-recorded demonstrations); (iii) post-lab (e.g., data visualisation and analysis) (Turner, 2020).

Videos are not, however, a medium without challenges. They need careful design to ensure students are not cognitively overloaded and require elements of active participation from students to maximise learning gains and avoid them becoming a linear, passive medium for content delivery (Fyfield et al., 2019). Some specific active learning approaches highlighted in video usage by #DLRS contributors include:

- Deliberate errors are placed into the recorded demonstration, which the students then identify.
- Silent videos, where students are asked to record a narrative to demonstrate understanding.
- What happens next? Incomplete videos for students to identify the next step.
- Live streaming with students directing the actions of the demonstrator.
- Quizzes embedded into the videos require an attempt to be made before the recording can be resumed.

Simulations

A well-designed simulation replicates the sequence of interactions a user can expect when operating a system. Within the practical context of a laboratory, this manifests itself as the replication of techniques, methods, or equipment, in digital format. Where simulations differ from videos is the indeterminant branched endpoint that is dependent on the actions of the user. This permits students to experience multiple iterations of a method or technique that might otherwise be logistically impossible due to time or cost restrictions (Jones, 2018).

The use of simulations can be considered a form of inquiry-based learning, with students manipulating parameters within the simulated scenario, which can be recorded and analysed as a process in their own right to optimise the experimental design (Gormally et al., 2009; Pedaste et al., 2015). By passing ownership and control of the experimental optimisation to the students, they experience an authentic task that enhances critical transferrable skills, such as problem-solving (Bassingdale et al., 2021). Crucially, these skills can then be transferred to the physical environment, so students have already experienced what it is like to solve given problems and can focus on developing the kinematic psychomotor skills required to complete the task.

Virtual labs can bridge scientific theory from taught material to laboratory practice in the same way physical labs do. The ability to attempt multiple iterations of the experiment in a compressed timeframe can enhance the link (Francis et al., 2022). Students have reported that they develop an understanding of correct equipment usage, troubleshooting, accurate record keeping and data analysis and interpretation skills from simulated labs, which align closely with the learning objectives for face-to-face wet labs experiences (Bassingdale et al., 2021).

Examples of simulation usage from #DLRS members include:

- Data recording in an electronic lab book through a [Do][Explore][Act] framework.
- Interactive virtual lab usage to allow students to explore given scenarios (e.g., Labster (www.labster.com)/LearnSci (www.learnsci.com) resources)
- OpenSTEM labs (www.stem.open.ac.uk), online virtual labs from the Wolfson Foundation that provides remote access experiments and virtual simulations using real-time data.
- Virtual learning tools such as Benchling (www.benchling.com) incorporate an electronic lab book with an embedded suite of molecular biology analysis tools.

AR/VR

Augmented reality (AR) integrates digital information with the physical environment allowing simultaneous interaction between the digital and physical environment. Virtual reality (VR) creates a real-time, fully immersive simulated digital environment (Huang et al., 2019). AR is a more emergent pedagogical tool than VR, which has been implemented successfully in various educational settings, including HE (Huang et al., 2019). Several commercial providers facilitate the use of virtual laboratories, combining VR with simulations, videos, and interactive worksheets to produce rich, immersive, active learning environments for students. The use of AR in life sciences has been less well studied, but its potential is starting to be recognised (Barrow et al., 2019). Members of the #DLRS community became early adopters of AR and VR to supplement or replicate practical teaching, however, they acknowledged the barriers to adoption as a pedagogic tool. These include the cost of equipment, the skillset required by staff to develop and students to utilise resources and the institutional infrastructure, including student access to hardware. Some highlighted examples of AR and VR use include:

- 360º videos using ArcGIS StoryMaps to provide virtual field trips for students, allowing them to interact with multiple fieldwork sites.
- Virtual marine field trips created using ThinkLink, allowing students to navigate and explore coastal landscapes whilst conducting real-time experiments with embedded experimental tools and videos.
- Creating AR protein structures that aid students with visualising the crucial theoretical concepts from lectures in an interactive manner.

Datasets

Data generation and analysis is a critical skill developed during the laboratory experience. Pre-pandemic, many practical and field classes focused on generating data in numeric or image format, which were subsequently used for analysis and interpretation. Within the post-practical teaching environment, datasets are often subject to statistical analysis to reveal meaning. Therefore, the ability to manipulate and work with data, apply appropriate statistical analysis, and interpret meaning are crucial skills required of scientific practitioners. Within the #DLRS context, this has resulted in students generating datasets using simulations or tutors using coding strategies in R, C++, Python or HTML5.

An advantage of this approach is that each student can be assigned a unique dataset to work with, with algorithms providing the solutions to tutors based on the original input parameters. Through the, near, limitless datasets that can be generated, students can develop the key skills of data interpretation and analysis whilst mitigating against collusion and encouraging students to collaborate on processes rather than answers. Specific examples showcased to #DLRS include:

- Automatically generated datasets using R. Specific variables can be randomised to introduce set ranges and errors within the datasets. Unique identifiers allowed tutors to quickly access solution sheets.
- Interactive experiments coded using HTML5 allow students to generate datasets within a web-based environment. Answers can be inputted into automatically marked worksheets.
- LearnSci produces interactive, self-marking worksheets which can be embedded into virtual learning environments. The worksheets allow students to enter their own unique datasets and provide guidance and feedback as the student attempts questions providing a rich assessment for learning opportunity.
- CellProfiler has been used to perform High Content Image Analysis with students provided with existing images that were unique to each student.

The main pitfall of computer-generated datasets is the lack of ownership felt by the students with the data production and, therefore, more limited engagement with the analysis. Synthetic datasets, constrained within nominal parameters and ranges, may not provide the diversity of data, nor model experimental trends and errors seen in student-generated experimental data. However, the advantage is the reduced marking burden that can be associated with automatically marked worksheets.

Conclusions

The COVID-19 pandemic rapidly accelerated the adoption and evolution of pedagogical approaches that underpin practical delivery. Once educators were able to adapt to the remote and blended learning approaches, a rich and diverse range of strategies began to be described and adopted. At the start of the lockdown, many of these ideas were applied in isolation as educators struggled to provide a meaningful learning experience, however, we are now witnessing more joined-up strategies, with multiple approaches being integrated with each other to produce robust teaching and learning resources both pre- and post-practical. It needs to be noted that none of the approaches described here can fully replace the physical laboratory experience, as the kinematic skills developed in face-to-face environments remain the cornerstone of science-based degrees, confirming the findings of de Jong et al. (2013). However, where immense value is added is in the preparatory phase, allowing a scaffolded approach to student learning where they can link the theory of lectures to the application of laboratory practice prior to even setting foot in the physical space. Post-class, student learning of data analysis, interpretation and presentation can be enhanced allowing for a greatly enriched educational experience.

Although the strategies and approaches described here have been focused on biosciences, they are applicable to most other disciplines within and beyond STEM. Communities, such as #DLRS provide a valuable, open platform for the free sharing of ideas and resources driving teaching approaches' adoption, refinement, and enhancement. The networks will be able to adapt to future challenges, driving a long-lasting change to the pedagogic thinking around laboratory provision with the continued use of resources developed during the pandemic as a return to more traditional delivery methods ensues.

Eleanor C. Sayre, Kansas State University
Eugene Y. Vasserman, Kansas State University

Abstract: Discipline based education research (DBER) seeks to understand how people learn and grow within a discipline. It is a highly interdisciplinary field requiring knowledge in the specific discipline in question, as well as education and related fields. DBER attracts many faculty practitioners who did not conduct their degrees or post-doctoral work in education. These practitioners often find themselves without formal support or opportunities for formal introduction to education research. We discuss how the Professional development for Emerging Education Researchers (PEER) program supports these emerging education research practitioners in learning the ropes in this new field. PEER's theory module is a recently created addition to the program, which is undergoing continuing development, and is our example of how the PEER program is adapting to participants' needs.

Introduction

Discipline based education research (DBER), a cousin field to the Learning Sciences, seeks to understand how people learn and grow within a discipline. Typically conducted at the university level and from within disciplinary departments or schools of education, DBER interests faculty with diverse research and disciplinary backgrounds. Some may have studied education research in graduate school, or pursued post-doctoral work in it, having prepared for research through training and practical exposure to ideas, theories, methods, and common practice within the field. Faculty may become interested in DBER after obtaining their faculty position (often, but not always, a teaching-focused position) (Bush et al., 2017) or after tenure and promotion. These faculty rarely have formal DBER training or practical experience, even as they may have varied experience as educators. As a result, they struggle to orient themselves to the field's understanding of theory, methods, and research practice and as they set up their research programs within the field.

The Professional development for Emerging Education Researchers (PEER) program was established to support these emerging DBER practitioners (Franklin et al., 2018). PEER offers workshops and mentoring to support emerging DBER practitioners in developing their education research skills and succeed in their personal education research projects. In this paper, we focus on one PEER module about research theory as a case of how the principles and design of PEER came together with lessons learned from participants.

Who are the authors?

In the context of PEER, our participants are practitioners. They are new to the practice of education research, and they engage as emerging DBER practitioners in PEER activities. This paper seeks to discuss how we support newcomers in engaging in the practice of education research. The first authors on this paper take the dual perspective of researchers on PEER as a program and practitioners (PEER participants); the following authors take the dual perspective of researchers on PEER as a program and PEER workshop facilitators. Just as a professional development program for teachers around improving classroom teaching counts their participants as practitioners of classroom teaching, we count the participants in our professional development program as practitioners for engaging in DBER.

We incorporate the research principles of PEER in our daily work, and study the PEER program in the hopes of making education research more accessible to disciplinary scientists. In our capacity as part of the PEER research team we work with the PEER coordinators and facilitators to better understand the needs of the program and its participants. Our research supports the development of the program, and helps to ground the program in participants' needs.

The philosophy and why of PEER

PEER is strongly grounded in two theoretical perspectives: responsive teaching, and communities of practice. Responsive teaching is a model of teaching in STEM education that places high importance on centering and responding to the ideas of students and the connections they are making (Robertson et al., 2015). PEER embodies this responsiveness at a workshop level by centering individuals' research interests and questions in its activities. Modular, multi day workshops are organized and constantly reevaluated to center participants' research interests and projects as a subject for development making practitioners the drivers of ideas.

PEER workshops also seek to develop a local community of practice among participants (Wenger, 1999). Many emerging practitioners are still developing their identity as education researchers, and a community of fellow practitioners is critical to supporting that development. As a theory of education, communities of practice highlight learning as engaging in shared practice (Wenger-Trayner & Wenger-Trayner, 2022). PEER's community of practice consists of practitioners and facilitators engaged together in researching education and instruction.

The theoretical grounding of PEER has led to four core guiding principles: research is *responsive, playful, collaborative,* and *communicative*. These four principles are explained in Table 1. Additionally, in keeping with these ideas, PEER takes a non-linear view of research as a practice. This nonlinearity encourages *playful* generation of ideas throughout the process, regular and planned *communication* of those ideas, *collaboration* with colleagues to share ideas and play with, and results in a research process that is *responsive* to the evolving needs and ideas of practitioners.

Table 1
The guiding principles of PEER, for professional development and research practice

Responsive	Research responds to the needs and ideas of researchers, subjects, and the community.
Playful	Research is play, engaging with each other's ideas in an actively positive way to encourage idea building and research development. There are no bad ideas, only incomplete ones.
Collaborative	Research is better with friends. More minds and perspectives mean more ideas to play with, and more research and collaboration opportunities.
Communicative	We communicate our research ideas at all stages of the project via different media (posters, talks, publications, etc.), and actively think about how we will do that.

The four principles of PEER do not only apply to research, but also to the program. Research is fundamentally a process of discovering and generating new knowledge, a process of learning. PEER is a professional development program, participants come here to learn and develop new skills in education research. Accordingly it makes sense to ground the learning and knowledge development that participants engage in at PEER in the same principles that we wish participants to adhere to in their research practice.

What is theory: Needs of emerging practitioners

Emerging DBER practitioners often struggle with the role of theory in education research, especially if their prior experience with theory is through a STEM discipline. In response to repeated and ongoing requests from PEER participants to train them about theory in DBER, we conducted research around emerging DBER practitioners ideas about theory and iteratively developed and tested a module to address their needs and concerns.

Participants have often expressed interest in learning about various theories, how to use a theory or multiple theories applied to the same data, or have even requested a module on "What is theory anyway?" Over the years, PEER coordinators had struggled to design a workshop module that felt like it addressed participants' needs and answered their questions in appropriate depth. Recent interviews with emerging DBER practitioners shed some light on what they wanted to learn about theory (Hass et al., 2022), for instance Ryan stated: "[There are so many] different theoretical perspectives that one can adopt when you're looking at your data..." and went on to say: "Where you just kind of do what you know and if you don't know it, you can't do it." The lessons learned from this research have allowed us to construct a new theory module.

Currently this module focuses on having participants discuss and think deeply about what they expect from theory in their projects. The module begins with a collaborative role play activity, and moves into alternating facilitator presentations and small group discussions about theory, interspersed with personal writing time. The module then moves into reframing research questions based on theory choices. It closes out with a large group question and answer session, and context discussion. This is a fairly common overall format for PEER modules, which focus on giving participants ample time to connect module content to their own research projects, with help from facilitators.

PEER's theory module

Facilitators present briefly (5 minutes) about big questions to consider when selecting among theories, responding to emerging practitioners' questions in a pre-workshop survey. Next a case study gives participants the opportunity to generate ideas about theory in a way that is *playful* rather than critical. The case study is a role playing session in which participants split into groups of 3 or 4 and are given a scenario to role play out. Members of the group take up the roles of Lauren and James (in a three person group one person is an observer). They then come back together for a group discussion about how the role play went, with Laurens, James', and observers taking turns reporting out. Participants are explicitly not given definitions of theory before the case study, and are intentionally given the case study at the beginning of the workshop before learning more about theory. The case study given to the participants is included below.

> *Lauren and James are thinking about collaborating on a paper to submit to Physical Review Physics Education Research about how to help students who are stuck while problem solving. They have video data and transcript of a small group of students problem solving in a lab. They are both new to Education research, and are struggling to choose an appropriate theory. So they reached out to a colleague who does this, whose first question was "What do you want theory to do for you?"*
> *They say they'll have to think about that more, and then head off to discuss theory together.*

Many participants express feelings of uncertainty about theory (a participant anonymously asked in a pre-workshop survey "Why do you even need a theory?"), but also feelings of uncertainty about their newness to education research (Mariah says in a pre-workshop interview "I was a little intimidated by that because I'm not like an education researcher…"). Building *collaboration* into the workshop gives emerging practitioners the opportunity to be confused about theory, openly and together, so that they know that they aren't alone. We also want to give participants space to discuss their own great ideas about theory (because it turns out they have lots) before we dive into other people's ideas about theory.

Emerging practitioners are also struggling to understand what role theory plays in research practice, as James says "I try and put myself in that researcher's shoes and understand how they're connecting the dots. And I try really hard to extend that all the way back to their theoretical framework…". After emerging practitioners have had a chance to think about what theory is, and their ideas about theory, facilitators give a presentation on the research process and theory's roles in a research project. PEER's nonlinear view of research means theory takes on different roles over the course of a project. Research is *responsive*, and as a project evolves and as researcher's thinking and perspective changes, theory must respond to those changes.

At this point, the theory module moves into a mixture of presentation from the facilitators, and question and answer. Facilitators respond to the concerns and individual ideas of participants, while also attending to and celebrating shifts in participants' thinking. Time is built in intermittently (usually about 5 minute chunks) for participants to do some generative writing, where they write about their ideas and how these ideas connect to their research plans. Generative writing is a philosophy of writing that takes the act of writing as generative, in writing things you come up with new ideas. Writing often and lots is good for producing, solidifying, extending, and exploring ideas. This supports *playfulness* by generating and recording new ideas to play with and share. It also supports *communicative* aspects of research by supporting the creation of posters, presentations, and papers later in the research process.

Next, facilitators discuss a method of categorizing theories, *responding* to emerging practitioners' wish for a way to map different theories and their purposes. The method is just one of many, and focuses on categorizing theories according to the level of their focus. Participants are given an activity where they work in groups to take a research question, and adjust it to suit different categories of theory. Then, they are asked to go back to their own projects and consider what their current research question says about what level of theory they might need. Again, notice that participants are encouraged to engage directly in the process of research as part of the workshop, and are invited to play *collaboratively* with the ideas presented to them.

The workshop ends with a practical discussion of how to find theory, in *response* to emerging practitioners' struggle to find relevant theories in the dauntingly vast literature. This last part of the discussion also includes time spent on the possibility of creating one's own theory, when that would be appropriate, and what it entails. Theory, like all parts of the research process, should be *responsive* to one's needs, so we discuss how to adapt and create theory when one needs to.

Implications for education researcher development

Paying attention to the needs of emerging DBER practitioners is important, as catching them early is an opportunity to help them grow in the practice and become engaged with our community. As a community this makes us more productive and our practice stronger. Alternatively, ignoring them leads to feelings of isolation and can drive them out of our community. It can also result in lower quality work within our practice.

Attending to emerging practitioners' needs means building a partnership, in which both our emerging practitioners and community members work together to build ideas. These partnerships lead to learning both for junior and senior community members, and bring benefits to all parties involved. Collaborations, publications, opportunities for mentorship, and building lasting friendships are all benefits that come with supporting emerging practitioners. Further these partnerships can lend insights into the values of our field, and also the behaviour and ideas that we take for granted (for instance the definition of theory, and the many different terms surrounding it). It is key, when building such a partnership, that all parties have the power and ability to set the agenda.

Finally, creating and iterating on the theory module has required us to look for the concerns underlying problems voiced by emerging practitioners. Though they often ask for particular theories, or particular questions about what theory is used for and where it comes from, deeper issues underlie these questions. For instance, concerns about legitimacy, acceptable practice within the community, and the friendliness of reviewers. Finding and understanding what these deeper issues are is important when attempting to support emerging practitioners in their growth.

Abstract: Incorporating embodiment into learning environments has increasingly been accomplished using motion-detection technologies to create extended reality (XR) experiences. While these XR experiences typically use specialized hardware (e.g., Microsoft Kinect), computer vision algorithms and embedded laptop cameras have advanced to the point where they can be incorporated into educational interventions and research tools without the need of expensive peripheral technologies. In this paper, we present a scalable research tool, The Hidden Village-Online (THV-O), that leverages these technologies in the form of a web-based, narrative-themed videogame. Preliminary pilot results indicate that this tool was able to replicate findings of a similar embodied cognition study that used software powered by the Microsoft Kinect. These results suggest that web-based XR experiences requiring only an internet connection and an embedded laptop camera, like THV-O, are mature enough to serve as a viable alternative approach for creating technology-enabled embodied learning experiences.

Introduction

Over the last decade, increasing interest in embodied cognition has seen the development of novel opportunities to learn through integrated and high bodily-engaged tasks (Skulmowski & Rey, 2018). Advances in computer-based motion-detection technologies have produced a variety of options to incorporate embodied experiences into learning environments (Georgiou & Ioannou, 2019), often leveraging a host of peripheral hardware such as the Microsoft Kinect (e.g., Abrahamson & Bakker, 2016; Rallis et al., 2018), virtual reality headsets (e.g., Johnson-Glenberg et al., 2021), and mixed reality devices like the Microsoft Hololens 2 (e.g., Walkington et al., 2022). One of these embodied learning environments, *The Hidden Village* (THV; Kirankumar et al., 2021; Nathan & Swart, 2020; Nathan & Walkington, 2017), uses 3D-motion capture to elicit and track players' cognitively relevant movements (Nathan & Walkington, 2017) that benefit players' mathematical reasoning about geometry conjectures. Benefits arise because players' are more inclined to generate embodied simulations of the potential transformations of geometric objects while they explain their reasoning as they formulate mathematical intuitions, insights, and proofs (Swart et al., 2020; Walkington, Nathan, Wang, & Schenck, 2022).

Though these studies suggest that players' geometric reasoning improved as a result of using this technology-based intervention, THV's reliance on dedicated peripheral sensor hardware limits its scalability and sustainability as a classroom activity and research tool for a number of reasons. First, rapid developments in extended reality (XR) technologies (i.e., augmented reality and virtual reality) caused several peripheral XR hardware projects to be discontinued, including the Microsoft Kinect, Oculus Rift, Google Glass, and Leap Motion controller. Continuing to use these outdated technologies requires researchers to seek costly and specialized software development to push forward their research agendas (Fogel et al., 2021). Second, peripheral hardware such as XR headsets can only serve one student at a time and purchasing enough to serve all their students is an expense that prevents many schools from widespread classroom adoption.

Fortunately, significant advances in the quality of embedded laptop cameras combined with open-source computer vision packages have enabled development of an easily accessible web-based version of THV that tracks and records players' movements without additional hardware or client-side software. As a proof of concept, we present *The Hidden Village-Online* (THV-O), a novel browser-based XR implementation capable of creating effective embodied learning interventions using ubiquitous consumer-grade technologies.

Methods

Technology

THV-O leverages players' movements for both navigation as well as core gameplay using consumer grade webcams and algorithmic-based software packages. THV-O uses the Mediapipe Holistic Pose Detection Algorithm (Lugaresi et al., 2019), which identifies key landmarks on a player's body (e.g., wrists, elbows, shoulders, and fingers). These landmarks are then used by THV-O to determine whether players have positioned their bodies in the correct poses (i.e., the directed actions). Graphics and interface for THV-O (alpha version) was implemented using ReactPixi for graphics and XState.js for state logic. To evaluate whether participants had adequately matched a pose, we wrote an algorithm to calculate the angle between a set of a participant's body parts (e.g., the angle between a participants left wrist, elbow, and shoulder) that compares it to the corresponding angle of the model's body parts (Figure 2, right).

Platform and flow

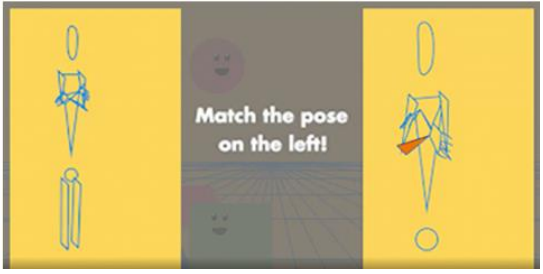
THV-O takes players through an eight-chapter story set in a two-dimensional world populated by different shapes. Using a webcam, the game detects participants' bodies in real-time and leverages the positional data to animate the player's avatar, effectively displaying a mirror image of the player in the fictional world of shapes (e.g., the avatar on the right side of the screen in Figure 1). In each chapter, participants read narrative dialogue between their character and one of the shapes, and then performed a task to “assist” the shape. Each task consisted of four stages: (1) Animation, (2) Pose Matching, (3) Intuition, and (4) Insight.

Figure 1
Player avatar in the world of Shapes

I'm Equila the Triangle, you're the Multi-shaper and this is the world of Shapes! In this world, we're all different shapes... but you... you are a very rare multi-shaper!

In the Animation stage, participants watched a 15 to 30 second animation of a model performing a set of directed actions (Figure 2, left). After the animation had finished playing, during the Pose Matching stage participants were prompted to move their avatar (using their own body) to match poses demonstrated by the model in the animation stage (Figure 2, right).

Figure 2
Player’s avatar (left) attempting to match model’s pose (right)

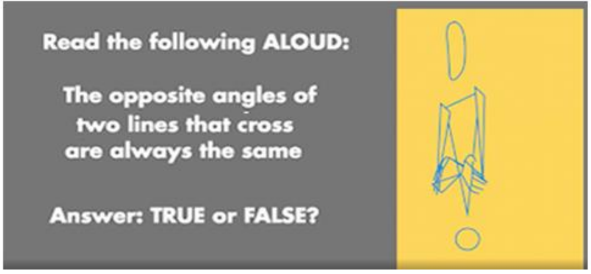


Match the pose on the left!

Next (Figure 3), during the Intuition stage, participants were asked to read a geometric conjecture aloud and assess whether that statement was always true or false. Lastly, participants were shown a final screen (the Insight stage) in which they were asked to explain *why* they believed the statement to be true or false. The conjectures and directed actions were used in previous studies that showed improved performance on the task when players performed the game-based directed actions (Nathan & Walkington, 2017; Walkington et al., 2022). The goal of the tasks was to investigate the influence of movements on cognitive states and, reciprocally, the influence of cognitive states on movement, a core tenet of the Action-Cognition Transduction framework (Nathan and Walkington, 2017). The directed actions for each conjecture were designed to be cognitively relevant to reasoning about the given problem. Collecting participants’ True/False responses for the Intuition prompts and multimodal explanations from Insight prompts were separated so researchers could evaluate whether participants’ answers changed as a result of engaging in grounded embodied reasoning.

Figure 3

Example geometric conjecture about which players reasoned



Read the following ALOUD:

The opposite angles of two lines that cross are always the same

Answer: TRUE or FALSE?

Preliminary pilot data

An initial pilot study of THV-O was conducted to test the platform's viability (Fogel et al., 2022). A convenience sample of university students (N=27, $\bar{x}$=21, n_{male}=15 [56%]) was recruited for the study. Participants were videotaped as they played through four conjectures (four chapters) on the THV-O platform, with presentation order of conjectures determined using a Latin-square factorial design. Video recordings of participants' gestures and transcriptions of their verbal reasoning were qualitatively analyzed.

Preliminary data from this pilot experiment revealed that people using THV-O performed spontaneous gestures representing mathematical concepts across 74% conjectures that were completed. Moreover, the results suggested that making *dynamic gestures* that simulated the various transformational states of the mathematical objects under investigation during their explanations was associated with more correct insights (a replication of Nathan et al., 2021).

Discussion

In this work, we discuss using web-based XR interventions utilizing embedded webcams and computer vision algorithms to replace embodied interventions that relied on costly peripheral hardware. We demonstrated the viability of this approach through THV-O as a proof of concept to serve both researchers and educational intervention designers. While the platform utilized motion-capture data to power the gameplay experience, integrated data collection was not developed in THV-O's current iteration as a result of the limited resources available for prototype development. Fortunately, browser technology enables the collection and saving of data used by researchers to answer fundamental research questions. Thus, future iterations of THV-O will support data collection functionality enabling researchers to record participants' speech (audio), actions/gestures (video), as well as body position (motion-capture accuracy, time, attempts).

Though this approach shows the potential of technology-enabled embodied educational interventions, it is not without limitations. Changing the angle or height of the web camera influenced how well the algorithm was able to determine whether participants had adequately matched a pose. As a result, the height of the camera influenced THV-O's ability to compare the calculated difference in angles of a participant's body to the angles of the model body for a given pose. Improving the pose matching experience by reducing the algorithm's sensitivity to camera placement is a goal for future work. Additionally, many of these types of highly performant open-source computer vision algorithms currently only detect a single individual at a time. Thus, researchers may be unable to investigate the benefits of collaborative embodied learning, as was possible with the Kinect sensor array (Walkington et al., 2022). Finding alternative methods to study collaboration using THV-O will require utilizing new algorithms to detect and track multiple participants in the same frame. Nonetheless, the current study highlights some preliminary benefits for using embedded webcams and computer vision algorithms to deliver embodied learning experiences over the web. Moreover, it offers a new and promising method for developing a scalable, low cost educational intervention and research tool.

Humanitarian Aid Project as a Source of Building a Community of Practice in the Educational Institution

Abstract: This paper analyses the process of conducting the Humanitarian Aid for Ukraine initiative in an educational institution and defines the learning outcomes of the project. We used learning paradigms of communities of practice and service learning to describe and indicate essential steps of the project. The result of this practical work is an instructional guide to a humanitarian project within an educational organisation. This paper documents best practices, suggests improvements and reflects on the educational value of the activity to its participants and the hosting organisation. All the process is described by the characteristics of community of practice: domain, community, and practice, which make it easy to replicate in other educational institutions.

Introduction

The classical educational process is going through many transformations and redefinitions at present. Despite these innovations, people tend to think of an educational process as something constructed in advance by educational specialists with predetermined objectives and learner trajectories (Earle, 2002). In this paper, we would like to address the following question: how does learning take place when it is not thought of and designed in advance but rather occurs due to an external event? The current paper explains how a highly dedicated community created a learning opportunity for itself by successfully managing a fully-fledged humanitarian project in a crisis situation.

On February 24, 2022, a full-scale Russian invasion of Ukraine began. A Humanitarian project, called The Humanitarian Aid for Ukraine initiative, was launched at the end of February 2022 at Learning Planet Institute (LPI) – the institute for interdisciplinary research in Paris that hosts one bachelor program, three master programs, a doctoral school and numerous researcher fellows (1). The community coordinator – the main initiator of the project – is a second-year Learning Sciences student of the EURIP Graduate School (Ecole Universitaire de Recherche Interdisciplinaire de Paris - Learning Planet Institute / Université Paris Cité (2)). The project was created in cooperation with the Association of Ukrainian Scouts in France (Plast – Scouts Ukrainiens de France) and the Embassy of Ukraine in France (Ambassade d’Ukraine en France).

As civic activities are at the core of the EURIP graduate school and Learning Planet Institute (for example, Imhotep – the association created to build efficient health communication (3), Learning Planet Youth Council – the communication platform for young activists around the world (4), and many other student and research community initiatives (5), the board of Learning Planet Institute and EURIP supported the humanitarian action for Ukraine.

It is noteworthy to mention that humanitarian aid, in the form of material donations, has proven instrumental in enabling numerous countries to surmount natural and man-made disasters (OCHA, 2022). Such donations are frequently gathered and transported by small non-governmental organizations (NGOs) adept at functioning locally (Ibidem).

This project is an example of the successful creation of a community of practice and implementation of the concept of service-learning on the institutional level. Service-learning means integrating civic initiatives and volunteering into student curriculum and education programs (Levesque-Bristol et al., 2011). Communities of practice, according to Wenger, are the following:

> Communities of practice are groups of people who share a concern, a set of problems or a passion about a topic and who deepen their knowledge and expertise in this area by interacting on an ongoing basis (Wenger et al, 2002, p.4).

The community of practice can give newcomers the necessary skills and make the experience of its members personalised. The community of practice is also a fertile ground to explore new concepts and implement new strategies while mutually learning and improving. To sustain the community of practice, there should be a bond of communal competence and deep respect for particularity and experience. (Wenger, 1998).

The communities of practice are based on the following dimensions (Snyder & Wenger, 2010, p.100):

- **Domain** – defines the identity and concerns of the group. It is necessary for the group to share a passion for the domain.
- **Community** – the relationship between the members and the feeling of community should be strong, The members' expertise levels should vary. A "community coordinator", along with the core group, should take over the leadership of the community.
- **Practice** – the practice of the different groups in the community should share and develop the knowledge of practitioners. Practice contains a range of tools, frameworks, methods, stories and activities connected to learning and innovation.

Project overview

The experience explained in this practice-oriented paper can serve as a generalised blueprint for further usage in collaborative learning. In the paper, we would like to describe all the processes, from the generation of the original idea to the implementation of the active phase. For that purpose, as Snyder and Wenger suggested, we will focus on the following characteristics – the domain, community, and practice, that define the project as a community of practice.

In the case of our project, the domain is humanitarian aid, the community – volunteers concerned by the situation in Ukraine, practice – tasks, activities and learning methods used for the project.

Domain

The initial idea of opening a collection point of humanitarian aid resonated with the needs of Ukrainians and the will of Parisians to engage in humanitarian action. Indeed, the first phase of the project was the need for action that arose from the Russian invasion of Ukraine: more than 7.7 million internally displaced people and more than 15.7 million people requiring humanitarian assistance with food, hygiene, medical and other supplies (United Nations, March 2022). Within the first three days after the beginning of the full-scale war in Ukraine, numerous concerned people in Paris were working on ideas of launching projects to help civilians affected by the war.

As one of the authors of the paper is also a member of the Plast – Scouts Ukrainiens de France Association – the branch of Ukrainian scouts located in Paris. This association has connections with numerous NGOs in Ukraine and collaborates closely with the Embassy of Ukraine in France. Hence it was decided to launch the project in cooperation with the Plast – Ukrainian Scouts in France and the Embassy of Ukraine in France.

Several master's students of the EURIP graduate school for interdisciplinary research proposed the project to the board of the institution at the end of February 2022.

The *main tasks* were the following:

- Opening a humanitarian aid collection point at the Learning Planet Institute: collecting, sorting, packing and sending donations (food, hygiene, baby care products, medicines and equipment for civilians) to Ukraine.
- Organising the team of volunteers from the EURIP graduate school and partnering organisations.
- Designing and maintaining the learning program for the volunteer community members.
- Sustaining active communication within the Learning Planet Institute community and French media to raise awareness about the problem and current needs in Ukraine.

The first author of the current paper was responsible for the project deployment and coordination.

Community

During the first three days, the community coordinator was in charge of the reception of donations, stock management, logistics, and communication with donors, local activists, and the media. 3-5 volunteers on site were responsible for sorting and packing donations. Due to the significant growth in the number of donations and people willing to help over the first days, the decision to enlarge the project scale was made. That is why we developed the learning system to create and sustain the community of volunteers. The learning system included the following elements:

- Communication channels for volunteers dedicated to asking questions, offering improvements and giving feedback.

- Workflow guidelines that depend on the task (welcome point, sorting, packing, community management, logistics, etc.).
- Community-building events (regular common lunches, feedback sessions, outdoor activities and discussions for volunteers).

The community of volunteers grew from 3-5 people to more than 100 volunteers in the peak phase of the project (the first two months), and 50 community members stayed active from the beginning of the project until the end of the active phase (4 months in total). The community included: students and researchers from EURIP graduate school, Learning Planet Institute staff members, and people related to partnering organizations.

It is worth mentioning that during the first days of community building, as volunteers were learning how to run the humanitarian aid project and giving multiple pieces of feedback, the team implemented changes to upgrade the practice to enhance the equity, well-being and efficacy of volunteers. That makes the project an example of a co-constructed learning community in which diverse perspectives were included.

Practice

Therefore, among all changes implemented within the first week of the project, one of the most significant was the implementation of management positions for experienced volunteers, which included:

- *Project coordinator:* workflow and logistics management, communication with partners and media, reporting, event organising, and cooperation with recipient organisations in Ukraine.
- *Communication manager:* social media management (content creation, communication with the online community of donors, partners, and volunteers), scheduling visits of media representatives.
- *Responsible for volunteers:* managing shifts schedule, planning the shifts, distributing the work between volunteers, resolving issues of the volunteers, and providing learning materials.
- *Stock manager:* administering the stock spreadsheets, registering each categorised box of donations to the system, creating delivery notes with detailed lists of items sent and delivery vehicle and driver details, preparing custom clearance documents for drivers, and managing the work of senior volunteers.
- *Senior volunteers:* responsible for several categories of donations: food, hygiene, baby care, equipment products and medicines (requirement: medical diploma holder). Those volunteers managed the work of junior volunteers regarding the reception, sorting and packing processes.

Community members were assigned management positions depending on their expertise and availability throughout the week. The volunteers met regularly at the collection point, and they were trained by senior community members that had already gained experience by being involved in the project workflow since its early stages. During the regular feedback sessions and informal gatherings, community members repeatedly reported an increased sense of belonging that improved their well-being.

Learning outcomes

Based on all the processes explained above, various competencies were acquired as part of the project. Thanks to the regular feedback sessions with volunteers, we derived the following learning outcomes:

- *In entrepreneurship:* conceptualising and creating a project idea, calculating necessary resources, and establishing the project lifecycle.
- *In project management:* building processes in the team, establishing roles and responsibilities, organising the logistics system, creating shifts and schedules, and writing reports.
- *In communications:* creating visibility in social media, creating content, communicating with activists, media representatives, and public speaking.
- *In event management:* organising formal and informal events for volunteers and stakeholders, organising a final gala for the community of volunteers and project stakeholders.
- *In education management:* designing a learning and mentoring system for new volunteers.
- *In self-development:* gaining the capacity to work in conditions of crisis and psychological instability, understanding the value of self-support and giving a hand to others.
- *In professional development:* providing volunteers with recommendation letters to facilitate their employment-seeking, validating the project as a master internship for the project coordinator.

Conclusion

During the active phase of the project, organisers succeeded in building a community of practice of more than 100 volunteers and establishing partnerships with more than 40 organisations in France (local governments, schools, education communities, logistics companies, various enterprises, NGOs, etc.) and more than 15 NGOs in Ukraine. Within the four months of the project, the team successfully sent more than 75 tons of humanitarian aid, which translated to 45 different vehicles and 6754 boxes packed by volunteers coming from numerous countries of the world (Ukraine, France, USA, Poland, Italy, China, India, Sri Lanka, Peru, Russia, and others).

The project also allowed the students to regularly interact with researchers and employees of Learning Planet Instituteas well as with volunteers and activists from outside of the institute. Learning outcomes of the project impacted several domains, such as entrepreneurship, project management, communications, event management, education management, self-development, and professional development.

Improvements

According to the related literature, it would be beneficial to implement such projects as integral parts of the bachelor's and master's programs curriculums (Owusu-Agyeman & Fourie-Malherbe, 2021; Boland, 2014; Kingston et al., 2014). However, for the organisers of the initiative mentioned above, it was essential to keep the project open to the participation of the employee and research community of the institution and ensure inclusivity for the volunteers not affiliated with the institution.

To conclude, the example of this project deployment and coordination would be helpful for the other institutions willing to engage in civic activities and implement communities of practice and service-learning.

Transformative Learning: Space as a Third Pedagogue

Esther Tan, Mercy Ships, esther.tan@mercyships.org

Abstract: Empirical works on transformative learning have investigated transformative learning processes and outcomes across various learning activities and learning contexts. However, not much is known about Wimmer (2009)'s notion of 'space as a third pedagogue'. This paper discusses the theoretical constructs of transformative learning to inform the design and implementation of formal and informal learning activities on board a hospital ship. It proposes a conceptual framework to investigate the theoretical assumptions of transformative learning processes and outcomes in such a unique learning context where an academy, a floating hospital, mariners, and a crew taking on different roles live, work, study and thrive together in this shared space. In particular, the first insights on space as a pedagogy, invites learning sciences researchers and practitioners alike, to a scholarly discourse on the significance of extraordinary learning spaces that could have a significant bearing on transformative learning processes and outcomes in a self-contained community of learners.

Introduction

Transformative learning has its root in young adult learning, adult education, and lifelong learning where scholarly works, empirical studies and instruments of measures investigated transformative learning experiences across a variety of educational and social contexts of learning. Mezirow defined the process of transformative learning within the constructivist lens as "the social process of constructing and appropriating a new or revised interpretation of the meaning of one's experiences as a guide to action" (Mezirow 1994, p.222). According to Mezirow (1991), the social construction of new meanings through new experiences are susceptible to influences by the social as well as other co-existing structures e.g., political, institutional, economy. On the same token, these respective dynamics are instrumental in modifying established meanings and known values when learners consider them to be dated or dysfunctional. Further, Mezirow (1994) also posits that learners go through critical teaching and learning moments that are connected to their past lived experiences.

The theory of transformative learning has witnessed a substantial amount of empirical studies across various disciplines and scholarly work such as transformative learning review in arts-based learning (Blackburn Miller, 2020), technological adoption for teacher professional development (Schols, 2012), adult educators and teacher training (Christie, Carey, Robertson, & Grainger, 2015), and transformative experiences for international graduate students in educational and non-educational activities (Kumi–Yeboah & James, 2014). These empirical works investigated different cognitive activities that facilitated transformative learning as well as transformative processes and outcomes but with similar end-goal i.e., learners will become more critically reflective of belief systems, social and/ or cultural values and they will be able to re-define and/ or reframe a problem/ issue through transformative learning. However, Wimmer (2009)'s notion of "'space' as a 'third pedagogue' in arts education programme, which to date, received little attention in empirical research. Hence, this paper discusses transformative learning: foregrounding 'space as a third pedagogue' with a focus on the adult crew members living and working in a self-contained community on board a hospital ship.

Transformative learning experiences, processes and outcomes

Transformative learning experiences: Instrumental and communicative learning

Mezirow (1981) identifies two domains of learning that are central to transformative learning, namely, instrumental and communicative learning. These two channels of transformative learning provide critical platforms for questioning, weighing and evaluating known assumptions and beliefs which ultimately lead to a perspective shift (Cranton, 2006; Mezirow, 1991). Instrumental learning "controls and manipulates the environment" with a focus to improve 'prediction and performance" whilst communicative learning focuses on how learners communicate their ideas, feelings, needs and desires (Mezirow, 2003, p. 59). Of equal significance would be the nature and types of transformative learning experiences which triggers instrumental and communicative learning.

According to Cranton (2006), there are three dominant perspectives on transformative learning experiences. One is the cognitive/ rational perspective that has its focus on rationality, critical reflection, and discourse where the construction of new meanings and/ or revised interpretations works towards personal goal for autonomy and independence (Mezirow, 1991). Learning activities that facilitates cognitive/ rational processes would encompass critical reflection, action, experience (critical life events), disorienting dilemma, and discourse. The second perspective is coined as beyond rational/ extrarational perspective which places emphasis on the emotional, imaginal, spiritual that reach beyond rationality (Stuckey, Taylor, & Cranton, 2013). And the third is the social critique perspective which drew its theoretical arguments from 'ideological critique, unveiling oppression, and social action' as the context for transformative learning (Stuckey, Taylor, & Cranton, 2013). These transformative learning activities often lead to collective social actions.

Transformative learning experiences: Space as a third pedagogue

As forementioned, research on space as a third pedagogue remains scarce. Learning and teaching spaces are a 'third pedagogue' because they affect the very foundational elements that determines learning behaviour and learning success in transformational self-directed learning and the ability to concentrate and/or receptivity (Leiber, Carlos, Bruckmann, & Rosa, 2021). On a similar strand, Talbert and Mor-Avi (2019)'s study on abstract active learning classroom exemplifies the importance of designing learning spaces to optimize the practice of active learning and amplifies the positive effects in learners from young learners to higher educational level learners. The practice of active learning can be understood in Nohl (2009)'s works on "initial spontaneous action" and "renew spontaneous action". And on the concept of change in 'meaning perspective', spontaneous action and transformative learning provides another lens to view Mezirow's (1994) notion of a change in one's frame of reference - meaning structures. A change in meaning structures implies more permanent changes in how one manages life transactions. In this context, Nohl (2009)'s concepts of phases of transformative learning where the "phase of initial spontaneous action" precedes the "phase of renewed spontaneous action" seem to suggest that the transformative learning experiences as well as the learning spaces could be instrumental in framing the processes and outcomes of transformative learning.

Transformative learning processes and outcomes

In the process dimension, Schols (2012) reiterates that critical reflection is pivotal to bring about the desired transformative learning outcomes – reframing problem/ issues as aforementioned. A transformational change in one's frame of reference is best explained by Mezirow's (1991) notion of reflective thinking where he accentuates three types of reflective thinking: content reflection, process reflection and premise reflection. Content reflection refers to the critical investigation of the content or the description of a problem; process reflection is about weighing and engaging the different strategies and approaches in solutioning; and premise reflection takes place when learners start to question the basis or premise problem itself (Schols, 2012). Apart from reflective thinking, communication and creative thinking are also essential transformative learning processes. Communicative learning enhances learners' communication skills such as conveying one's ideas and presenting one's works and creative thinking processes are fostered through improvisation, imagination, and creativity (Blackburn Miller, 2020). On the concept of creativity, Guilford (1967) postulates that there is essential four categories in creative thinking, namely, originality, flexibility, fluency and elaboration.

In the outcome dimension, Cranton (2006) posits that content and process reflection could possibly bring about initial perception change but it is premise reflection that critically transforming one's world view, beliefs, and values. To which Mezirow (1994) likened such a transformational change to a process change in one's frame of reference – meaning structures (meaning perspectives and meaning schemes).

Method

Participants, design and implementation

The new Mercy Ship - Global Mercy is the largest civilian hospital ship with six operating theaters and advanced medical training facilities. Global Mercy has presently more than 300 adult crew and about 60 children onboard, representing more than 50 nationalities. Crew serve in various positions e.g., surgeons, nurses, medical personnel, ship engineers, academy teachers, housekeeping, dining, and galley staff. The total number of crew on board the ship at any one-time changes owing to on-going recruitment when short-term crew depart. All adult crew serving on the hospital ship for more than three months are required to attend a full-day 8-hour course - "Equipping to Serve (ETS)". All year-round informal learning activities include the weekly community gatherings and social activities. These activities are not mandatory but often see high attendance and community engagement.

The theoretical constructs of transformative learning experiences, processes and outcomes are encapsulated in Figure 1. This theoretical framework provides the premises to discuss the design of transformative learning activities and the transformative learning processes and outcomes of the crew living and working together in a self-contained community on the hospital ship. The learning activities in the ETS course serve not only as an induction for the crew into the community but also to equip and to empower crew to live and work effectively as a self-contained community. Table 1 provides an overview of the learning objectives and transformative learning activities for each of the five thematic sessions. On the average, we have about 8 to 10 crew for each ETS training course. ETS is usually held in the guest lounge: conducive for both plenary and small group discussions.

Figure 1
A Framework for Investigating Transformative Learning Experiences, Transformative Processes and Outcomes.

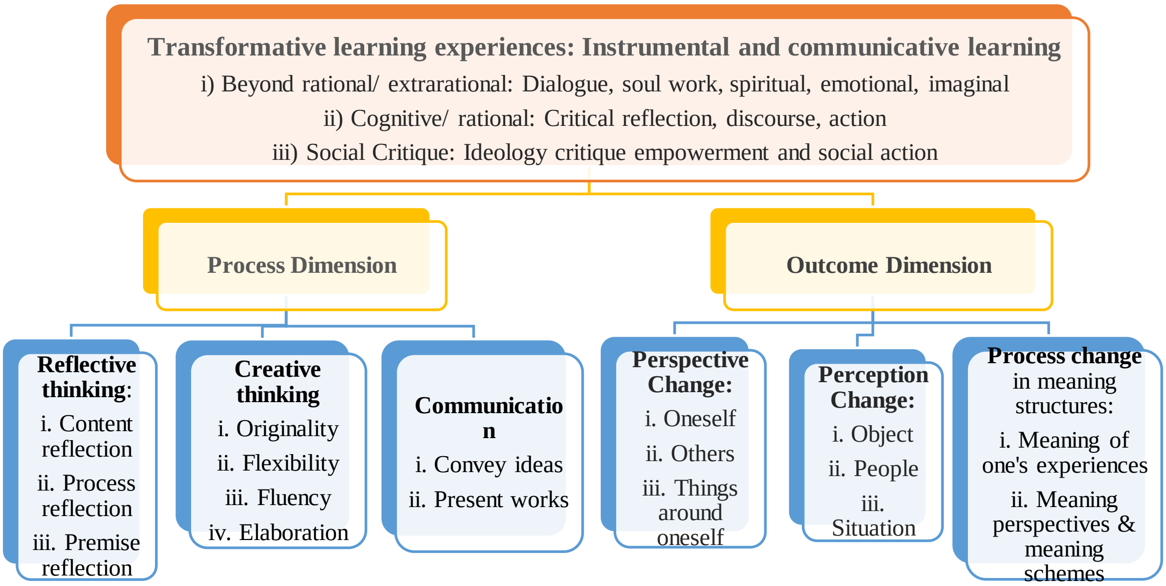

Table 1
Overview of Learning Objectives and the Transformative Learning Activities.

Learning Objectives	Transformative Learning Activities
To know the hospital ship's mission and vision statements, and her four core values.	Plenary presentation by chaplaincy Small group work & presentation on concrete examples of the four core values in relation to the individual, community & organizational level
To develop an awareness of ship safety and security and one's role in the community.	Plenary presentation by the captain Individual activity cards for reflection and response
To appreciate cultural differences on board the ship and understand change and transition.	Plenary presentation on hot vs cold climate cultures, change and transition by staff development Small group discourse on experiences with and responses to the different cultures & challenges
To identify the core tenets of the Philosophy of Service (i.e., serving west African nations).	Small group work on philosophy of service model Socratic discussion: Partnership vs Paternalism
To develop an awareness of the hospital work and medical capacity building (MCB).	Plenary presentation, video clips, Q &A by hospital director and MCB projects director.

Initial findings

All ETS participants are asked to complete an evaluation survey consisting of two demographic questions, one Likert scale item (on the five thematic sessions) and two open-ended questions on what they like about the sessions and what can be improved. At the recent ETS evaluation survey, 8 out of 9 participants indicated that they found the thematic sessions insightful and the small group discussions facilitated critical moments of reflection on past lived experiences esp. the philosophy of service and volunteering on a hospital ship with more than 50 nationalities. However, findings on perspective changes were derived from informal channels of conversations over time e.g., during social activities, sharing of testimonies and/ or when crew are departing. Firstly, they experienced a process change in meaning structures as they started to question their existing frames of reference pertaining to personal life and work undertakings. Secondly, the transformational change (perception, perspective or change in meaning structures) that occurs, lies not so much on the acquisition of new information and knowledge, but rather, on the shared vision (serving the African nations and patients) and a shared living and working environment i.e., space as a third pedagogue. The shared living and work space plays significant role to bring about a transformative change in their perspective and perception of previously perceived worldview. We attribute that to the interaction with the affordances of the environment as well as the social actors in these spaces that have evoked new lens and viewpoints over time leading to a change in learners' perception and perspective.

Conclusions and future works

This paper essentially provides a conceptual framework to both discuss and to investigate the theoretical constructs in the transformative learning experiences, processes and outcomes of a unique self-contained community on a hospital ship. The initial formal and informal findings provide some first insights into 'space' as a third pedagogue: not only the learning activities in the formal learning space (e.g., course training room), but the day-to-day transactions at the individual and the collective level in this shared living space – the hospital ship. Future action-research could investigate the different types of transformative learning activities, and the measure and extent of transformational changes these transformative experiences evoke over time. Qualitative research will also provide more in-depth study on Nohl (2009)'s concepts of "initial spontaneous action" and "renewed spontaneous action" as they have implications on a mere perception/ perspective change or a more radical change in one's frame of reference and meaning structures and understanding space as a third pedagogy. Align with this year's theme on "Building Knowledge and Sustaining our Community", this practice-oriented paper aims to initiate some scholarly conversations on space as a third pedagogue in transformative learning in other emerging learning/ working spaces such phygital spaces, remote learning/working propelled by the recent pandemic.

Abstract: Communities of practice (CoPs) have been used to support practitioners' efforts to adopt new teaching methods. In this paper, we summarize how our team facilitated knowledge transfer by forming and leveraging several CoPs that shared the common objective of implementing Inquiry-Based Labs (IBL) in science curricula. Over two years, our team members played the role of linkage agents in the CoPs to bridge the gap between education research, by sharing our own research findings, and practice, by collecting feedback directly from IBL practitioners about their challenges with implementation. As various needs of the members were well met – to be informed, to share thoughts, to belong – the CoPs have since evolved into stable, sustainable entities. Through these powerful social interactions, CoP members themselves have become linkage agents, connecting us to the larger community that would otherwise not engage with our research and thus further bridging the gap between research and practice.

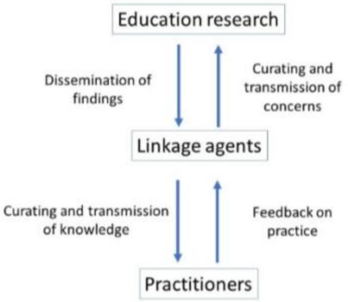
Introduction

Advances in education research are often unacknowledged by practitioners, notably those teaching in the domain of Science, Technology, Engineering and Mathematics (STEM) at post-secondary institutions (Ma et al., 2019). Despite overwhelming evidence regarding the effectiveness of numerous teaching approaches, many practitioners have difficulty adopting these classroom practices (Marion & Houlfort, 2015). Faculty report a number of barriers impeding their ability to change such as time, their personal identity and beliefs about instruction, departmental and institutional culture, and the lack of incentives to change one's teaching approach (Brownell et al., 2013; Henderson et al., 2011).

It is well documented that knowledge transfer in education is difficult to achieve (Becheikh et al., 2010) and the ability for practitioners to mobilize and apply new knowledge into practice is challenging for a number of reasons (Hemsley-Brown, 2005). Traditionally researchers resort to presenting their innovations, along with supporting evidence for their effectiveness, through conventional means of dissemination, however, such approaches have proven ineffective in inspiring practitioners to adopt new instructional strategies (Henderson et al., 2011). On the other hand, the literature does reveal several successful approaches for encouraging change. Such strategies are characterized as having i) focused objectives, ii) coordinated efforts by the individuals involved, iii) structures to provide time for work on these objectives over extended periods, iv) mechanisms for performance evaluation and feedback and v) the explicit intent to change faculty perceptions (Fullan et al., 2018; Henderson et al., 2011). Furthermore, questioning of the status quo, having a clear plan of action, being able to actively recruit new allies, and drawing personal confidence from collaborating with others are other hallmarks of successful change strategies (Fullan et al., 2018). Finally, linkage agents, or individuals who can function as intermediaries between researchers and practitioners, can prove useful in communicating the immediate needs and concerns of practitioners to researchers, as well as relaying research findings back to practitioners in a feedback loop (Becheikh et al., 2010), thus ensuring knowledge transfer is achieved.

Communities of Practice (CoPs) can serve to circumvent the challenges associated with knowledge transfer. Rooted in change theory, CoPs provide forums for faculty to share their concerns about teaching, to collaboratively design possible solutions to these challenges, to learn about best practices and, consequently, to participate in educational reform (Abigail, 2016; Gehrke & Kezar, 2017). Through a mix of knowledge sharing, knowledge-creation, identity building and social interaction, CoPs can be positive vehicles for engaging faculty in adopting novel practices (Abigail, 2016). A CoP composed of members acting as linkage agents can provide a mechanism through which knowledge transfer is more easily facilitated (Henderson et al., 2011). We started a number of CoPs to promote interest in our team's larger research on what types of scaffolding best support the development of scientific thinking in students exposed to Inquiry-Based Laboratory (IBL) instruction. The objectives of this project were to: 1) profile Quebec-based college (cegep) teachers who used or were interested in implementing IBL approaches, 2) identify the forms of scaffolding that best supported learning using an IBL approach, 3) assess whether there exist disciplinary differences in the implementation of IBL pedagogy, and 4) conduct design-oriented research to assess the development of the scientific process. We identified three key areas where our CoPs could address our research needs: a) the recruitment of qualified participants who teach either chemistry, biology, or physics; b) the need for both physical and temporal spaces through which we could consult with our participants routinely; c) the creation of a social community where participants could support or inspire each other in the practice of using IBL instruction. Consequently, the CoP is part of a feedback loop where our research team acts as a linkage agent, i.e., by communicating our findings to a captive audience, then later receiving feedback from IBL practitioners to further inform our research (Figure 1).

Figure 1
The role of linkage agents in facilitating knowledge transfer



Educational context

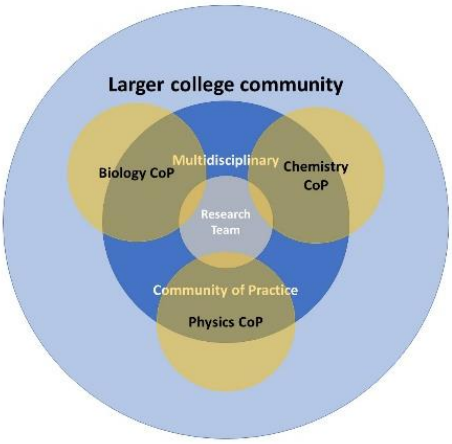
The educational context for this study is at the post-secondary level in the province of Quebec, the structure of which is unique from the rest of Canada: STEM-bound students must complete a two-year college or cegep degree (corresponding to grades 12 and 13) consisting of general education courses (literature and language, philosophy or humanities, and physical education) and domain-specific courses notably in chemistry, biology, physics, and mathematics. This degree is prerequisite to attend university STEM programs. There exist ~60 cegeps all teaching the same Ministry of Education-mandated program, either in French or in English. Colleges have the freedom to set their own program planners, grids, courses, etc. albeit within certain limitations, meaning that local programs and even departmental cultures vary from institution to institution. Instructors are discipline experts having at least a bachelor's degree in the discipline they teach, but most having a master's degree. Some teachers may have an education degree, but this is not mandatory to teach in the cegep system. Consequently, cegep instructors lacking such a background may be incapable of identifying with educational research.

Our research team is comprised of cegep teachers. We are both researchers and practitioners, which facilitates the implementation of an action-based research program. Our research questions are embedded in our teaching concerns and are developed to generate results that are both rigorous and applicable in a classroom. Aware of the difficulties of knowledge transfer in education, we planned this research project to be situated close to common concerns facing science educators, anticipating that our research questions and results would then be meaningful to them and their teaching practice.

The start of the multidisciplinary CoP

At the start of our research project, we invited science teachers from both French and English colleges to a large online meeting. Although the context was to discuss the common challenge of implementing the new cegep Science program slated to start in 2023-2024, the meeting served the dual purpose of forming a large, multidisciplinary community of practice (MCoP) that shared a common concern (Figure 2). At this meeting, we presented how our IBL research both aligns with the learning objectives of this new program, as well as also how this paradigm can help address shared challenges educators face in STEM education. To foster social connections between the participants, we asked them to discuss several topics raised during our presentation in small, disciplinary groups ("breakout rooms"). As Wenger (1999) describes, such participation is key to successfully forming a CoP as it provides both action as well as connections between members. The strategic use of breakout rooms also provided opportunities for reflection on the potential advantages of using IBL in the new Science program, enticing attendees to reach out to our research team about knowing more on IBL or even to become research participants. Finally, attendees of the MCoP were invited to join a mailing list, keeping them appraised of our research and of other meetings or workshops offered by our research team.

Figure 2
Organization of our Communities of Practice (CoPs)



Creation of discipline-specific CoPs

Following the creation of the MCoP, our research team invited members to join smaller, discipline-specific CoPs (DCoPs). DCoPs were composed of a small number of core participants who were always present at each meeting (Table 1). Topics for each DCoP meeting were set by coordinators who were members of our research team – i.e., linkage agents. Although many discussions were about IBL, multiple topics were discussed per session. Members were surveyed before meetings for their suggestions of discussion points and these persons often acted as moderators for these topic discussions. This bottom-up approach ensured that discussions were always meaningful to the participants and validated the time and effort required on their part to partake in the DCoP.

Table 1
Number of participants in CoPs meetings

	Chemistry	Biology	Physics
First gathering of MCoP	46	21	16
Typical DCoPs meetings	15	12	8

Modes of engagement

To facilitate attendance, both the MCoP and DCoPs operated in either of the following formats: completely online, which proved beneficial for connecting members both during and after covid pandemic isolation, or co-modal with members being present either in-person or via web-conferencing software simultaneously. These flexible modalities afforded members who could not make face-to-face meetings, or were uncomfortable doing so, access to the DCoP. Furthermore, Web 2.0 tools or group management software were used to store shared resources, to store recorded meetings or to continue asynchronous discussion between meetings.

Knowledge transfer via linkage agents

Given that it was the theme of our larger MCoP meeting, IBL was the focus of first meetings with the DCoPs. Members of our research team acted as linkage agents by not only presenting from existing literature the history and theoretical framework of IBL instruction, but by providing practical knowledge about how STEM instructors could successfully implement it. IBL-experienced DCoP members shared success stories affirming the literature findings, which in turn encouraged non-practicing DCoP attendees to reflect upon the merit of using IBL-based pedagogy. For those that opted to try implementation, both the time and effort needed to do so were considerably reduced through the sharing of expertise and ready-made resources offered by DCoP members. For new practitioners, this support also helped them gain the confidence to see the implementation through. Seeing value in what they were gaining, individual MCoP/DCoP members asked our team to host additional IBL workshops for their local departments or programs. These motivated CoP members helped bridge a gap between our research team and the wider cegep community who otherwise would not have engaged with our research (Figure 2). In so doing, these members not only became champions of change, but through interactions with us have become linkage agents themselves by connecting other practitioners to our IBL research.

Outcomes and future of the CoPs

Through our team's desire to challenge the status quo re: STEM lab instruction, we formed sub-groups of individuals willing to engage with our research and ultimately put it into practice. The CoPs provided the time and social support required for our participants to address the common goal of learning about and implementing IBL pedagogy and in so doing, helped move our research forward. However, what is worth noting is that our DCoPs have since evolved into self-sustaining entities that now address pedagogical questions beyond our original mandate. The self-selection of the members ensured we recruited individuals who were initially invested in a common goal, but our willingness to have members contribute their own pet topics of discussion ensured continued viability of the DCoPs. Additionally, multidisciplinary concerns continue to be addressed via larger gatherings of our MCoP where concerns and solutions raised there funnel back into discussions at the DCoP level. Consequently, members of the various CoPs are now positioned as members of the community that can connect us to other practitioners that would otherwise not engage with educational research. Technology also facilitates the exchange of resources between members and helps keep the CoPs socially connected.

It cannot be understated that our tiered CoP structure benefits from our research team's continued involvement as linkage agents who can connect practitioner concerns to the educational literature, and vice versa. We would recommend to those taking part in action-based research to consider leveraging CoPs as a means for ensuring knowledge transfer takes place, as well as to connect faculty, who would otherwise not engage with the educational research, to learn about it as well as its implementation in practice.

We thank all CoP participants for their openness and enthusiasm towards science education, as well as their insightful participation in our research. We would also like to thank our research assistant, Chao Zhang, for her continuous help in this research project.

Deepening the Integration of Computational Thinking and Science Through Decoding in a Middle School Summer Program

Abstract: In this paper, we describe DecodeNYC, a summer program for New York City 7th and 8th graders at the American Museum of Natural History (AMNH). The goal of DecodeNYC was to support students' learning of Lyme disease ecosystem dynamics and computational thinking through experiences with an online computer modeling and simulation platform called StarLogo Nova. In DecodeNYC's curriculum, the well-established "Use–Modify–Create" learning progression was augmented with a newly described practice known as "decoding", wherein learners make explicit connections between mechanisms in code and the scientific processes they represent. We describe the DecodeNYC curriculum and share findings from an exploratory study of the curriculum's impact on student learning. We close with a discussion of how research findings informed revisions to curriculum and instruction over the course of three years of remote and in-person implementation and a summary of the benefits and drawbacks of this approach from a practitioner's perspective.

Introduction

The ability to model and simulate the behavior of complex systems has been foundational to understanding phenomena across disciplines. Thus students' attention to relationships within complex systems and manipulation of systems through modeling and simulation are authentic to scientific practice. Engaging in these activities anchored in science phenomena is encouraged by the Next Generation Science Standards (NGSS, 2013), particularly practices of developing and using models and using mathematical and computational thinking. Working with scientific models offers learners an opportunity to engage in computational thinking (CT), a set of thinking skills, habits and approaches that are integral to solving complex problems using a computer and widely applicable in the information society (Wing, 2006).

However, research shows that dynamics of complex systems are difficult for middle school students to grasp (Gotwals & Songer, 2010), and ecosystem dynamics are particularly challenging to teach at the middle school level (Yoon et al., 2018; Grotzer et al., 2017). Educators can engage students more easily in specific NGSS practices, such as asking questions, planning an investigation, and analyzing data, but find it difficult to engage students in constructing models and CT practices (Davis et al., 2017).

Several studies have tackled this issue by developing and testing curricula where students can gain an understanding of complex systems through a learning progression in which students use a model, then modify it, and then create their own model. The progression of "Use–Modify–Create" (UMC) (Lee et al., 2011) is well-established as a trajectory to engage students beyond surface level understandings of models. Recently, however, scholars in collaboration with practitioners using the UMC progression observed that when CT was taught, its relationship to the scientific phenomenon in question was being overlooked (Lee et al., 2022). For students to gain a better understanding of how the code represents scientific processes, they must engage in the additional step of "decoding," mapping the relationship between mechanisms in code and the scientific processes they represent. For DecodeNYC, we developed and implemented a curriculum centered around decoding, with learners applying this skill at each step of the UMC progression. This focus encourages students to see models as representations of the real world and as powerful tools for scientific sense-making rather than mere computer games.

Decoding in practice

StarLogo Nova: A tool for decoding

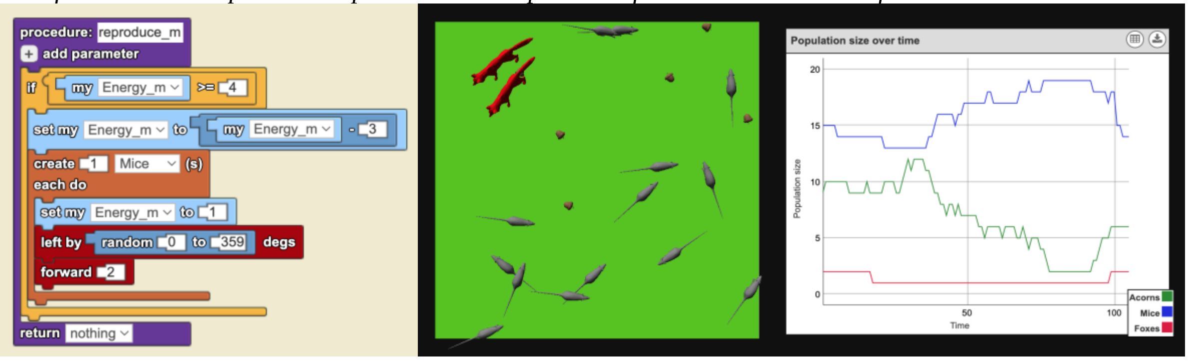
It is important to use a learning tool with features that support decoding. Participants in DecodeNYC used, modified, and created computer models using StarLogo Nova (SLN), a free browser-based computer modeling and simulation platform created by the MIT STEP Lab. SLN was developed within the constructivist tradition to enable users to control the behavior of thousands of agents at the same time, making it a valuable tool for modeling complex adaptive systems such as ecosystems that consist of many interacting parts. SLN has three primary areas: an information area, a simulation area called "SpaceLand", and a modeling area called the "Workspace". SLN enables connections to be made between the code in the Workspace and the execution of that code as simulation in Spaceland, providing an avenue for learners to practice decoding and mechanistic reasoning.

Two SLN models were developed for DecodeNYC in collaboration with an ecologist at Columbia University (Diuk-Wasser et al., 2021): A model of acorns, mice and foxes intended to exhibit population dynamics (Figure 1) and a model of mice, ticks, and deer that represents the tick lifecycle as well as the spread of Lyme disease-causing bacteria in the environment. Additionally, simplified models were created to help students experiment with and learn key SLN concepts.

An example model is shown in Figure 1 below. The code specifying agent behavior in the acorn-mouse-fox model includes an "Energy_m" variable whose value is reduced during movement and reproduction and increased during nutrient consumption. Behaviors such as reproduction and death occur only if this energy value reaches a certain threshold. The agents in Spaceland reflect these behaviors, moving, generating new agents, and being deleted as dictated by the biological constraints encoded in the Workspace. The corresponding graph helps learners keep track of population sizes over time and recognize trends.

Figure 1

Code for the mouse reproduction procedure and Spaceland from the acorn-mouse-fox SLN model



```
procedure: reproduce_m
+ add parameter
if  my Energy_m >= 4
  set my Energy_m to  my Energy_m - 3
  create 1 Mice (s)
  each do
    set my Energy_m to 1
    left by  random 0 to 359 degs
    forward 2
return nothing
```

UMC in the curriculum

The curriculum for DecodeNYC followed the UMC progression, with students primarily using SLN models in the first third of the program, modifying them in the second third, and creating their own models in the final third. During the first half of the program, students used and modified the acorn-mouse-fox model to solidify their understanding of population dynamics and energy flow in an ecosystem. Subsequently, students used and modified the tick-mouse-deer model to learn about the Lyme disease ecosystem and test different interventions for Lyme disease remediation before spending the last several days creating their own code to add a new species into a tick-mouse-deer model.

In order to encourage and support students in making explicit ties between code and science, the curriculum designer created numerous opportunities for learners to employ decoding, both to extrapolate from what they saw in the code to what they knew about the scientific phenomena and in the other direction, from science to code. Some decoding-focused activities across the UMC progression include: After learning the basics of SLN code blocks, students were asked to decode functions from the acorn-mouse-fox model of the type shown in Figure 1; Midway through the program, students completed a series of pair programming challenges wherein they needed to modify and debug broken models by adding values, rearranging blocks, or adding new blocks to the code; Finally, as a concluding activity for the program, groups of students worked together to create their own models based on the tick-mouse-deer model that incorporated a new agent representing another animal in the ecosystem.

Impacts

Decoding in student work samples

In our study we analyzed student work such as Google form data to search for evidence of students linking between coded mechanisms and the scientific processes they represent. Decoding was evidenced when students described the code's function in terms of scientific concepts rather than effects on the agents in the model. For example, after working in groups to decode procedures from the acorn-mouse-fox model, students were asked to respond to the prompt: "explain in simple English what your procedure does." Some responses demonstrated mapping between code and the phenomenon modeled: "When an animal has no energy left it dies", whereas others did not: “Create one acorn and scatter it xpercent of the time.” Later, after completing each of the programming challenges in the second third of the program, students were asked to respond to the prompt, “What is one thing you learned or noticed while completing Challenge [X]?”. While many student responses were reflective of increasing knowledge of the StarLogo Nova tool and specific code block functions, some revealed ecosystems understanding using decoding. For example, one student responded as follows: “I noticed that when the turtles reproduced they didn't loose [sic] energy so they kept reproducing.” This student is drawing on their understanding of energy flow in ecosystems in their analysis of the code. Students also demonstrated decoding in their responses to reflection prompts after “modify” activities.

As the program continued, more students used mapping to scientific processes (or decoding) to solve computational challenges, even when *not* specifically prompted. In the concluding “create” activity students applied their decoding skills without being instructed to do so. Notably, students decoded both from code to scientific phenomenon and from phenomenon to code. For example, one student remarked:

> since the spider is a hunter, at some point, if the spider has one or less energy or some certain amount of energy or less, it will hunt the ticks at double the speed as the regular real walk. And it's hunting the ticks, which means we're going to use detection blocks.

This speaker noted the spider is a “hunter”, or predator, drawing on their knowledge of ecology. Then they acknowledged that the spider might change its behavior based on its available energy, and finally specified the particular SLN code block that would be needed to encode the hunting behavior.

KS-CT survey: Evidence of decoding skill

In addition to the embedded assessments in the curriculum, changes in students' decoding ability, understanding of science concepts, CT, and mechanistic reasoning was captured with the DecodeNYC KS-CT pre- and post-survey. The DecodeNYC KS-CT is a multiple choice instrument that draws items from a previously validated version of the KS-CT and five ecosystems items from the Harvard-Smithsonian Center for Astrophysics’ MOSART instrument (Sadler et al., 2010). The KS-CT survey was administered to participants before and after completing the DecodeNYC program as well as by a control group of students who did not participate in the program. The DecodeNYC program had a statistically significant positive impact on students' learning. From pre to post test, students in the treatment group (n = 18) increased their KS-CT scores by an average of 2.44 points out of a total of 19 points whereas students in the comparison group (n = 10) increased their KS-CT scores by an average of 0.2 points out of a total of 19 points. Results were statistically significant (p = .002 for sign test; p = .004 for signed-rank test) and the effect size (Cohen’s d) was 0.66552 (between medium and large). The scale with the largest increase was decoding (mapping code segments to the scientific processes they represent); the average score on this scale increased from 8.5 (47% correct) to 14.25 (79% correct). The average score on the ecosystem scale increased from 57% to 66% correct.

Student feedback

Three focus groups of four students each were conducted at the end of the first run of DecodeNYC to capture thoughts and feedback from participants. In discussions with the program’s evaluator, students organically mentioned decoding and how it enhanced their experience. For example, one student said:

> Well, coding helps in the ecology aspect because you're able to use the coding to prove different aspects of that ecosystem. Like we were trying to show the infection rate of Lyme disease in our ecosystem that we created in StarLogo Nova. And it was really easy to see it because it was just right there, and we were able to figure out what aspects of the ecosystem were creating it by just looking at our code.

The general consensus among students who had been exposed to coding in school was that DecodeNYC was “way better” because the coding had a specific purpose, in this case learning about the Lyme disease ecosystem. This suggests that a decoding-centered curriculum is not only an effective way to integrate computational thinking and scientific learning, but it is also a rewarding and motivating experience for young learners.

Conclusion

Participants in the DecodeNYC program were faced with a challenging task: They were expected to learn a new coding interface; learn how to use, modify, and create agent-based scientific models; develop mastery of ecosystem and population dynamics concepts; and apply all of those skills to a complex disease ecology system. Thanks to the decoding skills they developed during the program, the students rose to this challenge, demonstrating increased understanding of each of these components in surveys, focus groups, and student work samples.

Developing and implementing this program has revealed for our team of practitioners the value of decoding as a core skill for the integration of computational thinking and scientific inquiry. We have found SLN models to be an excellent tool for guiding students through this process and consider decoding a crucial addition to the UMC framework. As we revised the DecodeNYC curriculum over the course of the three years of implementation, we refined the opportunities for student decoding at each stage. We added additional decoding-specific prompts to reflection worksheets and created specific activities to address gaps in understanding.

One possible drawback to decoding-centered curriculum design is that students may not get a deep enough exposure to CS constructs (loops, conditionals) to be able to effectively modify or create new programs. Students are encouraged to see the code as representing a real-world phenomenon rather than a logical unit unto itself. We hope future work will elucidate how best to teach students to read code for information about processes.

Practitioner-Researchers Engaged in Practice Situated Design-Based Research: The Challenge of Positionality

Edel Connolly, Paul Flynn
E.CONNOLLY27@nuigalway.ie, paul.flynn@universityofgalway.ie
University of Galway, Ireland

Abstract: This paper explores the challenge of positionality as both limiting and liberating in the context of a design-based research PhD study carried out by a practicing teacher in a real world second level education setting. The study outlined here, in order to explore this issue, sought to enhance our understanding of academic buoyancy in second level students (N=255) and to produce an adaptable and/or adoptable model emergent from three iteratively refined Design-Based Research Design Cycles. Lessons learned from this journey are presented for other practitioner-researchers to consider as they grapple with positionality as part of their practice situated Design-Based Research journey and strive to ensure that what they produce is replicable as actionable knowledge.

Introduction

Applied research in the field of the Learning Sciences often employs Design-Based Research (DBR) sometimes referred to, in a European context, as Educational Design Research (EDR) (Sandoval, 2013). This approach to problem solving in educational contexts has fast gained a reputation as being a robust methodology of choice for researchers in the field of teacher education and teachers who wish to carry out research in their classrooms as part of continuing professional development (McKinney & Reeves 2013). This is hardly surprising as the cyclic and iterative processes involved in DBR are aligned with the authentic design of educational environments; hence, there is a natural alignment between design research and research in education (Kelly et al, 2008). Indeed, it is underlying premise of DBR studies, rooted in second level classroom practice, to generate actionable knowledge (Flynn, 2018) and to develop artefacts that advance theories capable of leading learning in naturalistic settings (Flynn et al., 2022). In this respect, DBR is a methodological approach that supports an investigation of learning by those who are best positioned to determine its effectiveness or otherwise - teachers.

However, there is an element of carrying out DBR, particularly for in-service teachers completing PhD studies, that presents a challenge to the adaptability or adoptability of the output of the study and that is positionality (Flynn et al., 2022). Positionality is the role that the researcher has chosen to adopt within a given research study and that position influences how research is conducted, its outcomes, and results (Rowe 2014). Being the researcher and the practitioner integrates theory and action, putting theory into practice, while addressing the issue by working together with those who are experiencing the issue, in this case presented here - the second level student. The challenge of positionality for practitioner-researchers addressing complex problems in their classrooms is explored in this paper, framed by the research study in question. In keeping with the research methodology employed, the overarching research aim of this study was twofold: a) to enhance our understanding of academic buoyancy in second level settings; and b) to iteratively design and refine an innovative pedagogy that supports the enhancement of academic buoyancy in the context of the real-world messiness of second level classrooms. This paper presents insights on the challenge of positionality from the perspective of a full-time in-service teacher carrying out a DBR, PhD study on how to enhance academic buoyancy (Martin & Marsh 2009) in second level students (n=255), within the naturalistic context of that teachers ’classroom.

What was designed and what was done to date

Academic buoyancy generally refers to a students ’ability to respond to everyday challenges in an academic setting, and plays a significant role in how individuals respond to the challenges they will experience within and outside formal educational settings (Martin & Marsh, 2009). The multi-cycle study presented here sought to iteratively design and refine an innovative pedagogy that supports the enhancement of academic buoyancy in the context of the real-world messiness of second level classrooms. As the lead researcher is a practicing teacher, convenience sampling was employed within the lead researchers own school setting across three DBR design cycles for the recruitment of participants (N=255). All participants were female with an average age of 15.5 years. The participating all female second level school is located in a rural setting in the West of Ireland and the school management team were supportive in facilitating this research study. The designed intervention was aimed at students enrolled in a yearlong elective programme called the Transition Year (TY) Programme. The TY Programme is intended to act as a bridge from a relatively passive academic environment in the first three years of second level education to a more self-directed learning experience in the final years where enhanced academic buoyancy would benefit students (Clerkin, 2016).

Informed by a multi-ontological conceptual framework that included key design informants of collaboration (Stahl et al., 2014) engagement (Yu, Martin et al. 2019) and reflection (Lousberg et al., 2019) an initial pilot, semester long, module was developed for implementation by the lead researcher with her own class group. The intervention, a twelve-week long module, required students to attend and engage with pedagogically informed activities for one hour each week. For the pilot study, and subsequent iterations, in the initial sessions with the students the researcher used a negotiated content development approach to ensure the intervention catered for the diverse needs of the participants in the school. Employing this negotiated process allowed the students to address social issues in school and also enhanced the likelihood of engagement by the participants. The pilot study was completed in Autumn 2020, a second iteration in Autumn 2021 and the final application of the intervention, or Design Cycle III, was in Autumn 2022. A mixed methods data collation and analysis strategy was developed to ensure comparison across design cycles (Flynn et al., 2022). In consultation with the author, an Academic Resilience Scale (ARS-30) (Cassidy, 2015), was employed as a design effectiveness informant. The ARS-30 is based on a three-factor measure of student ability to bounce back from academic setbacks, and to deal with academic adversity. The scale also provides a measure of the efficacy of interventions in terms of developing the students ’academic resilience and buoyancy skills. In conjunction with this, the Academic Buoyancy Scale (ABS) (Martin & Marsh, 2008) which comprises four items to check the extent to which students can deal effectively with hurdles in everyday academic life. At the beginning of the module of intervention and then again at the end of the module, students were asked to rate their academic buoyancy on the scale. These results, as well as structured end of class reflection sheets and unstructured reflective journals, were triangulated to provide feedback on the effectiveness of each cycle. The qualitative data collected, in particular, allowed the researcher to adjust the design from iteration to iteration so that the experience of the participants was enhanced. Essentially, the very nature of unification in qualitative data relies upon incremental efforts made during the research process to ensure reliability mechanisms are woven into every step of the research process (Morse et al. 2002). This approach to reliability is vital in the current study as the initial implementation phases of research were conducted by the researcher who is also the practitioner. Ongoing reflexivity throughout researcher/practitioner research is necessary (Holmes, 2020).

Hence, the positionality of the researcher is an important factor in this study. The researcher/practitioner acknowledges their personal position and how it might have the potential to influence the participants. DBR ideally enables the development of robust effective interventions, and cognisant of this, the concepts of validity and rigour were established throughout all cycles of this research. The rigour of a study may be measured by the degree to which the researcher is transparent about the design and role in the research process. The quandary resides in the fact that a researcher brings their own lens to a study. Design Cycle I and Design Cycle II, for the most part, developed the researcher’s agency and influence in bringing this module to fruition in the school. The researcher acknowledges their personal position and how it might have the potential to influence the participants. In order to mitigate this issue, for the third iteration of the intervention, the researcher/practitioner took a step back from delivering the module and recruited four other teachers to take charge of the rollout of the intervention. Therefore, interpretations are not wholly derived from one source, thus adding credibility to the findings.

Implementation

Second level classrooms are complex social environments with different groups of people from different backgrounds with varying levels of experience (McIntyre, 2000). In such contexts, standardised educational interventions might be considered as, at times, unworkable. In contrast design research methodologies are popular as they allow for innovation and careful evaluation. The iterative nature of DBR in particular allows for a design process where results of the first cycle are evaluated, the impact understood and, where necessary, adaptions made before moving on to Design Cycle II. Similarly, adaptions made from Design Cycle II to III. It became clear in the early stages of Design Cycle I that students needed to play a pivotal role in the design and development of this module through their participation in a consultative, student-centered learning experience. The participants themselves emphasised this inter-connectedness as being essential to their engagement in this dynamic learning experience in their reflective submissions. This empowering process of co-creation in the initial stage of this cycle promoted student engagement throughout the module as the process provided an authentic and rigorous approach to incorporate the student voice in the module, with the underlying view of promoting engagement. Design Cycle I was implemented by the lead researcher with a group of 84 female students. A key recommendation emerging from the results of this cycle was the need for further instruction in the area of reflection. The researcher believes the value of deeper more critical reflection by participants is vital to progression in becoming more aware and efficient in dealing with future setback for the participants. At this point, the researcher realised that the position adopted by a researcher affects every phase of the research process. While it may have been advantageous to mitigate this issue further in Design Cycle II by the researcher limiting their participating to the re-design aspects only, instead the researcher worked together with one other teacher to roll out the module, again over a 12-week period with 75 female participants. This cycle involved greater instruction in the area of reflection. Arising from the quality of reflections in Cycle I, it was decided to incorporate three lessons on reflection in the module of intervention for Cycle II. Design Cycle III had 96 participants. Considering what was best for the study in relation to researcher/practitioner positionality, it was decided to pass on the implementation of the module to four teachers in the department allowing the researcher to take a back seat and focus on coordinating the implantation of the intervention. The maturity of the design in Design Cycle III allowed the researcher/practitioner to transition from that position to that of purely researcher. Findings from each of the first two Design Cycles show positive results in the participants buoyancy levels, and this held true for the final Design Cycle. The researcher/practitioner, having engaged in a reflexive approach, is confident of a reduction in bias. Having removed themselves partially in Design Cycle II and completely in Design |Cycle III, the researcher accepts that this is not a guarantee to eliminate bias completely, however, being detached from the participants is on the right path to report on the findings without bias. The time-consuming nature of DBR provides a challenge with many competing priorities for practicing teachers. Securing teachers to commit to rolling out the intervention can also be a challenge to overcome. The timing of making this transition from researcher/practitioner to researcher is critical.

Lessons learned

Lesson No. 1: Practitioner/researchers must carefully consider positionality at the outset of a DBR study

Some authors use the terms practitioner researcher/design researcher/action research interchangeably, noting an important characteristic of this type of research being that the practitioner/researcher is the doer of the research (Bartlett & Burton, 2005). In this study it is the teacher in their classroom and not an outside researcher conducting the research. Put simply, it is research done by teachers for teachers. By employing DBR and thinking carefully about the concept of positionality from the outset of the work, the difficulty of putting theory into practice is mitigated in this instance, and a creative space exists where both module content and teaching methods can be modified. With an important goal of the Learning Sciences being to better understand the cognitive and social processes that result in the most effective learning for the student, this knowledge is used to redesign classrooms and learning environments so that people learn more deeply and more effectively (OECD 2008). Practitioner research has a valuable contribution to make in advancing teaching and learning in the classroom.

Lesson No. 2: Recruit colleagues early - you don’t know when you will need them to help

Wenger describes communities of practice as groups of people who share a concern or a passion for something they do and learn how to do it better as they interact regularly (Wenger-Trayner et al., 2014,). These communities are designed to bring people together with the intent of engaging in collective learning. The need to find supportive academic partners and to form a collaborative relationship with them became evident during the second phase of data collection for this DBR study. Going into Design Cycle III, the researcher had a cohort of four teacher colleagues who agreed to take over the delivery of the intervention. In hindsight, these teachers could have been involved earlier in the research journey as critical friends which may have informed development of the research.

Lesson No. 3: Timing is everything - know when to hold and know when to fold

From the outset of this paper the authors have highlighted the challenge of positionality as it relates to a teacher who is conducting research in the naturalistic context of their classroom. Indeed, the first lesson learned is that greater attention should have been paid to how much of a factor this can be in a DBR study such as this. In order to achieve an intervention workable in a real-world classroom setting, and one which can be taught by all teachers, it is important that the researcher distances themselves from the module rollout and passes this role to other teachers. The timing of this is critical. In the first instance the researcher/practitioner must know how long to hold onto the reigns to ensure the intervention is ready for others to work with. At the same time, they must be willing to fold responsibility for the delivery and pass it to others to test. It is in this instance that the role of researcher/practitioner transitions to that of researcher, the final design must pass its final test without its creator.

Conclusion

In this paper we have outlined the challenge of positionality in DBR studies carried out by practitioners in their own real-world classrooms. The DBR study outlined here, in exploring this issue sought to enhance our understanding of academic buoyancy in second level settings and to iteratively design and refine an innovative pedagogy that supports the enhancement of academic buoyancy in the context of the real-world messiness of second level classrooms. The authors conclude that interventions refined in such contexts require a careful consideration of the influence of positionality on the reliability of any final output and the role that design maturity plays in mitigating this issue. Finally, the authors suggest that in developing a community of practice around a situated DBR study, as described here, it is possible to use the act of addressing positionality as a transition point from being practitioner/researcher to researcher and address challenges to the reliability of a Design-Based Research PhD study.

Design and Implementation of Capacity Building Programs for Senior Education Functionaries in India

Gomathy Soundararaj, gomathy.soundararaj@gmail.com

Abstract: Capacity building programs equip education systems to be better prepared for the unknown future by enhancing the skills of its members. These programs are customized and contextualized based on the needs and role of the participants. This paper details the aspects of design and implementation of one such capacity building induction program for District Educational Officers in India. By exploring the characteristics of the program, the learnings present the components to build an effective capacity building program for senior functionaries who are new to the system. To make learning effective for this particular group, it needs to be social, collaborative, situated in authentic contexts with learners as active constructers of knowledge. The happenings should be relevant, it should ground new experiences and connect to the prior knowledge of the participants. These foundation principles of learning with concrete example of the induction program will promote informed creation of impactful and meaningful learning experiences for senior education functionaries.

Introduction

According to United Nations (UN), capacity-building is defined as the process of developing and strengthening the skills, instincts, abilities, processes and resources that organizations and communities need to survive, adapt, and thrive in a fast-changing world. The UN also mentions that an essential component in capacity-building is transformation that is generated and sustained over time from within; transformation of this kind goes beyond performing tasks to changing mindsets and attitudes.

The effect of the pandemic has pushed the education systems around the world to rethink their existing practices and work towards a paradigm shift to prepare themselves for the unknown future. This preparation has been translated into developing and implementing capacity building programs for stakeholders across the education sector at both the state and national level. In India, department of education of the respective state government plans and administers capacity building programs in the form of upskilling, Professional Development (PD) training for teachers, head teachers and educational officers. These programs are done in collaboration with universities, State Council of Educational Research and Training (SCERT) and District Institute of Education and Training (DIET). The ultimate focus is to improve student learning outcomes by training stakeholders in a particular skill or competency; or building their capacity in their roles to function effectively.

The programs are designed for senior education functionaries such as principals, educational officers at the state and district level offer capacity building in leadership, academics and administration. The influence of such programs is directly on the team of the educational officers which either has other officers or teachers and head teachers depending on the organizational hierarchy. The impact of senior functionaries at the classroom level is difficult to trace and measure, hence there is minimal focus on design and implementation. However, there is a dire need to examine the learning design in such large-scale capacity building programs for senior functionaries as it is crucial in shaping the culture, beliefs and mindsets of the entire education system. This paper details out the design and implementation of a capacity building program for District Educational Officers (DEOs) in an Indian state by the University.

Theoretical background

The sociocultural theories on learning emphasized the idea that knowledge is constructed and is a social process (McMahon, 1997). Aligning to this, the learning sciences research also states that learning needs to be situated, social and distributed (Fishman et al., 2022). The central idea of situativity is that learning is more effective when situated in authentic contexts (Fishman et al., 2022). The authentic contexts can involve using video and other representations of practice, using educative curriculum materials, and using cognitive and digital tools. The social and distributed nature of learning can translate into building communities of practice, creating knowledge building communities, coaching, mentoring, design-based research and research-practice partnerships. Community of practice refers to the creation of a learning environment in which the participants actively communicate about and engage in the skills involved in expertise (Lave & Wenger, 1991; Wenger, 1999). Such a community leads to a sense of ownership characterized by personal investment and mutual dependency (Collins & Kapur, 2022). For any Professional Learning Communities (PLCs) to be effective, the participants need to discuss problems of practice, engage in collective sense making, have collaborative conversations, contain shared values and norms and reflective dialogues. This study draws from these principles of learning for analysis of the design and implementation to understand the practices that enable impact in capacity building programs.

Context

Senior education functionaries comprise of Joint Directors (JDs) of the department of education, Chief Educational Officers (CEOs), District Educational Officers (DEOs), Block Educational Officers (BEOs), SCERT and DIET principals and faculty. They are primarily involved in administration, management, and leadership duties along with providing academic support. The senior education functionaries start their career as a teacher and with experience move up the ladder to various designations. By the time a person becomes a JD he/she has been in the system for many years. The system observed that this long journey to leadership positions is a hindrance to fresh ideas, perspectives and innovations. Hence, as a step to bring in young and energetic people directly into the leadership position, the state government introduced a direct recruitment system where qualified candidates working as teachers apply out of their own volition and passion, go through an assessment process and directly become BEOs/DEOs.

The state Department of School Education in collaboration with the university designed and implemented a six-month orientation program for 20 DEOs who were directly recruited in the year 2021. It was piloted in July 2021 and completed its course in January 2022. It is important to note that the DEOs who were recruited before this cohort were expected to learn on the job and were not provided any induction from the state. The utmost significance of this program is that these 20 DEOs are in the age range of 30-40 and will be a part of the system for the next 20-25 years. They have the authority to shape the future education system of the state. DEOs function as an inspection authority, authority for opening, closure and renewal of schools, appointing and approval authority of government, government aided and private schools. They are responsible for primary, middle, high and higher secondary schools. The vision of the induction program was to develop a cohort of DEOs who would be academically oriented to the educational policies and objectives of the state and the country, administratively adept with all aspects of the role and be able leaders capable of providing vision, guidance to the system and accountable to the aims of the Department.

Design

The program was designed collaboratively by the School Education department of the state and the University. The objectives of the program are to:

- Deepen the understanding and appreciation of DEO’s roles and responsibilities
- Build capacity and capability to effectively perform the roles and create the desired outcomes
- Respond effectively to the everchanging contexts
- Explore interlinkage between personal vision, values, and practices with the profession

To achieve these objectives, the broader content domains of leadership and management and education perspectives were chosen. Under the domain of leadership and management, the themes assigned for each month were Leadership, Task management, Understanding self, People management, Driving improvement and change. Each theme covered multiple topics, for example, the theme of understanding self included topics such as Personal Vision, Values and Drivers, Direction, Goals & Norms and Communicating with Effectiveness. The education perspectives domain comprised of topics like Introduction to the study of childhood in the Indian context, Reimagining Schooling, Child Development and Learning, Assessment, Quality of Education and Parent’s aspiration.

The program was conducted in the medium of English and consisted of three modes of engagement: Workshops (face to face Sessions and expert talks), Webinars (online expert-led and assignment-based) and Field Projects (research projects and school visits). The six-month timeline of the program was divided in a way to provide equal weightage to both the content domains and field projects. The workshop was for 4-5 days a month adding up to a total of 25-30 days. The short courses or webinars were for 150 hours, and the field projects were for 60 days. During the program, each DEO trainee was allocated a mentor who were DEOs who engaged with the trainees in conducting the field projects effectively. Feedback was collected consistently in both formal and informal ways. Through informal WhatsApp group, emails and face-to-face workshops DEOs and the resource persons discussed, shared, and addressed specific concerns or clarifications. Formal feedback google form was designed by the university faculty and shared with the participants on the last day of the program.

Implementation

The program chose a blended integrated approach where three modes of engagement were executed simultaneously every month. The specific theme chosen for each month reflected in all three modes of engagement. The content domain of leadership and management was entirely implemented through workshops. The webinar sessions were on topics from the domain of education perspectives. The focus of the field projects was a combination of both the domains.

The workshops session was augmented by talks by field experts, school observation visits and debrief, project presentation and feedback. Each workshop was a rich combination of illustrations from the field and exercise and discussion-based sessions. Different exercises were designed to provide DEOs with personal space to think critically and reflect. The small-group discussions ensured that they step out of their comfort zone and concretized the ideas developed during the program. The activities of the orientation workshops were aimed to deepen understanding, to reflect and develop strategies for personal and systemic transformations. Each session had visual inputs in terms of PowerPoint presentations.

A key part of the orientation was the focus on building academic perspectives on schooling, children, teaching- learning and assessment. To bring this aspect a series of webinars was a crucial element of this blended program design. Each webinar was delivered by experts from the university and anchored by the resource people facilitating the program. Each 90-minute webinar explored perspectives around the chosen topic and was interspersed with discussions and assignments. The anchor interventions tied the topic to the overall workshop themes and to specific aspects of the DEO role. The rationale for assigning field projects was for the trainee DEO to get an in-depth understanding of the various systems, processes, resources, and people they would be engaging with in their role. Each project had clear guidelines for research focus and presentation. The DEOs presented their projects during the workshops to the resource persons, field experts and mentors and received specific feedback. The field project findings were woven into the session topics by the facilitators. This helped in situating the research findings and data in specific contexts and was relatable to the roles and responsibilities of the trainees.

In the face-to-face sessions held every month, a component of talks by field experts, local school observation visits followed by in-depth debrief, IT and legal sessions were organized. Each of these engagements were enriching experiences that added significantly to DEOs' experience and preparation to hit the ground running when they took charge officially. The informal forums inputs on webinar facilitation, language clarity, timings were addressed on a timely basis. The workshop discussions on session feedback enabled the resource persons to incorporate feedback into their presentations. The google form captured the DEO trainees' opinions and feedback on all workshop sessions, webinars, projects, learnings, critical inputs, and ways to improve the program. Currently, as a continuation of the program, the faculty from the university are visiting DEO offices across the state to observe and analyze the status of the directly recruited DEOs and provide suggestions, recommendations and assistance.

Learnings

The conversations with faculty of the University on the collaborative program designing process, the implementation experience along with the participant feedback presents key reflections on components that build effective learning experience in capacity building programs for new senior education functionaries. The program design enabled interactions and bonding between a group of 20 officers who were at the starting point of their journey. This combined state of professional life along with the sense of purpose empowered the DEOs to learn from each other. The program was built in a way that there was collaboration, peer-learning and group projects. DEOs, when they start their role will have their own team and might become isolated carrying out their responsibilities. Hence, building this team spirit and tight knit community right at the beginning paves way for Professional Learning Communities (PLC). PLCs promote reflection, sharing, collaboration and support which is essential to their job role. Learning experiences are effective when learning communities of trust and respect are established with the inherent belief that learning is social in nature.

The varied modes of engagement ensured that the program has a balance of theory and practice. The workshops and webinars introduced new concepts to the participants. The field projects equipped the participants to understand the ground reality and gave them a trailer of their roles and responsibilities. The participants looked at the ground reality from the lens of the concepts that they learnt during the sessions. This provided relevance, meaning and preparedness towards their role. At the same time, they also got the essence of the challenges and difficulties. DEOs were able to grasp reality and place themselves in the context before they started. Through this it is evident that learning experiences need to be situated in authentic contexts (Fishman et al., 2022) for it to create impact. The workshops and webinars of the program provided ample opportunities for participants to discuss, question, share and reflect. Active engagement throughout the program empowered the participants to learn from the reflection of their experiences during school visits. They constructed meaning by connecting the concepts to practice. During the discussions, the participants were able to discuss their personal vision and goals in the role of a DEO and find meaning. Apart from this, the sessions pushed the participants out of their comfort zone to explore current realities of schools and classrooms in the state. These sessions involved collecting qualitative and quantitative data through observations, interviews and engaging with state database. They developed skills such as critical thinking, data interpretation and analysis, reasoning and prioritization. When the learners are actively engaged in construction of meaning and knowledge (Chi &Wylie, 2014), powerful learning occurs. Learning becomes more effective when learners are encouraged to ground new experiences and concepts in perceptual and motor experiences, language and prior knowledge (Nathan, 2021) like the examples stated above.

Overall, learning experiences are effective when they are collaborative, situated in authentic contexts, allowing learners to actively construct knowledge, ground new experiences and connect to prior knowledge. These components are essential when building a capacity building program for senior education functionaries. Through this program, the DEOs started their journey with clarity, vision and support. The program enabled them to set expectations and direction from the beginning and build a more equitable and just culture in their work. The sustained impact of the program can be witnessed post 6 months from the end date. This impact is seen as results on the field and from observations during the visits of the faculty. Interactions with JDs of the state reveal that the mindset, beliefs and attitude of the DEOs who underwent the program are progressive, futuristic and upholding the values of the state. During the visits, the faculty witnessed transformation happening in smaller pockets in administration, leadership, management and academics.

Relevance

The paper is highly relevant as education systems around the world are encouraging young people to join the system which has had its traditional roots for centuries. It is necessary for the system to provide induction for the people to navigate through the existing conventional practices, have the courage to break the shackles and pave the way for the future. It is essential to prevent the newly joining people to either follow the old ways or lose trust in the system. Designing capacity building programs with the foundation of principles of learning sciences results in active, impactful and sustained transformation. The aim of these programs is to provide training to get the participants started in their professional journey and over a period, create PLCs and support systems which makes them self-sufficient. Such programs as detailed out in this paper can be researched on for their impact and can be scaled up across systems. While this program is specific to educational officers, the design and pedagogy of it is transferable to any discipline.

Identity Inquiries: From STEAM Self-Portraits to Identity Mapping

Scarlett L. Calvin, Emma C. Gargroetzi, Hakeoung Hannah Lee, Matthew E. Hertel
scarlett.calvin@austin.utexas.edu, egargroetzi@austin.utexas.edu, hklee@utexas.edu, hertelma@utexas.edu
University of Texas at Austin

Abstract: This paper outlines how an elementary STEAM educator presents, reflects, and enhances identity inquiry practices for students as they build and share knowledge together over multiple years. Utilizing a consistent, integrated approach to STEAM learning in the classroom coupled with annual self-portrait development and reflection, salient themes arise in how young people can guide each other in the reformation of roles in science, technology, engineering, arts, and math and how to engage civic action in their developing worlds.

Introduction

Sociocultural theories of learning include identity as a central component of learning (Lave & Wenger, 1991; Wenger, 1999). Research in STEM education - including research in science, engineering, and mathematics education, as well as in the explicitly interdisciplinary STEM education field - has widely taken up identity development as a meaningful construct for examining children's participation and experiences in STEM learning (Avraamidou, 2020; Capobianco et al., 2015; Carlone & Johnson, 2007; Graven & Heyd-Metzuyanim, 2019; Patrick & Borrego, 2016). Research shows that conceptions of what it means to be a scientist or mathematician are heavily informed by dominant stereotypes of mathematicians and scientists as old white men (Carlone & Johnson, 2007). When these stereotypes are not upended, challenged, and dismantled in elementary school, minoritized students entering middle school risk diminished participation in their formal STEM learning spaces (Archer, 2010). Elementary school is a critical time for children to have opportunities to challenge and reinvent traditional notions of STEM identities and reimagine what science is and can be.

Purpose and research questions

This paper explores the ways in which an elementary STEAM teacher (science, technology, engineering, arts and mathematics), now also a novice researcher, worked to support student identity development through instructional tasks in a connected and continued fashion with students in Pre-k through 5th grade over multiple years. As such, many students participated in a STEAM identity development task every year for multiple consecutive years. Through an approach incorporating STEAM self-portrait drawings coupled with age-appropriate writing reflections and technology integration as a beginning of year tradition, students created work that offers insight into their journeys of human development, including their emergent written and artistic literacies and, here, of primary interest, their identity development connected to civic engagement.

We conceive of these tasks as *identity inquiries* - an investigation of what it means, or has meant, to oneself to be a person who participates in a community or discipline. We propose that these identity inquiries may serve as a way to surface and thereby challenge stereotypes about who participates in STEAM disciplines, what that participation looks like, and the possible roles of STEAM in our world. Likewise, they can evidence young learners' emerging and changing understandings of themselves as participants in STEAM and in their own communities. Looking at student identity inquiry work produced and collected over five years, our analysis then asked: *1) How is STEAM represented in relation to civic learning or civic participation? 2) How do students challenge stereotypes through STEAM integrated civic learning and participation?*

Background and context

First author, Scarlett Calvin, has been teaching STEAM integration enrichment classes across PK-5th grade classrooms for the last six years at a small public/charter elementary school in a central Texas city. Aligned with the school's mission to "develop students into lifelong learners through rigorous, research-based curricula, individualized instruction, high expectations, and a nurturing environment that includes parental and community involvement and serve as a model of an exemplary educational program for diverse learners," the STEAM self-portrait project has been presented to students during the beginning of every year as a preliminary activity to activate prior learning, uncover interest and involvement with the natural world, and to tap into student ideas of applied integration with math, science, and expressive content driven by student experience. The activity is introduced by asking students to "draw themselves doing anything STEAM related". We collaboratively discuss what STEAM is, practice naming the disciplines, and students are encouraged to interpret the assignment freely.

While drawing their portraits, they are asked to respond to a series of written questions, to probe prior ideas involving STEAM experience and the importance of STEAM learning.

In Spring 2022, Calvin became a participating teacher-researcher in the Transdisciplinary Civic Learning Collaborative (TCLC), a multi-sited, multi-disciplinary group of elementary and secondary teachers and education researchers working on designing and implementing transdisciplinary civic learning units at diverse school sites that may arm students with tools to develop empowered STEM and civic identities. While the learning units designed differ substantially across school sites, they share a student-facing guiding question developed collectively across sites: *How do we leverage our individual assets and identities to collaborate, imagine, and sustain healthy communities?* Noting that the first portion of this guiding question references individual identities, and agreeing collectively that in order to support meaningful civic engagement, we must start with the self, teachers across the TCLC designed and conducted varied forms of what we have now come to refer to as *identity inquiries* across sites and classrooms.

When Calvin joined TCLC, we realized some of her oldest students had been participating in identity inquiry for much of their elementary careers. In realizing this work could shed light upon TCLC goals, we began digging deeper, uncovering themes contributing to developing the notion of reimagining STEM learning spaces for innovative young students. In addition, Calvin used TCLC's big guiding question to enhance the identity inquiry task for 4th and 5th-grade students who had already been participating in this campus tradition to further expand their engagement and journey within this realm of elementary student identity inquiry development and set them up for success in navigating participation into potential STEM-affiliated careers. In Fall 2022, 4th and 5th graders created digital identity representations highlighting ties to relevant communities they are a part of and issues that face those communities. They then presented works in a collaborative setting to reflect, challenge, connect and build upon ideas.

Data and analysis

Data for this analysis included approximately 220 STEAM self-portraits created by 44 children throughout their 1st – 5th-grade years from 2018-2022 and 88 civic identity webs created by 4th and 5th-grade students in 2022. All students take STEAM courses, with the data samples reflecting the racial demographics of the school (65% Hispanic/Latinx, 16% Black/African American, 13% white, 2% Asian, 4% two or more races). The analysis examined (a) how students chose to physically represent themselves within (b) what they represented as a "STEAM" affiliated setting, and (c) how they meaningfully integrated STEAM and civics concepts. Calvin initially coded looking for themes. She then shared these themes with the team and we settled on three macro-themes for further exploration. In analyzing each of these themes and summarizing our findings we attend to setting, tool and artifact use, and the culmination of each in relation to broader community problem-solving potential and civic identity development. Selected student work products are presented and examined in Findings to illuminate both commonalities and variation within each of the themes.

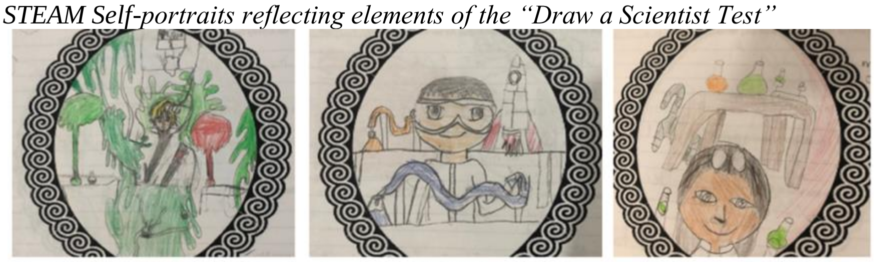
Findings

Data revealed evidence of stereotypes and dominant conceptions of STEAM largely resonant with dominant conceptions of science. We also identified concurrent evidence of students challenging these stereotypes as well as civic identity mapping as a space for building forms of resistance through relevant multimedia and connected culture. Findings are presented in three sections; each section shares evidence from student work to illuminate themes found across data, shedding light on how students can make sense of, develop, and collaboratively reinvent stereotyped notions of STEAM using elements of civic learning and participation.

Stereotypes and dominant conceptions of STEAM

Across the data, students of every age, created drawings with standard or commercialized versions of scientists reflecting themes well documented in the "Draw a Scientist Test" literature (Chambers, 1983) such as "the scientist as a man who wears a white coat and works in a laboratory... wears glasses... and is surrounded by equipment … a jungle gym of blown glass tubes" (Mead & Metraux, 1975, p. 386). Similarly, Figure 1 shows three samples created by students depicting themselves as scientists wearing lab coats (1.1, 1.2 & 1.3) and goggles (1.2 & 1.3) with short hair (1.1 & 1.2) and light skin (1.1, 1.2 & 1.3) provoking the imagery of white men. Tables, faucets, and wires (1.2 & 1.3) indicate indoor lab work with green liquid (1.1) and beakers (1.2 & 1.3) that denote explorations with potions, slimes, or explosions. It is difficult to discern a context where the students are working, or what problems within the community they intend to solve, if any. Students depict having fun with science, shown by smiling faces, but do not explicitly connect context to the broader sense of community connection or future problem solving.

Figure 1
STEAM Self-portraits reflecting elements of the "Draw a Scientist Test"



1. Slime and explosions Scientist
2. Labs and Beakers Scientist A
3. Labs and Beakers Scientist B

Challenging stereotypes and dominant conceptions of STEAM

In contrast to the decontextualized scientists noted above, another theme of student work of all ages included evidence of complex STEAM integration tied to community engagements including, but not limited to, mechanical engineering in construction settings, robotics in makerspace settings, ecological film making, animal rights initiatives, and more. Figure 2 portraits reflect student interaction within various applied learning settings, solving community problems in relevant contexts, using technological tools, while integrating STEAM content. Figure 2.1 shows a digitally created scientist on the roof of a neighborhood home, installing solar panels with tools. A majority of the work is created using geometric shapes pieced together in meaningful ways to create a portrait of a student using solar energy science to solve the relevant problem of increased energy consumption in her neighborhood community. Figure 2.2 is a digital drawing of a scientist engineering a house with a green drill tool next to a large growing crop and a red "garden" sign above a raised garden bed containing various foods. This student poignantly uses elements of gardening and health science to give meaning to the building of which she's engineering for her community to solve food sustainability and scarcity issues. Figure 2.3 shows a hand-drawn scientist collecting plastic in a basket in an aquatic setting. She includes a tree depicting elements of life to show the diversity of ecosystems and the importance of conservation. All three drawings appear to challenge traditional physical depictions of what scientists can be as they are portrayed outdoors in many different styles, shapes, and colors but most notably, connecting the self to community and solving issues of passion.

Figure 2
Challenging stereotypes through integrated STEAM learning and community engagement.

1. Solar Panel Installation in a neighborhood setting
2. Engineering a home in a community garden setting
3. Ecological Conservation in an aquatic setting

Building resistance through virtual STEAM identity mapping

Through collaborating with the TCLC around the idea of identity inquiries, Calvin conceptualized an extension assignment for 4th and 5th grade students following STEAM self-portraits. The extension assignment, *Virtual Identity Maps,* was presented to students to take the STEAM self-portrait project to the next level to include self-reflection and community engagement but also advocacy and cultural ties, to reimagine what STEAM can be, representing future generations. Students were encouraged to add relevant pictures, reflective writing, and broadly consider a series of questions including *1) What makes me unique and special? 2) What do I care about in the world, and what would I change? What kinds of communities am I a part of or wish to be a part? 4) How can I make the world a better place?* Students created a diverse range of media reflecting a number of issues, visuals, cultures, contexts, and STEAM content. In addition, students reflected themselves as scientists in ways they conceptualized, often resisting stereotypic forefronts, instead creating portfolios of complex ideas, goals, aspirations, and connections to communities. Figure 3, one example from the extension assignment, evidences a plethora of global issues, STEAM disciplines, personal expression, and problem-solving. Rather than teasing these apart, we suggest it is more meaningful for teachers and researchers to learn from and celebrate the holistic vision and organized intent of a young student, reflecting upon their developing identity in relation to their call for change utilizing STEAM knowledge and skills, empowerment, and self-actualization.

Figure 3
Identity map integrating STEAM, writing, culture, and advocacy

Discussion and implications

Looking at elementary-aged students' expressive and self-guided work, we see that it's possible to meaningfully create and inform the future of STEAM knowledge and roles through experience with continual and consistent STEAM and civic identity inquiries. As indicated in the findings, a range of identity development can be noted for students of all ages, setting the stage for meaningful cooperative learning, sharing, and apprenticeship within situated learning contexts (Lave and Wenger, 1991). While it's evident some students reflect stereotypic notions of science, their interaction and experience within the classroom context can inform and reinvent STEAM related learning and issues through the interaction of others. Additionally, the use of media in probing civic issues related to identity development can better aid students in communicating relations and dreams associated with civic participation in communities they are developing. Through identifying these themes, future goals for additional research within the data will examine questions like 1) How do students guide each other in resisting stereotypes? And 2) How can longitudinal reflection and connected creation set the conditions for learner insights into their own developing identities, minds, and futures with STEAM?

Designing and Implementing a Societal-Context Course for Physics Undergraduates

Carolyn D. Sealfon, Ronin Institute and University of Toronto, carolyn.sealfon@ronininstitute.org
Garrick Burron, Ontario Institute for Studies of Education, garrick.burron@mail.utoronto.ca

Abstract: Through a self-study research-practice partnership, we discuss the design, implementation, observations and lessons learned from active learning integration in an upper-level university course. This one-semester course on physical science in contemporary society aims to empower physics undergraduates to develop transferable skills and 21st century competencies through design elements including a student-driven curriculum, student-led classes, an open-ended final project, and ungrading. The class was judged to be a success based on student outputs of final projects, student-designed classroom activities, and student reflective writing.

Pedagogical objectives

We live in a global, interconnected world in which science plays a vital role, as illustrated recently through the COVID-19 pandemic. Yet physics is often taught as an objective discipline, impervious to societal concerns. How do we prepare physics students to grapple with vital questions regarding complex relationships between physics and society? In this self-study, we examine the design and implementation of a university course on physical science in contemporary society. Each year, roughly forty third-through-fifth-year physics undergraduates take this one-semester course, which fulfills the ethics requirement for physics specialists at a large research university. This study examines the depth of learning and the efficacy of our student-driven course design. In particular, we aim to engage students equitably, mitigate any resistance to a nontraditional course format, and empower students to critique and ameliorate the culture(s) in which they live (including physics, academia, and beyond). Learning goals include: (1) to explore relationships between individual people and physics; (2) to explore relationships between society and physics; (3) to communicate effectively.

This self-study is a research-practice partnership that focuses on a second iteration of the course taught by the practitioner (Sealfon) with observations and analysis provided by a trusted observer (Burron). The practitioner’s first iteration was half online and half in-person due to the COVID-19 pandemic. Previous iterations of the course, not taught by the practitioner, were less student-centered and involved less active learning.

Theoretical framework

Active learning has been recognized to be a superior form of educational practice overall, resulting in superior student understanding of content (Kolloffel et al., 2011; Muukkonen & Lakkala, 2009; Song & Looi, 2012) regardless of the testing methods used (Haak et al., 2011). For our working model of active learning, this study uses SALTISE's definition of active learning activities which include: inquiry-based learning, problem-based learning, project-based instruction, concept mapping, and debates (SALTISE, n.d.). We pair these categories of instructional methods with Chi et al.’s ICAP Theory (Chi et al., 2018) that conceptualizes the success of active learning through the products of the students. In ICAP, the goal of active learning is to connect the ideas that are presented in class to ideas and concepts that are in the students’ lived experiences. These connections serve to avoid “encapsulated or inert knowledge” (Chi et al., 2018, p. 1728) which aids in subsequent retrieval and enactment of the knowledge. Chi argues that manipulation of new knowledge, and interacting with other students using that knowledge, entrenches that knowledge within existing knowledge schemas.

Pedagogical changes can be difficult to evaluate and enact without the ability to have feedback of some form. We address this issue by using the “self-study” methodology which allows practitioners to critically examine their pedagogical practices, evaluate the success of that pedagogy, and to have a trusted observer to act as a check to potential self-bias (Loughran, 2004; Russell et al., 2020).

Data sources

This self-study draws from seven sources of data: logs of classroom observations, post-class reflections by the instructor, student works and feedback, the class syllabus, assignment documents, and interviews of the instructors. These multiple data sources help to triangulate the effectiveness of the observed and assigned active learning pedagogies. The trusted observer observed 30% of the course and took notes on the sequence of events, the reactions of the students, and any publicly-facing student works. After each class, the observer collected a reflection from the instructor for later documents analysis. We also collected mid-semester student feedback via an anonymous, optional, online survey, which about half the class completed.

Course design and implementation

The practitioner sought to design a successful student-driven course with an enrolment of 30-40 students who are accustomed to traditional lecture courses with solo problem sets. Most students were not used to expressing themselves in class, articulating their own learning goals, working collaboratively, or designing their own project. The challenge was to balance structure and independence. Active learning at this scale would be most feasible with learning assistants (Barrasso & Spilios, 2021; Otero et al., 2010), yet institutional constraints prohibited this. So the practitioner opted to engage the students themselves, as they are upper-year undergraduates, in the facilitation of classes.

For the facilitation assignment, students signed up to facilitate one hour of class in groups of up to four. In the first iteration of the course, the practitioner chose the topics and students simply signed up; in the second iteration, the practitioner engaged the students in co-creating the list of topics. The practitioner provided a guided "Facilitation Worksheet" for each group to complete to scaffold the steps they would need to design an effective active-learning lesson. The practitioner then reviewed each completed Facilitation Worksheet, added comments and suggestions, and met with each group to discuss their lesson plan and what would make it successful in the classroom before each group's facilitation. In the most recent iteration, the practitioner discussed and finalized students' facilitation grades, based on both preparation and in-class facilitation, during a debrief meeting with each group. The facilitation assignments helped students develop their communication skills, gave each student a turn in the spotlight (with support and with a group of classmates), and enabled dynamic class discussions around a wide range of important topics. To set the stage for productive discussions, the practitioner invited the class to co-create a list of class discussion norms on the first day of class, which groups would revisit before class discussions.

These peer-led classes were paired with weekly writing assignments. In the first iteration, the writing assignments were based on pre-class readings and due before class, helping to establish a common knowledge base for the class discussions. However, these assignments proved too onerous and time-consuming, and the resulting stress compromised learning and quality. In this iteration, we assigned each facilitation group to write a coherent one-page summary of the background readings for their topic with citations to original sources. This summary was shared with the class one week in advance, and students completed a brief online pre-class quiz based on these summaries, reducing the burden for the rest of the class to arrive prepared. We shifted the focus on writing skills to weekly post-class assignments, in which students were asked to complete a reflection that applied what they learned in class to a different real-life situation and connect it to their experiences. This writing prompt was supported by insights from Chi et al. (2018) who emphasized the importance of connections between new knowledge and older knowledge to encourage retention. The students' reflections then allowed teaching assistants (TAs) to engage with the students about critical thinking, appropriate writing skills, and bringing the student's self and opinions (a difficult proposition for this student population) into their writing. We used ungrading (Kohn & Blum, 2020) to encourage growth in writing abilities. TAs gave students weekly feedback on three criteria adapted from the VALUE rubrics (Association of American Colleges and Universities, 2009): (1) identify and communicate a position or perspective; (2) analysis and integration of knowledge; (3) writing syntax and mechanics. TAs also provided a mid-semester estimated grade. Towards the end of the semester, students completed a self-assessment of their growth in the three criteria as demonstrated through their written submissions. They then met with their TA for fifteen minutes to discuss and finalize their post-class writing grade.

The last major component of the class was a final project, enabling students to delve more deeply into a class topic. The practitioner based the final project structure on Jim Martinez's assignments that engage students in interdisciplinary, open-ended, creative projects (Martinez, 2017). Students could work in groups of up to five on any topic that involves a complex issue and pertains to relationships between society and physics. They could consider creative formats for their final product beyond a typical paper or essay (e.g. podcast, video, play, blog, research proposal, etc.). Three stages helped scaffold the final project, and the practitioner provided feedback after each stage. In the last few weeks of class, students shared their learning from their projects with the class; these project presentations were graded in part on how well presenters engaged the class in active learning. This course iteration included a phase of peer feedback and self-evaluation after groups submitted their final products, and final project grades were finalized in a meeting between the practitioner and each group.

Results and discussion

A principal concern of the practitioner was that some students in the previous iteration “phoned it in” when facilitating active learning activities with the class. In these cases, the students simply read off slides that summarized papers the class had already read. Though the feedback from the previous iteration was favourable, especially regarding presentations that were interactive, concerns about this “phone it in” behaviour prompted redesign. To combat this behaviour, the practitioner engaged with her presenting students in design meetings, provided scaffolds for active learning instructional planning, and changed the weighting for the presentations from 10% to 30% of the total grade.

Though students were initially reticent, the class became accustomed to the alternative delivery format and then eventually started to enjoy the activities. Students demonstrated impressive knowledge development through their oral comments and the thinking they summarized on their whiteboards. However, some facilitation groups were more successful than others at preparing adequate background knowledge with their classmates. This challenged these groups' ability to engage the class in deep discussion because of the inadequate, or unbalanced, background information limited nuanced discussion of the topic. For future iterations, we propose separating out the facilitation group’s preparation assignment into two parts, with the summary of the background readings for the class due earlier than the rest of the lesson plan. This would allow more time for the practitioner to give feedback on gaps, or biases, in the background summaries.

We also used ungrading on writing assignments to discourage students from ignoring feedback and focusing only on the grade. This process proved incredibly successful as students’ writing improved in nearly all cases, and nearly all students appeared to be taking the feedback into account in subsequent submissions. While early writing from students was poor, with few exceptions, nearly all students approached the VALUE rubric’s definition of mastery-level writing after five or six assignments. For students who were slow to respond to the ungrading feedback, the use of a non-binding midpoint grade appeared to influence these students to pay attention to the feedback and subsequent submissions showed a marked improvement. Survey data also supported that students engaged with the TA feedback across weeks.

Student surveys showed a universally positive opinion of the class, with students praising the work of their classmates, the feedback from the TAs, and the practitioner. For example one student wrote:

> “The in class discussions, especially when they were global, i.e. involving the whole class. It provides students an opportunity to interact with their colleagues in a personal and meaningful way, a rare and valuable experience that most other classes just cannot provide.”

Students also pointed out that the class was unique in their experience and that they appreciated the opportunity to think and interact with the issues. For example:

> “I've been able to talk to more people that are studying similar things to what I am so I am able to get more exposure. This class has allowed me to make more connections, see their perspectives on issues and inform me more broadly on physics.”

One student, who admitted to initially not wanting to take the class, commented that they now believe the class should be obligatory for students in the physics program.

Conclusions and relevance

This class design seems to have worked well, even with a population of students that tends to be reticent about writing, speaking, or engaging with social issues.

Given the surprising success of ungrading for student feedback, future work employing ungrading in post-secondary classes may be useful, especially in instances where the growth of the students’ abilities can be iterative (e.g., in a writing context, weekly assignments, or science lab reports e.g. Etkina et al., 2008).

Using the ICAP framework to emphasize connections between physics and social issues, as a direct learning outcome for writing, appears to have deepened the students’ understanding of the relevance of physics within a social context. Making connections integral to the learning objectives, though it may feel artificial, does seem to deepen student connections to the topics presented, as reflected in mid-semester survey responses that reference this advantage and in the growth of student achievement in this area.

As having students design and implement lessons worked very well in this context, further work to incorporate student-led learning in physics classrooms may show similar results. Though students may initially resist this educational style, the evidence shows that most, in our case all, eventually appreciated it.

Students also commented extensively on the social aspects of the class and how other students were helpful and accommodating. This type of co-creative course design and facilitation may help with pro-social aspects of post-secondary learning in fields that are not perceived as human-centric (Holmes, n.d.; Segarra et al., 2018).

Abstract: We report on a practitioner-researcher crafted semester-long biology inquiry-based lab approach which implemented a new script based on conceptual progression. Students were required to make decisions in well-scaffolded contexts relating to each component of the scientific process separately, but progressing in an order supporting the knowledge and skills to be learned, from experimental design and statistical/procedural methods, to formulating hypotheses, and ultimately drawing conclusions. In each module, students took up agency for a single component, but scaffolded within an exploration of the entire scientific process, including reflecting on how their work integrated into a full pre-prepared journal article. The progression concluded with students completing a small comprehensive project on their own. Results were encouraging, as students met the significant challenge of the final project, meaning our approach could serve as a model for other biology instructors. Further research will explore the success of the various scaffolds employed.

Objective

Inquiry-Based Labs (IBL) is an instructional approach based on social constructivism and aimed to promote the learning of scientific practices and processes. It focuses on engaging students in the thinking and procedures by providing them with opportunities to make decisions as part of the laboratory component of a science course. It is a departure from traditional verification/confirmation labs that often look like recipes from cookbooks, leaving little room for students to use skills and knowledge that are central to scientific experimentation and analytical skills (Holmes & Bonn, 2013). Increasingly, higher education science programs are questioning the effectiveness of using traditional labs (Holmes et al., 2020). The effectiveness of IBL arguably relies on appropriately scaffolding decision making and supporting the knowledge construction used in task completion (Hmelo-Silver et al., 2007).

To date, most theoretical and empirical research with IBL has been based on types of single labs (e.g., Blanchard et al. 2010), and there is little evidence-based information to guide the design and development of a college-level biology IBL curriculum. This paper reports on a semester-long IBL that explores a new script for IBL based on a "*conceptual progression*", instead of that proposed as typical implementations, as described in other studies.

Background and design

The literature has used two dimensions to classify the IBL approach: (1) the amount of instructor guidance (decision-making autonomy/agency afforded to students), and (2) the stage in the scientific process selected for the decision-making activity (research question, methods, results analysis, discussion). Science education researchers (Blanchard et al., 2010; Buck et al., 2008) have classified IBL implementations into typologies based on the intersection of these factors, which associate higher levels of inquiry with increased student decision-making (agency), but which constrain and prescribe the stages where this decision-making takes place. According to these typologies, lab activities with lower levels of inquiry (i.e., higher levels of instructor guidance) all encourage student agency only in the late stages of the scientific process (drawing conclusions), while providing strict guidance throughout all early stages. Inquiry levels are then constrained to progressively and sequentially increase backwards through the earlier stages (analyze data, design methods, formulate hypothesis, ask RQ). Essentially, per these typologies, students are only afforded agency to make decisions for first steps of the scientific process when they can complete an activity requiring them to make decisions throughout the entire process. While this *backward progression* seems typical of IBL described in the literature, it arguably does not reflect an ideal conceptual progression for IBL and overlooks the interdependent nature of each stage of the scientific method. Furthermore, those studies categorize individual labs in isolation and do not explore sequencing across a course, a critically important aspect to practitioners.

The semester-long IBL intervention on which we report sequenced lab modules by the specific knowledge and skills to be learned, following what we believed to be an ideal conceptual progression and unconstrained by the backward progression identified in other studies. Each module required students to make decisions associated with its particular learning objectives, while prompting them to integrate the associated knowledge into the larger process of scientific experimentation. In this way, students were progressively required to consider each component of the scientific process separately in a well-scaffolded context, and finally to put their understanding of each component together in a more comprehensive small project. The IBL was the product of a practitioner-researcher partnership, with both collaborating equally and extensively to adapt existing lab activities within the framework of our ideal conceptual progression model.

Context of the IBL case study

The IBL case study was set in a college-level General Biology I course (first year university equivalent, first biology course in the Science program), the institution situated in the province of Quebec, Canada. It consisted of five lab modules, each focusing on a particular aspect of the scientific process, which is the key characteristic of our approach. We also designed a variety of scaffolds to support the task completion. Typically, these scaffolds were embedded in the module as part of the instruction, or as background information, rubrics and models of high-quality performances.

Importantly, one of the scaffolds used in this IBL case study is embedded in the affordances of an online platform called OCLaRE (Online Collaborative Laboratory Reporting Environment). This is based on a “writing-to-learn” pedagogy (Reynolds et al., 2012) with structural features and templates that format the components of a typical lab report into the layout of an authentic scientific journal article. In our IBL modules, we used these affordances in a “complete-the journal article” activity, which required students to reflect on their choices for the particular aspect of the scientific process when viewing their section of the article within the context provided by the entire paper.

Lastly, the design team collected all student output, including lab reports within the online platform, which together we consider the biology-focused performance data. To assess the implications of this design on learning we developed a suite of instruments: a pre-post-test to assess changes in scientific reasoning (George’s Ice Cream, adapted from McDermott, 1995), an epistemic belief questionnaire (Topic Specific Epistemic Beliefs, Strømsø, et al., 2008), and a survey and interview questions on perceptions rela(ted to the course and levels of confidence.

Design of the IBL case study

The first IBL module was significantly more elaborate than the other four because it developed skills needed throughout the rest of the semester. It focused on providing opportunities for decision-making related to analytical skills, specifically aimed at developing the ability to design simple experiments and use simple statistical methods. The curriculum develops these skills first because we consider them the bedrock upon which other components of the scientific method are built. For example, the appropriate statistical/analytical tools to use depend on the study design and data collected, and proper interpretation of results for the purposes of drawing conclusions is challenging without understanding these two elements together. Simultaneously, a proper scientific hypothesis needs to be testable, so students must be able to conceive of how a hypothesis could be tested before they can formulate one. Thus, in module 1 students made choices to design an experiment to test a hypothesis about sugar content in peaches, to run a statistical analysis using data provided, and ultimately to produce a results section for a scientific article,

IBL module 2 was on measurement protocols and data manipulation, module 3 on using background information to formulate hypotheses, and module 4 on drawing conclusions and inferences from results (see Table 1). These modules were adapted from current lab practices and were thus presented in an order which reflected the content and regular lab activity progression of the course: in module 2 students designed a study to determine whether particular plant and animal cells were different in size, in module 3 students used detailed background information to formulate a hypothesis about the pattern of inheritance for a particular fruit fly gene, and in module 4 students used results of an experiment to draw conclusions about which evolutionary mechanisms had led to changes in allele frequencies for a gene in controlled fruit fly populations. However, the order of the interventions also reflected what we view as a logically coherent progression for scaffolding development of scientific skills, by first establishing the fundamental understanding of design and analytical methods, building upon this to formulate testable hypotheses, and finally considering the entire process and drawing conclusions. Collectively, these four modules represent the main components of the scientific method, but also map to the four sections of a traditional scientific publication.

The final component of this five-part curriculum, IBL module 5, was an open-ended task which required students to write a full scientific paper. This was based on a SimBio simulator called “How the Guppy Got Its Spots”, which itself is modeled directly on a classic paper in evolutionary research (Endler, 1980). The simulator roughly reproduces the environment where the research took place, including the tools Endler used to run the experiments. Given Endler’s research question, students had to formulate a hypothesis, design an experiment using the simulator to test this, analyze the raw data output, and draw conclusions. Scaffolding the IBL, students were provided with a full grading rubric, support documentation that accompanies the simulator, and the actual Endler (1980) publication that the simulator is modeled on. A social annotation assignment, using an online platform, was generated for the latter.

Elaborating on the conceptual progression model (see Table 1), it’s important to note that the decreased number of decisions associated with modules 2-4 belie the complexity of the reasoning and knowledge resources required to complete these modules. For module 2, students needed to consider and describe procedural constraints associated with taking measurements of cell sizes, as well as assumptions about cell shape that would be required to manipulate data for the purposes of comparison. These constraints/assumptions were not explicitly provided but were critical to assess confidence in the results and conclusions. For modules 3 and 4, the background knowledge required to formulate a hypothesis or interpret results and draw inferences was quite complex for students at this level. Scientific inquiry is rooted in a deep understanding of the subject matter, and the final tasks associated with these two lab modules required students to draw heavily upon fundamental conceptual knowledge from the course.

Table 1

The five-module (Mod.) curriculum outlining the conceptual progression model of students’ decision making

	Student choice	Mod.1	Mod. 2	Mod. 3	Mod. 4	Mod. 5
Introduction	Form hypothesis from background information			x		x
	Write introduction			x		x
Methods / Design	Design experiment from RQ and hypothesis	x	x			x
	Incorporate replication into design	x	x			x
	Systematically vary independent variable	x	x			x
	Write methods		x			x
Analysis, Discussion, and Conclusions	Select appropriate analytical approach	x				x
	Interpret data and draw inferences				x	x
	Write results	x				x
	Write discussion and conclusion				x	x

Implementation script

The workflow of the first four IBL modules followed a five phase “script” (Dillenbourg & Jermann, 2007). Phase 1 was a synchronous lab activity focused on teaching the identified skills and/or collecting data. In most instances this meant that students were introduced to the research question and worked together to answer that question, while, notably, the identified decision-making task was foregrounded. Working through the components of the scientific method together in groups acted as a scaffold for the particular element students needed to explore themselves. For phase 2, students were asked to write a draft of the paper section being targeted by that module. To assist with the completion of this task, they were provided with scaffolds that included standards and criteria as well as models of quality performance. Materials included: reviews that they completed in the synchronous lab, videos of particular methods where appropriate (necessary for online labs), descriptions of the goals of that written section and how they related to the scientific method, a detailed grading rubric which would be used to assess their work, and a highquality student submission from similar student work in previous semesters which was annotated to identify strengths and weaknesses. In phase 3, students submitted their draft section using OCLaRE. As described earlier, the objective of this phase was to have students consider a coherent scientific report of the entire process that links the storyline of the pre-written sections to the student-written section. OCLaRE inserted their draft section of the paper into a full high-quality student report submitted in a previous semester, and allowed students to view the entire paper in proper publication format. For phase 4, students were asked to complete a reflection assignment. They considered their own submission, as well as examples of the pertinent paper section of varying quality, all relative to the full publication describing the entire scientific process obtained from OCLaRE and the particular criteria required to properly complete the specific section. Lastly, phase 5, students completed the final draft of the section of the paper and submitted.

Discussion and relevance

The conceptual progression approach to IBL instruction was conducted within the context of a larger three-year study on the mechanisms and value of inquiry-based learning, and data from the semesters are still being processed and analyzed to attempt to answer larger research questions. To date, generally speaking, the results of this case study are encouraging for our practitioner-researcher team. Notably, student artifacts achieved standards consistent with high level quality at the introductory college level.

Given the nature of this practitioner-researcher project, it is important to note that the different stakeholders view the results differently. The course instructor (first author) is most interested in the results of the final module, which required students to undertake and make decisions throughout the entire scientific process, each of which would impact downstream decisions and have consequences on the final product. Thus, while the total of our IBL intervention could be perceived as simply providing an algorithm to follow of the scientific method, students could not have produced the high-quality papers submitted for the open-ended final module simply by following a recipe. Rather, the outcome could potentially be better perceived as having provided the students with an iterative set of decision-making practices, focused initially on each step of the process separately, but which students were ultimately able to compile together successfully, possibly due to our emphasis throughout of viewing each step within the context of the whole. Meanwhile, the researchers are curious and skeptical, currently examining the results of each module and which scaffolds were taken up and which were not. In particular, one focus for further investigation is the role played by OCLaRE. Those data are yet to be examined closely to identify how the task of reading through a full scientific article in the “complete-a-journal” activity mediated the understanding of the experimental process, as a whole.

In summary, from the data collected and analyzed to date, it appears that providing students with the agency to make decisions for all steps of the scientific process, with the exception of formulating a research question, is challenging and requires the design of additional scaffolds. That said, results of a post-semester survey indicate that, while the final assignment was extremely challenging, student confidence in having been prepared to meet that challenge was high. In the view of our instructor (first author), the students did indeed display their ability to meet the challenge, assessed by the quality of their final lab reports. In addition, most students displayed acceptable to impressive levels of competency for every stage of the scientific process and outcome, evaluated by a grading rubric designed for a typical biology course. Thus, from a practitioner’s perspective, this approach to IBL can be deemed a success, and could serve as a model for other biology instructors with first year undergraduate students. From a researcher perspective, this case study, of what we are calling a “conceptual progression” IBL model, provides insights into the process of designing and scaffolding for students’ autonomy and the release of agency.

Data-Informed Course Improvement: The Application of Learning Engineering in the Classroom

Anne Fensie, University of Maine, anne.fensie@maine.edu

Abstract: Learning Engineering is a practice and process that can be used by any teacher in the classroom to apply the learning sciences in their instructional design, while collecting and analyzing data to determine the effectiveness of their interventions. This practice-oriented paper reports on three examples of the learning engineering approach applied to course improvements in higher education to address self-regulated learning, social presence, and interleaving.

Introduction

Learning engineering can be intimidating for the typical classroom teacher. The word “learning” is familiar, but the word “engineering” may be misunderstood or may make an educator feel unqualified to explore this approach. Much of the literature on learning engineering describes large teams engaged in a project (Dede et al., 2018), scaling up learning solutions (Saxberg, 2017), or utilizing the approach by educational software developers (Goodell, 2022). However, the good news for teachers is that the learning engineering process and practice can be applied on a smaller scale in the individual classroom by any teacher, at any level, and in any subject area, who wants to improve learning outcomes for her or his students. By applying the learning sciences to our instruction, planning for collection and use of data, and understanding our learners and the effect of a unique context, we can make our classrooms more effective, equitable, and enjoyable. These are the processes involved in learning engineering, and teachers may find this systematic approach to be attainable and beneficial. In this paper, I will provide a brief overview of learning engineering and then share how I have used this approach in my own classes with promising results.

Learning engineering

The IEEE industry consortium on learning engineering (ICICLE) defines learning engineering as “a process and practice that applies the learning sciences using human-centered engineering design methodologies and data-informed decision making to support learners and their development” (Goodell, 2022, p. 10.). While learning engineering teams do exist in some organizations and there are increasingly more job postings for the role of learning engineer (V. R. Lee, 2022), this approach can be used at a smaller scale. All that is required is an understanding of the learning sciences, familiarity with some engineering principles, and a willingness to be adaptable in your instruction based on the data from your learners to iterate improvements.

The science of learning can be helpful to instructors who are using evidence-based practices in their teaching to help them understand why these practices are effective and in what circumstances (Daniel, 2012; McMurtrie, 2022). One critique of the science of learning is that the studies are often too controlled, conducted in a lab setting or with strict controls in a classroom environment (Daniel & Chew, 2013). The learning sciences have brought principles to educators such as the role of prior knowledge, skills, and beliefs; desirable difficulties; error management; feedback; active learning; retrieval practice; spacing and interleaving; metacognition; self-regulated learning; multimedia principles; and problem solving (Benassi et al., 2014). While learning sciences researchers often apply theory in practice in ways that encompass the whole learner (V. R. Lee, 2022), learning engineering allows us to examine these concepts in a specific context with a unique group of learners to understand the limits and applicability of these phenomena.

Barr et al. explained that “engineering is the application of creativity and science to solve problems, and learning engineering is the application of the learning sciences to creatively solve problems for learners and learning” (in Goodell, 2022, p. 131). They noted several principles of engineering that can be applied to designing solutions to learning challenges, including addressing specific problems, end users who are intended to benefit from the solution, testability, maintainability, integrity, well-defined external integration, ethics, and management (p. 131). Learning engineers use systems thinking to explore modular design, constraints and tolerances, operating conditions, trade-off analysis, and feedback loops. Engineers and research scientists often use data differently: while the learning sciences are often focused on group means, learning engineers probe outliers and individual cases to explore boundary conditions (Goodell, 2022).

Use cases

I teach at an institution that serves nontraditional learners in distance education. My students often have not been in a classroom for many years, have negative past experiences with school, have work and caretaking responsibilities outside of classes, and often face other life stressors that place them at risk for not completing a course. In order to address these challenges, I turned to the learning sciences. I now provide three use cases from several semesters of an introductory computer applications class illustrating how I have utilized learning engineering in my practice as an educator. Each of these consists of the core components of learning engineering: a learning problem or challenge, the design of a solution that applies the learning sciences, implementation with data collection, and investigation with data analysis, including iterating improved designs (Goodell, 2022).

Self-regulated learning

Learning challenge. Traditional face-to-face classes often provide the on demand supports and structures that regulate student learning, but these can be absent in online learning unless intentionally designed, requiring students to regulate their own learning. First generation students have significantly lower levels of self-regulated learning skills (Williams & Hellman, 2004), and participating in online learning does not necessarily improve these skills (Barnard-Brak et al., 2010). Deficits in self-regulated learning skills can negatively impact distance learners (Bol & Garner, 2011), especially adults (K. Lee et al., 2019). I have seen this in my own learners.

Design solution. Pintich's (2004) model of self-regulated learning includes four phases (plan, monitor, control, and reflect) and four areas (cognitive, affective, behavior, context). Using this framework, I included a section in my course syllabi with tips for success that included questions students can ask themselves to regulate their learning, such as, "How long will it take me to complete this assignment?" and "How can I make this assignment meaningful to me?" I modeled task analysis for students by showing them how I would plan out my week if I were taking this class, including learning tasks in addition to completion of assigned and graded work. I displayed a sample weekly routine in calendar format with tasks spread out over the course of the week to encourage spaced practice (Dunlosky et al., 2013) with estimated times for each task so that students could plan within their busy schedules. I created separate Google Docs for each student that included four reflection questions they would complete weekly as an exit ticket. The document included a table with one question in each column and a new student response in a row for each week of the semester. Students were instructed to reflect on their learning experiences but not to spend more than five minutes on the task. The questions were:

1. What did I learn or what questions do I have? (cognitive)
2. How do I feel about my learning experiences this week and why is what I learned important to me? (affective)
3. What did I do that helped me succeed or what should I do differently? (behavior)
4. What was helpful about the structure of the class or the way I interacted with others? (context)

Data collection and analysis. By explaining the purpose and benefits of completing the optional learning tasks, such as practice quizzes and studying, as well as helping students to map them out into their schedule, I did see an increase in the number of students who completed those tasks. When not all students were completing the exit tickets, I assigned five percent of the final grade to completion and began tagging students immediately who did not complete it. This led to more than 90% compliance over the course of the semester with this short weekly assignment, an increase from prior semesters. Every week, I was able to see what each individual student found important and where they were confused, what strategies they were using for learning, and where I might make improvements to the course. By responding to student reflections with the commenting tool, I was able to tag them with resources and suggestions or ask questions for clarification on issues or suggestions. Students could reply to these comments from their email, which often led to ongoing conversations in the document throughout the semester. Students often provided excellent suggestions in their exit tickets for small changes I could make in class to improve their learning, such as providing assignments for multi-week modules in a calendar format instead of just a checklist. Whenever I try a new technique, I now ask for feedback from students in their exit ticket.

Social presence

Learning challenge. Social presence of any kind online can be defined as "the degree of feeling emotionally connected to another intellectual entity through computer mediated communication" (Sung & Mayer, 2012, pp. 1738–1739). Indicators of social presence can be affective (expressions of emotions or mood), interactive (acknowledgement of another), and cohesive (things that build or sustain group cohesion) (Rourke et al., 1999). Adult learners find teaching presence to be essential for their learning and seek deep interactions with content rather than surface learning, with peer interactions a bonus (Angelaki & Mavroidis, 2013; Ke, 2010). Mayer (2014) suggested that this connection helps to foster deeper processing during learning.

While the exit tickets had helped me to develop relationships with each individual student, I found that students in my synchronous online classes were reluctant to communicate with each other or speak up in front of the whole class. Teacher immediacy behaviors have been shown to have a positive impact on learner emotions and learning gains (Ge et al., 2019; Liu, 2021), while emotions (Plass & Kalyuga, 2019) and social connections are integral to the learning process (National Academies of Sciences, Engineering, and Medicine, 2018). To address the social distance and emotional connection in my classes, I looked for strategies that would help students to develop learning relationships with me and each other.

Design solution. One strategy I implemented was an opportunity for bonding in the first class meeting. I presented to the students my commitments to them: share tips for being a successful student, be patient with explaining the same thing in many ways, care about you and your experience in this class, make class meetings worthwhile, help you meet your learning goals, and appreciate your efforts. I then split the class into breakout rooms to introduce themselves to a smaller group, asking them to make commitments to each other. I followed this up with other teacher immediacy behaviors throughout the semester, such as referring to students by name, using a more informal and relaxed meeting platform (www.kumospace.com), using "we" and "our" language, narrating my thinking as I worked through problems, using cute praise memes in assignment feedback, and having informal conversations with students at the beginning of class.

Data collection and analysis. Students often commented in the weekly exit tickets described above how much they enjoyed playing review games together and working with a partner on an assignment because they were able to help each other and explain concepts in a different way. This was a marked change to the comments I had seen in earlier semesters where students rarely referenced one another. By setting aside approximately an hour per course each week to review exit tickets, I was able to maximize my personal connection with each individual student. The inclusion of other teacher immediacy behavior strategies and the frequent partner and small group work appeared to make the students more at ease as evidenced by comments in the weekly exit tickets, more students turning on their cameras during course meetings, more interactivity in the course chat, and more engagement and small talk during small group work. In future iterations, I will make these strategies explicit to the students and ask them to reflect on the impact to their learning experience.

Interleaving

Learning challenge. One thing that often frustrated me when teaching a computer applications class was that students frequently forgot content from the beginning of the semester by the time we reviewed for the exam. The curriculum consisted of a module on Windows, three modules each of Word, PowerPoint, and Excel, and a short module on databases. After learning about interleaving, and it occurred to me that it might be possible to switch up my coverage of the curriculum to help address this learning challenge. Interleaving is the act of mixing together study of multiple related topics rather than learning individual topics one at a time (Birnbaum et al., 2013).

Design solution. In the next semester, I planned to rotate the applications each week, rather than teaching them in a block. In the introduction to the course, I told the students about this approach and that I hoped it would help them to see the connections between all of the Office applications while mitigating the forgetting that often happens. I planned to examine the quality of assignment submissions, quiz scores, and comments from students in weekly exit tickets.

Data collection and analysis. An analysis of the data revealed a clear improvement in the quality of assignments that were submitted and a slight increase in weekly quiz scores. Students became more focused on the commonalities between the Office applications, such as the structure of the window, the tools on the ribbon, and using features like SmartArt and image editing. When reviewing for the final exam, students had retained more information on features of Word because they had utilized the program every three weeks throughout the semester, rather than in only three weeks at the beginning of the semester.

Conclusion

Using evidence-informed strategies in the classroom can be beneficial to learners, but the use of learning engineering has taught me the value of using evidence-*generating* strategies to understand my students, their learning experiences, and their learning outcomes. In this practice-oriented paper, I described three scenarios of course redesign in my classes where I used the learning engineering approach: I identified a learning challenge, applied the learning sciences to an instructional solution, collected data, and analyzed the data for evidence of effectiveness of the new strategy. In most cases, I made small changes to iterate the design throughout the semester based on the student data. While the emerging field of learning engineering primarily focuses on developing learning solutions on a larger scale, this process and practice can be utilized by any educator to improve learning experiences for their students.

Designing a Modern Apprentice Program for a Digital Era

Mary Kate Morley Ryan, Accenture, marykate.morley.ryan@accenture.com
Tessa Forshaw, Harvard University, tforshaw@fas.harvard.edu
Beca Driscoll, Accenture, rebeca.driscoll@accenture.com

Abstract: Policymakers, education institutions, businesses, and workforce development providers increasingly promote apprenticeship programs to address professional skilling needs. Yet, many of these programs act as recruiting pipeline strategies and fail to consider the learning experiences. While traditional models of apprenticeship offer a foundation for these programs, a revival that considers the many differences between traditional craft programs and modern ones is needed. Through a practitioner-led research and design project with the world's largest professional services firm's apprenticeship program, this study marries lessons learned with learning sciences research to position a Pedagogy of Modern Apprenticeship.

The case for modern apprenticeship program design

Globally, apprenticeships are on the rise, and they are no longer just for trades but are increasingly popular to skill workers for professional and technical roles. Policymakers and workforce development providers see apprenticeships as essential to address economic mobility, and Fortune 500 businesses are increasingly establishing apprenticeship programs. Analysis indicates an opportunity to expand this model to new occupations, including many in which employers require a bachelor's degree (Fuller & Sigelman, 2017., Federal Reserve Bank, 2019). This global trend has a stronghold in Europe and a recent policy revival in the US, where the Biden Administration stated that "Apprenticeships can change lives" (The White House, 2022).

While a renewed focus on apprenticeship is promising, traditional programs focus on developing narrow skills deeply embedded into specific contexts. And some function as a recruitment pipeline more than a learning experience. This may be because they leverage historical models of craft apprenticeships, which have been effective for centuries. Yet, as modern apprenticeship programs scale globally, involve multiple "master apprentices" to learn from, and include an increasingly digitalized work environment, it is time to adjust the design to address the needs of the adaptive and transferable skills required in the Future of Work.

This paper focuses on the in-progress implementation of a large-scale modern apprenticeship program at the world's largest professional services firm, Accenture. It discusses the company's journey of investing in apprenticeships as a talent pipeline and community impact initiative, prioritizing apprentice learning and ongoing career opportunities. It outlines how a joint team from Accenture and Harvard's Next Level Lab engage in a practitioner-led research approach to create a Pedagogy of Modern Apprenticeship.

Practitioner led research and iterative design of an archetypal program

We decided to use Accenture's North America Apprenticeship Program as an archetype of a modern apprenticeship program as a place to study, test and implement. The apprenticeship program was established from Accenture's collaboration with City Colleges of Chicago, Illinois, US, to inform the community college's information technology curriculum. Out of that relationship, Accenture brought on its first cohort of 5 apprentices into its internal technology team. Since launching the apprenticeship program in North America in 2016, Accenture has onboarded over 2,000 apprentices across 40 cities. These apprentices specialize in one of many tracks ranging from cybersecurity, digital transformation, and data science.

Under the company's US Corporate Citizenship program, the initiative focused on the company's goals to help bridge the opportunity gap via hiring from nonprofit organizations and community colleges. In 2017, the program expanded to two additional pilot cities and the following year to each city in which the company launched an innovation hub, tying the company's investment in innovation with job growth in local communities. Localized organic growth continued alongside expanding to new cities, adding role tracks into predominantly client-delivery roles, and ongoing iteration on the program's learning and employee experiences.

Building on the success of the early cohorts and Accenture's broader skills development strategy, the program has been integrated into Accenture's talent strategy. After growing and evolving steadily from the first cohort of five apprentices, in fiscal 2022, Accenture set and exceeded its goal for apprentices to make up 20% of North America entry-level hiring and extended the goal to fiscal 2023. Since the initial cohort, the design of the program continues to mature in several ways, including expanding to over ten learning and career tracks that foster learning by doing, creating more formal supporting roles (experienced others), embedding opportunities for self-assessment, choice, and reflection, while staying committed to apprentices being fully immersed in the organizational culture, processes, and structure.

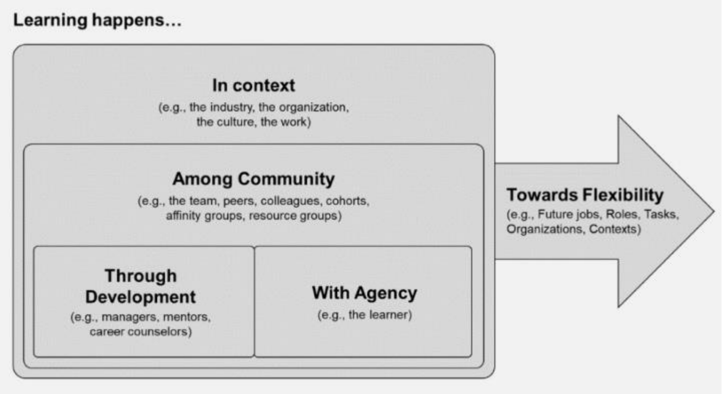
Apprentices are paid with benefits through the full-time, year-long earn-and-learn model. The minimum requirement is a high school degree or equivalent. Apprentices have a demonstrated interest in the role for which they apprentice, with a selection process focused on potential. The program includes, on average, 240 hours of structured technical and professional skills learning and 2000 hours of on-the-job learning.

Since 2016, the program has continuously evolved in response to participant feedback, advances in research about learning in situated environments, and a desire to move towards a program that prioritizes the learning experience of the apprentices over purely the recruitment pipeline potential. Interestingly, a chi-squared analysis of our participant and retention data suggests that starting year in the program and program conversion are strongly associated (X-squared = 2062.8, df = 24, p-value < 2.2e-16). Participants who enrolled in the program in recent years were much more likely to convert to an ongoing position than those who started in the program's earlier years. Once converted, program graduates typically have significantly higher retention than industry averages (LinkedIn Data Insights, 2022).

The pedagogy of modern apprenticeship

Drawing upon six years of lessons learned, participant interviews, case analysis, and an extensive literature review of research in the learning sciences, we describe five key features of how learning happens in Modern Apprenticeships. Each builds upon the research of how people learn (figure 1) and amplifies what is working about traditional craft apprenticeships while positioning additive features. For each feature, we ground in theory why this feature is important, define the feature, highlight some of the design of Accenture's apprenticeship program, including implementation details, and share abstracted learning for wider implementation.

Figure 1
The Pedagogy of Modern Apprenticeship



Learning in context

The context in which people learn is crucial to how they learn (Greeno & Engeström 2014). Apprenticeships are a long-held way to help people learn in the physical context they will apply it (Collins & Greeno, 2010). However, modern work is changing what it means to work in context to include physical and digital spaces, multi-geographic cultures, and international practices. Therefore, how programs are designed for context needs to evolve. Learning in context refers to the circumstances of a digital ecosystem that inform when and how an individual engages with digital tools to learn and do global work, cross-industry and adjusts quickly to changing demand and pressures.

The company's goal for the program is to embed apprentice roles into project teams doing real work; 93% are roles supporting client work. The Accenture apprentice learns in context through a specific learning and career track, working on project teams in which they learn from and contribute work alongside experienced others. Examples of projects that apprentices work on include user acceptance testing, creating training materials, and crafting relationship maps for large global teams. In addition, all digital tools are made accessible, including equipment, digital worker toolkit, virtual meeting cadences, and knowledge pathways (e.g., Google Cloud, AWS App Dev, Splunk, Salesforce) to enable learning and project-based work.

The apprentice program is structured such that an apprentice typically contributes to client projects for 10 of the 12-month program. Apprentices join teams with a specific role and appointed supervisors. Apprentices may be staffed on multiple projects through the program. Roles are built into its talent planning process with the goal of 20% of entry-level hiring. Planning cascades to business group and project team staffing.

Learning among community

Many programs recognize networking and community as important. However, most see it as secondary to learning core skills and often center the community around the apprentice cohort rather than other workers the apprentices are situated within. Yet, a lot of what people learn is through observation of experienced others and participation in a community of practice (Brown & Duguid, 1991). To develop the nomenclature (Toulmin, 1999) and tricks of the trade, learners need opportunities for peripheral participation (Lave & Wenger 1991). Learning among community refers to the relationships between apprentices, their cohort, support system, and the organization.

In the Accenture model, there is equal emphasis on the apprentice community of support and inclusion in the company-wide community. Apprentice-specific structures include apprentice cohorts that start the program together, a Success Toolkit specific to the apprentice experience, a Microsoft Teams site and channel to connect with others in the apprentice community in any location, program-wide monthly apprentice community calls, office hours with HR, and on-going touchpoints with 'Local Apprentice Champions.'

Apprentices are encouraged to engage beyond the apprentice community with programs that include non-apprentice employees. Eighty-six percent of apprentices in the most recent program survey report feeling engaged with their business unit beyond the program, indicating that the overwhelming majority felt included in the wider Accenture community. This is in response to intentional efforts; for example, apprentices are offered opportunities to lead parts of local office meetings, join Employee Resource Groups, engage in town hall sessions with their location, industry, practice, etc., and participate in company volunteering programs. Digital tools further drive connection by removing physical barriers and giving access to local, national, and global experiences. The multiple layers of community enable scale alongside localized context and personalization.

Learning through development

The master and apprentice structure is a hallmark of traditional apprenticeships. Experienced Others are essential to supporting learning from novice to expert for specific skills (Vygotsky, 1978; Bronfenbrenner, 1979; Collins, 2005). However, the master and apprentice relationship has changed dramatically from traditional apprenticeship programs. For one, today, a learner often has many "experienced others" from whom they are learning. Furthermore, since they often did not graduate through traditional apprentice-craftsman-master models, many "experienced others" are less practiced in the skills needed to perform the role.

Learning through development refers to the actions taken by multiple experienced others to intentionally develop the apprentice throughout their experience, and the program emphasis on preparing the experienced others to do so. In craft apprenticeships, the experienced other is considered capable of guiding the learner based on deep knowledge of a topic and process, having learned through apprenticeship themselves. In the digital context, being an expert alone does not qualify the experienced other to support apprentice growth. A modern apprenticeship includes the intentional development of experienced others to support the apprentice.

In Accenture's model, five experienced others interact in formalized roles with the apprentice. The model includes a peer mentor, project supervisor, people lead, apprentice champion, and human resources partner. Each experienced other are provided training on the mechanisms and goals of the program, expectations of their role in the apprentice experience, coaching skills, and a structure for working with each apprentice.

Learning towards flexibility

Teaching skills deeply embedded in a specific job context can make it harder to transfer them to other performance environments. This works well when apprenticeships focus on craft expertise that was narrow and situated. However, apprentices in modern programs need to be empowered to transfer learning across contexts and roles (Lobato, 2012). They need framing to presuppose knowledge can be transferred to different contexts and novel problems (Engle, Lam, Meyer, & Nix 2012.). Learning towards flexibility refers to the awareness of the diverse use of skills and knowledge across contexts or to novel problems.

Accenture realized that to be successful, apprentices need to take past experience and learnings from formal and informal training and apply it across different roles, varying projects, and divergent client contexts. Apprentices work with experienced others to complete their internal resumes, including identifying transferrable skills from past work, such as customer experience, data analysis, and risk management skills from work in a restaurant. On each new project, apprentices bring forward existing skills, often into a new context, such as industry, and layer on new skills specific to work at hand.

Throughout the program, apprentices are given time to reflect explicitly on this question and seek input from their experienced others. During these reflections, apprentices often hear from experienced others how their learning can apply to other areas of interest, priority areas for the business, and in the external market; this reinforces the importance of flexibility for their continued success.

Learning with agency

A shift from traditional to modern apprenticeship programs is that they must prioritize enabling agentic behavior from learners (Nolen, Horn & Ward, 2015). In times past, obedience has been valued above agentic behaviors. However, modern apprenticeship programs prepare workers for professional roles in a digital era. To thrive in this context, construct new knowledge, develop expertise, and know when to apply it, learners need to be agentive by combining these three factors – the learning environment, the experienced others, and the apprentice (Grotzer, Gonzalez, & Forshaw. 2021 & Duckworth, et al. 2009). Learning with agency refers to the combined role of the learning environment, experienced others, and apprentice to prioritize agentic behavior from motivated and self-efficacious learners (Nolen, Horn & Ward, 2015., Bandura, 1994).

Accenture actively seeks individuals with that proclivity in the hiring process and emphasizes this skill by offering self-advocacy training modules. Once in the program, apprentices can influence how they get involved, within and beyond their project assignment, and have the flexibility to seek learning opportunities that align with their goals. In addition, experienced others give feedback, and prompt reflection.

Agency in apprentices' on-the-job learning is also critical. In the most recent program participant survey, 74% reported feeling empowered to own the work assigned in month three and 87% in month 10, indicating a high and increasing sense of control as the program progresses. Safety and risk tolerance is supported by establishing clear guidelines for escalating issues with the apprentice and experienced others, normalizing asking for help, and regular feedback.

Next steps

As we continue working together in our practitioner-led context, our work is evolving more towards a Design-Based Implementation Research approach where we will leverage our joint focus on this work to inform the iterative design of the Pedagogy of Modern Apprenticeship and how each feature manifests in the development and deployment of the Accenture North America Apprenticeship Program.

Abstract: Through a collaboration between a Minnesota-based CS education non-profit, learning scientists, and elementary and middle-school CS educators, we are collaborating to envision new ways to support students with the frequent impasses they experience when writing code. In this paper, we describe how we worked toward recognizing problems of practice, built on prior interaction analyses of classroom discourse, assembled a team of CS educators, developed (and critiqued) our shared language around debugging, articulated our rationale for particular learning designs, and calibrated our approach. We hope this paper serves as one concrete and generative example of how to use classroom-based interaction analyses as points of departure for empowering teacher-driven pedagogical imaginings.

Introduction

This paper provides a snapshot of an emerging research-practice partnership (RPP) between Code Savvy, a non-profit computer-science (CS) education organization (represented by Andrea Wilson Vasquez), Minnesota CS educators, and learning scientists studying debugging (David DeLiema, Jeff Bye, Megan Goeke). Our ongoing RPP centers CS educators in the discovery and specification of problems of practice and pedagogical approaches that draw inspiration from a previously underemphasized dynamic in debugging education: students and teachers select, modify, and discuss debugging pathways among many valid possibilities, including when noticing problems, positioning causes, and pursuing fixes (DeLiema et al., 2021).

Practitioner context: Code savvy and experience with debugging pedagogy

Our RPP is rooted in the work of Code Savvy, who has recognized that CS education is severely under-supported in Minnesota. Across the U.S., there is increasing demand for and interest in CS skills; but in Minnesota, where most of the people born in-state stay for their adult lives, there is a particular need to increase support for local development of a CS-informed community. Currently, Minnesota has no state standards regarding CS, and only 21% of Minnesota high schools offer any CS courses, placing Minnesota last of all 50 states in CS offerings (Code.org et al., 2022). Where CS is offered, these teachers tend to be the only CS educators in their school, district, or in some cases, geographic region. Unlike more common subjects, CS teachers in Minnesota cannot turn to their immediate teacher network for CS education support. Code Savvy was established in 2013 to address the specific, intersecting concerns in Minnesota CS education: lack of curricular guidance, isolation of CS teachers, and lack of access to CS educational opportunities, which collectively increase risk of inequitable CS experiences for Minnesota's young people. Driven by the goal of expanding equitable and engaging CS education, Code Savvy supports a network of CS educators across Minnesota ranging from full-time high school CS teachers to elementary teachers integrating CS into existing curriculum through a variety of professional development (PD) opportunities. The PD community serves as a support system for Minnesota's CS educators, acting as a place to articulate why to teach CS, how to teach CS, and how to navigate administrative structures. Currently 625 teachers strong, Code Savvy - with sustained leadership from Andrea between 2015 and 2023 - is uniquely positioned to both understand the needs and priorities of Minnesota's CS educators and to support dissemination of critical CS education findings.

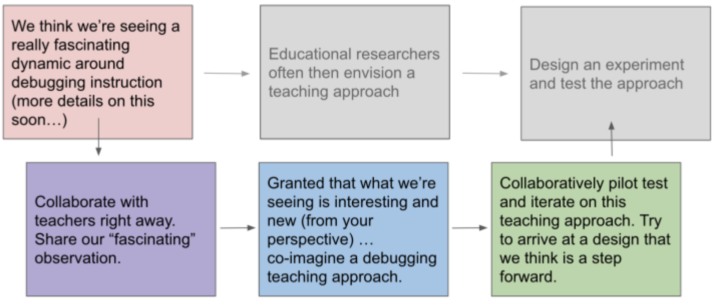
Andrea's personal experience across 10 years invested in CS education is that debugging receives the least attention in PD sessions with CS educators. Debugging, which roughly speaking is the process of noticing problems, searching for causes, and implementing fixes, is an essential and common part of programming teaching and learning (McCauley et al., 2010), and a practice that is often backgrounded in formal CS education spaces (Perscheid et al., 2017). When she started teaching at a high school makerspace, Andrea had to develop techniques for teaching students how to learn from debugging, and recognized that supporting students to develop strong debugging skills was an essential part of the classroom's culture of belonging – as all students will experience moments of impasse during coding. Knowing that in Minnesota we have limited chances to engage students with CS, it is our ethical responsibility to ensure that when students are in our CS classrooms, they are fully supported and included. Generating practical support for teaching debugging is directly related to expanding equitable and engaging CS education.

RPP origin story

Debugging was equally a topic of interest among our RPP's learning scientists. Attending to the existing debugging research literature (e.g., Fields et al., 2021) and using interaction analyses (e.g., Jordan & Henderson, 1995) of teacher-student discourse during debugging in naturalistics classroom settings, our earlier work had led to a framework that emphasized the open-ended process of teachers and students altering, foregrounding, and explicitly discussing different debugging pathways (DeLiema et al., 2021). That is, in many debugging situations, teachers and students have a wide range of pathways they can take through noticing problems, implicating causes, and pursuing fixes. For ease of reference, we refer to this as the debugging pathways framework. Andrea invited the learning sciences team to share the debugging pathways framework with the Code Savvy CS educator cohort she was leading, and we repeated this process annually over three years. Each time, we were struck by the CS educators' expansive reflections on debugging in ways that far-extended the framework and how it could inform pedagogy. Inspired by educational research that decenters research priorities and foregrounds participants' goals (e.g., Bang & Vossoughi, 2016), we pursued grant funding (see Acknowledgments section) and started to work together on a plan to turn these short sessions with Code Savvy cohorts into a sustained collaboration. We pursued this collaboration for several reasons: (a) debugging has persisted as a problem of practice both for teachers and educational researchers across several decades; (b) the pedagogical horizon opened up by the debugging pathways framework was vast and our team felt it was essential to center teachers' perspectives on where to take pedagogical designs; (c) our partner teachers were interested in investing time reflecting on debugging pedagogy; and (d) in our earlier Code Savvy sessions, teachers had both expressed interest in thinking with the debugging pathways framework and developed ideas about pedagogy that they signaled would be new to their classrooms and worth pursuing.

Moving into our RPP work, we held researchers' humility to educator expertise as a core value. Figure 1 is a screenshot of a flow chart we used to communicate this value and process to the CS educators in our RPP. We anchored this value in four additional design choices. First, in part to stave off too-early ideological convergence (e.g., Philip et al., 2017), we framed the debugging pathways framework as a draft fully open to revision. Second, we emphasized opportunities for educators to look at video data of programming classrooms and offer their own insights. While a rich tradition of video-viewing exists for teacher professional development (e.g., Sherin & van Es, 2005), we diverged from those efforts in that we did not have an intended learning goal or valued way of noticing classroom experiences in these data sessions. Third, we made concerted efforts to center teacher voice. All workshops prioritized time for our RPP leadership team to listen to the discussion and reflections of our CS educator collaborators. Fourth, we held back from quickly centering a specific problem of practice. That is, we viewed the debugging pathways framework as a provocation to both find new problems of practice and spark novel pedagogical approaches.

Figure 1
Framing in color our collaborative work in the RPP, contrasted with "top-down" research paths in gray.



We think we're seeing a really fascinating dynamic around debugging instruction (more details on this soon…)

Educational researchers often then envision a teaching approach

Design an experiment and test the approach

Collaborate with teachers right away. Share our "fascinating" observation.

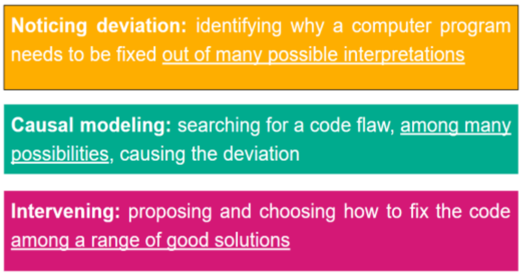
Granted that what we're seeing is interesting and new (from your perspective) … co-imagine a debugging teaching approach.

Collaboratively pilot test and iterate on this teaching approach. Try to arrive at a design that we think is a step forward.

Workshop design

Our approach to workshop design reflects the tradition of participatory design-based research (Bang & Vossoughi, 2016), in which researchers develop pedagogical approaches in close collaboration with teachers, paying attention to problems of practice centered by educators, power dynamics within the team, and design solutions proposed by the educators, through iterative stages of implementation, data collection, and analysis. The workshops were designed as a year-long series with 5-7 CS teachers working with different aged students. Most of the teachers who ended up joining had found out about the RPP because they had checked a box on a short survey expressing their interest in hearing about research opportunities following our earlier Code Savvy PD workshops. The remaining teachers knew Andrea through her CS education network. All teachers received stipends for their time in the workshops. In the first session, David and Jeff planned to introduce Figure 1 (above), make space to talk about the overarching goals of the RPP, and share the debugging pathways framework (see Figure 2 for a simplified version), which they had developed with Vijay Marupudi. This was meant to provide a perspective, language, and empirical focus on debugging that we hoped would unsettle the typical backgrounding of debugging in professional learning communities and provide a provocation for discussion about debugging pedagogy. In this way, the prior interaction analyses and framework (DeLiema et al., 2021) served as a point of departure for inquiry, not a pedagogical prescription. In sessions 2-4, we planned for our teacher collaborators to look at video data of students debugging, interpret the video, and discuss ideas for approaching scaffolding of student debugging. During these later sessions, we planned to have our RPP leadership team collaborate with the teachers to develop and iteratively revise conjecture maps: visual devices that provide an argument around a theory of design, short-term processes observable in the classroom, and valued long-term outcomes (Sandoval, 2014). This approach drew on prior work involving collaborative conjecture mapping in CS education (e.g., Lee et al., 2022). We planned to invite the teachers to pilot approaches in their own classrooms, documenting the results and their own reflections in iterations to the conjecture maps. After piloting, the entire RPP would have two additional sessions to consolidate the classroom pilots into a single unified conjecture map.

Figure 2
Debugging Pathways Framework



Noticing deviation: identifying why a computer program needs to be fixed out of many possible interpretations

Causal modeling: searching for a code flaw, among many possibilities, causing the deviation

Intervening: proposing and choosing how to fix the code among a range of good solutions

Implementation

Alongside 4 middle school CS educators and 1 first-grade CS educator, we have completed the first 4 workshop sessions and will soon begin classroom pilot work. In this reflection, we focus on two shifts in our process that took place during implementation and that are critical to the work of our RPP. First, we had intended to share the debugging pathways framework as a draft and then shift to envisioning pedagogical approaches. However, as the CS educators in our RPP reflected on the framework and applied this lens in video data sessions, the conversation kept returning to the framework as educators argued about its meaning and potential. In these arguments, CS educators critiqued both the focal terms in the framework (e.g., "my students would look at me sideways" if we used the word "deviation" in the classroom) and assumptions about the linear flow between these steps, even while embracing the notion that debugging in the framework was considerably more open-ended than traditional debugging models conveyed. To welcome this critique, David noted at the beginning of each workshop that we had put the "fascinating" interaction analysis observations from research in scare quotes in order to understand what the educators in our RPP made of these open-ended debugging dynamics. This shift pointed to fundamental questions about how to position interaction analysis in RPPs to stoke conversation while ensuring they are still treated as flexible representations in need of fine-tuning.

Second, we changed the structure of the fourth workshop from a group conversation to individual conversations with each CS educator. We had noticed that the framework sparked a wide range of learning design proposals, but the collaborative workshops did not provide enough space for each educator to unpack these imaginings; instead, discussions during group conversations leaned into contrasts between specific learning design proposals and contexts (e.g., noticing that an exercise wouldn't work in a particular classroom). In short, the substantial heterogeneity in learning design proposals left little space for deeper commonalities to be noticed and named in the moment. Shifting both our process and our goal, we moved toward individual conversations with CS educators to allow for each educator to articulate their thoughts in greater depth, without needing to connect to others' ideas in the moment. We introduced the conjecture map representation in each of these individual sessions and gave time to each educator to start assembling a process-based argument for why a particular debugging pedagogy might work and toward what ends.

Current results

We held a collaborative data session among the RPP leadership team following these individual meetings, with each leader 'representing' the conjecture map from one educator. We examined commonalities across disparate maps to glean a common pedagogical vision. Instead of arriving at a shared pedagogical approach (e.g., specific tools, curricula, pedagogical moves), we recognized shared lenses guiding specific designs. Megan further refined these notes into 4 lenses that stretched across all educators' unique pedagogical visions around debugging. (1) *Nonlinearity* captured how debugging involves engagement with – but not necessarily sequential progression between – the 3 framework steps. (2) *Future orientation* focused on making space to connect a current debugging solution to potential future codes and bugs. (3) *Community of support* addressed classroom teachers and students as a debugging support team. (4) *Multiplicity* focused on celebrating multiple, heterogeneous approaches to debugging. Our next step is to discuss these themes as a full RPP team, allow each educator space to assess whether their approach is captured by all 4 lenses (and what may be missing), and then consider what purchase they provide for refining each educator's unique pedagogy before classroom pilots.

Conclusion

Our RPP has embraced a process of flexibility and balance. Our approach has taken seriously a problem of practice noticed by a CS education non-profit and responded to a re-framing of debugging from learning sciences scholarship. At the same time, we made space to critique that prior research (including our own) and allow for considerably more individual expression of debugging pedagogies, even while we have worked to glean common lenses across these unique conjectures. As we work together to envision expansive forms of supporting debugging, we are committed to continuing to level the power between our non-profit leaders, learning scientists, and CS educators, working toward a common, ambitious vision for supporting students that makes possible individual forms of pedagogical expression and fully embraces the expertise of educators.

Amalgamation of Narrative Discourse and Maker-Spaces as a Tool for Critical Pedagogy

Ridhi Aggarwal, Rahul Aggarwal
ridhi@swatantratalim.org, rahul@swatantratalim.org
Swatantra Talim Foundation, India

Abstract: We run a contextual and cultural maker-spaces in two villages of Uttar Pradesh. The vision of the maker spaces is to have a discourse around critical pedagogy as envisioned by Paulo Freire : social justice, student empowerment, co-construction of knowledge, and critical thinking. In the village, the 12-16 yr old learners study in affordable private schools after completing their elementary education from government school which wasn’t the case earlier. Families are engaged in agriculture, young boys migrate at the age of 10-12 years to West India. Girls are generally married at the age of 13-14 years. This vicious cycle of marriage, birth and livelihood doesn’t allow the mindset to change. In this paper, we will explore how in the above context narrative discourse when integrated with the maker-spaces acted as a tool for critical pedagogy.

Design and implementation

Looking at the context of Ramdwari, the possibilities of change seemed very few and extremely far. There is monotony around with the same routine year after year which led us to question — What’s to be done? We thought of narrative discourse pedagogy as students seemed to be excited by stories. Therefore, we thought of bringing powerful ideas which are similar in nature. With these stories, we felt that the students and community members would see some hope through the change that has happened in similar communities in different geographies. But, to get inspired is not the only thing. One has to think a little deeper into it. One has to identify the problem in their context, have the courage to challenge the status quo, discuss alternatives and find a solution.

To perform prototyping of ideas, we set up contextual and cultural maker spaces in which contextual objects could be repurposed, re-imagined, altered, added or modified so as to bring some ideas in action for social transformation and a positive cultural change.

In this particular project we started with the narrative discourse based on the story ‘cycle par sawaar auratein ’(translation — women riding bicycles). The story is about cycling as a women’s movement in rural Tamil Nadu, an article published in People Archives of Rural India. The whole phenomenon was the brainchild of the popular former district collector, Sheela Rani Chunkath. Her idea in 1991 was to train female activists so that literacy would reach women in the interior. She also included mobility as a part of the literacy drive. This flowed from the fact that a lack of mobility among women played a big role in undermining their confidence.

The story was chosen because girls ’freedom in the Ramdwari community was frowned upon. The girls ’ were not allowed to go and study outside their village after completing grade 8 from a government school. From the story, discussions erupted around gender inequalities as boys were allowed to go outside the village. From the discussion it moved to various problems or issues faced by the children everyday that are there in the community which gave us generative themes to work in the maker-space. Another point which got discussed was around the role of a bicycle as an emancipatory tool.

This led to a question that -- can bicycles act as a tool for social change other than providing access for mobility? To explore this question and deep-dive into generative themes we as facilitators designed sessions under three domains -- looking closely, exploring contextual objects, finding solutions.Even the simplest objects reflect the culture and more importantly the context (social and physical) in which they were created as well as the contexts in which they continue to be used. A close observation of these everyday objects not only sparks students ’curiosity but leads to increasingly complex thinking.

In the first session, the students were asked to observe a bicycle and draw its systems and subsystems. In this exercise, the students analyzed the various parts, its purpose and the correlation between them. The students drew detailed sketches of the bicycle and started co-relating various sub-parts based on speed, safety, comfort, etc. They also figured English alphabets while observing the shapes of parts or sub-parts. The students observed the minutest details, one of them being the study of why the front sprocket is bigger and the sprocket in the rear wheel is small?

When the students were observing the parts and subparts, one question emerged whether any of the subsystems can be used as a system in itself or a part of a different system. Further exploration emerged and we moved to doing take-apart the bicycles. Students have to dismantle an old cycle in 1.5 hours and then assemble it back in the next 1.5 hours in teams of 4. Proper tools like hammer, screwdriver, wrench, and spanner were arranged. This activity has been done after previous sessions on cycle where we had a lot of discussions and observations around the cycle. But then learning can be enhanced when we use our hands rather than ears. Multiple science concepts are covered in a cycle like force, transmission of force, work energy, speed, momentum, circular motion, friction, energy, center of mass, moment of inertia, torque, stability, spring, mass distribution, etc. As a single cycle can be used to explain so much of science, why not open it and understand the details of it.

Initially we thought that since the cycles are old and have lots of rust on nuts and bolts, the dismantling part would be tougher and once it is done, the students will assemble it back in half of the time. But we were wrong. They learnt more about mechanisms and observed little details during the assembling part of the task.

This is because while dismantling they were in a hurry or chip off the parts which were not coming easily and hence those distorted parts caused a lot of troubles. Some parts require special tools and such jobs can be only done by them. Hence normal tools took a lot of time.

The other factor is that the assembling process demands more focus from the students. For example - both the wheels of the cycle are very different from each other. But the general image is that a wheel is a wheel. 2 out of 4 groups put the front wheel to the rear side and when they had to put the chain on it, they realised their mistake and dismantled it once again. Then the students explored the mechanism of chain sprocket, brake by paper and locally available materials. This exploration led to a discussion around tools and objects in the community which use similar mechanisms or in certain cases the parts of the bicycle.

To converge both the things — generative themes and the explorations done on the bicycle as a contextual tool, the students were divided into different groups according to their interest, issue that they wanted to work on.

In each group, the students researched on their problem at hand and ideated solutions around them using the various mechanisms of the bicycle. Thereafter they did prototyping on one idea selected by them. Some of the ideas are:

- Group One thought that cutting grass/weeds on the agricultural field is always a problem. Therefore the group thought that if she attached a sharp blade from the front hub of the bicycle then she and others could easily cut the small and medium size grass/weeds by manoeuvring the handlebars of the bicycle. This will take less time and less effort and would cut the grass from the roots easily.
- Group Two has made a model to cut the grass/fodder with an attached bicycle. The same structure is available which runs on electricity but since there is an erratic supply of electricity in the village, the student thought of making a design which can work with bicycles. The grass/fodder which after cutting can be given to livestock as food for their nutrition.
- Group three attached a wiper through the front part of the wheel. During rains when the drains overflow, it becomes very difficult to ride the bicycle on swampy roads. Through this innovation when you are riding the bicycle, the sludge and the mud on the road could be moved to the sides of the road allowing movement on the bicycle. This could also prevent accidents due to balancing issues.
- Group four made a bicycle-enabled handpump in which instead of a handle the pump rod is attached with the crank of the bicycle. When one pedals, the crank moves which in-turn helps in moving the piston rod. When the piston rod moves up and down it helps in taking water out from the outlet thereby reducing the time and effort.
- Group five thought of attaching an umbrella on the top of a bicycle and a plastic sheet at the back so that the girls of Ramdwari could attend school during rainy days. The umbrella covered their body and the plastic sheet covered their bags.

Figure 1

The students taking-apart the parts of the bicycle (Right); The students have made a bicycle-enabled fodder cutting machine (Left)

After multiple rounds of talks and testing in the community, two of the projects were finally made and put to use for the community. The two projects were bicycle-enabled fodder cutting machine and an umbrella on a bicycle.

Cycle as an object offered a tactile experience for students, which challenged them to observe and conceptualise their thinking. While the teacher facilitates the session, the students construct meaning for themselves through their interactions with each other centred around the object (Hannan et al. 2013).

The problems students came across after the narrative discourse pedagogy did not only restrict to problems of their individual lives but also the problems faced in their communities for an extremely long period of time. This exercise enabled them to challenge the status quo, put some ideas together and test them for its workability in the maker-space. Therefore, maker-spaces and narrative pedagogy act as an outstanding tool for critical pedagogy.

Reflections

What we have experienced in these years working with the community and children is that narrative discourse pedagogy is deep rooted in critical pedagogy which critiques the dominant knowledge within curriculum. It critically examines inequalities in society and focuses on tools to develop critical consciousness, agency and empowerment through a problem posing approach in a learning context.

Bruner had mentioned that narratives are fundamental to human learning and act as a meaning-making tool with great pedagogical potential. The narrative discourse supports the identification of a contextual object through which students started to deep-dive as well as nurture the abilities around questioning and challenging the status quo among the community. The explorations in the maker-space supported the meaning-making process. As the narrative pedagogy built the reasoning skills among the students, the maker-spaces hold the power of perspective taking while devising solutions for the problems. This amalgamated approach led to high-level thinking that is central to making which is geared towards social transformation.

The narrative discourse as the starting point also changes the trajectory from the focus on finished product to the process of making. The process of design follows a linear structure, starting with ideas and ending in a re-presented material form; this is why the students in two groups initially struggled to align their approaches with creative collaboration. This changed through a playful, exploratory approach to the materials, take apart and mechanism exploration. Thus this amalgamation also emphasises the social, multi-sensory and affective aspects of exploring materials.

The process in the maker-space led to interactions among students which generated a lot of stories emphasising the rhetorical power of storytelling. In this case, ‘cycle par sawaar aurtein ’story illustrated how narrative could be used to make sense of questioning the status quo and connecting solutions for real world problems. Purposefully eliciting narratives from students that are related to problems closer to their worlds would likely resonate more powerfully, fostering a sense of ownership and identities among children as problem solvers.

In this sense, although situated at a micro level of interaction, this study also look sup-stream to connect to maker-spaces and stories based on notions of empowerment and participation in cultural change.

Abstract: The Community Outreach, Retention, and Engagement (CORE) program is a community-based, informal STEM program designed for multicultural students and families in the Twin Cities area. We aim to build a more inclusive STEM field systemically, and our goal is for students to engage in STEM long-term through pursuing their own STEM pathway. We designed a culturally-relevant and holistic program, and we implement our programming with the FACE of CORE – *F*amily engagement, *A*cademic support and social-emotional learning, *C*ollege and career readiness, and *E*xposure to the STEM ecosystem through hands-on experiences. In less than two years, we have used systems of reflection and feedback to increase our participation and improve the quality of our programming, both of which positively impact CORE students and families.

Introduction

The Community Outreach, Retention, and Engagement (CORE) program is a community-based, informal STEM program housed within the Office for Equity and Diversity at the University of Minnesota. The CORE program provides free high-quality STEM programming for multicultural students and families in the Twin Cities area. Students join CORE in middle school and continue until the end of high school with the cohort model. Our goal for this paper is to tell the story of how we *became CORE* within our first two years by building on the structure and goals of previous versions of our program, adapting the model to meet our current needs, and embodying the newest version of the program to successfully serve our students and families. The process of *becoming CORE* began in spring 2021, when Audrey Breland was hired as the Program Director and immediately started bringing the program model to life. She built relationships with local schools, recruited students from partner schools, and connected with university faculty to provide STEM programming, all of which propelled us into a successful first year of programming in 2021-2022.

Our second year (2022-2023) of programming was facilitated by seven members of Team CORE. CORE is led by our program director and supported by the leadership team (Seth Thompson and Keisha Varma). CORE is enacted on-the-ground by four graduate assistants (Marisa Peczuh, Delina Brown-Jackson, Nawal Maxamed, and Otiti Mayo), each of whom take responsibility for one primary area of programming – STEM engagements, event logistics and CORE Crew, family communication, and media and marketing, respectively. Our program serves 126 students in grades 6-9 of diverse races and ethnicities – 95 Black, African, or African American; 11 Asian or Asian American; 7 Hispanic or Latino/a; 1 American Indian or Alaskan Native; 9 white; and 3 families who elected not to respond. In our two years as a team, we have continued to build from our program's foundation, reflected on our first and second years, and improved in our programming. We have aligned our objectives, design, and implementation, and we aim to share our model and best practices with others working in informal STEM settings.

Objectives

The overarching objective of CORE is to shift the culture of STEM at a systems-level to be more equitable and inclusive for multicultural students and families. Although our program welcomes all students, our program is designed for multicultural students. We consider students who identify as African American, Hispanic/Latino, Asian American and Pacific Islander, Native American, Hmong, Somali, and/or multiracial as multicultural. We focus on multicultural students because they are woefully underrepresented in STEM fields (National Center for Science and Engineering Statistics, 2021), not for lack of interest in pursuing STEM, but because of the historical practices that have systematically excluded these students (McGee, 2020). Our objective is to reimagine how STEM fields themselves, which have been white-normed over centuries of development (McGee, 2020), can serve the needs of an increasingly diverse population (Honey et al., 2020). Our first system of focus is at the university level. We collaborate with many STEM faculty and departments within our programming, and we work with these groups to reimagine how STEM at the university can further engage in the community and be culturally relevant. Ultimately, we aim to create a more equitable university STEM ecosystem through these partnerships.

At the program level, we have two further objectives. As an informal STEM program, our goal is to promote students' retention and engagement in STEM to contribute to a more diverse STEM field in the future. Specifically, we aim for students to graduate from high school, matriculate, and be retained in college in a STEM or STEM-adjacent field, and develop STEM career aspirations (Chen, 2013; Chittum et al., 2017). Within this objective, there are many possible pathways, such as choosing a STEM field, type of college (two- or four-year), and career. We empower students and families with information, opportunities, support, and agency to meet their individual goals within the general discipline of STEM.

Design

The CORE program is designed to move beyond a single focus on STEM by creating STEM experiences that are community-based, culturally relevant, and holistic. We collaborate with school principals, STEM educators, and family liaisons to learn about our partners' and families' needs, and we adapt our program accordingly. We are culturally relevant by valuing and integrating aspects of students' cultures into our programming (National Academies of Sciences, Engineering, and Medicine, 2015; Simpkins et al., 2017). We take a holistic approach by acknowledging that students' participation in STEM goes beyond interest in STEM to include other aspects of students' lives socially and emotionally (National Academies of Sciences, Engineering, and Medicine, 2015). Then, we work with STEM partners (e.g., faculty, departments, institutes) across the university to provide scaffolded STEM programming over seven years through our COREXperience model, which was developed by our program director to reflect the longitudinal experiences of CORE students. We recruit students in grades 6-8 to begin as COREXplorers, where students are exposed to a wide range of STEM majors and fields to foster interest. As students continue to participate in CORE, they become CORE Scholars in grades 9-12, where they narrow their interests and receive more intentional opportunities for college preparation and career readiness. Throughout this time, all students participate in hands-on STEM engagements, career pathways exploration, mentorship, and social-emotional learning. The design of our program promotes continuous exposure to new STEM experiences while also allowing students to develop individual passions.

Implementation

The FACE of CORE

While CORE generally aims to implement community-based STEM programming, our program director created the FACE of CORE to represent the pillars of our programming and focus our implementation – *F*amily engagement, *A*cademic support and social-emotional learning, *C*ollege and career readiness, and *E*xposure to the STEM ecosystem through hands-on experiences. First, we intentionally include families in our programming as key contributors in students' lives and participation in STEM (Sha et al., 2016). Our definition of family is broad, and we encourage students to bring important adult figures to events if their parents are unable to attend. For example, many of our students are accompanied by their school's family liaison. During events, students participate in activities alongside their family members, allowing them to learn and grow together. Our family engagement is culturally-relevant. We communicate in multiple modalities (i.e., text and email) and languages (i.e., Somali and English) when necessary. We also send a monthly newsletter to share additional information about CORE, review past and upcoming events, and provide conversation starters.

Second, CORE focuses on academic support and social-emotional learning in two main ways. We recruit undergraduate and graduate students to our CORE Crew, who serve as mentors to our CORE students (Afghani et al., 2013), in both paid and volunteer capacities. These students provide hands-on support at events, assist with STEM activities, and talk with students and families about their experiences. We also foster social-emotional learning through intentional programming to build students' self-efficacy, resilience and perseverance, goal setting, and positive identity within STEM (Jagers et al., 2019). Students have learned about stories of challenge and success (Lin-Siegler et al., 2016) as experienced by scientists of color, and students participated in an activity where they made a collage about their lives in ten years – a time when they will likely be obtaining their first higher education degree and considering career pathways.

Third, we offer college preparation and career readiness information for students and families. CORE Crew members share about their college and STEM experiences through Lunch and Learn Panels or Mentor Mingling at our events. These are powerful opportunities for students to learn about real student stories as well as gain access to informal mentoring. Undergraduate students are also likely to benefit from these experiences, such as developing life skills (Afghani et al., 2013). We also ask our STEM partners (to be discussed in the next paragraph) to illustrate their STEM stories by sharing about their personal and professional pathways from high school to their current role. This provides students with additional vocabulary and knowledge about the steps necessary to reach their STEM-related goals.

Finally, we provide students exposure to STEM at the university through engaging and hands-on learning experiences (National Academies of Sciences, Engineering, and Medicine, 2015). We have created a coordinated STEM ecosystem, composed of CORE collaborations and partnerships with existing STEM programs, to deliver an unparalleled scope of STEM programming for CORE students. We developed a K-12 STEM Opportunity Repository to document all STEM departments, institutes, outreach efforts, student groups, and more at the university to further connect this ecosystem. We have embraced that CORE is an asset to other STEM programs at the university, and we make new partnerships by reaching out to groups from the repository, describing our "asks," and offering partners "takeaways" that will contribute to their goals. Through meetings with these partners, we build strong, grassroots collaborations and plan for ways that the STEM partners can facilitate STEM engagements at our events. When working with STEM partners for a specific event, we provide feedback pre- and post-event based on our experiences, which provides them with the confidence to facilitate high-quality programming for our students and families. Therefore, CORE acts as a liaison to ensure that multicultural students and families know about the university's STEM programs and are supported in identifying, enrolling, and fully participating in them, whether at CORE events or beyond. This model avoids creating another set of exploration experiences for students in a saturated STEM ecosystem at the university. Instead, we focus on coordinating and enhancing the programming that already exists by crossing boundaries and building bridges. By partnering with these existing programs, CORE can focus on investing additional resources into academic support, social-emotional learning, and college and career readiness.

CORE programming

CORE's Family Engagement Programming implements the FACE of CORE through monthly events, including Fall and Spring Kickoffs, Saturday Scholars, Individual Growth Plan (IGP) conferences, and field trips. First, our Kickoff Events are like STEM fairs, where students and families visit booths and participate in various STEM activities. Second, Saturday Scholars are our signature events for four hours on two Saturday mornings each semester. Students participate in STEM activities, social-emotional learning lessons, and Lunch and Learn sessions, providing a holistic experience throughout the day. IGP conferences are individual meetings between students and the program staff to check-in, discuss personal strengths and weaknesses, and create intentional college and career plans. We also facilitate at least one field trip a year, where students are able to experience STEM outside of a classroom setting. Our typical programming occurs on campus, and during field trips, students are able to experience STEM in new settings off campus. In an effort to make the program accessible and culturally relevant, not only are these events free, we also provide meals, parking vouchers, and transportation. We have also implemented the CORE Roadshow as an effort for CORE to reach a greater number of students in the Twin Cities and to continue bridging schools and the university. During the CORE Roadshow, CORE plans STEM engagement opportunities with partner schools, and CORE STEM partners visit the schools in ways that meet each school's individual needs.

Lessons learned

In less than two years of programming, CORE has enhanced our programming in a number of ways. We have learned from the success of our program and also remain flexible for continuous opportunities for improvement. We use internal and external feedback to adjust our programming to further *become CORE* and meet the needs of our students and families. First, as a team, we debrief every event using a DNA Analysis, where we describe our *D*istinguishing practices, *N*eeds, and *A*ction steps. This routine allows us to share successes and challenges during our events, and we are able to make practice-based decisions at a fast pace to implement enhanced practices at subsequent events. Second, we use feedback from our students and families via sCORE Cards. Our sCORE Cards include questions about what students learned and enjoyed about the event, and families can rank their experiences from 1-5 on the FACE of CORE. With these responses, we are able to better understand the experiences of our students and families and adapt to programming according to their feedback.

Using these systems for improvement, we have found that our greatest success and challenge is the growth of the program, particularly in the number of students and families. First, we have realized the difficulties of coordinating events for a large group of people, but we have been able to think of creative logistical solutions (i.e., having rotating stations) and implement specific practices with STEM partners (i.e., meeting more frequently) to position STEM engagements for success. Second, providing individualized support for students requires significant time and effort. Therefore, we have shifted our focus to creating differentiated and personalized experiences, particularly for students in grades 10-12, beyond STEM via "More CORE." Students in each of these cohorts will be paired with Team CORE and CORE Crew members that will remain consistent throughout the year, allowing for a more relationship-based approach. Additionally, we will design a curriculum focused on *A*cademic support, social-emotional learning, *C*ollege preparation, and career readiness to prepare students in achieving their individual goals.

Relevance for others

We have highlighted many aspects of CORE's unique approach, and we believe certain components of the model could be useful for practitioners providing informal STEM programming for multicultural students and families. First, our partnership model, both at the local and university level, is one in which other programs could adopt. We have worked collaboratively with partner schools to meet their needs and improve our programming, which ultimately supports students across settings (National Academies of Sciences, Engineering, and Medicine, 2015). We have also bridged existing resources at the university, which allows for collaboration across the university and exposes students to a wide range of experiences. Second, we redefine STEM at both systems and local levels. We are changing the culture of STEM at the university by focusing on cultural relevance and inclusion, rather than simply recruitment. We have also developed a STEM program that is holistic by acknowledging students' academic, social, and emotional needs to ultimately support their long-term pathways in college and careers.

Our purpose in writing this paper was to describe how we have *become CORE* in two years of programming. Our objectives and design have served as a foundation, and we have implemented adaptable practices to meet the needs of our partners and best serve our students. We look forward to serving many more multicultural students and families in our loca area and supporting them in participating in a more equitable and inclusive STEM field in the future.

Abstract: The presence of makerspaces, that have been implemented with the idea of advancing science education in a city in Northeastern Brazil, have also catalyzed new connections between teachers, and integration of other disciplines into the makerspaces while spreading innovative pedagogies in lessons beyond STEM disciplines. The goal of this paper is to illustrate the development of a collaboration process between a makerspace and a Portuguese teacher who co-designed a learning sequence related to text types such as narrative, descriptive, expository and argumentative writing, for students to learn, in the makerspace, with their hands-on and minds-in. This paper also highlights the challenges of implementation as well as the takeaways and learnings from this process, that most of all helped teachers realize the potential of co-designing and using new spaces and resources to create environments where learning goals are achieved while maker- and student-centered learning is present.

Introduction / objectives

An integrated effort to design new science standards, implement makerspaces and a professional development program for makerspace and science teachers to promote more practice-based science teaching and learning has been taking place, for the last 5 years, in a city in the Northeast of Brazil (Fernandez, Haegele, Blikstein, 2020). In this context, makerspace teachers and the makerspaces themselves are also becoming a catalyst for school community interaction and innovation in teaching practices beyond STEM disciplines. This paper describes the development process of a learning sequence focused on text types such as narrative, descriptive, expository and argumentative, that was co-designed by the makerspace teacher, the Portuguese teacher and a group of researchers who were working on the implementation of the new science standards within this city's school network. In 9th grade, students approach several communication situations with a more critical stance, and in dialogue with a wider audience, therefore at this stage, the curricular units in writing focus on text types related to action in the public realm, with emphasis on journalistic, opinion, investigative and descriptive writing. The issue of the reliability of information and the proliferation of fake news also has significant relevance in the Portuguese curriculum in this grade (Base Nacional Comum Curricular, 2022). The presence of the makerspace in the school aroused students' interest, and the Portuguese teacher suggested a collaboration with the makerspace teachers to design a new curricular unit related to these text types. Initially, all the Portuguese teacher had envisioned was the possibility of the use of the makerspace for students to engage in research on the internet using the laptops. As soon as the Portuguese teacher approached the makerspace teacher, she organized a meeting, with the researchers as well, to brainstorm possibilities for a hands-on and minds-in learning experience related to text types and writing. As the conversation evolved, so did a co-design process for a whole learning sequence of 6 lessons that aimed at achieving the Portuguese learning goals, while also introducing the students to the makerspace's tools and their creative potential.

In Brazil, the cost per student in public schools is still much below the average of developed countries, approximately US$3800/year as opposed to US$ 8600/year in other countries. (Nova Escola, 2018) In this context, little investments are made in professional development, infrastructure, and teacher salaries. Therefore, few opportunities for co-design, for the implementation of innovative pedagogies and access to digital resources and tools are present. A collaboration as the one described here is not commonplace, which makes it very meaningful, as a case that may spark interest and inspire other educators. The goal of this paper is to illustrate the development of this collaboration between the makerspace and the Portuguese teachers, detail the sequence that was co-designed, and highlight the challenges, as well as the learnings in the process.

Design

The design of this learning sequence on text types began with the curiosity of students about the new makerspace that prompted the Portuguese teacher to approach the makerspace teacher and propose a collaboration. The study of text types and genres arises from the need for communication and sociocultural activities. In Portuguese writing classes it is important to work with students on text types, as it helps in the construction of reading and writing knowledge. Seeking to improve the Portuguese lessons within the skills proposed in the Brazilian national standards (BNCC) the idea was to design a sequence for 9th graders, on this subject, using the makerspace. It was something new for all involved, nonetheless, the makerspace teacher, the Portuguese teacher and the researchers all began to think of a sequence that would engage students with their hands-on and minds-in using the space and resources of the makerspace. It took a few conversations for the Portuguese teacher to realize the goal was to create a learning experience that went beyond using the space for research on laptops, and that students would actually be able to use their hands to interact with and build artifacts that would help them think about and make sense (Papert and Harel, 1991) of the different text types being studied. The design process started with the briefing by the Portuguese teacher to the makerspace teacher and researchers on the main goals and learning expectations for 9th graders related to text types. Through a backward design process (Wiggins & McTighe, 2008), the team began thinking of possibilities where students would engage in a maker-centered experience that could also scaffold the writing of specific pieces in class, after the sessions in the makerspace.

The redesign of traditional classes to a model focused on teaching practices that have principles such as "hands-on" and "minds-in", learning through investigation and the student as the main author in the construction of their own knowledge is not an easy task. The makerspace teacher, in this context, was essential in this process, researching and studying ways to meet the objectives of the Portuguese teacher, within this new teaching perspective and curating materials and kits that would be used throughout the unit. The design of the sequence included 6 lessons, 4 of which happened in the school's makerspace and 2 in class where students engaged in writing activities. The text types explored in this sequence included Narrative, Expository, Descriptive and Argumentative writing. The strategies designed into the learning sequence to explore these different writing genres in the makerspace were:

- The Circle of Inventions, which is a practice that involves reading, making and the sharing of new narratives (Ricci P., Lederman K. S. and Junqueira R. 2019), which was used for the exploration of narratives in the form of chronicles.
- The Parts, Purposes and Complexities thinking routine (Clapp, Ross, Tishman 2017) which was used for students to explore the makerspace, as well as learn about descriptive text types as they wrote a descriptive text about different tools and equipment in the makerspace.
- An unplugged coding lesson, where students had to "program" the teacher to spread butter on a piece of bread, followed by a discussion about expository texts that have to be objective, clear, and logical such as an algorithm, or a recipe.
- The creation of an invitation to all of the school highlighting the benefits of learning in the makerspace, after the thinking routine Making Meaning (Ritchart and Church, 2020) on learning in the makerspace, as a way to practice argumentative writing.

The sequence includes discussion, reflection, instruction and writing after all the hands-on sessions, making sure, throughout the unit students have their hands-on, but also their minds-in the learning process and goals.

Implementation

The implementation of the sequence happened with two different grade 9 groups throughout 6 sessions of 2 hours.

Session 1 - The first session of the sequence, which took place in the makerspace, began with a brief presentation about the makerspace and was followed by a Circle of Inventions to spark a discussion and thinking about Narratives. In this practice students participated in a read aloud of the chronicle "Assalto" by Carlos Drumond de Andrade. Then, engaged in a making moment, prompted to create an artifact that could help them narrate an episode from their lives, that was significant to them, and that contained, as a thread, a misunderstanding, an aspect that was present in the chronicle they had read. In groups, students shared stories and began creating new collective narratives inspired by their own experiences as they "thought" with their hands and created an artifact, such as a prop or a model related to the narrative they thought about. Students used craft materials and simple circuits for this activity. By the end of the session students shared their artifacts and new narratives. The Portuguese teacher listened and asked the students questions about what they noticed, if they saw any connections between the chronicle and the narratives that emerged. She finalized the session formalizing an explanation on Narratives as a text type.

Session 2 - Students also created a Padlet with the images of the artifacts, summaries of the narratives and a reflection about the activity, which was used in class, as inspiration for the writing of a short chronicle. Throughout the sessions, both teachers took notes, made observations and documented the activity. Debriefing the experience, it was surprising for the Portuguese teacher how engaged the students were, even after the making moment, when time came for the reflection, formalization and writing, all students, even the ones who normally are disruptive and not involved were participative. The possibility of bringing their stories to life, concretely, through the creation of an artifact, helped connect students to each other, to themselves and to the subject in a way that brought a sense of confidence, belonging, autonomy and the meaningfulness to the proposed activity (Bondie & Zusho, 2018) which, translated into motivation and engagement.

Session 3 - Once again in the makerspace, students explored different tools and equipment such as Gogo Boards (a low-cost physical programming board), the laser cutter and the 3D printer. Students, organized for group work (Cohen and Lotan, 2017), engaged in a thinking routine called Parts, Purposes and Complexities where all aspects of the object in question had to be explored, in this case the equipment in the makerspace. They first looked closely at all the different parts of the object and wrote them down, then discussed their purposes and finally thought about how these parts and purposes connect to each other. The makerspace teacher then heard their descriptions and spoke a bit about these objects and their potential for learning and creating. The Portuguese teacher used these descriptions of the objects in the makerspace to introduce the topic of descriptive text types.

Session 4 - The strategy used to work on expository text, was a typical unplugged coding activity used to teach about algorithms. As the makerspace is a realm where digital tools are used as creative resources, coding is an important language to be learned, and it was an interesting way to talk about how computers follow instructions while also tackling the topic of expository text, that have to be logical, objective and clear. Students were supposed to give detailed instructions, to the teacher to spread butter on a piece of bread. After a lot of laughter, students finally realized the importance of giving very precise, step by step instructions to the teacher in order to get the results they wanted. This playful activity was a preamble to a presentation by the Portuguese teacher on the expository text types, as well as an introduction to algorithms by the makerspace teacher.

Session 5 - Students came back to the makerspace to reflect upon the experiences and learning they had there. For this the teachers proposed an activity named Making Meaning (Ritchart and Church, 2020), where they had to collectively think, write and connect different ideas, in a mind map format, about learning in the makerspace.

Figure 1

Students during the activities in the makerspace, and writings derived from the hands-on experiences.

Session 6 - These mind maps were used in the final session to help students write a text inviting different teachers and students to use the makerspace. In this piece they used argumentative writing to highlight the benefits and challenges of learning in this space. The sequence was finalized by the Portuguese teacher summarizing their experience and highlighting the aspects of text types planned for the sequence.

Takeaways and learnings

The development, implementation and reflections about this integration between makerspace teacher, Portuguese teacher and researchers, that lead to the development of the textual typologies sequence described above, illustrate how, when an open stance for cooperation as well as time are available for co-planning, new ways of thinking, teaching, learning, and engaging students in the makerspace are possible in fields beyond STEM. This experience points to the need for co-planning time and openness to explore learning possibilities in makerspaces with hands-on and minds-in in all curricular subject areas. The students' engagement throughout the process brought to light the potential of group work, innovative approaches and possibilities of integration between subjects through the work in the makerspace. The integration of the makerspace with writing lessons, enabled a clear perception of the connection between them, as well as led the Portuguese teacher to look beyond the traditional pedagogical practices already used, and realize the construction of knowledge related to language could also take many new forms. The Circles of Inventions, the unplugged algorithm activity, and the parts, purposes, and complexities thinking routine were strategies that allowed for an exploration of the makerspace, of some of its materials and tools while also reaching the Portuguese teacher's objective: to make students able to differentiate and practice writing different text types. Through the strategies used, we observed greater engagement of students, including those with more difficulty in concentration and discipline, which leads us to think that adopting hands-on and minds-in methodologies may increase student participation, in this case, allowing for a wider number of students to be active and participative and also generating learning related to collaboration, making, articulating ideas, telling stories and writing.

Despite having been a successful experience, building interdisciplinary learning experiences within the conceptions proposed by a makerspace is not a simple task. A significant challenge was to find methodological strategies that allowed for the goals of the Portuguese teacher to be achieved while also proposing mindful "hands on" activities. Time for co-planning between the makerspace teacher, the Portuguese teacher and the researchers was sparse and a significant part had to be done asynchronously which demands organization, commitment and a willingness for compromise between the team for the final decisions to be made in time for the implementation. Another point for thought and evaluation is the distribution of time within the proposed activities, as students still have difficulty performing some activities in the makerspace as these are not part of what they usually develop on a daily basis. It would be fruitful for students to have more time in the makerspace to gain more hands-on repertoire. Last but not least, the perception that the makerspace can be a catalyst for innovative pedagogies to spread through the school grew amongst teachers who also realized the need for a team, a community of practice to be collectively engaged in the thinking and planning of such integrations.

Abstract: Professional learning for in-service teachers, so necessary for education, can be a challenge for teachers in public schools in Brazil with lack of time and resources. Proposing innovative maker-centered learning may be complex for many homeroom teachers who have never, themselves, experienced a maker-centered classroom. In this paper, we share the design of a workshop to introduce constructionist learning to educators, that is planned around the Circles of Inventions framework, that is easily adapted to different contexts, while bringing up the value of experience itself and metacognition to the professional learning process.

Introduction / objectives

Professional learning for in-service teachers is an ongoing need for education practices to be reviewed, reflected upon and for best practices and research findings to enter classrooms and affect the learning of students. Organizing meaningful and profound professional learning experiences for in-service teachers, however, in the context of Brazilian public schools, is a significant challenge for school leaders and teachers with very limited time available to learn, work and plan together. For the last 5 years, the authors have implemented numerous learning experiences using a framework named Circles of Inventions (Ricci P., Lederman K. S. and Junqueira R. 2019) - which includes reading, making, reflecting and the sharing of new narratives and thoughts - with students in public schools and in other educational settings, as well as with educators, in Brazil and abroad. This framework has allowed for interesting professional learning processes related to Constructionism, through 2 hour workshops, that are accessible and profound as they enable teachers to: 1. immerse themselves as students, 2. think with their hands, 3. have their voices heard, 4. connect to other practitioners in a meaningful way, 5. make connections to their own curriculums and 6. work in groups in an equitable way. This paper intends to illustrate the design and implementation of this workshop in different contexts and highlight the challenges and learnings from these implementations to spark further discussion on how this framework may be used in diverse professional learning settings with multiple different learning outcomes intended.

Design

In order to foster a constructionist learning experience, where something meaningful, shareable and thought provoking is created (Papert, 1991), among teachers who are not necessarily familiar with maker centered learning practices, we came up with a variety of Circles of Inventions workshops which bring up the value of experience itself and allow for a metacognitive experience for teachers to think about their learning as well as of their teaching. For each group of teachers and each singular occasion, we chose specific texts capable of catalyzing a creative process, reflection and the articulation and sharing of new ideas. Elements that are aligned with constructionism and the 4 P´s described by Resnick - Projects, Peers, Passion and Play. (Resnick, 2020)

The Circles of Invention are made up of three distinct moments: First, the **Circle of Reading** where a story functions as an immersion into a common territory of meanings which could be interpreted as a “microworld” to foster tinkering. This microworld may be interpreted as a safe place, a leverage for the child’s personal ideas to emerge, and subsequently the tinkering itself becomes a microworld for new narratives to emerge and for the learning of story building and storytelling. This cycle could be related to Edwards’ functional view on microworlds, where learners are expected to experiment, manipulate objects, engage in open-ended explorations as well as receive and interpret feedback, iterate and create new objects, solutions and challenges (Edwards, 1995. P. 144).

Second, the **Circle of Making/Tinkering** is not a moment to represent one’s understanding of the story, but a time and space to tinker, think with one’s hands about the questions raised by the educator. These prompts, must be carefully crafted to spark a possibility of inquiry and a creative process, individually or collectively. Third, the **Circle of Narratives**: a fundamental part of the framework where participants have the space and time to share their inventions and stories. From the thinking with these artifacts created, which connects to the concept of objects to think with (Papert, 1991) of constructionism, new narratives and thoughts emerge for the issues in question, as well as space is made for the participants to express themselves, be heard and also listen to peers. (Ricci P., Lederman K. S. and Junqueira R. 2019)

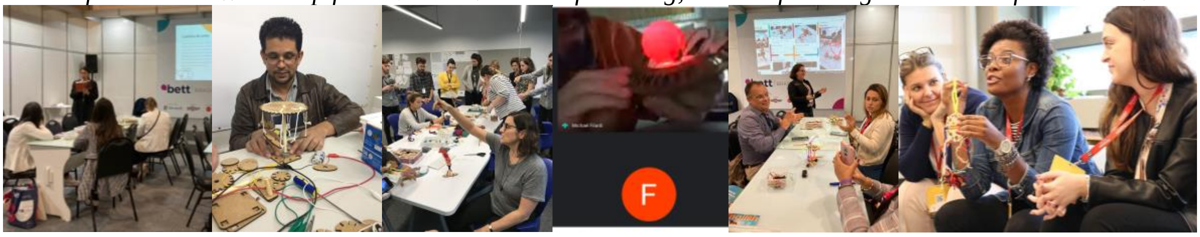
These professional learning workshops were designed to allow for equitable access into the learning experience, with low floors, high ceilings and wide walls (Resnick, 2020) and to fit in the busy schedules of public school teachers, both in urban and rural areas. The design of the workshop, carefully adapted to each context, also worked in educational congresses and conferences both in Brazil and abroad. Making visible the learning in the workshop is of utmost importance in this design, therefore in all workshops a digital sharable mural was used for the sharing of the participant´s artifacts, narratives, ideas and reflections derived from the workshop. The discussion and conclusions present in this paper were also informed by the evidence of learning made visible in these murals.

The design of the workshop comprises the following 6 moments. 1. Welcoming participants and introductions - creating a safe space for listening, thinking, making, sharing and reflecting. 2. The Circle of Reading - a carefully curated text is selected depending on the context and specific goals of the educators in the workshop, to spark thinking about a topic that leads the educators to reflect on their own and new educational practices. 3. In this stage of the workshop, the thinking routine Connect, Extend, Challenge (Ritchhart, Church, Morrison 2011) was adapted to provoke thinking about their own learning and teaching practices. In this adaptation, educators think about ways in which they connect to the text read, then extend their thinking through a group discussion related to their own practices and the ideas. 4. The third part of the thinking routine, Challenge, is transformed into a "making" challenge when the educators are invited to create an artifact to think with (Papert, 1991), to express an idea related to the previous discussion. This challenge, which becomes the Circle of Making/Tinkering, depending on the context, will be individual or in a group. During the Covid-19 pandemic, these productions were individual, but in in person workshops they tended to be as a group. 5. The sharing of this artifact with the group and the narratives that emerge are a vital part of the workshop. These narratives then feed the facilitators with information and insights for the final part of the learning experience, connecting everything to theory and practice. 6. The facilitators end the workshop sharing observations on the process, the artifacts and the reflections of the educators (students), making evident the big ideas and principles of Constructionist learning.

The design intends to be both a model for practices with students in diverse settings and disciplines, but also, and most of all, a lived constructionist learning experience that will spark thinking and possibilities for new meaningful and engaging approaches for teachers and students.

Figure 1

Circle of Inventions Workshop for educators. Circle of Reading, Circle of Making and Circle of Narratives.



Implementation

This workshop was implemented in at least 12 different educational contexts, such as urban and rural public schools, private schools, in an educational congress, in different conferences, as well as for research groups in universities in Brazil and abroad. The implementation described below will focus on one example of the workshop in an international conference with a multicultural group which we believe is representative of the experience. It is important to reiterate that in each context the reading offered and the provocation made were designed to be sensitive to the local audience, culture and specific workshop learning goals.

Soon after the lock down period was over, while teachers and students were beginning to go back to schools, we had a precious opportunity to design and deploy a Circle of Inventions with educators from around the world, during an online conference. For this event, we chose to read a poem by Maya Angelou, called Life Doesn't Frighten Me, celebrating the courage within each of us, while making fears visible. We chose this text believing that at that moment, the experience of fear was something really tangible for so many of us, something that connected people from different backgrounds and from where the participants can explore possibilities, tinker and build up meaningful and shareable "objects to think with" (Paert,1991).

For the challenge of making something meaningful, followed by the reading, we used another insightful Thinking Routine: "Imagine If" (Project Zero, Agency by Design, HGSE, 2018). We asked all the participants to answer, with their hands on, using materials available at their homes, the following proposition: Imagine If you could transform a childhood (or present) fear into something that puts you into action, makes you strong, and resilient. Build an artifact that could help you in this transformation.

Before the workshop, we shared with the participants a suggestion of materials that they could gather at home in order to tinker with during part of the meeting. When we have the chance to work with teachers in person, we use the Catalyst Kit, composed of sustainable items such as mdf pieces in organic and geometric shapes, pegs, rubber bands, pipe cleaners and also LEDS, motors and batteries, when and if possible we may also include robotic boards or programing apps into the activity. In online settings we ask participants for available things such as aluminum foil, any kind of wire, pieces of cardboard, tape and other possible reusable materials to be used.

An example of an artifact created by one of the participants was built upon his fear of spiders. We used a padlet to encourage them to post brief narratives about their inventions, and what this specific participant shared was: “I am frightened of spiders. I imagined if.... I can turn the spider's web into a colorful pattern with nature inspired flowers, petals etc. that becomes a bouquet.” As participants share their artifacts and stories, it is a moment for facilitators to document aspects of these descriptions that may translate into important principles behind Constructionism and may be used as references at the closing of the session. In this workshop, it was also very evident how these authentic narratives that are born from each one's tinkering moment bring the group closer together, creating a safe space for exploration of ideas, discussion of sensitive topics and the building of a sense of community. The way in which all artifacts and stories are valued in the discussion and may bring new insights into a topic also allow for voices that may be silenced in other contexts, to find welcoming space and be listened to.

The discussion propelled by the artifacts and narratives, allowed for the building of understanding of the relevance of the Circles of Inventions as a practice that can be used with students in different occasions and disciplines, and also made possible for facilitators to pinpoint the main ideas behind Constructionism such as learn by doing, technology as a construction tool, hard-fun, learning to learn, freedom to make mistakes and learn from them. The Circle of Inventions, its process and products also springboarded the possibility of tackling constructionist concepts such as, 1. microworlds as they became immersed in the shared meanings of the story, 2. body sintonicity, as their whole bodies became engaged in the tinkering and sharing processes 3. debugging, as obstacles were reached during the “making” process, when iterations and reviews were needed to reach a final shareable object. 4. transitory objects, as they reflect upon how much thinking happened with the objects they created 5. powerful ideas, as educators think about teaching and learning, which are big ideas, as they listen, make and share. As one participant put it, in the digital mural: *“I loved the way this experience was designed - very refreshing. The narrative itself helps one to reflect upon one's own personal experiences and then motivates one to create something that is personally relatable and yet also more universal.*”

Conclusion

Having an object constructed by themselves, to think with and tell stories with, was extremely powerful and relevant for educators to make their thoughts visible, in the most varied contexts, from a professional learning session in Brumadinho in the interior of Brazil to a session at Teachers´ College, Columbia University. The process of making and tinkering with different materials was very significant for participants to elaborate new narratives provoked by the Circle of Reading. After running Circle of Inventions for six years, we can say that the narratives participants come up with would not be the same without having this opportunity to think with their hands, and notice new meanings and angles not previously thought of as regards to a subject. In one occasion for example, after the reading of a text on sandcastles that get washed away by the ocean, a teacher mentioned she initially could only think of a hole, but after the tinkering moment she had created a kite and shared a story related to the possibilities of escape and movement created by these transformations.

Experiencing with their bodies a Circle of Invention from the beginning to the end, and not only hearing or reading about the framework and its fundamentals, is crucial for the whole understanding of how powerful this practice can be. We have observed that educators that have participated in the workshop, feel confident and keen on implementing this constructionist practice, the Circles of Invention, in their classroom. The participation in a workshop helps them realize that: 1. It is a low floor practice that does not demand much previous knowledge related to making skills 2. With wide walls, the Circle of Reading opens numerous possibilities for integration with the curriculum, for socioemotional learning, and for connections between students and teachers. 3. And has tall ceilings as each participant, or a group, has the chance of making something really significant, meaningful and sophisticated, connected to previous knowledge and experiences, also valuing different ways of thinking and knowing into the group

For teachers who are not familiar with teaching and learning maker practices, the Circle of Inventions may be a comfortable place from where to start. Another key point is that the hands-on process is not oriented to a product that works, but actually to something that carries meaningful ideas and even feelings, something that makes thinking visible and shareable. For those teachers who are more into technology, the Circle of Invention framework contributes to bring back the “meaning ingredient” that unfortunately many times happens to be missing in highly equipped makerspaces. The artifacts can be drafted and created digitally and then fabricated with the use of 3D printers and laser cutting machines. The feedbacks below, received after implementing this Professional Learning Workshop using the Circle of Inventions framework, encourages us to engage in discussions to improve and spread even more this practice among other educators, in Brazil and abroad:

> *“…I think Circles of Invention are a brilliant idea that is full of possibilities for improvisation. I believe that the structure is one that builds a much-needed bridge from STEAM to social emotional learning. ….I also believe that something different happens when you allow people to "think with their hands" and then reflect on the wisdom that they can see in what their hands have made real. ”* Susan Klimczak
>
> *“I think the most relevant aspect of this experience was to relate an abstract thought to a tridimensional object. Not only did the ideas give life to the object but also the object gave life to new ideas.”* Participant in workshop

Abstract: Rural high school science teachers often work in isolation with fewer collaborative and professional learning opportunities. One opportunity they have missed is deep learning about and how to implement three-dimensional science lessons. To bridge the geographic isolation of these teachers and increase their capacity with three-dimensional science, we developed a novel professional learning model called Technology-Mediated Lesson Study (TMLS). This engages teachers in iterative, collaborative cycles of lesson design, teaching, observations via technology, and lesson redesign with a team of colleagues aimed at high-impact professional learning and enactment. This paper presents the program design and activities with science teachers who collaboratively design and implement lessons using the TMLS model.

Introduction

A major challenge for secondary science teachers in rural schools is isolation: being the only science teacher in the school or the only teacher of a particular subject. As a result, rural science teachers have fewer or no opportunities for meaningful collaboration, even though collaboration is a key characteristic of effective professional learning. When professional learning is up-to-date, ongoing, collaborative, practice-based, and connected to local contexts (Kennedy, 2016; Desimone, 2009; Penuel et al., 2007) it is more effective at changing teaching practice. Lesson Study is an established professional learning model that has shown success (Cheung & Wong, 2014; Kanellopoulou & Darra, 2019) in meeting teachers' professional learning needs by improving collaboration, helping them examine their practice, and enhancing student learning.

In one western state in the United States, rural schools are organized around four regional education service centers in which participating school districts collaborate to improve instruction in their region. These regional service centers provide professional development in broadly applicable categories such as educational technology but lack the resources to support science-specific professional learning and enactment. In this state, new secondary science standards are being implemented in the schools. These standards are built from the National Research Council's A Framework for K-12 Science Education (NRC, 2012) that established the foundation for the Next Generation Science Standards. The new state standards are similar, also using three-dimensional learning, combining science practices, crosscutting concepts, and disciplinary core ideas.

Many of the urban districts in the state are already training high school science teachers in three-dimensional science teaching, while most rural teachers have not received any training on the new standards. The program described here is designed to address the lack of professional learning opportunities for rural science teachers by using technology to bridge the geographic isolation they experience. Building from lesson study (Lewis & Hurd, 2011), we developed a novel professional learning model called Technology-Mediated Lesson Study (TMLS). TMLS engages teachers in iterative, collaborative cycles of lesson design, enactment, observation via technology, and lesson redesign with a team of colleagues from their region, resulting in high-impact professional learning and enactment. Improved science teaching in these regions will provide equitable access to high-quality science for all students who live in the rural regions of the state, many of whom are economically disadvantaged.

The purpose of this paper is to present the program and collaborative design and enactment using TMLS with rural science teachers. Initially, a small cohort of teachers engaged in collaborative codesign activities building shared capacity around the three-dimensional science standards, developing professional learning materials and experiences for other rural science teachers, and enactment of newly designed lessons through technology-mediated lesson study. This cohort of teachers then worked with more teachers to engage in building their capacity with three-dimensional science and the TMLS process.

Lesson study

Originating in Japan, lesson study is an instructional inquiry model that involves a group of educators organizing together under shared goals focused on student learning and co-creating lessons to meet those goals (Lewis & Hurd, 2011). Four essential teaching tasks—designing lessons, teaching, observing and analyzing student responses, and reflecting on implications for future lessons—are all foci of the lesson study process (McDougal, 2022). Lesson study slows down the lesson creation process, allowing teachers to concentrate on critical elements, such as the planning and reflection stage, to which they may not otherwise devote significant time. They are also given opportunities to observe another teacher's lesson—an opportunity that, for many teachers, is not frequently available. Watching someone else teach allows the observers to focus on student learning and misconceptions, which teachers can miss while teaching due to divided focus across an entire class. This close observation can help the teachers think about the design process and how to improve the lesson so misconceptions can be addressed. The repeated steps of lesson study develop educators' knowledge and motivation for teaching and helps develop a robust professional learning community (Lewis & Hurd, 2011; Murata, 2011).

Technology-mediated lesson study

One of the practical difficulties of lesson study is accommodating teacher schedules so they can fully participate in a lesson study group (Choppin et al., 2020; Huang, 2020; Soto et al., 2019). For rural teachers it can be almost impossible to meet with other teachers in the same discipline as they are often at other schools a considerable distance away. Technology-Mediated Lesson Study (TMLS) utilizes technology resources to allow teachers to interact and learn together when not co-located. This interaction among remotely isolated teachers connects them with colleagues they otherwise would have no connection with, including those in other districts. In TMLS, teachers initially gather as a group, set a goal or purpose of the group; which might be learning something new about teaching and learning or new curriculum writing. They then collaboratively work on the aim of their group (e.g., writing a lesson plan). Taking turns, they implement in their classroom where they record the enactment and share it with their group. The implementing teacher reflects, and the other teachers comment on the enactment. Then they meet virtually where they discuss and revise, ready for the next teachers to implement with the updated materials.

Primary goals of the program

This program has three goals. First, principles: an innovative model for rural science teacher professional development via technology-mediated lesson study that supports translating professional learning into classroom practice through social support systems among rural teachers. Second, people: building expertise and capacity among the rural science teachers to support three-dimensional science teaching. Third, products: creating and disseminating high-quality three-dimensional science lesson plans aligned with the new state standards and the Next-Generation Science Standards that will be shared with teachers in the state and across the country.

Conceptual framework

The design and research activities of this work are built on an ecological model described by Sallis et al. (2008) for changing health behaviors and is applied to changing teaching practices to incorporate three-dimensional science teaching. Teachers choose instructional practices based on personal factors (e.g., attitudes, self-efficacy), social factors (e.g., peer, administrator, and student expectations), and contextual factors (e.g., physical, material, and time resources). The program targets personal factors by supporting rural science teachers' development of knowledge, self-efficacy, and positive attitudes about three-dimensional science teaching. Social factors via cohorts of subject-region teams provide a sense of community and support for the instructional changes needed for the new state standards.

Design and implementation activities

Design activities in this program are facilitated by the teachers and supported by the researchers. In the first year five researchers and four teachers, from the four rural regions of the state, met five times in-person in two-day workshops to learn more about three-dimensional science, design a three-dimensional lesson, implement the lesson, and engage in the technology-mediated lesson study process. In the beginning a shared knowledge of three-dimensional science was needed, and through different activities this shared understanding began to grow. Once a strong base of understanding was established, a lesson was designed. This collaborative process among the teachers required understanding of their different contexts within the rural settings. Some teachers were very geographically isolated, were the only science teacher at their school, or taught a variety of students with different needs, including academic and socio-economic challenges. This caused some complexities in the design of the lesson. This included, but was not limited to, selecting a phenomenon, finding the best examples to use in the lesson that would be understandable by all their students, and teacher preferences with the format of a lesson plan. The teachers knew that many areas of the lesson would be improved through the enactment and technology-mediated lesson study (TMLS) process.

Using TMLS, the teachers implemented their initial three-dimensional lesson plan. In this process, one teacher implemented the lesson and recorded it using a Swivl. After uploading the recording and providing some initial reflections on the enactment, the other teachers watched the recording and commented with questions, praise, and ideas for improvement. Then they meet as a group in Zoom to reflect and discuss the enactment and make changes to the lesson. Then, another teacher would implement the lesson and the whole process was repeated. After each of the teachers implemented the lesson a final design on the lesson was completed. The teachers assessed the lesson plan using the EQUIP rubric.

After the first year and small cohort of teachers, they collaborated with the researchers in designing a summer workshop for nine additional rural science teachers. This workshop introduced additional teachers to three-dimensional science and the TMLS process. The summer workshop was five days and in small groups, facilitated by the first cohort of teachers, a new science lesson was designed. In the first few months of the school year these three groups of teachers engaged in the TMLS process and iteratively redesigned and implemented their lessons. During the 2022-2023 school year, these teacher groups designed and implemented a total of four lessons per group (total of 12 lessons) aligned to three-dimensional science. Each group used the TMLS process as they refined their lesson plan.

What we have learned

We have learned that the teachers appreciate the process of collaborating together. Since the majority of them are quite isolated, they enjoy working together and focusing on three-dimensional science lessons (devoid of any school issues). It is pure design focused on the science. They enjoy the TMLS process because the technology provides a means for further collaboration and engagement together, but also because it has iteratively improved their lessons. They have improved their collaboration skills and made new connections. One teacher said, "It's so nice having other people…who have different strengths but then also different perspectives. They're going to notice things I don't notice. And it's so nice having a group that is very focused on creating content and not dealing with school drama. There's not external education problems. We're just creating content."

They have enjoyed observing each other teach. Many of these rural teachers do not have the opportunity to observe other science teachers as some are the only one in their building (or even district). They do not always like watching themselves teach, but they are learning from each other beyond the intent of this work. Many of the teachers expressed how surprised they were by how much they learned through the TMLS process. One teacher mentioned, "This has been the best professional development I've been involved in. Because of [other group members,] I can see the value in what we are doing. I can see the advantage of having three or four teachers in the same subject in a school." Another teacher said, "You go to a [professional development] meeting, they tell you what you're going to do and then you don't get the time to practice it, so you just kind of fall back into the same rhythm that you were in before. Whereas this [TMLS] model has been that they told us what was expected and then we had time to practice it. And then when it wasn't right, we had time to fix it and then have more time to fix it until it was to where we were happy."

They enjoy learning about and how to implement three-dimensional science. It is exciting for them to engage together, but more to observe changes in their students. They have observed engagement, motivation, and questioning/language changes with just one implementation of a three-dimensional science lesson. The large amount of time to collaboratively design and iteratively implement and redesign a lesson is worth the changes they see in their students. In changing about how they think about three-dimensional science now one teacher said, "The DCIs, the SEPs, and the CCs are now things that are conscious on my mind when I am planning a lesson; whether I implement every single one, every single lesson is another story. But they're in my mind, and I do my best to implement at least a couple of those things into each of the lessons I plan."

We have learned that group dynamics is a complex system and often is quite delicate too. Becoming close to each other, understanding each other, and learning how to work together are important elements to make the design and TMLS process successful. Each of the groups have been facilitated slightly differently by the first-year cohort teacher, but each group has made progress throughout the TMLS process. The program is an iterative process of learning and growing individually and as a group. Keeping our eyes on the purpose is important, that helps everyone remember their roles and responsibilities in the process.

What others can learn

Others can learn from our design and implementation activities. There are a lot of programs that target three-dimensional science, but not many focused in rural high school science teachers. Learning about who they are connected to and how to help them connect is important. We have learned that technology is a powerful tool that can be utilized in our favor. Technology can connect people and can be used for design and observation activities. With that, lesson study is a powerful tool for connecting teachers and designing and implementing lessons. Even teachers who are not isolated could find ways to use technology and technology-mediated lesson study in positive ways.
